I know landlords in this neighbourhood who let their cottages at a low rental; this is what I call practical philanthropy. Now, many admit the wages' question to be right, but say, "Can the farmer afford to pay higher wages in the face of the dry seasons of the last two or three years?" With that, however much you may sympathise, you have nothing to do, because, after a consideration of this question there may be a continuation of wet ones, and where the hay is short now the grain may be short then. And how about the right time? Others charitably suppose for you that if you get more you will only be spending it on drink and tobacco. Of course this is shelving the question until the weather is made better and the people by some temperance pledge. The last kindly argument does not say that a man earns no more, but finds fault with his way of spending it. One of our great writers says that the labourer is surely worthy of his hire; and the wages of the industrial labourer ought to be equal to all the decent wants and respectabilities of his position in life; and though political economists may say that the labour market is not regulated by considerations of this kind, let us stand on higher ground than this; let us say that such a portion or value of a commodity as is equal to his properties is believed by the producer, and that a landlord, merchant, &c., ought to be content with what remains after the producer has been provided for; whereas too often the reverse is the case, many of the producers having to be content with the crumbs which fall from the rich man's table. I would ask you how is the Education Act to be carried out in its entirety if there is to be no advance of wages—every child to be at school, a longer time to be at school, and a higher standard to be passed? The men must have more wages, for I know too well that many of them are unable to pay with only a part of the children at school—that this will cause an increased expenditure in two ways—first, by more of a family being at school, and secondly, by being a longer time in school—no earnings because of no labour; and if the same ratio of wages is to prevail, how is that family to exist who now live principally on bread? We must look these things fairly in the face. One statement which was made at your first meeting I am prepared to modify a little, although I did not make it. They said the wages were lower in this neighbourhood than anywhere else. I know there are many places where they are higher, but there are places where they are lower. A few days ago I was through Gloucestershire and Wiltshire, and inquired the state of wages, and found them to be lower than here; but because there are others worse, it does not follow that you ought not to be better. This is where you deserve commendation, because although you are not organised you have not rushed into as bad a state as theirs, but nobly, earnestly, and courteously you have begun the battle for the right. In this question I cannot, nor do I wish, to lay all the blame at the door of the farmer, for I wish to speak justly of all; but I believe the landlord is equally to blame with the farmer. Many landlords will not make this remark, that there are many landlords and many farmers who pay justly, but there are many who do not. The answer to all solicitations is, the supply regulated by the demand. This may suffice for produce; but beyond a certain limit it ought not to be for human beings; you see the result—people starved to death. But we maintain that property has duties as well as rights; and if landed proprietors took more interest in the labourer it would be better for all. It is not a healthy state of things to see on large properties labourers without work, as at the present time there are. Why not all true-hearted landlords, when they find this to be the case, employ the surplus labour in the improvement of their estates?—for in consequence of these men being out of work it causes a reduction in the wages, and in consequence an increase of misery, pauperism, &c., whereas if employed this would be spared. How many of the landlords themselves are not giving their men the just value of their labour. If this be the case, is it a good example to set the farmer? For, after all, the farmer is only the tenant, while the landlord of course is owner. Were it not for the unusual and unhealthy competition for farms which we see, after all it would come back on the head of the landlord. Let this competition pass away, and it will do so. When was not neglect followed by evil consequences? The landlord may look with pleasure upon improved farms and estates of more value; but after all there is something more. If with the improvement of estates comes no bettering of the condition of the poor, but in consequence of an increase of population increasing squalor, pauperism, and degradation, I ask, is one a sufficient compensation for the other? Let us just look around us, and do we not know villages which are very beautiful, houses fit to live in, nice gardens, and men in a splendid physical condition; and do we not know of villages where quite the opposite is the case, where you see a degraded peasantry, and a general want of comfort? Why is this? One is cared for, the other not. We have heard some little objections brought forward against the men having a cow,—not that I have heard any one say it was a bad thing; on the contrary, I confess I do not see the slightest difficulty in the way, except getting the land. In the first place they say all cannot have it; we do not ask for all to have it. In the next place, they say that all men cannot buy a cow. Others say that the women are so ignorant it would be of no use for them to have a cow. Well, who are the women the men marry? Are they not domestic servants chiefly, and when in service does not one employer give a good character with the servant to go to another employer? How is it after being in service for some years and learning cheese and butter making —how comes it, after getting experienced, they all at once become so helpless and ignorant as not to be able to look after a cow directly they are married? Others say you will have no time to look after a cow with its belongings; in answer to these I would say that if many of the women have to be away from their homes now, from 8 until 6 working on the land, could not these hours soon be cut off to enable them to look after a cow? And then if there was something extra, hours being from 6 to 6, the man could do it before, or after. Others say that it is impossible for a labourer to have 4 acres and do his work, because out of that he would have some village land. To these we would say we do not stipulate four acres, although we mentioned that quantity; but we merely mentioned that quantity as a standard to go by. What we want is land sufficient to keep a cow, quantity to be determined according to quality. Others say that it could be left to the farmer to allow the workman to run a cow with his own. I think not that if the labourer had the land himself it would be preferable, because otherwise it would always affect the man's wages, which would make it a doubtful benefit. We have stated that it should be one in proportion to every hundred acres. We do not say do this all at once, but try two or three of the best men and worthy women who will be able to do it in each neighbourhood, and I am convinced it would do. If this could be done in the proportion we have stated, we should have some hundreds of thousands more cows in the country, and millions of pounds of butter brought into the market, now at present butter and cheese making seem at a discount in many places. These pounds of butter mean an increase of grocery to the butter-makers, an increase of business to the shopkeepers, and a little account at the savings bank for a rainy day and old age. I venture to hope that the landed proprietors and employers have your cause too much at heart to lay it aside for a few rails or a cow shed, or some trifling inconvenience, which will only affect them for a few moments, but which will benefit you for life.

In regard to emigration, some are against it because they say it is not needed. In the first place, have we a surplus population or not? We have to buy food—that is grain, &c., to the amount of nearly £50,000,000 yearly, because it is not produced at home. I know there are millions of acres of waste land which may be made productive, but if we have a surplus in place, have we not always a great number of people either out of work or earning such small earnings as scarcely to be able to live? This, I think, will prove that we have a surplus population. Then is it not better for a man, who is barely able to keep his family from want, to go to a country where he may live, thrive, and have some comforts for himself and family? We know it is done among the families of the great. Fathers send their sons to India to live for years in order that they may escape poverty. Do you think that if a gentleman of high standing could get his son into a like position at home he would not much rather do it than to send him very likely to die in India? Well, if it be good for the sons of the great to go to India to acquire wealth, is it not equally good for the sons of the poor to go to America or elsewhere to acquire a competency, or at all events to live? If there should be a greater call for a trade at a town you will directly see tradesmen flocking to that town from other towns. I ask you what is the difference between going from one town to another, or from one country to another, excepting the question of distance, which, after all, is now a trivial affair. I believe the only obstacle is ignorance, because you have hitherto thought that you should do no better at one place than another.

I would say to those above us, not to think, because the surface is rugged and distasteful to the polished and refined mind, that nothing can be seen by stooping but ignorance, immorality and crime. If they would but stoop, they would discover something more—they would see suffering, patience, and heroic fortitude; they would see simplicity of life and nobility of character; they would see the lowly battle of life fought in a manner worthy of the Bayards of our philanthropists;

they would find beneath coats of coarse and ragged frieze, hearts beating as true as that of Sydney or Raleigh; struggling year after year to keep want from the door; watching with fond devotion over a sick wife and children; going forth to labour with a dry crust so that he may be able to pay his way, and, if able to do anything more, to leave at least an honest name behind him. Stoop, and you shall find men like these in the homes of the lowly. Yet, though placed lowly on earth, they belong to the nobility of God. In conclusion, I ask, does not God will that humanity should be raised from its degradation? Then let God's will be carried out, cry, and God defend the right.

CLEE, a labourer, said that the wages of an agricultural labourer ought not to be less than 15*s.* a-week. He maintained that if the golden rule of doing unto others as we would wish others to do unto us was universally observed, there would be no occasion for such a meeting as that. As to England's greatness, what did it consist of?—the Bible and the labourer. Take away the Bible, and the country would be dark indeed. Stop the plough and the spade, and where would the people be? Farmers called themselves the bone and sinew of the land, and so they were to a certain extent; but they could not be so without the labourer. He had heard it maintained formerly the wages of an agricultural labourer were 7*s.* a-week; but in those times there was a different feeling between master and man to that which now existed. Then, besides their wages, there were some extras, as he had—a dinner or a supper every now and then; but where were such things to be got now? He urged his fellow workmen not to be afraid of asking for an increase of wages; and he thought they should do so then, though some little disturbance might at first arise, no permanent harm could result from doing that which was right. As to the cow question, he wished every labourer could have land enough to keep a cow, the rest would be much benefited, as there would be more butter and milk to be had than at present. As to milk, there were some farmers who would rather give it to their pigs than sell it to their labourers. The wages should be 15*s.* a-week, 15*s.*, with the best men getting 18*s.* or 20*s.* He got 20*s.* a-week, and they saw that he had a pretty good coat on his back; and he wished every man to have as good or better coat than himself.

HOLLAND had not much to complain of himself, having but a small family, but he well knew of the hardships of many others. Labourers' wives were often much blamed; but he thought those who blamed them should take their positions for a short time, and show what they could do in properly feeding and keeping tidy a large family upon 9*s.* a-week. If they could manage better, the labourer's wives would be glad to have some leaving out of their books. But how could the labourer's wife manage properly if she had to be out at work all day, and then sit up till midnight mending her own and the children's clothes?

KINSEY contended that if the labourer had not been true to his employer, the latter could not have risen so high in the social scale as he had done; some getting from the donkey-cart to the gig, and others from the yoke to the carriage and pair. It was their duty to ask for an increase of wages, no matter what the answer might be; and also that they should keep a cow.

REEVES congratulated the meeting upon the presence of Mr. Smythies, who set a noble example in the treatment of his labourers. Mr. Smythies' shepherd had this year received between £2 and £3 for the lambs, and was not that an encouragement?

MR. SMYTHIES, in answer to a call, said that owing to the lateness of the hour, he must defer speaking till another occasion. He congratulated them upon the fair and temperate way in which the meeting had been conducted, and on the efforts which had been made by Mr. Strange.

WARD contended for the keeping of a cow, not only on a pecuniary ground in its advantage to the family, but in the advantage of the labourers' daughters learning to milk, their boys to know something of cattle, and thus be more valuable when they went out to service. He was opposed to large farms, considering that 300 acres was enough for any man to pick a living upon.

Two or three of the speakers dwelt strongly on the advantages to be derived from an improved physical condition of his labourers. At present many had to go to work with only a dry crust and a weak cup of tea for breakfast.

KINGSCOTE.

THE annual ploughing match, meeting, and dinner of this association took place at Kingscote on Wednesday, the 23d ult. The ploughing match (the principal event of the day), was held in a field in the occupation of Mr. J. Nicholls, Symondshall, close to Kingscote. It was a 41-acre field of two-year-old Clover sod, but was in splendid condition. Sixty-one teams entered for competition—about an average number, but it was observable that there was no entry in the class for double ploughs, for which a prize was offered for the first time, and that in the champion class for farmers' sons there were only two entries, and as no start was allowed with less than three entries the match did not come off. The work done was of an unusually high class, and was universally praised, the boys' class being the best of all. There was a large gathering of agriculturists and other spectators, who took a profound interest in the operations of the day.

At the dinner, the Chairman, in proposing the toast of "Prosperity to the Kingscote Association," said: When they saw the number of ploughs that had started, it was obvious they were prospering. It was, however, a matter of great regret to him that two classes had failed that day, although he did not think they had ever had a failure before. A prize was offered for the double plough for the first time, and he had certainly looked forward to seeing Ransomes & Sims, and some of the other makers present, but causes beyond their own control prevented their putting in an appearance. He had been told that 50 years ago or more the double plough was freely used in this part of the world, but since then it had been given up. It might be right or wrong, but he would have liked to have seen it tried again. He believed that, to be worked with advantage, it should be upon light lands. A double plough would certainly save one horse, if the work could be done as well, and did not kill the horses. Tried by means of the dynamometer, they said the draught was not more for three horses than for four. That remained to be proved; but he should like to have seen it tried that day. However, they must think the prize again next year, and see if the entry filled then. It was also a matter of regret that the class for the sons of members did not fill. The sons of the tenant-farmers ought to compete in large numbers. In all farming matters, unless a man could shew those under him that he could do a thing he would derive very little advantage from being a farmer at all. He was certain of this, that if he had not an efficient steward to look after his farm it would do him no good; and when he saw a man mowing badly he longed to take off his coat and shew him how to do it. He was glad to see that the Society was prospering. The gatherings they had around that table, and more particularly during the winter months in the room below, were a sorce of great pleasure and instruction to him. The more they could meet together and tell each other as practical men how such and such things had turned out, the more it would be for the advantage of each of them. Those societies did them all good by bringing them together to exchange ideas, and he sincerely trusted the Kingscote Agricultural Association might exist for many years to come, and be as prosperous and as practically working as he believed it was at present.

Notices of Books.

Journal of the Bath and West of England Society.

The seventh volume of the Journal of the Bath and West of England and Southern Counties Association is before us. It opens with a report of the Farming of Kent, Sussex, and Surrey, by H. Evershed, in which the agriculture of each district is illustrated by the description of a well-managed representative farm. The following note on wages, which ends this article, is of considerable interest:—

"121. a week was the lowest wage for day men in any parts of the three counties that I visited last winter. Within a distance of 20 miles of London, as well as in the Hop district of Kent, they are paid rather more; 15*s.* per week. *Surrey:* Guildford, 12*s.*; Dorking, 14*s.*; north of the hill, from 13*s.* to 14*s.* *Sussex:* Horsham and districts, 12*s.*; South Downs, 13*s.* or 14*s.*; cattle men 2*s.* extra. Farm bailiffs are rent and tithe free, under shepherd, 13*s.*, and £2 a year extra; head shepherd, 16*s.*, a house, £3 at lambing, and 30 stones of pork at 2*d.*, flour at 1*s.* a gallon: a quart of beer a day and 30*s.* extra in harvest."

Next follows a long disquisition upon sheep in general, and especially Downs and their crosses, by Mr. Joseph Danby, in which considerable labour is expended upon the investigation of the origin of improved breeds.

Mr. Corbet contributes a paper on Breeds, in which the "Management of our various animals is discussed. Mr. Evershed again appears as a writer upon the Improvement of Cultivated Plants, in which Darwin's observations are freely quoted.

"Certain Enemies of our Cereals" are treated of by Mr. Peard; Mr. Tegetmeier contributes a paper on Poultry as profitable farm stock; next in order are some observations on Pleuro-pneumonia, by Professor Brown, in which we arrive, after evidence for and against, at the conclusion that the disease is communicable from sick to healthy cattle. "Sanitary Improvements at Broadyat," by T. D. Acland, M.P.; Whitby on the drought of 1870, and the reports on the Guildford show conclude this portion of the volume. The "Note Book" contains interesting matter concerning the cultivation of Cabbages and Hops, upon the profitableness of peat, and a valuable note by Mr. Lawes upon the guano trade.

Farm Memoranda.

EAST BARNS (*continued from p.* 1120).—5. *Potatos.*—Potatos are taken after seeds and after Oats. In the former case the lea is ploughed as for Oats, and, as a system, hitherto no manure has been applied on land that has been two years in seeds. Recently, however, Mr. Murray has applied a little artificial manure, and he thinks that the result justifies a continuation of this practice, although in former days manure was thought to render the tubers more liable to disease. The Oat stubble for Potatos receives a heavy dressing of either farmyard manure or town manure in the autumn, which is ploughed in sooner or later, as may be convenient, or as the season may require, sometimes not until after the lapse of several weeks. Whole Potatos are never planted, and those selected for the sets are of a medium size, neither too large nor too small. The sets are made by cutting slips off the tuber, each slip containing but one eye, or, if more than one, the superfluous ones are scooped out. The "rose-end" of the tuber is left until last; it is then split, and all the eyes but one scooped out of each part. The object is to have each Potato plant, if possible, with but one stalk, as the crop is then more even in size and almost wholly fit for the London market. There may not always be so great a weight of Potatos as under the other system, but the farmer naturally looks more to £ *s. d.* than to tons, cwts., and lb. The sorts usually grown are Walker's Regent and Victoria, about half a ton of Potatos being required to plant an acre under this system. Some time after planting the land is harrowed, when the annual weeds are well grown and as soon as the plants appear they are horse-hoed and cleaned with the hand-hoe once or twice, as may be required. When thoroughly clean and beginning to get bushy, they are earthed up by the double mould-board-plough and two horses. When ready for lifting, which is generally from the middle to the end of October, but sometimes not until the first week in November, the double mouldboard-plough is again used, with an addition which throws the Potatos well out. The crop is pitted as soon as taken up, the Potatos being laid in long heaps on the surface of the land, about 5½ feet wide at the base, and not more than 3½ feet high. Great care is required to prevent "sweating;" it is therefore desirable to cover with straw first, and a light covering of earth, leaving chimneys at intervals of 3 feet, and finally, to keep out wet and frost, the covering of earth is increased as may be deemed necessary.

The largest Potatos go to the London market, the seconds are pitted anew and sold for seed, and the smalls are sold or used for cattle food, or are purchased by starch manufacturers. Last year the Potatos sold for 35*s.* per ton on the spot for feeding purposes.

6. *Pulse.*—The Potatos after seeds are followed by Beans on the heavier land, and by a mixture of Beans and Peas where the land is not so strong. In either case the Potato land is ploughed during the winter from 7 to 9 inches deep; and the spring, just before sowing time, the land is harrowed down and left for a day or two previous to ridging, which is done by six ploughs, in the same manner as for Turnips, 27 inches apart. The Bean-sowing machine deposits the seed in the intervals between the ridges. Before the corn drum ploughs, distributing from 2 to 2½ bush. of Beans per acre, or a mixture of 2 bush. of Beans and half a bushel of Peas. In two or three weeks annual weeds have got a good braird, and are then destroyed by thorough harrowing. Horse and hand hoeing is done when the Beans are well up, and the crop is cut with the sickle.

7. *Wheat.*—This crop follows Potatos and pulse. In the former case no manure is applied to the land, but in the latter it receives a good dressing either of farmyard manure or of sea-ware. The whole of the break for Wheat is ploughed from 7 to 8 inches deep after the Potatos have been taken up, and the whole to end of November. The land is harrowed and the Wheat drilled at any time from November 22 until the end of December, according to the weather. Before drilling, the land will have at least one double and one single harrowing, and afterwards only a single tine, to cover the seed and level the land. Rather less than 2 bush. of Woolly or Rough Chaff Wheat are sown per acre. The after-management consists of one horse-hoeing wherever annual weeds appear, and of a top-dressing to such portions of the Potato-land Wheat as may seem to require it, perhaps the whole; but no stimulant is applied to the manured Wheat. The top-dressing consists of a mixture of 1 cwt. each of nitrate of soda and guano, put on broadcast in April when the Wheat plant is fairly growing. Reaping generally begins about the middle of August, but this year it commenced on the 9th of the month.

The white crops are usually cut by machine; generally three machines are working together, but a fourth is kept on the farm as an adjunct, or in case of accident.

Until the last one or two years, however, the reaping-machine did not come into favour with Mr. Murray; his crops were very heavy, and overpowered the machines which he had tried; but recent improvements have nearly removed his objections, and he now uses machines for most, if not all, his grain crop. Wheat is cut early, before it exhibits the "sere and yellow" leaf and stalk. A shorter or longer period, according to the season, is necessary to put the cut grain into proper order for stacking. Sometimes three or four days are sufficient; at other times 14 or 15 days are not too much. In carrying, four stackers are generally set to work, each having two carters, and they one forker; the stacker has a stout boy on the stack, to put the sheaves to the hands of the stacker, and otherwise assist him. A few extra hands are always required in harvest. Formerly, a great many Irish reapers were employed, but now the machines are

in use a small number only are needed. Everything is done by day-work.

Seed.—The best Scotch farmers are very particular about their seed, and Mr. Murray's practice in this matter is by no means exceptional across the border. He gets Wheat generally every year from the South, as this crop does well coming from a slightly warmer climate. Seed Oats, on the contrary, are invariably obtained from a colder climate, as experience has shown this practice to yield the best results.

A few Cabbages and Carrots are grown; this year about half an acre of the former and less than 2 acres of the latter.

Produce.—In an article in *The Farmer*, for September 5, 1866, the following information is given on this subject:—"The produce of the Tillyfour (Oat) is from 90 to 100 bush. per imperial acre, weighing from 40 to 41 lb. per bush.; and of the Potato variety, from 50 to 60 bush. per acre, weighing 45 lb. per bush. Barley is a more important crop than Oats at East Barns, the variety grown being the Chevalier, of which the produce ranges from 55 to 60 bush. per imperial acre, weighing from 57½ to 59½ lb. per bush." . . . . "Last year [1865] the Wheat crop at East Barns produced 60 bush. per imperial acre, but this year [1866], from the influences of the season, it is much inferior, and probably will not yield more than 40 bushels." The average yield is from 50 to 55 bush., weighing from 64½ to 65 lb. per bush., and occasionally somewhat more." *Journal of Royal English Agricultural Society*, vol. vii.

The Week's Work.

SEPTEMBER 2.—*Scotch Harvest.*—September is still counted harvest month in Scotland, as August is termed harvest month in England, but the old calendar rules of harvest months and harvest moons are fast falling behind the progress of field practice, faster perhaps in the North than in the South; thorough drainage and improved cultivation, manuring and seeding, having shortened and advanced the period of harvest 14 days in some places, and fully a month in others.

Buckwheat harvest before it begins to shed its first ripe seeds. Owing to the manner in which the plant flowers and ripens the whole cannot be secured, and as a rule the first ripe is the best. Part of the plant being thus cut green, the small sheaves or bundles require to be left loose and exposed in the best manner for drying, and also to be turned once or twice; and in cutting and turning very great care is requisite to prevent shedding of the seed. Some thresh out in the field, and store the seed, which makes excellent food for poultry, and also for cattle, when ground into meal; others bind up and stack, as Turnip seed.

Aftermath Meadow and Clover Hay cut before the crops begin to rot at the bottom. Both crops are more liable to injury from wet weather and heavy night dews than the first crops, and therefore mowing should be deferred until settled weather sets in. In other respects, the work is similar to harvesting the first crops.

Grass Seeds, for hay or pasture after a corn crop, sow on a clean stubble, and chain-harrow in, as directed for Autumn. The practice is preferred by sowing the seeds with the corn in spring, as a much closer and healthier bottom of young grass can be obtained before winter.

Hop Picking generally commences this month. When equally ripe, the flowers may be picked as one quality, but this is seldom the case in the best of seasons; and when they ripen unequally, they are divided into three qualities in the picking—the dark or over-ripe, the brown or ripe, and the green. The three qualities are then taken to the oast and kiln-dried separately, and when cool put into sacks, technically termed pockets. Fine weather is essential to the successful harvesting of this crop, as the slightest damp from rain or dew injures the flavour and strength of the bitter principle, thereby reducing the market value of the crop.

Cabbage Seed, if not already sown, sow in beds for spring planting. Advanced seedlings remove to a nursery in rows 6 or 9 inches apart. Transplanting them a second time by simply shifting will check over luxuriance of growth, and harden and fit them for standing the winter. By thus shifting the young plants will be more uniform in size, stronger in the stem and better rooted, and less liable to run to seed next summer, or to be attacked by insects, than when left in the seed-bed throughout the winter.

Autumn Fallows.—Continue to plough, dig, or smash up by steam as soon as the crops are removed from the ground, as directed last month. The advantage of breaking up stubble early with a deep trench-furrow has been known from time immemorial, but with horse-power this could seldom be done in the case of heavy clay soils until rain fell to soften the land; and when the weather breaks it frequently happens that clay land becomes too wet for profitable tillage. But with steam-power the land may be broken up immediately the harvest is over, and the drier the more effective the operation.

Farm Horses.—Autumn fallowing and stubble Turnips have greatly increased the labour of the teams at this season, rendering an extra allowance of corn necessary along with a cooling diet of green forage, as sewage grass, Clover, Tares, Lucerne, Sainfoin; or, in the absence of such, steamed food should be given. On no account allow farm horses to lose their sleek summer coat in Autumn.

Milch Cows are in too many instances neglected at this season, more especially in our northern counties, what they get in the pastures being insufficient to support them. They should have grass, Clover, Tares, Lucerne, or Sainfoin, and be housed at night whenever the cold weather sets in. In some places an early plot of Globe Turnips is grown for cows. The tops are objectionable, and the bulbs should be steamed along with chaff and bean meal. Old or worn-out cows may be allowed to run dry for fattening. In our southern counties early September is generally favourable for milch cows, the weather being mild, and the grass plentiful; but to this there are many exceptions, the weather either being wet, or the pastures burnt up, or the bite deficient naturally; and of the two, a cold wet bed at night is the most objectionable to an in-calf milch cow timed to calve about the close of the year. Cows should continue to have plenty of soft filtered water to drink. Very great improvements are now being made in some dairies for controlling the extremes of temperature during summer and winter, and it is just as necessary to attend to the temperature of the cow during the process of secreting the milk, as it is to the temperature of the dairy in the several processes that take place after the milk is withdrawn from the udder.

Notices to Correspondents.

DESTROYING THISTLES: *A. H.* writes:—Will you or any of your correspondents be so good as inform me the best plan for destroying Thistles on grass land where it is pastured by deer, a few Brittany sheep, and two or three cows, and about 5 acres in extent? [Spud them below the ground and drop a little salt upon the cut surface. Mow just before they flower.]

SEWAGE IRRIGATION. Communications on this subject have been received from "H. F. M." and "Waste-paper."

WORKS ON AGRICULTURE: *T. E. H.* Stephens' book having been revised and re-published during the present year is the most likely to answer your purpose; published by Blackmore and Son, 52, 6*d*. each. Also a work published a list of useful books some years ago. See also Catalogue of the Royal Agricultural Society Library, 12, Hanover Square, London.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Aug. 28.

The number of Beasts is smaller than on Monday last, and the demand is good; consequently prices on the average are higher, and a fair clearance is effected. The supply of English is smaller than has been known for a very long time; we have a large number of foreign, but this does not make amends for the deficiency of English; prices for choicest qualities have advanced, with a ready sale. Trade is dull for Lambs, the season being far advanced. Calves are lower. Our foreign supply consists of 2650 Beasts, 14,360 Sheep, 355 Calves, and 10 Pigs: from Ireland there are 20 Beasts; from Norfolk and Suffolk, 30; and 1550 from the Midland and Home Counties.

Beasts, 4350; Sheep and Lambs, 23,840; Calves, 393; Pigs, 50.

THURSDAY, Aug. 31.

We have a much larger supply of Beasts than on Thursday last, the increase being almost entirely in foreign; trade is very slow, and prices on the average are lower. The number of Foreign Sheep is larger, and of English rather smaller, than last week; trade is not so active as of late, but there is not much reduction in price of choicest qualities. Choice Lambs and Calves are making nearly as much as of late, but it is difficult to dispose of inferior qualities. Our foreign supply consists of 800 Beasts, 7365 Sheep, and 400 Calves.

Small Pork, 4*s.* 8*d.* to 5*s.* 0*d.*; Large Pork, 4*s.* 0*d.* to 4*s.* 4*d.* per 8 lb.

ENGLISH WOOL.

Business during the past week has been on a fair scale, at prices fully 4*d.* to 5*d.* per lb. above the opening prices of the clip, and everything appears in favour of rates being maintained. For the moment, however, owing to the very high rates asked, and to the fact that manufacturers have stocked themselves pretty freely, there is not the same excitement in buying that there was a fortnight ago.

MARK LANE.

MONDAY, Aug. 28.

There was a better supply of English Wheat from Essex and Kent to this morning's market than for some time past (including about 1500 qrs. of new), which sold slowly at the prices of this day se'nnight. The attendance was good, but only a moderate demand, Russian and American bringing an advance of 1*s.* per qr. Beans and Peas were without change. Grinding Barley 1*s.* per qr. cheaper. Oats were a slow sale, at a decline of 6*d.* per qr. Flour was unaltered in value. There were a few samples of new white Mustard shown, but no business resulted.

WEDNESDAY, Aug. 30.

A steady tone has been observable in the grain trade to-day. A moderate supply of new English Wheat has been on offer. There has been a healthy demand, and prices have been well maintained. Old samples of both home and foreign grown have been steady in value and inquiry. The supply of Barley has been good. The trade has been steady on former terms. Malt has been quiet, at late rates. Oats have been in large supply and moderate request, at the rates previously current. Beans have been quiet, at late currencies. For Peas the demand has been inactive, at about previous quotations. Flour has changed hands quietly, on former terms.

LIVERPOOL, Aug. 29.—To-day's market was fairly attended by buyers of all classes, and in Wheat there was a moderate business, at about Friday's improvement of 2*d.* for the finest red, 3*d.* for white descriptions, over last Tuesday's prices. Flour of all kinds, dull. Corn more especially, was in more request, and commanded rather higher figures. Fine old Oats scarce and firm; new English pressed, and tending downwards. Oatmeal dull, and now reduced 1*s.* per load. Egyptian Beans and Canadian Peas both quiet, at previous rates. Malt slow, but not cheaper. Barley, no sound on offer; unsweet rather easier. Indian Corn met a fair consumptive demand, at the currencies of this day week. American white is quoted at 35*s.* 6*d.* to 36*s.* 6*d.* per 480 lb.

SEED MARKET.

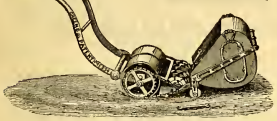
Our seed trade continues in a quiet state. In Clovers of all kinds there is but little passing. Trefoils are firm. Trifolium is in improved request, at the recent decline. New Rape seed is scarce, and must be quoted 32*s.* to 42*s.* per qr. dearer. New Mustard comes to hand at moderate quotations. Hemp and Canary are unchanged in value. Winter Tares do not at present come forward very freely. The chief characteristic of this year's produce is an abundance of haulm; this is a great comfort is prejudicial, both to quantity and quality; hence many complaints are made of the yield of both cereals and seeds.

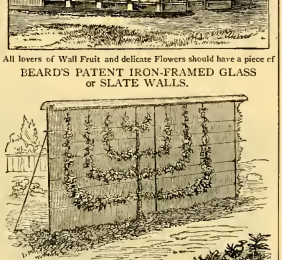
JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

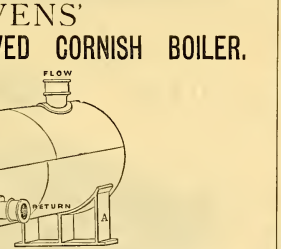
HOPS.

BOROUGH MARKET, Aug. 31.

Messrs. Pattenden & Smith report that there is scarcely any inquiry for 1870 Hops, and prices are consequently merely nominal. A few pockets of the new growth have arrived at market, the quality of which is fairly good for early pickings, but they do not find a ready sale.







GREENHOUSES, FORCING-HOUSES, VINERIES, and ORCHARD-HOUSES, made of the best Yellow Deal, Glazed with 15-oz. Sheet Glass, painted four times: 20 feet by 12 feet, £40; 30 feet by 12 feet, £60; 40 feet by 15 feet, £85; 50 feet by 18 feet, £110; 100 feet by 20 feet, £270.

The above prices include Brickwork, Staging, Delivery, and Fixing, within 50 miles of London. Plans and Estimates sent on receipt of size required to

R. STEVENS, Horticultural Builder, Simpson's Road, Bromley, Kent.

GASELIERS in GLASS or METAL.—The increased and increasing use of Gas in Private Houses has induced WILLIAM S. BURTON to collect from the various Manufacturers in Metal and Glass all that is new and choice in Brackets, Pendants, and Chandeliers, adapted to Offices, Passages, and Dwelling-rooms, as well as to have some designed expressly for him, which present, for novelty, variety, and purity of taste, an unequalled assortment. They are marked in plain figures, at prices proportionate with those which have tended to make his Establishment the largest and most remarkable in the Kingdom, viz., from 12s. 6d. to £3. Brackets from 1s. 9d.

TEA URNS, of LONDON MAKE ONLY.—The largest assortment of London-made BRONZE TEA URNS and KETTLES in the world (including all the recent Novelties), is on Sale at from 30s. to £6.

DISH COVERS and HOT-WATER DISHES, in every variety, and of the newest and most recherché patterns, are on show. Block-tin Dish Covers, 7½d. the set of six; elegant modern patterns, 9s. 6d. to 40s. the set of six; Britannia metal, with or without silver-plated handles, £3 2s. to £6 8s. the set of five; electro-plated, £9 to £26 the set of four; Block-tin Hot-water Dishes, with wells for gravy, 12s. to 30s.; Britannia metal, 21s. to 80s.; electro-plated, on Britannia metal, full size, £5 5s.; do. on Nickel, full size, £10.

FENDERS, STOVES, KITCHEN RANGES, FIRE-IRONS, and CHIMNEY-PIECES.—Buyers of the above are requested, before finally deciding, to visit the SHOW-ROOMS. They contain such an assortment of Fenders, Stoves, Ranges, Chimney-Pieces, Fire-Irons, and General Ironmongery as cannot be approached elsewhere, either for variety, novelty, beauty of design, or exquisiteness of workmanship, or price.

Black Register Stoves	..	from .. 8s. to £9 9s.
Bright ditto, Or-molu ornaments ..	..	from £3 8s. to £33 10s.

EPIPHYLLUMS, in variety, good.

Prices on application to B. WHITHAM, The Nurseries, Reddish, near Stockport.

Orchids.
JAMES BROOKE AND CO. beg to invite attention to their splendid stock of ORCHIDS, adapted for supplying a regular succession of the most exquisite cut flowers. The singular beauty, and the long continuance in cut flower, of the varieties recommended as better suited than any others for high-class ornamental purposes, including use by gentlemen and there is no reason why a skilful gardener should not have abundance of them almost always at command, and a little more trouble than is required for select Dutch Bulbs.

Messrs. BROOKE AND CO.'s stock includes all the best sorts for cutting, the Bulbs are well matured, and they are certain to yield plenty of blossom.

57 and 58, Victoria Street, Manchester. Nurseries: Fairfield, near Manchester.

JEAN VERSCHAFFELT begs to offer the following, in fine healthy plants, at the undermentioned low prices, viz.:—
CAMELLIAS, 2 to 3½ feet high, with buds, best sorts, all named varieties (descriptions left), 1, 2, 3, 5, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100 strongest, 6s. 8d., £12 and upwards per 100.
OTAHEITE ORANGES, 2 to 3½ feet high, 30s. per 100.
JASMINUM GRANDIFLORUM, fine grafted plants, flowering all through the winter, 12s. per dozen.

Early orders are respectfully solicited, especially as regards Camellias, which are a scarce article this year. Apply to

JEAN VERSCHAFFELT, Nurseryman, 134, Faubourg de Brabelles, Ghent, Belgium.

New Bedding Plant, Thymus citriodorus aureus
MARGINATUS (Lemon-scented gold-edged Thyme).

MESSRS. FISHER, HOLMES, AND CO., Handsworth Nursery, Sheffield, will send out the present autumn an exceedingly pretty Thyme, of an erect-growing but much-branched habit, with large obovate leaves, which are of a very bright dark green in the centre, and of a broad rich golden-yellow margin. Variegated variegation; is very handsome and attractive. It will prove very effective for the purpose of forming beds, borders, or edgings, and for growing in masses on banks, or in other varied forms; it may be grown in large pots or pyramids for conservatory decoration, having proved perfectly hardy. Altogether, it may be considered as one of the most charming bedding plants known, and with the additional delicious fragrance of the sweet-scented Lemon Thyme.

It received the Royal Horticultural Society on June 21, 1871, and received a First-class Certificate; also at the Royal Horticultural Show at Nottingham, a First-class Certificate.

PRICES:—
1 plant for 2s. 6d. | 12 plants for 18s. | 50 plants for 65s.
6 plants for 10s. 6d. | 24 plants for 32s. | 100 plants for 125s.
Trade terms on application.

THE LONDON MANURE COMPANY (ESTABLISHED 1840), have now ready for delivery, in fine dry condition—

PURE DISSOLVED BONES.
CONCENTRATED ORNITHACAL MANURE, for Top-Dressing.
FURSER'S BONE TURNIP MANURE.
SUPERPHOSPHATE OF LIME.
NITROPHOSPHATE.
MANGEL, HOP, and POTATO MANURES. Also
PERUVIAN GUANO (as imported by Messrs. Thomson, Bonar & Co.), NITRATE of SODA, SULPHATE of AMMONIA, &c., &c.

110, Fenchurch Street, and 21, Mincing Lane, London.

REES AND CO.'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in bags. It is believed to be the best Artificial Manure yet produced. Its base is Peruvian Government Guano; it contains 25 per cent. of Soluble Phosphates, 5 to 7 per cent. of Ammonia with Salts of Potash. See reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Lawes, and others. Delivered in 2 cwt. bags, each of which is secured by a leaden seal, bearing the Company's Trade Mark. The analysis is guaranteed to be true, each sample undrawn.

REES AND CO. (Limited), 58, Old Broad Street, London, E.C.

DEPOSITIONS by Dr. A. VOELCKER, Consulting Chemist to the Royal Agricultural Society of England.

"Analytical Laboratory, 11, Salisbury Square, Fleet Street, E.C., "London, 4th May, 1871.

"SIR,—Enclosed you will find the results of a careful analysis of a sample of your Biphosphated Peruvian Guano. These results speak for themselves. I need, therefore, hardly add anything in commendation of the high fertilising character of this valuable Artificial Manure. The samples examined by me contained only 10 per cent. of moisture, and fully the percentages of soluble and insoluble phosphates which I understand you guarantee to furnish, and was in a fine state of preparation. The more generally this Manure will become known to practical farmers, the more I am convinced it will be appreciated by them.—Believe me, Sir, yours respectfully,

(Signed) "AUGUSTUS VOELCKER.

"The Secretary, REES AND CO. (Limited), 39, King William Street, London, E.C."

CLASS 5.—COLLECTION of DESSERT PEARS, 3 fruits of each variety.

1st, Silver Gilt Medal. | 2d, Large Silver Medal.

CLASS 6.—COLLECTION of KITCHEN PEARS, 3 fruits of each variety.

1st, Large Silver Medal. | 2d, Bronze Medal.

CLASS 7.—COLLECTION of GRAPES, 2 bunches of each variety.

1st, Gold Medal. | 2d, Silver Gilt Medal.

CLASS 8.—The LARGEST BUNCH of GRAPES.

1st, Silver Medal | 2d, Bronze Medal.

CLASS 9.—COLLECTION of ORANGES, LEMONS, CITRONS, LIMES, &c.

1st, Gold Medal. | 2d, Silver Gilt Medal.

CLASS 10.—MISCELLANEOUS FRUIT, not mentioned in either of the above classes.

By Order of the Council,
HENRY V. D. SCOTT, C.B., Major General,
Secretary to the Royal Horticultural Society.
And to Her Majesty's Commissioners of the Exhibition of 1851.

The Gardeners' Chronicle

SATURDAY, SEPTEMBER 9, 1871.

A SEASON of unusual horticultural exertion and display is drawing to a close, and the thoughtful part of the outside public, as well as the originators of and contributors to the EXHIBITIONS, must naturally ask themselves how far the efforts of the latter are producing any permanent and real impression on the general mass of the people—whether the increase in the love of flowers, which is indicated by the number of exhibitions and the interest taken in them, belongs only to the upper classes, or is extending its way downwards and leavening the whole mass ?

Jaded and exhausted by the summer's work, we anticipated the holiday of our legislators, and ere they had broken up had already spent a few weeks in visiting different parts of the country in search of ozone and health, and have thus had an opportunity of comparing the present state of things with what we remember 30 years ago in Kent, Berkshire, Derbyshire in its wilder parts, the south of Scotland and Perthshire, and, with the readers' good permission, we shall ask them to compare their impressions with ours, and see whether we have not arrived at a right conclusion in the matter.

So far as regards Kent and Berkshire, we would at once eliminate them, or rather put them in a special category peculiar to them and those parts of England which lie within villa-range, that is, the distance of a morning's railway ride from London or the great provincial capitals. The villa-range is expanding itself with marvellous rapidity, and wherever it reaches, there town influences, town capital, and town ideas make themselves felt, so that we cannot get at the natural and undirected bent of the mind of the people. If, in such a district, we see a cottage tastefully embowered in flowers, and with a gay, tidy and well kept garden, we cannot set that down to the taste and natural inclination of the inhabitant. No doubt it may be so, but much more probably it is due to his being employed by the master of the neighbouring villa, who likes beautiful surroundings, and has suggested the decorations, supplied the plants, and possibly lent his gardener, besides offering prizes or other artificial inducements to pay attention to his garden. It, therefore, tells us nothing as to the degree to which the love of flowers has penetrated into the hearts of the people, or how far if left to itself and free from any artificial fostering, it would be developed, and show itself practically. We would also put aside, as a special and exceptional development, consequent on a peculiar condition of life, the love of flowers exhibited in the suburban districts of great cities, as at Spitalfields, Nottingham, &c. These do not concern our present inquiry.

Turning from such places to the less peopled regions, where a foot of the stranger may still find room to wander from the path unchecked, where each side of the highway is not preserved from intrusion by an 8-foot wall, and where thatched cottages with kailyards stand in lonely patches, or scattered at long distances, we shall have a better chance of seeing how far the natural genius of the people has been affected by the advent of Flora.

We happened last month to be present at the pretty little village of Dalbeattie, in the stewartry of Kirkcudbright, at the time when their local Horticultural Show was held, and had the honour of assisting at the *concours*. We were also not long since present at other country shows in similarly circumstanced places, and with the exception of trifling differences due to the greater or lesser size of the place, the greater or less number and wealth of the neighbouring country magnates, and the greater or less zeal, energy, and skill of the managers of the shows, the same features showed themselves in all. Unless where the place is of sufficient magnitude to have a nursery in the neighbourhood, the contents of the show all divide themselves into three well defined sections,—the contributions of the neighbouring gentry, those of the traders and townspeople, and those of the cottagers. At Dalbeattie, under a tent of a deep crimson colour, of the hue patronised from time to time by the Royal Horticultural Society, we penetrated into a good-sized apartment with tables round the walls, and three parallel tables running up the middle, all well loaded with plants. The central tables were principally filled by greenhouse and hothouse plants of good size and well cultured, clean, healthy, and vigorous, such as Screw-Pines, Palms, good varieties of Caladiums, double Balsams, &c. We did not need to ask, in order to know that these were the contributions of the neighbouring gentry, and accordingly, on inquiry, we found that they had been sent by Mr. WELWOOD MAXWELL, of Munches, the member for the county, and the nearest landed proprietor. Next we found a table devoted to cut Gladioli, Tricolor Pelargoniums, Petunias, Fuchsias, &c., these represented the well-to-do tradesmen of the village. Then, *longo intervallo*, came the simplest and most common everyday flowers of the open border, such as Antirrhinum, Pyrethrum, French Marigold, &c. These were the product of the cottage garden, and many of them (most of them) could scarcely be called the product of care or attention, but must have been merely culled from old plants which happened to be growing in the kailyard of the house which the exhibitor chanced now to occupy. That these were exhibited at all was an indication of the fostering thought of some one above them who kindly sought to introduce a taste, but no indication whatever that the taste existed where it was sought to be planted.

No doubt if we knew all the outs and ins of the motives and state of mind of the exhibitors, we might see that we are doing them great injustice ; but, judging from appearances, we should say that this little exhibition showed that, so far as regards the upper classes, horticulture stood here exactly at the same high level as in London and any other part of England. The same habits, tastes, knowledge, and modes of thought, pervade the upper stratum of society in every corner, chink, or cranny of the kingdom. Comparison with 50 years ago tells of little change in love of horticulture as regards them. Horticulture is more advanced ; but, as then, they are still at its head. A much greater change has taken place in the middle classes, and especially the lower ranks of the middle class. Formerly contented with no gardens at all, or only with yards like those of the cottager, they are now not satisfied unless they have their trim beds, their choice plants, nay, their greenhouses and conservatories. The advance has been great in that rank of life. But with the cottager pure and simple—the country cottager unsupported by the presence, the aid, the promptings of his superiors, we are bound to say that we can see no advance ; in places we could point out, rather seems to us that there has been retrogression. We remember in our youth the luxuriant yard with its side beds edged with Chamomile, Hyssop, or Daisy, its Lily of the Valley in the shady corner, the large white Rose bush, the Valerian, the Campanula, and the big bush of Southernwood, which scented all the church on Sunday. When we have lately gone to refresh our memories with another sight of them, we have found their place occupied with a stack or a pigstye ; and we are told by inhabitants of the rural districts of which we speak (beyond squirearchal influence) that the taste for flowers has rather diminished ; that where formerly some old gardener or enthusiast could be pointed to who had a love for flowers, and a special collection of them, now-a-days there are none such : you must go to the towns for them.

In one respect, however, we must qualify the opinion we have expressed. If Flora is neglected, the cultivation of vegetables has made more progress. Any improvement in what is to gratify the lower appetites, or to put money in the purse, seems more readily to make its way ; what is to improve the mind and gratify the higher and more delicate sensations stands still. This improvement in the cultivation, and especially in the sorts of vegetables, probably comes to the cottager through the farmer. Let us hope that as progress is being made in the more material aims of horticulture, its more refined influences may also follow to the class of which we have been speaking.

THE annual dinner of the MARKET GARDENERS, NURSERYMEN, and FLORISTS' ASSOCIATION was held at the Fox and Hounds Hotel, Putney, on Monday last, when the President, Mr. HENRY MEYERS, occupied the chair, and was supported by nearly 100 of the leading agriculturists and market gardeners of the Home counties. After the usual routine business had been got through, the Chairman, in proposing "Prosperity to the Association," said that in the year 1828 a proposal was made by the then Duke of BEDFORD to rebuild Covent Garden Market, and as considerable doubts were raised in the minds of the producers as to what would be asked, a few of them, himself included, formed themselves into a committee, which ultimately developed into a wealthy and influential society, to watch over the interests of the producers generally. There were not more than four of the original members now alive, for the society had been in existence 43 years, but now, rather than at any other time, was the influence of the society most felt. They wanted a new market, simply because no effort was made to give them accommodation at Covent Garden, and, aided by their strength and influence, they would have one. They were backed, by their united action, that they were entitled to more consideration than had been shown them. Their interests were the interests of the whole metropolis, for not only did they stock the markets which supplied all London with vegetables, but they were also instrumental in upholding the health of the metropolis, by daily removing the refuse and filth, and utilising it in the production of further supplies of fruit and vegetables for the markets. Why had they not been more looked to, and their interests more studied ? It was all very well for the people of London to set their faces against the removal of the market from Covent Garden ; but did they know the shameful neglect of all accommodation and inducement for the grower to continue his supply to the market in question ? Did they know that for hours in the bleak winter morning, in rain or snow, the market gardeners had to stand out in the open air, because a wealthy proprietor would not so much as cover in a market which was returning large profits ? It was not his wish, or the wish of other producers, to remove Covent Garden Market ; but what they asked for was

a good central market, where they could send their produce if they thought proper, and not be entirely in the hands of a landlord who would do nothing to accommodate them.—Mr. D. CLARKE (another large grower) cited many instances of the injustice under which, he said, the producers were placed. Many of his men had had long illnesses through having had to stand with their waggons at Covent Garden exposed to all weathers. He also alluded to the fact of so many applications having been made to the Duke of BEDFORD to have the whole area of the market covered in, and the point-blank refusals on the part of his agent.—In response to the "Health of the Visitors," Messrs. BONTEMS and RUDKIN (members of the Market Committee of the Corporation of the City of London) returned thanks. The former explained that there was no desire on the part of the committee to bring about the removal of Covent Garden Market. A great want was felt in the City of a contignous fruit and vegetable market, and as Farringdon Market was the most unsatisfactory of the City markets, the committee had resolved to improve it; and if by doing so they could meet a want felt by the market gardeners, their object would be materially assisted. The committee's province was to provide markets for the better accommodation of the City; and, next to that, their study would be to suit the convenience of the producers.

—— A correspondent writes, "Our Oaks have very few acorns, but are covered with growths like the enclosed. What are they? are they general this season?" We reply, they are ARTICHOKE GALLS, caused by the puncture of a female Cynipidous fly, called Aphilothrix gemmæ (Linné). These galls are, to the detriment of our Oaks, very abundant almost everywhere this season, and the idea of harvesting acorns must be abandoned wherever the fly has got a firm foothold. If our correspondent will gently remove the hop-bloom-like fibres from the cup covering, he will find a small stunted acorn within. Let him now take his penknife and remove a flat slice from the shell, he will then perceive a cavity, within which a fat, white, footless maggot is nestling, biding the autumnal time, when his "Diogenes' tub" will fall to the ground, remaining quiescent and shortly after the full spring liberates the mature fly. We attribute the increase in the numbers of the fly to the reckless way in which our Oaks are often managed. Everywhere the fine timber is felled, giving place to unhealthy undergrowth, or upshots from the ancient roots remaining. Such copses are nurseries, from which issue swarms of these flies annually, whose oviposition in the buds of full-grown bearing Oaks destroys all hope of a harvest of acorns. We must give up "saving our bacon" so long as we encourage the wholesale felling of mature Oak timber, without taking care that its place is filled up by properly planted, healthy young trees. *Alb. M.*

—— We have received a copy of a circular announcing, in the names of His Grace the President and Council of the Royal Horticultural Society and of Her Majesty's Commissioners of the Exhibition of Industry of 1871, that a GREAT INTERNATIONAL EXHIBITION OF FRUIT, in which all home and foreign growers are invited to take part, will be held at South Kensington on October 26 next. Prizes, consisting of gold, silver-gilt, silver, and bronze medals will be awarded for the most complete collections of Apples, for collections of dessert Apples, for collections of culinary Apples, for the most complete collections of Pears, for collections of dessert Pears, for collections of kitchen Pears, for collections of Grapes, for the largest bunch of Grapes, for collections of Oranges, Lemons, Citrons, Limes, &c., and for miscellaneous fruit, not mentioned in either of the above classes. All packages of fruit for the exhibition are to be addressed to "The Secretary of Royal Horticultural Society, South Kensington, London," from whom schedules of prizes may be obtained. For further particulars see the advertisement in our present issue.

—— The MAXIMUM TEMPERATURES of the AIR for the week ending September 2, ranged from 82° at Blackheath, to 66° at Aberdeen, with a mean for all stations in England of 78°.5, and in Scotland of 72°.2. The MINIMUM TEMPERATURES of the AIR ranged from 52°.5 at Liverpool, to 44° at Hull. The mean for the northern country was higher than that for the southern; that for Scotland being 48°, and for England 47°.1. The MEAN TEMPERATURES ranged from 64° at Blackheath, to 56°.1 at Dundee, the mean for England being 61°.1, and for Scotland 57°.9. The greatest falls of rain were 0.55 inch at Leeds, and 0.56 at Bradford. The mean fall for England was 0.18 inch, and for Scotland 0.08 inch. (See Mr. GLAISHER'S Tables, p. 1171).

—— Those who have experienced difficulty in planting the stronger-growing AQUATICS may find the following hint, which occurs in one of Mr. BUCKLEY'S papers on Water Plants in the "Florist and Pomologist," useful to them, the more so, as he observes, that it is almost ludicrous to note some of the cumbrous modes recommended by persons who seem inclined to mystify the subject. Any urchin, he says, knows how to dispose of an old offending "grimalkin," by tying one end of a short string round a brick, and the other end round the neck of the nocturnal prowler. Behold in this simple all the mystery of planting Water Lilies! If the rhizomes are thrown into the water without some weight attached, they will certainly rise to the surface, and so float and perish; but when planted in this way, by the time the cord has decayed they will have taken root and become fixed. When the lake is large, it is best to use a boat, and just drop them where they are wanted to grow. If near the margin they can be thrown in. After this they will take care of themselves.

—— It is stated in Dr. LINDLEY'S "Vegetable Kingdom," ed. 3, 1853, that the PLACENTA in CARYOPHYLLACEÆ is proved to be really central by a monstrous Cerastium figured in this Journal (1844, p. 557), (see fig. 265), in which the carpellary leaves are partially turned inwards without touching the placenta, which bears a cluster of ovules, and is perfectly clear of all connection with those partitions. In some normal species, however, the ovarium is furnished at the base with delicate septa, which soon vanish, and it does not appear that the argument in favour of free central placentation is much strengthened by Prof. BABINGTON'S monstrosity.

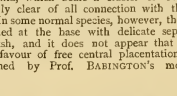

FIG. 264.—AXILE PLACENTA IN CARNATION.

Dr. LINDLEY had forgotten, however, that in 1850 some absolute evidence was published in this journal (p. 612), showing that in a monstrous Carnation really marginal placentæ were produced with ovules attached, while in other cases ovules were freely produced from the free margins of the carpellary leaves. We have now a monstrous salmon-coloured Clove, in every flower of which not only is the inflected margin of the carpels distinct from the base to the apex, but in an early stage of growth the connection between it and the two divisions of the axile placentation is perfectly distinct, as is the solution of continuity a little farther up. The case published in 1850 appeared to us quite decisive as to the point; but

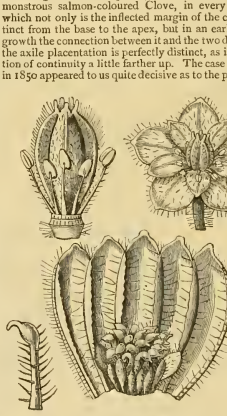

FIG. 265.—MALFORMED CERASTIUM.

if any doubt could be raised as to its real bearing on the subject, that now before us is beyond all doubt. Our figure (fig. 264) represents a section from the base below the point where any ovules are produced, one higher up, showing the connection of the axile placenta with the carpels; above this point the connection is often broken off on one side, while it remains on the other; the lower figure merely shows the connection a little enlarged. *M. J. B.* [To our correspondent's remarks, we may add that a similar malformation was described and figured by Dr. MASTERS in "Saponaria," in the Journal of the Linnean Society, 1857, p. 161; and that other cases are cited, and references given to many other recorded instances of like nature, in the last-named writer's "Vegetable Teratology," pp. 96—100, 483. EDS.]

—— We may note that one of the most interesting of formal subjects for summer conservatory, and terrace garden decoration is to be found in STANDARD LEMON-SCENTED VERBENAS (Aloysia citriodora). The plant is always a favourite for its gratefully-scented leaves, and trained up, with a well-balanced head, as a standard, it has a very good effect. In the noble gardens at Ashridge Park, the seat of Earl BROWNLOW, we lately saw a very fine set of plants of this character growing in tubs, and set out on the terrace walk in front of one of the conservatories. They were perfect in symmetry, and not only effective but novel in their appearance. These plants had clean stems of about 5 feet high, and bluntly conical heads, formed by careful and judicious pruning, some 3 feet deep and 2 feet or more in diameter at the base. In the same gardens we noticed a most valuable decorative Tropæolum with deep blood-crimson flowers, an accidental seedling, we believe, but evidently a cross between Tropæolum majus atrosanguineum, and some of the Lobbianum varieties, and combining much of the colour of the former, with the less coarse and nonexuberant foliage of the latter.

—— In reference to the late blooming plants of LILY OF THE VALLEY, referred to at p. 1041, Mr. FLEMING tells us that he has had many in the same state; indeed, he finds it a common occurrence with the patches of foreign origin. They are the plants first put in heat for Christmas, and from not being ripened, or from not having had sufficient rest, not one in a dozen of the patches will start; and if these are left in the houses, and are turned out in spring, they will then go on growing, and bloom late [July]. Some illustrative examples sent us are quite like those referred to, as to their general appearance.

—— Lieut.-Colonel CORMACK, of Shawborough, Tewkesbury, writing recently in the *Field*, mentions a most extraordinary instance of ACORNS INCLOSED IN AN ELM TREE, and requests an explanation from those learned in dendrology. He writes:—

"Two years and a half ago I felled, amongst others, a large Elm tree 12 feet in girth, and allowed it to lie until last October, when I commenced cutting it up. On sawing off the butt we discovered a cavity in the very centre of the trunk about 6 inches in diameter, and running up about 15 inches, which the cross cut divided as nearly as possible in the middle. In the cutting was no doubt complete than about a pint of Acorns fell out of the cavity, which I immediately picked up. To my utter astonishment, in that instant of time, on exposure to light and air, each Acorn sprouted about a third of an inch (!), and on examination I found them in as perfect preservation as if they had just dropped from the parent tree, although they must, for reasons which I will presently detail, have been inclosed any time from 100 to 120 years in the heart of the Elm. I took 25 of the Acorns up to the garden, and planted them in a bit of ground I inclosed for the purpose, and at this moment I have 25 as promising young Oak trees from them as are to be seen in the West of England. The Acorns were evidently a squirrel's winter hoard, for the marks of the little animal's rodents were quite fresh upon some of them. The cavity was an incipient decay, which the Acorns had apparently been just stored, when, by some unaccountable occurrence, it must have become hermetically closed, and so remained for a period, over the length of which, from the following description, I shall wish to ask the opinions of your scientific readers. As before stated, the tree was 12 feet in girth; the cavity was 6 inches wide, 15 inches high, and 2 feet from the ground; from the edge of the cavity to the bark, 2 feet 2 inches; and no less than 120 rings of wood had added to the bulk of the tree, and grown over the hollow, with its inclosure of Acorns, since both had become hermetically sealed up! Adopting even the usually received theory, that trees add one ring of wood annually, the Acorns must have remained with unimpaired vitality for 120 years; but I am inclined to think that an Elm tree, as it increases in size, requires several years to form a ring. Hills is, however, precisely the point on which I should feel obliged for information. The circumstance is anyhow worth noticing; but the problem I wish solved is, 'How long could the Acorns have remained in the tree, 120 rings of wood having grown over them since first inclosed?'"

—— On the 11th inst., the SALE of the NURSERY STOCK of Mr. H. LAURENTIUS, at Leipzig, will begin with the hardy Coniferæ. The catalogue contains 4125 lots, including something like 60,000 plants. Conifers, evergreens, and seedlings, 253 lots; hothouse plants, 483 lots; greenhouse plants, 221 lots, &c. Fine specimens of large Orangé and Pomegate trees, Tree Ferns, Palms, Camellias, Azaleas, Dracænas, Agaves, Yuccas, Pitcher-plants, Orchids, Amaryllises, &c., are amongst the numerous lots offered for sale.

—— On referring to some old correspondence with the *Gardeners' Chronicle*, we find that precisely the same affection in GRAPES was brought to our notice at the beginning of September, 1856, by a correspondent signing himself "A. M.," and dating "C. M., September 6," as that to which attention was drawn last week (p. 1139), as produced by a species of Gleosporium in Muscat of Alexandria. He does not mention what was the particular variety affected, but, after trying all sorts of remedies in vain, the disease spread over the whole house, and was very destructive. It was stated the following week that it was due to a species of Gleosporium, but without giving any specific name, and the specimens have remained ever since in the Herbarium, with the MSS. name Gleosporium uvicola. We are, however, now of opinion that it does not differ from G. lyticolor, which is occasionally destructive to Peaches and Nectarines, and it is the more necessary that this identity should be recorded, as, where Grapes are grown in the same house with stone-fruit, the malady may spread upwards, especially as the pale, salmon-coloured spores ooze out in the form of little tendrils. Those who have Peaches or Nectarines which are affected should, of course, be removed at

once. Both on Grapes and stone-fruit the spores of the Fungus are very variable in size, so that no stress can be laid on mere measurement. A figure of the closely allied species, *C. fructigenum*, will be found in "Cooke's Handbook," copied from this Journal, 1856, p. 245. *M. J. B.*

— In the "Journal of Botany" for the present month we find the following note relating to ROSA GALLICA, gathered by Mr. WILSON SAUNDERS in a hedge near Charlwood, in Surrey. "Where it grows," says Mr. SAUNDERS, "it is as wild as Rosa canina, R. arvensis, and R. micrantha, all found in the same broad copse-like hedge so frequent in some parts of Surrey and Sussex. In place on the west side of this hedge facing a cornfield, through which there is no footpath, There are two patches of the Rose, one about two or three yards in length, and containing only a few plants, the other many yards in length, and containing a considerable number of plants. The cornfield alluded to is situate about intermediate between two farms, which are nearly half a mile apart, and no buildings nearer. After diligent search, I cannot find the Rose in any other locality about Charlwood, either wild or in the gardens of the farms and cottages. It is a complete puzzle to me, this locality of this Rose. I cannot conceive it to be originally wild there, but how it could get so thoroughly naturalised where it is, is equally difficult to understand. It must, I think, have been very many years where it is." Can the Rose in question have been cultivated at any time in the locality for druggists' purposes?

— We learn that the fourth and, we regret to say, concluding part of Mr. J. T. MOGGRIDGE'S FLORA of MENTONE will be issued before the end of October.

New Garden Plants.

ONCIDIUM BRACHYANDRUM, *Lindl.*

Pseudobulbus oblongus arcops prasinus superne gregarie atropurpureo-maculatus vix sulcatus unifoliatus, unus latus, diphyllus. Folia grameneo-pergamenea, ligulata, acuminata, ad quatuor pollices longa, dimidium pollicem vix lata. Pedunculus gracilis, uni usque biforus. Bracteæ hyalinæ triangulæ. Sepalum impar cuneato-oblongum acuminatum. Sepala lateralia lanceolata falcata acuminata. Petala subæqualia, latiora, cuneato-oblongo-lanceolata, limbo externo flavido angulis quibusdam flavidis. Labellum cuneato-rhombeum obtusangulum antice retusum, lamina. Lateralia geminæ foliolatæ in disco, lamella subæquali externa magis basilari utrinque adnata. Columna trigona brachio ligulato obtuso carthagineo utrinque supra bucculas infrastigmaticas situ callum basilarem sc. unguem carinæ labelli excurrentem recipientes. Labelli cuneus munc utrinque auricula obtusangula.—*Oncidium brachyandrum*, Lindl. Sert. ined. ab t. 25; M. Wiss. Oncid. 111.

A very delicate little plant, very near the well-known Oncidium graminifolium, Lindl., but totally different in the leaves (unknown to Dr. Lindley), and the column and the lip. It is a very delicate, tiny thing. It appeared some time ago in the collection of Messrs. Veitch. Just now it has flowered with J. Day, Esq., who kindly informs me it came from Mexico in company with Epidendrum vitellinum and Lælia majalis. *H. G. Rchb. fil.*

ODONTOGLOSSUM PLATYODON, *n. sp.*

Affine O. Lindenii, Lindl. Sepalis unguiculatis oblongis acutis; tepalis cuneato-ovatis obtuse acutis; labelli laciniis basilaribus obtusangulis, lacinia antica oblongo acuta; carinis geminis per basin, parum infra brevi medians aequantibus, utrinque addito dente lato prostrato et denticulo parvo; columna aptera arcuato ascendente.

A yellow-flowered species, perhaps not without interest when bearing a full panicle of hundreds of flowers, but as the Calanthes, Oncidia, &c., gain favour, not by the single flowers, but by the mass of them. It comes from New Grenada, and appears to be distinct in the calli of the lip from the very polymorphous O. Lindeni, Lindl. It is now also called Odontoglossum platyodon in gardens. The plant is very vigorous, and may prove easy to manage. I have got dry wild specimens from my invaluable correspondent, Stuart Low, Esq. *H. G. Rchb. fil.*

THE POTATO DISEASE.

DR. JULIUS KÜHN has devoted much time and attention during the past and several previous seasons to ascertain whether the Potato blight (Peronospora infestans), is really communicated from tuber to tuber, either in the ground or after they have been stored away; or, as some assert, whether it invariably proceeds through the haulm to the tubers. The cause of the blight in Potatos admits no longer of the least shadow of doubt, but few persons have the time and facilities for microscopical investigations to watch the progress and development of it. It is now quite certain that this blight is due to, and the effect of the attack of the above-named parasitical Fungus. The spawn penetrates the substance of the tubers. Whence the germinating spores come—or rather what their exact nature and capabilities are—is still an unsolved problem. There is such an infinity of forms of these lower organisms, that even the researches of those who have devoted their best years to the study of this branch of natural history have produced little beyond negative results. The theory that many of these apparently different blights and moulds originate from the self same kind of spores is a very attractive one, and one which has long had its supporters, both in this country and on the Continent.

Indeed, it does seem probable that the spores of these Fungi, which pervade the air at some seasons of the year, are capable of accommodating themselves to circumstances, and also of assuming different forms under different conditions. At all events, some curious discoveries, bearing upon this point, have been reported, tending to confirm the theory of the variability these organisms are liable to; hence we must allow that this view possesses a certain amount of plausibility. The great variability of plants of more complex organisation is a fact patent to all, and recent researches have shown that many of the supposed species must be united, amongst the Fungi, which have been founded upon different stages of the same plants. Many parasitical Fungi are conveniently named after the nurse-plants upon whose tissues they prey, but it is possible [In some cases certain] that the same species preys upon different plants, and exhibits certain peculiarities according to the structure and properties of the nurse-plant.

But to return to Dr. Kühn's investigations into the possibility of the spread of the disease from infected to healthy tubers. It is pretty generally supposed that the Fungus does not continue to maturity in or upon the infected tubers, and, consequently, that the disease is not conveyed from one tuber to another. Those Potatos afterwards found diseased in which no trace of it could be detected when stored away, are presumed to have had the germs of the disease in a latent state when they were taken out of the ground. The mycelium continues to spread throughout the substance of the tuber, but as no zoospores were believed to be formed, and as the mycelium could not penetrate the skin of a sound tuber, it was naturally inferred that only those previously infected with the haulm originated. But from Kühn's numerous experiments and the examination of tubers in different seasons, it is shown that the Peronospora does increase and perfect its reproductive organs as freely underground, or when the tubers are stored away, as on the haulm above-ground. The ramifications of the mycelium bearing sporophores emerge from the skin of the tuber in any part, though chiefly from the cavities of the eyes. And as the zoospores are abundantly produced, the least dampness will cause the disease to continue to spread and commit its ravages.

There have been reports of cases of diseased tubers where no trace of blight had been observed on the haulm, but the probabilities are that it existed in small patches only, and thus it was overlooked.

This discovery naturally impresses upon us the importance of storing Potatos in dry heavy land, and providing dry storage for Potatos. They should if possible be harvested and stored during dry weather, and never placed in thick layers or large heaps, where they would be likely to heat or induce condensation of moisture, for, however slight our knowledge may be on this subject, we know that moisture is the most favourable agent for propagating the enemy.

[Since the appearance of Dr. Kühn's article, above alluded to, on the propagation of the Potato blight, a very interesting paper on the "Cause of the Potato Disease and its Remedy," by Herr von Waldenburg has been published in the "Wochenschrift," and we believe it to be sufficiently interesting to warrant us in giving it in full. The reader will perceive it is in direct opposition to the views of most physiologists of the present day.]

According to Dr. Kühn's communications, above alluded to, and the now widely-spread view, the cause of the Potato blight is wholly due to the parasitical Fungus, Peronospora infestans, and hence prevention is to be sought in the destruction of its spores. Since Von Martius first pointed out the existence of a Fungus, Fusisporium Solani tuberosi, in the Potato disease, and the publication of Unger's memoir on the exanthemata of plants, wherein he alludes to the distribution of parasitical Fungi, attention has been directed to the Potato Fungus, and the spread of the disease to the tubers has been attributed to infection from the haulm. And this view has been the more strongly insisted upon, because the spores have been developed upon sound tubers when cut asunder, and placed in moist air under a bell-glass; but still, the infection of large quantities of tubers stored for winter purposes in masses has by no means been proved; and, although the presence and approach of moulds in diseased Potatos admits of no doubt, it has not been shown that the origin of the disease is to be ascribed to the attacks of the Fungus; and the opinion that the disease may be prevented or cured by the employment of means to destroy the Fungus, will deceive those who rely upon it as their safeguard. The Potato disease consists of a withering or dying-off of the cellular tissue, and the vessels with their contents, which is visible in the discoloration and separation of the cells long before the appearance of the Fungus. In the tubers this decay is first seen immediately under the epidermis, which causes the latter to peel off when touched, as is the case with a frozen or scalded tuber. Here no Fungus is to be found, and this state, in the course of the disease, cannot be brought about by infection with Fungus spores. The Fungus makes its appearance at a later stage of the decay, along with the chemical decomposition of the decayed parts, in a similar manner as it does upon all other putrifying and mouldering bodies, as upon mouldy bread or fruit. And then the supposition that only one species of Fungus, whether it be Peronospora or Fusisporium, originates upon rotten Potatos, is erroneous. The species are numerous according to the different conditions, a fact overlooked by previous observers. Especially I have remarked a great difference in the species of Fungi in the two different forms of Potato disease, the dry rot and the wet rot. When dry rot takes place the most diverse moulds are found belonging to the division of the Mucedines, not only Fusisporium and Peronospora, but also species of Botrytis, Aspergillus, Penicillium, and Sporotrichium; whilst in cases of wet rot—where, however, Fungi are much rarer—the species belong to the Mucorini, amongst which the common Mucor mucedo is the most abundant. Thus in regard to the species of mould which prey upon decaying Potatos, there is nothing different from what is found on any other decayed vegetable matters, and the mould on Potatos is as little the cause of their decay, as in the case in stale bread. [This theory seems hardly tenable, even when restricted to the Potato blight, and is in opposition to the opinion of our learned mycologist, "M. J. B.," and most scientific men when more generally applied. Plants and animals are not necessarily always unhealthy previous to the attacks of Fungi, and we should be inclined to consider them the cause of the disease or decay, as in the case of mildew on many plants, though doubtless in many instances they follow in the track or assist some organic disorder. Hence we find many Fungi growing upon sound Potatos when left to themselves, as in blighted Potatos, but we certainly should not ascribe the decay of frozen tubers to the attacks of the Fungi. If, therefore, Fungi are not the first cause of the Potato disease their destruction will not help us much, even if we admit that the rapid spread of the Fungus can hasten or modify the course of decay.

Certainly, then, the real cause of the disease in Potatos must be sought elsewhere. The causes can be no other than the decay of the living tissues and beginning of their chemical decomposition, brought about by the sudden changes of temperature and moisture, under the influence of which the haulm and tubers may rot in the total absence of Fungi.

The Potato is a tropical, mountain plant, which enjoys in its native country a cool May temperature, with constant moisture at the roots; thus during its growth it is neither exposed to heat nor cold, nor to the repeated changes from wet to dry which it is subject to with us. Here in Brandenburg we often have in seasons of Potato disease a dry heat whereby the ground becomes heated to 40° R., equal to 122° F., and naturally these tubers like others, under it, become more or less scorched in places, and if they do not decay at once the disease may break out at a later period. If we wish to meet the true cause of Potato disease, we must endeavour to give the Potato as near as we can the same conditions that it enjoys in its native country, i.e. constant control climate and weather, we must do what we can in choosing suitable soil and position. A light, loose, somewhat sandy soil that does not readily part with its moisture, and becomes little heated by the rays of the sun, is the best adapted for the purpose, because the chances are not so rapid in this as in a heavier, closer soil. *R.*

THE AMATEUR GARDENER.

Soil for Potting Plants.—This is a not unlikely subject with inexperienced gardeners, and often a perplexing and trying one for those of considerable experience. We have, we believe, lost at least a dozen Camellias, during the last 12 months, from using improper soil; and on turning out some fine Lilies, which had not done well, we found them sickly from the same cause. With us, the cause of these failures was, we presume, but the want of care in selecting our materials, for we used a kind of sand which hardened like burnt clay, and would not incorporate kindly with the other ingredients. Yet it has always been a favourite axiom of ours that compost, with little additions or subtractions of certain items, may be made to serve for all the potting purposes which can come before ordinary gardeners. Such plants as Heaths, and many stove varieties, must have special soils, but the amateurs, for whom I write, will judiciously refrain from trying their hands at such delicate and touchy subjects.

When a plant is potted well, with suitable soil, it will let the water slip readily through on its being applied to the surface, instead of remaining for some time before it disappears. The pot will also feel light in proportion to its size, instead of heavy, like a lump of clay. The soil cannot be reckoned good which turns to fine dust when dry, but, on the contrary, it should be porous and lumpy rather than powdery, though, of course, the best soil will acquire the latter character by frequent watering if the surface is not occasionally renewed. When a plant potted in the right material is turned out for the purpose of inspecting the roots, they will be found to have run freely into it, while, in the contrary case, they will appear unnaturally confined by a clammy and cold surrounding material. It is clear, therefore, that an appropriate soil should be secured by the gardener before he can expect his collection of potted plants to flourish as they ought to do, and as by doing they can alone repay him for his labour.

We have just made up about a small cartload of

such soil as we think we can use for most purposes, in the following manner:—A barrow-load of leaf-mould, made of leaves thrown in a heap last autumn, and subjected to all the weather of the winter. If left for two or three years, the mould will be too fine, for the stalks and other fibrous parts of the heap are necessary to keep the mould porous, and without them it is apt to become too close, and even tenacious. Next, the same quantity of a good hazel loam, taken from an old pasture, with the fibrous matter in it. The best plan is to take up some turves growing in such a loam, and pile them up for a year or two, when the whole being chopped up together will admirably answer the purpose. But anything clayey must not be mistaken for loam; the genuineness of the latter being known by its feeling, when squeezed in the hand, like sugar, not like soap. Thirdly, the same quantity of rotten frame manure of last year, which is thoroughly fermented and decomposed, but has not lost the fibrous character of its materials. Last of all, to the whole of this material add a peck of white sand, that known as silver sand being the best. Mix all these ingredients well together, but do not be too anxious to break up all the lumps, for these will be most serviceable in potting. The whole should then be piled up in the open air, if possible in an angle formed by two walls. When winter comes on, a sufficient quantity for all purposes during that season may be housed in a shed, so as to be ready for use at any time. If this is not done, frost and wet may now and then leave the gardener without the necessary soil when he wants it. This compost should never be sifted, as is the ignorant practice of some people, for the fibrous matter in it will be found most valuable, as securing the results which we have mentioned above.

We confess that to the compost now described we added a barrowful of peat, the refuse of a turf heap, which had been exposed all last winter, and which was thoroughly reduced to the condition of ordinary garden mould. Perhaps this was done without due consideration, for we feel a little doubtful of the result of the experiment. It may possibly make the compost too clayey and retentive of moisture, and therefore we advise our readers not to try it. The four other materials will, we think, make a useful soil for almost all purposes. *H. B.*

BOCCONIAS.

Bocconias are not so much seen in gardens as their striking appearance would lead us to expect. The foliage is bold, and with a peculiar glaucous bloom; the flowers elegant, and of a cream colour. The species best known is the old B. cordata, sometimes called Macleaya cordata, a perennial which is quite hardy in the country, at any rate in the south, and well suited for the front of shrubberies or borders. B. frutescens is of a shrubby habit, and more tender, but when sheltered it forms a fine plant for the subtropical garden.

Bocconia japonica, a recent introduction, is, as will be seen from the accompanying illustration (fig. 266), a fine bold plant, admirably suited to give effect on our lawns, but requiring to be grown in a sheltered situation, and to be removed to the greenhouse in winter. The culture of these plants is of the simplest. They prefer a rather compact moist soil, and should not be exposed to full sunshine.

It would hardly be supposed, at first sight, that the nearest relationship of these plants is with the Poppies; such, however, is the case. They are Poppies with a different habit, no petals, and a two-valved capsule.

FIG. 266.—BOCCONIA JAPONICA.

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—VII.

Subgenus 2. Lilium Proper.—Bulbs squamose; stigma a thick head to the style, with three blunt lobes—(*Continued*).

Group 4: Martagon (Turk's-cap Lilies).—Perianth broadly bell-shaped, always drooping, its divisions lanceolate, broadest about the middle, not distinctly clawed, reflexed (usually from half or two-thirds of the way down) when fully expanded. Stamens diverging much on all sides from the central axis of the flower.

Like the Isolirions and Eulirions the Martagon Lilies fall conveniently into two sets, one with whorled and the other with entirely scattered leaves. As this is the largest group of the four I shall have to spread it over three papers, and will in this take first the species with verticillate leaves, which are as follows, viz.:—

Flowers purplish-red, casually white. 19. L. Martagon.
Flowers scarlet, passing into bright yellow.
Whorls of leaves usually one; style ½–1 lines long. 20. L. maculatum.
Whorls of leaves usually 3—4; style 1—1½ inches long. 21. L. canadense.

19. *L. Martagon*, Linn. Sp. Plant., p. 435; Jacq. Austr. t. 351; Bot. Mag. t. 803 and 1634; Red. Lil. t. 146; Kunth, Enum. iv. 257; Eng. Bot. t. 279, 3d edit. t. 1518; Spae, Mon. p. 26; Reich. Icones, t. 451.—Bulb ovoid, 1—1½ inch thick, the scales bright yellow. Stem 2—3 feet high, erect, terete, usually more or less densely clothed with fine grey pubescence. Leaves typically in three or four regular whorls of six to nine leaves each, with a few scattered ones placed usually between the uppermost and the inflorescence, oblanceolate-spathulate, the lower ones 3—5 inches long, 9—18 lines broad three-quarters of the way up, narrowed rather suddenly to an acute point, thinner than the average of the genus in texture, glabrous or inconspicuously downy below, spreading nearly horizontally, the two or three indistinct main veins spreading from the midrib at an acute angle, and not produced clearly to the point, the edge often seen with a lens to be ciliated. Flowers 3—12 in the wild plant, or as many as 20 under cultivation in a narrower and more regularly pyramidal raceme than in any other species, and which in fine specimens reaches a foot in length, and 4—5 inches in breadth in the lower part. Lower pedicels 1—3 inches long, drooping at the apex, not bracteolate, but furnished with a pair of lanceolate or linear bracts at the base. Perianth pendulous, 15—18 lines deep, typically a dull purplish-red, with copious spots of dark purple, the divisions oblong-lanceolate, cucullate and pubescent at the lip, distinctly pubescent down the back, soon much reflexed from three-quarters of the way down, 4—6 lines broad about the middle, not distinctly clawed, not papillose or pubescent down the groove. Ovary 5—6 lines long; style slender, 8—9 lines long, curved from the base; filaments 8—10 lines long, all much curved; anthers linear-oblong, 4—4½ lines long; pollen reddish; capsule turbinate, bluntly angled, an inch deep.

The commonest wild European species, stretching from Spain and France all through Central and Southern Europe, and in Asia far into Siberia, but in the extreme East and Japan appearing to be entirely replaced by maculatum, which is confused with it in Ledebour's "Flora Rossica." It is the old original Turk's-cap Lily of the gardens, and is mentioned in Gerarde's list of the plants cultivated in 1596, but it has now given way to a large extent, as a popular favourite, to its allies with brighter coloured flowers. It is a very well-marked plant, not likely to be confounded with any other species, and, though so widely spread, it is very little liable to variation in its characters. The principal forms which have been named are the L. hirsutum of Miller's "Garden Dictionary," No. 10 (L. Milleri, Schultes), a robust plant, with a densely puberulous stem; L. glabrum, Spreng. Syst. Veg. ii. 62, a more slender form, with white flowers, and subglabrous stem and leaves; and the two forms (dalmaticum of Maly and Catanii of Visiani), lately brought into notice by Herr Leichtlin, with very thick perianth segments of an exceedingly dark purple shade. L. Martagon is quite different from all other Lilies in the colour of its flowers. I have seen a single specimen gathered by Bourgeau in Piedmont, in which the leaves were entirely broken up, and the leaves scattered indiscriminately down the stem.

20. *L. maculatum*, Thunb. Linn. Trans. ii. 334; Kunth, Enum. iv. 258; Miquel in Ann. Mus. Lug. Bat. iii. 156; Spae, Mon. p. 30; *L. canadense*, Thunb. Fl. Jap. p. 135, non Linn.; *L. Martagon*, Lod. Fl. Ross. iv. 149, ex parte; *L. avenaceum*, Fischer MSS., Maxim. in Regel, Gartenfl. 1865, p. 290, t. 485.—Bulb ovoid, an inch thick. Stem 1½—2 feet high, straight, terete, glabrous. Leaves arranged usually in a single whorl of about a dozen leaves near the middle of the stem, and a few scattered ones both above and below, the whorls rarely two, and sometimes, as in its allies, all scattered, 3—5 inches long, ½—1½ inch broad at or very near the middle, narrowed gradually upwards to a long acute point, and downwards very gradually to the base, quite as thin as those of Martagon in texture, glabrous or very faintly downy below, the two or three main nerves on each side of the midrib faint and indistinct. Flowers in the wild plant 2—6, but reaching up to 12 under cultivation, arranged in an irregular corymb, the erecto-patent slender pedicels cernuous at the apex, the lower ones reaching 2—4 inches long, and bracteolate at the middle. Perianth 15—18 lines deep, varying from bright yellow to bright scarlet, the divisions lanceolate, bluntish and faintly pubescent at the tip, 4—6 lines broad at the middle, not distinctly spathulate at the base, much reflexed from two-thirds of the way down when the flower expands, copiously spotted down the face with dark purple, not papillose or pubescent down the groove. Ovary 4—5 lines long; style 6—7 lines long, growing gradually thicker upwards; filaments 9—12 lines long; anthers linear-oblong, 3—4 lines long.

A native of Kamschatka, Manchuria, the Kurile Islands, Japan, and the shores of Russian America, in all which countries, I believe, but am not perfectly sure, it entirely replaces Martagon. It comes between Martagon and canadense, and, as will be seen from the synonyms given, has been confounded with both. I have never had the opportunity of studying it in a living state, and, indeed, am not aware that it has been grown in this country. It differs from Martagon by its glabrous stem, normally solitary whorl of leaves, irregularly corymbose not regularly racemose inflorescence, bright-coloured flowers, shorter ovary, style, and anthers, and, according to Maximowicz (who has studied the plant on its native soil), ovary and gives an excellent account of it with the plate in Regel's "Gartenflora"), in the form, colour, and structure of the bulbs. He says that the Manchurian form has more orange, slightly fragrant flowers, whilst the Japanese plant is scarlet and inodorous. I hope that some of our English Lily cultivators will turn their attention to the species, and introduce it, for no doubt it is perfectly hardy. From all the forms of canadense it may be recognised easily by the size of the flowers, and thinner texture and indistinct veining of leaves, which only quite casually make more than a single whorl. It would seem that these three verticillate Martagons curiously supplement one another in their geographical distribution, not overlapping one another, but the three together stretching all round the world in the north temperate zone, one beginning directly another stops.

21. *L. canadense*, Linn. Sp. Plant. p. 435; Bot. Mag. t. 800 and 858; Kunth, Enum. iv. 258; Spae, Mon., p. 27; *L. pendulifloram*, Red. Lil. t. 105; *L. pendulum*, Spae, Mon., p. 28.—Bulb more or less obliquely rhizomatous. Stem 2½—3 feet high, erect, terete, glabrous. Leaves typically in four or five regular whorls 2—3 inches apart, of 6—15 oblanceolate leaves, spreading nearly horizontally, pale bright green

above, thicker than those of Martagon in texture, the lower ones 2–4 inches long, 6–9 lines broad a little above the middle, narrowed gradually to an acute point, indistinctly spathulate downwards, both sides quite glabrous, or the nerves below distinctly ciliated, the main veins stronger and more distinct than in Martagon, mostly three on each side of the midrib, the upper whorls especially liable to be broken up, and often a few scattered ones between the uppermost whorl and the inflorescence. Flowers 1–2 in the wild plant, commonly 3–5 in cultivation, pedicels 2–6 inches long, with usually one, or even two, linear bracteoles; perianth 2—2½ inches deep, the divisions spreading from about half way down when expanded, much less reflexed than in Martagon, varying in colour from bright yellow to pale bright red, with copious spots, especially in the lower two-thirds, of dark purplish-red, the divisions lanceolate, not distinctly clawed at the base, pubescent at the tip, not down the back, 7–9 lines broad at the middle, not papillose or pubescent down the groove. Ovary 7–9 lines long; style 1—1½ inch; filaments 1½–1¾ inch; anthers 5–6 lines; pollen bright crimson. Capsule 1¾ inch deep, oblong, bluntly angled.

Common in Canada and the northern United States, stretching eastward as far as Lake Winnipeg, and southward to Georgia, along the Alleghanies. The typical form is quite hardy with us, and widely spread in cultivation. It appears to have been one of the first plants introduced to European gardens from America, and is figured in Parkinson's "Paradisus" in 1629. There are several allied forms on the western side of the American continent, which differ more or less conspicuously from the Eastern plant, of which the following are the principal which I am acquainted. I am informed by M. Leichtlin that all the Canadenses Lilies that grow on the west side of the Rocky Mountains may invariably be separated from the eastern ones by their regular ovoid bulbs, and that several species have been recently described by Kellogg, in a Californian serial, which I have not had the opportunity of seeing. I hope to be able to say more on this subject to give an account of his observations on the group. The two extremes of the Eastern plant, as regards the colour of the flower, one with an entirely yellow groundwork (the variety flavum of Kunth), and the other with an entirely red groundwork (the variety coccineum of Kunth, and L. pumilum, Redouté, not Redouté), are given in the two plates quoted of the "Botanical Magazine." I have several times seen this Eastern form in gardens lately under the name of L. canadense occidentale, a designation which ought to be suppressed, as I do not think this form grows at all on the west side of the continent.

Var. 1. *parviflorum*, Hooker, Fl. Bor. Am. vol. ii., p. 281; var. *minus*, Wood, Proc. Acad. Phil. 1868, p. 166; *L. Sayii*, Nuttall, MSS.—Stem more slender than in the type, glabrous. Leaves varying from 3—4 regular whorls to many or all scattered, the lower ones 2–3 inches long, ½—1 inch broad. Flowers generally 2–4, the lower pedicels reaching 4–6 inches long. Perianth 15–18 lines deep, the divisions rather more deeply reflexed in the expanded flower than in the type, the inner ones 4–5 lines, the outer 3—4 lines broad. Ovary with style 12—15 lines long; filaments 12—15 lines.

Stretches from Vancouver's Island and British Columbia to Oregon and California. The form of canadense that comes nearest to Martagon and maculatum.

Var. 2, *Humboldtii*. L. Humboldtii, Roezl in Hort. Leichtlin.—A robust form, reaching 4—5 feet high, with glabrous green stems, mottled with red. Leaves nearly all arranged in 4—5 regular whorls of 10—15 leaves each, 3—5 inches long, the lowest ones 5 inches long, by an inch broad three-quarters of the way up. Flowers 4—6 in the specimens I have seen, but said to sometimes exceed 20. Perianth-segments 3–4 inches long, spreading from rather more than the lower half down in the expanded flower, a very bright orange-yellow, spotted throughout with large claret-red dots. Bracts ovate, about an inch long. Inflorescence with more of a tendency to run out into a raceme than in the type. Ovary, style, filaments and anthers longer in proportion.

A very fine form, found in California, and lately introduced and liberally distributed by Herr Leichtlin, who, I believe, considers it distinct, at least as a subspecies, and who has noted differences also in the bulb between this and the type which he will no doubt explain fully when his observations are committed to print. In several points, as will be noticed, it approximates to the eastern L. superbum, and these two are certainly the princes of the canadense set of forms. My notes above are taken from living specimens communicated by Leichtlin to the Kew collection. I believe Torrey's var. puberulum (Torrey, Bot. Whipple, p. 90), to be essentially the same form, differing only by its markedly puberulous stem. Two other striking forms, known to me only from dried specimens, are :—

Var. 3. *Walkeri*, Wood, Proc. Acad. Phil. 1868, p. 166.—Stem stout, glabrous, at least 3 feet high. Leaves narrower than in the type, not more than ½—¾ inch broad, arranged in distinct whorls of 8—12 leaves each, 6—7 inches apart. Flowers up to 12—15 in a narrow raceme a foot long, the slender main ascending pedicels reaching 2—2½ inches in length, the bracts linear. Perianth 12—15 lines deep, reflexed only towards the tip; the divisions not more than 2–3 lines broad. Ovary 4 lines long; style filiform, 7—8 lines long; filaments 9—12 lines; anthers 2½—3 lines.

Collected in California long ago by Bridges, and distributed as No. 268 of his collections, and described lately by Professor Wood from specimens gathered by Mr. Elkanor Walker. Will very likely prove to be quite a distinct species when brought into cultivation.

Var. 4, *Hartwegii*, Baker.—Leaves all scattered, linear, much ascending, quite glabrous, like the stem, the lowest 4—5 inches long, 3—4 lines broad. Flowers 1—2 in the specimens seen, on long bracteolate peduncles, 3 inches deep, the divisions lanceolate, half an inch broad, narrowed very gradually to the point, reflexed from more than three-quarters of the way down in the expanded flower. Ovary 8–9 lines long; style 15—16 lines; filaments 2—2½ inches; anthers half an inch.

Gathered by Hartweg, in 1848, in the mountains of Santa Cruz, in California.

Turning to the East again we have the following, which is usually regarded as a distinct species, but which is scarcely worthy of the name in the sense in which I am using it.

Subspecies *superbum* = *L. superbum*, Linn. Sp. Plant. p. 434; Bot. Mag. t. 936; Redouté, Lil. t. 103; Kunth, Enum. iv. 258; Spae, Mon. p. 28; Flore des Serres, t. 1014-5.—A more robust plant than typical canadense, reaching 4—6 feet high, with the stem in the lower part, half an inch thick. Whorls of leaves more numerous, often 5—6. Leaves longer, the lower 5—6 inches long, narrowed rather more gradually at the base. Flowers more numerous, often 6—12 (reaching in an extreme case up to 40 according to Dr. Asa Gray), the inflorescence in well-developed specimens a broad pyramidal raceme. Perianth 3—4 inches long, spreading from lower down than in typical canadense when expanded. Ovary, style, and anthers longer in proportion.

An exceedingly fine plant, spread from Georgia northward through the northern United States, where it is rather common in rich low ground. It is a plant which might be well cultivated in our gardens much more abundantly than it is at the present time. The following is intermediate between superbum and typical canadense.

Var. *carolinianum*, Gray; *L. carolinianum*, Michx., Flora, i. 199; Bot. Mag. t. 2280; Bot. Reg. t. 580; Kunth, Enum. iv. 258; Spae, Mon. p. 29; *L. Michauxii*, Poir, Enc. Suppl. iii. 457; *L. autumnale*, Lodd., Bot. Cab. t. 335.—Stem slender, 1—3 feet high. Leaves like those of canadense, shorter and more oblanceolate than those of superbum, and flowers like those of canadense, not more than 1—3 in the wild plant, smaller than those of superbum, but, as in that, with the divisions reflexed from much below the middle when expanded.

Similar to superbum and canadense in its geographical range, but said to flower later. *J. G. Baker.*

(*To be Continued.*)

Home Correspondence.

Challenged Censorship, &c.—"Best collection of 10 dishes of fresh select varieties." I recently competed in a class thus defined, and was disqualified by the judges for showing two Pines—a smooth-leaved Cayenne, and a Queen—in the collection. I don't feel satisfied, mine being the best fruit shown. In a collection of outdoor fruit I showed two dishes of Plums, distinct, and the best prize. *Exhibitor.* [The judges were certainly in error, the two Pine-apples being thoroughly "distinct varieties." Eds.]

——At the B—— Horticultural Society's show Mr. M—— took the 1st prize in the open class, with the following 6 stove plants :—Allamanda neriifolia, worthless; *A. grandiflora*, very good; Dipladenia rosea, nice plant; Alocasia metallica, very good; Coleus Queen Victoria, without shape or colour; Caladium Chantinii, good. Mr. B——, who was awarded 2d prize, had splendid plants of Allamanda grandiflora, well-flowered; *A. Hendersonii*, very good; Dipladenia boliviensis, very good; Bougainvillea glabra, well flowered; Vinca oculata, good; Anthurium Scherzerianum, very fine, the rest averaging about 3 feet 6 inches high by 2 feet 7 inches wide. Which of these two sets ought to have had the 1st prize? It would be well if country judges knew a little more of the nature of growing plants and their value, and then we should not be troubled with so many complaints. *Fairplay.* [According to this statement, B.'s plants should undoubtedly have been placed 1st, the very fine Anthurium being the principal feature in the entire collection shown by M., and was besides well backed up by other good plants, well grown. Eds.]

——1. Is it permitted to exhibit Tomatos in a "collection of fruit" for a prize given for "best collection of fruit"? 2. Are not Chasselas Musqué and J. Josling's St. Alban's one and the same Grape? *D. R. S. H.* [1. No, not in this country; they are here regarded as an esculent vegetable, falling into the same category as the Vegetable Marrow. 2. Yes. Eds.]

——Were the judges right in awarding the 1st prize at a recent local flower show to a collection of "variegated plants" containing a specimen of Herrania palmata, which is strictly a greenhouse stove plant? I may add that the judges themselves admitted that the plant in question was not admissible, but that they were influenced by the size and greater rarity of the collection over that awarded the 2d prize, although the latter consisted of well grown and valuable plants. *W. G.* [Herrania palmata is not a variegated plant in any sense, and should, therefore, have disqualified the collection, if the class was defined as one of "variegated plants." There is no more frequent mistake made at country shows than in being influenced by the size of one collection as compared with another, or of certain individual specimens in a collection over those in competing collections. The first question, however, in all cases is, Is the schedule complied with? If not, the exhibition should be disqualified in the class in which it is entered, even if it has so much merit that a supplementary award is made to it. Eds.]

Lawn Mowers.—I see by the *Gardeners' Chronicle* of August 26 that we have yet another patent lawnmower, upon the old system. Now the machines of all the different makers cut well enough; where we want improvement is in the grass-box. A box constructed to hold more grass is what we want. I should like to see such an one, that will go 100 yards without requiring to be emptied. This would be a sensible improvement. *Y.*

Hardy Succulent Plants (see p. 1133).—The specimen of Cereus tubulosus was a bought example, and was, I fancy, grafted on *C. rostratus*, but I cannot speak with certainty. Some growers consider that *C. tubulosus* is much more vigorous and floriferous when worked on another species, but such is not my experience, nor was it the opinion of the late lamented Mr. Bruce, of Kingston. I find it strikes freely, the wood much thicker, its beautiful blossoms quite as abundant on its own roots; and, further, you save the trouble of grafting, and, as in my unhappy case, stand a better chance of saving your plants in the event of your water-pipes being frozen. *John Daniel, The Terrace, Ipsom.*

——I am of opinion that the note on the above subject at p. 1133 is likely to cause some disappointment, should any of your readers act on the experience of Mr. Daniel. I should be obliged if he would state the exact amount of exposure which the plants in question received—was they in the open air, or not?—and if so, on the level ground, or on rockwork? or were they under glass without any other protection? If the latter, the plants being perfectly dry would assist them. It is known that Echinopsis oxygonus, multiplex, Eyresii, and Zuccariniana will pass the winter in a cool frame; Opuntia bafinesquiana, O. cylindrica, O. vestita (O. humilis, Engl.), Mammillaria vetula, and two sp. novæ, found by Dr. Parry on the Rocky Mountains, are quite hardy; but Agave americana and variegata seldom stand the winter even in a cool shed, though covered with hay or straw. *J. Croucher, Gr., Sudbury House, Hammersmith.*

Yachting Shoes.—Those who, like myself, find great difficulty in mounting grassy hills in summer, or in cutting trees in dry woods, should buy a pair of 3*s.* 6*d.* yachting shoes. For most purposes they are better even than the expensive cricket shoe for cricket, as they give you a much firmer grasp of the ground. *Somerset.*

Lightning-Struck Oak.—Half-an-hour since I was sitting at an open window observing a storm, when a flash of lightning struck a large oak tree in the middle of the "grass meadow" here. A very superficial examination since leads me to believe that the trunk is split down the middle from top to bottom. An opening in the bark extends all down one side; on the other there appears to be a ribbon of bark, about a foot wide, entirely stripped from the tree, but neither at the top or bottom; in fact, if removed it must be cut at each end, and then it will fall away at once. Being most desirous of doing all I can for the old favourite, I would like to have an opinion whether this strip of bark had better be removed, or whether it can be fastened in any way so as to again be of benefit to the trunk. A sheep lying beneath was struck dead, and some of the arms are completely denuded of bark and smashed. *A. C. M., Lorrenden, Ospringe.* [There is not much chance of saving the tree. Pare the edges of the wound as well as you can, replacing bark, and cover the denuded surface with tar and cowdung. Eds.]

Pruning Yew Trees.—I have recently moved 14 large plants of Yew, 12 to 14 feet high, and some of them as much through. They were moved with good balls, and have been well replanted in good soil and well watered and syringed overhead. They are intended to form part of a Yew hedge, and must be cut in for that purpose. Would it be better to cut them in at once or leave them till next year? My own feeling is in favour of cutting them in on one side at once, and leaving the other side till next year, a little later than this. My idea is, as the roots have been cut, if I reduce the heads I give the roots less to do; at the same time may not the buds on the branches suffer from the production of fresh roots, and so do more good than they do harm, by affording a larger surface for evaporation? *C. F. P., The Grange, Kingston, near Taunton.* [Cut them in, in a few weeks' time. Eds.]

Parsons' Mignonette.—I, too, have grown this new Mignonette during the past summer, and can disinterestedly vouch for what it has no lack of odoriferous qualities, nor is it deficient in strength of hab^t. My packet of seed was sown in a box in the greer March, and the plants when two inches in he pricked out about 6 inches apart in a single ' open ground, and in very moderate soil. owing to the prevalence of cold winds, th rapidly became "small by degrees, and less;" but when once a start was made,

was rapid indeed, until the row finally covered a space 3 feet in width, and dense from end to end. It was the strongest development in the Mignonette under ordinary culture that I have ever seen; the plants were generally true to character, and the size and length of spike unusually large, whilst the perfume was exceedingly powerful, not a visitor came but remarked it. The most disappointing feature about it was the discovery that the colour of the flower differed in no degree from that of the old variety, and required rather a stretch of the imagination to term it white. That it may come purer in colour under glass, there can be no doubt, but the same might be said of the old variety. Reseda odorata ameliorata is less striking in colour and flower, and has a shorter spike; but it is also more short jointed, and stiffer in habit, and very robust. Indeed, could a pure white variety, having the habit of the latter, be secured, we should then possess almost a perfect form of the Mignonette. *A. D.*

Preserving Tomatos.—Can any of your contributors inform me of the way that Tomatos are preserved in America? I believe that they are pickled in brine in some way or the other, but, whether the seeds are taken out, or whether they are simmered over a fire, I do not know. *Old Charlie.*

Fruit of the Mountain Ash, Preserving of.—I understand that the fruit of the Mountain Ash, or Rowan tree (Pyrus Aucuparia), is made in a preserve or conserve in Scotland which is highly esteemed. Will some of your Scotch readers kindly give us southrons the benefit of one or more recipes for converting them into sweetmeats? They are plentiful this year, when other fruit is not. *W. Marshall, Ely, September 6.*

Fertilisation of Leschenaultia.—As "F. W. B." inquires, in your number of August 26, about the seeding of Leschenaultia, I will give my small experience. During 1860 and 1862, I was led to make some observations on the fertilisation of L. formosa and biloba, from having read that with these flowers self-fertilisation was an inevitable contingency; and this, from what I had seen during many years, seemed to me highly improbable. I found, as "F. W. B." states, that before the flower expands, the anther opens and the pollen is shed. This occurs in a considerable number of plants, as in most Leguminosæ, Fumariaceæ, &c.; but it can be clearly shown that this by no means necessarily leads to self-fertilisation. In Leschenaultia the pollen, when shed, is neatly collected in a cup-shaped indusium, the mouth of which is at first widely open, but soon closes. Thus far I can follow "F. W. B.;" but he will, I think, find, on further examination, that the pollen must, in order that the flower should be fertilised, be subsequently removed from the indusium, and then placed on an exterior stigmatic surface. This no doubt is effected by insects, tempted to visit the flowers by the copious supply of nectar. On the outside of the indusium there is a viscid surface, and when on two occasions I placed some pollen-grains on the surface, I found, after an interval of about 20 hours, that it was deeply penetrated by numerous pollen-tubes. I was so much surprised at this position of the stigma, that I asked Dr. Hooker to dissect some flowers, which he did with care, and he confirmed my conclusion with respect to L. formosa. He also examined two other species, and found no trace of a stigma within the indusium. I should here add that Mr. Bentham has subsequently described the structure of the parts in this genus, but I cannot at the present moment lay my hand on his paper. When the flower is fully expanded the lips of the indusium fit closely, and cannot be very easily opened. If, however, a finely-pointed, small camel-hair brush be held parallel to the pistil, and be gently inserted into the flower, so as to imitate the entry of an insect, the tip of the brush, by pressing against the slightly projecting lower lip of the indusium, opens it; and some of the hairs enter and become smeared with pollen. If the same brush be now successively inserted into several flowers, pollen-grains will be found left on the exterior viscid stigma. During the early part of the summer I treated in this manner several flowers, but with no result. Towards the end of July, however, five flowers were thus treated, and the germens of all soon became much enlarged. Two of them, after a time, shanked off, but three remained on till the autumn, and each contained about 25 seeds. My plant produced hundreds of flowers during two or three summers, but the germens of none spontaneously swelled, with the exception of two growing close together, which I imagined had been visited by some insect. These two produced some seeds, but fewer in number than in the above case. All the seeds were in external appearance good, but when sown they did not germinate. The flowers were necessarily fertilised with pollen from the same plant, but it would have been incomparably better if pollen from a distinct seedling plant could have been employed. This would have been all the more advisable, as the late Mr. Drummond, of Swan River, in Australia, to whom I wrote, asking him to observe in the proper season what insects visited the Leschenaultias, informed me that the species growing there in a state of Nature very rarely produce seed. It appears at first sight a surprising circumstance that in this genus and in some allied genera, the pollen, whilst the flowers are still in bud, should be scooped out of the anthers, in which it might have remained ready for use, and then be immediately enclosed in a specially contrived receptacle, from which it has afterwards to be removed, so as to be placed on the stigma. But he who believes in the principle of gradual evolution, and looks at each structure as the summing up of a long series of adaptations to past and changing conditions—each successive modification being retained as far as that is possible through the force of inheritance—will not feel surprise at the above complex and apparently superfluous arrangement, or the other still more complex arrangements, though they may all serve for one and the same general purpose. Any one desiring to learn how diversified are the means for preventing self-fertilisation, even within the limits of the same family of plants, should study Mr. Bentham's short but extremely curious paper, just published [in the Journal of the Linnean Society], on the styles of the Australian Proteaceæ. I cannot resist specifying one of the remarkable contrivances described by Mr. Bentham. In Synaphea the upper anther does not subserve its proper function

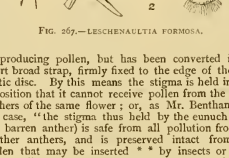

FIG. 267.—LESCHENAULTIA FORMOSA.

of producing pollen, but has been converted into a short broad strap, firmly fixed to the edge of the stigmatic disc. By this means the stigma is held in such a position that it cannot receive pollen from the fertile anthers of the same flower; or, as Mr. Bentham puts the case, "the stigma thus held by the eunuch (*i. e.*, the barren anther) is safe from all pollution from her brother anthers, and is preserved intact from any pollen that may be inserted * * by insects or other agencies." *Charles Darwin.* [In order to render this matter more clear we reproduce the woodcut from p. 1103. EDS.]

Malformed Pear.—By this post we send you a Pear fruit grown on a Jargonelle Pear, and which appears to us to be peculiar. *J. Dickson & Sons, Chester.*—[The change in question is not uncommon,

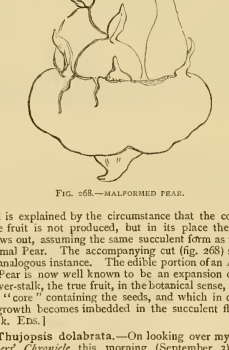

FIG. 268.—MALFORMED PEAR.

and is explained by the circumstance that the core or true fruit is not produced, but in its place the stem grows out, assuming the same succulent form as in the normal Pear. The accompanying cut (fig. 268) shows an analogous instance. The edible portion of an Apple or Pear is now well known to be an expansion of the flower-stalk, the true fruit, in the botanical sense, being the "core" containing the seeds, and which in course of growth becomes imbedded in the succulent flower-stalk. EDS.]

Thujopsis dolabrata.—On looking over my *Gardeners' Chronicle* this morning (September 3), the first thing I read was your account of that interesting Conifer, Thujopsis dolabrata, growing in the pleasure-grounds at Ashridge, and until doing so I was vain enough to think I had the finest specimen of it in England, but I find now I must content myself with saying mine is one of the finest, not the finest plant in England, for the Ashridge plant beats mine. You say it is 5 feet 6 inches in height, and fully as much through at the base. My specimen is only 5 feet 1 inch high, and the same, or may be an inch or two more, through the base; and, as to health, to all appearance it could not be more healthy or robust; but I have had it 12 years, and I fancy it is a very slow grower. Five feet is not much in 12 years. Perhaps it may go on better in the future, as it must be tolerably well established by this time. If any of your correspondents have finer plant, will they kindly publish particulars of it? I have also a smaller specimen, which has the "abrupt unfinished appearance" you mention. I am thinking of making a rough open fence of branches of some kind round it, and leaving it there for a year or two, to see if it will draw it up. There is a wonderful difference in the date of growth of many of our exotic Conifers; my Thujopsis dolabrata is growing within 30 yards of two fine specimens of Pinus Benthamians, which came to me at the same time (the early spring of 1859), done up in a brown paper parcel—seedlings drawn out of the seed bed in which they were raised—root, top and all not more than six or seven inches, tied together with four others with a piece of bast, and then wrapped up in brown paper; they are now 21 feet 6 inches, and 25 feet 10 inches in height respectively, and as robust and handsome as they can be. *C. F. P., The Grange, Kingston, near Taunton.*

Faults in Dinner-table Decoration.—A very able letter to the *Times*, on the 1st inst., by Mr. E. B. Denison discusses some of the faults in modern architecture; and his opinions on this subject so exactly accord with mine on the subject of dinner-table decoration, that I venture to ask for space for the following extracts:—"The idea of making buildings handsome by their proportions seems to have perished out of the earth." "Contempt of proportions and symmetry, and an accumulation of ornaments, seem to be the leading characteristics of what may be called the Victorian style." "The ancients, of all styles, had ideas of proportion, and an eye for it; they did not fancy that they could produce effect by height, out of all proportion to length or width." (I commend the foregoing extract in particular to some worthy and excellent friends of mine, who advocate the flat style of table decoration.) "Mediæval architects were not afraid of making 12 or 13 bays of a long building all alike, except sometimes in their detail; while many architects of the present day cannot give us three or four in succession without some startling variation to avoid their great bug-bear 'monotony.' And yet their buildings are monotonous, in having but one tone of fussiness and overdoing and want of repose everywhere." "Everything that is permanently pleasing, both in art and mankind, must have that undefinable quality called repose, which involves (though it does not mean) simplicity. And our architecture will go on getting worse and worse, more and more vulgar, if this passion for over-decoration is not stopped, and old principles restored." *W. T.*

Water Weeds.—I beg to thank Mr. Campbell for his reply to my water weed question, but beg further to ask him what was the extent of the lakes he speaks of, and the number of swans that were introduced on to them. Swans were recommended here for the purpose of keeping the weed under. Accordingly, in the winter of 1869, nine swans were procured, which have likely increased their number to 13, but unfortunately they have not had the desired effect, as the lake has never been known to be so full of weeds as it has been this summer. So dense is the Myriophyllum that I think no reasonable number of swans would be able to keep it under, the size of the lake being about 30 acres. *W. E.*

The Potato Disease.—Although agreeing with what has lately been advanced in your columns relative to the propriety of planting Potatos wider apart than has hitherto been customary, as a means of rendering them less liable to the attacks of the dire epidemic, by allowing the "tops" more space for development and exposure to the sun and air, I still consider that the innate constitution of the variety has as much as anything to do with its ability to resist the attack of the disease [No doubt]; in exemplification of which I may remark that a case in point has recently presented itself to my notice in the shape of a few rows of Bresee's Peerless and Prolific Potatos, which I planted on March 30, sometime after being planted in drills soil, in a somewhat shady part of the garden, in rows about 30 inches apart; which distance proved insufficient, as the tops of both kinds grew vigorously, and soon became interlaced, resulting, however, in a heavy crop of handsome tubers. And although the "tops" of both varieties were alike severely affected by the disease, the Prolific had but three or four of its tubers affected, whereas the Peerless was diseased to the extent of about a third of its crop; hence, I think, conclusively proving that the natural constitution of the variety is as much to be taken into consideration as are other conditions. In further substantiation of this view, I may add that in a reserve garden here, but in a more elevated position, and less rich soil, several other varieties of Potatos, planted somewhat earlier than the foregoing, were more or less diseased, notably so Ne Plus Ultra (kidney), which was planted about a yard apart every way, by way of experiment, but which was badly affected; whereas such as the Gloucestershire Kidney, Ashleaf Seedling, Mona's Pride, and Veitch's Ashleaf, were comparatively free from the disease, though considerably separated by intervening rows of Broccoli.

The reverse, however, occurred to Early Coldstream, Princess Dagmar, Early Emperor, Prince of Wales, and Edgecote Seedling, all of which were more or less shaded by intervening beds of the Brassica tribe. I may add that I have invariably found that early kinds early planted prove infinitely less liable to the influence of the disease than either early or late varieties late planted. *William Gardiner.*

Grape Growing at Kingston Hall.—As the temperature of the border may be readily ascertained from the outside surface, the fact of its being heated cannot be disputed. The bar to the circulation pointed out by Mr. Cruikshank, simply proves that each set of pipes has its special duty to perform. The narrow passage which contains the pipes under the front of the house is for the border heat, and the heat circulates in the chamber under the border, in the manner customary in Mr. Sylvester's arrangements, viz., through pigeon-holes in the outer wall. This is the identical mode of heating originally adopted for surface heat, and it was made to serve two purposes, for when it was not wanted in the house the valves could be closed, and the waste, or spare heat, was forced into the border chamber. Mr. Cruikshank says there are no ventilators to be seen in the front wall. Certainly not, why should there be? The object was to force the heat into the border chamber, and that could only be accomplished by preventing its escape in any other direction. As I have before stated, the only alteration made in the inside wall was that of stopping the ventilators, so as to confine the heat to its proper object—that of heating the border. "F." frankly admits his inability to speak positively upon this point; but from where he made his observations—the inside chamber—the same particle of heat goes into the border chamber, except what passes through the solid brick wall. You will thus perceive that my previous statement is substantially correct. As for the crops of my predecessor, not having seen them I cannot speak of their quality. Report says that enormous crops had been produced. At the time the Vines passed into my charge many of them had 70 to 80 bunches upon them; and the fact that the crop had coloured badly for years, furnished unmistakable evidence that fast life in their youth had bent if not broken their backs. Add to this the presence of insect pests, and it may be readily perceived they were only the shadows of their former selves. If there is any doubt upon this question, Mr. Sowmy, now the gardener at Highnam Court, Gloucester, who was foreman for years to Mr. Mackay, can settle it. *Geo. Westland.* [We think enough has been said on this question. EDS.]

Covent Garden Prices.—Three or four letters have appeared on the above subject. Being an old Covent Garden man I may, perhaps, be allowed to state my opinion. I begin with Pine-apples, which, at certain seasons of the year, are not worth growing; at other times, namely, from October to July, few things pay better. Queens are very good, but many realise so much hard cash as Black Jamaica. Then as to Grapes: the most suitable are Black Hamburgh, White Muscat, Lady Downes' Seedling; for very late, Muscat is the favourite, and none of the other varieties command so good a price. Grapes should be laid in baskets, 2 lb. each, in precisely the same way in as put up for exhibition. Send your own man to the railway station, and let him give them into the guard's hands; let your salesman know, in order that his man may meet them in London. In this way, literally speaking, they go out of the grower's hands into the salesman's. Never forget to shake hands with the guard, and your fruit will always go right. I may mention, if the bloom is not perfect it is of little use sending them, so particular are the great buyers on this point. Peaches and Nectarines also command a good price, but few growers send them to the right woman; for this reason, they pack all together—little and big. The proper way is to gather just before they are ripe, sorting them over to make firsts, seconds, thirds, and even fourths, packing each sort by itself in Peach punnets—label each basket with the number of fruit in it, quality, first or second, as the case may be. Strawberries (forced ones) sell well, almost always. My favourite is Sir Charles Napier for the market, still Keenes' Seedling and President are very good; but when good old British Queens are done well, they realise more money than any other I know of. They should also be packed in punnets, with a leaf between each fruit, and sorted over the same as Peaches, not forgetting to let the same man take them to the station on all occasions. I am happy to say I generally get good prices for all I send, my salesman being John Black; nevertheless, I know others equally good—Walter Davis, Solomon. I venture to say, if your correspondent grows good stuff, and packs it in the way described, he will find prices remunerative. *R. G., Stamford.*

Price of Peaches.—When I read in your paper such remarks as those of "A. D." at p. 1135, about Peaches, I wonder that advertisements are not more resorted to by those who have articles to part with. I have no doubt that if "A. D." had put in an advertisement that he had 50 dozen Peaches at, say 3*s.* per dozen, and that he would send them packed—so many per week or half week—that he would have found customers at once. The fact is, as he states, that we fathers of families never think of buying Peaches, because of the very high price charged at the shops for them; but there are thousands of us who would gladly supply our families with Peaches and other fruit, if we could do so at a fair price, from the growers. I have sold many things by advertisement, and scarcely ever put one in that I did not meet with purchasers immediately. *W. D. F.*

The Crystal Palace Show.—Every one who visited the show held at the Crystal Palace a few days since in connection with the Metropolitan Floral Society will bear witness to the correctness of your remark, that the right of the judges "to withhold the prize where they consider the subjects not worthy of it" would have been well exercised in the classes for Gladioli. Some of the spikes were certainly not worthy to be sent to an exhibition, and, on the other hand, some of the exhibits were of a very high character. I am induced to write to you upon one or two other points in connection with the Gladioli shown there. To my surprise, one stand of 36 had not a single flower named, and moreover it was made up so irregularly, that for some time I took the centre 12 to be an exhibit of itself, the other 12 on either side looking different, and standing a few inches away from the centre lot. Of all flowers the Gladiolus should be named, as you require to examine it for comparison with another, and another stand with the same flower. Both these stands had prizes awarded. Where was the committee of the Society? Do let us have placed fairly before us the *Gladiolus.*

Marigolds.—The accompanying Marigold blooms represent several types of habit as well as shades of colour, and are being selected in the hope that their respective forms may become permanent. The blooms marked No. 1 are African Marigolds, showing the finest forms that exist amongst them, comprising rich orange to bright yellow and lemon. The mixed flowers marked No. 2 are gathered from a number of French Marigolds having a very stocky, bushy, free-blooming habit, the height, including flowers, averaging 18 inches. In respect of habit they are very superior to the tall rank-growing French kinds, producing a much denser mass of bloom, as well as greater capacity to resist drought. No. 3 is a Ranunculus-flowered variety, the flowers being exceedingly double, and of the most pleasing appearance when growing on the plant, which has also a very dwarf dense character, rising in height about 14 inches. No. 4 comprises a mixed lot of flowers of a very dwarf section, consisting of plants varying from 6 inches to 12 inches in height, including flowers. No. 5 are flowers gathered from plants of the Dwarf Orange French, free blooming, averaging 10 inches in height; and No. 6 is a yellow variety, of the same habit. These are both very dwarf and continuous bloomers, standing drought well. *A. Dean.* [Very good examples of different types of Marigold. No. 2, with fine large flowers, is particularly handsome; and Nos. 5 and 6 are pure coloured, and likely to be useful for massing. The mixed Verbenas and Pentstemons sent with them indicate good strains of seed. The white Lobelia speciosa is very pure and good. You should send it to Chiswick, to be grown with other sorts in the next year's trials. EDS.]

Utricularia montana.—I have to thank "Ebor" for kindly furnishing us with some useful particulars as to the peculiar conditions under which this pretty blue plant flourishes in one locality. We as cultivators ought to be extremely thankful to real travellers when they give us their experience, which unfortunately is but seldom. The flowers of this plant (see fig. 233, p. 1039) are pure white, with a band of orange-yellow on the bigibbous portion of the limb of the corolla, and two streaks of the same colour extend down the throat. The manner in which it propagates itself I took the precaution of illustrating in my sketch. The plant would seem to be common enough in the tropics, and also somewhat widely distributed. Would "Ebor" oblige by stating whether it is constantly epiphytal in Trinidad. We have three species of Utricularia or "Bladderworts" in Britain, viz., U. vulgaris, U. intermedia, and U. minor, all being aquatic, or submerged plants. Those who have access to our "Englar's Botany" will find them figured or described in that valuable work. *F. W. B.* [A coloured plate of this Utricularia is given in the "Botanical Magazine" for the present month. EDS.]

Tabulated Lists of Flowers.—I remember, when the late Mr. Beck took the "Florist" in hand, he gave, from time to time, tabulated lists of the best Pelargoniums given in by all the best growers in the kingdom. And I well remember the interest and confidence that used to be felt in them by us country readers, and how much we missed them when they ceased to be given. Is it impossible for the *Gardeners' Chronicle* to adopt the same plan? Surely not. What information could be more useful, more interesting, more to the taste of your general readers, than lists so made up—of Roses especially—say the best 12, then the best 24, 36, and 50, given in by 12 of the best growers in the kingdom, eight of them being nurserymen, and four amateur growers. It is the combination of such effectual efforts which I look to, if such can be brought to bear. For instance, if all 12 agreed in recommending one Rose as the best of its kind, who could have any doubts of its being so? The same of the rest. Let those Roses which have the greatest number of votes stand in the first rank till they are beaten by others. The same with bedding Pelargoniums, for they seem to have local propensities, one kind doing best here, and another there, while others seem to have no particular taste. Do let upon the trial of bedding Pelargoniums at Chiswick as of the first importance, as all fight upon the same terms—a fair field, and no favour—a very important feature in my estimation. To those who visit the great flower shows of London and other places, such information is not so necessary, though not wholly useless to them; but to the general stick-at-home it is most important, and of all mundane information has the best share of his heart. *F. Y.* [We will endeavour to comply with your wishes. EDS.]

Potato and Artichoke Grafting.—Be good enough to allow me to state, in reply to Mr. Dean at p. 1135, that I had intended to exhibit my experimental tubers at South Kensington on the 6th inst. (expecting to be away from home on the 20th), but as both Mr. Dean and Mr. Fenn are expecting to put in an appearance on the 20th, I shall have much pleasure in deferring my exhibition until that date. I lifted my tubers on the 1st inst., chiefly because the disease was then commencing to show itself unhappily, there have nearly escaped its ravages. Whatever may be the ultimate results of my experiments time will prove, but an hypothesis of my own is that by intermixing the properties of the Artichoke and the Potato, the latter must necessarily be hardened in constitution, and consequently better able to resist the dissolving effects of the Potato murrain, although it may be deteriorated in quality. These anticipations may in the end prove fruitless, but one thing is at least certain, viz., that the union of the Artichoke and Potato (Helianthus and Solanum) is a *fait accompli* [in our correspondent's opinion]. Next spring I propose to re-graft these tubers into the Artichoke, when I anticipate a further development of the characteristics and properties of the Artichoke; and by repeated grafting in this way I am of opinion that the properties of the two genera will be so assimilated as to defy even the skilful and talented authorities at 41, Wellington Street, to prove which genus it [the tubers] originally belonged to. More at the time of exhibition. *Thos. Simpson, Broomfield, Sept. 5.* [We shall certainly be surprised if we cannot tell a Potato from an Artichoke. EDS.]

Asparagus Disease.—The whole of 21 acres of Asparagus—seedlings of various growths, young Asparagus which was expected to be cut from for the first time next spring, and beds which have yielded well for two seasons, have been attacked by a Fungus, and the consequences cannot fail to be very serious. The Fungus first appears in small brown patches on the stem, gradually spreading until the whole plant is covered with an envelope, which seems to ripen and then break, showing a black furry substance, which is the last stage of the disease. The result is in various qualities, some of it wet and other parts dry, the disease being the same in all. The seedlings and the young Asparagus were attacked early in July, and, until the last ten days, had apparently died away, presenting to the eye the appearance which is usual at the end of November; the seedlings are now apparently recovering, and looking green again, and the stems of the young Asparagus, which was expected to give a first crop next spring, are putting forth green sprigs, and shoots, although puny miserable things, are beginning to spring from below-ground; these young shoots are also attacked in the same way, but apparently in a milder form. The beds which were cropped this year were attacked much later, and at the present time have the appearance of bare brown poles, all seed having disappeared, and no fresh shoots being formed. Underground the plants have a very unhealthy appearance; the roots have in some cases rotted, and emit a very unpleasant smell. Many of the old shoots, which a few weeks ago were in a strong healthy condition, have now perished, and the others are putting forth a few feeble sprigs. I wish to mention that this has ever occurred before, and what can be done for the plants. *G. Hester, M.A., Ringmore, Teignmouth, Devon.*

Pinus pygmæa: Case of Reversion.—I send you a branch, evidently of Pinus orientalis[?], cut from a nice little plant of Pinus pygmæa growing at Chadacre Hall, the seat of Miss Halifax, about 8 miles from Bury St. Edmund's. The soil is a very strong loam resting upon clay, but many of the Pinus and Piceas, such as Pumpo, orientalis, and cephalonica, do well, and form nice trees. The present intelligent gardener, Mr. Foulger, has cleared a good many shrubs away that were used for shelter, which has shown off the plants to more advantage by placing them on the clear turf. This tiny tree was one of those so cleared, and I gathered the branch sent, which was only a portion of the sport, a few days since. Such sports among Conifers are rare, as far as my observation extends. Last year a gold sport, true, came on a common Yew of great age, here. *D. T. F.* [The Cembrasibiua Fir not unfrequently reverts to its original form in the same way. EDS.]

Foreign Correspondence.

PARIS IN 1871.—It was with strangely mingled feelings that I found myself, one morning in last month, after a night's travelling from Brussels, at the station of the Northern Railway in Paris. One's thoughts had been for months so full of the miseries and sufferings of its people, of the terrible war with Germany, and the famine consequent thereon, and the still more terrible war of the Commune, of the devastations and burnings that the wretches who held sway under the *régime* of the latter had occasioned, that one questioned whether the fair city of the Seine would be recognised as the same. Some said, "Paris can never be herself again; her beauty is so marred, her peculiar charm so disfigured that no amount of money can ever restore her to her pristine glory." Others, on the other hand, said, "The change is really very little; a few houses here and there—some of the fine buildings, indeed—are gone; but, after all, it is not much." And here was I to judge for myself. The truth, as usual, lies about midway. Get into a *fiacre*, drive from the Northern Station down the Rue Lafayette, the Rue Poissonière, on to the boulevards, then along by the Madeleine (you will miss the Vendôme Column, but, in an artistic point of view, this would be no great loss), up the Boulevard Malesherbes, to the Parc de Monceau; then on to the Arc de Triomphe, then again down the Champs Elysées to the Place de la Concorde, and you will say, "I do not see the least change." But if, instead of taking this route, you had done as I did, driven down the Rue Richelieu, by the Louvre, across the Place de Carrousel, over the Seine, to my hotel, in the Faubourg St. Germain, your estimate would have been different. You would have seen the blackened ruins of the Tuileries, of the Ministère de Finance, of the Chancellerie of the Legion of Honour —you would have wondered what had become of the Hôtel de Ville and of the Palais de Justice, and you would have been able to form some idea of the dreadful scenes that must have been enacted in the month of May. Inside Paris the Germans have hardly left any mark. All this is the work of the Commune—of wretches gathered from every nationality, which, it is to be thankful, the exception of England—marshalled by Poles, Russians, and Italians, but derided by Frenchmen, by those who have painted or carved on every public building "Liberté, Egalité, Fraternité," and then set fire to them, as an illustration of their meaning of the legend. From every Frenchman I met with—from English friends, who, like that gallant soldier of the Cross, the Rev. Dr. Smyth, of St. Germain, remained within all through both sieges—I heard but one story. Had the Commune had three days more, not a stone of Paris would have been left. But the readers of the *Gardeners' Chronicle*, to many of whom Paris is well known, and to most of whom its parks, &c., are familiar, whether through the splendid work of Alphand, the popular pages of Robinson, or the columns of this journal, will want to know, horticulturally speaking, what is the present aspect of Paris—how fare its public gardens and promenades, its flower markets, and its *halles*. Well, it was with this end I took my course, and, without going into any questions connected with its political or social aspects, shall just detail what I saw in connection with these parts.

The inner boulevards, that charming circle of tree-bordered streets, which give such a peculiar charm to Paris, are untouched. Whether it was respect for their city, or because the green wood would not burn, certain it is that they have been left untouched, and in the month of August were all in their leafy beauty. Outside the city it is different—the larger trees have been cut down, many battered to pieces by the shells of Mont Valerien; but inside the city it is happily different. During the Commune fuel was not scarce; supplies had entered of all kinds, and there was no necessity for the destruction of the trees, so that those who have been wont to enjoy their *café* under the shade of the Allantus and Planes on the boulevards can still do so.

On entering the public gardens, while you wonder at the order into which they have been brought, you at once see that they are very different to what they used to be. How could it be otherwise? When the Commune took possession of Paris, they cashiered M. Alphand, who had been the director of all the public gardens, and placed in his stead a man of the name of Carlier, who went by the nickname of "Pape-en-bois," and who had as little flower-feeling for the divine loveliness of his own person. M. Alphand happily now occupies his former place, and if France remains at peace with herself, another year will see things such as they used to be. But what could be done? La Mucrte, the great mercy of the city, which supplied the parks with plants, was nearly battered to pieces; and hence you will find—as for instance, in the Parc de Monceau, where the beautiful beds and the splendid tropical plants made such a scene of beauty—that annuals, and Petunias, and such plants as can be rapidly raised from seed, have had to take their place. It is the same way in the Champs Elysées; beds of flowers there are, but they are comparatively few; the only exception to this is the garden of the Luxembourg, where, dependent on his own resources, M. Rivière has been able to keep a supply of bedding plants sufficient almost for his purposes; but he has lost fine collections of Bromeliads and other plants, owing to the failure of fuel to heat the houses. The Jardin des Plantes is a wreck of its former self, though that I never thought much of; it always seemed to me a place utterly unworthy of French science, and of the illustrious names that have been associated with it, ending in the present able director, M. Decaisne. As a botanic garden, it was poor, while the collection of Orchids and other plants was utterly inadequate to represent the state of French scientific horticulture, so that I do not wonder that French *savans* think so highly of Kew. Although I have seen enough of German desolation, I do not believe that the damage they did to the houses here was intentional. If they had battered them down, and the Government had rebuilt them, it would have been a gain to all concerned. The houses are now complete, though empty, although, doubtless, ere long, the various establishments of Europe will help M. Decaisne in his endeavours to refill them; the garden is still occupied by soldiery. I thought to pass down the avenue on to the quai, but was stopped, the "Entrée d'abri" filled the avenue, and the red-trousered soldiers ("quantum mutatus ab illo"—the "illo" being the spruce dapper soldier of the Second Empire); and so I was compelled to retrace my steps. The Buttes Chaumont, which were beginning to take their place as the most original of all the Paris parks, is in a state of desolation, but it is being rapidly rearranged. The remarks that I have made with regard to these larger parks and gardens will apply equally to the smaller spaces, as the Square de Montholon, the garden of the Tour de St. Jacques, Place Louvois, &c., all, to one who has seen Paris before, much the same. Something, however, that I did not see it before, wonderfully neat and pretty; to every one, a matter of astonishment how in so short a time so much could have been done.

One of my earliest visits in Paris is always to the grand Halles Centrales, it was the first place I went to after the siege, to learn whether or not whether French market gardening is recovering itself. Where the things came from I do not pretend to know, but there they were fresh as ever,—the stalls outside with their fresh looking vegetables and their little neat assortment of cut legumes for the potage, and inside all the delicacies of the season—Melons, and Grapes. The fine Peaches of Montreuil, and the yellow good-for-nothings of the South, rich, luscious fruit, at 6 sous each, the very best; and Grapes (the Chasselas de Fontainebleau), both grown in the South of France, at 1 sous the pound. The *bouquetières*, making their nosegays as of old, and the crowns of *immortelles* (alas! poor France has need of many o*f* these); while, passing on to the fish departments, there were still the same crawling masses of escargots, the crayfish in the running streams, salmon (which, I think, perhaps come over from London), and other things as usual,—nay, I detected some of my old friends in the stalls, who seemed to have passed through the ordeal of two sieges tolerably well. And while speaking of the markets, let me say that the market gardeners in the neighbourhood of Paris have expressed their gratitude for the supplies sent to them especially of Potatos. Myatt's Ashleaf have been sent in considerable quantities; they have found its superiority to their own, and it will be largely planted another season.

But, I thought, doubtless the flower markets and the bouquetières will show the difference; there can be little money to spend on such luxuries now, and few people who would care to buy them. What was my surprise, then, on going to the flower market at the Madeleine, to see it almost identically as it used to be!—there the stalls had sprung up again, there were the same plants, the Roses, Lilies, Ixias, Pomegranates, arranged in their paper envelopes; while at Madame Fillul's, Borujon's, Privort's, and other well known *bouquetières*, there were the same daintily and tastefully arranged bouquets, and people entering the shops buying and carrying off their fragrant loads, as of yore, after all, many say, things are not so bad as it was reported, and the French Horticulturists' Relief Fund was not needed. "Aisy," as Paddy says. Have you ever, my friend, visited a country person of your acquaintance, located in some quiet peaceful spot, around him the fields of waving corn, the village, with its quaint old cottages and neat gardens, the Ivy-mantled church is close by—the schoolhouse, with its Roses and Honeysuckled porch, at hand; it is a fine autumn evening, there is not a breath to move the air, the harvestmen are bringing home their last load for the day, and you involuntarily exclaim, Ah! what a happy scene; peace must surely reign here, and contentment be the rule of every heart. Ah!—alas for human nature! your country parson will tell you his little village is but the epitome of the larger world in which you move; and beneath this apparent calm that reigns you would find that envy and strife, tales of shame and of sorrow, are to be found concealed within many a house there, as well as in the larger houses of a city. All is not gold that glitters; and so with Paris. Beneath the apparent restoration of everything to its former state, there is a mass of unrest and disquiet, of gloomy anticipation, of depressing feeling, which shows that all is not as it was. And so of horticulture. In my next communication I shall have to draw a very different picture—to tell of devastation and miseries, that make one's heart sick to think of, and which will show, I am constrained to think, that all the aid and sympathy that we can provide will be but as a drop in the ocean to that which is required. But I have thought it well to show what Paris is, and that those who have never visited it may yet hope to see it in its former beauty—the fairest city of the world. *D., Deal.*

Societies.

ROYAL HORTICULTURAL: *Sept.* 6.—Major Trevor Clarke in the chair. The usual preliminary announcements having been made, the Chairman said that to him the most interesting feature of the meeting was the excellent display of Onions, which had been gathered together after many years of selection and cultivation, and which had suggested to him how easy it would be to cross such plants by planting distinct kinds of such things close together. He had tried this method in the case of the Onion some years ago, and the result was the production of some beautiful varieties. He recommended this plan strongly to experimenters, and suggested that the plants to be so experimented upon, with the view to improvement, should be Onions, Cabbages, Radishes, Carrots, &c.

Floral Committee.—Dr. Denny in the chair. The display on this occasion was confined to the Council-room, and consisted mainly of an excellent lot of Dahlias. Asters, &c. The best 24 cut blooms of Dahlias, in the open class, were contributed by Messrs. Kelway & Son, Langport, and so fine was the collection that we give the names of all the varieties shown, as a guide to our amateur friends:—Julia Wyatt, Mrs. Dix, Miss Herschaw, Volunteer, Flag of Truce, Lord Derby, Lady G. Hervey, Mrs. Denny, Hugh Miller, Sydney Herbert, Ellen Potter, Lord Shaftesbury, Charlotte Dorling, Vice-President, Master of Arts, Pandora, King of Primroses, King of Sweden, Jessie Cooper, Miss Napier, Yellow Perfection, Princess of Gold, Princess of Wales, and Mrs. Foster. All the above were represented by capital specimens, and formed the finest stand that we have seen this season. Mr. Turner was 2d, with a stand of seedlings which comprised some fine flowers; and Mr. C. J. Salter, Castle Bromwich, was 3d. This collection contained superb blooms of James Cocker, Miss Roberts, High Sheriff, Mary Keynes, Queen of Beauties, and several of the aforenamed. The last named exhibitor was also 1st in the amateurs' class for 12. The best 24 Asters, not quilled—and an excellent lot too for the season—came from Mr. G. Wheeler, Warminster, Messrs. Kelway & Son being 2d, and Mr. J. Salter, Cambridge, 3d. For 12, not quilled, amateurs, Mr. Rowe, Rochampton, was 1st; Mr. E. Farndell, gr., Surrey County Asylum, 2d; and Mr. B. Porter, Isleworth, 3d. In the class for 12, in the nurserymen's list, Mr. J. J. Chater, with Mr. J. Walker, Thame, Oxford, 2d, and Mr. E. Rowe 3d, all very good flowers. Mr. Perry sent the best stand of 24 Verbenas, distinct, five trusses of each, and Mr. J. Chater was 2d. For 12 Asters, not quilled, Mr. Rowe was 1st and Mr. B. Porter 2d, both collections being rather poor. The only exhibitor of Lilliums was Mr. W. Bull, who took a prize with the class for six distinct, and of L. speciosum (lanceolatum), not less than three varieties, with very well-grown plants of L. speciosum, roseum, rubrum, rubrum superbum, punctatum, and speciosum album, tigrinum, auratum, &c. Messrs. Veitch & Son exhibited a small group of new plants, including a pretty new Masdevallia (amabilis?) which received a First-class Certificate; and the finest new annual of the season, Amaranthus salicifolius, an introduction from Manilla, which pitch a beautiful pyramidal form to the height of about 3 feet, with long narrow leaves, the predominating colour being orange-red, which varies to a deep bronze. The plant had been lifted from the open ground, establishing Messrs. Veitch's claim as a first-class bedding plant, and for conservatory decoration at this time of year; a First-class Certificate was awarded. Mr. Bull also sent a nice group of new plants, including a new and pretty Anthurium, free growing Aroidaceous plant from Central America, named Syngonium albo-lineatum; Saurauja nepalensis, a fine bold-leaved foliaged plant; Dracæna metallica and elegans, two of the best of the ornamental section, and D. splendens, a dwarf, stiff-growing form from the South Sea Islands, which received a First-class Certificate. From Mr. Croucher, gr. to J. T. Peacock, Esq., Sudbury House, Hammersmith, came a group consisting of a dozen new Cactaceous plants, including the very curious Echinocactus myriostigma, E. Kochii, E. calliricus, M. Wiscelenii, and E. Wiscelenii, Mammillaria bicolor cristata, M. sphærocephala, and M. rhodacantha, &c.; a Special Certificate was voted. Mr. Parker, Tooting, had some nicely-flowered specimen Ixoras and Dracænas; and Messrs. E. G. Henderson came a nice group of variegated foliaged bedding plants in the International Department. M. Jean Verschaffelt again contributed a fine group of new Agaves, of which the following were selected for first-class awards:—*A. Celsiana albida*, A. Toneliana (Ghiesbreghtii ?), *A.* Mescal nigrispinis, A. dealbata compacta; and *A.* dealbata compacta angustifolia had one of the 2d class. These, we hear, have all passed into the hands of Mr. J. T. Peacock, whose collection of these plants is now one of the richest in the country. First-class Certificates were also voted to Mr. Turner, for Dahlias John Standish, Mr. Saunders, and Souvenir d'Henri Fontaine; and Kate Haslam, delicate pink, fine in shape; to Mr. G. Rawlings, for Dahlia Maid of Essex; to Mr. G. Parker, Maiden's Green, Winkfield, for Dahlia Old Port, not described by us in June; to Mr. Henry Welbeck, for Gladiolus Celestial, white margined with bright scarlet; to Mr. D. Mackellar, gr. to C. Magniac, Esq., Colworth, Beds, for seedling Hollyhocks—Jeanie, white, and Rose of Sharon, crimson, large, and fine in shape; to Mr. J. J. Chater, for seeding Hollyhock Peerless, buff; to Mr. Keynes, for Seedling Dahlia Dolly Varden, fancy, pinkish white, tinged with crimson; William Laird, purplish blush; William Keynes, orange-red, very fine; and Marchioness of Lorne, creamy-

yellow, tipped with crimson, which received one of the second class. Special Certificates were awarded to Messrs. Veitch & Sons for a fine collection of Asters, and to Messrs. Ponsford & Son for cut specimens of Cleroden-dron Bungei, and Mr. Eckford, Coleshill, had a first-class award for Verbenas Lady Edith, very fine white, and Pluto, very deep scarlet, white eye.

Respecting the Chiswick trials of flowers, it has been suggested that the best plan of making up the collections at Chiswick would be for the various growers to contribute at this (autumn) season of the year, when they can be so much more conveniently looked out and dispatched, such kinds as they can spare of those already sent out. To further this object, it was also suggested that catalogues should be sent to Mr. Barron, for him to mark in them the names of those kinds which the Society already possessed. Mr. Barron is quite prepared to carry out this suggestion, with a view to making the next season's trials as complete as possible, and would be glad to receive at once any varieties of the undernamed flowers which are not already at Chiswick. In addition to the bedding Pelargoniums, which always form the principal group of trial plants, it is proposed to form also as complete sets as possible of Phloxes, Pentstemons, bedding Lobelias, and bedding Violas for outdoor culture, and of Fuchsias for culture in pots. Address: Mr. A. F. Barron, Superintendent, Royal Horticultural Society, Chiswick, W.

Fruit Committee.—G. E. Blenkins, Esq., in the chair. This was a very interesting meeting. Mr. Pearson, Chilwell, again sent several seedling Grapes, amongst which was a fine white one, which will supersede Foster's White Seedling, and named Duke, which received a First-class Certificate. Two other black varieties were requested to be shown again. Special Certificates were voted to Mr. J. Reid, gr. to the Earl of Crawford, Haigh Hall, Wigan, for very fine fruits of Passiflora quadrangularis [?] ; to Mr. Perkins, gr., Thornham Hall, Suffolk, for nice specimens of Queen Emma Melon ; to Mr. W. Paul, Waltham Cross, for a large collection of Apples ; and to the Rev. C. Wildman, Branebridge Vicarage, Lincoln, for excellent specimens of Veitch's Autumn Giant Cauliflower ; and to Mr. G. W. Pragnell, Castle Gardens, Sherbourne, for a magnificent collection of Onions, grown from seed, including the new Giant White Tripoli, Giant Rocco, White Lisboa, Bedfordshire Champion, Reading, Danver's Yellow, White Moscera, Italian Red Tripoli, Giant Madeira, &c. Examples of seedling Melons, two of which, a large fine-fleshed variety, was of very good quality, came from Mr. Cadger, Luton Hoo, and a green-fleshed variety, named Ne Plus Ultra, from Mr. J. J. Chater, who received it from San Francisco. It was rather over its best, but good in flavour, melting up to the rind ; Mr. W. Armstrong, gr. to T. D'Eath, Esq., Woodstock House, Hendon, sent a Queen Pine, weighing 4lb. 3oz., and Mr. Turner had fruits of the seedling Pine-apple Blouche, which received a First-class Certificate some three or four years ago, a variety much larger than the Green Gage, and quite equal to it in flavour. Messrs. G. Lee, Clapham, sent a fine example of a seedling White Grape, which ripens three weeks earlier than White Muscadine, but which it strongly resembles. Mr. Perkins, Thornham Hall, also sent a specmen of the Stoly Oak Cucumber, over 2 feet long ; and from Mr. C. Gilman, South Metropolitan Schools, Sutton, came a nice collection of vegetables. Mr. Turner also sent specimens of Bluegown and the Wizard Cucumber, which in the case of the latter variety fully bore out its high character. Messrs. Carter & Co. offered prizes for the best collections of Onions, of which the 1st was taken by Mr. E. Farndell, the Surrey County Asylum ; the 2d by Mr. J. Bawerstock, gr. to W. Hope, Esq., Old Ford, Barking ; and the 3d by Mr. Miles, gr. to Lord Carrington, Wycombe Abbey, who contributed excellent specimens. Mr. J. Garland, gr., Killerton, Devon, and Messrs. Barr & Sugden, were also exhibitors of Onions ; and Messrs. Carter & Co. sent examples a Runner Bean, named Canada Express, which appears to be a very free bearer.

DEAL AND WALMER : *Aug.* 31.—The show this year was very successful, owing in great measure to the efforts of E. Banks, Esq. For Achimenes the 1st prize was awarded to E. Banks, Esq., and the 2d to G. Gardner, Esq. Some of Pelargoniums were fine, especially the display excellent. The double-flowered Geraniums do not appear to have made their way yet sufficiently to displace the single kinds. The Dahlias, which were in great variety, were fewer than The Gladioli were numerous and beautiful, and the Verbenas in much better condition than are sometimes exhibited. The Zinnias fell far short in number and excellence. The prizes for flowers arranged in vases were awarded to E. Banks, Esq., W. J. Banks, Esq., and Mr. Street ; and for bouquets, to W. J. Banks, Esq., Mr. Street, and Mrs. Coode. Messrs. Masters and Klinmort, of Canterbury, exhibited, but not for competition, and their exhibits attracted much attention. Among them were a seedling Verbena, the Catherine, and cut flowers, of which the 12 Hollyhocks were good specimens, and scarcely less to be admired were their 24 Dahlias and 12 Asters. Among the cut flowers, Mr. Bunyard's 48 Roses were noteworthy. On no previous occasion were the selected baskets of vegetables so numerous and so well supplied ; Red Cabbage was shown very good, and Onions were of immense size.

Notices of Books.

Notes on the Food of Plants. By Cuthbert C. Grundy, F.C.S. Simpkin, Marshall & Co. Pp. 126. 8vo.

This is a plain and brief account of the process of nutrition in plants—trustworthy so far as it goes. As the relation of plants to nitrogen has lately been under discussion in our columns, we quote what Mr. Grundy, who adopts the orthodox view, has to say on the subject :—

"According to some physiologists—Priestley, Ingenhouss, Ville, and others—plants make use of the free nitrogen of the air for the formation of their nitrogenous compounds ; but the experiments of De Saussure, Boussingault, Woodhouse, Senebier, Lawes, and others, lead to an opposite conclusion ; and it is now generally admitted that vegetation has not this power. Apart from what experiments demonstrate, the former opinion seems unlikely to be correct, for although the free oxygen of the atmosphere is employed by plants in the formation of their compounds, and notwithstanding their marvellous powers of synthesis, it is hard to believe that they are able to overcome the remarkable antipathy to direct combination which characterizes nitrogen. Moreover, were the imbibition and assimilation of the free nitrogen of the air actually in operation, would it not be in opposition to the economy of Nature, so far as we understand it ? The presence at a large volume of nitrogen in the atmosphere is necessary for the continuance of life, and if vegetation were day by day assimilating this gas, the normal and necessary composition of the atmosphere would (no natural supply of free nitrogen having been provided), be quickly and for ever destroyed, and, as a consequence, man would cease to exist. Vegetation then, the destroyer, instead of as now the supporter of life, would degenerate, and quickly pass away, and the earth would become a barren wild. There can be little doubt that this important element is received in a state of combination ; and the observations alike of chemists and agricultural practitioners show, in fact, that events, the chief source whence plants obtain their nitrogen."

This extract will suffice to show the author's style and mode of treating his subject. Formulæ and technical terms are as much as possible avoided.

—— The second part of the new edition of *Varrell's British Birds*, by Prof. Newton (Van Voorst), has lately been issued. It includes the history of the hawks, kites, buzzards, and in part of the owls. Every one interested in birds, who has the means of so doing, must procure this new edition. The only regret is that already the Editor finds that the revision of the work will occupy more time than he anticipated, and that in consequence it will be impossible for the parts to appear monthly.—Another charming book is that of Bechstein, of which the 1st vol. now before us in an English dress, under the title of *Bird Life* (Van Voorst), translated from the German by H. M. Labouchere and W. Jesse. This is a popular book in the best sense, full of information, accurately recorded, well kept in hand, and free from technicalities. The translation is easy and fluent.

—— The recently issued number (65) of the *Journal of the Linnean Society*, contains several interesting papers, including those of Dr. Hance and Mr. Hanbury on the smaller Galangal of commerce, referred by the former to Alpinia officinarum, the characters of which are given at length. Adverting to the Chinese silkworm Oaks, Dr. Hance repeats his conviction that "all circumstances would seem to conspire to render the culture of the Oak silkworm in Europe a sure matter of success, if properly set on foot and fostered." The rearing of silkworms on the Oak is largely carried on in the south-west and the north-east of China, and it will be a matter of great interest to ascertain whether any Oak is employed for the same purpose in northern Birma or Assam, in both of which the genus Quercus is a characteristic type of vegetation, and from which Sweidoe is now received by the province of Yunnan. Dr. Masters contributes a short paper on the floral conformation of Byrsanthus, the Rev. S. Mateer one on the popular names of plants in Travancore, the MM. Tulasne publish a technical memoir on the Tremellineous Fungi, remarkable for the different forms assumed by their basidia and the multiplicity of their reproductive apparatus. MM. Tulasne are doing excellent service in co-relating the various forms assumed by the diverse reproductive organs of Fungi. From the pen of Mr. Edward Wray we have a short paper on the fertilisation of sundry South African Orchids and Asclepiads. The number is closed with a communication from the President on the styles of Australian Proteaceæ, and detailing the modifications of structure and method by which the pollen is prevented from obtaining access to the true stigmatic surface of the style, even though it be collected and deposited on other portions of the style. With the number of the Journal containing the above papers are issued some sheets of "Proceedings," a record of the work of the society during the session 1870-71, lists of donations, a very useful list of papers published in various journals, &c., on biological subjects, and the admirable presidential address from which we have already made some extracts.

—— Mr. Alfred Smee has published, under the sanction of the Accident Insurance Company, a capital little pamphlet of *Instructions for the Prompt Treatment of Accidents* (7, Bank Buildings, Lothbury), illustrated by woodcuts. The directions given are simple, intelligible, and judicious. One or two more might have been given to the bystanders, such as "Don't lose your heads." Much mischief is often done from the want of presence of mind, leading to unreasoning terror, and this results either in unfortunate meddling, or in the loss of a valuable opportunity of doing service. Another direction very necessary to be observed is "Stand clear." Too often curiosity brings a gaping crowd, whose room would be better than their company, around an unfortunate sufferer.

—— Mr. Rowell has reissued an abstract of several of his papers on the *Cause of Rain, Storms, the Aurora, and Terrestrial Magnetism* (Williams & Norgate). Mr. Rowell is a thoroughly honest enthusiast and a man of genius. For years he has laboured to convince the world that his hypothesis is the right one, and he now writes in the spirit of a disappointed man, complaining that those with means and opportunity have not tested the validity of his theories. It is not for us to enter upon the discussion of Mr. Rowell's views, which we are disposed to think would have been taken up had they seemed more feasible, but we may say, that in our opinion his gravest cause of complaint, though it may not appear so to himself, is that no one has placed Mr. Rowell in such a position that he could work out for himself, and, so far as possible, by himself, by actual experiment, the truth or falsity of his hypothesis. Had Mr. Rowell's studies been in the department of classical literature it is possible that the university within whose bounds he has passed his life would in some way or another have recognised his talent, and given him the opportunity he has sought for so long in vain. Physical science was thought till late quite unworthy a place in Oxford's learned curriculum, and hence a man who might, under proper direction, have conferred lustre on Oxford, and on himself, has been flattered by the sympathy of individuals, and left to his hard fate to follow an unconsidered occupation.

The Apiary.

The Hive, or what should Hold the Bees.—Messrs. Kirby and Spence think it probable that eggs which produce females are generally larger than male eggs, with the exception of the hive bee, in which the reverse takes places. Huber found the eggs of ants of different sizes, from which he was led to discover that they increase in size after being deposited. Thus, then, there is a difference between the drone egg and the worker (which is also, of course, a queen egg). Some other authority—I believe Swammerdam, and Latreille and Stephens besides, go into many details of the eggs of insects, with one great fact, the specific gravity of eggs of insects ; and in making experiments upon them, it should be remembered that no infertile or unimpregnated eggs will sink !—that they uniformly float. This will greatly assist in solving the difficulty of the proofs required whether the drone eggs are deposited fertilised or not, which screens the great theory of the German school of bee-masters ; and care must be taken in examining the late deposited drone eggs and those laid in the summer ; and should any bee-keeper be inclined to test any of those more delicate operations of microscopic examinations upon the fertility of the egg, I recommend Swammerdam's test of boiling. In the case of bee eggs, I advise that the eggs be put into a test-tube, in liquid coloured with madder, and that then this tube be dipped in boiling water for a few minutes. The outer corion and the spermatozoa will be more easily detected by division. This also is a good test and process to follow out in the larva stages, to discover the future image of the bee : but these fine dissections and distinctions require great watching as to the periods or ages of the eggs, the larvæ, the pupæ, and the imago, which are peculiarly rapid in the stages of the queen's life, whilst the drone is uniformly the same (weather or temperature admitted being equal). I must, then, again defer the question of the best hive for the bee-egg to be deposited in ; whilst I am quite aware the question will be asked, What does it matter, when the queen bee deposits her eggs in the centre of the comb, and a few of each cell ? I admit that, too, by an insect that only breeds in the warmer season and flower-producing periods of the year? *W. A. Munn.*

Garden Memoranda.

Hyde Park.—The management of this Park passed into the hands of Mr. Gibson, on the death of the late respected Mr. Mann, just early enough in the season to allow of his introducing such changes and improvements in the bedding-out as his long and varied experience suggested ; and this has been done so well that we can freely aver that we never saw the arrangements and decorations in better trim than they are just at the present time. The flower gardening proper is principally carried out on the long strip of land running parallel with Park Lane, from the Marble Arch to the Stanhope Gate, whilst the subtropical gardening is carried out on a nicely undulating, gently undulating piece of ground, lying between the Drive and Rotten Row, in a line from Hyde Park Corner to Albert Gate, and again to the north of this, in a line with and terminating near to the east end of the Serpentine. This portion not being so plainly seen from the main drives as the former, is rather apt to be passed unnoticed by the visitor, though here are to be seen some of the finest beds in the Park, especially of Cannas, Polymnia, and Aralias, &c.

Entering the Park at the Marble Arch it will be seen that nearly up to the Grosvenor Gate the beds on either side of the well kept walk are for the

most part situated immediately under the shade of large Plane trees, a condition anything but favourable, but still, with due attention to watering, &c., a very creditable display is made. It is worthy of mention that many of these trees are of large size, and were moved some two years since, but are thriving well. The first prominent object to strike one's attention is a large bed of the Nosegay Pelargonium, Waltham Seedling, a very neat compact grower, and exceedingly floriferous variety; and the next thing will perhaps be the splendid masses of yellow Calceolarias, amongst which there is scarcely an unhealthy plant to be seen. For effective bedding this plant is indispensable where it does well, and it will be a good thing indeed that will entirely supersede it. There is no doubt that certain varieties thrive better in some situations and soils than others, and the only one grown here is Gaines' dwarf, Mr. Gibson having discarded all others of the same colour. It is very robust, a tolerably vigorous grower, and very free flowering, and certainly one which is deserving of a trial where others have failed. Some of these large masses of Calceolarias are edged with the new Ageratum, Tom Thumb, which cuts a very poor figure indeed, growing very unevenly in size, the strong ones flowering not at all so freely as desirable, and the small ones being stained and dirty from the splashings of the water and rain. It does not at all impress one as the *beau ideal* of a bedding plant. Anything of its colour, with only decent credentials even, would be a decided gain. Pelargonium Comet, scarlet, bloom, is a very poor bedder, and as such will not be called upon to do duty here any more.

Approaching nearer to the Grosvenor Gate, the bedding assumes its proper character, and on the left-hand side of that entrance will be found a capital bed of Pelargonium Lucius, still one of the best, with a mixed edging of blue Lobelia, Dactylis glomerata variegata, and some yellow seedling Violas — not the happiest of combinations it is true, though it points to a moral of great service, and illustrates how well the Violas of the cornuta and lutea type thrive when planted amongst dwarf things which give a little shade to the roots. In this way some very pleasing combinations of colour may be had. It may be interesting to mention here that, in the London parks especially, there is a growing taste in favour of these mixed beds, which both Mr. Gibson, and his successor at Battersea, Mr. Rogers, find are to a certain extent more admired by the general public than those beds which contain only one primary colour. An example of this style is to be seen near the above gate, where there is a long bed of Pelargonium Crystal Palace Gem, amongst which the Viola cornuta is planted thinly and regularly, the blue flowers of the latter rising just above, and in pleasing contrast with the golden self-coloured foliage of the Pelargonium. The beauty of this bed is enhanced by having an inner line of Iresine Lindeni, and an outer one of Cineraria maritima, around it, as a frame. From this point to the Mount Street Gate the style of planting is altered, to afford variety. The whole of the beds on the right are edged with a bold outer line of the Golden Feather Pyrethrum, and an inner one of either blue Lobelia or Purple King Verbena. The best of these are filled in with Pelargoniums, Chieftain, scarlet, pyramidal; Model, scarlet, first-rate; Culford Rose, also first-rate; Model, dwarf and good; Duchess of Sutherland, very fine; and Madame Rudersdorff, salmon-pink, also a good bedder. Pelargonium Forget-me-not, pink, it is to be hoped, will soon be forgotten; its flowers are produced two or three on a truss being open at a time, and altogether it has a very poor appearance. It is not deserving of such a prominent position as it has here. In the strip nearest to Park Lane is a mixed bed, which, on account of its chaste appearance, and the unique character and great variety of the plants employed, is very much admired. It consists of small groups and single specimens, generally planted in pairs, of Solanum marginatum, Dracæna rubra, Palm-grass, Panicum sulcatum, Tradescantia discolor, and Centaurea candidissima, carpeted underneath, to throw up the above, with such plants as Alternanthera magnifica, A. versicolor, Iresine Lindeni, and Mesembryanthemum cordifolium variegatum, one of the very best plants of its kind of recent introduction, and one which is destined to become as useful and as common as the Golden Feather Pyrethrum, and which for forming edgings in steep or unlevel places it will entirely supersede. It was, we believe, sent out but a short time ago by Mr. W. Bull, to whom we owe thanks for its introduction, though, if we mistake not, it has been entirely ignored by the Floral Committee. Another Mesembryanthemum is also used here with very good effect, *i.e.*, the very quaint M. linguum, a thick, fleshy-leaved, prostrate-growing species, with yellow flowers, which are kept pinched off. It is used as an outer edging to some heart-shaped beds, next to which is a line of Golden Feather Pyrethrum, the centre being filled with a carpet of Alternanthera magnifica. These beds, which are situated next to Mount Street Gate, are raised about 6 inches above the level of the grass, and have a capital effect. It is a very pretty style of bed for employing to finish off the triangular junctions of walks, &c.

From the Mount Street Gate, for about 50 yards, we experience another change in style, the long beds on the left all being edged with Iresine Herbstii, with an inner line of Purple King Verbena, and filled in with such subjects as Gaines' dwarf Calceolaria, Heliotrope Miss Nightingale, a fine bed; Pelargoniums Waltham Seedling, Cybister, and Annie, &c., the latter silver-edged variety being mixed with that good old bedding Verbena, Ariosto Improved, a very effective combination. Then, on the right, all the edgings are composed of Gnaphalium lanatum, backed up with a line of Alternantheras, and filled in with two distinct contrasting colours, as Pelargonium Artemus Ward and Ariosto Improved Verbena, Pelargonium Variegated Stella and Verbena Purple King, which are

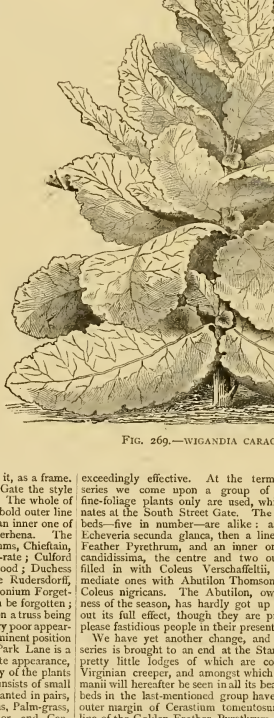

FIG. 269.—WIGANDIA CARACASSANA.

exceedingly effective. At the termination of this series we come upon a group of beds in which fine-foliage plants only are used, which again terminates at the South Street Gate. The edgings to these beds—five in number—are alike: an outer row of Echeveria secunda glauca, then a line of the Golden Feather Pyrethrum, and an inner one of Centaurea candidissima, the centre and two outer beds being filled in with Coleus Verschaffeltii, and the intermediate ones with Abutilon Thomsoni, carpeted with Coleus nigricans. The Abutilon, owing to the lateness of the season, has hardly got up enough to bring out its full effect, though they are pretty enough to please fastidious people in their present condition.

We have yet another change, and this interesting series is brought to an end at the Stanhope Gate, the pretty little lodges of which are covered with the Virginian creeper, and amongst which Clematis Jackmanii will hereafter be seen in all its beauty. The long beds in the last-mentioned group have on the left an outer margin of Cerastium tomentosum, and an inner line of the Golden Feather Pyrethrum, whilst those on the right have an outer edging of Dactylis glomerata variegata alternating with blue Lobelia, and an inner line of Iresine Lindeni. In the first named will be found distinct masses of most of the best of the bedding Pelargoniums, as Lord Palmerston, Mrs. Laing, Lucius, Amy Hogg, Waltham Seedling, &c.; and the latter are composed of silver-edged Pelargoniums mixed with Purple King Verbenas, the alternate ones having filled in with cross lines of Pelargonium Culford Rose, the long sides of Mrs. Pollock, and the ends of Crystal Palace Gem. The same varieties are not used all through, though the general appearance of all are alike.

In the subtropical department proper, in which a number of nice specimen plants of Palms, Musas, &c., are freely sprinkled about, the principal features are the beds of dwarf Rhododendrons, edged with Sempervivum repens and Echeveria secunda glauca; a long scroll-shaped bed of Cannas, principally C. Bihorelli,—one of the best, having broad coppery leaves, and orange-scarlet flowers—carpeted with a dark-leaved Coleus, like Murrayi, and edged with a dark bronze-leaved Beet, dwarf and compact, and apparently a well selected strain. The next to challenge attention is a very effective oval bed of Centaurea candidissima intermixed with Coleus Verschaffeltii, around which is a line of the beautiful Euonymus japonicus aureo-variegatus, and an outer one of Echeveria secunda glauca. Another one, of equal interest on account of its boldness, though sombre in colour, is filled with Caladium esculentum, carpeted with Tradescantia zebrina and edged with Farfugium grande. Passing some pretty designs worked out in Pelargoniums, we come to a large heart-shaped bed composed of tall plants of Ficus elastica, alternate with equal sized specimens of Eucalyptus globulus, and dwarfer examples of Musa superba; the whole being completed with Coleus Verschaffeltii, and edged with a row of Salvia argentea, and an outer one of Echeveria metallica. This has a very imposing appearance. Medium-sized plants of the Musa superba have a noble appearance when stood out singly by themselves, or when used as the centre attraction for small beds, as is the case here, the plant being surrounded with Coleus Baroness Rothschild, with a line around that of Golden Feather Pyrethrum, and finished off with a margin of Echeveria secunda glauca. The last design to notice in this portion of the Park, though not the last by any means to claim attention, is a large circular bed of Fuchsias, planted in circles of different colours, next to which comes a row of Iresine Herbstii, then one of Golden Feather Pyrethrum, and an outer one of large-flowering plants of Echeveria glauco-metallica, which has the character of varying in its habit, some plants being almost distinct enough to be reserved for separate use. For furnishing a little variety in winter, this portion of the park is planted with single specimens of bushy-headed standard Rhododendrons, pyramidal bushes of different varieties of Hollies, Conifers, and Box trees, which are now effectively grouped with such elegant Palms, Dracænas, Aralias, Strelitzias, and Musas as Mr. Gibson had at command.

Experience teaches us to believe that tall specimen plants of Musas will soon be discarded for this work, except for the most sheltered of positions, as, no matter how handsome they may be when put out, the first good gale of wind that comes rends their leaves into shreds, and transforms them like magic from objects of beauty into something like monuments of unsightliness; not so, however, those specimens which range to the height of 3 or 4 feet—they to a great extent escape from violent gusts of wind, and carry a noble appearance throughout the season. For the most exposed position in the subtropical garden we have no more useful or more elegant plant than Seaforthia elegans, the pinnate leaves of which stand the wind in the most admirable manner. Indeed, at the present time no Palms have come through this precarious season so well, or look better, than Seaforthias, Latanias, and Phœnix; the stiff wiry habit of the latter genus renders them invaluable, so well does it enable them to withstand the effects of wind-storms. Jointed canes have been used in plants as we found here doing excellent service, we have the Monstera deliciosa, Strelitzia Nicolai, Seaforthia robusta, Phœnix reclinata and P. dactylifera, and Aralia reticulata. These are all well adapted for standing about singly. Mr. Gibson says that, when so treated, their only requirements are to be plunged in their pots on a well-prepared bed of rubble to secure good drainage, and to be carefully attended to in the matter of watering.

In the kept grounds, on the north side of Rotten Row, some of the largest and most striking beds are to be seen, principally large masses of Ficus, Solanums, Cannas, Wigandia caracassana (fig. 269), Paulownias, Ferdinandas, Aralias, &c., all edged with the most suitable plants for contrasting, and doing well. In concluding our notice of the floral decorations in this Park we have only to say that the bedding-out at "the Temple," the Sunday resort of the well dressed multitudes, is this

year as attractive as ever; and that, thanks to the worthy and estimable superintendent, the lodges at the principal gates have received a touch from the master-hand in the shape of a suitable amount of much needed floral embellishment.

Obituary.

In the obituary of the week we have to record the death, at a comparatively early age, of Dr. Hyde Salter, F.R.S., physician to Charing Cross Hospital, and well known in scientific circles for his extensive attainments in physiological science. Dr. Salter early gained a prominent place as a physiologist and anatomist at King's College, and subsequently, as a practising physician, more than maintained his reputation. As a teacher, he was always ready to render aid and counsel where science was in question; as a kind, earnest friend, he was no less helpful, so that his loss will be severely felt, even beyond the limits of his immediate friends and associates.

August 31.—Very fine. The clouds gradually cleared off as the day advanced.

Sept. 1.—Hazy and misty in morning. Variable amounts of cloud prevalent. Fine.

— 2.—Cloudy in morning. Generally cloudy till night. Rain fell between 9 and 10 A.M., and again between 1 and 3 P.M. Distant lightning in afternoon. Lightning at night.

— 3.—Generally cloudy. A little rain fell in the afternoon.

— 4.—Generally cloudless till 9 A.M. Overcast afterwards. Rain fell almost continuously from noon till 9 P.M.

— 5.—Light clouds till night, then cloudless. Very fine day.

— 6.—Foggy in early morning. Generally cloudy throughout. Frequent flashes of lightning in the evening. Rain fell occasionally at night.

JAMES GLAISHER.

Miscellaneous.

Nettles for Food.—One of the most neglected, and certainly one of the most common of our British plants, is the Stinging Nettle (Urtica dioica); three species are known in this country, but the one mentioned is, perhaps, the most common. Many country people believe in Nettle-tea as a useful spring medicine, and not a few boil and eat them as a green vegetable; they were, in former times, grown in Scotland as a potherb, and if forced and blanched by earthing up in a similar manner to Asparagus and Seakale, the young tops make a very good dish. In Belgium, Germany, and other parts of Continental Europe, Nettles are much more generally used as food than they are with us. *Food Journal.*

Cricket.—A match was played at Battersea Park on Thursday, August 10, between two elevens chosen from the nursery establishments of Mr. Wm. Bull and Mr. J. W. Wimsett, Chelsea, when the latter were victorious by one innings and 66 runs.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

As we have to some extent entered upon the autumn period, it will become necessary to husband our resources to the utmost in the matter of providing flowers for an early future. *Valletas* which are late in showing for flower may be placed in a cool, shady situation out-of-doors, so as to retard them to the utmost. The earliest *Primulas* and *Cinerarias* should be encouraged to form good heads of bloom by liberal exposure to the sun. Many of the beautiful *Amaryllis* may also be pushed along by placing a batch into a rather close and warm atmosphere. *Eria conrcta* and *E. floccosa*, too, may, where planted at a proper time, be brought in very usefully for flowering in October and November. These and many other like plants help materially to brighten up Chrysanthemums, as well as to extend the display. Every possible assistance should now be rendered to *Brassottias*, to enable them to perfect a strong luxuriant growth. This must be done by frequent applications of liquid manure to the roots and by surface sprinklings overhead, which they enjoy very greatly and turn to good account. It is not advisable to shift Poinsettias after this period, except in the case of late-struck cuttings, which may receive a very small shift. *Chrysanthemums* must now receive unremitting attention in regard to protecting them from earwigs, which do much mischief to the tender young shoots and flower-buds. The only safe way to get rid of the pests is to burn them in flowerpots containing dry Moss, or, what is better still, with old Broad Bean stalks cut into lengths and stuck about amongst the foliage. *Zonal Pelargoniums* should now be encouraged to grow freely in all instances where they are required for conservatory decoration late in the season, by giving them weak manure water and by sprinkling them overhead morning and afternoon. Keep them fully exposed to the sun, and encourage well ripened wood to form. *Lachenalias* should now be transferred to a moderately exposed position out-of-doors, where a strong sturdy growth can be made. *Cyclamen* which have been grown on quickly from seedlings in bottom-heat, may now, if they are early and flowers are forming freely, be kept somewhat cooler and more airy. This will tend to increase the strength and general vigour of the blooms, as well as heighten the colour. Do not delay the removal of all kinds of Orchids, such as *Dendrobiums*, *Epidendrums*, *Cattleyas*, &c., which have finished their growth, into a cooler, more airy and sunny house, where they will perfect their pseudobulbs more quickly and better. Such Orchids as are still growing freely should be hurried on as fast as circumstances will permit. I refer to such plants as *Sobralias*, *Huntleyas*, &c., which have not yet completed their season's growth. *Indian Azaleas* and *Camellias*, such as are required in bloom very early and which have perfected their flower-buds out-of-doors, may now be removed into any cool structure having a sunny aspect. Push forward the potting of late *Cape Pelargoniums* that a strong healthy young growth be assured before the severe winter weather sets in. Make a strong effort now to destroy every kind of insect pest, and this may be done without any determined effort made at this time will be the means of destroying many, and will prevent much uneasiness and cause for dissatisfaction at a late date.

FORCING HOUSES.

Most late *Vineries* should now have the assistance of a little fire-heat, not only to ripen the fruit, but also to insure the wood being thoroughly matured, without which no healthy success can be expected. Let the sashes be placed upon *Peach* and *Nectarine houses* intended for the earliest forcing, to ward off the autumn rains. See that there is no red spider upon any of the trees. It is not enough to surmise that the trees, having perfected their growth, will be safe from such injury. The beds containing *Cucumber* and *Melon plants* must, now that the cold nights increase in length, have additional assistance in the form of an occasional renewal of the linings. Though artificial aid is thus desirable, do not dispense with the giving of air freely at all proper times.

HARDY FRUIT GARDEN.

Owing to the peculiarity of the present season, many hardy fruit trees, *Apples*, *Pears*, &c., will exhibit an unusual tendency to grow. Even those carrying good crops of fruit, which are few and far between this season, exhibit like symptoms. It will be necessary to pinch these young growths back determinedly as they continue to push, and so endeavour to centre the tree's whole effort in the production of flower-buds. Such fruit as are good ought to be watched regularly, so as to pick them at the earliest possible moment, so scarce is good fruit likely to be this season. I observe that some kinds of *Pear trees* are suffering greatly for want of root moisture, notably so the variety named Dr. Nelis. It will be desirable, therefore, to water young trees showing such signs, especially if they have a crop of fruit which is swelling off indifferently. All Apples and Pears, when gathered, should be placed on shelves in an airy room, where they will finish the ripening process. It is not at all advisable to let any kinds remain until they are what is called "dead ripe;" they do not keep any better, and only afford a greater temptation to insects. Especially should such early Pears as Jargonelle, Beurré d'Amanlis, Louise Bonne of Jersey—the two latter being very fine in this neighbourhood this season—be picked somewhat by anticipation, not only because of the facts above stated, but because they suffer greatly by dispersion from the branches during wind storms, which may prevail at any moment; so also does Fondante d'Automne, a somewhat later sort.

HARDY FLOWER GARDEN.

Should the present dry weather continue, it will be necessary to give more frequent root waterings to *Pentonas*, *Pampas grasses*, *Cannas*, and large foliage plants in particular. Prick out seedling *Perennials* into neat nursery beds, where they can stand the winter through. Immediately another rainy period comes round it will be necessary to transplant into their permanent winter quarters any *Perennial Plants* which have struck from cuttings, such as *Crimson Thrift*, &c. These make very beautiful edgings, and should be more extensively grown. Summer flower-beds will now require a larger share of attention than usual in picking off the dead leaves, removing decaying seedy blossoms, and shortening neatly any gross shoots which attain to a greater altitude above their fellows. Proceed vigorously with propagation, as every week counts for much between now and winter, at the earliest advent of which most kinds should have formed roots, and become tolerably well established. Immediately the temperature falls below sufficient roots, let them be fully exposed to the full sun and air.

KITCHEN GARDEN.

The water-pot will have become the vegetable grower's chief tool during the last week or two, and it must continue to be so if we have not a change soon. Especially will this be needful in connection with salads of all sorts, and more especially *Lettuces*, *Lettuce*, &c. In connection with *Peas*, *Beans*, *Cauliflowers*, and the like, do not be constantly slopping about, but rather give a good watering about twice a week. Attend to the hoeing over of the surface of all artificially watered soil as soon as it gets dry enough to work upon. This tends to retain the moisture by breaking up the surface and assimilating the excessive action of the sun's rays. Further sowings should be made of *Radishes*, *Golden* or *Australian Crest*, *Lamb's Lettuce*, and *Onions*, to use young for future winter salads. Take up and harvest *Onions* of the main summer crops, preparing the beds subsequently for *Spinach* or to stand for spring use. Collect a further supply of the necessary materials for successional *Mushroom beds*, bearing in mind that these materials must be so dried as to preclude any possibility of becoming excessively heated in process of fermentation. *W. E.*

Notices to Correspondents.

Ants: *O. V.* writes for a remedy for black ants in sandy soil. Watson's sand for destroying Daisies in lawns is advertised in our columns.

Arbor-vitæ: *E. J. P.* We should be inclined to refer the withering of the ends of the branches in question to electricity. Perhaps our correspondent may remember whether there was any great thunderstorm on the day when the damage was done; there certainly was about that time in others parts of England.

Australian Pea: Messrs. Kennedy of Dumfries send us samples of this Pea, which seems a good late cropper, and a continuous bearer. The Peas are when cooked of a good colour and flavour, considering the season. The pods are studded with curious cellular excrescences or warts.

Black Bryony (Tamus communis): *W. E.* The point of the leaf has apparently been injured at a very early stage of growth, hence the deformity.

Books: *Paul Maxwell*: "Book of Evergreens," an American book, to be had of Trübner & Co., will perhaps answer your purpose; or, Grigor's "Arboriculture" (Edmonston & Douglas).

Cauliflower Excrescence or Pelargonium: *R. P.* A swelling or hypertrophy of the tissues, accompanied with the production of a number of adventitious buds, is not a very unusual occurrence. A case of the kind was noticed in our columns, p. 725, 1855.

Dracænas: *W. G.* By a specimen of such plants as the Dracæna is meant a single plant originating from a single stem—not two or three plants put into one pot, which would be a fair reason for disqualification. A plant with suckers is altogether different.

Dwarf Box: *J. W. B.* We never heard of this producing flowers. Inquire of Charlwood & Cummins, Covent Garden. The Alpine Strawberry should be procured from any respectable firm.

Fruit Growing: *Hampshire.* A letter addressed to the gardener, C. Beard, Esq., Bury St. Edmund's, would probably secure the information you require.

GRAPES: *S. A. H. F.* Your Grapes and Vines are literally eaten up with thrip. The leaves you sent were swarming with the insects; we scarcely ever saw a worse case. It is all produced by mismanagement and neglect, and it will be years before your Vines recover. As your Grapes of this season are worthless, cut them off and throw them away at once, as well as all the worst of the leaves, then fumigate with strong tobacco and syringe copiously and repeatedly every leaf and stem, and, indeed, every part of the house; at the same time you will have to give abundance of air, so as to ripen the wood thoroughly. When the Vines are at rest, paint the stems with a good coating of soft soap, sour, and sulphur, and clean the house thoroughly. If even only air and more water had been given—*i. e.*, had a more genial atmosphere been maintained—your Vines would not have been as they are now.

GREENHOUSE PLANTS: *R. S. Jones.* It is very doubtful if any of the plants named would succeed in a greenhouse, even though it were kept "warm." Some of them might live on if kept dry, close, and at rest in winter, but their value would be but a lingering death at the best.

GOAT MOTH: Several correspondents have this week sent specimens of this destructive pest, an illustration

FIG. 270.—THE GOAT MOTH.

of which we reproduce from a former volume. They may be destroyed by blowing tobacco smoke up the holes in the trees,—that is, if you blow hard enough!

MUSHROOMS: *H. Y.* Any sulphurous gas which would prove injurious to plants in general, should not be encouraged in your Mushroom-house. The only thing we advise as a little more ventilation at the top, as in other respects your house appears to be a fittiug one for the purpose—all other conditions being equal.

NAMES OF FRUIT: *J. C., Bromley.* Your Fig was quite rotten when received. It is impossible to say what it is.

NAMES OF PLANTS: *J. E.* Hydrangea quercifolia, a fine old neglected plant, and we should think well adapted for a trellis against the house, such as you describe; the large panicles of white flowers are very beautiful, as are those of H. paniculata grandiflora.—*N. C.* You have made some mistake, the plant enclosed is a Pinus of some kind, not a Spiræa.—*F. Stokes.* One of the varieties of the African Marigold, Tagetes erecta.—*J. C., Bromley.* The Genera is one of the varieties of the G. zebrina type, of which there are too many garden forms to admit of their being recognised in the cutstate. The Begonia not recognised without flowers.—*A. W.* Daucus Carota, wild Carrot. One of the specimens has all the flowers of a purple colour.

RENEWING PEACH-BORDER: *H. Y.* Though we agree with you in the matter of adding an entirely new soil as you propose, we certainly cannot recommend clay as an artificial basis. Rather procure good stiff loam, and with the addition of a moderate amount of good manure form your border thoroughly throughout. Peaches like stiff loam, but clay would act adversely during wet summers and in winter.

THE KEEPING OF A GARDEN: *G. S.* Given the extent of a garden, how much labour is required to keep it? The question is one put to us is extremely difficult to answer, so much depends upon style. One garden of two acres may require just double the labour that another of the same size may do, and still not look or even be much better. As a general rule, the market gardeners reckon upon one man to every acre of land. You would thus require three men to keep your kitchen garden of 3 acres and the fruit trees, &c. They ought, however, to keep it well, and keep up a thorough good supply of vegetables all the year round. We would, therefore, consider three men, with the working head gardener and a boy, about the proper staff to keep your place.

CATALOGUES RECEIVED: Hooper & Co., General Catalogue of Dutch, Cape, and other Flowering Bulbs.—James Carter & Co., Catalogue of Flower Seeds, Fruit Trees, and Roses.—Dicksons & Co., Descriptive Catalogue of Dutch Flower Roots, New Pansies, Violas, Fuchsias, &c.—Robert Parker, Catalogue of Bulbous Roots, Fruit Trees, and Miscellaneous Plants.—Thomas Sampson, Catalogue of Bulbous Flower Roots.—Barr & Sugden's Autumnal Descriptive Catalogue of Bulbs and Plants, for Winter, Spring, and Summer Flowering.—Charles H. Dickson, Autumn Catalogue of Choice Dutch Flower Roots.—Thomas Sampson, A List of Bulbous Flower Roots.—Butler, McCulloch & Co., Autumn Catalogue of Dutch and Cape Bulbs.—E. P. Markets.

COVENT GARDEN.—Sept. 8.

Business here is very quiet, though there is a very fair demand for good fruit and vegetables. Peaches and Nectarines are more plentiful, and of better quality. We are receiving large consignments of foreign produce, but of home-grown goods the supply is about equal to the demand. In the Potato market we have no alteration to report.

FRUIT.

	s. d.	*s. d.*
Apples, per ½ sieve .. to 3	Nectarines, per doz.	2 0 to 8 0
Apricots, per dozen 0 6 — 2 0	Oranges, per 100 ..	8 0 — 16 0

Enfield Rural Board.

To LANDSCAPE GARDENERS, NURSERYMEN, and OTHERS.

THE RURAL BOARD of this PARISH OFFER a PREMIUM of TEN POUNDS for the best or approved PLAN of Laying-Out, Forming, and Planting the Ornamental Portions of the Cemetery at Brigadier Hill, Enfield, at a cost not exceeding £300 (not including the making the Roads or Drainage).

A Plan of the Ground, with Conditions, can be had at the Office of Mr. T. J. HILL, the Architect, 29, Bedford Row, W.C.

By Order of the Board,
JOHN PURDEY, Clerk.

Enfield, Sept. 6.

WANTED, a HEAD GARDENER, at the country residence of a Gentleman in New England, U. S., about January 1, 1872, who can give the most undoubted recommendations as to honesty and sobriety of character, steady industry, and who is thoroughly experienced in the care of all Stove, Hot, and Greenhouse, the Grapery, and Pine-pit Departments. The place is extensive, and the situation a very desirable one. Wages £90 per calendar month, with a house rent free, and vegetables. Applications, by letter, giving references and full particulars, may be made to Mr. JOHN G. McARTHUR, 24, St. Vincent Place, Glasgow.

WANTED, in a Nursery near London, a young Man Head, to act as FOREMAN, Potter for Market, and a good Propagator. Character unexceptionable.—J. R., *Gardeners' Chronicle* Office, W.C.

WANTED, as NURSERY FOREMAN, in a country Nursery, a good general Man, well up in Fruits, Roses, and with a knowledge of the other Stock generally; met with in a good Nursery. Above all, must know how to do his work, and to keep the head of the other men employed.—Address, stating full particulars, B. S., 31, Mincing Lane, E.C.

WANTED, a General NURSERY FOREMAN.—Must be well up to the business in all its branches, especially indoor, and have a thorough knowledge of the value of Plants. Good address indispensable. None need apply whose character will not bear the strictest investigation as to honesty, industry, and sobriety. State in own handwriting, stating age, wages expected, whether married or single, and where at present or last employed, to JOHN KELLETT, Wellington Nursery, North Chapel, Sussex.

WANTED, a GARDENER, without family, and of middle age preferred; the Wife to take the Laundry. One accustomed to attending Church Services preferred. A Cow is kept. A good character for steadiness and sobriety indispensable.—Mr. W. PARKINSON, Oak Bank, Reigate.

WANTED, in a short time, GARDENER—a good Plantsman, to Manage a small Vinery, small Conservatory, and a large Greenhouse. No Kitchen or Flower Garden. Wages £25 per year. Only one Children can have constant employment.—ALFRED PAGE, Nottingham.

WANTED, in a Nursery, an energetic MAN, for the Houses. Must be well acquainted with Potting, Syringing, and Tying Plants, and handy at Packing. None need apply who are not well up in such work, and strictly sober and honest.—Apply, in own handwriting, stating wages required, F. C., Post Office, Richmond, Surrey.

WANTED, a good PROPAGATOR of Soft-wooded Stuff, Florist Flowers, Roses, and Fruit Trees, Grafting. Good references as to ability and sobriety indispensable.—Apply, stating age, wages wanted, to WM. CLIBRAN and SON, Milbank Nursery, near Warrington.

To the Seed Trade.

WANTED, a WAREHOUSEMAN, an ASSISTANT, and a CLERK.—One of the largest establishments in the North of England has openings for a thorough WAREHOUSEMAN, who has a knowledge of agricultural seed orders with carefulness and despatch. He may have to take short journeys occasionally. Also an ASSISTANT for the Counter. One who has a good knowledge his appointment. Also a CLERK. He must be an expert penman, and conversant with accounts. Answers will be treated confidentially. Character and abilities of each must bear strict investigation.—Address, with particulars where communications will be made, wages required, to D. V. T., Messrs. Hurst & Son, 6, Leadenhall Street, London, E.C.

Parker to SELL by AUCTION, without reserve, on the Premises, The Nurseries, Tooting, Surrey, on TUESDAY, September 26, at 11 for 12 o'Clock precisely, thousands of extra STOVE and GREENHOUSE PLANTS, in the whole of which are in a very healthy and thriving condition, comprising quantities of Allamanda nobilis variegata, Ardisia crispa, Aphelandra Daedema, Phormium tenax variegatum, Ficus, Epiphyllums, in splendid variety; Euonymus Rhodendroides, choice double Camellias and Azalea indica, and numerous others. Also a large quantity of choice ORCHIDS, including Vanda suavis (Paxtoni), Aerides maculosum and Lobbii, Lælia prestans (true), Angræcum sesquipedale, Cypripedium Spicerianum, Thunia Bensoniæ; and hundreds of exotic FERNS, fine greenhouse and stove PALMS, and a selected assortment of SUCCULENT PLANTS, barely HERBACEOUS PLANTS, &c.
May be viewed the day prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers and Valuers, Leytonstone, Essex, E.

4000 Araucaria imbricata.

To GENTLEMEN, NURSERYMEN, and OTHERS.
HILLFIELDS, BURGHFIELD, near READING.

MESSRS. HASLAM AND SON have received instructions from J. B. Garland, Esq., to SELL by AUCTION, without reserve, on a Field adjoining the Gardens of Hillfields, Burghfield, on FRIDAY, September 22nd, at 1 o'Clock in the afternoon punctually, in suitable Lots, 4000 ARAUCARIA IMBRICATA, raised from choice seed, and specially imported by Robert Bland, Esq., direct from Arauco.
Note.—The Auctioneers desire to draw special attention to this Rare and Choice Lot. They have been transplanted several times, and are now strong, healthy, and well-rooted, varying from 1 to 4 feet in height, and in the best possible condition for immediate removal. The whole will be sold without the slightest reserve.
May be viewed one week prior to the Sale on application to the GARDENER at Hillfields; and Catalogues had at the Office of the Auctioneers 17, Friar Street, Reading.

LARGE SALE by AUCTION.—On account of the illness of the Proprietor the very extensive collection of STOVE and GREENHOUSE PLANTS, as well as the large general NURSERY STOCK of the Horticultural Establishment of Mr. H. LAURENTIUS, at Leipzig, Saxony, will be DISPOSED OF on SEPTEMBER 11, and following days.
Catalogues have had an application at the above Nursery. In consequence of the Large Stock in all branches of Horticulture, the days of the Auction of each of the respective branches are fixed for the convenience of purchasers.

Re Mr. R. Glendinning, Deceased.

PRELIMINARY NOTICE of IMPORTANT SALE.
To NURSERYMEN; FLORISTS, and OTHERS.
High Road, Turnham Green, nearly opposite the Duke of Devonshire's Avenue to Chiswick House, the Residence of H.R.H. the Prince of Wales, near the Toll Gate, and known as Chiswick Nursery, late the Nursery Grounds of R. GLENDINNING, Esq.

MR. J. A. SMITH is instructed by the Executrix to SELL by PUBLIC AUCTION, at the Roebuck Inn, close to the Toll Gate, on TUESDAY, October 3, and following days, in TWO LOTS, the valuable LEASES, GOODWILL, &c., of the important Business and ESTABLISHED PROPERTY, established nearly 30 years in the Name of Glendinning, extending over about Eleven Acres of rich Land, in trading cultivation, and each held at very low Rents. The Nursery at 58, Chiswick High Road, is held, and may now underlet; Chiswick Lane at £50, cottage underlet to Dr. Tuke, at £30; nett rental £80 only. Frontage to the High Western Road, about 325 feet, and 350 feet frontage to Chiswick Lane.
Auction Offices, 84, King Street, Hammersmith, W.

Elvaston Nurseries, Borrowash.

PRELIMINARY NOTICE of a HIGHLY IMPORTANT and EXTENSIVE SALE of FIRST-CLASS NURSERY STOCK.

MESSRS. POTT AND SALE have received instructions from Messrs. Barron & Son to OFFER for SALE by AUCTION, on TUESDAY, September 26, and following days, 11 and 12, a considerable portion of their most valuable NURSERY STOCK, consisting of rare Coniferæ, Evergreen and Deciduous Shrubs, Standard and Dwarf Trees, Roses, Herbaceous Plants, &c.
May be viewed any day prior to the Sale (except Sundays) after October 1.
Full particulars will appear in future Advertisements.

Brockton House, Eccleshall, Staffordshire.

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on TUESDAY, September 26, at Brockton House, Eccleshall, the ENTIRE HERD of PURE BRED SHORTHORNS, the property of Mr. Bell, long known as Brockton Head, which have been very carefully bred for the last thirty-two years from the far-famed Kirklevington blood. Mr. Bell's long association with the late Mr. Torr, of Tarporley, is a sufficient guarantee for their excellence and purity of descent. Among them will be found several of the "Peach Blossom," "Vicar," "Grosvenor," and other families in the sale.
The cows and heifers are in calf to Colonel Gunter's Bapton Duke (16,810), and the produce of several young Bulls are offered in the sale.
Catalogues, with Pedigrees, may be had of MR. BELL, Brockton House, Eccleshall, or of JOHN THORNTON, 15, Langham Place, London, W.

Extensive Sale of Pure-bred Shorthorns in Lincolnshire

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on THURSDAY, September 14, at Panton House, Wragby, Lincolnshire, the celebrated HERD of PURE-BRED SHORTHORNS, the property of Lord Yarborough, the Hon. Mr. Dudding.
The success that has distinguished the Panton animals at the Royal, the Yorkshire, and County Shows, the old-established character of the Herd, and the various bulls of Bond Street Duke, Grand Duke, used—Mr. T. C. Booth's Mansfred (26,801) and British Crown (21,329) being now in use—will, it is hoped, secure a large attending and excellence of the stock, which contains a large number of cows and heifers of great substance and quality, as well as several prize-winners, including several young bulls.
Catalogues, with Pedigrees, may be had of JOHN THORNTON, 15, Langham Place, London, W.

Holly Bank, near Burton-upon-Trent.

MESSRS. LYTHALL and CLARKE will SELL by AUCTION, on TUESDAY and WEDNESDAY, September 26 and 27, the ENTIRE FLOCK of THREE HUNDRED SHROPSHIRE SHEEP, including FORTY RAMS; the HERD of SHORTHORN CATTLE, including a selection of them being of pure Bates' blood; HORSES, PIGS, IMPLEMENTS, &c., the PROPERTY of Mr. Thomas Salt, of Willington Wood, Esq., who has let his Home Farms.
Conveyances will meet the Trains at Barton and Walton Station, on the Midland Railway, and at Wichnor Junction, on the South Staffordshire Railway.

ORDER OF SALE.

TUESDAY, September 12, the entire Flock of Sheep.
WEDNESDAY, September 13, Shorthorn Cattle, Horses, Pigs, Poultry, Cheese, &c.
Luncheon on Tuesday at 11.30; Sale at 1 o'Clock.
Luncheon on Wednesday at 10.30; Sale at 12 o'Clock.
The Flock is nearly pure bred, very compact, symmetrical, and possess plenty of muscle. The Ewes are remarkably true in character, with great scale, and very prolific. Among them will be found, in addition to the pure-bred Ewes belonging to them in the flock, many purchased at a high price from Messrs. Beach, Baker, Byrd, &c.
The Shropshire Sheep are remarkably well bred, many having three or four crosses of pure blood.
The Cattle are of the Bates' cob colour, and good milkers.
The Young Stock are well worthy the attention of gentlemen wishing to procure pure bred stock.
The Auctioneers can confidently recommend this Sale as a first-rate opportunity to any one desirous of founding a flock or herd of Shropshires or Shorthorn Herd. As Mr. Wood is giving up his farm, the whole of the lots will be sold without the slightest reserve, and it is seldom a better bred or more useful lot of Sheep and Cattle are disposed of.
For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Bingley Hall, Birmingham.

IMPORTANT SALE of SHROPSHIRE SHEEP.
MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, at Bingley Hall, Broad Street, Birmingham, on THURSDAY, September 14, at 1 o'Clock precisely, the whole of their SHROPSHIRE RAMS, and 750 EWES and THEAVES, the property of Messrs. Thomas Bowen, Wm. Bowen, and Thos. Bowen, Jun., Yates, and other most eminent Breeders, and including many Show Sheep at the Royal Agricultural Show at Wolverhampton, and other important Exhibitions.
For Catalogues, apply at the Auctioneers' Offices, 39, New Street, Birmingham.

Milcote, near Stratford-on-Avon.

HIGHLY IMPORTANT SALE of the MILCOTE DOWN SHEEP.

W. HUTCHINGS has been honoured with instructions from the Executors of the late Mr. J. Hutchings to SELL by AUCTION, at Milcote, near Stratford-on-Avon, on WEDNESDAY, September 20, at 1 o'Clock precisely, the whole of the celebrated FLOCK of MILCOTE DOWNS, comprising 400 Shearling Ewes and Theaves, 100 Superior Two-tooth and Weather Lambs, 22 grand symmetrical Shearling Rams, and 24 extraordinary Lamb Rams.
The great celebrity of this Flock demands a few words as to its formation. With Oxfordshire Downs as a foundation, the late Mr. Hutchings, by judicious crossing, succeeded in obtaining the Cotswold and Hampshire Down blood, and with much judgment and discrimination combined in producing a distinct type of Down sheep. With great size, grand symmetry, good colour, and hardy constitution, the Milcote Downs are remarkable for their heavy weight of lean meat and of wool, and for their early development and maturity. The rams will be brought forward in a natural and unforced condition. The Auctioneer can, with great confidence, call attention to this Sale; and can assure Flockmasters that an entire Flock of such high character is seldom offered to Unreserved Public Competition.
Catalogues will be circulated in due course, and may be had of the Auctioneer, 28, Bridge Street, Stratford-on-Avon.
Trains stop at Milcote Station as under:—From Paddington, Oxford, Banbury, Leamington, Warwick, and Birmingham, 8 at 10.18. From Paddington, Oxford, Moreton, Evesham, and Worcester, 8.35, 12.0, and 1.25.

ALTRINCHAM AGRICULTURAL SOCIETY.—The EIGHTEENTH ANNUAL SHOW will be held on THURSDAY, September 28, when FIVE HUNDRED POUNDS and SILVER CUPS will be offered in PRIZES for Horses, Cattle, Horses, Sheep, Pigs, Dogs, Poultry, Roots, Grain, Cheese, Butter, Implements, &c.
ENTRIES by SEPTEMBER 16. PRIZE LISTS, with FORMS of ENTRY, can be had on application to the Secretary, 28, Church Street, Altrincham. R. DAVENPORT.

SMITHFIELD CLUB SHOW, AGRICULTURAL HALL, ISLINGTON, DECEMBER 4 to 8.
IMPLEMENT DEPARTMENT.
The LAST DAY for receiving APPLICATIONS for SPACE for IMPLEMENTS and MACHINERY, &c., is OCTOBER 2.
Printed Forms of Application, with Rules and Regulations, may be obtained of Mr. DAVID PULLEN, Assistant-Secretary, corner of Half-Moon Street, Piccadilly, London, W. All communications should bear outside the words "Smithfield Club."

SMITHFIELD CLUB FAT CATTLE SHOW.—The ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS, will be held at the FAT STOCK HALLS, LEADENHALL MARKET, on MONDAY afternoon, December 4, and Four following Days.
Intending Exhibitors are requested to apply for Certificate Forms by the reference letters as under.
CATTLE.—Form A. For an OX or STEER (in any Class).
" B. For a COW or HEIFER (in any Class).
" C. For a BEAST in extra Stock.
SHEEP. " D. For a Pen of three WETHERS.
" E. For a Pen of three EWES. [Stock.
" F. For a SINGLE WETHER SHEEP in Extra
PIGS. " G. For a Pen of three PIGS (in any Class).
" H. For a SINGLE PIG in Extra Stock.
ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.
Prize Lists, Forms of Certificates, and all information, may be obtained on application to Mr. DAVID PULLEN, Assistant-Secretary, at the Office of the Honorary Secretary, corner of Half-Moon Street, Piccadilly, W.
N.B. All communications respecting the Show must be addressed to the Assistant-Secretary, as above, and should bear outside the words "Smithfield Club Show."

The Agricultural Gazette.

SATURDAY, SEPTEMBER 9, 1871.

WE have found a mine of WEALTH in our OLD PASTURES, by ploughing them up and taking repeated crops of corn. It is like breaking up the prairie, or turning up the virgin soil of the forest; the land is full of the raw material of crops, which costs so dear to buy in the form of manure, and which sells at such a high price when worked up into marketable produce.

A certain amount of fertility arises from the decay of the old turf and its roots and fibres, but this is only a shallow supply, which is soon exhausted. We then fall back on the natural powers of the soil. How much available food does it contain? In other words, how many crops will it yield before it will require manures, solvents, tillages, and the usual round of operations and treatment necessary for exhausted soils?

Ploughing up old turf is a heresy; and the answers to these questions will decide whether repentance is likely to follow. There is always a sacrifice in ploughing up old turf, because so good a pasture cannot be obtained again for several years. You sacrifice the time it takes for superior pasture grasses to establish themselves, and if the land contains only a shallow supply of the raw materials, so that you may expect to have to resort, in two or three years, to the accustomed routine in order to obtain a crop; it must have been wrong to disturb the old turf; but if you can rely on getting a succession of first-rate crops of corn, seeds, Potatos, &c., by merely ploughing and sowing, it is evident you have opened a mine of wealth.

This discovery has been made on some of the most famous pastures in the country. Plaistow Level, and other Thames-side marshes,* have yielded to the plough of late years, and the splendid pasturage of Romney Marsh has been attacked. The celebrated marsh, 100 years ago, observed "the vast flocks of sheep" in Romney Marsh, and remarked on the beef, "the largest in England," fed in that part of the country: but LELAND, whose antiquated orthography we must modernise, says, "It is a marvellous rank ground for feeding cattle, by the reason that the grass groweth plentifully upon the ooze, some time cast up by the sea." But even this recent evidence, compared with the antiquity of Romney Marsh. The Saxons called it *merseware*, and its inhabitants marsh-men. They, or some earlier improvers, fenced it from the sea and drained it; and the conservation of the sea-wall and of the dykes was provided for by local laws and observances, termed "ancient and approved customs," so long ago as HENRY III.

It had its own ancient breed of sheep, which were, and are, able to withstand the humid air and such winter breath of old Neptune as would "melt" or "dissolve into dew" any other breed that clips 8 lb. of wool, and weighs 12 stones. The old breed, too, had acquired the habit of avoiding the ditches under circumstances that

* See page 389.

would result in *felo de se* or accidental death in the case of any other sheep.

One would suppose that the whole of this rich level of 44,000 acres—the ooze of the sea—would prove of similar and uniform agricultural value or quality. But this is not the case, and adjoining fields differ so much that they may be worth £80, £100, or £120 per acre respectively. These are actual values, for there are no fancy purchasers. It is found that the worst land is that which bears the mark of having been ploughed for the purpose of crop growing some years since, and subsequently laid down again. So it would appear that a portion of the fee simple was exported in the crops. This is the view of present proprietors, who allow turf to be broken up only on condition of receiving an increased rent. Thirty shillings an acre is the annual addition usually charged for the privilege of breaking up the old turf and taking crops without restriction. As the sheep get no cake on the marsh, and no stock is kept to yield manure, except four horses for every 60 acres of ploughed land, and as a marsh farmer despises artificial manure, and disbelieves alike the nitrogen and the mineral theory, it is evident that the store of plant food contained in the "ooze of the sea" must be very great.

The land must be tamed before it will bear corn, and a succession of such crops as Potatos, Mangel and other seeds, Carrots, &c., is taken before the usual course commences of—1, Turnip seed; 2, Wheat; 3, Beans; 4, Wheat; 5, Clover; 6, Turnip seed or Wheat. The land has never yet tired of Wheat or any other crop; it must, therefore, contain an inexhaustible supply of nitrogen as well as of mineral constituents,—unless, indeed, cultivated plants, like wild plants, are able to obtain sufficient ammoniacal food from the air when the soil contains an excess of their ash constituents. However this may be, we never knew a richer mine of agricultural wealth than Romney Marsh, and it will be unfortunate for occupier and owner—who are often one and the same person—when the weakest link of its fertility fails, and they have to fall back on salts of ammonia and superphosphate, like those of their countrymen who do not farm in what may truly be described as England *Petite*. That such a time will come is indicated by the mark left by the ancient ploughing.

The system of non-restoration, though a present success, may be a future loss, but exhaustion is a very slow process. An excellent authority, it is true, informs us that the cropping in the Isle of Thanet has been too fast, and that corn has become less productive than it was 40 years ago in cases where it has received only the manure arising from a seven-course rotation. The marshes above Sandwich have undoubtedly been reduced from their former quality, but a little cake soon restores them; and Romney Marsh 1800 years under grass has not yet failed.

There is a wide difference, however, between the "ooze of the sea" and ordinary land, for while it seems impossible to injure the one it is very easy to do violence to the other; and if we accept the authority of the common farm lease, there are several rules so exhausting that they ought never to be grown. Our usual rotations, so different from the above, prove that no inexhaustible wealth exists in the soil. If our readers can find a few acres of really fat turf-land they may perhaps safely plough it up, but we do not think the food supply is likely to be much increased by such discoveries. Romney Marsh itself is only a plot on the coast of Kent, and does not include a twentieth part of that productive county. One-half of Kent lies on chalk, far above the ooze, and, admitting there is something in site and subsoil, its character is imparted to it, a great measure, by the sheepfold and the despised "artificials." These are the aids on which we must rely, and the prosperity of agriculture and of the country requires that steps should be taken to increase the raw material of crops.

—— A short supply of English Wheat at Mark Lane on Monday was cleared off at 1*s.* advance on the prices of that day se'nnight. Monday's prices obtained on Wednesday: trade steady.——At the Metropolitan Cattle Market on Monday prices for beasts were lower, without effecting a clearance. Sheep made high rates, and calves a good price. Choice beasts, at Wednesday's market, sold dearer than on Monday, and there was a further improvement in calves.——Trade in the Seed Market was quiet, owing chiefly to the want of rain.

—— Mr. J. Algernon Clarke, of Long Sutton is endeavouring to promote the establishment of a Beet-Sugar Factory near Long Sutton. It appears that Mr. Arnold Baruchson, Mr. G. G. Martineau, and Mr. H. Tate (sugar refiners of Liverpool and London), with other gentlemen, have visited that district with a view of ascertaining its suitability for the purpose of establishing a Beetroot sugar factory. It is believed that the soil, water supply, facilities of transport, and labour supply, are adequate in every respect; and occupiers have already promised (conditionally) very nearly the requisite acreage of roots. The crops will not altogether take the place of highly-manured Potatos and Mangels, but be an additional source of profit to the grower; and as the natural yield per acre is two-thirds the weight of Mangels under similar treatment, the return may be stated at about 20 tons (ranging from somewhat less up to 25 tons or more) per acre, which the proposed company will purchase at 20*s.* per ton delivered at the works. The total cost of production, including rent, may be stated at £4 per acre. Owners of land have signified their consent to the growing of the new crop, under proper limitations as to acreage, manuring, or consumption of the "pulp," which is equivalent to one-fifth of the crop in weight, but contains the major part of the constituents supplied from the soil. Mr. A. G. Bruchson by his endeavours, by a personal canvas to induce his neighbours to accept the proposal which these gentlemen have made, that £5000 out of the £30,000, or more, which will be needed as the capital of the company, shall be furnished by the growers of roots, as in some guarantee of continued local support, without which condition they could not prudently erect costly works and plant. The favourable promise of the desired investment appears from the fact that this proposal is guided by the commercial success of Mr. James Duncan's Beetroot sugar works at Cheltenham, in Suffolk, now in their fourth year of operation. In a recently published letter, Mr. Duncan declares that after writing off 15 per cent. for wear and tear of buildings, plant, &c., he made a nett profit last year of 15 per cent., which would have been very much greater had he obtained the full value of the sugar contained of his works; and he further says, from his practical acquaintance with sugar factories, that profits of 20, 30, and even more per cent. are frequently realised.

—— From various parts of the country we receive such reports concerning Cattle Diseases as to lead us to the conviction that these are now unusually rife. The *Yorkshire Post* of the 29th ult. gives the following confirmatory evidence on the subject:—

"If we have fortunately kept out the rinderpest, pleuropneumonia has made much mischief in the country, and in Ireland also. In France, rinderpest continues to commit ravages in the department of the Ardennes. It has just shown itself at Rivoli-lez-Givet, on the right bank of the Meuse. The Belgian frontier is thirty-five miles in direct length of this department as far as towards Longwy. Precautionary measures are thus more requisite than ever. The foot-and-mouth disease is the disease most prevalent at the present time. Since the warm weather commenced it has from a few centres spread throughout the country. The cattle markets are now full of infected cattle, and in nearly every village and hamlet the complaint has made its appearance. In the grazing districts reports are becoming appalling. Herds of animals nearly ready for the knife are now panting in pain, and wasting beef daily under the combined influence of the burning sun and the fever arising from the inflammation appearing in the mouth and feet. To whatever cause this visitation of the disease is due, our own cattle traffic now unquestionably diffuses the infection daily over new areas. Severe restrictions against moving cattle from infected herds must, therefore, again be put in force, and farmers must leave it to policemen to see the law carried into effect. They must inform the authorities of all infractions of regulations, and denounce every thing else and punishment upon those stupid, self-willed owners of stock who care nothing for their neighbours' interests, and bring, incautiously or ignorantly, infected cattle into fresh districts. In a noble country, in which annually fed upward of 500 head of cattle, the present occupier has the upwards of 2,000 animals down in the disease, and possibly the whole herd will go through the complaint. This national waste of blood is a grievous and glaring evil, augmenting the consuming public, but ruinous to the producing grazier. In the above case the disease originated from the careless but highly reprehensible conduct of an adjoining occupier, who brought a few fresh-bought animals into his pasturage. Had he only suffered, his want of caution at this season of the year would have been properly punished, but unfortunately in this, as in most cases, ignorance not only injures its perpetrator, but others who are innocent of the consequences. From every county the same reports come of a sudden and unaccountable increase of outbreaks of the disease. In Cheshire the cases are augmented a hundredfold in a fortnight. In Lancashire and Yorkshire the disease is spreading equally rapidly; and in Cheshire and Derbyshire the centres of infection are nearly equally numerous. Now that the enemy has got in amongst us we must take steps to limit its spreads no further. Keep all stock in their own quarters till they go to the butcher, and put lean stock on a long quarantine in a separate and detached pasture."

—— At the Barnet Cattle Fair, during the past week, the usual immense gathering of farmers, graziers, and others interested in cattle, has taken place. Dealers have obtained advanced prices for all descriptions of store cattle, owing to the favourable prospects of the Turnip crops and the abundance of grass feed and straw fodder. Welsh black cattle met an eager demand, well-grown steers, at £9 to £11 a head; large promising ditto, £13 to £14. Scotch cattle for stalling made £16 to £18; ditto in forward condition, £20 to £23; Highland steers, £13 to £16. Well-bred Devon steers realised £16 to £18. Large Shorthorn steers, £17 to £21; and large, weighty ditto, £25. Promising Hereford store steers made £16 to £21, and heavy beasts £24. There was a large field of well-bred milch cows disposed of, and the London dairymen were large buyers. Large-framed Shorthorn-bred cows in full milk made £20 to £26 each; second-rate ditto, £16 to £19; Durham, Ayrshire, and Alderney cows, £15 to £18; well-bred in-calf heifers, £12 to £14, and cows to calve soon, £10 to £17; Dutch milking cows, £14 to £16. The horse show is large, and the pony droves occupy a large section of land

—— Our Belfast correspondent writes, under date August 29, respecting the exaggerated rumours of disease in the Irish Potato Crop:—

"Rumours having been industriously circulated that the mysterious disease incidental to the growth of the Potato has broken out with all the virulence of former years, and that the crop is almost a failure, I wish to state that I have reason to believe, from personal observation, that the statements which have appeared are exaggerated, and that there is but faint warrant for existing fears. Certainly in the case of Ulster no signs of failure are apparent, and a good average yield may be expected. The season is well advanced, the tubers are maturing rapidly, and, so far, there is no such percentage of disease in the roots turned out as to justify any general alarm. In many districts, blackened and withered stalks are to be seen in the Potato fields; but in no years, for the last quarter of a century, have there been wanting these indications of something wrong. Most of these blights have always been seen in the Potato lands of Ireland; and at one time they attracted but little notice; but since the great failure, and the great famine which resulted from it, every withered stalk is a 'bugbear' to scare and strike terror into the farmer's mind, and every missed drill at once fills him with alarm of the dreaded disease. If people who happen to find blackened stalks and ugly appearances would but have the patience and forbearance to examine the state of the tubers, they would, in all probability, find them sound in ninety-nine cases out of a hundred. No reasonable man need expect to turn out his whole root crop without finding some bad specimens. When it is known that the yield of Potatos is reported to be this year unusually large, that we have got almost over the month of August, it is but right to state that the chances prognosticate in favour of our having a fair average Potato crop in Ireland this season."

—— "G. A. H." objects to our recommending Cabbage as a Snatch Crop, that it will not stand a severe winter. He states: "If you plant out Cabbages in November, the chances are that you lose three out of four." "G. A. H." is mistaken: thousands of acres of Cabbage are planted in the fields in November in the neighbourhood of Reading, in Essex, and they seldom suffer from frost, though the district is not particularly sheltered, and the varieties are the East Ham, or Enfield, Cabbages, which are early but not particularly hardy. The crop is in perfection in May and June. There are also Savoy Cabbages, which are far less liable to injury by frost when grown large than other sorts.

—— In our notice of Mr. Rigden's sale, Lord Norbury's name, as that of one of the leading purchasers, was unfortunately mis-spelt. His lordship hired one of the highest priced rams at the sale.

OUR LIVE STOCK.

CATTLE.

The Holly Bank cattle, which will be disposed of by Messrs. Lythall & Clarke on the 12th and 13th inst., comprise 36 Shorthorn dairy cattle, many of which are remarkably well-bred, having three or four crosses of pure blood. They are of great size, rich colour, and good milkers. The pure-bred Shorthorns consist of 12 animals, two of which are descendants of *Annette* by Horror (13,591), two are descendants from *Isabella* by Accordion (5708), two are from *Flounce* by Chilton (10,054); *Zeal 11th*, a descendant of *Zeal* by Roman, forms an attraction; lot 133 is Bonny Duke by 6th Grand Duke, and of the "Wild Eyes" tribe; and among the remainder we notice Lord Derby by Earl of Bantwood, and of the "Certainty" tribe, and Oxford Lad, also by Earl of Barrington, and out of *6th Duchess of Oxford*.

—— Brailes House on the 21st, and Ellington, near Kimbolton, on the 28th inst. Such are the two important announcements which will now occupy the attention of Shorthorn breeders, after the excitement of the past week down in the West. The Brailes House event is the fourth biennial sale which Mr. Strafford has held there, and from the pedigrees in the catalogue we should expect the cattle to be fully equal to those shown on former occasions. *America* by Marmaduke, and her five daughters and descendants, constitute a group representing *Acomb* by Belvedere (1706). *Clarence* by Grand Sultan 2d (17,999), is the first of half-a-dozen of the "Craggs" tribe; *Lady Emily 2d*, lot 3, by 7th Duke of York, and her son, Earl of Warwick-

SHIRE by 18TH DUKE OF OXFORD, are good instances of Bates upon Knightley; the four representatives of *Countess of Barrington* by 3D DUKE OF GLOUCESTER need no recommendation, and the same may be said of the Furbelow, Cathleen, Pintail, Walnut, Foggathorpe, and Annette heifers and bulls, all of Knightley origin, which will be offered. *Darlington 12th* by DUKE OF GENEVA, *Woman in Red*, of the "Blanche" tribe, and Lord Wenlock's BORDER by 18TH DUKE OF OXFORD, and of the "Fillet" tribe, will be among the other attractions.

—— Mr. Ladds' sale takes place on Thursday, the 28th. The principal features of the catalogue are a large assortment of Red Duchesses, and numbers of the Farewell, Verbena, "J," Flirt, and Picotee tribes. For many years Bates sires have been used, such as CAMBRIDGE BARRINGTON 1ST (14,223) by DUKE OF CAMBRIDGE (12,742), out of *Lady Barrington 8th*, a winner at the Royal Society's meeting at Lincoln in 1854; DUKE OF CAMBRIDGE (15,919), of the "Cambridge Rose" tribe, now so fashionable; the Barrington bull SIR JOSEPH BANKS (20,836), by the renowned 7TH DUKE OF YORK (17,754); LORD ROYSTON (24,463), of the "Blanche" tribe; and, more recently, the grand Waterloo bull WELLESLEY (25,421), bred by Lord Penrhyn, a son of his 600 gs. DUKE OF GENEVA (19,614), DUKE OF BARRINGTON 2D, a first-class sire, bred by Mr. Sheldon, of Brailes. Fifty-nine of the lots are by WELLESLEY; the cows and heifers are chiefly served by this bull or by the EARL OF BARRINGTON 2D.

—— Mr. Thornton has issued a catalogue of 72 cows and 12 bulls, constituting the entire herd so long bred by the Misses Duddin, of Panton. This grand lot of animals will be sold at Wragby on Thursday. The reputation of the Panton herd has been maintained by the use of such well-bred sires as Mr. Foljambe's ROBIN (24,968), Mr. Jonathan Peel's STUART (27,630), and Mr. Booth's Warlaby bulls MANFRED (26,801) and BRITISH CROWN (23,322). Previously, among other famous bulls, we notice the names of RAVENSWOOD (22,682) and ROYAL BUCKINGHAM (20,718), both of the "Bonnet" family, and celebrated stockgetters. These, allied to cows by VANGUARD, SIR HODGE, PRINCE ALFRED, and other first-rate bulls, have left a "grand lot" of stock, characterised by size and uniformity.

—— The Brockton House herd will be sold by Mr. Thornton on Tuesday. It comprises about 50 head of the famous Kirklevington blood, which Mr. Bell obtained directly from Mr. Bates. The catalogue contains representatives of the "Peach Blossom," "Georgiana," Duchess tribes. The cows and heifers are in calf to Colonel Gunter's 8TH DUKE OF YORK, which will be offered for sale.

—— The Chapel Brampton sale of Shorthorns has been unavoidably postponed.

SHEEP.

Mr. LANE, of The Cottage, Northleach, who has so long been known as a breeder of Cotswold sheep, disposed of his flock on Wednesday week, Messrs. Acock & Hawk acting as auctioneers. The flock consisted of 115 ewes, 51 theaves, 85 ram lambs, 87 ewe lambs, and two shearling rams. The average of the whole 338 sheep was £5 12*s.* each; the ewes and theaves averaged £5 2*s.*; the ram lambs, including two shearlings, made £8 8*s.* each; and the ewe lambs £3 3*s.* each. The most extraordinary feature of the sale was the competition for theaves. Very high prices were given, which culminated in Mr. Swanwick purchasing a pen of five for the unprecedented price of 17 gs. per head. These sheep were the cause of a brisk competition, in which Mr. Brown, of Marham, and Mr. Swanwick bid against each other, until they were secured for the College Farm, at the high price just mentioned.

—— Mr. Willoughby Wood, of Holly Bank, who has for so many years occupied a leading position as an agriculturist and Shorthorn breeder, has let his home farm, and advertised his stock for sale. Messrs. Lythall and Clarke have issued a catalogue of Shropshire sheep, some useful dairy cattle, and the remaining pedigree Shorthorns which remain over from the last sale. The catalogue opens with a list of 28 shearling rams; 38 ram lambs, 130 shearling and young ewes, and 70 ewe lambs. The sheep are by well known rams, such as Forester, bred by Mr. Keeling, Lord Uffington, Stockley by the Nugget, 2d Lord Kinver by Lord Kinver, Baronet by Valiant 2d, Monarch by Old Norton, Holly Bank by Baronet, and Horley's No. 14 by Evans' No. 10. These excellent sires have been allied to ewes by Pride of Freeford of the Patentee blood, Lease Farm Ewe, Holly Branch, Hannibal, and many are by the rams already named as sires of rams.

THERE are four species of llamas and alpacas, and only four of the animal known by the generic term *llama*, viz., the alpaca, llama, guanaco, and vicuna. The two former are domesticated, and vary in colour; the two latter are wild, and are always of one colour. The most valuable of all these animals is the alpaca, called *peccha* by the Indians of the country. It is smaller than the llama proper, has the raised croup, droops towards the fore legs, and is covered with a long silky wool. They feed in large herds, only on the highest plains of the Andes, on the grass growing on marshes. They are owned by Indians, who cut the fleece every three years, and bring it to this city for sale. Each fleece is divided into two, being the wool taken from each side of the animal as it hangs down from a parting down the back, and the half fleece is called a *bollon*, and weighs on an average 3 lb. There are five distinct colours; jet black, pure white, grey, coffee, and light fawn. The llama proper is a larger animal, with a straight back and clumsier head. It has coarse wool mixed with hair, which is never shorn off, as it is valueless. The animal has been used by the Indians from time immemorial as a beast of burden, and is so now, large herds entering the city daily, loaded with alpaca wool, and returning to the interior with bags of flour or small cases of English beer. A llama carries only about 100 lb.; thus two cases of a dozen bottles of Bass' pale ale form a load, and are conveyed as far as Cuzco, a distance of 100 leagues, at the rate of about 4 leagues per diem, the animal travelling for several days without water. As the alpaca and llama pasture together, there is a well-known cross-breed between them called a *huarizo*; and it is much to be regretted that, from the carelessness of the Indians, this crossing is allowed, as the wool of the cross-bred is much inferior, and the animal is mostly useless as a beast of burden. The llama also is of various colours, the same as the alpaca. The two wild species, the vicuna and guanaco, are much alike in colour, being a light fawn; the vicuna yields a wool, while the guanaco, like the llama, has a coat of hair. The guanaco is a larger animal, and is found from Cape Horn to the northernmost parts of Peru. The vicuna is most abundant in Peru and Bolivia, where immense herds are found; and many are killed yearly for the wool, which is very short, but silky. The average annual export from Callao for the last 20 years has been about 6500 lb., and as each animal only yields about half a pound, 13,000 of these animals must be killed annually to supply this export, independently of the considerable quantity of this wool used by the Indians in their own manufacture. Both the guanaco and vicuna can easily be domesticated, but domestication is not carried to any extent. A cross has been known between the alpaca and vicuna, but it is excessively rare; the guanaco and vicuna in their wild state never cross with each other. Specimens of the alpaca, llama, and guanaco exist in the Zoological Gardens, Regent's Park.

RAM SALES.

Lincolns.—The Panton ram show and letting took place on Tuesday, the 29th ult., under the direction of Mr. Calthrop, auctioneer. Messrs. Dudding's shearlings this year are chiefly by the two Manchester and Lincoln prize sheep in 1869, by a celebrated ram, Old Topper, the line of the Oxford and Steaford prize two-shears, and by an old sheep hired at 66 gs. The first eight shearlings were let for 131 gs., being an average of 16½. No. 3, a grand ram, was taken by Mr. Robinson, of Huttoft, for 20 gs., and No. 5, one of the best sheep of the flock, fell to the lot of Mr. Parish, of Toynton, for 20 gs. Of 2-shear sheep six let for 137 gs. No. 72, a noted show sheep, was knocked down to Mr. Needham, of Huttoft, for 31 gs., and lot 74, a magnificent well-fleeced ram, was taken by Mr. Garfitt, of Scothern, for 38 gs. No. 22, a ram of enormous width, by a sheep of Mr. Kirkham's, was purchased by Mr. Hotham, of Barmston, for 20 gs. The ram by Champion, 3d at York, was bought by Mr. Garfitt, of Scothern, for 40 gs. There were 73 rams, most of which were sharlings, and the prices for the rams sold ranged from 6 gs. to 40 gs., the whole flock showing an average of £14 6*s.* 4*d.*

—— Mr. Vessey, of Halton Holgate, who has for a quarter of a century been noted for improving the breed of the fine old Lincolnshire sheep of the marsh district, let his rams on Monday, the 28th ult. They were a very regular uniform lot. Shearlings let at from 12 to 40 gs., the 2-shear, 62 in number, at from 10 to 50 gs. and the 3-shear, 40 in number, at from 15 to 40. No. 44, one of the choicest rams penned, if not the flower of the shearling flock, was hired at a high figure by Mr. J. L. Needham, of Huttoft, a gentleman distinguished for his judgment and success as a breeder of rams.

—— On Thursday, August 31, the annual letting at Biscathorpe took place, and a large company, many of whom were themselves ram breeders, assembled to do honour to the occasion. Of the 100 sheep penned, 40 were shearlings. We have seen Mr. Kirkham's shearlings in better condition, and some of them were scarcely up to the mark of previous years, the 40 realising an average of only £13 14*s.* 3*d.* No. 7, a very symmetrical and well fleeced animal, was let to Mr. Woolhouse, of Willingham, for £47. No. 10 was taken by Mr. Needham, of Huttoft, for £27; No. 8, by Mr. Mackinder, of Langton, for £21; but in no instance was anything like a fancy price realised. The 2-shear sheep, 37 in number, were as fine and perfect a pen as could be produced, and it would have been difficult to find a bad one amongst them. They were let at an average of £16 3*s.* 9*d.* No. 45 was taken by Mr. Marshall, of Stanefield, for £42; No. 48 fell to the lot of Mr. Clarke, of Scopwick, for £50; No. 53 was taken by the same ram breeder for £53; No. 65 (the best shear of 1870) was secured by Mr. Isaac Sharpley, of Boswell, for £31. The 3-shear sheep, 23 in number, were let at an average of £15 10*s.* 5*d.*, No. 81 fetching the highest figure, being taken at £50 by Mr. J. Clarke, of Welton. Mr. Vessey, of Holton Holgate, got No. 82 for £30, and 83 fell to the lot of Mr. Grime, of Holton Holgate, for £33. Considering the very superior character of the flock the average on the whole of £15 1*s.* was not so much as had been anticipated by many persons present.

Shropshires.—Messrs. Lythall & Clarke, of Birmingham, held their third sale in the Smithfield, Shrewsbury, on the 29th ult. There was only a small attendance of buyers, owing to the harvest, but anything of really good quality sold remarkably well. The first lot of rams (Mr. T. S. Meire's four grass-fed shearlings) made £8 2*s.* 9*d.* each, which, as they were only in store condition, must be considered a fair average. Mr. Matthew's 20 ranged from 4½ to 9 gs., the latter price being given by Mr. Lythall, of Radford, for the 2-shear ram, rejected. Many of the breeders present thought him too fat to be of use, or he would certainly have made considerably more. There being no demand for Messrs. Morris's rams, they were withdrawn. Mr. Yates' made from 6½ to 7 gs.; Lord Willoughby de Broke's shearlings from 5 to 7 gs.; one good shearling being 14½ gs. Mr. H. J. Sheldon's, which came next, were sheep of remarkably good quality, with good heads, but rather small. The nine made an average of nearly 8 gs., one fetching 11 gs. and another 12 gs. W. O. Foster, Esq., of Stanford Hall, Loughborough, no one could wish to turn out. Mr. Peake bought the first at 24 gs.; Mr. Rogers the next, at 15 gs.; the third was let to Mr. Jarvis, of Upton Magna, at 12 gs.; Mr. Trevor gave 18 gs. for No. 4; Mr. Bright 20 gs. for No. 8. The rest made from 11 to 7 gs., the average for the 20 lots being £11 5*s.* The 2-shears fetched from 6 to 7 gs., Mr. Picken's 5 to 5½ gs., and Mr. Ashton's 4½ to 7 gs. The ewes sold much more freely, making from 55*s.* to 110*s.* each.

Leicesters.—Mr. Robert Boulton held an annual ram letting at Great Givendale on August 25. The day was a very favourable one, and a goodly company, for the most part ram breeders and farmers, assembled. The sheep were offered in their natural condition as driven up from the fields. Mr. Knapton, of Kelk, led off by taking the three first sheep offered, after which the first race among the ram breeders began, Mr. Stamper and Mr. Thompson competing for No. 4, which was at last knocked down for the Anlaby flock at £15. No. 6 had especial favour from the breeders, five of whom were in the field, but the sheep also went to the Anlaby flock for £30 5*s.* Mr. S. Staveley, of Ayton, Pocklington, took No. 7 for £18 5*s.*, and Mr. Jordan, of Easthurn, No. 8 for £15 5*s.* No. 12 went to the Kiplingcotes flock at £16 10*s.*, and Mr. Staveley took No. 14 for £11, and No. 15 for £12 5*s.* The average price of the yearlings was over £9 11*s.* Although the shearlings were admitted to have been the best lot ever shown at Givendale, the 2-shear sheep were almost as successful, in some cases going to the same flocks as they did as shearlings. The notable sheep were No. 45, to Mr. Maggitson, of Towthorpe, for £10; No. 35 to Mr. Brown, for £13; No. 39 to Mr. Walmsley, for £20; and No. 40 to Mr. Jewison, of Raisthorpe, for £10. The average was about 9 gs. There was a remarkable competition for the 3-shear sheep, of which No. 44 went to the Holme flock at £15 5*s.*; No. 47 to the Raisthorpe flock at £15 15*s.*, No. 50 to the Highfield flock at £20, No. 53 to the Ness flock at £10 5*s.*, and No. 55 to the Holme flock at £11 10*s.* No. 45, however, had the honours of the day, jumps of £5 occurring in the bidding, "all among the breeders." Eventually a settler came from Mr. Skelton Jefferson, of Whitehaven, and for the Cumbrian flock the sheep was knocked down, at £35. The average of the 3-shears reached £11 15*s.* Among the aged sheep Mr. Jewison took No. 58 for £12. The average was about 9 gs. and the takers were Mr. Jewison, Mr. Hotham, and Mr. Horsley.

FREE TRADE IN LAND.

WE do not pledge ourselves to the views expressed in the following excerpts from a forcibly written pamphlet, from the pen of Mr. Arthur Arnold, author of "The History of the Cotton Famine," &c., and assistant commissioner 1863-66, in the cotton manufacturing districts. The questions discussed by Mr. Arnold are unquestionably important, and bear directly on the cultivation of the land. Neither can they long escape attention at a period when every institution is subjected to searching criticism. The writer is an enthusiastic admirer of Cobden, an enemy of entails and conveyancing, and a friend of registration, actual ownership, and security for the tenant as well as the landlord. After eulogizing Mr. Cobden, our author proceeds as follows:—

"I really do not believe that any one possessed of great influence in the Legislature questions the beneficial influence which a free exchange of land would exert. We Englishmen," as Mr. Gladstone said last year at

Greenwich, who have received from Mr. Cobden a special commission and a special charge,' have strangely neglected our calling. Believing in their utterances, it can only be supposed that the conscientious men who direct the powers of the State have been waiting long years for favourable breath of public opinion and for a clear channel. The present head of the legal profession has said that in 1815 he read Adam Smith, and that the study of the works of that great economist was the cause of his taking up the principles to which he has ever since adhered. In 1859 the present Lord Chancellor—a man possessing, perhaps beyond any of his predecessors, the respect and confidence of his countrymen—spoke scornfully of the law, of which he was even then a pillar, so far as it related to land. He said: 'I shall here the limitations of your law affect the transfer of your land. It is only on account of these that you have difficulties as to title; because, if it were not for the complexity of limitations, a system of registration would long since have been established, which so far as fraud and rapidity of transfer was concerned would have freed us from any difficulty of title whatsoever. You have now the combined effect of fraud and the complicated investigation of title, which operate in the most serious manner to prevent the free transfer of the land in our community. What I wish, and have long wished for, is a free transfer of land'—in other words, free trade in land. Sir Edward Sugden Who uttered these words has quitted the atmosphere of commonality—so much more free on this subject than the air of the gilded chamber in which he now presides—yet I do not doubt that Lord Hatherley holds the same opinion. But it is not statesmen alone who have been indifferent to this great question. The people have permitted the monopoly of land to become more and more restricted, without interference. Thirty years ago Mr. Cobden. He said: 'It is astonishing that the people are so tacit in their submission to the perpetuation of the feudal system in this country as it affects property in land, so long after it has been shattered to pieces in every other country.' But he knew the reason why; he declared the cause of this languid acquiescence to be that 'the great success of our manufacturing system has given such an expansive field of employment to the population, that the want of land as a field for investment and employment of labour has been comparatively little felt.' Long, he predicted, 'as this prosperity of our manufactures continues, there will be no great outery against the landed monopoly.'

"I say the time has come when this tacit submission exists no longer; when the maintainers of the present land system must accept reform, or run the risk of years of revolution. Slowly but surely the people are mastering this question. Every wind that blows brings to the shores of England testimony to her matchless wealth and to her unequalled poverty. Englishmen know, it is true, very little of other countries; but they are aware that our land system, so far as it is known abroad, excites the wonder or moves the admiration of the world. There is nothing like it. There are countries of despotic proprietors, like France, Switzerland, and Belgium; there are other lands with a class analogous to our landed aristocracy; but there is no other portion of the earth where the land is for the most part owned by one class, farmed by another, and tilled by a third. I anticipate the criticism of the opponents of reform, who at this point will exclaim triumphantly that such an exceptional position is the cause of that stability of country and the institutions of this country have preserved, and that therefore, the maintenance of the existing law is desirable. It will surprise those only who are ignorant that free trade in land is both a truly Liberal proposition and also a thoroughly Conservative measure, that I should frankly admit this.'

The writer next proceeds, with much candour, to render plain certain political advantages of the English system of land economy.

In glancing at our "land system," Mr. Arnold in the first place directs attention to the small and decreasing number of landed proprietors, who have been estimated at about 30,000 persons in all. The causes which tend to decrease the number of landowners, next claim attention in the following passage :—

"What are the chief of these causes? I should say, the increase of capital, and the cost, together with the uncertainty of the cost, of conveyance. The wealth resulting from manufacturing industry has tended to this result, for the overflow of these riches has narrowed the land market, because it has passed into the hands of men who are content to sacrifice a large portion of the ordinary profits of capital to purchase the social distinction which acres confer, and upon whose large purchases the cost of conveyance is not a heavy charge.

* * * *

"Our manufacturing prosperity has done more than this to strengthen the land monopoly. Some of the princes of manufacture have become successful amalgamators of the soil, and of many more the fair daughters have carried in their hands the gains of industry to expand the ring-fence of the landowner.

* * * *

"The monopoly of land is directly fostered by the cost of transfer. The landlord is willing to invest his money with a return of 2½ or 3 per cent., and the lawyer does all he can to keep the small capitalist from competing. Among the most industrious nations of the Continent, the cost of the conveyance of land is a percentage on the purchase-money, which passes to the coffers of the State, so that while the expense on a purchase of £100 would be £5, that of the conveyance of property worth £100,000 would be £5000. But here the operation of the law imposes a system precisely the reverse; it practically forbids the purchase of small properties by imposing legal charges, the percentage of which invariably declines with the increase of the purchase-money. A well-known land agent asserts—and the experience of hundreds will be similar—that he has often signed deeds for the purchase of property of small value, when the legal expenses have equalled one-third of the purchase-money. Yet, perhaps, the uncertainty of the cost of conveyance exerts a more powerful influence in the limitation of the number of agricultural landowners. The charge is unduly magnified to the prejudice of the small capitalist. An example of this occurred within my own knowledge the other day. Solicitors now permit themselves to charge by a percentage for the costs of a mortgage, and an owner of land valued at £7000, anxious for certainty, agreed to pay 2 per cent., or £140. The lawyer told me the title was so simple that he could not, if he made out a bill, have charged more than £40; so that this unfortunate person needlessly paid £100, merely from fear of the uncertainty of the amount of law charges. It is not necessary to explain how often more strongly the same motives would operate upon the man whose entire property consisted of land valued at £200 or £300. I do not hesitate to express a confident opinion that the soil of England, speaking of the country generally, is reduced in selling value to the extent of from two to four years' purchase by the incubus of this system of conveyancing.'

The grave evil resulting from encumbered entailed estates is shown in its bearings both upon farmers and labourers, the first being necessarily thwarted in their endeavours at improvement, and the second degraded and demoralized by insufficient house accommodation. Regarding the labouring population Mr. Arnold says:—

"I wish carefully to avoid invidious dealing with any class: the fault is in the system rather than in the men. Disgraceful and immoral overcrowding has been the result of the monopoly of land. Landowners refuse leases to build new cottages, and hundreds of parishes will furnish such a scene as I will briefly describe from official records. In the thatch-covered roof of a single-roomed cottage—a loft of rest—sleep two beds occupied respectively by unmarried sons or by cousins or divisions of any kind; one bed held the father, mother, and infant son; the centre bed was occupied by three daughters, of whom two were upwards of 20 years of age, and the third but little under. In the sons, aged respectively 17, 15, 14, and 10. Take 'S. G. O. S.' testimony as to cottage beds in a room of 13 feet square. 'On the first lay the mother, a widow, and her two illegitimate children; on the second, two unmarried daughters 18 and 12 years of age; on the third, a young married couple, whom I myself had married two days before.' Looking on these things, can we wonder that the English peasantry is demoralized in the matter of sex? The statistics on this point are shocking, yet they conceal the whole truth, because our population is so largely manufacturing, and these marry and have generally excellent cottages. I blush to quote the evidence of an English clergyman, who said:—'I never recollect an instance of my having married a woman who was not either pregnant at the time of her marriage, or had had a child before marriage.' Before her answer to this frightful immorality, which every country clergyman can confirm, to the charge of the system of entails, which reduces the landowner to the position of a tenant, and, what unfortunately is a helpless tenant, to which alone he can provide something for his younger children—to improve the property of his eldest son? Before the passing of Mr. Locke King's Act, if he had saved a little money, this would be liable for the debts of his father on mortgage-debt in the event of his death, in spite of any testament by which he sought to bequeath it to his otherwise penniless daughters. But, then, the tenant may be ejected, and he may, though more often he has scarcely half enough for the most efficient cultivation of the soil. And if he execute the works of improvement he will want some consideration. He will demand a long lease, or he will be liable for the increased demands for rent, to repay, in so many years, the cost of the permanent improvements; and neither of these things is the nominal owner disposed to grant. If landowners could be compelled to grant leases on equitable conditions, and for sufficient term of years, then the evils consequent upon the system of entails would be mitigated. But they dislike leases; and if ever they do contemplate such an arrangement, it is as full of complicated provisions and restrictions as the deeds by which they hold the nominal ownership of the land. The signal and peculiar misfortune of agricultural England is that for the most part it is 'no man's land'—it is held in perpetual mortmain—the landlord is a life-tenant, and the farmer a dependent. There are exceptions; I record most notable words to the contrary with peculiar pleasure. The present Lord Derby said, in 1869:—'I think every good tenant who is expected to stay permanently on the farm he holds, is entitled to ask for a lease from the proprietor. It is a very simple alternative; if a man is not fit to settle on an estate with a lease, he is not fit to settle without one; if he cannot be trusted with a lease, he cannot be trusted with the land. . . . I say this—and in what I am saying I am rather, in my own mind, addressing landlords than tenants—that, if a tenant is to be expected to lay out capital on his farm, it implies no distrust of the landlord—it is simply an ordinary and proper business precaution that he should insist on having some lease.

"I believe that these two things—one, the making the giving of a lease a general rule, and the other, having leases drawn more simply than as a rule they are at present—would go very far to settle that question of land-ownership of which we have heard something of late.'

Further remarks follow upon the evils attendant upon the law of "settlement," in which the author shows how energy on the part of the nominal owners is thereby stultified; and also what a gigantic field there is for the investment of capital, could the land only be released from these legal trammels. Finally,

"In order to establish free trade in land—of which in these preliminary remarks I have endeavoured to establish the need—I shall suggest legislation directed to the following points :—

"1. The devolution of real property in cases of intestacy in the same manner which the law directs in regard to personal property.

"2. The abolition of copyhold and customary tenures.

"3. The establishment of a Landed Estates Court, for the disposal of settled property.

"4. A completion of the Ordnance survey of the United Kingdom upon a sufficient scale.

"5. A system of registration of title, which shall be compulsory upon the sale of property, the fees upon registration—sufficient at least to defray all official expenses—being a percentage on the purchase-money; the same percentage for all sums. A certificate of title would be given free of all costs in respect of any freehold lands, of which the reputed owner could prove undisturbed possession for 30 years. Any title could be registered in the Land Registry Office upon evidence of title for 40 years; the fees being the same as in case of sale, when the registration would be compulsory.

"6. That, preserving intact the power of owners of land to bequeath it undivided or in shares, no gift, or bequest or conveyance of life estate, or any other trust establishing such an estate, should hereafter be lawful; the exceptions being in the case of trusts for the widow or the infant children (until they attain majority) of the testator, or for the benefit of a child born within due time after the death of the testator.

"In this work I would ask, and I expect to obtain, the co-operation of the landowners. They are most largely interested in promoting the measure. The abolition of the law of primogeniture—by which I mean the gift by the State to the eldest son of all the real property in cases of intestacy—when the State ceased to inculcate primogeniture, has removed all the reproach now about their necks—restored to a natural position; not seeming rich and being unutterably poor. They would be real owners of their property. A large proportion of the 30,000 families which now monopolize the agricultural land of the country could give, without trouble or expense, satisfactory evidence of acts of ownership for 30 years, and they might then burn those mouldy parchments, each reference to which at present costs a fee, and which they preserve them as curiosities and part of the family history. The registration of their property would supply an indefeasible title in the place of these cumbrous muniments, and would give an increased value to their land. When registration became general, as it would by this plan, and being made compulsory on sale, we should see estates advertised for sale as 'registered' land, and for such the price would be higher than for unregistered land, probably by two to four years' purchase upon all but the most extensive or costly properties."

THE WHEAT CROP OF 1871.

A VERY severe winter, a cold spring, and a great excess of rain in June and July are not conditions of season favourable for an abundant crop of Wheat. In the "Meteorological Journal" for January last Mr. Glaisher states that such a period of cold weather as occurred between December 21, 1870, and January 13, 1871, has only been exceeded twice during the previous 27 years. It unfortunately happened, too, that during a considerable portion of the period of intense cold comparatively little snow fell; while, of that which did fall, much was swept into deep drifts by blows, and heavy and the high gales winds which prevailed. In many fields the Wheat plant, thus deprived of the protection of the snow, was either killed or very much injured. In some of my fields the injury was strikingly apparent on the side of the lands sloping towards the north and east. Mr. Mechi, in his "Agricultural Notes," mentions the same thing as occurring in other severe winters. A cold spring and summer frequently follow a severe winter. The mean temperatures of May, June, and July were below the average this year, and June and July were both very wet months. At Kothamsted the rainfall between April 1 and August 1 was 14·5 inches in July, giving a total of 7.86 inches for the two months, which is 3 inches more than the total which fell during those months in the three preceding years taken together. Heavy storms of wind and rain occurred in July, beating down the crop, and twisting it about in all directions. The ripening machine has been useless on much of the land on which it would otherwise have been employed, and hand labour has been unusually scarce. The brilliant weather which prevailed throughout the month of August has, however, been of immense service in drying the soil, drying and ripening the crop, and arresting blight and mildew. Although coming too late for the production of a full crop, the favourable change has enabled farmers generally to secure what there was in good condition.

The following Table shows the produce of Wheat by different manures in 1871, obtained in a field which has now grown Wheat for 28 years in succession. It also gives the produce on the same plots in each of the

eight preceding years, there having been no change in the condition of the different plots as to manure during the last 20 years :—

* Equal 24 bush., at 61 lb. per bush. † Equal 28 bush., at 61 lb.

It is seen that, in 1871, the produce by farmyard manure is considerably above, and that without manure, or from artificial manures, much below the average over the years under the same conditions as to manure. The characters of the season appear to have a far more marked influence, both for good and for evil, on the crops grown by artificial than on those grown by ordinary manure. Plot 2, with farmyard manure, and plot 7, with artificial manure, give nearly the same average produce over 20 years. But, while the difference between the highest and lowest produce obtained over that period is with farmyard manure only 25 bush., it is with the artificial manure 31½ bush.; and, taking only the nine years referred to in the Table, the difference is with farmyard manure only 16½ bush., and with the artificial manure 31½ bush.

Taking, as in former years, the mean of the produce without manure, of that by farmyard manure, and of the three artificial manures taken as one, we get an average produce for 1871 of 25½ bush. This is more than 6 bush. less than last year, and nearly 4 bush. less than the average of 20 years. As shown in the lower part of the Table, the average weight per bushel fluctuates very much from year to year. In order, therefore, to make the comparison more correct, it is necessary to assume a uniform weight per bushel. Adopting 61 lb. per bush. as the standard, the 25½ bush. at 57½ lb. per bush. will be reduced to 24 bush. of 61 lb. This is 4 bush. below the average produce of the last 20 years' calculated in the same way; and the deficiency is equal to rather more than 14 per cent.

Before accepting the above result as indicating the probable average yield of the crop of 1871 throughout the United Kingdom, it will be well to take into consideration the amount of produce obtained in some cases of ordinary cultivation, and to compare them with the results obtained somewhat similarly in former years. The best portion of a field which had been summer-fallowed, and folded with sheep, has given 37½ bush. per acre, and another 33½ bush. Again, during the last two years, a number of well-known varieties of Wheat have been grown at Rothamsted, the field and manure selected each year being such as it is considered should grow the fullest crop of the season. The following are the results obtained during the last three years with six of the varieties in question :—

Bushels of Dressed Corn, per Acre.

Harvests.	No. 1. Red Wonder	No. 2. Old Red Lammas	No. 3. Bristol Red.	No. 4. Red Nursery	No. 5. Woolly-headed Chidham.	No. 6. White Chidham.	Aver.

1871	59	62	60§	63	61§	62½	61§

The deficiency of the produce of 1871, compared with that of the two preceding years, is, upon the whole, considerably greater in these cases than in those in which Wheat has been grown for so many years in succession on the same land. In the latter the crops stood up comparatively well against the storms of wind and rain in July, while every one of the 20 varieties grown together in an adjoining field was more or less laid, and some of them very much so.

In my letter on the Wheat crop of 1870, published in your journal of August 26 last year, I estimated the average produce of the United Kingdom at 30 bush. per acre, and that it would require an importation of rather more than 7½ million quarters to supply an average of 5½ bush. of Wheat per head of the population. The actual quantity of imports, less exports, from September 1, 1870, to August, 31, 1871, is, according to the returns, a little over 8,000,000 qr. My estimate was founded upon the assumption that the average population of the United Kingdom requiring to be fed would amount to only 31,000,000, whereas the recent census returns show that this figure was probably about half a million too low. Again, I took the number of acres under Wheat in 1870 to be somewhat less than in 1869, but equal to that in 1868—namely, 3,937,275 acres ; but according to the agricultural statistics since published, this estimate of average for 1870 was too high by 163,612 acres, the actual number returned being 3,773,663. Adopting for the harvest year, September 1, 1870, to August 31, 1871, the increased number of the population and the reduced area thus indicated, the amount of Wheat required to be imported for the supply of the period would be rather over 8½ million quarters.

Calculated according to the census returns of 1871, the average number to be fed in the British Islands during the next 12 months will be 31,843,970 ; and, assuming the average consumption to be 5½ bush. per head, the total amount of Wheat required will be little short of 22 million qr. Taking the home produce at 24 bush. per acre (of 61 lb. per bush.), and the area under Wheat to be the same as returned for 1870—namely, 3,773,663 acres—the gross produce of the United Kingdom will amount to 11,321,000 qr. Deducting from this 2½ bush. per acre for seed, we have left for consumption as food about 10½ million qr., leaving a requirement of over 11½ million qr. to be supplied from foreign sources. How far this estimate is well founded time will show. It may be that the Wheat crop has suffered more in this than in the average of districts ; but there can be little doubt that, at any rate, in many districts the yield will be below the estimate formed of it, and that disappointment will follow the test of threshing. There are several circumstances pointing to a large consumption of Wheat during the coming harvest year. Meat is exceedingly dear ; labour is in great demand, and full wages are paid. The Potato disease has appeared in various districts, and, although it is too early to form any estimate of its ravages, it is certain that the crop will not be one of average yield, as was the case during the past year. The information at present at command leaves no reason to fear that there will be any deficiency of foreign corn to supply our wants. But those wants will undoubtedly be large ; and as France will require considerable quantities to supplement her own deficient crop, it is probable that the price of Wheat will advance considerably before the spring of next year. In conclusion, I may remark that although my Wheat crop is so deficient, both Barley and Oats are, on the same farm, unusually abundant. *J. B. Lawes, Rothamsted, Herts, September 2 (in the "Times").*

UNCULTIVATED PLANTS.

The question of utilising our railway banks and waste spots of land by the growth of plants requiring little or no attention, is one which might be made to pay, if made available for paper materials, has been from time to time advocated and discussed without any satisfactory result being arrived at: Considering the great demand for paper-making substances, it appears to us the price they would command would quite compensate for the small outlay necessary for their production on comparatively worthless sites. There are many also that might be made to yield returns in more ways than one, for, besides materials for paper-making, some of the produce might be utilised for the manufacture of dyes. Nearly all our paper materials at present are brought from the Continent or other foreign countries, and realise such prices as pay for their production and freight ; the stems of Sorghum vulgare, and other species of Millet, which are largely imported for the manufacture of carpet-brooms, may be instanced as among the most important. These Millets are cultivated all over the South of Europe for the sake of their seeds, which form an important food crop, not only for the use of man, but also for horses, cattle, poultry, &c. The flour is very white, and makes excellent bread. The cultivation of this subject has been more than once attempted in this country as a grain crop, but the climate has been found too cold or damp for the seeds to ripen properly, so as to prove a remunerative crop, and consequently its growth has not been persevered in. As a cereal crop, cultivated only for the seed, experience has proved it to be unsuited ; but we do not recollect whether the market value of the stalks, after the removal of the grain, has ever been taken into consideration, either as a paper or a broom material.

Another well-known plant, having a wide distribution over Central and Southern Europe and temperate Asia, is the Gold of Pleasure (Camelina sativa). Though it is often found growing with corn and Flax in this country and in Ireland, it is supposed not to be a native, nor even capable of assuming the title of a naturalised plant, but to have been largely introduced with foreign seeds. The plant is an annual, about 2 feet high, with a branching stem and lance-shaped leaves. It has long loose racemes of yellow flowers, which are succeeded by small fruits or pods about a quarter inch long, and containing a quantity of small seeds. In many parts of Continental Europe the plant is even cultivated for the sake of the oil which is expressed from the seeds, and which is used for a variety of domestic purposes. It is of a clear yellow colour, and has a smell somewhat similar to linseed oil. It is sometimes used for lamps, and is said to burn slower than olive oil. Its chief consumption is by soap makers. The cake or "mast" left after the expression of the oil is used to feed cattle ; but though it contains a great deal of nutritious matter, its acrid and pungent properties cause it to be more or less dangerous, and consequently not much sought after. Birds, however, are fond of the seeds, readily picking them out of the fields, and so are also geese and other poultry, who readily fatten on them. The plant has been grown as green fodder for sheep, and if sown early may be so fed off, and then allowed to run to seed. In the southern States of North America the plant is cultivated, and highly valued by agriculturists. In some parts of the Continent where its cultivation has been introduced, the seed is sown either in rows about a foot apart or else broadcast. This is done in March or April ; during its growth it needs little attention but weeding. The seeds, in about July, and the crop is then cleared either by pulling or mowing. It is estimated that from four to six pounds of seed is required to sow an acre of land, and this yields from 18 to 24 bush. The stems contain a large proportion of fibre, and are commonly used in the districts where cultivated for making linsey.

Another cruciferous plant is the well-known garden Cress (Lepidium sativum), which, though not a native of this country, has been cultivated since 1548. The plant is too well known to need any description. With us its only uses for salads or for the purpose of garnishing dishes, but in Russia the branches and stems are collected after the seeds have ripened, and are made into excellent brooms. At one time the Dittander, or Poor Man's Pepper (Lepidium latifolium), a plant common on many parts of our coast, was cultivated in cottage gardens as a culinary herb, but it is now seldom seen. The much-branched stem of this, like those of the garden Cress, might, however, be made useful for brooms or for paper-making, as might, also, those of L. draba.

The wild Mignonette (Reseda luteola) is a common plant on waste places, more especially on clay or chalky soils. It has been used from very early times for producing a yellow dye, which is prepared by making a decoction of the whole plant. At one time it was largely used by dyers and paperstainers, and it is said that the colour and beauty of pink is still preserved in it. It is a plant that grows without any care or attention, and besides the colouring matter yielded by it, a quantity of fibre is contained in the stems, which we should think might be made available both for brooms and paper-making, though we are not aware of their ever having been tried.

Amongst leguminous plants the Broom (Cytisus scoparius) deserves a first place. It is a well-known shrubby plant, usually from 2 to 5 or 6 feet high, and found growing on heaths and commons. The plant has been used in medicine as a diuretic, and had at one time a place in the Materia Medica. It was given in the form of a decoction made from the tops of the twigs, or a tincture prepared from the seeds. In days long gone by, before the introduction of Hops, Broom tops were used to impart a better flavour to beer, and even now it is said they are sometimes used to increase its apparent strength. The flower-buds in a very young state are occasionally gathered in country places and pickled as capers, and the ripe seeds have been used as a substitute for Coffee. Besides these applications the stem contains a quantity of excellent fibre, which is easily extracted after maceration. The twigs are used in many parts of the country for making brooms and baskets, and they have been before advocated for, if not actually applied to, the manufacture of paper ; and as they contain a quantity of tannin, they might even be used, if other materials failed, for tanning leather. The plant is tolerably hardy, but sometimes suffers by very severe frosts.

Amongst other common fibrous plants, we may may mention the Nettle (Urtica dioica),. and Hop (Humulus lupulus). The first of these, though so exceedingly common, and so impulsive to the touch of its stinging properties, might be made a very useful plant. In many parts of England young Nettles are collected, boiled, and eaten by the peasantry. Though cattle refuse to eat the full-grown plants, they will feed upon them when they are young, and do not object to them when mixed with hay, showing that it is the poisonous matter of the sting which alone prevents their more general use. Though Nettles might be made use of in various ways, it is more particularly as fibre-yielding plants that we now wish to draw attention to them. It has been proved that they will produce 5 per cent. of a very beautiful and easily bleached fibre. The order to which they belong is essentially a fibrous one, the China Grass (Boehmeria nivea), and some of the Indian species of Urtica, being noted for the large quantity and very excellent quality of the fibres contained in their stems. Nettle fibre has been used in England and Scotland as a substitute for Flax ; and an old writer quaintly remarks, "In Scotland I have eaten Nettles, I have slept in Nettle sheets, and I have dined off a Nettle table-cloth. The young and tender Nettle is an excellent pot-herb ; the

stalks of the old Nettles are as good as Flax for making cloth. I have heard my mother say that she thought Nettle cloth more durable than any other species of linen." In France and Germany paper of the finest quality has been made from Nettles. One objection that has been urged against their growth in this country for commercial purposes is, that land suitable or their cultivation might be sown with Flax, which would yield a more profitable return. This may be true, but as Nettles will grow without cultivation, and do grow in immense quantities on almost every spot of uncultivated ground, why are they not collected and made use of? The Hop is another plant abounding in strength, which may be extracted by macerating the stems in water; when properly prepared the fibre is equal in appearance to Hemp, though it is not so strong. In Sweden it is used for weaving into a coarse kind of cloth. Hop-bines have been used, both by themselves and conjointly with other materials, in the manufacture of paper, and, considering the quantity annually produced under cultivation, it seems high time something was done towards their more general utilisation. Amongst oil-yielding plants, which have been recommended for cultivation in this country, is the Madia sativa, a Composite plant, a native of Chili and North California, where it is also cultivated. It is an annual, and grows from 1 to 2 feet high. "From its valuable property of enduring winter and spring frosts, the Madia may either be sown in autumn or spring, the ground being previously well pulverised. Four pounds of seed will suffice for sowing one acre in drills about 6 lb. for the same space broadcast. The young plants should be thinned out, so as to stand at least 4 or 5 inches apart. The crops should be reaped when the earlier seeds acquire a grey colour, and disposed in handfuls to facilitate drying; after which it should be immediately thrashed out, as the seeds of the husks the viscid matter which adheres to the foliage would cause fermentation. The seeds should afterwards be washed in warm water, to clean them of the same viscid or glutinous and strong smelling substance." The oil is said to be of a very fine kind, superior even to olive oil.

The Ling (Calluna vulgaris), the Heath (Erica tetralix and E. cinerea), the Marsh Mallow (Althæa officinalis), and many other plants of easy or certain growth, might be mentioned as illustrating the importance of utilising waste land and plants of spontaneous growth. But we will content ourselves by quoting a paragraph on the use of Thistles which, though it appeared in an Australian paper some few years back, is quite as appropriate at the present time.

"It is so customary to think and speak of the Thistle only as a nuisance to be extirpated, that the settler is slow to believe this much-despised plant can be of any value. It is a fact, however, worth noting, that horses and cattle are exceedingly fond of the Thistle. It is true they will not crop it as it grows from the ground; but this is simply because the sharp spines, or prickles, with which the plant is studded injure the animal's lips and mouth, and prevent him from chewing it. But let the Thistles be cut down or rooted up, and allowed to lie exposed for a day or two, the spines will then droop, and become quite soft, and in that state horses or cattle will greedily eat them almost any kind of green food. Within these few days past, we have seen horses, rejecting rich grass-feed, indulge themselves on Thistles which had been rooted up a few days before, and had become quite withered, and mistaking the relish with which the animals were feeding. A gentleman in this neighbourhood, who had noticed the fondness of the horse for the Thistle in this state, and observed the fattening qualities of the animal, has resolved to have a quantity growing in his paddock, which he cuts when young, for use. Both horses and cattle, with an exercise of instinct which almost amounts to reasoning, have been known to trample on the Thistle when growing in the ground, for the purpose of crushing the spines, after which they will eagerly eat the plant. It may be observed that the Thistle which abounds in these districts is of the variety known as the Pampas Thistle, and was originally introduced from South America, the seeds having been probably conveyed entangled in the manes of imported horses. The plant is of a very succulent nature, and since it seems almost impossible to extirpate it, it would be good policy, at all events, to turn it to some useful account, as may easily be done by any one who will be at the trouble to try the experiment.

F. K. S.

AGRICULTURE AND THE LAND QUESTION.

[The following admirable speech was made last Tuesday at the annual meeting of the Manchester and Liverpool Agricultural Society, which has been held during the past week. It is 12 years since this Society has had a show in Liverpool. The entries number 4400, being enormously in excess of previous shows. The amount of prizes is also very large, being £3000, the amount subscribed on the former occasion having been but £696. The entries of implements, machinery, and miscellaneous articles number 1574. There are 200 entries of cattle, all the principal breeds being represented. The number of horses is exceedingly large, being 546, the roadsters and hunters numbering about 150. In this department considerable interest is created by a special prize of £50 for the best hunter. The entries of sheep number about 160, the largest representation being among the Shropshire Southdowns. The Leicesters and Southdowns are also well represented. The show of pigs is proportionately large.]

The Earl of Derby, in proposing the toast of the evening, said,—I rise to propose "Prosperity to the Manchester and Liverpool Agricultural Society," and fortunately the figures in my hand enable me to assure you that that prosperity is not merely a wish for the future in mine, but an accomplished fact. The society has existed now in its present form for nearly a quarter of a century, and its history is one of steady rapid growth. In 1850 the number of persons who paid for admission to the showyard was 3300, in 1860 it was over 20,000, and three years ago at Manchester it was 33,000, or just tenfold the number of 17 years before. The entries of live stock, produce, &c., are not increasing at higher rate than any former year, and in implements especially the increase has been enormous. In that department the entries at the present meeting are 2000, which, I am told, is 1600 more than at any previous show. We have 750 members, of whom 150 were admitted within the last 12 months. We have £1000 laid by for a rainy day; we have an income which was last year over £2000 in excess of the highest figure in

and that the popular theory, that it is so locked up that nobody can buy, rests on no solid foundation.—The noble lord resumed his seat amid great applause.

THE HOP HARVEST.

[We abridge the following Hop reports from the *Maidstone and Kentish Journal* of the 26th ult.]

THE reports with which we have been favoured, through the kindness of numerous correspondents, accurately represent the position of the Hop crop. Mid Kent is evidently this season a favoured district, but after carefully analysing the reports, we find that even here an average of not more than 3 to 3¼ cwt. per acre is to be calculated upon. Of course the average of the country will not come up to this, as it is well known that in East and West Kent the growth is almost a total failure. Where picking of the Prolific and early sorts has commenced, we are invariably told that—as they have done with the Wheat crop—growers have been over sanguine, and their estimate of the produce has been much too high. The Rochester district is most unfortunate. In many grounds, we are told, a bin will scarcely be placed; and around Maidstone there are districts where the cost of picking cannot be recouped to the grower. The late high winds have done much damage, and as the season is getting late, there is a danger of their recurrence. Mould, although it has appeared in several grounds, is, fortunately, not at all general, and the samples, therefore, we may hope, will be bright and marketable.

Ashford.—The past fortnight's fine weather has been very favourable for the growth of the Hops. In the grounds where there was any bine, from 3 to 5 cwt. per acre will be grown.

Bonnington, Aldington, Chilham, Hernhill, Goodnestone, and Graveney.—In this immediate district the following classification would give an estimate as near the truth as possible under present circumstances—a destructive wind is raging while we are writing. Dividing the acreage into fifths—say 1, 1 cwt. per acre; 2, 2 cwt. per acre; 3, 4 cwt. per acre; 4, 5 cwt. per acre; 5, 8 cwt. per acre; 5-20, say 4 cwt. per acre. A late improvement is now likely to be seriously checked by winds and cold rains, to be followed by mould. The above may be less, but more is very doubtful.

Boughton Monchelsea.—Here and there a small piece will produce 15 cwt. per acre, more 7, many 5, a few 1. The average in the district we mention may be taken at 6 or 7 cwt. per acre, but directly the visitor gets away from this line it is a very sorry affair indeed —from nothing up to a ton.

Brenchley.—The Hops in this immediate locality are about an average of the plantations. Should warm weather continue, the best grounds will grow from 8 to 12 cwt. to the acre.

Canterbury.—The Wincheap grounds (close to this city) are still very bad. Some few have made a little improvement, but others are almost a blank. We should not think they would average 2 cwt. per acre.

The average expectancies in other parishes are as follows:—Capel, not 4 cwt. per acre; Collier Street, 2½ to 3 and 6 cwt.; Cranbrook, a good yield; East Farleigh, a good crop; East Lenham, 2 to 3 cwt. per acre; Eynsford, not 1 cwt. per acre; Frittenden, very light—say 2 or 3 cwt. per acre; Hadlow, about 4 cwt.; Hartfield, a small crop.

Headcorn.—About 5 cwt. per acre.

Horsmonden.—3 cwt. if the weather continues favourable; should it prove unfavourable it will not realise so much. The quality of the Goldings here will be remarkably fine.

Ifield.—Very short. Some few may grow 2 or 3 cwt. per acre.

Langley.—This parish is expected to yield from 6 to 7 cwt.

Lenham.—Our Hops will, I think, average 4 to 5 cwt. per acre.

Mereworth.—7 cwt. per acre is quite the full quantity, rather a high set. The plantations are improving a little.

Northiam.—The Hops are going on well, and we expect the growth will be larger than a month ago could have been anticipated.

Offham.—There is an unexpected change for the better in some grounds here. The crop, however, will be very small indeed.

Pembury.—The crop will be generally good, especially where there has been high farming.

Rochester and Hundred of Hoo.—The Hops near Rochester, and through the Hundred of Hoo district are very bad. In many gardens there is a total blight, and they will not have a bin put into them.

Shorne, near Gravesend.—The crop in this district will be exceedingly short.

Speldhurst, August 28.—The high winds and cold nights are much against the full development of the Hop, which is closing up, and consequently, the crop must be short, even of my last week's report. The gale on Thursday battered most grounds severely, and will very materially affect the colour of samples of the few Hops we shall grow in this neighbourhood.

Teston.—Our prospects are pretty favourable, but the crop will not be so good as in some of the neighbouring parishes.

Tenterden.—Our Hops, where the blight did not stop the heads of the bines, are doing all they can, but, taking the parish as a whole, we shall not produce quite a third of last year's crop.

The Holmesdale Valley, near Sevenoaks. — The Holmesdale Valley will not produce more than a pocket per acre, if it reaches that. The fearful wind now blowing must damage and prevent backward burr, and will seriously bruise the better and forward Hops.

Tonbridge.—The heat of the weather which prevailed from the first up to the middle of this month, combined with the recent rains, have improved the condition of the Hops. Many farmers have hopes of a small crop.

Tudely.—The Hops in this parish rest with two or three of the largest growers, who will grow from 8 to 9 cwt. per acre; the rest of the parish will not grow more than 2 cwt. per acre.

Tuckhurst and Neighbourhood, August 27.—In our opinion the quality will be very fine, much better than last year, but as to quantity not one-third shall we average; and if we set it at 5 cwt. per acre, taking a radius of 4 or 5 miles, with Ticehurst as the centre, we shall be putting them at the very top of the tree.

Uckfield.—In some of the best grounds it is estimated that 12 cwt. an acre will be grown, while in others the average is calculated to be about 5 cwt. The plant has improved wonderfully the past few weeks.

Westhurst.—Prospects are very encouraging, and we shall have a better crop than could have been expected. In some places picking is talked of to commence this week.

Wateringbury.—Our estimates of the growth per acre of Hops in the undermentioned gleanings as is follows:—Wateringbury, 6¼ cwt.; Offham, 3¼ cwt.; West Malling, 2¾ cwt.; East Malling, 2 cwt.

Whatlington.—In our most favoured grounds we hope to realise 8 cwt. per acre, while others will produce 2 to 3 cwt. per acre. This estimate is, however, subject to favourable weather and other contingencies.

SHORTHORNS IN AMERICA.

[The following extract from Mr. Thornton's "Circular" for July, concludes an interesting series of papers on this subject.]

SHORTHORNS are not confined to the Southern and Eastern States, they have been sent of late years into California, Washington Territory, and Oregon, extreme Western States, whose shores are washed by the Pacific Ocean; into Colorado in the centre; and into Minnesota and Wisconsin in the North. Col. W. S. King has recently purchased the borderings of Minneapolis, a growing city near Minneapolis, 1500 miles from New York, where he has erected splendid farm buildings and purchased several of those animals which Mr. Cochrane recently imported from this country. He also bought some fine cattle from Mr. Sheldon and Mr. Wallace (Cultivator). I went through this new country and the Shorthorns under the adverse circumstances of food and climate. After leaving Chicago, one of the most wonderful and rising cities on the whole continent, the railway takes a perfectly straight course, and for 200 or 300 miles passes through a most fertile country, said to be good corn land, and growing prairie grass and a few scrub Oaks; it is as yet comparatively a wilderness, with 5 and 6 feet of good black soil. The Indians had a custom, which in some degree accounts for the absence of timber, of burning a portion of the prairie grass every autumn, considering that it improves and sweetens the next year's growth for the buffaloes. Near a river or watercourse, magnificent trees flourish. Col. King's buildings are so arranged that calf boxes are behind each cow stall. They are very lofty, and the hay and corn is stored away in them. Also, an enormous vat is also filled with water, and protected against the severe frosts. The cold is very severe here, but being a dry fine climate, it is not so keenly felt, though the thermometer, during my visit, stood at 22° below zero. The cows are turned out every morning; they blow the hoar frost and snow away before it becomes too deep, and graze the scanty grass that is to be found; icicles hang to their nostrils and eyelids, and after an hour or two out, they are put in and well fed. Lady Pigot's celebrated cow *Rosebole* was here as fat and as large as any; her heifer also, *Rosedale's Duchess* by the 11TH DUKE OF THORNDALE, is very thick and good, though hardly so handsome as her dam, Also Messrs. Mitchell's *Blue Bell.* The prize heifers, *Countess of Yarborough, Queen of Diamonds, Lady Solway, Roberta,* and Booth's *Lancaster,* were considering that as young, as they stand in the snow, with a bright sun and brilliantly blue sky, that would be hard to match at home. *Duchess 97th*, in a comfortable box, looked very elegant, but, milking heavily, was thin. Mr. Harvey's *Wild Eyes 26th* has grown into a large good cow, and *West Blizz, Flower of Warlaby,* and GENERAL NAPIER are fine representatives of the Aylesby herd. Two very good Oxford heifers are also here and breeding; they were purchased as the two best from the Geneva herd previous to Mr. Sheldon giving it up; also 6TH DUKE OF GENEVA, a pure 2-year-old Duke full of great size and growth. On the broad back of *Constance of Lyndale,* a roan yearling heifer bred from Mr. Fawkes' stock, the hair waves 3 inches long, and OLD SAM (Mr. Crabb's prize bull at the Essex show) seems to have grown and done well in his new home. It has since transpired that Mr. Cochrane has repurchased *Duchess 97th*, the two Oxford heifers, *Wild Eyes 26th*, with 6TH DUKE OF GENEVA, from Col. King, who in the present unopened state of the country prefers to breed from animals of not such extreme value; indeed, great credit is due to him for the spirit and enterprise with which he has invested a large fortune in farm buildings and fine stock, both of horses, Shorthorns, Ayrshires, Lincoln sheep, and pigs, in a country where scarcely a quarter of a century ago the Indian built his wigwam and the buffalo grazed, and where even yet a few hours' ride will convey one without the bounds of civilisation.

Another new herd has been recently started in that district by Mr. Geo. Murray, at Racine, Wisconsin. Most of the animals have been purchased at auction or privately. Among them are many remarkably good animals, which have been extremely well selected as to type and blood. *Louan 21st*, an 8-year-old cow, was bought at Mr. McMillan's sale, Ohio, for about 720 gs.; *6th Louan of Oakland*, a yearling, for 400 gs.; and *Forest Queen*, descended from *Aylesby Lady* by BARON OF WARLABY (7813) for 560 gs. Several very fine Shorthorns are in the number, also an Airdrie Duchess, from Mr. Alexander's and some of Mr. Sheldon's herd. Two Duke bulls, 11TH DUKE OF AIRDRIE, red, and 13TH DUKE OF THORNDALE, roan, both large, fine animals, are the sires. Messrs. Parks, at Washington, are in the same neighbourhood, are also establishing a herd.

Ontario, or as it was formerly called Western or Upper Canada, more particularly in the neighbourhoods of Brantford and Toronto, has long had fine Shorthorns. The Messrs. Miller of Pickering were among the earliest importers. Mr. George Miller, who emigrated about 1832, took out Galloways, Leicester sheep, white pigs, poultry, and pigeons, and had a good stock, but the Galloways have given way to Shorthorns, chiefly from Mr. Syme's stock of Annan, N.B., the Leicesters to the Cotswold, and white to the black or Berkshire pig. Mr. John Miller made several purchases in this country last year, chiefly from Mr. J. B. Booth, Mr. Currie, and Mr. Marshall. His herd contains many fine animals, especially some of the Atha tribe, descended from Robert Colling's ANNAN PIPPIN, and the Booth's "ELVIRA" tribe, the same family as the well-known prize bull EDGAR (19,680). OXFORD MAZURKA, by ROYAL OXFORD from *Mazurka*, Mr. Torr's FAWSLEY CHIEF (26,143), and Mr. G. Bedford's KOSCIUSKO are the bulls in use. The Provincial Agricultural Society continue to encourage the importation of stock by giving additional premiums at their shows; three times the amount of the prizes being awarded to bulls and twice the sum to cows if imported 1st-prize animals. At the Toronto show last year there were 188 entries, and Mr. J. Miller won the 1st, 2d, and 3d prizes for cows in milk, for 4-year-old, 2-year-old, and yearling bulls, and the diploma with FAWSLEY CHIEF for the best bull of any age. Mr. John Bell, of Pickering, has also a good even herd, all bred from Mr. Syme's cow *Jane*; and it is considered in that part of America that the best reared by nursing from a cow and giving them gruel of oat and other meals; opinions, however, differ as to this plan. The farming is very fine in this district, and the land well laid out in squares of about 400 acres, the roads running at right angles, three east and west extending a mile and a quarter, and those north and south half a mile. Upwards of 40 tons of Swedes are grown to the acre; Peas and Barley are generally splendid crops, and Indian Corn cut green for fodder will often stand 12 feet high and yield about 36 tons to the acre. It is chiefly peopled by Scotch settlers, who have by their own energy, perseverance, and frugal industry raised themselves to wealth and position. The necessities of the country and want of appliances develope the faculty of invention, and ingenious contrivances for lessening labour may frequently be observed. A simple apparatus at Mr. Cochrane's farm for lifting the heaviest animals by means of a leathern apron and straps attached to a beam and windlass, would be particularly useful on any breeder's establishment. Among the other good herds in Western Canada are those of Mr. F. W. Stone, of Guelph, who has been a large importer both of cattle and sheep for many years, and has greatly improved the stock of his district; the Hon. David Christie, who imported from Mr. Douglas; the Hon. Geo. Brown, Mr. John Snell, Mr. Thomson, and others, but time would not permit me to visit them. Hereford cattle also have been imported into this territory, but experience has shown that the stock of the country assimilates better with the Shorthorn than with the Hereford.

The United States and Canada have been mutually benefited by imported cattle. Before the civil war broke out the Canadians gave great prices at the Southern shows, and encouraged American breeders. During the war prices declined, and breeders in the troubled districts were not only glad to realise at low figures, but many sent their cattle away for safety into the quieter States. When peace was restored the demand for good cattle arose, and a duty of 20 per cent. on the declared value was charged on all animals going from Canada to the States; yet Mr. Cochrane's great importations, in the teeth of this restriction, commenced soon after; and the celebrity of the cattle was so great that the public in great numbers came many miles, during the summer and autumn, to see them

Many drove long distances, brought provisions, and after inspecting the stock, begged hot water and picniced beneath the Plane and Maple trees that encircle the homestead at Hillhurst. Notwithstanding the duty a large trade was done with the Americans, and the high prices given by them have, doubtless, had a great influence during the last three years on prices in this country. This duty was withdrawn during the present spring, and all cattle for breeding purposes are now imported into America free.

In the New England States great attention is paid to the dairy properties of Shorthorns, though the barren nature of much of the soil, and the exhaustion that even that has undergone, renders breeding a difficult and uphill course. Mr. Augustus Whitman, of Fitchburg, Massachusetts, has a large herd of pedigree Shorthorns kept especially for milk. Some are of the "Knightley Rosy" tribe, and others of the "Sockburn" and "Princess" families, which have been much esteemed in the district on account of their dairy properties, though they have become somewhat light fleshed. They are nearly all heavy milkers. 6TH DUKE OF THORNDALE, a fine light roan bull, was here. The food is steamed, and a mixture of chaff and shorts, with corn and oil meals, are given daily with 5 lb. of long hay; it is all carefully weighed before being served out, the quantity of milk given by each cow measured, and every animal is weighed the first of each month. The calves get new milk for three or four weeks, and afterwards porridge of meals and milk. The milk is sent into Boston, and sold at 1½*d.* a quart in summer, and 2½*d.* in winter.

The Herd Book is published by Mr. Lewis F. Allen, of Buffalo, and the 10th volume has just appeared. It is prepared very nearly on the same plan as the English book, but more profusely illustrated. The first volume, with which is given a history of the breed, was brought out, partially through the instigation of Mr. Clay, in 1846, but there was little support on account of the low prices and general depression in agriculture, and the second volume did not appear until nine years afterwards. In 1857, the third volume was issued, in which several errors that had inadvertently crept into the previous volumes were corrected. The volumes after that were small, rarely more than contains the least number of pedigrees. Since then the trade increased, and the entries were returned so fast that the volumes are now issued almost annually. Vol. ix. is in two parts, and contains over 5000 pedigrees, but, unlike the English book, many of the contributors are not subscribers, and the work is not pecuniarily successful, although about 4*s.* are charged for each pedigree, and two guineas for the volume. Continuous numbers are given to the bulls, but the English volumes are necessary to thoroughly investigate a pedigree. Breeders in America, like those in this country, are greatly indebted to those who undertake the laborious, tedious work, requiring the utmost vigilance and care.

A stranger, accustomed to the "roast beef of old England," will possibly notice in the States the absence of fat and flavour in the beef, and often it is both lean and tough. There are several reasons for this. An Australian, having large herds in New South Wales, remarked that the large droves of cattle which he saw travelling on the roads in the Western States to market were not near so fat as those on the runs in his native country. The natural prairie grasses being somewhat long and dry, have, probably, a tendency to fattening properties; and the leanness of the buffalo meat, which when young is uncommonly good, in a degree corroborates this. The "quality" or "handle," so greatly considered by our old-established breeders here, is not so closely studied on the other side, where many of the animals are thin handed. Moreover, the great distances that many cattle travel before they are slaughtered somewhat affects both the quantity and the quality of the meat. Beef and pork are chiefly eaten, and fetch almost the same market value, namely from 7*d.* to 9*d.* per lb., and they are generally under the English price. Mutton is not so much appreciated by Americans when in England frequently remark that our lamb and mutton are fuller of flavour than their own.

Many bulls are now being sold to cross the Texas cattle, which are brought up from that immense State to graze in the border districts of Kansas, where they are sent off at five to six years old. These cattle are mostly yellow in colour, with black noses and long horns; they are deep in the body but rather narrow, and not large in size; the crops are good, loins broad, and quarters rough and uneven; one bull calf is saved to every fifty cows, and they are generally marked on the ear, and branded. The best cows weigh about 800 to 1000 lb., and fetch from 14*d.* to 2*d.* per lb. live weight, in Chicago market. From their appearance a good thick Shorthorn bull, with fine quality, would make a wonderful improvement among them, and a few of the more enlightened are beginning this plan; if pursued, it will open out a wonderful bull trade among the breeders in the Western States, where two or three good herds, Mr. Pickerell's, Mr. Isles', and others are already established. The railway truck system is not good, and this was borne in forcibly upon me by a ride of several hours in a cattle train in the entire absence of any other conveyance. After travelling about 150 miles, or about every 24 hours, the cattle are unloaded at certain stations, fed, watered, and rested, but they usually lose 100 lb. or more in weight before reaching their destination. A "cattle palace car" has been invented, like the improved trucks recently exhibited at the Highland Society's Dumfries meeting, but as yet neither have come into general use. The stockyards at Chicago are of immense size and laid out in large square wooden pens, where the cattle are placed untied. Thirteen railway companies have sidings into them. In 1869, 403,000 head of cattle was received, and 5246 was the largest number in one day. Mr. Griffiths publishes an annual report of the live stock trade of Chicago. It is now the great emporium for the packing of beef and pork, and about 2000 pigs are killed and dressed daily, and by a great division of labour, in a very quick time.

The market price of beef generally rules the prices of Shorthorns, which have been very variable in America. From 1833 to 1838, prices were high and colour not so much considered, even whites would sell well, but during the next 10 years they declined, and good heifers could be bought at 12 to 15 gs. each. In 1853 prices rose, and at one of the Kentucky importation sales, Lord Feversham's bull DIAMOND (11,357), sold for 6001 dols. (about 1200 gs.); another bull, CHALLENGER, went for 4850 dols. (about 970 gs.); and the celebrated cow *Mazurka* realised 3050 dols. or about 610 gs. 1857 was a year of commercial disasters; prices fell, and the war breaking out soon afterwards, the trade from 1859 to 1867 they have greatly risen, and a young bull, the 11TH DUKE OF GENEVA, has just been sold to two Kentuckian breeders, from the New York Mills herd, for 6000 dols. (1200 gs.). Mr. Cochrane, of Canada, has also paid and received high prices. A fine red bull calf, the produce of *Duchess 99th*, for which he gave Capt. Gunter 1000 gs., has been sold to Col. Kingscote, an English breeder, for 800 gs., and two heifer calves, the produce of *Duchesses* 101*st* and 103*d*, for which 2500 gs. were paid, have been sold to the Earl of Dunmore to come back to England for the same sum that the bull realised. Mr. Cochrane are also purchased two heifers of the "Oxford" tribe, and two of the "Red Rose" tribe, at equally high prices. Mr. Cheney, of Gaddesby, also imported in 1869, two Duchess heifers and a bull calf for 2500 gs., and has recently completed the purchase of 3 others, from Mr. Stephenson, of Warlaby, Mr. Campbell. These prices indicate the demand there is both in England and America for animals of fashionable blood; though they doubtless stimulate and encourage Shorthorn breeding as well as show the abundant wealth and great interest taken in good cattle by some of the leading men in the country, yet they have a tendency by their extreme value to hinder selection and prevent that fine judgment, by which the earlier breeders brought the best tribes to such great excellence. It is likewise thought that the taste of rich Americans is now tending more to country life and farming, as in England, and this consequently, for some time to come, the demand for Shorthorn and other cattle is likely to be great, especially too, as the railway system is bringing into direct communication immense grazing districts in the Western States, and vast tracts of country are coming daily into cultivation.

In these papers, which are written at the utmost but a mere sketch, I have set down fairly and honestly, and without prejudice or favour of any kind, such facts as I observed and such information as I gleaned from reliable sources; mis-statements may have unknowingly crept in, and I trust that those who may discover them will acquaint me, that they may be corrected.

And here, in conclusion, let me bear testimony to the warm reception I received, and also express my sincere thanks for the hearty welcome given me by every one whom I met both in the States and Canada. I felt this deeply, and sincerely regretted that my business would not permit me to accept many other invitations, or stay longer with those upon whom I called. Good feeling and a hearty welcome were extended on every side, and more frequent intercourse between our own people and those across the Atlantic would, I am convinced, not only mutually enlighten and instruct, but be the means of increasing friendship and uniting more firmly the bonds of friendship between the two countries.

Home Correspondence.

Sewage Irrigation.—Mr. Hope has chosen to reopen a controversy which you thought proper to close many weeks back, and has chosen to do so on the plea that "I will not let him alone," whereas it is he who will not let me alone, for I have not addressed the public on matters in difference between us since you cried "Hold! enough." Mr. Hope neglects the fact that my challenge anticipated his, for I had already invited the attendance at the Lodge Farm of any scientific gentlemen, practically acquainted with farming, to examine into the system pursued there. That invitation has been accepted, at times in small, and recently in greater numbers. The opinions of those gentlemen who made an inspection of the farm on August 3 (notice of which appeared in your journal of August 12), were communicated to the public by gentlemen who attended on behalf of the Essex press, and by Mr. Mechi, who recently addressed a letter to the *Times*. These reports, and the comments on the "broad beds," the facility of their irrigation, and the evenness of the crops on them, have, it seems, led to Mr. Hope's renewed attack on me—not because I was the inventor of them any more than he was the originator of the narrow beds, but because, in rejection of his *dictum*, I have continued to avail myself of the advantages they afford. I must again repeat that until Mr. Hope succeeds in growing crops as fine (and of course as even) as those raised on the Lodge Farm, and can show that they have been produced, other circumstances being similar, with a substantial reduction both in sewage and labour, I cannot be expected to accept "the principles" which it amuses him to "lay down." *Henry J. Morgan, Lodge Farm, Barking, August* 28.

Spoiling the Beauty of the Country.—I am told, and not unfrequently, by my fair friends, "Oh, Mr. Mechi, you are spoiling the beauty of the country by causing the removal of trees, pollards, and fences." Now I must entirely disagree with my censors, for I am thus unveiling the beautics of the country, and permitting a more enlarged view of British agriculture in the literal sense of the word; and this is the feeling of my labourers as well as myself; for we were discussing the subject, and we are all agreed that the removal of trees and fences by myself and my neighbours has given to us very pleasant and extensive views—a vast improvement on the old plan, where it was impossible to see beyond the fence in small fields of 4 to 10 acres. No horizontal outlines gradually swelling in the distance were then to be seen. It was like being walled in by an impenetrable green fence, studded with some ugly pollards, the farmers' robbers. Now I become enraptured when I have, in the pleasant distance, neighbours of various dignity. The church spire, the chapel roof, the old Layer Marney Tower, a glimpse of high tide in the Blackwater, are great improvements on the dull and depressing seclusion of a very limited vision. In fact, on the old plan one can't see the country, except in hilly districts; now the lovely pattern-card of variegated crops, just at harvest time, is visible and delightful. I don't believe that I was ever intended for a hermit. In a sanitary point of view, a close surrounding of the house with great trees is the cause of much physical damage; and we know that the healthiest parts are considerably benefited by the absence of so many hungry intruders. *J. J. Mechi.*

Sewage Skirmishes.—I have been following the passages of arms on "sewage irrigation," which have of late been so freely scattered over your sheets, and I fully agree with you that we have had enough of them, unless considerably more of useful information and rather fewer empty challenges be infused into them. I elicit from Mr. Hope little more about sewage irrigation than anybody else; I would therefore suggest that he should write for the public—who are not a tithe of them able to examine his Breton's Farm, or to judge of its merits if they did so—a little guide-book on sewage irrigation, suited to small minds, setting forth "mathematically and practically" all the merits of those methods by which he claims to be possessed. By this means he would raise himself a tower of strength, against which his critics and adversaries would naturally dash themselves helplessly to pieces, like butterflies against a window-pane. As it lacks time, inclination, or perhaps power to do so, I submit that in future it will be as well for all parties to lack time, inclination, and power for such bootless personal encounters as have recently graced your columns. Of their being utterly uncalled for, no better proof can be given than the total treatment of the many attacks he is at times subjected to by one of your most valued correspondents. Having thus myself entered the lists I condemn, I await, Mr. Editor, to see whether your sentence on my inconsistent expressions be—*Waste Paper.*

Protection of Corn in the Field.—When resident in Somerset, in 1840, I noticed a mode of protecting corn in the field from the effects of wet weather on the ridge of about Mendip range of hills, which are liable to heavy and continuous fogs in the autumn, that may be serviceable elsewhere in wet seasons. Three Fir poles, about 8 or 9 feet long, were fastened together in the form of a triangle by cross pieces nailed to them when placed 3 feet 6 inches apart at the bottom (say 1 foot above the ground), and 1 foot apart at the top, intermediate cross-pieces being added to strengthen the tripod and bear the weight of the sheaves. The heads of the sheaves being laid inwards, and resting upon the bottom cross bar, and their butts outside, a pike of sheaves, containing about a good cart load, was built up, which, with a cap of thatch on the top, was effectually protected from the rain, whilst at the same time the grain hardened, and it was fit to be carted to the stackyard as soon as the weather permitted. By placing the tripod across a furrow, the air can be admitted, if desirable, at the bottom. *Clericus.*

Reports of the Crops.—I do not for one moment question the accuracy of the reports provided by your correspondents, but if we are to judge of other counties, which I do not know, from the reports of Kent, which I do know, then they are not much to be valued. Your three correspondents hail from Dover, Isle of Thanet, and Wingham, all situate in the extreme south-eastern part of the county. Whatever can they give us of the general state of the crops in a county which runs 60 miles in length by 40 in breadth? Let any one take a map of the county in his hand, see the district compared

in their reports, and the absurdity of calling it a statement of the state of the crops in the county will be patent. Nothing is said of the Weald, of the marsh district, of the valley of the Medway; and yet people at a distance will regard it as a report of the county. I do not say it may not be true of the whole, all I contain is, that the report of so narrow an area ought not to be dignified with the title of a report of the crops of the entire county. *D., Deal.* [Our harvest reports, almost without an exception for a quarter of a century, have been justified by the result. Compare the conclusions to which they have this year led us with the letter of Mr. Lawes in another page.]

Condimental and Aromatic Cattle Food.—I am a believer in this: we have Nature as our guide and example. See what she does on our good pastures. How various the plants and their qualities! A handful of well-made hay is a nosegay; make it into hay-tea, how good it is! I wish that some of our learned contributors would define the peculiar properties of each of the various grasses, and enlighten us on this interesting subject. My lawn is naturally well planted with wild Chamomile. Are not condiments as good for our animals as for ourselves? Has any herbalistic book treated of hay-tea and its effects on the human as well as animal frame? Our pepper and mustard, mint, sage, parsley, thyme, savory and coriander, all come from Mother Earth, and so do most of our medicines or medicinal herbs. The various productions of our fruit and flower and vegetable gardens, as well as from our fields, all coming from the same dirty earth, may well fill us with wonder and admiration. The other day, when changing our lambs from Italian Rye-grass to red Clover, notwithstanding all our care, such as giving them only a little with other dry food, they began to scour, and we had to kill one. I ordered 1 lb. of Simpson's cattle spice —cost 6*d.*—to 120 lambs, and they went on comfortably, and continue to do so. Most farmers know that green Clover is very dangerous for lambs, especially if previously cake-fed. We give a portion of Beach's condimental food to our fattening cattle with decided advantage. I shall endeavour to satisfy my mind whether this cheaper mode—using the spices or buying the spiced food. I incline to the former. I believe that many of the heavy losses in cattle and sheep, by "blowing" and "scouring," might be prevented by condiments, spices, or stimulants. The Down mutton, fed on the downs, where there is wild Thyme, is delicious. *J. Y. Mechi, Spdenham.*

Freehold Tenure.—The advantages to the public of the general prevalence of absolute estates in land in preference to life tenancies, have of late been prominently brought forward, and some have gone so far as to wish to extinguish the right of creating a life estate. But it must be remembered that the power of creating an estate tail is very limited, that upon each change of trustees (for such estates generally are so settled) the public gain a stamp duty, and upon each death a succession duty. I am surprised, therefore, that no notice has been attracted to properties, which present all the objectionable features of life tenancies, without the collateral advantages which the public derive from the latter. I refer to the real estates belonging to corporations. I heard the other day that the revenue of one hospital alone was £50,000 a year. The total real estate belonging to similar bodies, and to the universities, must be of vast amount. Now the power of possessing these estates for ever is quite exceptional, for the common law, which is common sense, abhors a perpetuity. And if it be desirable, both for political and for agricultural reasons, that the number of freeholders should increase, it is obvious that the locking up of so large a portion of the land in perpetuity, without the remotest possibility of its being divided by some spendthrift heir, is a public evil. Even if it were thought too strong a measure to compel such bodies to sell, within a certain number of years, all land not required for their own use and occupation, there surely ought to be no objection to a law forbidding them to acquire another acre, unless for the purposes aforesaid. *G. S.*

Rugby Sewage Farm.—The cereal crops standing on this farm were recently sold by auction. They consisted of 14 acres of Wheat and 7 acres of Oats. The Wheat realised an average of £13 18*s.* per acre, and the Oats £10 10*s.* per acre; the purchasers to cut and harvest them. The Wheat land was last year in Oats, and after the crop was removed the land was irrigated for three weeks, and afterwards ploughed and sowed, without any other manure or dressing. The Oats followed Italian Rye-grass, and the land had a similar dressing to the Wheat. The Italian Rye-grass this year has been in great abundance, but, grass being very plentiful in the neighbourhood, the demand has not been so great as in former years. The price has therefore not exceeded 15*s.* per ton, and now and for some time past has been 10*s.* per ton. A considerable quantity has been made into hay, the greater part of excellent quality, and haymaking still goes on favourably. The root crops look very promising for a heavy crop. *T. E. Palmer, August 29.*

Turnip Seed Growing.—Permit us to reply to some of the remarks in your leading article on the cultivation of crops of Mangel, Turnips, and Swede for seed, which appeared in last week's issue. We think that your strictures as to the careless manner in which seed growing is practised in the present day, are rather too severe. We claim to have some little experience in the matter of seed growing, and we fearlessly state that at no time was the culture of seeds more carefully attended to than at the present; and we also assert that the care and attention bestowed on the cultivation of Mangels, Turnips, and Swede, is at the present time very different to what it was 10 or 15 years ago: therefore we think your sweeping condemnation of the present method of seed growing somewhat unmerited. We have been through most of the Turnip-growing districts, and are prepared to say that, in a large number of instances, the roots left for seed are sufficiently large to distinguish the sort, and are, for all purposes of selection, large enough. We don't mean to say that all the seed sold is saved from large roots, otherwise one man's reputation would be as good as another's; but we do say that selection and careful cultivation is practised by so many people that the worst quality seed now sold is a very great advance upon a similar class seed that would have been sold 15 years ago. Practical observation will bear us out in this assertion, as it is a rare thing now to see a bad stock of Mangel, Swede, or Turnip growing on any one's farm. Again, it is not fair to condemn seed that is grown from roots of scarcely any size. We saw this summer, in Romney Marsh, 20 acres of Swede in seed for a firm who sell "home-grown seeds," and the plants were like walking-sticks, with scarcely any evidence of bulb whatever. Now, we have special reasons to believe that this crop was grown from stock seed saved from very large and fine roots; and, as practical agriculturists, we are prepared to maintain that the produce of this would produce fine roots. Again, if you will allow us to speak for ourselves, we had a large acreage of Swede this year, where the bulbs averaged from 12 to 15 inches in circumference. Thinking probably the stumps had yet remained on the ground, we wrote to the farmer, asking him to send up a hamper of them; unfortunately, by his reply (which we enclose, but not for publication) we learn they have been burnt. However, the same gentleman is growing 2 acres of Mammoth Long Red Mangel for us, of a very select stock, and he has sent up a few of the stumps of these, by which you will see that all the seed offered to the public is not cultivated in the careless manner you suggest in your article. After all, the question becomes a question of pounds, shillings, and pence. Those who will have cheap seeds must be content with inferior quality, but those who are prepared to give a reasonable price can be supplied by most respectable seedsmen with an article that will in every way please them, at less cost and at half the trouble of saving their own seed. *James Carter & Co., 237 and 238, High Holborn.*

—— In your leading article, p. 1141, you give an interesting account of how to grow seeds, but omit one very important point; you say, "Swedes selected from roots left in any way are worthless," also, "The best way is to dig them in with a spade a yard apart." Now, the question I want an answer to is "When?" Swedes with me finish growing about the middle or end of November. Should they be taken up then, and immediately be replanted with a spade? Or, should they be left about the beds? Swedes left in the ground without being pitted are simply a skin full of rotten pulp in the middle March. Will burying them up to the neck prevent this? *G. A. H.* [Yes.]

Foreign Correspondence.

STETTIN: *August 22.—Some Particulars about the Liernur System.*—It will, I hope, be agreeable to your readers to have some particulars about the adoption of the Liernur system in different places, as I have been happy enough to receive them, by the kindness of one of the Berlin magistrates. These particulars will, at the same time, serve to justify me in my having dwelt upon the subject as one of importance. For it may be said that an invention, so new and novel as M. Liernur's system, can soon find its way if it were not rational and convincing of success, in a country so conservative as Germany.

Liernur's system is being executed in Olmütz, Prague, Brünn, Leiden, Amsterdam, and Hanau. In Vienna the patent is bought and paid for by a rich company, and Berlin it being talked of.

In Olmütz they are about to get it up in all the military barracks, and in Prague it is executed in most of them, as well as in some manufactories. In Brünn the system has been fairly carried out in some barracks and manufactories, and pending in others.

In all these towns there has been only question of large isolated buildings, and not of whole streets and blocks of houses. This, however, will not stand with the Northerns, who want summarily to get rid of the question of water-carriage and cesspools by a national system of organised scavenging, the dead weight and ugliest part of which is spared to the inhabitants and the scavengers by the Liernur pneumatic-canalisation machine, as it may be called.

Berlin is, after the precedent of some Dutch cities, I believe, going to give the system a fair chance, as the sewerage and irrigation matter in the south of Berlin has been condemned as totally impracticable. The plans have been drawn up, the money will be voted at one of the next sessions. Nevertheless, there is a deal of opposition to be overcome, many of the magistrates being somehow or other enamoured of great subterraneous buildings, and, it is said, the 20,000,000 dollars which the sewerage of Berlin would cost; whilst Liernur's system would virtually cost nothing, as the proceeds for the manure more than pay the whole.

The Dutch precedents are as follows:—In Leiden there are three streets with 114 houses being drained by means of only two reservoirs. In Amsterdam there are two streets with 52 and 68 houses respectively, the one drained with two reservoirs, the other by one only. In both the works will be adopted for the whole town.

In Hanau a trial has been recently made in one building, a hospital. The works are just completed, and of course answer well.

In Prague and Brünn I hear there has been a row, as the Beller company, the undertakers, are Germans, while the town authorities are Panslavonians and Czechs. For all the formalities and difficulties raised in the face of the urgent necessity of Liernur's system being executed as soon as possible, the result will be that common sense will be victorious, and the Czechs will give in. The company, sure of this, endeavour to secure beforehand a good market for the manure, the sale of which must pay the interest on the capital invested. Hence the suspicions of some inconsiderate persons, that the Liernur system consists in emptying cesspools by means of evacuated tenders, which error has even found its way into your columns.

Another reason of wrong notions about good things is said to be this—commissioners, magistrates, &c., set out to have a look at a whale and find a sardine, never inquiring into the matter, never looking at the science of it, but altogether contented with their eyes, their own healthy prejudices, and other people's blunders. *O. Beta.*

Societies.

ABERDEEN.

The Aberdeen Game Law Conference.—At a recent meeting of proprietors and tenant-farmer representatives held in Aberdeen, Sheriff Comrie Thomson presiding, the following recommendation of the subcommittee was read:—

The committee recommend that the following queries be addressed by the conference to each proprietor in the county who has a rental of £500 and upwards, in the hope that there will be no objections to furnish the information required, with any particulars bearing thereon:—

1. What are the conditions in regard to game contained in the leases or in the general regulations of your property? It is requested that you furnish copies of the clauses to the conference.

2. What is the actual practice (apart from such covenants) which obtains on your property in regard to game?

3. Have complaints, or claims of damages, in respect of alleged injury by game and rabbits, been made by any of your tenants to you, or to any one on your behalf, within the last five years?

4. If so, by how many tenants? what were the sums claimed? and how were the claims settled?

5. Do you preserve game and rabbits? and if so, what arrangements do you make to protect the crops adjoining your premises?

6. Do you let any part of the shooting on agricultural lands on your estate? If so, what arrangements are made for the protection of the agricultural tenant?

It was also recommended that the tenant representatives be invited to communicate to the conference, in writing, the views held by them as a body in regard to the matters under consideration of the committee.

Mr. JAMES ANDERSON said he still held to the opinion that, if they wished to elicit facts, they must go direct to the men who suffered, and who were best able to explain to them what they suffered from. He was clearly of opinion that it was immaterial what the answers by the proprietors might be unless they were to supplement them by sending similar schedules to the tenants. He thought that both parties, being interested parties in the matter, should be dealt with at once and direct, and that the farmers should not be asked to contradict their landlords after their landlord's answers had been on the table. He would ask "Who is your proprietor?" "Is the game reserved in your lease?" "Is the game let, or does the proprietor shoot over the farm himself?" "Have you ever suffered from game or rabbits, and if so, have you been compensated for same?" What sort of game or wild animals do you suffer from?" "Would your interest be sufficiently protected by the removal of the restrictions as to hares and rabbits?"

Mr. LESLIE (Warthill) would ask Mr. Hutcheon to limit the inquiry to proprietors to those whose rentals were £500 and upwards, and to tenants whose rents were £200. He thought one of the questions Mr. Hutcheon proposed to put was, "Who is your proprietor?" and the second was, "What is the covenant in your lease?" Well, the covenants in leases were not in many cases carried out, and he suggested to Mr. Hutcheon to adopt their second question, "What is the actual practice apart from such covenants?" That would qualify it, because many of the proprietors reserved the game in their leases, but did not practically

reserve it. He would put the same question both to proprietor and tenant, "What are the covenants in regard to game in your lease?" and then followed the question, "What is the actual practice apart from such covenants?" He had found there were 5937 occupiers of land at £20 and upwards, and that there were 6760 over £15. Now, he was quite willing to take the £15 rental in sending out schedules to the tenants.

Mr. EDMONDS suggested whether they should not postpone these questions to the tenants, because, when they got the answers to the queries from the landlords, they would be in a better position to apply to the tenants. It might not, indeed, be necessary to apply to the tenants when the laudlords' answers were received, and in that way they would save a great deal of expense, and a great deal of time.

Sheriff THOMSON said it was the view of the majority of the sub-committee.

Mr. EDMONDS said the question applying to the tenants could be easily put afterwards.

Colonel INNES said he would be quite willing to concur in the suggestion that the question to the tenants be reserved; but he wished to let it be understood that the landlords had no desire to quash any inquiry.

Mr. HUTCHEON said the country gentlemen who had appointed the committee did so on the understanding that there were complaints on the subject. Who was complaining? Not the proprietors; they were not complaining. It was the tenants who were complaining, and who could better state their complaints than themselves? The information given by the proprietors must be of a very general nature indeed, as it was generally the case that the great body of the proprietors in Aberdeenshire, whose tenants suffer from game, were in complete ignorance that such was the case. It was assumed that, in the great majority of cases, the proprietors did not themselves know what their tenants suffered in respect of game. How then could they exhaust the question by asking of the proprietors only the state of matters in regard to game? No doubt there would be some expense in sending out these schedules, but it did not appear to him that the question of expense was any good reason for the postponement of the schedules to farmers. He did not see how the matter of £40 or £50 should stand in the way of such a great agricultural county like Aberdeenshire, or such a body of men, when the object was to elicit such important information. Then suppose they took a £14 rental as the basis in sending out schedules to the farmers; that he thought was a fair proposal. He presumed they would not require to fee a competent person to collect the statements, and he did not think the expense would exceed £50. They could send out the schedules under the halfpenny postage, or, if they wanted secrecy, they could put a penny stamp upon them for return from the parties to whom they were sent. He took it for granted that they had already settled that the schedule on the table should be amended, and if they affirmed the principle which he had taken the liberty to propose, they should proceed to settle at once the form of the questions to be put.

Major ROSS said he thought Mr. Hutcheon was going on the ground that the proprietors thought no cause of complaint existed. He thought that was admitted, and being admitted, the extent was the question. Some made it more, some made it less; and, therefore, he agreed with what Mr. Edmonds had said, that much time might be saved and considerable expense by getting answers to the queries now adopted by the meeting, because he thought it very likely, from the information they obtained in answer to these questions, that they would be in a position to go at once to the general question before them without going into details, because the grievance was clearly before them. The answers being received, the proprietors might say they admitted the grievance so far. They would then have the statements of the representatives of the tenant-farmers as to what they thought would be the best way to remove the grievance.

Mr. SKINNER could assure them that there was not one tenant in fifty that suffered who wished to complain to the proprietors. He was quite convinced that a large number of the proprietors in Aberdeenshire were not aware of the damage done by game. If they were, he was sure they would give their tenants liberty to shoot them down. They had a high respect for their proprietors, and he thought if these gentlemen saw and understood properly the cause of complaint, they would, as reasonable men, agree that they would put them down. As to the estimation of the crops, no man could value damages on a field of Oats or Barley or pasture grass. A number of tenants had said to him that they would be under the necessity of complaining, but they never did.

Sir JOHN CLARK said he thought the question of expense a minor affair, and if Mr. Hutcheon would propose those questions, he would be very happy, from the landlord's side, to second the proposal that the schedules be issued to the tenants at the same time as to the proprietors.

Mr. LESLIE (Warthill) said he thought the grievance was all on the side of the tenants, and he did not think they could arrive at a satisfactory conclusion unless they put categorical questions to the tenant in the same manner as they did to the proprietors. The question, he repeated, should undoubtedly be put to the tenants as well as to the proprietors. Whether they were to be addressed to tenants over £20 or over £15, mattered very little. If they had the answers, then they would be able to come to some fair and just opinion as to the extent of the damage and the grievance.

Mr. EDMONDS inquired how they were to proceed when they got the returns? It was like examining 7000 witnesses in a case. Who, he said, is to condense the evidence? Will you, Mr. Sheriff? I have no hesitation in saying it will take 12 months to make up a report. I think the thing is impossible.

Mr. HUTCHEON said he saw no difficulty about the matter whatever, and the longer he thought about it it seemed to him the more reasonable. There could be no doubt whatever that gentlemen would be found who could read all these answers, and who could tabulate them all, so that they could be submitted to the joint committee, and form a basis of indisputable facts. He did not think it would take 12 days or 12 hours to do that, instead of 12 months. There was a way of doing business which, as it had been expressed in the newspapers, was, "How not to do it." But there were parties connected with business who would have no difficulty in going over the tables that were submitted to them. He presumed that there would not be more difficulty in collecting the 7000 schedules than there would be in collecting the agricultural returns sent to the whole of the United Kingdom, of which he had no doubt that, in a very short time, there would be an abstract before the public. Surely, in the matter of game, it would not be more difficult to put in a tabulated form the answers to the questions submitted. He thought, if the meeting affirmed the principle which he had proposed, the leading schedules to the tenant-farmers, as to the proprietors, he would be disposed to leave to the sub-committee the form of schedule to be drawn up. He begged leave further to say in regard to the expense, that if the sum was within reasonable limits, such as he had hinted at, he would guarantee to find, in the part of his agricultural friends, half the amount. He did not think the question of expense ought to warrant them to override the consideration of the matter. If it were admitted that there was a game grievance, they should not hesitate about full inquiry. He moved—"That the report of which a summary had been approved of, and that these queries, as amended, be issued to the proprietors, and further remit to the sub-committee to prepare a series of queries to be sent to all tenants in the county who pay a rental of £14 and upwards; and that it be expressly mentioned that the answers will be kept strictly secret, and that no names will be made public. The schedules to be sent to the sub-committee, and the members of that committee be authorised to open them and prepare a Table for the conference."

After the adhesion of many other gentlemen to Mr. Hutcheon's proposal, Mr. WALKER (Bithnie) said he was very much pleased to see so many of the proprietors willing to have the matter fully investigated. He thought it would be a pity when they had begun, not to elicit the whole of the facts; it would also be a pity if the matter of the expense could in any way deter them from going into the question. He hoped the gentlemen would agree to the motion made by Mr. Hutcheon.

Mr. LESLIE said of course the answers would not be made public in any form, or made known beyond the committee.

Mr. BARCLAY said the sub-committee should be custodiers of the papers, and it should be the business of the sub-committee to see that the matter was kept secret. He presumed the conference would have confidence in the committee in stating the returns, and he proposed that the matter be delegated to them.

The report as amended, was then approved as follows:—

I. That the following queries be addressed by the conference to each proprietor in the county who has a rental of £500 and upwards, in the hope that he will have no objections to furnish the information required, with any particulars bearing on the question, viz.:—1. What are the covenants in regard to game contained in the leases or in the general regulations of your property? You are requested to furnish copies of the clauses. 2. What is the actual practice (apart from such covenants) which obtains on your property in regard to game? 3. Have complaints, or claims of damages in respect of alleged injury by game, deer, and rabbits been made by any of your tenants to you, or to any one on your behalf, within the last five years? 4. If so, how many complaints or claims, and by how many tenants were they made, and how many have been admitted, and how were the claims settled? 5. Do you preserve game and rabbits, and, if so, what arrangements do you make to protect the crops adjoining your preserves? 6. Do you let any part of the shooting on agricultural land on your estate, if so, what arrangements are made for the protection of the agricultural tenants?

II.—That the tenant-representatives be invited to communicate to the conference in writing the views held by them as a body in regard to the matters under the consideration of the conference.

A meeting of the Tenants' Committee was held at the close of the above meeting, Mr. M'COMBIE in the chair.

After a good deal of desultory conversation, the clerk read the following as a statement of the conclusions arrived at by the meeting of the Farmers' Committee held in the Corn Exchange on June 23:—

I. That, on many estates in the county, the tenants have just cause for complaint with respect to game and other wild animals, the principal grounds being:—1. Damage to crops by hares and rabbits; 2. Damage by deer in the neighbourhood of deer forests, &c.; 3. Damage to crops by semi-domesticated pheasants in the immediate vicinity of pheasantine preserves; 4. The practice of gamekeepers on certain estates shooting, trapping, or poisoning dogs and domestic cats.

II. That the best remedy for the existing grievance between landlords and tenants would be to give the tenants absolute and unrestricted right to kill, either by their own hands or any one employed by them, hares and rabbits on the lands they occupy, the landlord's right of shooting remaining as at present.

The committee believe that this remedy would be effectual, except as to deer and semi-domesticated pheasants.

III. That to confer such right as a gift, revocable at the pleasure of the landlord, would not be satisfactory, and that no remedy based on compensation for damage to crops would settle the grievance.

Mr. DOUGLAS (Culsh) did not quite agree with those conclusions, thinking that the farmer should have power to protect his crops from all kinds of wild animals, and he was under the impression that that was the feeling of the meeting at the time.

Mr. COPLAND said the report read was a very good summary of the views expressed at the last meeting, but he thought the committee should not transmit it to the proprietors until they had received the returns from the various districts of the county, when additional information might necessitate some alterations.

Mr. WALKER (Bithnie) again urged delay in sending the conclusions to the proprietors. He thought the right to fix hares and rabbits would not be satisfactory. They should have power to defend their crops from all kinds of game, &c.

Mr. M'COMBIE, M.P., said: The question now under consideration is, what remedy would remove the grievance and laid feeling between landlords and tenants? I believe that the giving up of hares and rabbits would do a good deal to mitigate the grievance, and that it would be accepted by a majority of the tenant-farmers as such, except as regards deer and pheasants; but I hold in the general interests of the nation the game laws ought to be abolished.

Mr. COPLAND moved that the meeting do not proceed to an expression of opinion in the meantime till the returns be received from the various districts of the county.

Mr. HUTCHEON moved as an amendment that the meeting proceed.

The amendment was carried, and the clerk was instructed to forward a copy of the report to the sub-committee of the conference.

A vote of thanks having been passed to Mr. M'Combie for presiding, the meeting terminated.

Farm Memoranda.

MR. OFFIN'S FARM AT HUTTON.—We (*Chelmsford Chronicle*) wrote to Mr. Offin, asking if one of our representatives might go over some of his farms and make observations and inquiries pertinent to the subject under discussion, and the permission having been readily and cordially granted, the visit was paid on Thursday last. Suffice it to say, we repeat the statement which Mr. Offin made in one of his letters, that he farms more than 5000 acres, and when we add that these 5000 acres are intersected by numerous farms held by other people; that from the extreme point of one of the off-hand farms in Essex to the extreme point of another at Latchingdon the distance is no less than 36 miles, and that this goodly number of holdings touches no fewer than 26 different parishes, it will be sufficiently obvious, we think, that it was only a very moderate portion of the ground that we could go over in the half day we were assured, however, that, to use a plain phrase, Mr. Offin does not make fish of one farm and flesh of another, and that what we saw was only a sample of what we should have continued to see if it had been possible to cover the whole 5000 acres. But, if we had a year's loaf to go upon, we took such a slice by which we tested it should be correspondingly large. We are not quite familiar with the boundaries of the parishes about Mr. Offin's house, but we certainly went into two or three different parishes, and on to many different farms, stretching in an unbroken line of 3 miles from Hutton Hall, on one side, and of one mile on the other. It was to the condition of the labouring population, and to what concerned them, that we paid primary attention, but, as will be seen from what follows, we were naturally induced to make notes also upon points of general interest, having, perhaps, only a remote affinity to that subject. First of all, we had a good view of Mr. Offin's own residence and grounds. On sallying forth into the village of Hutton, we were delighted to find that, while dwelling in a "celled house" himself, Mr. Offin had not forgotten the claims of his poorer neighbours, but had provided them also with decent and convenient homes. Instead of that squalid poverty which we have heard so much of lately, and which undoubtedly does exist more or less in some neighbourhoods, the village of Hutton seemed to be oozing from an absolute excess of comfort. The population, we believe, is about 400

all told, and we saw no fewer than from 20 to 30 cottages, all of which have been erected within the past few years—some of them, indeed, have not long been finished. Generally, the cottages are in pairs, but the first block we came upon consisted of four, standing, by the way, upon the site of an old "Tom and Jerry," which institution has now no representative in the parish. Very neat are these, and all the other dwellings, in their outward appearance. Some have cemented fronts and blue slates; others—and these were the more recently erected—are of red and white brick, with the tiles common to the county. There is a piece of land both at the front and back of each house, sufficient for any man to employ in good cultivation in addition to doing his ordinary work. The land in front, we observed, was in most cases devoted to flowers and ornament, and was in all cases kept with great neatness, and even taste; in that behind, fruit trees and vegetables were the rule, and there was every indication that these ministered considerably to the comforts, and in diminishing the expenses, of the house. . . .

From the houses of the people we passed to the school where their children are taught. It is a pleasant-looking building, in dark red brick, entered by an ornamental porch, and having large pointed windows. . . . We next entered the church, which, small and old-fashioned, it is proposed to rebuild, from £1500 to £1600 having already been promised, we understand, in aid of the work. On the panels of a small west gallery we observed an inscription, setting forth the benefactions to the parish of Hutton. The last recorded was a bequest of £500 Consolidated 3 per cent. Annuities, by John Offin, gentleman, of Brentwood, uncle of the present Mr. John Offin, for the benefit of the National School of which we have just been speaking. This bequest was made in 1841. . . . So much for the home of the labourers and the provision made for the training of their children. Next comes the question of their wages. On this point we cannot do better than quote, with one or two supplementary observations, a sentence from Mr. Offin's first letter to the *Chelmsford Chronicle*. "The average wages of the majority of my men throughout the year," he said, "upon all my occupations, are from 15*s.* to 16*s.* per week." Some of the men, Mr. Offin told us, have done even better than this, for he was anxious that his statement should be under rather than over the mark. It must be remembered, too, in connection with the subject of wages, that the men have only to pay nominal rents for the cottages we have described,—that is to say, the cottages are let, free of all rates and extra charges, some at £4 and some at £4 10*s.* per annum, 2*s.* being returned to one class of tenants, and 2*s.* 6*d.* to the other, when the rent is paid punctually, as it invariably is. The cottages, with the land adjoining, are worth, we should say, nearly double what is charged. In addition to all this, the labourer gets his children taught for a mere bagatelle, so that he cannot by any means be said to be badly off. Just the same state of things prevails in the parish of Ingrave, where we saw some excellent cottages that have been erected by Lord Petre. Those standing in old places about the parish have a piece of extra ground attached, as at Hutton, while the tenants of those forming the village have allotments close at hand. Regarding the number of labourers employed by Mr. Offin—for that was a point to which "Observer" directed special attention in his strictures upon off-hand farming—we questioned two or three persons likely to be informed upon the subject. One man, who has known the whole district for many years, told us that there were at least twice, if not three times, as many men employed on many of the farms which Mr. Offin has acquired as there were when they formed separate holdings, and that the grand total of men was something considerably more than it was formerly. The way in which this large consolidation of farms is managed is somewhat after this fashion. Every separate farm is visited at least once a week either by Mr. Offin personally or by one of his sons, while, except in one or two cases, where they are let to tenants, the old farm-houses are divided into two tenements, one occupied by a horsekeeper, the other by a stockman or looker, and it is the business of these persons to see that all goes on as it should. The horse-keepers and lookers have between them the same amount of garden ground as sufficed for the old tenants, and, in addition to his wage, each has an allowance of 1*l.* per week for firing. In all there are nine lookers, and generally each has a horse to himself. Several horses are also kept for the use of Mr. Offin and his sons.

And now for a word on Mr. Offin's system of farming. Nearly all the land he holds is heavy, and the average depth of his drainage is about 3 feet. He uses the steam-plough, but only goes a moderate depth. In almost every grass field we observed a large herd of bullocks or a flock of sheep, so that he makes a good deal of his own manure, and what he uses besides are chiefly, if not entirely, Peruvian guano and superphosphate of lime—the home-made manure being applied to the grain crops, and the artificial to the green crops. He is what we should call a thin seeder, sowing 1½ bush. of Wheat to the acre, of Barley 2 bush., and of Oats 3 bush. Harvest had been commenced at Hutton the day before our visit; at Latchingdon, as is usually the case, it was commenced a week earlier. We thought, from what we saw at Hutton, there would be a good average crop of Wheat, and perhaps something above an average of the other grain crops and of roots. To his late uncle, Mr. Abraham Offin, the present Mr. Offin ascribes the seed of his success. The uncle died in 1855, at which time Mr. John Offin practically became his own master. He has, since that time, considerably augmented his holdings, many farms having come into his hands under circumstances which he described in

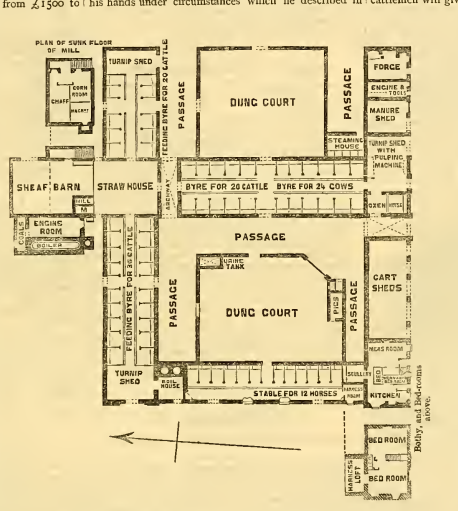

FIG. 271.—GROUND-PLAN OF THE FARM-STEADING AT TIPPERTY.

one of his letters, viz., by reason of their having been impoverished by resident tenants who had not capital enough to do fairly by them, and thus rendered worthless to other small tenants and a source of little but anxiety to the landlords. The amount Mr. Offin pays in tithes, rates, and other charges, must be something enormous; and if one only heard it named, we should doubtless be ready to exclaim, truly property has its duties—and duties which it performs—as well as its rights. We have nothing to do, here, with the question of "off-hand" farming in the abstract. It is Mr. Offin's case that has been particularly brought forward in the discussion, and it is with Mr. Offin's case alone that we have felt called upon to deal; and we must say, alike from what we have read and seen, that we are quite satisfied he comes out of the controversy without shame and without reproach.

TIPPERTY, NEAR ABERDEEN.—Aberdeenshire farmers keep a very large quantity of stock in proportion to the size of their farms, as will be seen by the following sketch of the method of the stock-farming pursued by Mr. William Murray on his farm known as Tipperty, near Aberdeen. This farm is 500 acres in extent, including roads and fences; it is all arable land, and is worked on the usual five-course system. Not less than 170 head of cattle of every description are kept on it every year, and the seeds are let from November until February for wintering 500 hoggs. The tenant was formerly a successful butcher, and exporter of fat stock and dead meat. The annexed ground-plan of the steading (fig. 271), which was designed by Mr. Beattie, will give a good idea of the arrangements on a modern Aberdeenshire farm, specially devoted to the breeding and feeding of cattle.

Seventy feeding beasts are bought, as 10-quarters-old steers, in February, and kept on until the next winter. About 20 queys are also bought every year, and after one calf has been taken from them they are fed off with the steers. Six dairy cows are kept, and their calves, as well as the others, are kept on until they are fattened for the butcher at three years old. Calves begin to drop in January, but some are as late as May. The calves from the dairy cows are brought up by hand, the others suck their dams for about eight months, and are then weaned on oilcake and straw, but are not setoned. The young beasts are fed in winter on pulped Turnips and chaff, the calves getting 2 lb. of cake in the morning for about two months. The first feeding beasts go into the byres about the middle of August, and get Tares three-fourths ripe with straw until the Turnips are ready, when they get whole Turnips, with their "shaws" on, and straw three times a day, and at night a feed of mashed grain and Potatoes. For the last two months they get oilcake, beginning with 2 lb. each per day, and increasing to 4 lb. at the finish. The following rules for the guidance of the horsemen and cattlemen will give further details on this subject, and also show the careful manner in which matters are regulated on this farm:—

Rules for Cattlemen on the Farm of Tipperty.

		A.M.
1. Clean out the stalls	.. until	6.10
2. Turnip the cattle ..	.. ,,	6.40
3. Clean out the byres ..	.. ,,	7.10
4. Clean down the rumps of cattle	.. ,,	7.30
5. Straw the cattle ..	.. ,,	7.45
6. Bed up the cattle ..	.. ,,	8.
		P.M.
1. Pull Turnips ..	.. ,,	12.
2. Turnip the cattle ..	.. ,,	12.30
3. Bed up the cattle ..	.. ,,	12.45
4. Straw the cattle ..	.. ,,	12.
		P.M.
5. Interval ..	.. ,,	2.
1. Clean the cattle thoroughly	.. ,,	3.30
2. Clean stalls and Turnip ..	.. ,,	4.
3. Clean out the byres ..	.. ,,	4.30
4. Straw the cattle ..	.. ,,	4.45
5. Bed up the cattle ..	.. ,,	5.
6. Interval ..	.. ,,	7.
1. Give the cattle oilcake or bruised Oats, &c.	.. ,,	7.30
2. Bed up the cattle ..	.. ,,	8.

P.S. Each cattleman to wash his cattle once a fortnight, and to keep the dung pit well levelled down, and to turn also his cattle every 14 days, and also to attend the threshing-mill when working after 8 o'clock A.M.

Rules for the Horsemen on Tipperty.—1. Each horseman on entering on his services at Tipperty, will have his horses handed to him with cart and plough harness, comb and brushes, carts, shelvings and frame, plough, shovel, graip, and key of press and corn chest, all complete; and he will have to hand the same over on leaving.

2. All horsemen to enter the stable at 4.45 A.M.; stable clean out, dungpit well levelled down, and horses led to the water, fed, and cleaned until half-past 5 until 6 A.M.; and from half-past 5 until 6 A.M.; and when horses are not working from 6 to 6, barn work, &c., until yoking time.

3. Horses returning from the yoke to be well rubbed down for 15 minutes, and fed; dinner until 12.15; horses receive Oats on entering the stable, and cleaned.

4. Horses on returning at 6 o'clock P.M., are cleaned down for 15 minutes, afterwards, being watered and fed, a few Swedish Turnips given.

5. Stable entered at 7 P.M.; horses cleaned well down, afterwards watered, receive Oats or bait, and suppered up; stable closed at 8 P.M. No horses to be allowed to leave the stable without a stall collar on.

Rules for Sabbath.—All horsemen to attend in the morning and evening on their horses, and in no case to be absent without appointing a substitute approved by the master, and one horseman to have charge all day by turns, commencing with the foreman.

These rules are pasted up in the bothy at Tipperty—an institution which is intimately connected with the condition of the agricultural labourer in Aberdeenshire. This subject has been very much discussed, and the mere name of a "bothy" has been made almost sufficient to conjure up visions of dirty ploughmen and ill-clad women. One result is, that Scotch farmers—who thoroughly appreciate the result of giving a dog a bad name—now designate as "barracks" those bothies which are used as bed-rooms, and as "kitchens" those in which the labourers get their food and spend their evenings. Whatever want of orthodoxy my opinion may possess, I cannot help thinking that the faults in the bothy system which are held up to public reprobation are to be seen as frequently in the cottages of East Lothian as in the bothies of Aberdeenshire. Therefore, it seems more just to lay these faults at the door of the labourer himself than at that of the system under which

he is housed and fed. The Aberdeenshire system is to have a "kitchen" for the unmarried ploughmen in a convenient position attached to the steading, or situated near it. This is a room furnished with a long table, three or four benches, some stools, and a separate locker for each labourer, in which he keeps his "household gods." It is generally the duty of an old woman to cook the food for the labourers, and to keep the room and furniture in a condition that is supposed to be clean. As a rule, the labourers sleep in attics over the byres and stables, and spend their evenings in the "kitchen." So far as the "kitchen" itself is concerned, I look upon it very much as a humble kind of club. The system of constructing dormitories over byres and stables is not æsthetically defensible; but, practically, it is liked by the men, especially in the winter, when it is piercingly cold outside and comfortably warm within. *Journal of the English Agricultural Society*, vol. vii.

The Week's Work.

SEPTEMBER 9.—*Trifolium incarnatum*.—Sow 4 bush. of the rough seed in the husk, or 20 lb. of clean seed per acre, and bush or chain harrow in on a clean stubble. Some give the land a stroke of the harrows before the seed is sown, purposely to raise a fine mould; others roll or clod-crush, when the soil is crusty; but a very fine mould is not desirable at this season. The cultivation of the crop is exceedingly simple. It follows Wheat, Barley, and Oats, and is sown from August to the close of September.

Liming in Autumn, for winter Beans, Vetches, Clover, &c., is preferable to liming the land at the removal of these crops for Wheat or other cereals; pulse crops being greater consumers of lime, and hence profiting more by its application than the succeeding white crops. It should be thoroughly incorporated with the surface soil, purposely to prevent its sinking to the bottom of the staple, which it is very liable to do. From 30 to 300 bush. of shells from the kiln are applied per acre; 100 bush. being a common dose. The quantity depends upon the nature of the land, the quality of the manures used, and the length of time between the limings. Some prefer frequent limings, others give large doses at a time, with long intervals between. Lime is also applied to grass land, either alone or in the form of lime-compost, and to land being laid down permanently to grass.

Winter Vetches.—Sow for soiling or ploughing in spring. Some make two sowings this month, for the purpose of successive soiling and folding, one early and the other late—the last of the season; others prefer the last sowing in October. The crop is partial to a rich clay soil, but will grow on friable land in good condition. If the land is foul, scuffle and clean it. Some manure on the flat—15 to 20 loads of farm dung per acre—ploughing in shallow, and then drilling 3 bush. of Tares, and 1 bush. of Rye per acre. Others smash up and drill in the above quantity of seed, with from 3 to 5 cwt. of guano per acre.

Laying down Land to permanent meadow and pasture.—The old rule, "fill the land with seed and manure," still applies; but modern systems of cultivation differ from those of the olden time. Thorough drainage and deep tillage are primary operations, that must never be neglected; and should the land require lime, chalk, marl, or clay, these should be applied before the manure and the seed. The seeding and management afterwards are similar to what is given above on renovating grass land. The quantity and kind of seed will depend upon the soil and climate. The quantity varies from 30 to 70 lb. per acre, so that 50 lb. is perhaps not far from an average.

Rye.—Sow, on land adapted for it, 2½ to 3 bush. per acre. There are large tracts of poor sandy soil capable of growing Rye, which will not grow anything else, and on such it should be grown. If kept clean such land is very easily cultivated, and being generally dry, there is no obstacle in the way of carting. Where there is a command of clay, 80 loads per acre—*i. e.*, half a load to a pole—will change, and greatly improve the texture of the soil.

Newly-weaned Calves, are liable to be infested with lice on the skin, and worms in the windpipe, &c.; our improved breeds more so than the older races. The former (lice) are easily seen behind the ears, and along the neck and back. Harsh, frequent, dry, husky coughing indicates worms in the windpipe—the malady being termed "hoose" or "hack," from the peculiar sound of the cough. "It follows," says one of our best authorities, Spooner, "bare pasture, with a bad supply of water. Cows are sometimes affected." Both lice and worms may be prevented by a liberal diet, with plenty of soft, filtered water to drink, so as to keep the calf growing sleek, and without losing its milk-flesh at the time of weaning. Keep other beasts in equally good heart. As for cure, consult your veterinary surgeon.

Rye-grass and *Clover leas* intended for Wheat should now be ready for seed. Some rib or rafter plough the lighter class of soils with the view of rotting the sward, and at the same time getting a proper seed-bed with the desired clod. If this was done shortly after the removal of the hay crop, the land, after lying a month, is coupribbed, or cross-ploughed, or scarified, as circumstances may direct; and when ploughed for the seed furrow an inch of fresh soil is brought to the surface, which forms an excellent seed-bed. In this way the grassy sward is broken and incorporated with the soil, thereby insuring its decomposition, with the destruction of insect life, more successfully than when ploughed with a single furrow. Others turn the green sward, by means of a skim-coulter, into the bottom of the furrow, to rot under the furrow slice, the land being thus left at one operation ready for the seed-drill. When Rye-grass and Clover lea lies one or two years in pasture the sward is thicker and more liable to be infested with wireworm. Insects seldom deposit their eggs in healthy pastures, but the presence of much effete matter is always to be suspected, and to rot such sufficiently for the safety of the Wheat a top-dressing of lime compost, artificial manure, or far better liquid manure applied before ploughing on either of the above plans, so as to set up the rotting process, effectually decomposing the green sward under the furrow-slice, thereby depriving the young insects of food in the spring-time when they first make their appearance in the grub form, and *per contra* supplying food for the Wheat plant. Another plan is to plough early, and to compress the furrow-slice with a heavy presser, and then by harrowing and rolling, at intervals of a fortnight or three weeks, the green sward is effectually rotted, and a sufficiently solid seed-bed secured for the Wheat plant to stand ripid without the frost-fallen. But this plan requires the land to be in tolerably good heart, otherwise compression will not rot the effete sward of a poor soil without some top-dressing.

Notices to Correspondents.

ARTIFICIAL MANURES: *Yorkshireman*, who wrote on this subject some time ago, should give us his name and address.

RAPE CAKE AND BEAN MEAL: *G. M.* The following is a comparison of rape cake and bean meal in the experience of a cow-keeping correspondent:—Having been rape cake strongly recommended for cows, I was induced to try it, but the results are unsatisfactory; several of my cows will not eat it at all. The cow I put on trial liked the rape cake, had coloured about three months, and an average quantity. She gave on rape cake 3 lb. 12 oz. of butter. When 4 lb. of bean meal was substituted for 4 lb. of rape cake, she gave 5 lb. 4 oz. of butter, and 4 quarts 1 pint more milk. In addition to the above trial, I have the cows 50 lb. a day of Turnips pulped up and mixed with hay and straw chaff; it is allowed to heat for 24 hours, and then given to the cows, who relish it extremely.

ERRATUM: *The Agricultural Gazette*.—The Editor wishes, however late, to correct a misprint on p. 1078, at the third line from the bottom of col. *c*. It is there desired, for the benefit of the labourer, that he should have full liberty to do the best he can for himself, without any the actual or implied, to farm or "parents." The word written was "parish," and the thing objected to was that local "settlement," with the habit growing out of it, which hinders the labourer from migrating to localities where labour is in demand.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Sept. 4.

We have an unusually large supply of Beasts, but they are chiefly foreign. Prices are lower for all kinds, and a clearance cannot be effected. There are a few more Sheep than last Monday; good English are very scarce, and make high rates. We cease to quote Lambs, the season being over. Choice Calves are making a good price. Our foreign supply consists of 3360 Beasts, 15,800 Sheep, 424 Calves, and 20 Pigs; from Ireland there are 250 Beasts; from Norfolk and Suffolk, 20; and 1620 from the Midland and Home Counties.

Pigs	5	6—5	6	

Beasts, 3150; Sheep and Lambs, 25,300; Calves, 438; Pigs, 65.

THURSDAY, Sept. 7.

The number of Beasts is much smaller than on Thursday last, the falling off being principally in foreign. There are very few choice qualities on offer, and they are sold rather dearer than on Monday. The supply of Sheep is very little altered, either of foreign or English. The trade is not quite so active as on Monday, yet prices are not much lower. Trade is brisk for Calves, at higher rates. Our foreign supply consists of 450 Beasts, 7490 Sheep, 367 Calves, and 20 Pigs.

JOSHUA BAKER.

MARK LANE.

MONDAY, Sept. 4.

The supply of English Wheat from Essex and Kent to this morning's market was very small for the season, and was cleared off at 1s. per qr. advance upon the prices of this day se'nnight. There was a good attendance, and a fair demand for all descriptions of foreign, at a similar improvement. Barley, Beans, and Peas are without change. Oats are in rather better demand, with the turn against the buyer. Flour was unaltered.

WEDNESDAY, Sept. 6.

The grain trade at Mark Lane to-day has been devoid of any feature of especial interest. There has been a moderate supply of English Wheat on offer, and the arrivals from abroad have been on a fair average scale; the trade has been steady, at Monday's prices. The supply of Barley has been moderate; the demand has been inactive, but prices have been steady. Malt has been dull, on former terms. The show of Oats has been good; the trade has been quiet, but no change has taken place in value. Beans and Peas have been disposed of at the rates previously current. Flour has been fair, at late rates.

LIVERPOOL, Sept. 5.—There was a full attendance at to-day's market. A large business was done in Wheat, at 1*d.* to 2*d.* per central advance on Friday's prices on both red and white sorts. Flour held for extreme prices. Beans 6*d.* higher. Oats and Oatmeal steady. Indian Corn in good demand, at the full prices of Friday last. Mixed American, 30*s.*

SEED MARKET.

Owing chiefly to the want of rain, and to the consequent absence of a consumptive demand, the seed trade still continues in the quiet state noted in our last. Neither white nor red Clover seed has yet present with any attention whatever. In new Trefoil seed a few transactions have been passing, at full prices. Trifolium moves off in retail, at late rates. Winter Tares are in fair demand, at recent currencies. White Mustard seed comes to market more freely; many of the samples, however, appear to be in poor condition. Rye-grasses are advancing in price. New Rape seed is in improved supply; it meets with a brisk demand. Bird seeds are unchanged in value.

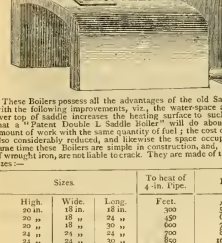
Illustrated Price Lists free on application.

THOMAS GREEN AND SON, Smithfield Iron Works, Leeds; 54 and 55, Blackfriars Road, London, S.E.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.



These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "Patent Double L Saddle Boiler" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and, being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	5 0 0

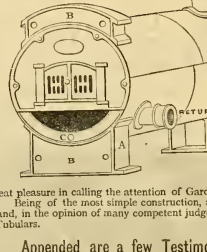
STEVENS' "TRENTHAM" IMPROVED CORNISH BOILER.



The Advertisers have great pleasure in calling the attention of Gardeners, and all interested in Horticulture, to the above excellent Boilers. Being of the most simple construction, and in wrought iron, they are very durable, economical, and powerful; and, in the opinion of many competent judges, are superior to all other Boilers, even to the most approved form of Tubulars.

Appended are a few Testimonials:—

"Royal Exotic Nursery, Chelsea, S.W.

"DEAR SIR,—Having now had your Boiler at work here for some months, we are very pleased to be able to report most favourably of them. They are certainly more powerful than the Tubulars they have replaced here, more economical as regards consumption of fuel, and they do not require so deep a stokehole.

"We shall be pleased for you to refer any one here who may wish to see the Boilers at work, and examine them. We have already recommended them to many people, and we are sure they will by degrees become largely used.—We are, dear Sir, yours, very truly,

"JAMES VEITCH & SONS."

"Combe Abbey Gardens, near Coventry.

"I feel that anything I can say in favour of Mr. Stevens' Boiler will come very far short of its real merits. The dilemma of choosing a Boiler has now been set at rest, by the advent of Mr. Stevens' Improved Cornish. Its introduction has made our heating a masterpiece, one Boiler heating 4000 feet of 4-inch pipe. It saves considerably both in time and labour, by comparison with the now discarded Tubular Boiler. "WM. MILLER."

"Ingestre Hall, Stafford."

"DEAR SIR,—I am delighted with your Improved Cornish Boiler. It is by far the simplest and most powerful Boiler I ever used, and economises my fuel and labour to an extent that I could not have believed possible, unless I had had ocular demonstration of the fact.

"W. PHIPPS."

"Huntroyde Park, Burnley.

"DEAR SIR,—We have had your Improved Cornish Boiler upwards of two years, heating more than 2000 feet of 4-inch piping, and I feel that I cannot speak too highly in its praise.

"I have worked a good many kinds of Boilers, but not one that requires so little fuel and labour to do so great an amount of work as yours, and when the Boiler becomes known it will be very generally used. "H. LINDSAY."

"Atherstone Grapery.

"DEAR SIR,—Your Boiler is the simplest and most powerful that I ever used, and I would back it to beat any boiler now in use, for economy of fuel and labour with thorough efficiency.

"It is a real *Gardeners'* Boiler, and will be as commonly used as the Old Saddle has been when it becomes known. "G. SAGE.

THE LANDS IMPROVEMENT COMPANY. (INCORPORATED BY SPECIAL ACTS OF PARLIAMENT.)

DRAINAGE, RECLAMATION, FARM BUILDINGS, LABOURERS' COTTAGES, TRAMWAYS, RAILWAYS, &c.

DIRECTORS.

John Clutton, Esq. Granville R. Ryder, Esq.
Frederick J. Dashwood, Esq. Granville R. H. Somerset, Esq., Q.C.
Henry Farquhar, Esq. Henry W. Wess, Esq., M.P.
Lord Garlies, M.P. Charles Watkin Williams Wynn,
John Hornby Lloyd, Esq. Esq., M.P. (Chairman).

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy in respect of their Glebe Lands.

Tenants may, with the consent of their Landlords, execute the necessary improvements upon the Farms which they occupy, charging them with the cost.

UTILISATION of SEWAGE.—The Company also advances money for the purpose of the Sewage Irrigation of Lands.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeemable principle and interest, over a term of years.

No investigation of title is required.

For Forms and further information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S.W.

Agricultural Land Improvements.

DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY.

(Incorporated by Act of Parliament in 1849.)

DIRECTORS.

T. Chapman, Esq., F.R.S. The Right Hon. Viscount Combermere.
George Thomas Clark, Esq. Edward John Hutchins, Esq.
John C. Colthurst, Esq. Sir William Tite, M.P., C.B.
Henry William Currie, Esq.

Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works by their own agents.

Tenant Farmers may also, by agreement with their Landlords, procure the execution of Agricultural Improvements.

The outlay, with all official expenses, may be charged upon the Estate, and repaid by a rent-charge of about 5 per cent., in 31 years, or at the option of the Landowners in a shorter term.

No investigation of title necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, Companies, or Individuals, for making the Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment or discharging in a fixed period the principal amount with interest thereon.

Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 29, Whitehall Place, S.W.

CENTRAL ARGENTINE LAND COMPANY, LIMITED.

Chairman—JOHN HEGAN, Esq.

Agent in the Republic—E. HARRY WOODS, Esq., C.E., Buenos Ayres.

Superintendent—WILLIAM PERKINS, Esq., Rosario de Santa Fé.

The Directors offer, on advantageous terms to Settlers, either as Tenants or Purchasers, PLOTS, varying from 80 to 400 ACRES each, of the COMPANY'S LAND, situate on each side of the Central Argentine Railway, from the Port of Rosario to the City of Cordova, the entire length of the line. Towns and Villages are being laid out at various points on the Line, where smaller Plots may be secured for Building purposes.

To secure the best class of Agricultural Settlers and facilitate the Emigration of Families, the Directors are prepared to treat for the Colonisation of Lands within easy reach of the Stations on the Central Argentine Railway, and adapted for immediate cultivation.

Further particulars may be obtained at the Offices of the Company: London—85, Palmerston Buildings, Bishopsgate Street, E.C.;

Buenos Ayres—Calle de Cangallo 1;

Rosario—Terminus of the Central Argentine Railway;

Where the Surveys of the Land (about 1,000,000 Acres), together with the Plans of the Colonies already established, can be inspected.

Works on Botany, by Dr. Lindley.

SCHOOL BOTANY; OR, THE RUDIMENTS OF BOTANICAL SCIENCE. In One Volume, 8vo, half bound, with 400 Illustrations, price 5*s.* 6*d.*

DESCRIPTIVE BOTANY: OR, THE ART OF DESCRIBING PLANTS correctly, in Scientific Language, for Self Instruction and the Use of Schools. Price 1*s.*

MEDICAL and ŒCONOMICAL BOTANY; or An Account of the Principal Plants employed in Medicine or Domestic Œconomy. In 1 vol. 8vo, with numerous Woodcuts, price 7*s.* 6*d.*

THE ELEMENTS of BOTANY, STRUCTURAL AND PHYSIOLOGICAL. With a Glossary of Technical Terms, and numerous Illustrations. 12*s.* cloth.

This completes the series of Elementary Botanical Works by Professor Lindley, of which "School Botany," and "The Vegetable Kingdom," form the other parts.

The first two parts of the ELEMENTS OF BOTANY, comprising Structural and Physiological Botany, and a Glossary of Technical Terms, are published in one octavo volume, price 12*s.*

These three parts form a complete manual of Botany for Medical and other Students who have made themselves acquainted with the Author's "School Botany."

N.B. The Glossary may be had separately, price 5*s.*

THE VEGETABLE KINGDOM; OR, THE STRUCTURE, CLASSIFICATION, AND USES OF PLANTS. Illustrated upon the Natural System. In One Volume, 8vo, cloth, price 36*s.*, with upwards of Five Hundred Figures.

EXTRACT FROM THE AUTHOR'S PREFACE.

"The Vegetable Kingdom contains, among a large quantity of plants of no value or importance to man, various species employed in medicine, the arts, or in the many branches of domestic economy. It is principally part of those which can be brought by teachers in Europe under the notice of students, or which, from their great importance, deserve to be among the earliest subjects of study, are mentioned in the following pages, where they are arranged in the manner proposed in the 'Vegetable Kingdom' of the author, with the sequence of matter departed from in a few instances, when it was believed that the convenience of younger students would be consulted by doing so. The number trusts that its contents will be found to have been made in such a way that all teachers who possess reasonably extensive means of illustrating their lectures, and all Botanic Gardens, may furnish the larger part of the species which are mentioned. A small selection was indispensable; firstly, because a greater work would have been beyond the reach of the majority of purchasers; secondly, because experience shows us that those who have to study a science of observation, such as Botany, require to concentrate their attention, in the first instance, upon a limited number of objects."

AND
MUSWELL HILL ESTATE TONTINE.

(TO TERMINATE ON THE 30th JUNE, 1886.)

THE ALEXANDRA PALACE
AND MUSWELL HILL ESTATE TONTINE.

To terminate on the 30th June, 1886.

TRUSTEES—JOHN CLUTTON, Esq., Whitehall Place.
JOHN HACKBLOCK, Esq., Bolton Gardens.
JOHN HORATIO LLOYD, Esq., Inner Temple.

The Palace is a splendid, capacious, and substantial structure, and the Estate comprises nearly 500 acres of beautiful freehold land within a radius of 6 miles only from Charing Cross.

The object of the Tontine is to complete the purchase and improve the property, and thus to provide for all classes of the inhabitants of the metropolis, and especially of its northern and eastern portions and suburbs, and for the many thousands of country excursionists, a Grand Institution of healthful recreation and elevating instruction, which will combine the solid advantages of the South Kensington Museum and Schools of Art, with the lighter pleasures and pastimes of the Crystal Palace at Sydenham, thus giving effect to the large and enlightened views of the late Prince Consort.

The main advantages of this undertaking may be said to be as follows:—

The holder of a Tontine Certificate for ONE GUINEA or upwards will become entitled to—

A share in the realisation of the estate in 1886, when the nett proceeds must be of enormous value.

Free admissions in the meantime, on certain occasions.

A share in the Art Unions (proposed to be held once in every three years), when the prizes will be considerable.

To be reimbursed 20s. for each Guinea paid in the event of the Life nominated, and upon which the Tontine privilege depends, not surviving till the 30th June, 1886.

Thus the Tontine (besides its other great privileges) presents the opportunity of making, at a very slight cost, an ample endowment for children, or of ensuring a very large return for the capital invested.

It being a "Trust," Subscribers incur NO LIABILITY, and must benefit.

If no issue is made, the Subscriptions will be returned in full.

For further particulars, see Detailed Prospectus.

Admissions to view the Palace can be obtained at the Offices of the Company, 5 and 6, Great Winchester Street Buildings, E.C.

THOMAS DIXON, *Secretary.*

ALEXANDRA PALACE.—The advantages offered to the Public were thus summed up by *The Times* of July 18:—"Under the title of 'Alexandra Palace and Muswell Hill Estate Tontine,' certificates representing 850,000 guineas are about to be issued, which will entitle the holders, in proportion as they may possess a single certificate of one guinea or any larger number, to participate in the various objects of the institution, or to take their share of the entire property of the Palace and grounds of 498 acres, should they, 15 years hence, be among the surviving holders. Under an elaborate but ingenious plan framed for the purpose, each subscriber will have several options as to the mode in which he may obtain a return for his investment, and be virtually guaranteed against loss. The Trustees and Board of Directors consist of experienced persons familiar with the management of London properties and of public establishments, and it may be hoped that the result of their arrangements will be to furnish to the population of the North of the metropolis a place of resort as attractive as that on the other side at Sydenham."

ALEXANDRA PALACE.—In an address delivered by that distinguished lawyer, Mr. John Horatio Lloyd, one of the Trustees of The Alexandra Palace and Muswell Hill Estate Tontine, "Mr. Lloyd explained the principle on which it was proposed to raise the necessary capital, and declared that he was perfectly satisfied that no possible loss could be sustained by any one investing; as, in addition to the value of the property, a system of insurance had been devised which was a practical guarantee against any possible failure. He declared that he would not have accepted the position of trustee had he not been satisfied that the undertaking was one offering many solid advantages to investors; commercially secure against failure, and commending itself in the highest degree to the favourable consideration of all interested in providing for the acknowledged wants of the working classes, and desirous to do so in some more substantial form than by mere words."—*Advertiser.*

ALEXANDRA PALACE.—The advantages offered to subscribers to the Alexandra Palace and Muswell Hill Estate Tontine are thus described by the *Builder*. The holder of a guinea ticket will have 780 free admissions to the grounds, five chances of an Art Union prize, ranging from £2 to £500, and a distribution share in 1886, which is estimated at not less than £10. If the nominee on the certificate die before 1886, £1 for every £1 1s. subscribed will be returned by the Insurance Company to the representative of the nominee or certificate holder. Thus each subscriber, the *Times* remarks, will be virtually guaranteed against loss. The Park and grounds contain 498 acres of well wooded ornamental land, nearly all freehold, commanding an extensive and beautiful view. The Palace covers 9 acres, and all within a radius of 6 miles from Charing Cross. The *Art Journal* remarks, we cannot afford to lose this spot, which, it duly preserved and tended, will be of priceless value in a few years.

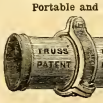
Portable and Fixed Hot-water Apparatus

FOR HEATING CONSERVATORIES, HOTHOUSES, CHURCHES, PUBLIC BUILDINGS, PRIVATE RESIDENCES, &c.



TRUSS' PATENT UNIVERSAL FLEXIBLE and LEAKLESS PIPE JOINT and PATENT CRACKLESS EXPANSION-JOINTED TUBULAR BOILERS, of a VARIETY of FORMS, PORTABLE or for BRICKWORK SETTING. They are the MOST POWERFUL, whilst ONLY CONSUMING HALF the FUEL of OTHER BOILERS. PORTABLE BOILERS, to HEAT ANY LENGTH of PIPING; and ANY PERSON can TAKE these BOILERS, as also the PIPES, APART, and SPEEDILY SET THEM TOGETHER AGAIN.

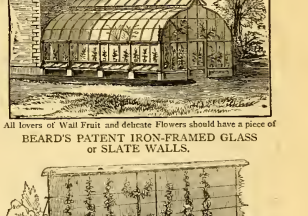
T. S. TRUSS begs to state that the immense number of APPARATUS annually Designed and Erected by him in all parts of the Kingdom, and for the Royal Horticultural Society at South Kensington and Chiswick, with unrivalled satisfaction, is a guarantee for skill of design, superior materials, and good workmanship; while the great advantage obtained by his Improved System cannot be over-estimated, consisting of perfectly tight joints with neatness of appearance; effects a saving of 25 per cent. on cost of Apparatus erected compared with other systems; facility for extensions, alterations or removals without injury to Pipes or Joints; easily and expeditiously erected; and perfectness of design supplied, insuring no extras.

BATH and GAS WORK ERECTED in TOWN or COUNTRY. The Trade supplied.

Price Lists, Plans, and Estimates forwarded on application to

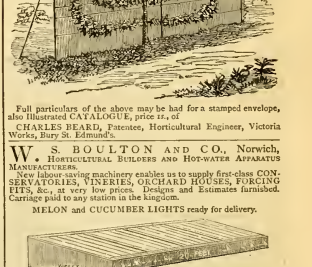
T. S. TRUSS, C.E., Sole Manufacturer,
Consulting Horticultural Engineer, Iron Merchant, Hot-water and Steam Apparatus Manufacturer,
Friar Street, Southwark Bridge Road, London, S.E.

BEARDS PATENT NON-CONDUCTING and VENTILATING METALLIC GLASS HOUSES will prove cheaper than wood.



All lovers of Wall Fruit and delicate Flowers should have a piece of

BEARD'S PATENT IRON-FRAMED GLASS or SLATE WALLS.



Full particulars of the above may be had for a stamped envelope, also Illustrated CATALOGUE, price 1s., of

CHARLES BEARD, Patentee, Horticultural Engineer, Victoria Works, Bury St. Edmund's.

W. S. BOULTON AND CO., Norwich, HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MANUFACTURERS.

New labour-saving machinery enables us to supply first-class CONSERVATORIES, VINERIES, ORCHARD HOUSES, FORCING PITS, &c., at very low prices. Designs and Estimates furnished. Carriage paid to any station in the kingdom.

MELON and CUCUMBER LIGHTS ready for delivery.

These are strong and well-made Sliding Lights, glazed, and painted three coats. Height of frame, 14 inches at front, 23 inches at back. With handles complete.

Prices.—Carriage paid to any station within 200 miles of Norwich, when orders amount to £3 and upwards.

8 feet long by 6 feet wide.. £2 15 | 16 feet long by 6 feet wide.. £5 0
12 feet long by 6 feet wide.. £3 17 | 24 feet long by 6 feet wide.. £7 5

If prepared with wood ellis, to build on brick wall, and lights to slide, prices, carriage paid as above :—

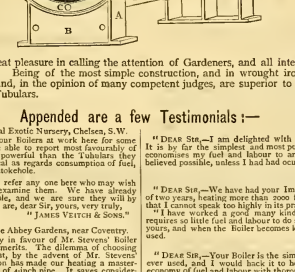
208 feet long by 6 feet wide.. £3 0 | 248 feet long by 6 feet wide.. £7 0
172 feet long by 6 feet wide.. £5 0 | 312 feet long by 6 feet wide.. £9 0

Other sizes at prices in proportion.

PLANT PRESERVERS.

Illustrated Catalogues free on application,
Rose Lane Works, Norwich.

STEVENS' "TRENTHAM" IMPROVED CORNISH BOILER.



The Advertisers have great pleasure in calling the attention of Gardeners, and all interested in Horticulture, to the above excellent Boilers. Being of the most simple construction, and in wrought iron, they are very durable, economical, and powerful; and, in the opinion of many competent judges, are superior to all other Boilers, even to the most approved form of Tubulars.

Appended are a few Testimonials :—

"Royal Exotic Nursery, Chelsea, S.W.

"DEAR SIR,—Having now had your Boilers at work here for some months, we are very pleased to be able to report most favourably of them. They are certainly more powerful than the Tubulars they have replaced here, more economical as regards consumption of fuel, and they do not require so deep a stokehole.

"We shall be pleased for you to refer any one here who may wish to see the Boilers at work, and examine them. We have already recommended them to many people, and we are sure they will by degrees become largely used.—We are, dear Sir, yours, very truly,

"JAMES VEITCH & SONS."

"Combe Abbey Gardens, near Coventry.

"I feel that anything I can say in favour of Mr. Stevens' Boiler will come very far short of its real merits. The dilemma of choosing a Boiler has now been at rest, by the advent of Mr. Stevens' Improved Cornish. Its introduction has made our heating a masterpiece, one Boiler heating 400 feet of 4-inch pipe. It saves considerably both in time and labour, by comparison with the now discarded Tubular Boiler. "WM. MILLER."

"Ingestre Hall, Stafford."

"DEAR SIR,—I am delighted with your Improved Cornish Boiler. It is by far the simplest and most powerful Boiler I ever used, and economises my fuel and labour to an extent that I could not have believed possible, unless I had had ocular demonstration of the fact.

"W. PHIPPS."

"Huntroyde Park, Burnley.

"DEAR SIR,—We have had your Improved Cornish Boiler upwards of two years, heating more than 1000 feet of 4-inch piping, and I feel that I cannot speak too highly in its praise.

"I have worked a good many kinds of Boilers, but not one that requires so little fuel and labour to do so great an amount of work as yours, and when the Boiler becomes known it will be very generally used. "H. LINOSAY."

"Atherstone Grapery.

"DEAR SIR,—Your Boiler is the simplest and most powerful that I ever used, and I would back it to heat any boiler now in use, for economy of fuel and labour with thorough efficiency.

"It is a real *Gardeners'* Boiler, and will be as commonly used as the Old Saddle has been when it becomes known. "G. SAGE.

The Gardeners' Chronicle

SATURDAY, SEPTEMBER 16, 1871.

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Sept. 20 { Royal Horticultural (Fruit and Floral Committees), at S. Kensington .. 11 A.M. / Ditto (General Meeting) .. .. 3 P.M.

WITHOUT attaching undue importance to what is sometimes facetiously termed "kid-glove gardening," and without in the slightest degree depreciating the value to practical men of the free and unrestricted use of their digits, it may, nevertheless, be maintained, that there are, in the PRACTICE OF GARDENING, many little MECHANICAL CONTRIVANCES, introduced frequently by amateur cultivators to facilitate the performance of certain operations, and which, while they may be safely recommended to their brother garden amateurs, are by no means to be despised by the practical professors of horticultural science. In this way is not unfrequently introduced some simple expedient by which to facilitate the performance of an operation otherwise requiring rather dexterous manipulation, and it is to one or two of these that we are now about to invite attention.

Among the many operations of gardening there are perhaps none more tedious than the thinning of Grapes, and the tying-out of the shoulders of large bunches. They are just the operations one can well imagine unpractised hands would find to be irksome; and yet they are operations, the former especially, which must be honestly faced, and that at the proper time, unless the crop is to be suffered to go to ruin. The experienced practical man takes his Grape scissors, and with this implement, aided by the thumb and finger of his left hand, he manipulates the clusters with more or less of expertness; but it is next to impossible even for him to avoid rubbing and touching the remaining berries to some extent—and to rub or to touch them does them no good, and may possibly do them harm, even though it may not, as some hold it does, tend to create rust. There is certainly the risk of damaging the outer coating of bloom, on the perfect condition of which the beauty of the fruit mainly depends.

A very ingenious mode of avoiding all necessity for handling the Grapes at all whilst thinning them has been practised, for his own convenience, by Mr. W. CHAPMAN, of Notting-ham, and it is so simple and so perfect in its working, and so greatly facilitates the operation of Grape thinning, that, with his permission, we proceed to explain in what his "Grape holdfast" consists. It is merely a thin narrow strip of deal, Elder, or any other light wood cut off to a convenient length, one end of which is bluntly pointed, and a few irregular and unequal notches are cut near the pointed end, as shown in fig. 272, A. All the sharp edges are then pared off, and the implement is complete. When in use it is taken in the left hand, the point introduced amongst the ramifications of the cluster, which one by one are lifted out clear from the remainder, being caught by one or other of the notches, and that without touching a berry, or injuring the fruit in the slightest degree. While the shoulder or branch of the cluster is thus held lightly but

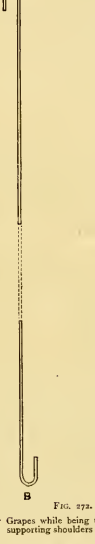

FIG. 272.

A, Holdfast for Grapes while being thinned; B, Wire Hook for supporting shoulders of clusters.

securely, the supernumerary berries are cut away according to the judgment of the operator, the holdfast is gently unhooked, and passed on to the stalk of another branch, and this is repeated until the whole cluster has been gone over. There is hence no fingering of the bunches or berries in any way, and the operation of thinning can be carried on quite as rapidly and as easily as if the fingers alone were in requisition.

Mr. CHAPMAN has another contrivance, equally facile, for supporting the shoulders of the Grape clusters. Usually these are held apart during the swelling and ripening processes either by inserting thin forked sticks across the bunches, or by tying up the shoulders by means of fine strands of bast matting. In either way the berries are very liable to be rubbed and thus disfigured. To avoid this Mr. CHAPMAN takes some of the very fine wire used for wiring the corks of lemonade and seltzer-water bottles, cuts it into convenient lengths, turns a small hook at each end, as in fig. 272, B, and by this means momentarily, and without handling the bunch at all, hooks up the shoulders, one by one, and supports them in the required position by catching with the hook at the opposite end an adjacent branch or wire, whichever may be most conveniently placed. In this way the thing is done in less time than it takes to describe the operation; and, of course, when the Grapes are gathered, instead of having to take out the forked sticks, or to cut down the strands of bast, all that is necessary is gently to unhook the wires. Their great advantage lies in the facility with which they can be used, and in the fact that they afford no harbour for insects.

These two simple contrivances, which greatly facilitate the thinning of Grapes and the open-ing up of the bunches during the swelling pro-cess, both of which have been devised and brought into use by an intelligent amateur, will, if we mistake not, recommend them-selves to the notice of our practical brethren—certainly to non-professional gardeners.

—— THE following correspondence, on the subject of COVENT GARDEN MARKET, recently appeared in the columns of the *Times*:—

"Sir,—Several statements have recently appeared in the public press reflecting upon the Duke of BEDFORD'S disregard of the interests of his Covent Garden Market tenants, in omitting to cover in, and protect from the weather, the open spaces appropriated for business pur-poses in the market.

"It does not appear to be generally understood that the widest diversity of opinion prevails in the market upon this question, and that a large and influential section of the tenants, whose interests entitle them to the most attentive consideration, have always been adverse to any proposal to extend the covered area of the market.

"In the year 1858, when such a proposal was under consideration, a memorial upon the subject, numerously and influentially signed by the Duke of BEDFORD'S tenants in the market, was addressed to Mr. HARDY, who was at that time his Grace's steward.

"I have enclosed a copy of this memorial, and have to request that you will kindly allow it to appear in your columns at an early date.

"I should add that, whenever a reconsideration of the question has been urged upon the Duke by the Market Gardeners' Association, counter-materials and protests similar to that below, have always been received by his Grace, and that his Grace has always been desirous of dealing with the subject in the manner most conducive to the general welfare of the whole body of his tenants having interest in Covent Garden Market.

"Possibly an opportunity may yet be afforded for recon-ciling conflicting views, and I am instructed by the Duke of BEDFORD to say he would gladly assist any effort which may be made in this direction.

"I am, Sir, your most obedient servant,
"THOMAS J. R. DAVIDSON.

"Bedford Office, Bloomsbury, Sept. 5."

"Sir,—We, the undersigned, beg leave to acknow-ledge the receipt of the correspondence between the market gardeners and yourself on the subject of covering in the market, and your letter of March 9, and to tender our respectful thanks for your courtesy in furnishing the same.

"After carefully perusing the correspondence, it appears to us to admit of but one conclusion, and that is, if the market gardeners choose to accept the terms and conditions proposed from the Bedford Office, the said proposition must be carried out to the imperilling of the interests of the parish and neighbourhood, and, conse-quently, as we believe, the interests of his Grace the Duke of BEDFORD himself; and we feel assured from the mass of evidence already obtained bearing on the subject from inspectors, salesmen, and others connected with the other markets, that the sanitary condition of your memorialists will be seriously affected thereby.

"It, therefore, appears to us necessary to trespass a little more on your time by stating that we cannot help thinking our views, as set forth in the memorial to his Grace dated February 4, on this subject, have not received that due consideration to which we feel them entitled, as your memorialists represent fully three-fourths of the income which his Grace derives from the market, and who represent, when compared with the market-gardeners, or 'Landed Association,' as they are pleased to style themselves, the principal agency by which Covent Garden market is rendered what it is in its attraction and its popularity, for we have no hesitation in saying, and we are prepared with evidence to prove it, that without the energy shown by the shopkeepers and salesmen, who have opened up remote markets, and who maintain constant communication with all parts of the United Kingdom, that not unfrequently a considerable portion of their pro-duce would remain unsold; and in this matter the market gardeners have never to our knowledge interested them-selves, but maintain much about the same stationary opinions they held 20 years since—always assuming the market to have been exclusively intended for them, and that salesmen and shopkeepers alike are interlopers. And if we place it in another light, we think it easy to show you that were all the 'Landed Association' to quit their stands in a month's time, plenty of other growers are to be found ready to avail themselves of the facilities offered here under existing conditions, and we are quite satisfied no difficulty would be experienced in indemnifying his Grace for all loss occasioned by the change.

"However, setting aside all reasoning and the com-parisons we have reluctantly ventured to draw, for the purpose of proving that we are, as a body, equally as important and deserving as much consideration as the 'Landed Association' in connection with the market, we beg leave to state that we are prepared, with the co-operation of the parochial authorities and our fellow parishioners, to take the matter up with them on public grounds; and, however much it may be opposed to our desires and inclinations to raise any unpleasantness among our neighbours, we feel it to be due to your courtesy and patience, and an act of justice to ourselves, to signify our

intention of opposing the Supplementary Act of Parliament whenever it is applied for, for the purpose of carrying the before-named proposition, by all legal means, and in all its stages, not in any spirit of coercion, or selfish opposition, but that the question may be set at rest once and for all.

"Trusting that some final decision may soon be arrived at in the matter, we venture again to solicit the earliest notice of such decision that may be compatible with your convenience."

—— The Disease in Asparagus which is noticed by Mr. G. Hester is by no means uncommon, and is known in some districts under the name of the Copper Web. It is not confined to Asparagus, but attacks Potatoes, whether the same Fungus or one closely allied is destructive to Saffron, Lucerne, and Mint. Rhizoctonia violacea on the two former is beautifully figured in Tulasne's "Fungi Hypogæi," but no perfect fruit was detected. Mr. Broome, however, found fructification on the Rhizoctonia of Mint, which is described in "Annals of Natural History," June, 1861. It is of a tawny tint at first, but the tips of the threads acquire a violet tint and produce subglobose spores, about $\frac{1}{1500}$ of an inch in diameter. The tufts of threads gradually become compact, and are converted into granular bodies about the size of Mustard seed, which are connected by a violet web. These bodies are in general quite smooth, but occasionally they retain about them little tawny patches still showing traces of the original threads. There is no distinct nipple-like tip, as in R. violacea (crocorum). They resemble more nearly the granular bodies on the plant when growing on Lucerne. It is probable that the perfect fruit has not yet been discovered, and the bodies discovered by Mr. Broome at present can be only regarded as a secondary form of fruit (conidia). *M. J. B.*

—— In a paper on the Fossil Plants of the coal measures, recently read before the Royal Society by Prof. Williamson, the common relationship of the Lepidendron and Sigillaria was insisted on, and the separation of the latter from the former as a group of Gymnosperms, suggested by Brongniart, was held to be untenable. The remarkable development of exogenous woody structure in most members of the entire family was considered to indicate the necessity of ceasing to apply to either of them, or to their living representatives, the term Acrogenous. Hence the Professor proposed a Division of the Vascular Cryptogams into an exogenous group, containing Lycopodiaceæ, Equisetaceæ, and the fossil Calamitaceæ; and an endogenous group, containing the Ferns; the former uniting the Cryptogams with the Exogens through the Cycads and other Gymnosperms, and the latter linking them with the Endogens through the Palms.

—— At a recent meeting of the French Academy of Sciences, it was remarked, in connection with the Extraordinary Cold experienced on May 18 and June 3, 1871, that in 1802 hoar frost was observed as late as the month of July. This appears to have been the worst year known for low temperatures in the summer months.

—— The Maximum Temperatures of the Air during the week ending September 7, ranged from 76°.3 at Blackheath, to 64° at Greenock, with a mean for all English stations of 72°.1, and of all Scotch of 67°. The Minimum Temperatures of the 8th ranged from 48°.2 at Bradford and Portsmouth, to 40° at Perth. The mean for England was 46°, and for Scotland 48°.8. The Mean Temperatures ranged from 60°.5 at Blackheath, to 54° at Perth, with a mean for the southern country of 58°.1, and for the northern of 56°.4. Rain was recorded as having fallen at all stations, and at three places falls of 2 inches or more occurred, viz., Portsmouth, 2.15 inches; Birmingham, 2 inches; and Wolverhampton, 2.52 inches. The mean fall for England was 1.42 inch, and for Scotland 0.44 inch. (See Mr. Glaisher's Tables in present issue, p. 1203.)

—— It is curious that we have now before us another case, quite different from those previously noticed (p. 1162), of plants attacked by Cladosporium Lyci-color. A large Cucumber, arrived at its full growth, and in consequence turned yellow, has been forwarded to us by Mr. Thos. Thornton, which is clearly attacked by the same Fungus. We have not detected it on the leaves, though very possibly, had they arrived in better condition, we might have detected the presence there. The Fungus in question is different from Myxosporium oribiculare, which is very common on decaying Gourds, and which is believed by Messrs. Tulasne to be merely the pycnidia of one of the commonest of Fungi, Sphæria herbarum. It indeed resembles it at first sight, but the spores are very much smaller, and equal in size. In the Glœosporium they are frequently $\frac{1}{1000}$ of an inch long, whereas in the Myxosporium they do not exceed $\frac{1}{2500}$. There are three other species found on Gourds, in all of which the spores are different. *M. J. B.*

—— The Botanic Garden in connection with Clifton College is now fairly established, and contains over 1000 hardy herbaceous plants, arranged according to the natural system. The arrangement is similar to that adopted in the herbaceous ground at Kew, consisting of long narrow beds, with grass paths between. A rockery has been built for alpine plants, and there is a collection of the common ornamental trees and shrubs. We learn from the last "Marlborough Report" that the Botanic Garden there has "fully realised the hopes of its originators;" and special subscriptions are solicited towards the expenses incurred by its formation. In both schools the herbarium receives many additions, that at Marlborough being already of very considerable extent.

—— Dr. George Bennett has published an interesting paper "On the Introduction, Cultivation, and Economic Uses of the Orange, and others of the Citron tribe, in New South Wales." A full account of the introduction and cultivation is given, founded on the author's own observation, and the practical experience of some of the extensive Orange growers in the colony, and the establishment of farms for the cultivation of the Orange for its commercial value in the art of perfumery, is advocated. The paper is full of information on Orange culture, and Dr. Bennett considers, from his own experience, that the Orange may, with proper care and attention, be rendered the most profitable of all the fruits grown in New South Wales.

—— It may be useful at this propagating season to recall Mr. Webster's observations on the Hardiness of Centaurea candidissima, published in one of our monthly contemporaries, and in which he says it is in reality perfectly hardy:—

"I have had it tested through the last winter (1869) in different situations; one of them was behind a north wall, where the sun's rays could not reach from September till March, and another at the base of a south wall, with full open exposure. The frost was long and severe, and a better trial of the power of endurance could scarcely have been had, as we had little or no snow to cover the ground. In some open and exposed places the frost penetrated a foot or more into the ground. Notwithstanding all this, the Centaureas came unscathed. It was curiously and firm as the outdoor ones. It will be an important matter to many to be able to save the winter room these plants occupy."

This was written from Gordon Castle, in the North of Scotland.

—— The energetic Dr. Ferdinand Mueller has lately delivered at Melbourne a "Popular Discourse on the Application of Phytology to the Industrial Purposes of Life," which is admirably calculated to direct attention to the subject, and contains, in a small compass, a vast number of suggestive facts. He advises the extensive introduction of foreign plants, especially such as could easily be naturalised, and are of practical importance; and advocates the permanent exhibition in the rooms of the Industrial Museum of "instructive portraits of all the edible and noxious plants likely to come within the colonist's reach." The subject is treated in a light and simple style, but none the less likely on that account to be impressed upon the hearers of Dr. Mueller's lecture.

—— In our answers to correspondents, May 27, 1871, is one relative to Spot in a Double Pelargonium sent by "W. C. B." After stating our opinion that spot arises from bad cultivation, we added, "we shall endeavour to strike the specimen, and if it becomes healthy we shall then believe that it is a local affection." That specimen is now perfectly healthy plant, confirming our opinion. As regards the white patches on the stem, we have since seen a similar case, and are pretty sure that they are merely an exaggerated form of spot. The condition is probably uncommon, as we have not found any experienced cultivator who has met with precisely the same form of spot. *M. J. B.*

—— The French Government offers a prize of 20,000 f. to any one who discovers an effectual means of prevention or cure for the New Vine Disease caused by the Phylloxera vastatrix (Peritymbia Vitisana of Westwood).

—— The current volume of the Woolhope Club contains an interesting translation of Prof. Fries' Autobiographical Sketch of his Studies in Botany, and of the circumstances and difficulties which induced him to devote himself to the subject which was to render his name illustrious among botanists:—

"By the time I had completed my twelfth year I was acquainted with all the principal parts of speech of the word 'lamella,' there so frequently recurring. So, shortly after, walking with my father, I said to him: 'Dic, pater, quid est lamella?' for my father never suffered me to speak to him except in Latin, so that I picked up Latin even before my native Swedish. 'A lamella,' he replied, 'is a thin plate.' With this explanation, the phrase seemed to me to describe so happily the fructification of Agarics, that by the next day I knew all the genera contained in that excellent work."

A photograph of Fries accompanies the sketch.

—— Mr. Graham Dunlop, the British Consul-General at Havana, in his report for the year 1870-1, observes that the papermakers of England, who are in lack of materials for carrying on their craft, should give attention to the enormous quantities of Fibrous Tropical Plants and trees which abound in Cuba. Successful experiments have been made by local papermakers on the fibre of the Bamboo cane, and on some of the creeping parasitic plants indigenous to Cuba. The Consul hears that attention is being given in Jamaica to the preparation of the fibre of the Bamboo for the papermakers in America. This beautiful plant grows abundantly in Cuba, and could be purchased and crushed at very cheap rates. It is said to excel for paper all the fibrous grasses of late used by our papermakers, and to mix easily with the linen rag pulp and other more ordinary materials.

—— A notice issued by the Postmaster-General states that on October 5 next the following Reduced Rates of Postage for inland letters will come into operation:—For a letter not exceeding 1 oz., 1*d.*; for a letter exceeding 1 oz., but not exceeding 2 oz., 1½*d.*; from 2 oz. to 4 oz., 2*d.*; from 4 oz. to 6 oz., 2½*d.*; from 6 oz. to 8 oz., 3*d.*; from 8 oz. to 10 oz., 3½*d.*; from 10 oz. to 12 oz., 4*d.* Any letter exceeding the weight of 12 oz. will be liable to the postage of 1*d.* for every ounce, or fraction of an ounce, beginning with the first ounce. A letter, for example, weighing between 14 and 15 oz. must be prepaid 1*s.* 3*d.* A letter posted unpaid will be charged with double postage, and a letter posted insufficiently paid will be charged with double the deficiency. An inland letter must not exceed the dimensions of 2 feet 6 inches in length, 9 inches in width, and 6 inches in depth. Concurrently with the reduction of postage on inland letters, the inland sample post will be abolished. From the same date inland book packets will be limited to the same dimensions as inland letters, viz., 1 foot 6 inches in length, 9 inches in width, and 6 inches in depth, and to a maximum weight of 5 lb. Any book packet which may be found to contain a letter, or communication of the nature of a letter, not being a circular letter or not wholly printed, or any enclosure sealed or in any way closed against inspection, or any other enclosure not allowed by the regulations of the book post, will be treated as a letter, and charged with double the deficiency of the letter postage. Any newspaper which may be found to contain an enclosure will be charged as a letter. In other respects the regulations affecting inland book packets and newspapers will remain unaltered.

—— In the "Florist and Pomologist" for the present month, Mr. Bennett, of Enville, has the following seasonable remarks and Storing Potatos:—

"Potatos should always be stored away in as dry a state as possible; and should any disease be discovered among them, I would recommend that but small quantities should be pitted together, certainly not more than a cartload in a clamp. In the centre of this clamp should be placed a lump of lime about the size of a man's head, and before covering them in, they should receive a good dusting of quicklime. The lime absorbs the moisture during the time they are sweating, and in so doing prevents the tubers from overheating, whilst its application also greatly improves the quality of the Potatos; no doubt it absorbs much of the water from the tubers, and consequently they are much lighter than if they had not lime. After the tubers have laid in small pits for at least one month, they should then be carefully looked over, and may be placed together in one or more large clamps, in the centre of which should be placed a large basket of hard lumps of lime; or should the clamps be long, it will be found beneficial to insert other baskets at about 12 feet apart. The whole heap should also be sprinkled well over with lime before covering it up. I always prefer to have my clamps made low and narrow, for they are then less liable to heat than those which are made up wide and high."

New Garden Plants.

Epidendrum bicameratum, *Rchb. f.*—Epidendrum squalidum, *Lindl.* non Lex.; E. Karwinskii, *Rchb. f.*, supra, p. 710, 1869.

When I proposed to name this plant Epidendrum Karwinski, I overlooked the fact that there was already a species bearing that name—a terete leaved one. I hasten to correct the mistake, and to give a new name, in allusion to the two hollows on the lip. *H. G. Rchb. fil.*

Bolbophyllum chloroglossum, *Rchb. f., et Warm.*

Affine Bolbophyllo recurvo, Lindl. Labello basi utrinque unidentato.

Bolbophyllum chloroglossum, *Rchb. f., et Warm., Orchid. Lag. Sant. ined.*

Pseudobulbus conicus angulatus et sulcatus. Folium cuneato oblongum acutum. Pedunculus deflexus paucivaginatus apice longius racemosus. Bracteæ paleaceæ lanceolatæ obtuse acutæ ovaria pedicellata subæquantes, uniformes. Mentum bene rectangulum. Sepala ligulata, lateralia paulo latiora. Tepala lanceata, acuta. Labellum oblongo-ligulatum, apice basin utrinque dente exsiliente. Columna apice tridentata.

A small species in the way of B. recurvum, but quite

different in the lip. It has small whitish or rosy flowers, often with some purplish dots and a green lip. It was found at Lagoa Santa by Dr. Eugene Warming, the Danish botanist, and has been introduced from Rio Janeiro by A. D. Berrington, Esq., with whom it first was flowered. *H. G. Rchb. fil.*

SOPHORA JAPONICA PENDULA.

THE accompanying portrait of this beautiful tree forms one of a series of several beautifully executed plates, prepared by Messrs. Letts and Co., from photographs of specimen trees in the Knap Hill Nursery, and used to illustrate Mr. A. Waterer's admirable catalogue. To praise the beauty of the tree is superfluous; the portrait speaks for itself, and being exactly copied from a photograph, it tells no false tales.

Sophora japonica was sent by Father d'Incarville, in 1747, from China to Paris, whence it was distributed by Bernard De Jussieu. It is a handsome, fast-growing, deciduous tree, and yields a fine, hard, handsome wood. Loudon notes one remarkable property of its foliage, namely, that in the very hottest and driest seasons it does not turn yellow or drop off, as does that of most other pinnate-leaved Leguminous trees, its deep-rooting habit being the probable cause of this retention of verdure, a property shared by the pendulous variety which forms our present subject.

We find no mention as to how, when, and where the weeping variety of the Sophora originated, but MM. Decaisne et Naudin, in their "Manuel de l'Amateur des Jardins," state that it has been obtained by cultivation, and is preserved by grafting. Among weeping trees, they observe, there are few so characteristic as the Sophora. Grafted on the stem of an ordinary Sophora some few yards high, and pruned so as to form a regular head, this drooping variety forms a tree which, in aspect, is at once strange and graceful, and whose pendulous branches are not tardy in reaching the soil. It is noted by Loudon as one of the most ornamental of pendulous trees, a description which it thoroughly justifies; nevertheless it seems but partially and imperfectly known to the general public. Mr. Mongredien, in his recent book on Ornamental Trees, does not appear to be even aware that it is a distinct variety, as he says, when treating of S. japonica, "when grafted on a standard, so as to assume a pendulous habit, it produces a most charming effect." We trust, therefore, that this notice and the accompanying illustration may help to bring it into greater prominence, since it certainly stands in the very front rank of pendulous-habited trees. In the catalogue above referred to, it is mentioned as "one of the most characteristic of all weeping trees, and one of the greatest elegance and beauty. It is so thoroughly pendulous in habit that the branches seem to fall sheer down in tufts or bundles, like the spray of an interrupted but perpendicular waterfall. The pinnate leaves have also a drooping character, being too long to sustain their own weight, and hence they fall down in the same lines as the branches." The peculiar manner in which the branches spray out in successional tufts is noteworthy, and it gives a very marked and characteristic appearance to the tree during the winter, when devoid of leaves. We have here one of those elegant arboreal objects of moderate stature, which can be pointed out as appropriate for the decoration of any garden or pleasure ground, sure to find a fitting place, however large, and not the least out of place, however small it may be. *T. M.*

FIG. 273.—SOPHORA JAPONICA PENDULA.

PRACTICE AND SCIENCE.

[The following remarks *apropos* of this subject were made by Prof. Liebig at the anniversary of the Royal Bavarian Academy of Science, Munich, on March 28.]

WE celebrate to-day the one hundred and twelfth anniversary of our academy. Great historic events have taken place since last year's festival; a new Germany has arisen; the dreams of our youth have become reality, and Germany has ceased to be a mere geographical expression. The English people have nicknamed Germany the Fatherland; but this byword has now assumed, in their mind, a respectable meaning, giving rise to serious reflection, for it is so unexpectedly great that it cannot yet be quite comprehended. In trying to define the true causes of success of our German armies, we shall discover them to be the very same as those which have shaped our progress in medicine and agriculture.

Eminent physicians and advanced agriculturists have been known at all times, and renowned military leaders in like manner. For centuries the fixed idea has therefore prevailed that in the so-called practical avocations practice and experience were all-sufficient, and that theory was not to be depended upon; and why? simply because true theory was not known.

Practical knowledge and aptness are indispensable in following agriculture, and not less so in medicine; but we are now aware that absolutely certain results depend upon the knowledge of causes, and intimate acquaintance with all the active principles by which phenomena are influenced; we know that this knowledge is real theory, and that genuine practice is the art of bringing these principles into play at the proper time and of assisting in their reactions. The old practice, based upon uncertain rules, gave way to scientific practice, which is founded on unalterable truths,—the happy inspirations of a genius who grasped a certain law without being able to account for its causes, are resolved into principles, and can be worked out and applied by others. The exclusive property of the genius which constituted his superiority, could, by scientific application, be owned by all.

The foundation of the German empire and the German victories steadily following one another have the closest connection with those military events which, 66 years ago, overthrew and shattered into fragments the State of Frederick the Great,—a State antiquated and ossified in red-tapeism. One way only existed to heal the wounds of the State and to impart fresh vigour, and this way Prussia followed to the salvation of Germany; by the foundation of the University at Berlin in 1810, the year of the death of the high-minded Queen Louisa, the road had become visible and had been sketched out; the inexhaustible vigour of the mind succeeded where the limited and worn-out material forces were wanting.

German science was destined to become the source of a new and youthfully fresh political life.

Thus we observe the Prussian people labour perseveringly to acquire that power which science alone can give, and all have witnessed the result to which this long and stern struggle has led. The incidents of a war, such as a siege or a defeat, are owing to causes which may be traced as clearly as those of natural phenomena; and the real secret of the superiority of Prussian strategics consists in the study of military sciences upon the basis of exact methods of natural sciences, and in the thorough investigation of, and acquaintance with the principles ensuring success or defeat.

Among the branches of instruction at the military academy at Berlin, those natural sciences are most carefully studied which may be utilised for warfare, and the discoveries of the last half-century have been made available for military purposes. And just as the philosopher, in order to solve a problem in exact sciences, must commence with the small, apparently trifling subjects, before he understands and masters the greater one, so we Germans had to pass through a long course of schooling and training, while other so-called eminently practical nations named us dreamers; but it was science which, in 1866 as well as in 1870-71, defeated unsound practice; knowledge that imparted strength and stability to force, and created in our adversaries a fear akin to horror of the German system of spies.

Our colleague, Professor von Giesebrecht, in his address as rector of the university, has dwelt upon the part which the German universities had in fostering the national idea of unity among the German races; he showed how the national feeling, long a glowing spark, kept alive in legends, and then roused and reared by German poets, at last ripened at the centres of German science.

We are proud that our king was the first German prince to give expression to the national idea of a German empire, and this deed will remain a brilliant monument for him in history.

It may not be out of place to state publicly, on behalf of our academy, that a hatred of races between the German and Latin nations does not and cannot exist. We look upon the heavy misery which Germany has suffered in former times from the French as upon an illness, the pains of which are soon forgotten on recovery.

The peculiar disposition of the German, his knowledge of languages, his reading of foreign characters, the culture of his mind, render him just to other nations, often to the extreme of being unjust to himself; and thus we do not forget how much we owe the great French philosophers, mathematicians and workers in natural sciences, who have been in many branches our teachers and our prototypes.

Forty years ago, when I went to Paris to study chemistry, accident drew Alexander von Humboldt's attention upon me, and a recommending word of his induced Gay-Lussac, one of the greatest chemists and physicists of the time, to propose to me, a youth of twenty, to continue and to complete, under his assistance, an investigation of mine; he placed me in his private laboratory as pupil and assistant; the whole course of my life was thereby decided.

Never shall I forget the kindness with which Arago, Dulong and Thenard met the German student; and how many of my German compatriots might I name who, like myself, thankfully recollect the active assistance in the pursuit of their scientific studies, given to them by French *savants!* Warm sympathy for everything great and noble, and disinterested hospitality are among the finest traits of the French character; they will revive and become active again on the neutral ground of science on which the best minds of both nations must meet in the pursuit of the high common object, and thus the indissoluble fraternisation, on scientific ground, will assist in softening the bitterness which animates the French national feeling towards Germany, the consequence of a war forced upon us.

POTATOS.

I PRESUME it will generally be accepted as an undeniable axiom, that as long as we eat Potatos so long shall we strive to improve upon the respective characters of our existing stocks. The wonder, therefore, is, where shall we finally get to! We seem likely to continue eating Potatos, as long as we have to rely upon food for subsistence. What, then, will be the Perfections, Kings, and Queens, of future generations? Doubtless, marvellous indeed. Hitherto our efforts in the direction of Potato improvement have mainly been devoted to the respective features of earliness, quality, quantity, and shape; and in these features, during recent years, no inconsiderable progress has been made. The Potato disease has now brought to the front another demand upon the esculent, namely, a combination of early ripening with late keeping; a combination that is at present both anomalous and non-existent. It is true that for certain kinds the opinion has been pronounced that they largely possess these qualities already, but the assumption is too vague, and only based on partial testimony. As far as my experience has hitherto gone, it has led to these conclusions,—first, that just in proportion as a Potato ripens early, so will it commence to form an early growth in the succeeding year; and second, that the keeping qualities of Potatos, whether early or late, depend more upon the temperature of the place where they are stored than is generally acknowledged.

I am not aware as to whether the subject has been scientifically considered; although I seem to be little doubt that the matter has engaged the attention of scientific men ere now), but I have an impression that from the time it is ripe for lifting until the time that it is ready for planting, a chemical change is going on within the tuber, and that that process of change is accelerated or retarded just as the conditions under which the tuber is placed are favourable or otherwise. In a few cases, where specially cool stores or cellars are available, the growth of Potatos may be retarded, but in the majority of cases Potatos have to be stored where the temperature materially depends upon that of the external atmosphere, and too frequently upon conditions that make the warmth greater rather than less. Here no late keeping qualities will avail, except those that have resulted from very late ripening. The very best keepers I have yet met with are Yorkshire Hero, Lapstone, Yorkshire Hybrid, and Paterson's Alexandra, and these are all late ripening Potatos. I do not be surprised to find it to be generally acknowledged that an early ripening Potato cannot be converted into a long keeper.

A far more likely improvement to be realised is that which shall bring large crops of good-sized tubers in conjunction with haulm of very moderate growth. A coarse, rampant growth of haulm is an evil at any season, but especially so when the disease rages. Take that largely grown variety, the Regent, for instance, and note to what a height the growth has extended during the past summer. Not only has it made the disease worse than it otherwise would have been, but where in market or other gardens a green crop was put out between the rows of Potatos early, the strong growth of haulm has almost strangled it, and in many cases the plants are not larger than when first put out. To rectify this evil I should recommend the culture of the American Early Goodrich Potato instead of the Regent, as it is rather earlier, is quite as heavy a cropper, tubers as good in quality, and the haulm is much shorter, and of a dwarf robust habit of growth that would not interfere with the growth of winter greens. If any beneficial results to the Potato are likely to grow out of the grafting process it will probably be in the direction of shortening the growth of the haulm. Where the cross has really proved effective, this result has invariably been attained; and the lesson that Mr. Fenn has learnt from his experiments hitherto, comes to this, that his grafts in the future must be sorts that produce heavy crops of good quality, but are burdened with far too much top growth. The stocks will be selected from kinds that produce short haulm, but lack that prolificacy that is so essential to the production of a first-rate Potato. A variety grafted into Yorkshire Hero produced haulm just half the height of the parent, and with tubers proportionally small. Hero grafted into Onwards produced haulm about one-third less in height than the parent, with a fair average crop of the very handsomest kidneys. Next year the strong growing Excelsior Kidney will be the graft, and one of Mr. Fenn's new early kidneys the parent stock, a combination from which good results may be looked for. A heavy cropping kidney Potato of first-rate quality, producing a short stubby haulm of from about 12 inches to 18 inches in height and speedy in its results, would prove valuable.

I fear after all that speculation as to the probable character of the Potato disease will lead to far less practical results than will discussion on the best remedial or palliative measures that should be adopted. And I am not at all sure that we shall find in "early ripeners" one of the most effective. I have seen this year the very worst forms of the disease that have come under my notice developed in Myatt's Ashleaf, certainly an early ripener, thus showing that even the early kinds cannot escape the disease. And I have seen enough this season also to convince me that just in proportion as the soil is enriched with application of raw manures at planting, so is the disease found to exist in the crop. This fact has often been urged upon the attention of growers, but its lessons seem to be easily forgotten. To put in a dressing of raw manure with a crop of Potatos is positively to court the disease in its worst form. I have enjoyed comparative immunity from its ravages in the tuber in the whole of my stocks this year, and attribute it entirely to an absence of any form of dressing but superphosphate of lime. The worst features we developed where a few barrowloads of decomposed vegetable refuse was dug in with the crop. The wisest form of cultivation consists in manuring for a previous crop of some other vegetable; but where that plan cannot be adopted, then the manure should be wheeled in early in the winter, the soil being bastard trenched, and the manure placed below the top spit. Another prolific promoter of the disease is close planting. We are too anxious to clutch a heavy crop, and thus sometimes over-reach ourselves. It is better at all times to give 6 inches too much room between the rows than 6 inches too little.

Coming now to the special purpose for which this paper is written, I wish to say a little with reference to my Potato trials here during the past summer. It is no small comfort to know that the soil seems to suit the Potato admirably, and drops out no one large samples as nice, clean, moderately-sized tubers, that suit both my purpose and taste completely. My trials, in consequence, have been very satisfactory so far as a fair test of respective qualities are concerned, and fully bear out the opinions formed of the respective kinds in the report that I had to make in the autumn of 1869. this year to entering very fully into the various merits or demerits of the kinds I have grown, for the simple reason that we are in view of a public trial of Potatos at Chiswick next year; from whence not simply one person but a hundred or more may directly draw their own conclusions. Hence it will be seen that I have come to kinds of recent introduction would be absurd. It will be necessary to grow in large variety the best old kinds, not only for test purposes, but also to synonymise the various classes into which all new kinds must be placed. Thus, in the matter of early kidneys, it will be found very difficult to distinguish any real difference between Royal Ashtop, Veitch's Improved Ashleaf, Harry Kidney, and several others, all of which are of the true Ashtop type. One of the very best of all this batch is Alma, a first-rate early kidney, and one I hope that will not be overlooked at Chiswick. The old Early Walnutleaf is a character that I know of are the Early Walnutleaf Kidney and the Burlington Prolific *alias* Sandringham Early; but neither seem equal to the Ashtop varieties. As a second early, the Waterloo Kidney still holds its place as one of the very best and most distinct, but several kinds of recent introduction are so essentially Lapstone in character, that I venture at once to name a batch, that, should representatives of them come under Mr. Barron's hands next spring, I hope he will plant them all in a lump—Cobbler's Lapstone, Haigh's Lapstone, Pebble White, Huntingdon Kidney, Early Paget, Yorkshire Hero, Rixton Pippin, Daintree's Kidney, Beaconfield, and Headley's Nonpareil. All of these have the true Lapstone blood in them, and have about the same difference in the appearance of haulm as exists between the famous "tweeddledum and tweeddledee." In the relative differences of quality and crop. They consist of Webb's Imperial, Emsworth Kidney, Wormsley Kidney, Excelsior, Coombes' Favourite, England's Fair Beauty, Cumberland Bangers, Chagford's, and Bryanstone Kidney, several of which have the positive merit of being first-rate Potatos. I take to be Webb's Imperial, Wormsley Kidney, and Excelsior. Closely allied in character is Milky White, Prince of Wales, and Berkshire Kidney, and these should be planted in close company to the others. One of my favourites still stands in a good position—the King of Potatos, sent out by the Messrs. Sutton, and the best of all their stock. It is a good clean second early kind, tubers always smooth and handsome, and a good cropper; the flesh unfortunately is yellow, but the flavour is good. It is a capital companion variety to the Waterloo Kidney, but lacks the whiteness of the latter kind. To lovers of the Fluke I can fully commend King of Flukes as a first-rate cropper and moderately early, and one of the best of its tribe. Mr. Taylor's new graft kidney, Yorkshire Hybrid, bears a close resemblance in the tuber to Golden Blossom, being of the old-fashioned type, large at one end and small at the other. The haulm is robust and it ripens late, but it is so highly commended by Mr. Radclyffe as a good keeper that I shall offer no further opinion upon its merits, preferring to leave that point to the Fruit Committee next year.

Coloured kidneys are becoming more abundant, and where prizes are offered for them, as is the case at many provincial shows, it becomes a matter of importance to the grower to have a good selection from which to choose his sorts. Fortunately colour is not their only recommendation, as there is no deficiency of other good qualities also. Of purple kinds, the two best are the old Purple Ashleaf for early showing, and Paterson's Blue Kidney, a really excellent white-fleshed and productive kind for later exhibitions. The old Red Ashleaf sometimes does good service, but is not so certain as is the wonderful Red Kidney, a handsome high-coloured variety. Somewhat alike in colour to the Early Rose, but generally handsome and more refined in appearance, is Mr. Allen's Eureka, a really fine Potato. For a red kidney for cottagers' growth none can beat the Cottager's Red, a high-coloured Potato, that is an immense cropper, of robust habit, and, though yellow in the flesh, is of most excellent quality, and having no deep eyes does not cut to waste. It keeps very late.

Round Potatos at present offer no very special features of novelty. Mr. Turner's Union is one of the best early white kinds, and will be largely grown. Fenn's Onwards is a first-rate second early, both in crop and quality. Early Emperor is still the very handsomest red kind, of the highest quality, and Paterson's Scotch Blue, as a pebble-shaped purple, is not excelled; this latter variety is a capital one for small gardens, as it produces so small an amount of haulm, and is yet a good early cropper, while the flesh is very white and good. Two very handsome later red kinds are Wellington, a white tuber, heavily blotched with red; and Red Emperor, with rough red skin. Both of these should be grown for late showing. Magpie has a tuber coloured nearly black and white, more novel than taking; whilst the finest purple-skinned kind is Alexandra, a fine late-keeping Potato, having very white flesh and of first-rate quality. These are just a picking from those that I have grown, the number that I have grown of round kinds. The American kinds have also come under notice, and include American Rose, King of the Earlies, Climax, Peerless, Prolific, Early Goodrich, Early Calico, Callao, Gleason's Late, and Mr. W. Robinson's Mormon Queen. King of the Earlies and Climax have far too many eyes for my notions of beauty, but I like Peerless better, and Prolific best of all. Putting aside cooking quality, in which respect all these kinds are much alike, I put Prolific as the very best of all the Transatlantic introductions. It would be all the more valuable were the colour of its skin pure white instead of being tinted with brown. Early Calico is the only purple variety, but it has very white flesh. Callao is a good cropper, producing tubers of a delicate flesh colour. The most singularly marked of all the kinds is Gleason's Late, a flattish late round, having a white coat heavily banded with red; when grown in light open soil it produces very handsome tubers.

I have grown here also this year some 40 or more of Mr. Fenn's more recent batch of seedlings, amongst which are some of exceedingly high promise. In the front rank comes his new Rector of Woodstock, the handsomest white round kind I have yet seen; it is a first-class Potato in all respects, and has been so acknowledged at South Kensington. Eliza Fenn and Goldfinder are also handsome kinds, of special merit; and as a hotel-shop Potato, to cook and look good, Mr. Fenn especially recommends the Mayor of Woodstock, so named in compliment to a respected hotelkeeper, the holder of that important office a year since. Cricket Ball and Cottager's Blush are two very handsome red kinds, and Betsy's Favourite is a handsome tuber blotched with purple.

Of the kidneys none can exceed in beauty Bountiful, a beautiful red kind and very productive. English Rose somewhat resembles its American *confrère*, but with more colour and fewer eyes; whilst of the white kinds, Mary Bowers will carry the sway for beauty. These, and a few of the best of the others selected for further trial next year, and of which Mr. Fenn will show samples at Kensington on the 20th.* He is devoting his energies to the production of kinds of sterling merit, and in the promotion of that object will not hesitate to destroy all that do not come up to high standard. In this well known small-growth section two most excellent early kidneys have been selected as likely to be suitable for forcing in pots, and are named Little Gem and Multum in Parvo. Perhaps Mr. Barron would not object to test a few of each kind in that way at Chiswick.

In concluding this paper, I would add that I am satisfied that no really useful trial of a large variety of Potatos can take place unless there is in the planting such an arrangement of sorts as shall throw all those kinds that have similar qualities into immediate growing contact to each other. In this way the work of censors is not only greatly simplified, but the labour of testing the merits of new kinds against older sorts of a similar character is rendered much easier. The process of synonymising is also materially aided, and if from 200 to 300 kinds are grown, it will be surprising what a "slaughter of the innocents" in this one respect only will take place. In all these respective matters I shall be only too happy to afford Mr. Barron the benefit of any small experience I may

* We understand that the Messrs. Sutton & Sons, of Reading, also propose to exhibit a large collection—some 50 varieties or more, including all the American sorts, as well as Suttons' Red-skin Flourball—on the same occasion. Eds.]

possess, and none will watch the proposed Potato trials at Chiswick next year with greater interest than *Alex. Dean, Belfont.*

BOTANY FOR BEGINNERS.—XIV.

In the preceding articles we have endeavoured to put before the reader descriptions of some of our commonest flowers. We began with those having the smallest number of parts and the simplest structure, and proceeded from these to others of more complicated construction. Moreover, we have endeavoured to explain the reasons for the increased complexity, so that the pupil who has followed us so far should be able, when he meets with any flower, no matter what its lineage may be, to form a pretty accurate opinion as to the points in which it differs from the simplest form of flower, and how those diversities may be explained, whether by addition of parts, their imperfect separation one from the other, their union one with another, their irregular growth, or what not. Incidentally we have called attention to the other parts of the plant, but, in the main, we have confined our attention to the flower. It is, however, absolutely essential to any one who wishes to know something of botany that he pay heed to the mode of growth, and to the forms of roots, stem, or leaf. These points are too often neglected by the beginner and the amateur, owing, perhaps, to the superior attractiveness of the flower over the other parts of the plant. No one with a real love of his subject will allow of such a plea; moreover, a very little study will show that the lessons to be learnt from these less gaily bedight organs are to the full as important as those taught by the flower. Moreover, they are of cardinal importance to the right understanding of the flower; and, again, they can be studied at all times and seasons.

As we are now about to deal mainly with the form assumed by the stem, and with the arrangement of the branches and leaves, it is as well to begin at the beginning, and to cast a glance at the baby plants as they emerge from the seed. Our countryman, John Ray, was one of the first to discover and make known the great importance of attending to seedling plants.

Some things, like a tropical Orchid of great price, are important from their rarity; other things, like the humbler Cabbage, are important from their frequency. It is in this latter sense that seedling plants are valuable to the botanist, and John Kay had the sagacity to see that, so far as constancy is concerned, there was no better mode of grouping the entire mass of flowering plants of all sorts and descriptions known to him than that furnished by the seedling plants. Speaking broadly, and disregarding for the moment exceptions too few in number to affect the general result, all flowering plants may be ranged under two categories, those whose seedling plants have one seed-leaf, and those which have two of equal age. These seed-leaves are known as *cotyledons;* and plants with one seed-leaf are called *monocotyledons;* those with two, *dicotyledons.*

The importance of this distinction is shown not only by its very general—almost universal—application, by its constancy as a botanist would say, but by the fact that this arrangement is almost invariably associated with other marks of difference between the two groups; and so we have cumulative evidence as to the distinctness of the two. For instance, Dicotyledons have almost invariably net-veined leaves, and the parts of their flower arranged in fours or fives, or some multiple of those numbers—their wood, when they have any, is arranged in annual zones, zone over zone, from the centre outwardly; while Monocotyledons have—barring a very few exceptions—straight-veined leaves, the parts of their flowers are in threes, and their wood is not arranged in zones, not to speak of other characteristics. This is enough to show the importance of paying some attention to the seedling, and there is no reason why, when a seedling cannot be got, its general characteristics can be pretty safely inferred from the leaves, or flowers, or wood, as just mentioned.

To illustrate the two forms of seedling, our artist has delineated a seedling Oak (fig. 274) and a seedling plant of Wheat, and we will advert to the more important features of each, premising that the beginner need not experience much difficulty in seeing these things for himself.

Grains of Wheat are easily procurable just now, and acorns (as well as, or, failing them, a Broad Bean or a Pea will serve the purpose equally well. Let some of these be sown in moist earth or sand in a flower-pot, or in damp moss or sand, and kept in a moderately warm place, and soon the life within the seed, at first not obvious, will make itself seen. It is a capital plan to suspend an acorn or other large seed in a bottle half filled with soft water; so that the seed just touches the surface of the water, put the bottle into a dark cupboard for a few days; for the exposure to full sun is not propitious to the first stages of plant growth; and when the shell cracks open and a root makes its appearance through the rent, then the bottle may be brought out from its obscure retreat, and the whole further process of germination witnessed.

The shell of the acorn is the true fruit—the ovary arrived at maturity, and greatly changed in appearance from what it was when it nestled like a tiny egg in the nest-like cup then bigger than itself, but since by comparison dwarfed. Within the shell of the acorn is the seed proper, whose structure we have now to explain. If an acorn be not at hand, a Bean or an Almond will answer the purpose as well, especially if previously soaked for a few hours in water.

The great mass of the acorn consists of two thick fleshy lobes, rounded on one surface, but flat where they come into contact one with the other; these are the two seed-leaves, the cotyledons, thick and fleshy, because they are the store-houses of food whence the young plant may derive its supplies before the root and leaves are able to supply its requirements (fig. 274, A, A). The seed-leaves are not always like those of the Oak. In other cases they are thin and green, soon pushed up above ground to fight for themselves, and differing but little, save in contour, from the ordinary leaves of the plant, indeed, fulfilling the same office as they do. Now, supposing that there is but little nourishment stored up within the tissue of the seedling plant, or within the seed investing it, it stands to reason that the seedling must quickly shift for itself, or succumb for want of proper nourishment. This is one reason for the quicker germination of some seeds than others; for instance, the common Mustard germinates very quickly, as every one knows. It sends its roundish, notched seed-leaves up above ground into the light and air with all possible despatch, to get food for the young plant.

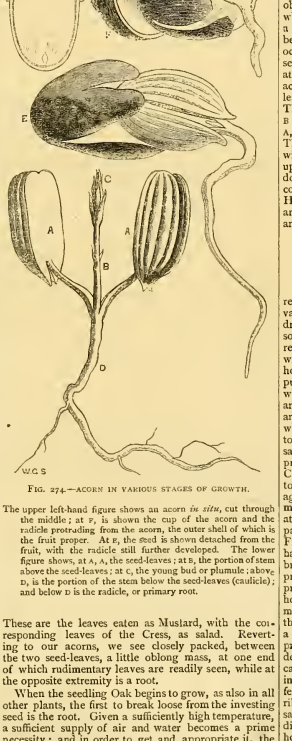

FIG. 274.—ACORN IN VARIOUS STAGES OF GROWTH.

The upper left-hand figure shows an acorn *in situ*, cut through the middle; at F, is shown the cup of the acorn and the radicle protruding from the acorn, the outer shell of which is the fruit proper. At E, the seed is shown detached from the fruit, with the radicle still further developed. The lower figure shows, at A, A, the seed-leaves; at B, the portion of stem above the seed-leaves: at C, the young bud or plumule: above, D, is the portion of the stem below the seed-leaves (caulicle); and below D is the radicle, or primary root.

These are the leaves eaten as Mustard, with the corresponding leaves of the Cress, as salad. Reverting to our acorns, we see closely packed, between the two seed-leaves, a little oblong mass, at one end of which rudimentary leaves are readily seen, while at the opposite extremity is a root.

When the seedling Oak begins to grow, as also in all other plants, the first to break loose from the investing seed is the root. Given a sufficiently high temperature, a sufficient supply of air and water becomes a prime necessity; and in order to get and appropriate it, the root descends—always descends—it may ascend for a time if put out of its course by any obstacle, but left to itself down it goes—a pretty good mark of a root: and note, it goes down continuously (provided there be no obstacle) as long as there is any necessity for it to do so, it is not arrested in its course, but continues to go on in the same direction as that in which it started—this is continuous growth. In other instances, as we shall see by-and-by, growth proceeds in one direction for a time, and then, from some cause or another, growth is checked; and if renewed, it goes on in another direction, at an angle to the former line of growth, perhaps in an altogether different place. Here we have illustrated two facts never to be lost sight of in studying plant growth—the continuous or indefinite mode of growth, as contrasted with the arrested or definite mode of growth.

The root of the acorn, under natural circumstances, and if not interfered with, developes into a tap-root, a valuable form for anchoring a plant in the soil, but not so desirable in the eyes of the nurseryman, who has occasion to shift the young plants, and hopes ultimately to transfer them altogether to fresh fields and pastures new; for this purpose a tuft or leash of roots is better than a single one. In transplanting there is less chance of cutting off the supplies when there is a tuft of fine feelers than when there is but one; hence it is a not unfrequent practice to pinch or cut off the end of the tap-root, after a little while, when a number of fibres or thread-like roots are developed, to carry on the work heretofore conducted by the one tap-root.

At the opposite extremity of the seedling plant are, as already said, the rudimentary leaves (fig. 274, C), packed in what is virtually the first bud. As this grows it lengthens upwards in a direction precisely opposite to that of the roots; the latter want water, and go down in search of it; light and air are essential requisites for the leaves, and they are thrust up to seek these life-giving elements. We know the fact, we know the object of this upward and downward growth respectively, but the way in which it is done is still, despite many curious experiments and much hazy speculation, obscure. Now it is a canon in botanical science that whatever bears leaves and buds is a stem, or a part of a stem, a branch, and that, per contra, a root never bears leaves and buds (always making allowance for occasional and very rare exceptions); hence in our seedling Oak that portion to which the seed leaves are attached, and which bears the young bud, is to be accounted stem, and that portion which bears neither leaf nor semblance of leaf and goes down is root. Thus, in our illustration (fig. 274), the space from D to B is to be considered as stem, bearing two seed-leaves, A, A, and a terminal bud, C, sometimes called the *plumule*. The portion below D is the *radicle*, or true root. It will be noticed that the portion from D to B tapers upwards, while below B the tapering is from above downwards. This outward difference of appearance corresponds with an inward difference of structure. Here we must leave our seedling Oak for the present, and defer the consideration of the seedling Wheat till another opportunity.

Home Correspondence.

The Potato Disease.—I was pleased when I had read your leading article on the improvement and cultivation of the Potato. It will prove a great means of drawing public attention to the esculent, which forms so important a part of our national food. I should require quite another seven years of life to meet the writer's views. By that time, if I am spared, I have hopes of being enabled to find the requisites there put forth. In order to do so, we must work to get white-fleshed early Potatos, with a smooth outline and few eyes, and which must also have good keeping and non-sporting qualities. I believe I have varieties which come as near to those requirements as any up to the present time. But my cropping desires are not satisfied. How nearly they are likely to become so, I propose to show next year in the rare old garden at Chiswick, under the care of Mr. Barron. I intend also to give the judges and critics on Potatos an opportunity again to try and discern for themselves the qualities of my improved and latest selected seedlings and crosses, at South Kensington, on the 20th inst. Mr. R. Dean's paragraph answered at once the chief request of Mr. Fish. I must beg, nevertheless, to thank Mr. Fish for having referred to my personality in a kindly manner but I fear that the "gold medal in bas-relief" would prove too uncomfortable for a civilian to wear. I am proud, however, to inform him that my cabinet already holds gold and silver medals, won by the sweat of my brow, and in fair competition; but honours of this sort are not thought proper for such as us to make a display of. "Emblazoned" medals can only be proudly and conscientiously "worn" by the destroyers of our species, so that my "best taters" can never be represented on my breast, though I trust in time that the worthy defenders of our country will feel the benefit of them in the way of "sticking to their ribs." Practically, as regards myself, I can happily say that I have grown better Potatos since than I ever did before the advent of the disease. I remember well how the barbarous "good old plan" used to play pranks in the form of dry rot, bobbin-jones, gapp-plots, &c. For the how and "wherefore of all this," I would refer Mr. Fish to the pages of a contemporary for many consecutive years, only I feel that it would be a work of supererogation, as in every probability he has been as familiar with those columns as myself. I may mention, however, that I have never laid special claims for my practice over that of my fellows. What I have done and written has been for the sheer

love of the thing, and to try and impress upon Potato growers to do likewise for their own good. In answer to "A. D.," I stated that the Potato was not a special victim to electricity. I think my critics have read my paper hastily. I said it was subject to be stricken by electricity, more so at the particular stage of growth which I pointed out, and this is still my conviction. The circumstance has become too familiar to my senses to allow me to "guess" about it. How to prevent it is what I also "want to know," and in this way critics do not help me in the least. Suppose I was to propose encircling our Potato grounds with galvanic wires as lightning conductors! Well, that is certainly no new idea of mine, so I take heart of grace, and feel to tread the earth firmly. But how about my new seedling crops, now growing in the orchard-house under glass? In lieu of "disproving the agency of electricity," it rather appears to confirm it; at any rate, some discovery is lurking anent the glass, either as proving it to be a non-conducting or repellent power, so far as the seedling Potatos are concerned, or why should they there remain scatheless? The glass certainly "rules" them unisonorous of the "disease originating force." An enthusiastic Potato lover, and a very good neighbour of mine, "steps in" occasionally to "smell the old Potato smell" given off from their green and flourishing tops, and to witness the yellow dying off of the foliage of the precocious ones, as I "used to mind and see them" during a hoe. I believe I shall eventually take up every tuber of them free from the least sign of disease, and I am keeping them constantly watered, both tops and bottoms, longer than is at all necessary, on purpose to test the wet theory, if it be a producer of the murrain, to the uttermost, and, in this case, to allay the surmisings of any afterdoubts of criticism. Per contra, those seedlings which I transplanted into the open yard, I took up, what remained of them, three weeks since. The haulm was black with disease, the greater part of it quite rotted away, and the young tubers diseased. Of these remained no murrain had attacked the mmore or less; they "keep going" to this very day, and I shall not be able to preserve one-third of them. The tempests proved too much for their voyage, and if it was not owing to electricity in connection with the "white rain," I must ask critics to convince me otherwise, for these seedlings were as healthy and promising before the lightning, thunder, and the rain came as their prototypes under the glass close by. Why did they not remain so, if my theory is incorrect? Again, in the open ground in this garden I have some tubers planted later than my general crop, which have taken the place of a bed of blind Strawberries. On August 9 they were in midgrowth, green and flourishing, with scarcely a fault upon their foliage. On the 13th I was walking in the evening, in the county of Middlesex, with he of Bedfont, and before us, and afar off, we became witnesses to the quick uprising of a magnificent outline of dark clouds. Nature's artillery was there, though silent for us. I said, "If that tempest is breaking in its full force over the rectory in Oxfordshire, and it pass away at once, my late planted Potatos will suffer no harm in their entirety, more than by becoming stricken with the 'spot.' Should the storm linger thereabouts, for only one day, the spots will become surrounded in their margins by Fungus mould; and should damp muggy weather continue upon the tail of that storm for two or three days, the 'zoosporces' that Mr. Berkeley said as of would, as an effect, and not as a first cause, become generated in continuation of the deadly work begun in the first instance by electricity or 'fire blight' (see p. 1135) upon the leaves; and the more glazed and firm of texture the leaves are, the more resistance they offer to the above destroying powers." I have one seedling Potato now in its fourth year of trial, having leaves of peculiarly firm texture, and remarkably glazed. This has stood throughout the season's ordeal triumphantly; all my other sorts have been spotted more or less, but that, I am happy to say, is not my chief harm. I never had better crops of Potatos, taking them altogether, and they are all of my own originating. Well, I returned to Woodstock on the 15th, and soon inquired if they had experienced a thunder-storm on Sunday night. "No," my wife said; "it lightened very sharp, but we had tempest with rain, slightly, all yesterday." I hastened to inspect the healthy foliage I left behind me, and upon it, sure enough, was impressed the fatal spot, and its accompanying Fungus mould, though the splendid after weather completely stopped it from doing further harm. The Potatos are ripe, and still in the ground, without, I believe, a single trace of the rot to be found upon them. I would ask your correspondent, Mr. Taylor, is there any other esculent under the sun that has suffered the neglect which the Potato has, in contention of Nature's intentions? Then pray do not let us go back; let us begin again, and try by good cultivation and care of the noble tuber to bring back that sound pristine health and primeval constitution, now lost to it through supineness and neglect. Useless retorts can do no good; the evil stares us in the face. In conclusion, allow me to relate how that I planted more Potatos in this garden on August 8, for the furtherance of the electrical test if possible; how they are now flourishing in full greenery of haulm; how they experienced rain for the first time on their foliage last Saturday the 2d inst., also on Sunday again. Yesterday (Wednesday) we had 12 hours of downpour, to-day it has been splendid weather. I have minutely examined the foliage, and not a single "spot" is visible upon it. We had no tempest with the rain; the air is not charged with electricity, but feels cool and refreshing, and the rain was not what is termed "white rain." *Ex nihilo nihil fit. Robt. Fenn, Rectory, Woodstock, Sept. 7.*

Propagation of Oaks.—Having what is believed to be a valuable golden variegated form of the Turkey Oak, which I believe is quite new, will you kindly advise me as to the best means of increasing it—inarching cannot in this case be practised. If budding be practised, should it be done in the open ground, or would it be better to procure a few stocks in pots, and work it in a frame? or will grafting, if properly done, be pretty certain? *R. A. D.* [We referred this letter to Mr. Charles Lee, of Hammersmith, who kindly furnishes us with the following reply:—" After several years' experience in propagating Oaks, I find that the only safe method is inarching. A very experienced grafter may get one in four or six to take, but it often results in the success of one in ten. Grafting on established plants in pots, under close handlights, may be more successful, but it wants much experience."]

Peach Culture at Madresfield Court.—The kitchen garden at Madresfield is a comparatively new one, and the site chosen is well adapted to the growth of fruit trees in general, the soil being of a calcareous nature. The walls are all newly built in height, and the trees have been planted five years. They are for the most part trained horizontally from an upright shoot, a mode of training which we seldom employ, although a favourite system with the French, and one which has, no doubt, some advantages, one of which is that a wall is covered with wood in the shortest possible time. And by this form of training Mr. Cox has in five years succeeded in covering the whole surface with the fresh green of the Peach tree, while the growth has been perfectly regulated, presenting an elegant appearance, reflecting the highest credit upon the cultural skill displayed by the gardener. It is the finest display of Peaches and Nectarines I ever beheld. To those who in despair announce their intention of giving up Peach culture on open walls, I would say, go and see for yourselves what is done at Madresfield, and judge whether such results are not worthy of great endeavours to imitate. The wall coping projects about 6 inches. This Mr. Cox considers of great advantage. When wide, permanent copings are objected to, it is best to have brackets permanently fixed into the wall, to receive temporary copings, for there is a doubt that, with wide copings, we should suffer less from the vicissitudes of our climate; and protection from spring frost is of first importance, for without this necessary precaution not only the blossom-buds, but the trees at times, suffer irreparable injury, and this without a doubt is the predecessor of those tree-limbed, unsightly-looking objects one sometimes sees, and which are a disgrace to gardens. The Madresfield Court Black Muscat, which originated in these gardens, is planted in several of the houses, and from its distinct and bold characteristics is at once discernible amongst the others, and is well worthy a place of the high encomiums passed on it. *George Westland.*

Influence of Scion upon the Stock.—I have not seen the following quoted amongst the illustrations of this which have been collected:—"'Tis by the descent of the particles from the graft, and their reascent, that the variegations appear in the other parts of the shrub: a pregnant example of which happened to Mr. Bridgman, gardiner at Hertford, who engrafting the Holly with ivy, into a Holly, which had another variegation appear'd afterwards below it, upon the same stock." (Blair's "Botanick Essays (1720), p. 386.) *W. T. Thiselton Dyer.*

Acer Negundo variegatum.—I am not quite sure that this very pretty hardy deciduous shrub is so well known as it deserves to be. I have been much pleased this summer with the effect which some standards planted in the shrubbery border here produce. In looking through a conservatory in a large establishment lately, I was agreeably surprised to see it used in the shape of low bushy plants for decorating; and well it looked, intermixed with other plants. I presume it was growing on its own roots, as the standards bought in are worked upon a green variety. I consider this one of the most striking "variegated plants we have, either for use indoors or out. *T. Wynne, Holbrook, Suffolk.*

Polemonium cœruleum variegatum as an Edging Plant.—Having failed to observe in the various reports on bedding plants which have from time to time appeared in your pages any notice of this comparatively scarce hardy herbaceous perennial as a bedding plant, I am induced, for the benefit of some of your readers, to remark that as an edging plant in particular it is entitled to prominent position, and especially in combination with Coleus Verschaffeltii its charms are eminently conspicuous, the rich crimson-purple coloured foliage of the Coleus contrasting so charmingly with the unique and elegant variegated Fern-like leaves of the Polemonium, as is exemplified by an example in one of the flower gardens here, which signally eclipses contemporaneous beds of Coleus and Iresine Lindeni, respectively edged with Geraniums Golden Fleece, Crystal Palace Gem, and Cloth of Gold—all of which are in a flourishing condition, lacking, however, the compact habit and elegance of the Polemonium. Apart from its excellent bedding quality, it possesses the property of comparative hardiness, requiring merely the protection of any cold glass structure throughout the winter, and if placed in a little heat early in the spring a quantity of side shoots is soon afforded, which if slipped off and inserted in small pots speedily become established plants. For indoor decorative purposes it is also invaluable, especially for table decoration. Amongst other novelties allow me to notice Mesembryanthemum cordifolium variegatum, which is also a charming edging plant, especially for small beds. At the present time I have it doing duty as an effective edging, in association with blue Lobelia, tea bed of Lady Constance Grosvenor Nosegay Geranium, and it is much admired alike for its pretty diminutive purple flowers as for its neat heart-shaped foliage. *William Gardiner, Lower Eatington Park.*

Blue Apron.—Is it possible to get the true stuff for making gardeners' aprons anywhere? if so, where? For many years now I have had the greatest difficulty in getting anything like the stuff that we used to be able to get quite commonly. Possibly the reason is, that the young gardener of the period is too much of a dandy to wear such a thing as an apron (if so, small credit to him), and that consequently there is no demand for gardeners' apron stuff. May I throw out a suggestion to the nurserymen: could not they add it to the list of things that they keep for the accommodation of the gardener; and thus every gardener, when he ordered his seeds or plants or bulbs, could also order his apron stuff at the same time. *N. H. P.*

Thujopsis dolabrata.—In answer to the request of a correspondent in your last, I send you the dimensions of a Thujopsis dolabrata that we planted here in 1863. It is 6 feet 6 inches in height, 5 feet 6 inches through the base, and 16 feet round the base. It was covered with cones this year for the first time. *T. C. Richardson, Gardener, Perryfield, Godston, Sept. 11.*

Moving Large Hollies.—It may be interesting to some of your readers, and those who attended the large sale by Mr. Stevens at the Royal Horticultural Gardens, to know that the purchaser of the bear that the whole of the large Hollies, 16 to 20 feet high, considered by many too large and unsafe to move, are all "alive and growing," breaking like Furze bushes, notwithstanding the severity of the weather just afterwards, and the accident they met with at the railway arches between here and Chiswick: several had 4 to 5 feet of their tops crushed, and others had to be shifted, in consequence of their being too high for the arches to admit them through. This was no easy task, as they were on ordinary stone trucks, and their weight from 1 to 2 tons each. *W. Yames Epps, Landscape Gardener, Lewisham.*

Extension of the Peach Season.—Much has been written in the gardening journals at different times, during the last few years, on the lengthening of the Peach season, and too much cannot be said in praise of such men as Mr. Rivers and Mr. Pearson, who, to attain this end, have directed their energies and great experience to producing early and late varieties of the Peach and other fruits. I feared previously been done towards the production of early Peaches, though, it is true, we have long had what were called "late October Peaches;" these were, for the most part, very insipid in flavour, but this is not the case with some of the new late Peaches—Rivers' Princess of Wales, for instance, which I have myself retarded till November, and found excellent. Those who have not gone to the expense of a series of glass houses are ever complaining of a glut of Peaches—all coming in at once, with a dearth of fruit before and after. The efforts that have been made by our great nurserymen (as before stated) have slightly obviated this evil, and the orchard-house has helped still further to the same end; for instead of boasting of 50 or 60 dozen Peaches on one tree, the owner of the orchard-house can show as much fruit in the same space as this tree grew, and that, too, under the most little divisions of different sorts, early and late, each containing their three or four dishes of fruit. But we want to extend the season far beyond these limits, and I have no hesitation in saying that it may be done, and with very little trouble. There is still considerable difficulty in persuading many gardeners that my "new method of growing fruit, &c.," is not a substitute for succession houses only, for no amount of succession houses would give the advantages claimed for it, and which are thus entirely overlooked. The high terms, however, in which it has been spoken of by some of our best gardening authorities, who have looked fairly into it without solicitation on my part, emboldens me to lay before your readers a process of extending the Peach season far beyond the limits which the new varieties command, and the pot system of the orchard-house further advances. I am, of course, not speaking of early forcing houses. It is unnecessary to do more

than touch upon the "new method" itself, as it is now pretty well known, being simply a combination winery constructed with movable platforms for trees and flowers, to be moved in and out of the house at will, and that at a moment's notice. Suppose a winery so arranged with five platforms: let the first be filled with the best early Peaches, Belle Beauce, Rivers' Early, Early York, &c., and let this platform be kept in the house as much as possible, except for an occasional warm shower in the early stage of the growth of the fruit, to keep the trees in good health; and let its occupants be subject to such warmth throughout their growth as the Vines have, till about a week before ripening, when they may be moved out, weather permitting, to flavour and colour the fruit. These Peaches being early sorts, and forced besides, will come in very early. Let the next platform contain early Peaches under mixed treatment; then would come mid-season Peaches, and, lastly, the best late Peaches, such as Walburton Admirable, Princess of Wales, Lord Palmerston, &c., and these should be kept entirely out of the house, as far as spring frosts and subsequent storms will allow, and, where practicable, shunted behind a north wall, to be retarded as much as possible, and then brought into the house in November or for the fruit to be ripened and finished off by fire-heat. This excessive retarding will, no doubt, affect the flavour of the fruit in some measure, according to the season, but it will produce Peaches when you cannot have them ripe at all by any other process that I know of, and also at much less expense, for one house will do the whole under the direction of a good gardener. *John Fountaine, Southacre Rectory, Brandon.*

Hardiness of Niphobolus Lingua. — It will interest many of your readers to know that what appears to have been an accident resulting from the disastrous siege of Paris, in the discovery of the hardiness of Niphobolus Lingua (as mentioned at p. 1098), may be of use to the out French frontiers of the concerned, but I may say that for the last 12 years I have planted this Fern in ordinary outdoor ferneries. Just 12 years since I was called in to enlarge and otherwise improve an outdoor fernery in this neighbourhood, and I was surprised to find a large patch of this singular Fern growing at an elevation of a yard from the gravel walk adjoining. It was in the most robust health, a round patch 18 inches through, made up of closely-packed foliage, as fine as any I ever saw grown under glass, and I was assured it had withstood the cold of several winters with perfect impunity. Since then, I have introduced the plant into hardy ferneries whenever opportunity has offered, and always have had reason to be satisfied with its hardiness. To insure quick and vigorous growth this Fern should be planted in lumpy, fibrous peat, and be liberally supplied with water till it is established. Under proper treatment, the wiry, mousetail-like rhizomes of this plant will push rapidly in all directions, and soon form fine specimens. Its dissimilarity to any other of the usual denizens of the outdoor fernery will render it an acceptable and interesting addition. *William Chitty, Stamford Hill.*

Taxodium distichum.—This superb ornamental tree is so little planted now, that I wish to draw attention to a very handsome specimen at Cadlands, near Southampton, the seat of E. A. Drummond, Esq. It is about 90 feet high, and the trunk is fully 12 feet in circumference at 6 feet from the ground, and bare to the height of 18 feet. It is growing close to a large ornamental pond, and in luxuriant health. Such a situation appears always to suit this tree, and both it and the pendulous form ought to be more generally planted. It is also known as Cupressus distichus, the deciduous Cypress. Close by were fine specimens of Hydrangea japonica and Magnolia grandiflora in flower, the latter shrub being extensively planted in the open borders and on lawns along the south coast. Figs also luxuriate in this district, and it is a common occurrence to meet with large trees 10 and 12 feet high with an abundance of fruits equal to that obtained under glass. *D. H.*

Diseased Asparagus.—Enclosed are portions of Asparagus stems and branches, which, I fear, strongly approximate the state of your correspondent's plants (see No. 36), whose description caused me to examine more minutely my own plants, some of which I have latterly observed had assumed an unusually brown and unhealthy appearance, including in some instances complete defoliation of the plants, but which I attributed to the ravages of the larvæ of the beetle (Crioceris asparagi), or some unseasonable influence. I have, however, as yet failed to discover that the disease—if disease it really be—had penetrated to the roots of the plants. Neither are the stems—that is, the portion meaate the soil—much affected. Comparing in 1-year-old plants, nor are the whole of our plantations affected alike, the less vigorous ones having been most severely affected. I may add that concurrently with your correspondent's remarks there is an account in the *Globe*, by a large grower in the west of England, stating that the majority of his large plantations of Asparagus are badly diseased, so much so that even the roots of many of the plants emit an offensive smell. A similar account was also this morning received by me from a neighbouring gardener, namely, that he has also latterly observed that his plants presented an unusually brown appearance, and that recent inspection had disclosed the presence of a fungus. Hence I think we shall learn that these are not isolated cases, though I trust the disease may prove to be of a casual and not an epidemical character. *William Gardiner, Lower Eatington Park, Stratford-on-Avon, Sept.* 11. [See p. 1194. EDS.]

Wasps' Nests.—This year we have been plagued hereabouts with a perfect cloud of wasps, and the quantity of nests taken within a radius of a quarter of a mile circle is nearly 50. I have myself taken four this week, and my neighbour has taken the same number; and he took eight the week before, and I four the same week. The damage they have done to the fruit is almost incalculable; one gentleman told me that they had taken all his Apricots, and they had begun at his Pears; but what I want to say is about taking wasps' nests. There is a general notion afloat that it is rather a difficult business to take a wasps' nest. Now, nothing could be more simple. Get a small watering-can filled with gas tar, find out your nests in the day time, either by following your wasps home or getting the country people to tell you when they know of any, but mark the nest in the daytime by a piece of white stick or lath, so that you can easily see it at night, and as soon as it is dark take your pan of gas tar and pour about a quarter to half a pint of tar into the hole of the nest, close the opening with a little sod, and all will be right. You can go next night and dig the combs out if you like, or if you have a friend a fisherman he will save you the trouble. If you are near a town where fishermen live you can get somewhat cheap the combs of grub by taking them to the fishing-tackle shops. However, let there be no more difficulty with wasps' nests now. I grant that the old way of taking them with fuzes of gunpowder and sulphur was an awkward one, and not always safe and certain, but I guarantee gas tar to be both safe and sure. *N. H. F.*

Plums.—The enclosed Plums are sent to show how exceptional the season has been in some instances. Generally we have a good crop of these—about 2 bushels. These sent will show you how some of the trees are loaded. My experience here this season has been that all fruit trees—and, in fact, cone-bearing kinds, Thujas and Cupressus in particular—escaped the frost and cutting hailstorms that we had in April and May. The Plums blossomed early, and except the Pears were in all their beauty when the hailstorm in the night of May 10 spread desolation amongst them, and only a few sorts escaped. How six or seven sorts should do so out of more than 1000 kinds I cannot divine, unless there were something peculiarly hardy in their nature. Those that so escaped are Belle et Bonne, Beurré de Capiaumont, Beurré Goubalt, loaded with nice clean fruit; Peach Pear, some of which I sent yesterday; Anna Audusson, and a few others. The Myrobalan Plums flowered in the end of February, beginning of March, and escaped entirely—leaves, fruit, and branches—in the most healthy condition. I intended to have sent you some fruit to show you in what fine condition they were, but I went from home, and the fruit was gone on my return. It is only occasionally we get this sort to fruit, although it is generally loaded with a mass of bloom early in March. How it escaped with other Plums in this neighbourhood, I am at a loss to know. It is certainly strange that nearly all trees that blossomed early for the most part escaped, and that those which blossomed in April, May, and June, with the single exception of those that blossomed here this season was that there was no male blossom on any of the Cupressinæ, yet they are loaded with cones, and I am curious to see whether any fertile seed follows; at present there is an appearance of it, but whether it will germinate or not remains to be seen. The exceptions to the rule are the Cupressinæ, loaded with fruit, and the seeds are, in their case, good. Nuts of all kinds are abundant in this locality; and here again is another instance of an escape from the destruction that befel later flowering trees. There is an evil that is likely to follow the stagnation and rest induced in many kinds of trees, especially Pears: these are now starting into young growth, and some trees are entirely covered with young branches and leaves, as if this were the beginning of spring instead of the fall of the leaf. I am afraid that in cases, where the trees will grow in the manner described, that it will be at the expense of the fruit-buds. However, all trees that were transplanted in the spring have done well, and grown in the usual way, and therefore will escape the weakening process of growing a second time. Fruit buds commencing swelling in all those that show an inclination to grow, and may thus stop them, and perhaps save them from the weak condition they will be sure to be in if left unchecked. *T. Scott, Merriott.*

Veitch's Autumn Giant Cauliflower. — With the view of testing the merits of this Cauliflower I made a sowing of it on April 17 last, planting out a good batch of it, along with the winter Broccoli. We cut the first heads about the end of August, and at the present time (September 7) there is a grand lot coming on, some of the most forward heads are nearly a foot across, firm, compact, and beautifully white. Whether it is cut small or large the flavour and colour are most excellent. I have a lot of Walcheren coming in, but the heads open before they attain half the size of the Giant Autumn Cauliflower, the colour is bad also, being a greenish yellow. However well the old sorts of Cauliflower do in spring and early summer, they seldom turn out so well in autumn. By making two sowings of Veitch's Autumn Cauliflower, one in the beginning of April and another in the beginning of May, I am confident a good supply of Cauliflower may, with proper cultivation, be ensured from the middle of August to the end of December. *D. Melville, Otley Gardens.*

Mimicry.—Your correspondent "J." mentions an instance of a Convolvulus which had become entwined with Lonicera aureo-reticulata, and produced leaves similarly reticulated. I do not myself think that the Japanese Honeysuckle had anything to do with this change of colour in the leaves of its neighbour. In this neighbourhood I not unfrequently find plants of Convolvulus arvensis and Bellis perennis growing wild, with beautiful aureo-reticulated leaves, which certainly never had the honour of growing near a Japanese Honeysuckle or any other variegated plant. *H. Harpur-Crewe, The Rectory, Drayton-Beauchamp, Tring.* [We quite agree with you. EDS.]

On Fruiting the Banana.—In reply to the inquiry of your correspondent, "E. N.," as to how long the Banana takes to ripen after the fruit is set, I may state the experience I have had with it here. In March, 1870, we planted a bed 28 feet square, in the centre of a house 40 feet square, with Musa Cavendishii, most of which is now in fruit, the flowering between and October, and these were cut in February, March, April, May, June, and July. About the middle of May of the same year, we planted two specimens of Musa sapientum in the centre of the bed: they both showed fruit in March and were cut in August. The heaviest fruit we had was from one of the plants of M. sapientum, which weighed about 75lb. Several of them weighed between 60 and 70 lb., and the remainder between 50 and 60 lb. *J. N.*

Parsons' Mignonette.—In February last I obtained, direct from Mr. Parsons, a small packet of what he called his "new Reseda odorata alba eximia, or white Mignonette," for which I was charged 2*s. 6d.* This I sowed in a pan placed under the shelter of a cold frame, and towards the end of April transferred the plants to an open bed, putting them in singly a foot apart every way. After they had made some progress, the tops were pinched out of the leading centre shoots, and the laterals pegged down. These shortly filled up the bed compactly, producing a profusion of bloom. Previous to planting the top soil was removed from the bed to the depth of 8 or 9 inches, some decomposed dung from an old hotbed dug in, and a compost that had lain heaped up during the winter, consisting of fibrous yellow loam three parts, rotted dung one part, and sand one part, well mixed together and sifted, substituted in the same proportion as what had been taken away. In another bed there sprang up a number of self-sown common Mignonette plants from last year's crop, which were allowed to remain just as they stood, being subsequently treated in the same way as the preceding. These also grew luxuriantly, and displayed a mass of blossom. On comparing the two kinds together, I could not discover any difference between them, either in colour or size of flower. The habit of Mr. Parsons', however, I admit, was more robust, but that was, I am inclined to have arisen from the superiority of soil in which it was cultivated. Some of my neighbours, who also tried it, fully concur in what I have here adduced, and several of my fair sex acquaintance to whom I presented bouquets, culled from both beds, unanimously agreed they could see no dissimilarity. Why, therefore, should in question should be designated "white," any more than the common large flowering variety, I confess puzzles me to know. In your editorial remarks, P. 1134, you say,—"Our own proved to be a very mixed and uneven example. The selected specimens now sent are fine." It is a very simple matter for a person to pick out from a bed or pots, two or three heads of the best flowers; but may I be allowed to ask, were the latter, or your own, in reality whiter? That I should like to see, and in what respect they differed from Mignonette, except, as I have before observed, in rankness of growth—which may or may not be an improvement, according to fancy. I also obtained from one of the leading London seedsmen a small quantity of seed of what was called "new crimson flowered Mignonette," which, in like manner, has turned out identically the same as the old sort. *A Subscriber, September* 7. [There has with us been no appreciable difference of colour, except in the "crimson," in which the anthers were of a darker chestnut, giving the mass a somewhat redder hue—but certainly not crimson. Mr. Parsons' pot plants, as shown last spring, were paler than the common sort, but whether naturally so or from indoor culture we cannot say. EDS.]

Swans and Water Weeds.—Judging from the very effective way my swans have done their work, I should say that one pair of swans to an acre would certainly not be too much. By simply leaving the 13 alone this summer, and feeding them in winter, another year ought to give your correspondent, "W. E.," enough swans to effectually clear his pond. *Somerset.*

Foreign Correspondence.

THE WINTER OF 1870-71 AT MONTPELLIER.—M. Charles Martins, the active professor of botany at Montpellier, has published his observations upon the winter of 1870-71, so far as it affected the Jardin des Plantes of that place, and the environs of the city. Some of the details noticed in his report are so interesting, that we translate them for the benefit of our readers.

Among the plants entirely destroyed in the garden are three Date Palms, three dwarf Palms, and an old Eriobotrya japonica, all of which endured the severe cold of January, 1855. Others, which perished in that year, and since then have not been affected until last winter, are Benthamia fragifera, Schinus Molli, and Opuntia Ficus-indica. A longer list is that of plants which do not suffer in ordinary seasons, but were unable to stand the excessive cold of the beginning of the year, and were killed down to the ground, although retaining their vitality; among these the Laurels have been much affected, both the old and young plants, although Prof. Martins says that he has observed with astonishment that the latter have relatively resisted better than the former. The largest Laurel in Montpellier is almost entirely dead, as are also those of the Jardin des Plantes. A third class is of plants which were injured in their leaves and branches, but which are usually unaffected by winter, and, in many cases, resisted the cold of 1855.

A second portion of the paper treats of the effects of the cold on the cultivated or spontaneous plants of the environs of Montpellier, to which the following remarks, by no means unimportant, are attached: "I cannot help directing attention to the fact that among all the plants the sensibility of which to cold we have mentioned, the greater number of those which are considered as indigenous (because they propagate themselves spontaneously in the country, where they have existed from time immemorial), belong really to exotic genera, of which they are the sole representatives in Central France; such are the Olive, the Bay Laurel, the Pomegranate, the Myrtle, Pistacia Terebinthus, and the Caper. * * By the philosophic botanist, all these plants ought to be regarded in reality as exotics in this sense, that their congeners are to be found in contrast as types with those of the Mediterranean flora. Several have been found in the miocene formation, and have remained in the existing flora, after having passed through the glacial epoch without disappearing altogether; but their rarity and their sensibility to cold, as well as their forms and botanical affinities, betray a paleontological origin, and show that they originated at a time when the climate of Languedoc was warmer than it is at present. I may be permitted by a comparison to show that this induction is logical and legitimate.

"Accusing for an instant that we did not know the date of the introduction to Languedoc of Agave americana, Aponogeton distachyon, Jussiæa grandiflora, Onopordon tauricum, and Opuntia inermis—all naturalised species. There is no botanist who would not be struck by their foreign appearance, and be astonished at finding them mingled with the indigenous flora. Tradition teaches us that they have been introduced by man, and all is explained. As to the other plants cited above, history is silent; we only know that they have existed in Central France from time immemorial—but the strong analogy which they bear to foreign origin, differing from those of the Mediterranean and northern floras, which, united, embrace the whole of the plants which now occupy the European shores of the Mediterranean."

Societies.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL: *Sept. 6.* The concluding show of the season was a crowded one. There were 1580 entries in the respective classes of plants, fruits, flowers, and vegetables; many of the articles exhibiting good cultivation, and at no former meeting had there been so magnificent a display of fruit. The dinner-table decorations from Colonel Buchanan of Drumpellier, and Colonel Campbell of Blythswood, were unquestionably the chief objects of attraction. The arrangement of both these designs was wonderfully good, the premier one being the most elegantly put up, although lacking the quality of fruit of the second. Mr. Lewin arranged his table with three crystal designs as centre-pieces, after the elegant Marsh design that finds so much favour in the metropolis. These were elegantly decorated with Maiden-hair Ferns, vegetable Cupids, Pandani flowers, and Bouvardia. The centre-piece had twisted appendages of glass, from which Ferns, &c., sprang, and the ground-work had a geometrical line of colour in Pansies, set upon golden Pelargonium leaves, with little sprigs of scented Geranium dotted in, making a most effective border. As corner dishes there were nice lots of Grapes, Melons, and Peaches and Nectarines, and between these again were little glasses filled with Ferns and the Bouvardia, stylish but easy. The whole was in a dessert service of burnished gold. Mr. Methven's style was a little different. His centre-pieces were not so elegant, and his design was more crowded. He studied the comforts of the table by giving ample space round the margin more than his fellow-competitor, and his dishes of fruit were beyond question much more luxurious, comprising, besides the fruits named above, a fine Cayenne Pine-apple, Bananas, and some of the commoner fruits. The collections of plants on longitudinal tables, three on the one side and three on the other, added immensely to the general effect of the transverse table of fruit. Here were Palms, Tree Ferns, and Screw Pines, towering high above their fellows, enlivened with the gorgeous Lilies from Japan, the beautiful Ixoras and Periwinkles from the East Indies, and the ever-flowered Heaths from the Cape. The Fuchsias seemed to look their very best, and the variegated Pelargoniums, always effective, gave a glow of colouring to the normal green, so largely represented in Ferns and Club Mosses. There were some of the best Ferns we have seen exhibited, the fine depending fronds of Adiantum assimile making up a beautiful plant, such as any lady would select for window adornment. Gold and silver Ferns make suitable furnishing for introducing among flowering plants, and it is almost a pity that subjects so admirable should be grouped together in classes instead of being interspersed among flowering plants of equal beauty. Pansies were, as usual, finely exhibited, and the spikes of the Gladioli were in splendid form. The line of Cockscombs, that formed the boundary between the exhibits of fruit, were in the best style of cultivation. The bouquets, both table and hand, were far too stiff and formal, and although they presented a neat outline, still they did not exhibit the very fine flowers, of which many of them were composed, to the best advantage. Roses were good—some of the stands better than might have been expected from the untoward summer. Hollyhocks were deficient in numbers and in quality; while Dahlias—the regal Dahlia of the florist, that is—were not exhibited. The tables of fruit were in fair character. The table of fruit above noticed was of a very excellent character. Dozens of competitors entered for Black and White Grapes, the palm of honour to Scotland in the hands of Mr. D. Y. Stewart, who, as Sir James Lumsden, Arden, both being hardly pressed in their classes by Mr. Collins, Maryhill, and Sir James Colquhoun of Luss. We have seldom, indeed, seen finer samples exhibited. The tables ground-floor—excellent fruit, Grapes, Peaches and Nectarines, Plums, Pears, and Apples. These classes were fully contested. Vegetables are generally much better shown in the West of Scotland than in any place in the kingdom, the climate being favourable and the gardeners put on their mettle. Mr. M'Lachlan of Greenock, showed a "vege cutter" that will economise time and labour to all who employ it in their gardens.

ENFIELD HORTICULTURAL *Sept. 7.*—The chief features of this newly-started show—for of the best we have seen for some time—consisted of foliage plants, Lilies, Ferns, and Asters, together with a good display of fruit, much of which was of a very high quality. The show, which was held in Mr. Jay's grounds at Adams, took place in a spacious tent, supplemented by two smaller ones, and owed much of its effectiveness to the tasteful arrangement secured by the indefatigable exertions of the honorary secretary, Mr. W. Marshall. Many of the foliage plants staged were conspicuous examples of the handsome Seaforthia elegans, from Mr. Anderson, gr. to D. Henry, Esq., and the grand Yucca-like Cordyline australis from Mr. Brockwell, gr. to P. Twells, Esq., Mr. Wilson, gr. to W. Marshall, Esq., had one of the finest masses of Alocasia metallica ever shown, and which must have borne as many as 60 or more well-developed leaves. Some fine examples of Ferns came from Mr. Wilson, Mr. Shaw, gr. to J. Muir, Esq., and others. Amongst the flowering plants was an exceedingly well managed specimen of the now seldom seen Clerodendron balfuria, from Mr. Brockwell, gr. to P. Twells, Esq., a plant about 3 feet high, bearing 14 panicles of its brilliant scarlet flowers. Mr. Brockwell had a grand specimen of Allamanda Hendersoni, exceedingly well-flowered, and which must have been quite 10 feet through. Alocasia the premier place in the exhibition. There was a grand display of Lilium speciosum, no fewer than five collections competing, the best coming from Mr. Cuthbert, who had a fine lot, some of the trusses being 18 inches in length. L. speciosum. Asters in pots were a pretty feature, but as it was a rule that they should have been grown in the pots, the choicest lot was disqualified; the best of those grown unconstrained to the schedule came from Mr. Mills, gr. to W. R. Arbuthnot, Esq. Ferns were shown in considerable numbers, and comprised many remarkably well grown specimens. There was a grand plant of Balantium lobatis, besides good examples of the Bird-nest Fern, Thamnopteris Nidus; besides which, we noted a magnificent example of Pleopeltis mussefolia, and good plants of Todea superba, Adiantum farleyense, as well as 11 luxuriously grown specimens of Adiantum cuneatum all from Mr. Marshall's collection. There was a fair display of cut flowers, amongst which some double Zinnias from Mr. W. Paul, and some Tiger and other Lilies from Messrs. Keynes & Son, neither of which, however, were conspicuous. In the competition for a device in cut flowers, which here meant a stand of flowers for the table, Mrs. Marshall was placed first with one of the Marsh stands tastefully filled; a very pretty stand from Miss Adams, rather weak in the filling, being placed second. The fruit was exceedingly good for a local show, and occupied a considerable space on the tables. Some of the more noteworthy examples were Grapes (Hamburghs), from Mr. Anderson; White Grapes (Buckland Sweetwater), from Mr. Shaw; Peaches (Bellegarde), an excellent sample, from Mr. Wilson; Nectarines (Violette Hâtive), from Mr. Shaw; Pears (Beurré Diel and Williams' Bon Chrétien), from Mr. Shaw; Cherries (Morello), from Mr. Anderson; and collections of 12 dishes from Mr. Cuthbert, and of 6 dishes from Mr. Anderson. The vegetables and cottagers' productions were very creditable.

BRIGHTON FLORICULTURAL AND HORTICULTURAL: *Sept. 13 and 14.*—This was perhaps the most successful autumn show held in Brighton for many years; indeed, it would be difficult to find a competitor for it at this season. Though the Pavilion buildings are not eminently suited for floral displays, it may be said, that for some things they are preferable to canvass marquees. The stove and greenhouse plants and Pelargoniums—which always form one of the most conspicuous features of the Brighton show—were in a large marquee on the lawn, and, with a few other plants, such as Fuchsias, cut Dahlias, Begonias, &c., constituted a very effective exhibition. The fruits, foliage plants, Ferns, and cut flowers, were in the saloons of the building.

The Railway Cup was this year offered for 48 Dahlias, and the veteran grower Keynes worthily carried it off—thus both cups went to Salisbury. Cockscombs in the county division were well represented. Begonias were well-flowered, especially B. weltoniensis. Kelway and Parsons had fine collections of Gladioli, the former taking the 1st prize. Of Pelargoniums there was a wonderful display, Parsons holding his own as usual. Fuchsias were by no means good, although large. Indeed, cut flowers, taken altogether, were quite equal to the general run. Roses, of course, were poor, the well-known Sussex man, Mitchell, standing out in 48 varieties.

The competition for the Ashbury Cup was keen, and the judges must have had some trouble in deciding the claims of the numerous competitors. The first on the list left little to be desired, and there were many others very tastefully designed. The too prevalent fault of overcrowding and massing the flowers was here, however, as apparent as it has been elsewhere, and we can only recommend the managers of provincial and metropolitan shows to continue to encourage this branch of floriculture. Stove and greenhouse plants were very good, notably Bougainvillea glabra, Allamanda Hendersoni, Vinca, Ixora amboinensis, and a few good Orchids were exhibited, but were so badly placed in one of the rooms that they were passed by almost unnoticed.

There were two or three good collections of wild flowers, including a nice bit of the Sea Heath.

Amongst fruits, Pines were poorly represented, an unripe though large Smooth Cayenne taking 1st prize. Black Grapes, especially the Hamburgh, were remarkably fine; and the collections of 12 or more dishes of fruits were good. Melons were numerous, Plums fine, and Apples and Pears inferior.

The wax and paper flowers exhibited by Miss Weekes and Mrs. Smith were so good as to require close inspection to convince one that they were not natural. A small basket by the former lady, containing Primroses, Forget-me-nots, &c., was excellent, and the same might be said of many of the artificial productions, including some woolwork Fassifloras!

Cripps, of Tunbridge Wells, exhibited a beautiful set of new seedling and named Clematises, and Messrs. Veitch their new and handsome crimson-coloured annual named salicifolius, resembling somewhat the narrow-leaved pendant Crotons. Mr. Ward, gr. to J. N. Miller, Esq., of Bishop Storford, was very successful with his fruit, taking 1st for Black and Black Grapes, and a collection of 10 dishes of different fruits. Mr. Chard, gr. to Sir F. Bathurst, of Salisbury, gained the Ashbury Cup for dinner-table decoration, comprising three stands. Altogether, the arrangements, under the superintendence of Mr. Spary, were admirable, and the attendance sufficient to justify the hope that the Society will revive.

SOUTH OF SCOTLAND HORTICULTURAL: *Sept. 5.*—The fifty-ninth annual exhibition of this Society was held in the Mechanics' Hall, Dumfries, under favourable auspices. Upon the whole the show was one of the most successful that has ever been held in connection with the Society, either as regards the number or the quality of the products exhibited. Amongst other exhibitors were Messrs. Milligan & Kerr, who sent a beautiful collection of Geraniums, comprising about 60 new varieties, such as Sir Garnet Wolseley, Louise Louise, and Sparkler. Messrs. Kennedy & Co. exhibited a beautiful collection of Asters, Dahlias, Fuchsias, Stocks, Liliums, &c. The various departments of the show were well represented, amongst other plants much admired were some Ferns standing on one of the centre tables. The 1st prize plant, exhibited by Mr. Farquharson, was especially noticeable on account of its great size and beauty, while the second prize taker, belonging to Messrs. Milligan & Kerr, was little inferior. The exhibition of fruit and vegetables was good.

Notices of Books.

Catalogo Poliglotto delle Piante. Compilato dalla Contessa de San Georgio. Firenze, 1870.

Deutsche Pflanzennamen. Von Hermann Grassmann, Professor am Marienstiftsgymnasium zu Stettin. Stettin, 1870. (Plant names.)

It is now 20 years since Dr. Seemann published his pamphlet "On the Popular Nomenclature of the American Flora," in which a polyglot dictionary of popular plant names was referred to, and a hint given that, at some future time, such a work might be accomplished by the same author. Since then Dr. Seemann has been steadily accumulating material, and as, from his extensive knowledge both of languages and countries, it would be difficult to find any one better qualified for the task, we may hope that at some time or other the work may be forthcoming. Meanwhile, in England, as on the Continent, the subject of plant names has attracted considerable attention, and we have, from time to time, referred to works bearing more or less upon the matter, and in more than one instance entirely devoted to it. The two, the names of which stand above, are the most recent contributions to the literature of this subject.

The project of a polyglot dictionary of plant names is by no means a new one. In 1682 was published a folio volume by Mentzelius, entitled "Index nominum plantarum universalis," which is very good in its way, although now-a-days of little use, owing to its ante-Linnean nomenclature. A similar dictionary was compiled by Gœrtner during his residence at St. Peters-

burg, but was never published. Indeed, when we take into consideration the nature of such a work, and reflect upon the incompleteness which it must of necessity manifest, however much care may have been bestowed upon its compilation, we shall not wonder that the death of the author has preceded the completion of the task. It is to this feeling that we must attribute the non-publication of the "Dictionnaire des Noms Vulgaires des Plantes" in 67 languages, which was compiled by Moritzi under the direction and with the assistance of the elder De Candolle, and which occupies in MS. four folio volumes. The objections urged against vernacular names may be freely admitted, and the uncertainty which sometimes attaches to their use be granted; but apart from this, there can be no doubt that, if a comprehensive catalogue could be compiled, even of the names of garden plants alone, it would be useful to many, as our "Answers to Correspondents" often show. There are many plants well known in our gardens by English names to which it is not always easy offhand to assign their Latin equivalents; and many which, although grouped together under one English name, used generically, belong to many different genera when scientifically considered. To take an example from a recent botanical catalogue, we find, besides the true "Lilies" of the genus Lilium, the following, to which the scientific equivalents are wisely added:—African Lily, Agapanthus; Atamasco Lily, Zephyranthes; Australian Gigantic Lily, Doryanthes excelsa; Belladonna Lily, Amaryllis Belladonna; Barbadoes Lily, Sarana kamschatika; Cuba Lily, Scilla peruviana; Day Lily, Hemerocallis; Guernsey Lily, Nerine sarniensis; Jacobœa Lily, Sprekelia formosissima; St. Bruno's Lily, Anthericum Liliastrum; Scarborough Lily, Valota purpurea; Lily of the Valley, Convallaria majalis; these, the whole, which occur to us as we write, may be added: Lily of the Nile, or Trumpet Lily, Richardia africana; Rockwood Lily, Ranunculus Lyalli; Barbadoes Lily, Hippeastrum equestre; Mexican Lily, H. reginæ; Wood Lily, Convallaria and Trillium; Lent Lily, Narcissus pseudo-Narcissus; Guernsey Lily, Pyrolirion; Brisbane Lily, Eurycles australasica; Rock Lily, Dendrobium speciosum; Checkered Lily, Fritillaria; Hedge Lily, Convolvulus sepium; to say nothing of the various Water Lilies and many more which might be added to the list.

Even such an example, the first book on our list appears in no favourable light—only six names are in the index under "Lily," of which two are genuine species of Lilium, and two do not appear in our enumeration. Indeed, viewed from whatever point we may choose, the polyglot catalogue is by no the least unsatisfactory. The list of authors consulted demonstrates this. None of the works which should be indispensable, such as Dr. Prior's volume, are enumerated; English names are taken from Bentham and Baxter; the "Botanical Magazine," and "Register," and Johnson's "Dictionary of Common Life" (!) with similar works; and for French and German names equally unsatisfactory authorities are quoted. Thus a large number of the English names can only be so called by courtesy, as they would never be used out of books, and are often mere adaptations, such as "Euphorbia bush, medicinal," for E. officinarum; "Guyana Centaury," for Exacum guyanensis; "Barton's flower, golden yellow," for Bartonia aurea; "Nitre plant, Russian," for Nitraria Schoberi, and so on. Nor do genuine English names fare better, inasmuch as they are too often misapplied: thus Galeopsis Tetrahit is given as the "common dead Nettle;" the name "Buttercup" is limited to Ranunculus repens and acris; and, worse still, misprints are so abundant on almost every page, that the meaning is obscure. Thus Medicago echinus is called the "Sea Egg-medick plant;" M. scutellata is the "Swain Shell;" while one page in the index gives us the "Macquarie Habour-Grappe plant," "Lords and Ladies," "Litmus plant," &c. Some such mistakes are perhaps to be expected in the English of a book printed abroad, but here they are so numerous that this excuse will hardly avail. The most satisfactory part of the book is the relation between the contents and the index; the plants are arranged alphabetically under their Latin names, and numbered consecutively, the synonyms in each language being given. We have then a separate index for each language, the number of the plants being given after the name, so that reference is easy. The work, however, is far from satisfactory as a whole, and will be of little use, so that a polyglot dictionary still remains a desideratum.

Prof. Grassmann's little volume is much more useful, as it contains not only the German vernacular names, but their Swedish, Danish, and other European synonyms, with notes on derivations, and copious references to previous writers on the subject. The chief fault we have to find with it, is in the invention of vernacular names—a system which has been proposed among ourselves, and carried out more or less fully in Mr. Bentham's "Handbook." Prof. Grassmann's plan is to take some common name of a well-known plant, and to render it generic, coining, as it were, specific names for each member of the genus. Thus, Cytisus Laburnum is generally known as "Golden-rain" (Gold-regen); the word Regen is then taken for the genus, and adapted to each species:—C. alpinus, Alpen-regen; C. argenteus, Silber-regen; C. austriacus, Oester-regen; C. capitatus, Kopf-regen; and so on through about 20 species. This example, taken at random, shows the unsuitableness of the system: the idea of rain is appropriate enough to the Laburnum, and is embodied also in the Swedish guldregn, but is quite out of place in connection with the majority of the other species, notably such as C. capitatus. The work is, however, on the whole of value, and will not be overlooked when a comprehensive polyglot dictionary of plant names shall be in progress.

Florists' Flowers.

THERE is much reason to fear that year by year the area of the cultivation of the TULIP as a florist's flower is becoming more and more circumscribed, especially when it is true that men who, because of their long connection with the Tulip, can worthily be termed veteran cultivators, are one by one falling aside from the beaten track, and are found offering their collections for sale. Many have learned with unfeigned regret of these acts of withdrawal, mainly carried out, be it stated, because of growing physical infirmities which interfere with that active supervision so necessary to a grower who would succeed. In the case of the retirement of Mr. George Lightbody, of Falkirk, who has been a florist since 1817, and of Mr. John Read, of Market Raisen, so well known to the floral brotherhood, through their various periodicals, under the sobriquets of "Dean," and what is a well-earned and honourable career as a cultivator of the Tulip also, there is cause for much regret among Tulip fanciers. To them it is like the passing away of the renowned commanders in the times of a country's greatest emergencies. It must not be supposed, however, that others are not stepping forward to supply the vacant places. Tulip growers are yet a numerous body; one occasionally stumbles on them in various places, tending their flowers with all that ardour that enters so strongly into the composition of an enthusiastic florist, and reaping the pleasant reward of much well-directed attention. No doubt the cultivation of the Tulip has much died out in the southern districts of England; in the north it is still pursued with much ardour.

At the National Tulip Exhibition, held at Cambridge in May last, the northern growers appeared in strong force, and their ardour and enthusiasm was manifested in a remarkable degree. It was a rare study of human nature to stand by a group of these men, gathering their opinions of the flowers staged, of the estimation in which certain points were held—and in this respect there was much difference of opinion, as well as in the estimate which had been formed by the judges and their decisions. The popular regard, also, went out largely after the Tulips—perhaps because of the novelty of their appearance, and the tent in which they were shown was crowded with visitors during the day.

The Tulip, to be certain of securing some approach to desired quality, must be grown under favourable conditions, and these are not incompatible with its perfect hardihood. Mr. Richard Headly has declared that the Tulip is a much hardier bulb than the Swedish Turnip. Experienced growers hold the opinion that it is most possible that either wet or cold, or combined materially, although submerged in a flood for days, or bound up by frost for weeks;" still there is scarcely a cultivator who would care willingly to expose his bed to such great risks. An undrained soil, which from its inability to pass away quickly the rain that falls on the bed must be kept in a state about the bulbs deadened and cold, is a thing to be particularly avoided; and it is no doubt owing to this that beds are invariably raised above the ground level. Some attempts are frequently made to protect the beds from frost and heavy winter rains; indeed this is generally done by means of a set of low iron hoops, with a line of laths passing along the top to keep them together; and over these Russian mats are thrown when requisite. One eminent cultivator has stated, and his words contain a warning worthy of note, especially in cold and late localities—that the greatest harm done to the Tulip is likely to arise when it follows with some severity on the heels of heavy rain; when the foliage is often filled with water, and that water is suddenly congealed to ice. The stems are thus nipped, and although the consequences are not immediately visible, future disappointments are to be predicted with certainty. They may stand apparently all right till nearly in full bloom, but at every visit to the bed the probability is that the florist will find some of his favourites lying prostrate, their stems being tainted half through. To obviate this misfortune, the foliage should be kept as dry as possible from the time when it first opens to the period of full bloom, and this can only be effected by having a top cloth on during all wet weather.

With Tulip growers it is a kind of tradition (with some of them at least) to plant on November 9. It is best to plant in dry weather, and not at a time when the soil is excessively wet through heavy rains. Generally the bed ranges from east to west, probably to get as much as possible the full action of the sun. The soil recommended is a good sandy turfy loam, applied to the depth of 6 inches, and well mixed with the soil in the bed, and left for three or four weeks before planting is done. The beds are invariably formed with turf sides and ends, about 9 to 12 inches in depth; and when planted the soil is levelled to the surface of the edging, or just below it, and the bulbs placed on it in regular positions, according to their height of growth, in seven lines: a little white sand is placed about each bulb, and they are then covered with soil to the depth of 5 inches in the middle, and three at the sides. This gives a kind of sloping or bevelled surface, and helps to throw off the rain.

The following list includes some of the best flowers shown at Cambridge in May last, together with others not seen on that occasion:—Bizarres: Dr. Horner, feathered, Everard, Richard Headly, Henry Groom, and Mr. F. Perkins, flamed, all first row flowers; Vivid, feathered, Caliph and Dr. Hardy, flamed, second-row flowers; George Hayward and Pactolus, feathered, Sir J. Paxton, J. R. Scrivener, and Polyphemus, flamed, third-row flowers; Royal Sovereign, Glory of Abingdon, feathered, Owen Glendower, King (Delaforce), and Lord Raglan, flamed, fourth-row flowers. Of these the following were specially fine—Sir J. Paxton, which deservedly obtained the premium prize as the best flower in the exhibition; Polyphemus, in superb style; Dr. Hardy, very fine; George Hayward, a grand flower; also a feathered form of Sir J. Paxton. Byblœmens: Queen of the North, Purple Perfection, and Wood's Rembrandt, flamed, first-row flowers; Victoria Regina, Storer's Clara, Battersby's Chancellor, and Violet Amiable, feathered, Walker's Duchess of Sutherland, and Juliana Amiable, flamed, second-row flowers; Lord Denman and Maid of Orleans, feathered, Queen Charlotte, Thalia, Nora Creina, and Claude, flamed, third-row flowers; Adonis, feathered, Alexander Magnus, and Princess Royal, flamed, fourth-row flowers. Of these Duchess of Sutherland, Queen of the North, Alexander Magnus (finely marked, but rather long in the petals), and John Kemble, were in fine condition at the National Tulip Show. Of Roses, the following form a good selection: Sarah Headly and Arlette, feathered, Lady Stanley, Naomi, and Soldier's Joy, flamed, and Blessington, flamed, first-row flowers; Heroine, feathered, Rose Celestial, flamed, second-row flowers; Mary Headly, Aglaia, Triomphe Royale, and Maid of Falaise, flamed, third-row flowers; Vicar of Radford, Gibbon's Duchess of Sutherland, and Claudiana, feathered, Emily, Elizabeth (Jeffey's), and Anastasia, flamed, fourth-row flowers. Roses were very fine indeed at Cambridge, and especially the following in the foregoing list: Aglaia, very finely marked; Heroine, very fine, and the premier rose; Rose Celestial, and Triomphe Royale.

This gives a list of 54 good reliable varieties, 18 of each section, arranged according to their height of growth. Of other good flowers not included in the foregoing lists, but shown finely at Cambridge, are Talisman (Hardy), a very fine feathered byblœmen; W. E. Gladstone (Headly), also fine in condition by Mr. R. Headly; Circe, flamed rose, very pretty; Prince of Wales (Headly), flamed bizarre,—this was very fine, large, and beautifully marked, but hardly strong enough in colour; Mrs. Pickerell, feathered byblœmen, and the premier feathered flower of the exhibition; Jacomb's Perfection, feathered bizarre, a variety little known but rightly named, one of the best of its class, and perhaps the richest coloured of any bizarre in cultivation; Nepanlese Prince, flamed byblœmen, finely coloured; Henry Steward, feathered bizarre, very fine; Captivator, flamed rose; Arethusa, feathered rose; and Sarah Leach, flamed byblœmen. *R. D.*

Garden Memoranda.

BATTERSEA PARK. — The bedding-out here will be found in excellent order just now. Mr. Roger has to a certain extent struck out a new line for himself, which is at once seen on going to those snug nooks and corners where we always expect to find something good, and which we shall take the opportunity of noticing as we come to them. Of course the change which is found in the open style of planting which Mr. Roger has adopted is not radical enough to entirely alter the whole character of the place, though this appears to have been adopted in every case where bold, striking foliaged plants are in question, and the results appear eminently satisfactory. Our provincial friends, we know, have a conception to the great number of plants which are crammed into the flower-beds of the public parks and private grounds in the metropolis, but then we have a reason for it, and a very substantial one, inasmuch as here, when the plants are put in, we must have a show at once, which can only be gained by thick planting in the case of the ordinary run of bedding plants, whilst it is quite probable that the gardens attached to the palatial and baronial mansions in the shires are never seen by the proprietors until the commencement of the shooting, or the termination of the fashionable London season, when a full blaze of beauty is of course expected to be found. Here, then, thick planting would not answer, nor is it attempted. The plants are put in moderately thin, they have plenty of time to "get up," as the expression goes in gardening phraseology, and are found "in a blaze of bloom" when wanted. In the case, therefore, of ordinary bedding plants, Mr. Roger has adhered to the usual system, but with the large, fine-foliaged plants proper to the subtropical garden, he has adopted a bolder course, as, instead of reproducing large massive beds of a single species, or variety, as the case may be, of any

popular plant, such as we have so much admired from the hands of his predecessor, Mr. Gibson, he has cut up these beds into sections, and planted them with two or three kinds, chosen for their general distinctness of character and adaptability for forming agreeable contrasts. Here is a case in point. The extreme ends and centre of a long bed situated at the bend of the walk, taken to the right on entering from the cricket ground, are planted with the noble-foliaged Wigandia caracassana (see fig. 269, p. 1170), 4 feet apart in the rows, and 3 feet from row to row, the two intervening sections being filled in, thinly in proportion, with Solanum marginatum. Under the Wigandias is a carpet of the fiery spined Solanum pyracantha, whilst under the Solanum marginatum is the cut-leaved Geranium anemonifolium, the whole being finished off with a line of the last-named Geranium alternating with Tussilago Farfara variegata, and an outer margin of Sedum virescens. The Wigandias have made a capital growth, and being allowed plenty of room, they stand out boldly and well in their noble proportions, whilst the silvery leaved Solanum, though it, too, has made good use of its time, is in the very nature of things considerably dwarfer. In this lies the great feature of the arrangement: it breaks up the mass, as it were, into small groups, and opens up any characteristic feature in the rear, which, in this instance, consists of a pair of fine Musas, and which are seen to the greatest advantage through the openings so made. Besides being a capital illustration of an excellent style of arrangement, this bed has another feature of originality, deserving of the attention of those seeking good useful plants for furnishing bold effective edgings, or for carpeting under tall-growing plants—we mean that it fully bears out Mr. Roger's high opinion of the merits of the many beautiful cut-leaved and sweet-scented Pelargoniums for the purposes above mentioned. He has employed several of these charming old plants to a considerable extent, and we believe intends doing more extensively, as his stock increases; and that they will do him good service we have ample evidence in the illustrations before us. A very bold and effective design, in the style above alluded to, is also to be seen on the opposite side, in which the ends and centre are planted with Solanum Warsewiczoides, and the intervening spaces with the New Zealand Flax, Phormium tenax, carpeted with a deeply cut leaved sweet-scented Pelargonium, and edged with variegated Ivy. In the same neighbourhood we notice that the fine bed of the prettily variegated Vitis heterophylla is this season rendered even more beautiful by its being made to do duty as carpeting to those really elegant plants Acæna lophantha and Grevillea robusta, which are planted thinly amongst it, with a very good effect. Other examples of tasteful bedding which we noticed in our stroll round, and think worthy of record, are a circular one of Coleus Verschaffeltii, with a tuft of Centaurea candidissima in the centre, and a line around of the same plant, next to which comes one of mixed succulent plants, and then a margin about 12 inches deep of Mesembryanthemum cordifolium variegatum, which here, as well as at Hyde Park, is regarded as one of the best plants for such a purpose in cultivation. For edgings, which are made almost perpendicular with cowdung and loam—a plan largely followed in the metropolis, to lighten the labour of watering, every drop of water going to the roots of the plants, instead of running over the surface, and caking it, as is too often the case when the convex form of surface is employed—we have nothing to equal it, in a similar colour—bright orange-yellow. The next is composed of Vallota purpurea, mixed with Agapanthus umbellata and Imantophyllum miniatum, around which is a line of Wills' golden-self Pelargonium Gem of Brilliants, with rich magenta flowers, which Mr. Roger speaks very highly of. The three first named plants are flowering very freely, but the Imantophyllum is scarcely decided enough in colour to warrant a more free use of it; besides, its flowers look washy, and in any case it should not be planted in the same bed with Vallotas, the intense scarlet flowers of which entirely kill it. A mixed bed of Vallotas and Agapanthus would have a capital effect. Another plant which, when in flower, commands considerable attention—Erythrina Crista-galli—is flowering unusually freely this year. Some round beds of this, edged with dwarf plants of Araiia papyrifera, have an exceedingly good appearance, the outline being easily and sufficiently defined, without the severely formal character produced by dwarf and more compact-growing plants. The latter style finds little favour with Mr. Roger, who employs the former and more graceful method much more freely with tall plants, and with excellent results. The large beds of Cannas are looking and doing well, especially those which are left in the ground undisturbed. These grow much stronger than those planted out annually; but the latter plan is the best where it is desirable that the beds should not exceed a certain height to fall in agreeably with their surroundings. The former, too, are liable from exhaustion to make a spindly growth; and, to obviate this, Mr. Roger, we believe, intends to take them up every three or four years, divide, thin out, and replant in renewed soil; and this will, no doubt, have a very beneficial effect in giving breadth and substance to the foliage. The Palms and Musas, which owing to the severity of the weather were put out late, are doing very well, especially Chamærops humilis, Seaforthia, and Phœnix sylvestris. The experience here is that any Palms in habit approaching in character to the above, are the best for subtropical work, and that Musas of the height of 3 or 4 feet are more serviceable than taller specimens, and in this we entirely agree. The tropical vistas, near to the Peninsula, are as attractive as usual. It was a happy thought that suggested the formation of these un-English nooks to Mr. Gibson, for in them we find a great variety of very interesting tropical subjects which cannot be trusted out in the open, and which we should otherwise miss from this thoroughly enjoyable place. The long geometrical beds, of which we gave plans last year, at p. 1158, are this season planted in the Grecian key pattern, the plants used being Alternanthera and the Golden Feather Pyrethrum; whilst the two round ones are planted with succulents, with a view to subdue the colour of the others. This is decidedly a change for the worse, as the design, though a pretty one in certain positions, is unworthy of the place now occupied by it.

The mass of Acer Negundo variegatum, which forms such an attractive feature in this portion of the park, now that the plants are getting up in height, well illustrates the exceeding valuable character of the plant (of which we give an illustration, fig. 275) for ornamental planting.

We have also a change to notice in the style of bedding carried out around the refreshment rooms, on the north side of the park, facing the Thames, which, in former seasons, consisted of ribbon borders and beds of distinct varieties of Pelargoniums, but which now—that is, the half circular border—is most effectively carpet-bedded in a design resembling a well executed piece of cornice work around the ceiling of a room, and very well indeed it suits the position. The ray beds on the left, near to the West Gate, are rather weak and dull, but this, it must be observed, is due to the circumstance that the plants first put in suffered so severely from the effects of the weather that it had to be nearly all replanted, and that, too, when nearly all the other bedding was finished — when the work could only be carried out at a very great disadvantage. Opposite the above, however, is one of the best beds in the Park—of Aralias, openly planted and edged with the emerald green-leaved and peppermint-scented Pelargonium tomentosum. Space forbids us from noticing any other of the many interesting things to be seen here, but we cannot conclude without remarking that Mr. Roger has discarded Calceolaria floribunda, and relies mostly on the good old Kayi; and that he has in a Verbena named Sportsman, bright pink, one of the best bedders ever sent out. It is exceedingly telling in rows, and has a capital effect here blended with Œnothera macrocarpa.

FIG. 275.—ACER NEGUNDO VARIEGATUM.

Obituary.

EVERY frequenter of the meeting-room of the Royal Horticultural Society will have missed of late the kindly, genial face of the chairman of the Floral Committee. Every member of that Committee—we may say every horticulturist, who came in contact with him, will grieve to read this announcement of the death of the Rev. JOSHUA DIX, M.A. (on the 12th inst., at Langley, near Slough). He may fairly be said to have died in harness, for we cannot forget how he, ever mindful of his allegiance to horticulture and horticulturists, contracted what has proved to have been his last illness on an occasion when he bore witness of the faith that was in him by performing the last sad rites over poor John Veitch. It was fitting that a clergyman who had so greatly identified himself with the progress of horticulture should be the one

to utter the solemn words of our burial service over the grave of one who may himself be reckoned among the martyrs to horticulture. It is sad to recall that in the exercise of that duty our friend was stricken with that sickness from which he had never thoroughly recovered, and in consequence of which we now have to lament his decease. The Rev. Joshua Dix was a graduate of Oxford, and officiated, we believe, as curate and *de facto* incumbent of a country parish in Kent for several years in the absence of the rector. There he gained the respect and love of his parishioners; there he contracted that love for Nature and Nature's handiworks which he never forsook him. We, whose duty it is to pen these lines can look back for nearly a quarter of a century, and recall our friend hot in the eager search for the "Purple Emperor," as he flitted over the top of a spreading Oak. We remember his exulting cry as he proclaimed that he had found the Loyal Fern (Osmunda). We call to mind how he showed us, then less than a stripling, the first Oxlip (so called) we had ever seen. This idyll was destined to be but as a dream. The curacy in Kent had to be given up, and our friend was promoted—save the word—to a small living in the heart of the city of London. Here amid "wholesale houses" and commercial emporiums, the lot of a true-hearted clergyman was cast. There was literally no field for his sympathies. His parish was, so to speak, one in name only. In the evenings and on the Sundays it was—almost—deserted. His congregation may be described literally as where "two or three were gathered together." It was under these circumstances that Mr. Dix devoted himself heart and soul to the concerns of the Royal Horticultural Society, or rather of the Floral Committee. Free from prejudice and party, looking forwards or against the Council or the exhibitors, Mr. Dix presided for some years over the deliberations of the Floral Committee, with an impartiality, a geniality, and tact which secured for him the cordial goodwill and respect of a large and somewhat heterogeneous body. Their respect was testified some short time since, at a time when it was felt that some mark of their esteem should be presented to their chairman—their sorrow at his loss will be shared by every one who knew him. *Requiescat in pace.*

We have to record the early death of Mr. FRED. PARSONS, son and successor of the well-known nurseryman and florist, of Brighton. The deceased succeeded to the business less than two years ago upon the retirement of his father, and for some months has been suffering from dropsy, to which he succumbed early in the morning of the 7th inst.

We deeply regret to have to record, on the authority of a foreign scientific journal, the death of Dr. MILDE, who has made many important contributions to cryptogamic botany, and whose valuable "Filices Europæ et Atlantidis," was noticed in our volume for 1867 (1174). Dr. Milde had also published some important observations on new Ferns, entitled Reliquiæ Mettenianæ, in twelve volumes of the "Linnæa" (see vols. xxxv., p. 385; and xxxvi., p. 43).

We have to record the death, at a very advanced age, of JAMES DE CARLE SOWERBY, the first Secretary of the Royal Botanic Gardens, Regent's Park, an office which he held till last year, when he resigned it in favour of his son. Mr. Sowerby belonged to a family, many members of which have distinguished themselves by their devotion to various branches of science, and to the pictorial illustration of natural objects.

On Tuesday, September 12, at Chatsworth, after a few days' illness, Sarah, widow of Sir Joseph Paxton, M.P.

Sept. 7.—Small amounts of cloud prevalent during the day; cloudless at night. Aurora and lightning at night. A little rain fell in the early morning.
— 8.—Rain fell in the morning and heavily from 7 P.M. till midnight. Generally overcast.
— 9.—Rain fell from 6 A.M. till 10 A.M. Cloudy till 3 P.M. Generally cloudless after that time.
— 10.—A very fine day. Light clouds generally present.
— 12.—Overcast till 10 A.M. The clouds disappeared towards night, and a sky perfectly cloudless about 6 P.M.
— 12.—Small amounts of cloud prevalent throughout. A fine day
— 13.—Generally cloudy throughout. JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

MAKE every preparation now for getting all plant structures ready at the earliest moment for the reception of their winter inmates, as it will be necessary to house all hard-wooded plants of any value immediately a decided change in the weather is perceptible. As it will be necessary also to house such cool greenhouse plants as may be "standing out," all stove plants which may have been placed in greenhouses at a time must be returned to their proper quarters. Not to overlook smaller though generally important matters, the amateur should also have his flues cleaned out and set in order, ready for work in the incoming season. Many kinds of plants should now be introduced into a somewhat moist heat, where quick and early solution display is of importance. These include perpetual flowering *Carnations*, Neapolitan *Violets*, Anne Boleyn *Pinks*, Tea *Roses*, having young growth now forming, such as would be likely to bloom in pots if hurried on somewhat, and some kinds of miscellaneous plants, &c. Gradually reduce the amount of atmospheric moisture in stoves and Orchid-houses proper, and so aid the plants to divest themselves of some of the watery matter contained in their system, and thereby harden them to better withstand the effects of the winter. In removing all plants that have been placed out-of-doors for a period into their proper structures, take care to wash the pots thoroughly clean, to remove any green mossy formations from the surface of the balls, and to look carefully to the drainage, to ascertain in this respect any of these necessary remedial measures. Look out for mildew amongst *Heaths*, as this pest not unfrequently makes sad havoc amongst them at or about the time they are taken in and housed for the winter. The best preventive of mildew at this season of the year is the free admittance and circulation of air. Freely should air also be given to cool plant structures subsequently to the housing of the plants—in the first place, to keep the temperature down, and to assimilate their present position to their past; and, in the second, to secure the ripening of the wood, which, under such conditions, is more effectually carried on. Each individual grower must now treat his forward stock of plants for winter decoration according to the date that he is desirous of having them in flower. These comprise *Helitropes*, *Salvias*, *Begonias*, *Mignonette*, and the like. Those who require an early bloom must not pinch any back after this date, whilst it is desirable that those intended to bloom later should be once more stopped; but the sooner this is done the better, that time may be afforded them again to break and grow.

HARDY FRUIT GARDEN.

Gathering the slight crop of *Apples* and *Pears* should now be proceeded with, and, considering what a limited supply exists, all possible care should be taken of every single fruit. Do not rub off the bloom, as even this beautiful covering has, we doubt not, within it highly conservative properties; and take care to lay each upon a shelf in such a manner that it be not bruised in the least degree. Still continue to go over *Peach* and *Nectarine trees*, and divest them of all superfluous gross lateral shoots, and so aid and encourage the ripening of those shoots which have been laid in for a permanency.

KITCHEN GARDEN.

When finally earthing up *Celery* endeavour to give all the freedom possible to those leaves which it is possible to maintain above ground. By destroying such, or indeed bundling them up so closely together that their proper functions cannot be performed, we countenance the very means which is likely to increase the propensity, caused already by earthing up, to form weakly drawn growth more than is necessary or proper. A small bed of late *Broccoli* may now be planted, if strong plants exist. There is just a chance that they will form a small head late in spring, though it is too late to expect in any reason to get proper Broccoli. Hereabout they plant the Purple Sprouting variety late, and if it does not head it goes into market as a green, stalks and all, by weight, at the poor Londoner's expense. Cut down now all *Herbs*, such as *Mint*, *Marjoram*, *Tarragon*, &c., the leaves of which become better prepared to withstand the hardships of the incoming winter. Where *Chervil* has come up very thickly in the seedbed, boe it out more thinly, and if stock sufficient does not then exist in the bed forming, transplant another bed from amongst the thickest of the plants. This is a herb much in demand in the kitchen during the winter months. Hoe well amongst the young growing crop of *Spinach*, thinning it out well betimes, that a strong young plant be formed for winter. Make just another small "chance" sowing of *Lettuce*. Cut off the old bloom-stalks from stools of *Globe Artichokes* immediately they cease to be useful. Transplant permanently the autumn-sown *Spring Cabbages*. I strongly recommend planting these upon the old Onion bed, without any attempt at digging it up. Hoe the surface well, draw the drill rows, and transplant for the Cup system for blanching. Draw the Onion crop wholly, and give all the subsequent attention necessary to harvest them efficiently. Weeds should now be hoed, and killed outright before the sunless days and long dewy nights of late autumn arrive, when their eradication, save by removal, will become impossible. *W. E.*

Notices to Correspondents.

ACHIMENES: *A Subscriber.* Yes. They should be covered with a thin layer of fine soil.

ARBORETUM: *B. C.* One of the most recently established that we know of is in the University Park at Oxford. The entire extent, we believe, about 100 acres, but we do not know how much of this is devoted to the growth of trees, though we think the collection numbers nearly 1000 species and varieties.

ARTICHOKE AND TOBACCO GRAFTING: *W. M. E.* We are greatly obliged for your hint, and value any suggestion of yours. You cannot, however, have been a very diligent reader on this subject, else you would know that early inarching has been expressed pretty decidedly on this matter.

BOOKS: *E. C. M.* Thompson's "Gardener's Assistant" was written by Robert Thompson, of *Covent Garden in the meyne moneth of Maye*. "Practical Gardening" (Journal of Horticulture Office), and "The Greenhouse as a Winter Garden" (S. Low, Son & Co.).

CATERPILLAR: *G. McG.* You ask us for a remedy against the grub whose description is beyond our power. Send us a specimen, and we will try to accommodate you.

FERNS: *Jay Aye.* Peg down one of the proliferous fronds of the Polystichum, and run a little silver sand in amongst the bulblets. The spring is the best time to do this, but if the plant is in a house, and growing, it may be done at any time.—*C. Lawton.* Trichomanes radicans is a British Fern in the usual sense of that expression,—that is, it grows wild in the British isles. Therefore it should not be shown as an exotic, unless in the form of some distinct variety. Not of British growth.

INSECTS: *L. B.* The small objects on the stem of the grass sent (Cynosurus cristatus) are an accumulation of the minute eggs of some species of insect. They are probably deposited by some small moth. *J. O. W.*

EDUCATION OF GARDENERS: *D. R.* Apply to the Secretary of the Royal Horticultural Society, South Kensington, and of the Society of Arts, Adelphi, London, respectively. You will find Oliver's "Lessons in Elementary Botany" (MacMillan) suit your purpose, or the article on botany for Beginners in our columns. We shall be glad to assist you if we can.

ENGAGEMENT: *Quiz.* Three months' notice is all you are legally entitled to.

FRENCH HAY: *Inquirer.* No doubt they can be procured from any of the large seedsmen or garden "sundry" establishments. They may be had of various sizes.

INQUIRIES ON ALDER-WOOD: *W. G.* The green tint on Alder-wood is produced by the spawn of Peziza æruginosa. The tinted wood is much prized at Tunbridge, where it is used for inlaying and other ornamental work. *T. F.*

GALLON ROSE: *D. M.* "Rohin's Piacusbion," — the work of an insect. Very common.

NAMES OF PLANTS: *W. T.* If the leaves are keeled at the base, the plant is Sparganium simplex; if flat, S. natans. The Labiate is Savory, Saturcia hortensis. The Orchid next week.—*B.* Cornus mas., the Cornelian Cherry. The pulp around the seeds of Tacsonia Van Volxemii is pleasantly flavoured.—*H. H. C.* Gentiana germanica, with many thanks.—*P. S. D., Slingsby.*

Mr Holus officinalis; common Meilot. The caterpillars on the Pear leaf were smashed. They may have been the larva of the saw-fly.—*An Old Subscriber.* Clethra alnifolia; native of North America.

New Edible Pea: *G. H.* It is the old, long known Chick Pea, Cicer arietinum—too tender for general use in this country. It is here only worth growing as a curiosity, but is largely grown for food in the South of Europe.

Passion-flower: *T. R.* Many thanks. We suspected when we saw the fruit that it was P. macrocarpa, and not P. quadrangularis, and we are confirmed in our opinion by the leaves you send; but without seeing the flower we cannot be absolutely certain.

Plum Trees Infested with Aphis: *A Subscriber.* There is no better remedy than that recommended by Mr. Rivers in his "Miniature Fruit Garden :"—Boil 4 oz. of quassia chips in a gallon of soft water, to minutes, dissolving in it, as it cools, 4 ounces of soft soap. It should be stirred, and the trees syringed with it twice or thrice. The trees should be syringed next day with clean water.

Preserving Filberts and Walnuts: *A Gardener.* See pp. 1314, 1347, of our last year's volume.

Spot in Pelargoniums: *P. Q.* We have examined your Pelargonium leaves, and find no Fungus on them. It seems to be a common case of spotting which arises from a bad condition of the roots, induced by bad draining and marked alternations of drought and drenching. *M. J. B.*

Top-dressing: *H. G.* The materials sent are insufficient. It does not, however, appear to have any special merit beyond others already in cultivation.

Violas: *T. C.* Much like other seedlings of Viola lutea. The markings discouraged some of the petals so much as to be but the large yellow without the spot in the eye is the best, so far as the blossoms are concerned, though much of their merit depends upon habit and profuseness of flowers.

Errata: *M. J. B.* We would gladly insert your errata if we could read them!

Communications Received.—W. H.—C. J. W.—T. B.—C. W. M.—H. H.—G. W.—R. S.—A. B. C.—R. G.—G. K.—W. M.—H.—C. P.—G. McG.—S. & Sons.—D. M.—A. R.—T. R.—A. H.—A. B.—J. W.—D. O.—King's Langley (box received without any communication).—A. F.

Markets.

COVENT GARDEN.—Sept. 15.

Business here still continues very steady. Late wall fruit is coming in very good, and prices rule a trifle lower. The market is badly supplied with Apples and Pears.

Fruit.

	s. d.	*s. d.*
Apples, per ½ sieve	1 0 to 3 0	
Apricots, per dozen	0 6 — 2 0	
Figs	1 0 — 2 0	
Grapes, per lb.	1 6 — 5 0	
Lemons, per 100	8 0 — 12 0	
Melons, each	2 0 — 3 0	
Nectarines, per doz.	2 0 to 6 0	
Oranges, per 100	8 0 — 12 0	
Peaches, per dozen	2 0 — 8 0	
Pears, per dozen	0 6 — 3 0	
Pine-apples, per lb.	2 6 — 6 0	

Vegetables.

	s. d.	*s. d.*
Artichokes, per doz.	2 0 to 4 0	
Beet, per doz.	1 0 — 2 0	
Brussels Sprouts, p. half sieve	3 6 — 4 0	
Cabbages, p. doz.	1 0 — 1 6	
Carrots, p. bunch	0 6 — 0 8	
Cauliflowers, p. doz.	2 0 — 4 0	
Celery, per ½ bun.	1 6 — 2 0	
— white, do.	1 0 — 1 6	
Cucumbers, each	0 4 — 0 6	
French Beans, p. lb.	0 4 — 0 6	
Herbs, per bunch	0 1 to 0 4	
Horse Radish, p. bun.	2 0 — 3 0	
Lettuces, per score	0 9 — 1 6	
Mushrooms, p. pott.	1 0 — 2 6	
Onions, per bushel	2 0 — 3 0	
Parsley, p. bunch	0 2 — 0 4	
Peas, per quart	0 10 — 1 0	
Radishes, per bunch	0 2 — 0 3	
Shallots, per lb.	0 8 —	
Spinach, perbushel	4 6 — 5 0	
Turnips, p. bunch	0 4 — 0 6	

Potatos (good samples). New Round, 5*s.* to 6*s.*; Kidneys, 5*s.* to 7*s.* per cwt.

WANT PLACES.—Letters to be Post Paid.

To Gardeners and Bailiffs (Head, Foremen, or Under).

JAMES CARTER AND CO. having many applications for Gardeners and Bailiffs from Gentlemen in all parts of the Country, will send NAME, ADDRESS, and COPIES of TESTIMONIALS, FREE OF CHARGE, to Gentlemen requiring GARDENERS or BAILIFFS only on receipt of a stamped envelope addressed to themselves. Only those who can produce satisfactory testimonials as to ability, honesty, &c., need apply.—JAMES CARTER AND CO., 237, High Holborn, London.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen requiring such Servants, on application to JAMES HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENER (Head).—Age 37, married, no incumbrance; has a thorough knowledge in all branches. Good reference.—C. M., 3, Standard Road, Bexley Heath, Kent, S.E.

GARDENER (Head), —Age 32, married; thoroughly practical in Fruit and Vegetables. Fifteen years' experience in good places.—A. B., Sutton Hall, Thirsk, Yorkshire.

GARDENER (Head).—Age 30, single; well experienced in the various branches of the profession. Good references.—J. M., Post Office, Cheadle, Staffordshire.

GARDENER (Head).—Age 35, married; thoroughly practical in every branch. Has had charge for seven years in nine months good character.—S. E., Post Office, Balcombe, Hayward's Heath, Sussex.

GARDENER (Head), in a large establishment, where a Man of trust and experience is required in the culture of Vines, Grapes, all Fruits and Vegetables, Plant Houses, Ornamental Trees and Shrubs, &c. Ozleworth Park, Wotton-under-Edge, Gloucestershire.

THOROUGH-BRED STOCK and FARMING EFFECTS.

MR. THORNTON will SELL by UNRESERVED PUBLIC AUCTION, on the Premises, on TUESDAY, September 19, at OZLEWORTH PARK, the ENTIRE HERD of PURE-BRED SHORTHORNS, PONIES, and FARMING STOCK, including 20 valuable HORSES, together with the FARM IMPLEMENTS, &c., the property of the late Sir John Rolt. The Shorthorns are bred from the celebrated Cole Moss, Mr. Oliver, and Mr. Styles Rich, and crossed with Bulls of the highly fashionable Bates blood, and the Horses are by Messrs. Cranwell, Bell, Bowman, Gillett, and Howell's well-known Flocks; and the Horses are very superior carriage and hunting Horses, with some good cart mares. Indeed, the whole stock is of a very high order, in excellent breeding condition, and will be sold without reserve.

Catalogues, with Pedigrees, may be had of Mr. PETERS, Ozleworth Park, Wotton-under-Edge, Gloucestershire; and JOHN THORNTON, 15, Langham Place, W.

Important Sale of Pure-bred Shorthorns and YOUNG HORSES.

MR JOHN THORNTON will SELL by AUCTION, without reserve, on WEDNESDAY, September 27, at Nether-houses, near Ulverston, about THIRTY HEAD of very superior PURE-BRED SHORTHORNS, chiefly of the renowned Duchess, Hoker, and Towneley blood, the property of Mr. Wm. Ashburner. Among them will be found several promising young Shorthorn Bulls, now in condition.

Catalogues, with Pedigrees, may be had of Mr. ASHBURNER, Netherhouses, Ulverston; and JOHN THORNTON, 15, Langham Place, London, W.

Brates House, Shipston-on-Stour.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions from Henry J. Sheldon, Esq., to announce that the PURE-BRED SHORTHORNS will take place on THURSDAY, September 21, at Brates House, Warwick-shire, and will consist of Forty Head of Cows, Heifers, Calves, and Heifers, chiefly of Kirklevington and Fawsley blood. Amongst them will be found Cows with Calves by Asia, Barrington, Blanche, Crimea, Darlington, and Surmise families, as well as from Fillet, Primrose, Rosy, Walnut, and other well-known families. The Bulls have been of the same fashionable sorts: the one now in service is the 58th Duke of Oxford (59,956), from the Duchess 35th family, and the Cows and Heifers are mated in calf to him. This Sale will afford a favourable opportunity to purchasers of first-class animals, as there will be sold only what remains in a healthy breeding state, and will be offered in the same *bona fide* manner as heretofore at the Castles.

Catalogues, with Pedigrees, may be had on application to Mr. STRAFFORD, 13, Eaton Square, London; or of Mr. SHELDON, Brailes House, Shipston-on-Stour.

Ellington, near Kimbolton, Hunts.

VERY IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to announce for SALE by AUCTION, without reserve, on THURSDAY, September 28 next, the entire PURE-BRED HERD of PURE BATES BULL, bred by and the property of Mr. Ladds, of Ellington, which numbers about 100 Head. Cows, Heifers, Calves, and Yearling Bulls forming them will be found several fine specimens from Red Duchess and Princess, bred by Mr. Christ. Turnbull, by Mr. Beasley; Farewell and Thistle, by Mr. Booth, as well as some old and other eminent breeders. First Marquiss of Exeter's, Mr. Robinson's, and other eminent breeders. First-class Bulls have been used for many years from Fawsley Hall, Cobham Park, Revesby Abbey, and latterly, Cambridge Barrington 1st (14,233), bred by the Duke of Devonshire, Wellesley (56,481), from Lord Penrhyn's, and 2d Earl of Barrington, bred by Mr. Sheldon from the Duchess 35th family, and by the Duke of Oxford 2d (59,956).

Catalogues, with Pedigrees, may be had, on application by post, of Mr. STRAFFORD, 13, Eaton Square, London; or Mr. LADDS, at Ellington, near Kimbolton, Hunts.

The Agricultural Gazette.

SATURDAY, SEPTEMBER 16, 1871.

WHETHER we believe in the direct interposition of Providence, or refer events to general laws, which maintain not only the physical equilibrium of the globe, but all the relations of the surrounding influences which regulate the fate of its inhabitants, no one can well deny that the system of compensation which prevails in all the arrangements of Nature has a marvellous resemblance to the operation of design. Even the most indiscriminate supporter of "natural selection" will admit that the effects which he refers to that cause at least indicate design, as may probably be due to a indifferent, if not reached by the most rapid and straight route. But there are cases of compensation which, although consequential, may be too unconnected to be intentional, and consequently can only be regarded as coincident. We draw the reader's attention to one in this doubtful position, not only for its bearing upon the subject of compensation, but on account of other claims which it has upon their interest.

The reader is familiar with the fact that the act of cast in destroying vast tracts of forest in Russia, America, and elsewhere has in some cases already produced, and in others has every appearance of being in the course of producing, an appalling deterioration of large portions of the earth's surface. An unconsciously compensatory action by man in the other direction has, however, now begun to make itself felt, viz., that where a settlement has been made in treeless plains, as in the prairies of North America, the result has been an improvement in the climate.

It appears, from a report by Mr. R. S. ELLIOT, "On the Industrial Resources of Western Kansas and Eastern Colorado," published this year along with other reports in the United States Geological Survey of Wyoming and contiguous territories, and to which we have just received access, that a popular persuasion in those districts that a climatic change is taking place, promoted by the spread of the settlements westwardly. The chief of the direct causes to which this is ascribed is the breaking up of the soil. Wherever this is done Mr. ELLIOT tells us "the wild Sunflower (Helianthus), and others of the taller growing plants, though previously unknown in the vicinity, at every spring are almost the spontaneous generation had taken place." These shade the soil more thoroughly than the short grasses, and thus check or modify the reflection of heat from the earth's surface, &c. It is also noted that even where the prairie soil is not disturbed, the short Buffalo-grass disappears as the "frontier" extends westward, and its place is taken by grasses and other herbage of taller growth. That this change of the clothing of the

plains, if sufficiently extensive, might have a modifying influence on the climate can hardly be doubted, but whether the change has been already spread over a large enough area, and whether the recent apparently or really wetter seasons are due to this, is a question which cannot be solved for years to come, when more extended statistics shall have been obtained.

The fact appears to be admitted, that rains have increased; and this increase has coincided with the extension of settlements, railroads, and telegraphs so decidedly that some have referred them to the mysterious electrical influence induced by the telegraphs. Prof. HENRY, a man in whose judgment we should be disposed to put more trust, thinks that the increased rains are due to extra mundane or cosmic influences not yet understood. If he is right, the change may be permanent, progressive, intermittent, or retrograde. If it is due to the settlements, then it must go on. Within the last fifteen years, in Western Missouri and Iowa, and in Eastern Kansas and Nebraska, a very large aggregate of surface has been broken up, and must hold more of the rains than formerly. During the same period, similar modifying influences have been put in motion in Utah, Montana, and Colorado. It appears that only very small areas of timbered land west of the Missouri have been cleared—not equal, perhaps, to the area of forest, orchard and vineyard, planted; hence it may be said that all the acts of man in that vast region have tended to produce conditions on its surface ameliorative of the climate. With extended settlements, Mr. ELLIOT anticipates (and we see no reason to dissent from his expectation) that the ameliorating conditions will be extended in a like degree, and that a permanent and beneficial change of climate may be experienced.

THE spirit in which questions connected with LAND and LAND LAWS have been discussed—as recently in Trafalgar Square—though beef is *10d.* a pound, shows that moderation and good temper are still national characteristics. It must be admitted the price of many articles makes the times trying. It has always been remarked that the temper of the community depends, in some measure, on the price of food. In periods of abundance order has usually prevailed; discontent has generally followed close upon a rise of prices; riots have always occurred during dearths.

We wish to call attention to one particular point in the politics of the "working man" and his leaders, in connection with agriculture. It is generally maintained by our Trafalgar Square friends that the inclosure of commons has, in some sense or other, been effected at the expense of the poor. It was not always thought so, and the idea seems to us to be erroneous. The great Inclosure Acts were popular when they were passed.

During the long series of deficient harvests, after the close of the remarkable era of abundance ending in 1765, when our exportations of home-grown corn ceased, and our increasing population began to be pinched, the legislature was forced, by popular agitation, to facilitate the methods of inclosure. Few other subjects occasioned the writing of so many pamphlets, even in that age of political pamphlets, as the waste arising from commons and the expediency of inclosing them. Such was the importance attached to the subject that Dr. PALEY introduced it in his "Theory of Moral Sentiments," expounding the arguments for inclosures, and showing their necessity and justice. Nor was this over-estimating the urgency of a question which involved that of feeding our increasing population.

Then followed the various Inclosure Acts, and especially the important General Inclosure Act of 41 Geo. III. During the war, a period of European scarcity when apparently one of the cycles of deficient harvests occurred, about 3,000,000 acres were enclosed. Subsequent inclosures have been comparatively trifling in extent, and only a small portion of the 8,000,000 acres of common land that are still uninclosed is naturally good enough to pay for improvement at the present time.

The question which is beginning to be asked throughout the country, and to be answered in various ways, some of them extravagant enough, is,—How is our food supply to be increased? It is a momentous question, for the high and rising prices of food not only diminish the profits of agriculture, but they increase the pressure of poverty and of pauperism, which is acknowledged to be a growing emergency, and they threaten to raise the cost of production, so as to invalidate our position as a manufacturing country.

Few persons realise that the cost of agricultural production must necessarily increase under the present circumstances while our agriculture has to fight against a national system of waste. It is unfortunate that the means of agricultural improvement are so little understood by the country at large, and that so many people should vainly anticipate improvements from mere political action which can only proceed from totally different causes. It is, no doubt, a matter of great importance to a country what form of government it adopts; but whatever the form may be, whether it be a little more or a little less perfect, so long as it is secure we do not think the food supply would be affected one way or the other.

The blessing of greater plenty depends on the application of knowledge in agricultural affairs, and not on mere politics. There is no doubt that legislation is needed, but in taking practical action for the general improvement of agriculture, certain hindrances can only be removed, certain prejudices overcome, and the necessary constructive measures adopted, when the teaching of science is more generally understood, and public opinion better prepared to sanction and demand the legislation that is needed.

Meanwhile those who aspire to teach and to lead the working classes, with a view to the improvement of their material condition, cannot do better than abandon mere politics, and take in their hand LIEBIG'S "Letters on Modern Agriculture," remembering that knowledge is power when properly applied, and that capital will flow to our fields when the public ceases to be careless of the truth.

WHEN conviction and energy are concentrated in the same individual, the world around will most likely be made aware of it. Such a person seldom hides his light, or muffles his tongue; why should he, when he is convinced he is right? After all, the world is very tolerant; we become accustomed to the loud mentors, speech makers, and prompters of society, and should miss them sadly from the agricultural arena, especially when they have held possession for long. Young performers, perhaps, are less admired, whatever their merits may be; but they have only to persevere, since fore will always be respected, whether it be physical or mental—thunder and lightning or enthusiasm.

The agricultural world usually rejoices in its large number of enthusiasts, and is exceedingly obliged to them for relieving the dull monotony that intervenes at certain periods of the year. May their numbers never be thinned, and may they retain their characteristics! An agricultural enthusiast should be regardless of results, and indifferent to pecuniary considerations; he ought to have no money interests; nobody ought to be able to follow his advice without suffering in pocket. His rules ought to be hard and fast so long as he holds by them; his opinions should be dogmatically expressed, and coincide with those of no other person; his general laws ought to bind no one, and suit no circumstances but his own.

An agricultural enthusiast, being less practical than most men, exercising less caution, and possessing less tact and judgment, than other people, should try all sorts of experiments. He should lose a great deal of money, and settle very slowly, if ever, to practical, successful farming. He should go on sowing his wild oats long after his contemporaries have finished. We have no opinion of a prudent enthusiast; if he becomes matter-of-fact, his character is gone, and nobody notices him. He should set up a standard which ought to be talked about and written about and recommended, on scientific grounds if possible, till it is forgotten, superseded or disbelieved, as the case may be. Practical success is a test which ought not to be applied by an agricultural enthusiast; it should be contrary to his principles to succeed in anything to the first intent, and without losing time and money. Success, in his case, like FLAXMAN'S early marriage, in the opinion of Sir JOSEPH, would "spoil him for an artist."

It would never do for an enthusiast to imitate those successful agriculturists who possess a faculty for farming, and an agricultural genius which guides them through all difficulties. He must not be misled by their varying practice, their power of correct observation and comparison; their pondering of the laws of Nature, silently and sometimes instinctively obeying her voice—scientific without knowing it, and successful without talking about it. Instead of that he must proclaim his doings on the house-top, and before his plans are carried out he must change his mind and begin something fresh. He should always remember he has a character to keep up as an agricultural enthusiast, and he should shun sound practice and plain sense as he would shun extinction.

WHEAT has again risen somewhat in price during the past week. In Mark Lane on Monday it was 1*s.* dearer; and on Wednesday the full rates of Monday were realised. Barley, also, was in fair request, at full prices.—In the Metropolitan Cattle Market the demand has been good, and the supply was rather short in relation to it, both on Monday and Thursday. Prices have thus been higher than they were on the previous week.

The following analysis of the extraordinary SHORTHORN SALE at HOLKER last week, described in another column, is taken from the columns of the *Field*. The average prices realised by the members of the several families represented deserve a record:—

"Oxfords."

Graad Duchess of Oxford 7th	..	..	£960	15	0

12 bulls	2638 12 0 ..	221 7 0
43	£10,360 7 0	£240 18 9

A correspondent in Thursday's *Times* speaks of the possibility of CONFINING RABBITS by WIRE FENCING properly fixed:—

"When renting a shooting manor in Bedfordshire I paid for three years an average of £18 a year compensation for damage round one dozen wood. I then determined to wire it in, and did so in the following way:—A plough was run round to make a trench 6 inches deep; into this was sunk wire 4 feet wide, and thus 18 inches only were out of the ground—light soil. I never paid another penny piece for compensation, and the wood was good for 1100 or 1200 rabbits a season. I have now, not having sufficient room in my walled gardens about three quarters of an acre of ground enclosed in the same way, and with the same width of wire, and have not lost a leaf. My neighbour preserves rabbits—so many that I can on any moonlight night count them by the score. I cannot keep a flower in my shrubberies, and some Cabbages in open ground are represented by bare poles. I see all round my netting where the rabbits have scratched, but, finding the wire, they, not knowing how deep it may be, I suppose, desist; and I grow Asparagus, Peas, Beans, Carrots, Cabbages, &c., within the wire, 6 inches under and 18 inches above ground, without being interfered with. I have never seen a rabbit jump or scramble wire, and I have watched them for years; in proof of this, flower-beds on my terrace, protected by wire 10 inches high, are safe, while the same flowers in the shrubberies are eaten.

"I farm, and make it a rule not only to shoot down, but to destroy all the stooks I can find. One of my neighbours put down 1600 yards of wire on the surface—the rabbits got under, of course; he then carthed up, but once under always under; had he sunk it, as I have done, he would have saved his crops. I told him, or rather his man, this when putting it down, but receiving for answer

that 'they knowed all about it," I rode on and left them to pay for their experience. I may add, in conclusion, that my supplementary kitchen garden was intact all last severe winter, when rabbits were found dead about me from starvation."

OUR LIVE STOCK.

CATTLE.

THE results of Mr. Strafford's Shorthorn sales of last week in the North prove that there is no diminution in the value of high-bred Shorthorns. At the long-to-be-remembered sale of Mr. Hegan's herd in 1865, "the trainer of the Duchesses was so delighted with the Duke of Devonshire's bid of 600 gs. for GRAND DUKE 10TH, that he rose and asked the auctioneer 'How much for the depreciation of Shorthorn prices?' an allusion which was caught up and highly relished." We may still, in 1871, repeat the same question, and thereby again arouse pleasant rejoinders. Six hundred guineas for GRAND DUKE 10TH appeared at the time it was given an enormous—a fancy—price. But the events of the past week have proved it to have been an excellent purchase, and we hope that the spirited bids which have so nobly competed with the Duke of Devonshire for his bold speculation, may be equally profitable to recent purchasers.

We have three important sales to record—the first on Wednesday week at Holker, the second on the succeeding day at Beaumont Grange, and the last on Friday at Kilhow.

—The sale of the Duke of Devonshire's stock at Holker far eclipses anything of the sort for some years past. The cows were large, good, and in excellent condition, and the heifers were a very fine lot, as, indeed, they ought to have been to have provoked such unprecedented competition. The general average over 43 animals was £249 2s. 10d. each; the average over 38 cows was £248 2s. 6d., and over 12 bulls, £221 11s., while the sum realised was £10,349 17s. The leading feature of the sale was the disposal of the "Oxford" tribe, eight in number, which realised £588 each. The price of the day, 1005 gs., was given for *Grand Duchess of Oxford 18th*, calved September 27, 1870, got by BARON OXFORD 4TH (25,580), and out of *Grand Duchess of Oxford 11th* by GRAND DUKE 10TH (21,848), who traces back to the *Matchem* cow by MATCHEM (2281). This splendid offer was made by Lord Bective, who seems bent on securing the best blood he can lay his hands on. A bull of the same family, also by BARON OXFORD 4TH, was purchased for 1000 gs. by Lord Feversham; and 300 gs. was so frequently bid, that we must refer our readers to the list for information regarding even such extraordinary prices.

Summary:—

31 cows at	.. £248 2 6 =	£7691 5 0
12 bulls at	.. 221 11 0 =	2658 12 0
43 animals averaged ..	£240 13 10 =	£10,349 17 0

—At Beaumont Grange, on Thursday, 19 females and 11 bulls were offered. The whole herd were suffering from foot-and-mouth disease, and yet in spite of this drawback some good prices were given. An average of £71 10s. 3d. was obtained over 28 animals sold. Nineteen cows realised £78 5s. each; 9 bulls realised £57 5s. 8d. each; and the sum total was £2002 7s. The demand for pure Bates blood was attested by the sale of a Lady Bates heifer to Mr. TEASDALE, born on February 19, for 500 gs.; and we may add that the general impression was that the calf was cheap. A similarly bred yearling bull was sold for 200 gs.

4 bulls at	34 15 0 =	139 5 0
56 animals averaged ..	£102 1 6 =	£5709 1 4

—At the Brockton House sale on Tuesday, 49 Shorthorns, bred by, and the property of, Mr. Thomas Bell, brought an average of £58 13s. 5d., and a total of £2874 18s. This high figure was due to the sale of the 8TH DUKE OF YORK, 1065 gs., the highest price ever given for a bull, at which sum he became the property of Mr. J. Fawcett and a friend. The sale of *Princess Victoria 7th*, by 13TH DUKE OF OXFORD, and of the "Place" family, to Lord Skelmersdale, was the only other important event. With the exception of two "Georgina" heifers, and two "Hilpas," descended from *Cornflower* by BASHAW, the remaining stock sold for prices under 50 gs.

RAM SALES.

Leicesters.—On Wednesday last, at Aylesby Manor, 66 sheep were penned for letting; of these, 33 were shearlings, in prime condition. The names all his rams, and amongst the shearlings, Warrior, let to Mr. Jordan, of Eastbourne, for 20 gs.; Wellington, to Major Taylor, of Barton, for 22 gs.; and Westland, to Mr. Tindale, of Branstone, for 15 gs., were decidedly the best shearlings; but curiously, where all were so good, pick may appear invidious. Ulysses, a magnificent full-grown 3-shear ram, was taken for £40 by Messrs. Dudding, of Panton, and Usher for £30, fell to the lot of Mr. Bonton, of Barton. The average scale of hire was £16. Mr. Torr still lets his rams on the old-fashioned principle of each customer only hire of his last year's ram, and if there is more than one customer for a shearling, the sheep is put up in a friendly manner by auction.

—In connection with the Border Union Agricultural Society, the annual sale of Leicester and half-bred rams took place at Kelso on Friday. The best Leicester ram sold realised the unprecedentedly high price of £115. It was one of the Mertoun lot, the property of Lord Polwarth, whose sheep have long been esteemed among the best on the Borders. This ram was purchased on behalf of Mr. Sanderson, and will go to Australia. Other rams of the Mertoun flock sold were £105, £65, £54, £50, £45, £43, £33, £28, £27, £26, £25, and smaller sums. The average price of Lord Polwarth's sheep (30) was £30 10s. At last year's sale Lord Polwarth also got the highest price for his rams, *viz.*, £160, average £22 14s.; in 1866, highest £42, average £15 0s. 5d.; in 1867, highest £86, average £25 14s.; in 1867, highest £106, average £25 12s.; in 1866, highest £98, average £27 1s.; in 1865, highest £95, average £37 18s. 10½d.; in 1864, highest £70, average £26 19s. 8½d.; in 1863, highest £60, average £21 6s. 3d. The rams which brought the next highest prices belonged to the Mellendean flock, the property of Miss Stark. The highest price obtained by these rams on Friday was £100, which was paid by Sir George Dunbar. The prices of other rams in this lot were £91, £60, £50, £43, £40, &c. The average prices obtained for the 47 Leicester rams of the Mellendean flock was £28 15s. 3½d. In 1870 the highest price given for the Mellendean rams was £32, average £13 10s.; in 1869, highest £109, average £16 9s. 4d.; in 1868, highest £62, average £18 0s. 10½d.; in 1867, highest £84, average £22 14s. 2d.; in 1866, highest £80, average £25 15s.; in 1865, highest £81, average £24 3s. Several of the other lots of rams sold brought very high prices. Among them were Rev. R. W. Bosanquet's, Rock, highest, £50; average for 66 rams, £14 3s. 3d. John Lee's, Marvingston, highest, £40; average for 20 rams, £12 10s. Mr. Forster, Ellingham, highest, £32; average for 82 rams, £10 7s. 6d.; and many others. The highest prices paid for half-bred rams were £20, £19, £17, £15 10s., &c.

Lincolns.—At Owersby the show was confined this year to 88 shearlings, bred by the late John Davy, Esq. No. 45 fell to the lot of Mr. Hall, of West Finsley, for 30 gs. The 88 were sold for £1009 12s., being an average of £11 9s. 3½d.

—Somewhere about 30 years ago it was computed that Lincolnshire fed 2,000,000 sheep, producing

22,000,000 lb. of wool. It is now estimated that the number of sheep in the county is upwards of 4,000,000, and the wool returns not far short of 50,000,000 lb. With the gradual extension of sheep farming, there has been a corresponding increase of ram breeders to meet the wants of the green-crop folk. Amongst the most successful of the North Lincolnshire sheep breeders, Mr. Havercroft deservedly takes a first-class position. His flock of 500 ewes, sheared rams, sold on Friday, would take a deal of beating, and could boast a goodly assemblage of customers, as well as admirers, to his pleasant homestead at Wootton Dale. This year the 60 sheep sold averaged £12 10s. 7d., the prices ranging from 7 gs. up to 46 gs. The latter price was given by Mr. Robert Walker, of Somerby, near Brigg.

Shropshire.—Mr. May, of Elford Park, near Tamworth, held his annual sale of rams and ewes on Tuesday. There were rather more rams than usual in the catalogue. Of those sold, Nos. 14 and 15 made the highest figure, viz., 18½ and 18 gs. to Mr. Ridgway, and Mr. Jones, of Sudbury. Mr. Beardall secured a good 2-shear, by Sailor, at 14½ gs.; the others ranging from 14 down to 5½ gs., and the average being just under £10 10s.

STEAM CULTIVATING COMPANIES.

At p. 1047 Mr. Jacob Wilson told us that "there was a steam-cultivating company which, only the other year, had got from 20,000 to 30,000 acres to cultivate. Their prices were moderate; they could earn a fair percentage for their money, and, what was far more important, it was a source of profit and accommodation to the tenant farmers of their district."

Let Mr. Wilson favour us with this wonderful company exists, and let him give all the particulars about this large number of acres worked at a moderate price, clearing a fair profit to the shareholders; and, above all, let him give the names of the farmers benefited thereby—giving the number of acres done on each farm, with time of working, &c.; for as yet I have never been able to learn that contractors have been able to work it at a moderate price, that would enable farmers to farm regularly by steam-power. I will repeat the questions that I asked in the *Times* on June 12, 1865, in reply to J. A. Clarke: "Where is their regular work? Where are their regularly cultivated farms? They have done a little experimental jobbing work by bit here and a bit there, and that is all" (see p. 589, 1865); and state that that is about all Mr. Wilson's wonderful company has done. If not, why does he leave the name of the company, &c., as stated by You say in your article, at p. 1046, on Mr. Bulstrode's letter, that "the only real annoyance in the farmer method (hiring) consists in having to wait the convenience of the contractor;" and then you follow up thus: —"There is constant risk of losing the great advantage of having the land worked at the right moment," and then you encourage "an accommodating spirit among those who employ the apparatus," advising the contractor to remember "a customer who has suffered from delay." This may look very kind and friendly upon paper, but the suffering farmer's pocket will not be relieved thereby, and, besides all that, while the preference farmer is getting a plaster for his sore pocket, it may be that another farmer is suffering, and thus a perpetual suffering will go on in one quarter or another. My own practice thoroughly convinces me that a system of perpetual suffering will never face success by steam-power, for I am certain the following results could have been attained only by having tackle at hand, to be brought out when needed. Take first my

Heavy Land.

Field No. 1.—16½ acres, Beans after Wheat: After harvest 12 tons of dung per acre were spread over the Wheat stubble; on September 29, the ridger and subsoiler was set to work by steam-power to work it 10 inches deep, and put it into ridges ready for the winter, to be planted with Beans in February. The cost of this operation was 6s. 3d. an acre. In February the Beans were planted by hand, two rows on a ridge, that is, one row on each side. The rows average 18 inches from row to row; the cost per acre was 3s. 6d., after which the rows were horse-hoed, at a cost of 1s. 6d. per acre each time. The cost of seed-bed and planting, therefore, was 11s. 9d. an acre. The crop, although slightly affected at the top of the haulm by the fly, is splendid; and when we remember that it is sixteenth under steam-culture, and also call to mind that a fine field of Wheat grew on this land last year, the conclusion is irrefutable, that under a judicious application of steam-power, clay land can be kept clean and subsoiled, without any resort to dead fallows, which may justly be regarded as "dead loss," not only to the farmer and the landlord, but in their not remote effects to the nation at large.

Field No. 2.—Here we have 28½ acres, Beans after Wheat. This field has been manured and treated exactly as the preceding, and the crop is quite as fine. Indeed, the two fields may be regarded as one, there being no fence between them; and it is a sight worth going to see—more than half a mile in length of fine, well-corned Beans. The crops under steam culture grown on this land for 16 years have been invariably good, and have been as follows:—In 1856 this field was in Wheat, and in the succeeding years the crops stood thus:—1857, Beans; 1858, Barley; 1859, Beans; 1860, Wheat; 1861, Swedes; 1862, Barley; 1863, Beans; 1864, Wheat; 1865, Beans; 1866, Wheat; 1867, Beans; 1868, Wheat; 1869, Beans; 1870, Wheat; 1871, Beans. The cost of seed-beds for the 16 crops stands at 9s. 2d. an acre each. With such evidence as this, who can doubt that steam culture beats horse culture both in cost and produce? These costs, 9s. 2d. an acre, are much less than half the cost of horse culture, and the crops have all been good; the present Bean crop is the best of the lot, and this without any fallow at all. Ponder over these facts.

Field No. 3.—29 acres, Wheat after Beans, excepting about an acre after dead fallow. The Bean-stubble smashing cost 4s. 3d. an acre, which, with a hasty harrowing, at a cost of 1s. 3d. an acre, made the cost of seed-bed 5s. 11½d. per acre. This is a fine field of Wheat (Essex Rough Chaff), strong in straw, and well headed, and will produce a good produce. This is the second crop on this land under steam culture. Three cwt. of superphosphate was sown per acre in March last.

Field No. 4.—24 acres Wheat, after a part in Peas and a part in Beans. The operations, manure, and costs were the same as in No. 3. It is a remarkably fine field of Wheat, and needs only suitable weather to ripen it. A small portion has been laid by the heavy rains, but with fine weather no harm worth speaking of will be sustained. This is the second crop under steam culture. About two years since, dead fallows and inferior crops were the order of the day on this land.

Light Land.

Field No. 1.—12 acres, Barley after roots: This field was ploughed with horses at a cost of 10s. 6d. an acre. The crop is very good, but a part of it was thrown down by the recent rains and wind.

Field No. 2.—13 acres, Wheat after Clover, ploughed with horses, at a cost of 10s. 6d. an acre: This is a remarkably fine crop, very strong in the straw, and wonderfully headed. It has withstood the rain and wind, and with fine weather the yield must be great.

Field No. 3.—11 acres, Clover after Wheat: The Clover has been mown, but, like the rest, is a Clover generally, the crop was light. Part of it will be mown again, but the plant is not thick enough to give a good crop. The hay crop throughout the neighbourhood this year has been under an average, and I generally badly got. I had about 6 acres driven away by a flood, and a neighbour lost 10 acres in the same way.

Field No. 4.—12 acres, roots after Wheat: Ridged, ploughed, and subsoiled as before, but, like the Clover generally, the crop was light. Part of it will be mown again, but the plant is not thick enough to give a good crop. The hay crop throughout the neighbourhood this year has been under an average, and I generally badly got. I had about 6 acres driven away by a flood, and a neighbour lost 10 acres in the same way.

Field No. 4.—12 acres, roots after Wheat: Ridged, ploughed, and subsoiled as before, but, like the rest, at a cost of 6s. 3d. an acre, and that was the cost of seed-bed, for all that the land needed in the spring was simply harrowing and drilling. There are 6 acres of Swedes, 4 acres of Mangels, and 2 acres of Kohl Rabi, all a full plant, with a certainty, with fine weather, of a good crop. The manure used was 12 tons of yard dung.

Field No. 5.—Wheat after Beans: The Bean stubble was left in sad condition, after the ridging and subsoiling by steam-power for the preceding crop, that it needed nothing but a scuffling with horses, at 2s. an acre, as the cost of seed-bed for this splendid crop of Wheat. It is the next to impossible to find a finer crop of straw, or of it has gone down, being too heavy for the recent wind and rain.

Field No. 6.—14 acres, Barley: This is the fifth white-straw crop in succession. It is a fine one, a little of it rather too heavy. The cost of seed-bed was 6s. 3d. an acre, worked a foot deep, by ridging and subsoiling by steam-power last October. The manure was 6 cwt. of superphosphate per acre. This land, although it has got its fifth white-straw crop upon it, is very clean; horse culture could not have produced such a cleanly result at four times the cost per acre yearly; indeed, I am of opinion that horse culture could not have produced such clean land under such heavy cropping as we have here, particularly for the last five years, under Wheat the first year, and barley the four succeeding years.

And last on my list, the following facts:—The steam-power work that produced the above crops was—53 acres of Bean and Pea stubble smashed in 6½ days, at a total cost of £1 12s. 9d., including 1s. 6d. an acre for wear and tear, &c., and 63 acres of Wheat stubble harrowed, ridged and subsoiled in 12 days, at a total cost of £20 6s. 6d., including 1s. 6d. an acre for wear and tear. The average day's work of smashing was 8 acres, at a cost of 4s. 8½d., with a harrowing of 5¼ acres. And so brought the cost of seed-bed for Wheat up to 5s. 11½d. an acre, and the average day's work of ridging and subsoiling was 5¼ acres at 6s. 3d. an acre, which was the total cost of seed-bed for Beans and Barley on ridged land as well as for roots.

The sixteenth year's farming under steam culture may be thus summarised:—78 acres of excellent Wheat, 53 acres light land. The seed-bed for the Wheat crops, 12 acres of roots (a very regular and rapidly growing plant), and 11 acres of Clover that has been mown once for hay, cutting about a ton per acre. This shows a total of 154 acres under culture, and not a fallow or a bare piece just ploughed up. The heavy weight of corn cropping—143 acres out of the 166—is worthy of notice. There is no fallow on the heavy land, and only 12 acres under roots on the light land. The seed-bed for the 78 acres of Wheat cost only 5s. 11½d. an acre; for Beans, roots, and Barley, the latter the fifth white straw crop in succession, the seed-beds stand at 6s. 3d. an acre. With this evidence before him, I am fully justified in saying that every farmer must have all his steam culture done in the autumn, or it would be impossible for him to obtain such results. Twelve years since I wrote:—"If steam-power is to be generally applied to the cultivation of the heavy lands, the farmer must possess a set of apparatus of his own. Two or three small farmers may have a set between them, or hire one of another, according to, arrangement, for September and October will not work all; and if the work is to be done well, it must be done in those months;" and experience has endorsed my judgment. My challenges in support of my views have remained unanswered; and, while admitting that the contract system may, under certain circumstances, be worked to advantage, I contend that it is not "a best application" of steam-power, inasmuch as it cannot do the work in the proper season only at a very high cost, and Mr. Robinson, of Wisbech (a contractor), I cite as a substantial witness upon the point. In further confirmation of my views, I quote the following letter from the *Agricultural Gazette* of January 20, 1866:—

"I and my brother are in partnership in our machinery, and this year I did not have the cultivator until he had finished; consequently I have done little, and of that can give no estimate. I consider steam cultivation far superior to horses, and with good fellows need not be attended with many breakages; but with careless men nothing is so much so. One thing I strongly recommend, *i. e.*, no partnership, for it might happen that one would receive great benefit and the other none, as so much depends upon the weather. *W. Addington, St. Neots.*"

With such evidence before me, with my own figures and results to support me, I call in question the permanent utility of the contract plan of working.

The Royal Agricultural Society may encourage it by dubbing the tackle that is the most suitable to work upon it as "the best application" upon the strength of opinion, for as yet there is no evidence to support that opinion; Mr. Wilson's case would be evidence, if he could support it by names and particulars. He tells us, that "he was himself in favour of Fowler's machines, but he was not prejudiced, if he could see a better to-morrow he would buy it." Then let him compare the summing up of my 16 years' practice given above with his own, over the whole of his farm, from his start, and give everything in detail, by way of proof that he is right in his opinion, or I shall take it that he jumps at conclusions. He is a Council member of the Royal Agricultural Society, and therefore it is quite natural that he should, and not rashly, jump at the conclusion that they must have the old plough, whereas my own evidence proves that old plough has never been needed on my heavy land for 16 years, and never will again. Let him ponder over this evidence of mine well, and "see" whether he may not spend his money "to-morrow" in finding some tackle superior to his own, that is, by finding tackle by which he may work his land better and cheaper than he has done heretofore. Mr. Mechi, in his article on "a thin-skinned land," appears to thoroughly understand the efficiency of deep-cultivation, deepening the soil on clay lands, and Mr. Wilson will do well to pay strict attention to what Mr. Mechi says upon the point, and the whole article will pay well for reflecting over. *William Smith, Woolston, Bletchley Station, Bucks, August.*

ASSOCIATED DAIRIES.

Their Present Position and Future Prospects.

Dairy farming is a branch of rural economy affecting the interests not only of a large number of landlords and tenant-farmers, but it has now attained a great national importance; while within the last 25 years all other branches of farming have made immense strides that alone of cheese-making has remained stationary, and in many instances a retrograde movement has even take place. The English dairy farmer has generally ignored the teachings of science, though supported by the patient researches of Liebig, Johnstone, and Voelcker, and the agricultural journals, with the arch keenness proverbial of their country, spared no expense in sending men of intelligence and ability to visit the best dairy districts of the country, and to make themselves thoroughly acquainted, both practically and theoretically, with the different methods of cheese-making, and their full and faithful publication they adopted the Cheddar system, so well described by Dr. Voelcker in the Journal of the Royal Agricultural Society, as the system best adapted for the application of scientific principles. The Americans, after repeated failures, have succeeded during the last three years in raising their manufacture to a high degree of eminence, and cheese of American make has been gradually superseding the produce of English dairies in our own markets—they have been reaping golden harvests, whilst we have only been the gleaners.

Dairy farming is most successfully carried on on soils of medium quality, and with about one-fifth of the acreage under arable culture. This furnishes a sufficient supply of straw and roots to carry the stock well through the winter. Climatic influences to a certain extent affect the produce, a moist climate and low temperature being favourable to the dairy farmer. In the south-western counties of Scotland a greater quantity of cheese per cow is made where there is no old permanent pasture, and where the whole of the land is worked on the five or six course system, and therefore only down for two years in six or seven, than is generally made from the old permanent pastures of the dairy districts of England. In the former case 480 lb. of cheese per cow is the rent at which on all the best farms they are let to bowers or men who make a business of renting cows, and who, in addition, must also make a sum sufficient to pay them for their labour of management, whilst in the latter, 400 lb. is the average make of ordinary dairies. This may be attributed to various causes. The Scotch dairy farmers, as a rule, are much higher feeders than the generality of English dairymen; where the farms are under a regular rotation of cropping, they derive great advantages from always having a liberal supply of straw and roots, which enables them to get their cows into good condition at calving—a most important point as regards the future produce; whereas on the old permanent pastures, with little arable land, they are mainly dependant on hay for their winter support. Again,

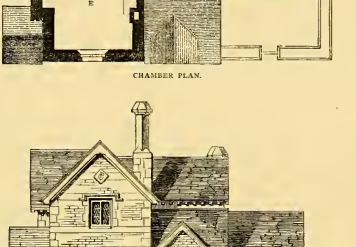
in the south-western counties of Scotland, the prevalent breed of dairy cows are the small Ayrshire, which are celebrated for their high milking qualities in proportion to the amount of food consumed. They are unsurpassed for the quantity of milk they yield by any other breed of cows with which we are acquainted. We think they might be profitably introduced more extensively into the west midland counties of England. Four Ayrshires could be kept on the same quantity of food as three large Shorthorns would require, and, on an average, each of the former would give a greater quantity of milk than one of the latter. The great objection to the Ayrshires is their small value for feeding purposes when drafted from the dairy. Even with the Shorthorn on some farms we find this to be the case, particularly with good milkers, which are often retained until they are of little value to the grazier. This system of management is also unprofitable to the dairyman, for old cows are generally large consumers, and beyond the fourth calf the quality of the milk becomes depreciated.

Cheese factories and associated dairies are increasing in public favour. Besides the originals at Longford and Derby, another has opened at Freeford, near Lichfield, under the auspices of Colonel Dyatt, M.P. for the city of Lichfield. One at Tattenhall, near Chester, is carried on by Mr. Geo. Jackson entirely as a private venture, while late in the season another on a small scale was started near Crewe. The committee of the Derbyshire association have this year made several alterations, and introduced what they consider some important improvements, their chief aim now being to make an article that will command the highest price in the market. There are certain peculiarities inseparably connected with all cheese made strictly on the American principle, and cheese so made in this country becomes deteriorated in value by being classed with American produce. The Cheddar system, under good management, produces an article of superior excellence, and this the Americans adopted as their type, but in their anxiety to save time and labour they hastened the operation beyond its legitimate bounds. The American system of employing high temperatures, both in the vat and the curing-room, light salting and heavy pressure, produces a cheese which rapidly matures, but is limited as to its keeping properties. In the Derbyshire dairies this year the temperature is kept down to about 86°, the whey is run off, and the curd packed, pressed, and ground, and the cheese pressed for two days; in fact, the pure English Cheddar system is strictly carried out. Each district has its own peculiar fashion as to shape and colour, and in order to enable us to get into the different markets, we are compelled to make a variety of shapes, though all of the same quality; there are the Cheddar size, 13 inches deep, both plain and coloured; and the Leicestershire, 17 inches in diameter and 4½ inches thick. These are all coloured; and, besides, there is the Derbyshire, 16 inches in diameter and 4 inches thick, uncoloured.

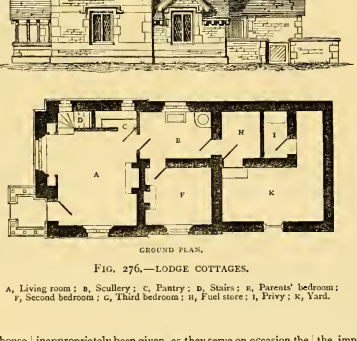
On the Cheddar system the labour is slightly increased, rather more salt is used; the cheeses require considerably more time to mature, and there is less loss of weight by shrinkage. Both the quality and keeping properties are greatly improved, and, according to our experience, less of the butter passes off in the whey. We find the Cheddar, though weighing 60 lb. per cheese, fit for market in the same time as the Derbyshire size, which weighs only 38 lb. The factory system is quite applicable to farmhouse dairies of from 30 cows and upwards, and the saving of labour, together with the certainty of making a more uniform article in point of quality, cannot fail to make it remunerative even on this small scale. At the Derby factory many experiments have been tried, in order to ascertain how the greatest quantity and the best quality of butter can be obtained from the whey. From 300 gall. to 400 gall. of whey are run into a vat, into which is placed a coil of copper pipes; through these a jet of steam is passed, and the temperature of the whey is raised to 180°, the top is then skimmed into narrow tin vessels, and these are placed in cold water till the temperature falls to about 60°, when their contents are fit to churn; this straining process entails a considerable cost in fuel and labour, and has the effect of throwing up a large quantity of casein, intimately blended with butter, and rendering it difficult to churn. The butter obtained in this way is fair flavoured; but we find that by running the whey into double-bottomed tin vats, between the bottoms of which cold water can circulate, (after standing 24 hours) an equal quantity of butter may be obtained with a much less amount of labour, the quantity to be operated upon being much less. For every 100 gall. of milk delivered at the factory, we obtain about 1 lb. of whey butter. The value of the whey for feeding purposes principally depends on the amount of sugar it contains, and therefore it suffers but little deterioration by the abstraction of the butter. In arranging the plan of a cow factory, it should be specially designed with the view of reducing labour to the minimum. The floor of the make room, on which the cheese vats stand, should be at least 3 feet above that on which the whey vats stand, so that the whey flows by its own gravitation from the milk to the whey vats, and thence again into the sour whey cistern. The butter dairy room may be a cellar under the floor of the curing room. This will secure a cool equable temperature in the hottest weather, and prevent the butter from getting soft. *Gilbert Murray, Elvaston Estate Office, Derby.*

LABOURERS' COTTAGES.

THE design represented by the accompanying woodcuts (fig. 276), and furnished by Mr. Bailey Denton, jun., is intended to illustrate a class of cottages for rural estates to which the name of "lodge cottages" has not inappropriately been given, as they serve on occasion the double purpose of gate cottages or lodges and dwellings for agricultural labourers.



CHAMBER PLAN.



GROUND PLAN.

FIG. 276.—LODGE COTTAGES.

A, Living room; B, Scullery; C, Pantry; D, Stairs; E, Parents' bedroom; F, Second bedroom; G, Third bedroom; H, Fuel store; I, Privy; K, Yard.

Although representing the most expensive form in which cottage accommodation can be provided, single or detached cottages may be conveniently placed at the entrance of a park, at the commencement of the private road leading to the farm-house or mansion, or in situations where one labourer is all that is wanted.

Upon an examination of the plans it will be seen that the windows of the living room are placed so as to command a view in all directions, and that a bedroom has been provided on the ground floor, with the view of diminishing as much as possible the trouble incident to opening the gate after it has been locked at night.

The cubical contents of the cottage, exclusive of the outbuildings, is as follows:—Living room, 1416 feet; scullery, 616 feet; pantry, 97 feet; staircase, closet, and cupboards, 319 feet; parents' bedroom, 1491 feet; second bedroom, 616 feet; third bedroom, 680 feet; making a total amount of 5235 cubic feet.

The total cost of the works shown on the drawings may, under ordinary circumstances, be estimated at about £220. This sum is in excess of the general cost of cottages, owing to the fact that the building in question is built singly, covers a great deal of ground, is more expensive in construction, and more ornate in character than labourers' cottages usually are.

TIPTREE HALL.

I RECENTLY paid my first visit to Tiptree Hall, and devoted the day to Mr. Mechi and his farming. Thus, in going and coming, I thought and talked of Tiptree and its doings to all sorts of people, and in all sorts of places—in the train and by the wayside, in cottage and workshop, with labourers and mechanics, clergymen and tramps, squires and farmers, I turned the subject Tiptreewards. I am happy to say that I received but one testimony, viz., that Mr. Mechi was a good man, a kind master, and a good farmer, and that his crops were very good, first-rate—better than any of his neighbours; that he had done a great deal of good, and that others were following his example, &c. Most of these, and many other similar testimonies, were collected within 6 miles of Tiptree, and they are at least equally trustworthy with the idle gossip of some farmers' rooms that found its way into your columns some years since. I was reminded of some of the latter tales by an incident that occurred on my way from the station. Meeting an old man, and inquiring the distance to Tiptree, he said, "You'll see some rare crops there, sir. There be some about there that speak against Mr. Mechi." Pointing to a farmhouse, he added, "The farmer that lived there once told me that Mr. Mechi wrote lies in the papers; and I said to him, 'If that is so, why don't you write and tell him so, and put your name to it; that's what I would do if I were a farmer. I would not say such things behind his back. Tell him so to his face like a man.' The farmer, who is dead now," said my informant, "came up and put his hand on my shoulder, and, pointing with the other to his Wheat, said, with a knowing wink, 'I say, old man, I have a good crop there, have I not?' From that day he never spoke against Mr. Mechi nor his farming to me." It is to be hoped that all others will take the old man's hint, and that we shall have no more false reports of a great man's doings, nor idle gossip paraded with the authority of veritable facts. So much for jottings by the way, which are a fair set-off against much that has been raked up on the other side. I should not have made them but for the damaging letters before referred to. I put no leading questions to my informants, and confess that I was quite prepared to hear a different account of Tiptree from its neighbours, for Mr. Mechi has not escaped the usual penalty of reformers. No man has been more pelted by the heavy artillery of prejudice, discharged from entire batteries of strongly entrenched ignorance. The greatest reformer the earth ever saw has likewise told us that a prophet or teacher is not without honour, save among his own people. We have seen that Mr. Mechi has been no exception to the rule, and no wonder. What could seem more supremely ridiculous to the mind truly rural and wholly agricultural than that an alderman or a lord mayor of London could teach it better farming. But seeing is believing—often the only kind of faith, indeed, acknowledged in the country. By force of annual demonstrations Tiptree has compelled belief in its success; those who carp and deny are those who have not been to see. It was gratifying to find that not only Mr. Mechi's immediate neighbours had made the discovery, that the great pioneer of the improved agriculture of the future was amongst them, and that they have begun to know and honour him as such.

Arrived at Tiptree, I found all grades of agriculturists busy taking mental notes or making memoranda —landlords, tenants, farm-proprietors, corn dealers, dry farmers, who believe in muck, and wet farmers, who have faith in sewage; and, best of all, Mr. Mechi was there himself, as plain all as ever in his happy style, and dispensing a hospitality and manifesting a kindness that have often been adverted to in your columns, but which no pen ever has, or ever will, do full justice to.

I do not purpose giving a detailed account of the farm. To most of your readers Tiptree Hall is familiar as a household word; all of them ought to contrive to see it for themselves. My expectations were pitched high, but not one of them was disappointed. The general verdict on the crops was—"We have seen nothing to equal them this year." The Wheat, of which there were several varieties, was uniformly good, remarkably regular in height of straw and in size of ear; every stalk stood bolt upright, like a guardsman on sentry duty. I did not see a single ear down on the farm. This evenness of the Wheat crop is the more singular, as the rotations at Tiptree are anything but fixed. One piece of splendid

Wheat, for instance, quite equal to any other, was the third Wheat crop in four years.—Mangel, which followed two Wheat crops, and yielded 39 tons an acre, last year, is succeeded by a splendid Wheat crop, that assuredly boasts no sign of distress, as if the land were corn sick, or had its back—that is, its productive force—broken by carrying all this grain in so short a time. Here are the past, present, and future doings of this field, as given by Mr. Mechi himself in the *Brainiest Advertiser* of yesterday :—

"In 1867 the Willow Field produced a heavy crop of Clover; in 1868, 8 qr. of white Wheat per acre, sold at £23 per acre without the straw, which was worth £3 more; 1869, 7 qr. per acre of Shirreff's Wheat; 1870, 39 tons of Mangels; 1871, an excellent crop of red Wheat. Next year it will be Beans; in 1873, Wheat again; in 1874 Tares sown in October, 1873, followed by Kohl Rabi, or Cabbage transplanted in July, 1873; and in 1875 Oats sown down with red Clover. This finishes the rotation after red Clover. I thus get every year, one rich Clover crop, four Wheat crops, one Bean do., one Oat do., one Mangel do., one winter Tares do., and one Cabbage or Kohl Rabi do."

Beans, again, on land naturally indifferent quality were a splendid crop. Spring planted Beans were full of pods along nearly the entire length of their very tall stalks; they were a very heavy yield. Barley, which was mostly cut, looked well.

Mangel and Kohl Rabi were marvellous crops. I have seen nothing to equal them this season. They were spoken of like a crop to harvest in October, than one in the beginning of August. The Mangels look like making from 40 to 50 tons per acre. The hay crop has been excellent, and the Clover layers were full of growth, some ready to cut a second time. Tare stubbles had been double ploughed, smashed, and planted with Cabbage, or Sarvey, or Kohl Rabi. Pea and Bean stubbles will be served in the same way as soon as they are cleared. Mr. Mechi has boundless faith in the enriching and ameliorating influence of sun and shower upon land. Whatever surface is not covered with growing crops is broken up deeply and roughly, to collect and fix gases and vegetable nitrogen-plants.

The solid manure used is mostly spread upon the surface and ploughed in, in the ordinary way; then a strong subsoil-plough, without mouldboards, follows the other, and tears the land up in huge pieces to the depth of 18 inch or more. So stubborn is some of the land, that huge pieces occasionally come tumbling over the handles of the plough; and this huge mass of clods and manure is left to be broken fine by the pulverising hammer of the atmosphere—that is, if it may be left fallow a few months; if not, a heavy Crosskill is sent to battle with and smash the surface down sufficiently to get in a crop. The rougher the mass remains below the better Mr. Mechi likes it. The interstices are full of air and manurial gases, and the roots have a free course and a full larder.

Mr. Mechi is by no means favoured by soil. There is considerable variety, but none of it would be called good for farming. The heavy soil is too strong even for brick-making; the light, a black, dead-looking sand, full of huge lumps of plum-pudding stone. In dry weather this heavy land is hard as iron, during wet it is soft as butter. The prices given for the land is a good test of its commonplace quality. Good land could not have been bought for £23 per acre. A gentleman who knew the place well many years ago assured me that a more unlikely place for good farming could hardly have been found. Spring-water, holes, hedges, ditches, straggling trees, and poor half-starved crops were the order of the day before the Mechian era. Neither is it necessary to go back a generation to prove this. Why, stationed within sight of Tiptree, I saw Wheat crops that would hardly pay for the seeding, and there is still a great deal of indifferent farming to be seen from Tiptree to Kelvedon.

But I hasten from these controversial points, which would obtrude themselves on me on my journey to Tiptree, to give an epitome of the foundations of Mr. Mechi's success as they revealed themselves to me on the spot. First among these are deep drainage with small pipes. Twenty years ago a field was drained 5 feet deep and 50 feet apart, with inch pipes, and the drainage is as perfect as ever. In many cases we get rid of the water too soon, in two senses—first, in regard to time, and, second, too near to the surface. We want to get all the caloric and manure out of rain-water before we let it go. Deep drains, and of small bore, by giving the water a long journey, enables it to leave all that is useful to the land behind, before it leaves it; hence, I believe, their success. The more haste with drainage the less speed, or rather an excess of speed is dangerous.—The second point is deep culture. Mr. Mechi is by no means satisfied that he goes deep enough. On the contrary, he talks of advancing from half a yard to a yard, or even beyond. The root of a Parsnip will run down 6 feet, he remarked; why should we not provide something good for it all the way? Why not, indeed? But I need not dwell upon this, having so recently adverted to the importance of deep culture in your pages. Mr. Mechi has reached from a foot to 15 inches, and is boring away for 2 feet.—The third point is, no robbers allowed. I noticed neither weeds, nor trees, nor hedgerow-timber, nor o'ershadowing wood to shut out the light and shelter vermin to prey upon the crops, at Tiptree. The fields are large and square, or at least even-sided, and the crops had the full usufruct of the whole area of earth and air.—A fourth point—and it is a vital one in the Mechian system—is no overcrowding. Every plant has room to grow without being overborne by its neighbour. The consequence is, that instead of a motley crowd of pigmies, we have an imperial army of giants. Each plant reaches its full stature—grows to its utmost size. From hence comes a great economy of force. With fewer plants there is more vital energy expended, and consequently more produce grown. For produce cannot be computed by numbers alone, but by power expended upon growth, thought is a fact established beyond all controversy by Mr. Mechi's practice of thin-seeding, and by other analogous practices in cultivation, that 10 plants may yield more bread, or beef, or sugar, than 100. Hence there is a double saving in thin-seeding—we save the grain that would have been wasted in the earth, and get larger crops from fewer plants. An opponent of Mr. Mechi has admitted that his advocacy of thin-seeding has already saved several millions a year; and that, were his practice generally adopted, probably the nation would be £10,000,000 per annum the richer in consequence. I see no reason why thin-seeding should not become general. With high farming there is no fear of a lack of plants. The maximum for Wheat at Tiptree is 1 bush. per acre. Over one large field only 2 pecks were used. Mr. Mechi challenged a neighbour to a match in my presence as to which was which. None of them could do so, and yet over the thin-seeded about 200 barn-door fowls all ran freely winter and spring. One splendid piece of Wheat was pointed out that had looked wretched in the spring. The slugs, &c., had been busy at it. A gentleman thought he entertained it ploughing it up,—no uncommon thing in the neighbourhood last spring; but, instead of this it was dressed with 2 cwt. of guano and 3 cwt. of common salt to the acre, and now, if there is any difference in the Wheat at Tiptree, this was the best of all.

The fourth merit of thin-seeding is, that the straw is sufficiently strong to carry the ears. Much corn is badly laid this year. None is down at Tiptree. This is of the utmost importance. Another point with Mr. Mechi is to feed his land well. To starve land in the matter of manure is to be sure of a bad crop. High farming is never to withdraw the full balance of productive force from the land. Always put in more with each crop than you take out. Even a tenant-at-will would find this to his interest: treat the land generously, and it will treat the cultivator with corresponding liberality. The tenant will gain with it in the matter of its food, and the land will prove itself an adept in returning evil for evil. Tiptree crops, as they proudly stand up in their full strength, or cover the furrows with their large green leaves, give eloquent testimony to the importance of a full supply of rich stuff and cake. Even the straw at Tiptree is mixed with cake or pulp—not only that it may make beef for the butcher, but richer manure for the land. And dry chaff is more savoury with oilcake soup, and served out hot with the same dual object—that meat and much may be made the faster.

Mr. Mechi's fluid as well knows supplies much of his manure in a liquid state. At least two great advantages arise from this. No liquid excrement is wasted, and the manure is at once available for the plants. These statements are easily made and read, but it is hardly possible to estimate their full import-ance. Could it be truly written on every farm. No waste here! the produce of England would be doubled. And then there is a most prodigal waste of time in the manner of making and applying manure. Roots cannot eat solid dung; it is worse for them than it would be for us to set upon a dinner of beef and unground Wheat. We could nibble enough of these to keep us alive, but roots are incapable of consuming solid muck. Mr. Mechi cooks it for them. His famous tank is the great stewpan of his farm; there he makes plant soup of the most nourishing kind, and on a regal scale. It is there also that the richest turtle soup of all sorts of enrichment are thrown into this gravy pot—whole carcases of horses, cats, dogs, rats, solid excrements, liquids, rinsings, drainings of all sorts and varieties—all poured in here. Water is added to suit the taste and the wants of the crops; the whole is broken down by a blow-pipe from the steam-engine, and then lifted up and forced forth by steam-power, and distributed on a liberal scale to the growing crops. Mentally, we can see them smacking their lip-leaves as this rich gravy soup is served out to them. Filled with such good things as that, they must grow. And the grand merit of this mode of feeding is that the plants are filled at once; there is no waiting for their meal till slow-paced decomposition, like a heavy waggon-horse, has done its work. The roots absorb, the plants assimilate, transform the liquid food once for all, to a great extent, the potency of liquid manures—they are instantly available. This fact forms the very keystone of the sewage system. It offers the best food, in the best form, at the cheapest rate, in the most readily convertible mixtures. Long before solid manures can be rendered fit for plant food, liquids are transformed into the food of man. With such a fact generally recognised the waste of sewage must cease. What would be thought of the sanity of a London club that poured all its turtle soup into the Thames? But such a folly and waste would be wisdom itself compared to the great folly and unkindness of wasting day by day enough plant food of the richest sort to supply the wants of a farm of 30,000 or 40,000 acres. Mr. Mechi, who can write with authority on this subject, calculates the waste sewage of London would enrich so much land, and make it equal the sewage farm at Barking in its productiveness.

But Mr. Mechi feeds his land with other things besides manure, he has diverted two streams of capital towards it, that of a liberal landlord and a most enterprising tenant. Being his own landlord he has perfect security for both these streams of gold; what he has spent as a landlord is not generally known, but it seems to have been well spent, for I heard on the spot that the land that he bought for £23 or £25 an acre would probably now fetch from £80 to £100. His tenant's capital is £16 per acre; he says he believes from £20 to £25 would pay him better; and yet, though this is a model farm, there is no extravagance to be seen upon it. He keeps but seven horses, and the farm did not seem to be by any means overstocked with men. There is no attempt at gingerbread farming, nor extra cleanly mucking of yards, &c., the whole of the arrangements were business-like and labour saving, without any attempt at mere show.

Finally, knowledge and business seem inscribed on everything one sees at Tiptree. Fortunately for agricultural progress Mr. Mechi had nothing to unlearn. I was much impressed with a remark he made going round his farm. "Had my father and grandfather been farmers I never could have done this. I should have followed them, most likely. It is so much more difficult to unlearn than to learn." Mr. Mechi has had many difficulties to encounter, but he escaped one—the most difficult of all perhaps—that of a master. Overcoming prejudices to overcome, no deep ruts of antiquated routine to wrench himself out of; and hence, to a large extent, his success. At Tiptree we see what business principles, marvellous stores of knowledge, and an unexhaustible stock of common sense, energy, and geniality, can effect in agriculture. These qualities, in spite of all opposition, converted a most commonplace poor farm into a model for the nation, and given a stimulus to farming that is being felt throughout Europe and the world. If it be true, and it is, that that man is a benefactor to his species who makes two blades of grass to grow where but one grew before, what shall we say of a gentleman like Mr. Mechi? I say this, that no honour in the power of his sovereign to bestow, could be too great as a recognition of his services, and a token of his country's gratitude. Titles, gifts, thick as Blackberries in September, have been showered on victorious soldiers; statesmen have been duly honoured and enobled; literary men have not been without their laurels-wreaths of fame, and their occasional coronets; the time seems to have come when other victories, and especially those achieved on the bloodless fields of agriculture, ought to have their reward. "Great hath its victories as well as war," but it hath but scant measure of the prizes. Among those eminently entitled to national recognition and honour for the highest public services rendered to the state, I know none more worthy than Mr. Alderman Mechi, of the City of London and Tiptree Hall. He has overcome great natural obstacles and cost to himself, how the country may be enriched in two ways—by wasting less and growing more. As we bound along in the future by express, on the line of improved production, towards the final terminus, maximum yield, let it not be said that we neglected duly to honour him who, almost single-handed and alone, and amid laughing jeers and sharp-pointed opposition, and stinging words whizzing around him like infuriated bees, well and truly laid the rails, got up the steam, and has driven the car of agricultural progress at a safe speed to the present time. *D. T. Fish, F.R.H.S., August.*

HAYMAKING.

On the Making of Hay by Twisting it into Ropes.

I made some experiments more than 20 years ago at different seasons, in summer and in autumn, to test the powers of air drying as applied to the curing of hay, and found that without any great cost it could be dried and duly harvested in the ordinary changeable weather of June, July, and August.

A quantity of loose hay in a field looks one of the most unmanageable articles one could have to do with when the weather is "catching," for if it were bound in sheaves like corn it might be set up on end, but being either shaken out or shaken together, when foul weather sets in there is little else for it but to rot, and, obeying the ordinary laws of fermentation, it will heat, sweat, and finally burn, just as its bulk and its moisture will admit. The farmer can easily dry grain, malt, and like fire on his kiln, but in the drying of other articles he seems sadly deficient, for example, when he washes wool for market it is very questionable whether or not he ever could dry it thoroughly except on the backs of the sheep, so he washes the whole animal before shearing, and thus gets the wool washed by using every sheep as a clotheshorse to dry its own fleece. When I have seen a flock of sheep passed from hand to hand across a river during the washing process, I could not help thinking what an important

item that was in the way of cleaning and drying wool at little cost, for from being dripping wet the wool gets air-dried in a very short time, ready for shearing and storing.

In making hay the natural juices and the green colour should be dried into the hay, and by no means washed or bleached out, for sun and rain will not only bleach linen yarn but bleach also most other vegetable tissues, and in England, at least, whilst we dry the grass we should still keep it as green as possible. In the North, hay made from Rye-grass and Red Clover is generally dark in colour and wiry in quality, but as it suits their purpose they will not change, for in this they are incorrigible, being wedded to the windle-straw system of over-drying. Of the countless millions of bricks that are made during eight or nine months of the year all over the country, most of them are air-dried, for the sun is only second to the wind in air-drying, and when once bricks get well stacked they seldom fail to get dried sufficiently. There is a great difference between the deceptive bulk of hay when scattered all over a field and the real bulk of the same article when trussed for market, yet the 1 ton upon a cart or the 2 tons upon a waggon are often all that a whole acre of very good land has produced; it is, therefore, clear that hay, shaken out, deceives us as to its bulk, but hay compressed and weighed deceives no one. The simplest way of compressing green hay is to twist it into ropes, and then wind the ropes on a wooden core, or centre piece, so as to form hollow cylinders, just like a ropemaker's coil of hempen rope. Contrary to all the ordinary rules of haymaking, this spinning is best done when the hay is damp, and experiments were made with a bobbin or centre piece of 6 inches in diameter, and the length of the coil, or cylinder about 18 inches, and the size of the hay-rope would be about 1 to 1½ inch in diameter, and the two ends should be turned into the hollow centre. In making these ropes, it takes two men to turn and another to spin, but to mention this way of making samples not to complicate the experiment, just as if there were no other method of making ropes, as I am anxious that parties should be able to give the thing a fair trial during the autumn, and thus be able to judge of what can be done by cord pressing and air-drying. Walls should be built of the coils of hay-rope, similar to the walls in a brickfield, but thoroughly open for the wind to pass freely. It is worthy of remark, that as the ropes dry they open more and more to admit air, as if they anticipated the farmer's wish.

I have lived long enough to see several reports of mine carried out, and not only become a general practice but actually a system: for example, the dry earth closet was observed by me in good working order in 1832, and little did my relative think that his ingenuity would be largely developed, and however contemptible the thing may appear in the beginning to see grass made into hay-bands by hand, there is no other way of grappling with the weather but by setting one system against the other, so that the wind may undo what the rain has done; and as the hay is so much reduced, many things can be done with it when coiled in ropes that could not be attempted with loose hay.

Let no one imagine that I ever thought of this system superseding the "making of your hay whilst the sun shines," but only reckon upon it as a valuable auxiliary, for a July and a windy wind over-combined is, and ever will be, the "heyday" of our haymaking; but as the rain usually comes vertically, whilst the wind blows horizontally, there is room for an ingenious hitch, as the sailor would express it, to "haul in" the wind, and at the same time try to give the rain a wide berth." If the chaff had not been lighter than the corn, it might have been troublesome to separate them, but as it is, the wind is "hauled in," and separates the corn from the chaff most effectually. It has often been remarked that there is more hay damaged in a stackyard than ever was made in a field, and if this system will help the field practice, it cannot fail to be of service, for I claim the credit of being the first to set the hay crop up, or, in other words, to take it off the ground.

Whoever has seen a pile of cannon balls can easily form an opinion of the open nature of a pile or stack of cylinders, for they do not lie dead flat, like bricks, but resemble a honeycomb, save only that the section of the bobbin is a circle, whereas that of the honeycomb is always six-sided; but a honeycomb set on edge will give an excellent idea of the windrows of this system of haymaking.

Could we only predict the weather, what a saving it would be to the farmer in his haymaking; for we see the scientific and industrious man, with the barometer before his face, and the direction of the wind, the moon's age, and the like all taken into account, often lose his hay crop; whilst the slovenly cultivator, believing in blind chance, bides his time, and will often get a good hay harvest about the time that the corn is ripe, and though rather untimely, yet has it at very little expense. Surely those who are clever with the unseen world, who can take a walk with a clairvoyant over half a continent in a few minutes, could, if they liked to turn their attention to such simple subjects as haymaking, tell us when to cut our grass with a fair prospect of getting it saved, but—and there is always a reservation clause, and three days' grace given in prognosticating the weather, such as "Snow may be expected about December 25, the day before or the day after." I think it was O'Connell that said of fortune-telling, that as Lucifer was the "Father of Lies," no dependence could be placed upon what he might say or swear; still the weather must be predicted in one way or the other before the farmer can set his men to work, and it is just this necessity that creates the demand for quacks, who pretend to consult the stars, and print impudent falsehoods in the weather column of the penny almanack, as if it were founded on facts. Hay must be dried by farmers, and with such means as we have in hand. Some parties at last despaired, and when hay has been spun, coiled, and windrowed, if need be, it could be kiln-dried, and the spinning process could be done in any barn or shed whilst the rain was falling on the hay in the field. Only let a trial be made. If the grass has lain long enough to get flaccid, make a rope of it, and hang it up to dry in the wind, and out of the rain, and it will then speak more eloquently than words can as to the powers of air-drying. When clothes cannot be put out-of-doors to dry on the clothes-lines during a wet washing day, they can be dried without fire in a garret, and manufacturers do a large business in the drying of cloth by means of air only.

When hay lies on the ground in wet weather, after a few days its own weight sinks it into the stubble, and the under-grass rots rapidly through it, and thus the wind is prevented from touching the bulk of it; for whatever force it may have on trees, wet bricks, and the like above ground, it can have little effect on anything hugging the ground in this manner. Those who have little faith in air-drying should watch the rain-drops that fall on the window-pane after a shower, and how soon the wind will carry them away. I have mooted this subject more than once, and it may have to be reiterated for years to come, before any effective measures may be taken with it; but I am convinced of its efficiency when tried in good earnest, and it is not every farmer that can make a good rope of either hay or straw, and you seldom see a good tool for making one. I have seen some five or six different kinds of twisters, and all of them were bad, so that it was simply a waste of time to use them. I saw a thatcher yesterday stick a hay-fork upright through a haystack and commence spinning a straw-rope, making the wooden reel do the work of a boy twisting. This was all very well as a curiosity, but such a person would hardly earn 6*d.* a day at this kind of work; and I can easily imagine the remarks that would be made by men of that school on making hay-bands.

When the "ancient mariner" gets on deck in the morning his first idea is to consult the prime mover, and watch how and from whence the wind blows, for although he has no power over the mountain wave beneath, neither has he over the hurricane, or the storm overhead, yet he can shorten sail and take in every stitch of canvass, and show only bare poles to the fearful force that would otherwise engulph him. The hay-maker has equally to battle with the weather, for as long as the grass field is open to the sky so long will there be a battle with the elements, with as much, or rather less danger than with meadow grass, with this exception, that when it has to be made into hay it requires what Burns styled a "lowan drouth." But it would not be believed, without calculation, how much the farmer has shortened sail by twisting his hay, for the surface exposed to the wind when the cylinders are piled in windrows, and roofed with a wisp of straw, will be so small that it will be to him a hay-barn, where his fodder will be as safe as if it were under thatch and rope in the stack. *Alex. Forsyth*, 9, *Islington Square, Salford, Aug.* 26.

THAER ON TILLAGE.

SIXTY years ago the chemical changes produced by tillage were unknown; but the effects of tillage were as well understood as at the present day. The conjectures of such a man as Thaer are exceedingly interesting, and if they add nothing to our actual knowledge at the present day, they show in what spirit and with how much caution an able man pursued his theories, and put them to the test of practical experience.

A more ingenious explanation of the *rationale* of tillage could not have been given at a time when the chemistry of the soil was unknown. The attempt to unravel the mystery of hidden causes, even when the knowledge sought for alone can ensure success is imperfect, has led to the highest achievements; and even agriculture may gain from it. The most ancient of arts may justly be proud of resting its practice and success on the experience of all time; but even ancient practice may be improved when its foundation has been investigated and explained. The first steps towards knowledge are always taken by superior minds. Any indifference, therefore, to the labours of men of science, and too implicit a reliance on routine, would deprive us of the fruits of that patient and ceaseless inquiry which is the source of all improvement.

The following remarkable speculations from Thaer's "Principles of Agriculture" (1810), exhibit the keen insight of a man of genius. He fairly picked the lock for which chemists have since found a key. It recalls the wonderful foresight of Copernicus, who declared the revolutions of the heavenly bodies long before the discovery of the law of gravitation:—

"The more a soil is pulverised the more equally will it be penetrated by the roots of plants growing on it; the more hair-like and fibrous roots will these plants put forth, and the more will the ramifications of these roots be extended, so that thus all the nutritious particles contained in the soil are brought into contact with one or other of the suckers put forth by the roots of the plants." Jethro Tull must have been in error in attributing the fertility of a field to its pulverisation, "because, though an exhausted field may be made to produce grain by this means, that is only because the nutritive juices and particles which the soil contained are thus brought within the reach of the roots of plants, and not because this operation is able to create one particle of nutrition."

"Jethro Tull imagined that he could altogether dispense with manure, and replace it by the application of frequently repeated tillage applied to the crops, sown in rows, and by the complete division of the particles of the soil produced by that means. The plan at first turned out favourable for himself and his followers, for they had a fertile soil to work upon, which had for a long time previously been plentifully supplied with manure; in fact, by repeated tillage, and the consequent exposure of the soil to the action of the air, all the nutritive particles contained in it were converted into extractive matter, fit for the food of plants, and thus brought into the service of the roots and their fibres. But this effect could only last a few years; and if this system of drawing upon the riches of the soil were closely followed, it would eventually render it so poor, that plentiful and repeated manurings would scarcely restore it to fertility.

"There certainly are some kinds of land naturally so rich in themselves, and so little impoverished by cultivation that they do not require manure; but these are rarely met with, and form exceptions to the general rule. It frequently happens that the high degree of fertility possessed by a particular field is entirely owing to its having been used as a meadow and grazing ground, and this is often wrongly attributed to the special nature of the soil."

These conclusions, confirmed as they are by practice, and explained by science, show the observant and thoughtful character of Thaer's mind, which was not misled even by the mistaken theories on the nutrition of plants which were then held by the learned. The absence of knowledge on the chemical constitution of soils is shown by the following quotation:—

"With regard to that portion of the earth which cannot be decomposed, and which consists in the action of fire, the experiments made by De Saussure and Schroder tend to prove that it has little to do with the positive act of vegetation, and only contribute to it by receiving the roots of the plants and preserving their nutritive matter, but is itself incapable of affording them sufficient nourishment for their support." "But as the plants derive the substance necessary for their nourishment from the humus, or decomposing animal and vegetable matter, it of course follows that in this matter must be diminished, and in course of time exhausted, by the vegetation of plants in the soil; and the rapidity and degree of this diminution and exhaustion will be in proportion to the nutrition which they contain, supposing, however, that they are gathered and taken off the ground.

"Although Nature furnishes a number of substances which tend to quicken vegetation when they are entering the vital principle, or by assisting in the decomposition of the mould, it is only the mould or humus (finely divided organic matter) or the vegeto-animal manures, which supply to plants the most essential principles from those most necessary for their nourishment. I say their most essential particles, because they could likewise derive some nourishment from the decomposition of water as well as from the gaseous substances contained in the air.

"The exhaustion or impoverishment, occasioned by crops of grain, may be repaired in three ways. 1st, by manure; 2dly, by the conversion of the fields into pasture grounds. The putrefaction of the herbage which grows spontaneously, and the worms and insects that lodge in it, and the excrements of the cattle which pasture on it, communicate to the soil a nutritive power, which is greater or less in proportion to the state of the land when it was left to Nature, to the abundance and vigour of the vegetation, and to the quantity of excrements voided by the cattle; 3dly, by a dead summer fallow, attended with proper cultivation; by means of which the soil will not only be cleaned and pulverised, but will likewise receive positive nutrition, as well from its different parts being successively submitted to the fertilising influence of the gases contained in the atmospheric air, as from the putrefaction of the plants and roots, buried in it by the operation of ploughing, being hastened and expedited. The more vigorous and better the soil the more efficacious does the fallow appear to be; provided that its preparation be complete, and the soil has been thoroughly cleaned, pulverised, and aërated, and the nutritive particles which it contained brought into action, will the subsequent crops be abundant. It is, however, a fact, that in this manner a greater degree of exhaustion is subsequently created."

"There is no doubt that the fallow absorbs or attracts the fertilising properties of the atmosphere, and that the better the cultivation of the soil the greater is the quantity of nutritive particles thus absorbed."

"Others endeavour to obtain the same end by means of trenching with the spade, acting on the belief that the under fertile soil would become additional mould while it lies buried and inactive, and that when brought to the surface it will bear abundant crops; and they fancy that by changing the layer of the earth every year, they shall receive crops, without being obliged to replenish the land with nutritive matter."

"It certainly does occasionally happen that on some soils where the layer which is turned up and brought to the surface is composed of a mixture of substances which contain combinations of oxygen and hydrogen susceptible of decomposition, this system appears to be successful for a time; but it will not endure for any length of cultivation, for after having produced a few crops without being manured the land becomes so poor as to be incapable of affording the smallest nourishment to plants. Moisture

does not penetrate into argillaceous close or tenacious soils. When a clod of this nature remains unbroken in the sun, and becomes dry, it preserves the dryness in the centre during the whole summer. But the more the particles of the soil are separated from one another, and the more deeply the land is turned up, the more easily does the moisture penetrate into the interstices; in fact, the deeper the ploughing is, the more easily does the land absorb and retain humidity. When land has been thus prepared, the water does not flow back to the surface so soon, nor is it so easily dried up and evaporated in dry weather, but is communicated to the surface in proper proportions. These observations will be found to be everywhere confirmed by experience; and it has invariably been noticed that land which has been deeply and carefully turned over and stirred up does not soon become hardened on the surface, neither does it suffer so much as other land from drought. Every gardener who has dug up any portion of his land must acknowledge the truth of this observation. Soils which have been ploughed in the autumn resist the drought of spring in an almost incredible manner; in fact, they preserve a fair degree of humidity at the depth of an inch below their surface, while others are parched to a very great depth. It is not, therefore, literally true that ploughing fertilizes land; such an effect can only be produced when the ploughings are deep and frequent, and always performed in dry weather. It has been observed that a slight ploughing, which only moves the surface of the soil, is apt to preserve than to dissipate the moisture; and consequently, the insensible absorption of moisture by the soil from the air is greater than the evaporation. The humidity which is enclosed in the interstices of the soil, and which amasses there in large quantities when the land is fallowed before winter, causes such soils to become light and friable; and they divide easily, provided that we wait until they are dry. This is a natural consequence of the evaporation of that water, the elasticity of which had separated the particles of the soil by introducing itself between them.

"In the neighbourhood of large towns, where manure can be obtained at a little price, and in countries where, on account of the great extent of pasture lands, a large number of cattle is kept, little labour is bestowed on the ground; it is never suffered to lie fallow; the proper rotation of crops is observed; the land is sown with grain every year, and frequently with the same kind of plants. In those places, on the other hand, where, from the want of fodder, only a small quantity of dung can be obtained, farmers seek to improve their land by constant ploughing and cultivation, and particularly by allowing it to lie fallow, and either by converting it into pasture ground or leaving it perfectly inactive. But the maximum produce can only be obtained when the soil, the manure, the labour, and the kind of grain, are in their relative proportions to each other."

"And if we deduct from this sum the value of the impoverishment occasioned by the crops produced in the course of the rotation, the balance which remains will indicate the natural fertility of the soil at the close of the succession or rotation, or that number of degrees with which the cultivation will commence. There can be no doubt that there is a certain regularity and proportion existing in the exhaustion occasioned by the crops. After a fine crop of autumn corn, the spring crop generally proves successful, and in the triennial rotation, with fallowing the autumnal crop in the second year, after a remarkably good crop of spring corn, will not be found to answer so well. A succession of abundant crops having been favourable to the temperature, improves the fertility of the soil very considerably, while in bad seasons a larger quantity of nutritive matter is left in the soil."

"We are led to believe that a crop of Wheat will impoverish a fertile soil in the second year, 40 degrees, while a crop of Barley will only exhaust 30 degrees, and a crop of spring grain 25 degrees."

This is an excellent account of the theory and results of fallowing. Notwithstanding the defective knowledge of the real food of plants, the practical conclusions with regard to the question of the rotation of corn proved by undoubted facts. No one will maintain that soils are inexhaustible who has seen that over the greater part of Europe they are, in fact, almost exhausted. The average yield of Wheat, after a bare fallow, is, in the corn districts of France, where little is restored to the land, about 12 bushels per acre. In all corn-exporting countries, where a small population does not admit of cattle feeding, and returning to the soil the constituents removed from it in the crop, the same result of comparative exhaustion is reached on the richest soils, after some years of cropping. In this meat-producing and corn-importing country the land ought to become richer, and would do so if it were not for the waste of human excreta; we could, however, point out many instances of the rapid exhaustion of land when cropped for a few years without a restitution of the plant food removed from it.

Home Correspondence.

The Land Question.—Some people who write about the land question, in the *Agricultural Gazette* and elsewhere, appear to me to jumble up three or four things (as transfer of land, tenant-right, game, and primogeniture), which have about as much to do with one another as the moon has to do with the statutes at large; and perhaps this may apply in some degree to Mr. Arnold's pamphlet, but the greater part of what he says is undoubtedly true, and it appears to me, and always has done, that such measures as the abolition of entails and the registration of titles are needed by the landlords far more than by the tenants. I am a landlord in a part of Yorkshire where leases are not the custom, and my opinion must be understood as referring to what I am familiar with; and I am convinced that the land may be perfectly well cultivated, and all the people connected with it may be perfectly comfortable and prosperous, under the present system, with the exception of the ruinous and destructive practice of entailing property, so that the person who ought to be the owner of it has no power to do anything that the owner of an estate ought to do for it. One would naturally suppose (if any one could think on the subject in an unprejudiced manner) that it ought to be a great advantage in the cultivation of land to have one person who should have a permanent interest in it, and whose duty it should be to do everything for it that would permanently improve it, and another person who should understand the management of farming, and whose capital should be invested in stock and crops; and that neither of these should have the manual labour to do, which, of course, would in most cases make scientific improvements or scientific farming impossible. It is clearly the landlord's business to do everything on an estate which improves the land in value permanently. His interest in the land is merely the total of his own property which has already been invested in such improvements—at least more than nineteen-twentieths of it is this—exactly in the same way that the interest which a shopkeeper has in a bale of calico which belongs to him represents the value of the labour, &c., which has been expended upon converting the raw material into calico. It is now no reason whatever why one should be treated in any way differently from the other. In Yorkshire we have already a registry of deeds, and I have long thought that we ought to obtain an Act of Parliament to make it also a registry of titles, so that any one who pays the requisite possession of land for a period of 30 years, and upon giving due notice of intention so to do, might register his title much as is suggested by Mr. Arnold. What are the supposed advantages of dividing landed property amongst a number of sons I do not quite see. A property ought not to be so large that a person could not look after it, and do the works necessary for its permanent improvement; but with this limitation, I am utterly unable to see why it should be divided amongst a number of sons any more than the business of a banker, or of a watchmaker, or of a blacksmith. It is no more common than it used to be for a landowner to recognise the fact that the management of landed property is a distinct business, which it is his duty to learn and understand; and if the iniquitous system of entails were abolished, so that landowners were in a position to sell to other people to make a right use of their property, I have no doubt that a great many more would do this. One word as to Mr. Arnold's sentiments respecting cottages. I have, as you know, spent a good deal of time in promoting the improvement of cottages, and I consider it one principal "permanent" improvement of landed property which a landlord ought to provide, but bad cottages are certainly not the chief cause of the immorality of the labouring class: bad public-houses have much more to do with it, and the utter indifference of employers as to the character of those whom they employ has also much more to do with it. I have for a good many years given away quarter sessions, and for a good many other years chairman of a board of guardians, and I am certain that what I say is true, in this part of the country at least. *C. W. Strickland.*

The Common Nettle.—In an article, headed "Uncultivated Plants," in the *Agricultural Gazette* of September 9, mention is made of some uses to which the Nettle may be put; but the author of the said article does not seem to be aware of the medicinal virtues of this neglected plant, or, as it is generally termed, weed. For years I have used the Nettle, with other herbs, in making broth, and also mixed with vegetables for ordinary table use; and I do not think that any herb growing has better effects on the blood. This herb, when properly used, is a most cooling, refreshing, and healthful beverage may be made from it, by simply boiling the Nettles in water; strain off the liquid, add to it a little yeast, and, after it shows signs of fermentation, and has become cool, bottle, and tightly cork. It should be put into small bottles, as it possesses almost the effervescing properties of soda-water. If Nettles were more frequently used in the spring and autumn, I fancy we should have much less need of the services of doctors. *J. R. R.*

The Crops of 1871.—The threshing-machine by this time has very generally revealed the probable yield of Wheat for 1871. I am one of the few who took a sanguine view of it, and so far as I am individually concerned, the result has favoured my expectations; or, as I gave an opinion of a district, the estimate I found has been verified. I have threshed about 30 acres, the yield of which is about 6 qr. an acre, and sold at an average of 59*s.* a quarter. I have also learned from inquiries, that over the district which I represent the yield is an average one, with more than an average amount of straw. With these facts before me, I do not understand the great deficiency which such authorities as Messrs. Lawes and Sanderson attribute to the crop of the present year. A writer in the *Daily Telegraph*, in his review of Mr. Lawes' letter, makes the following remarks:—"The area under Wheat is 3,773,663 acres; and thus it would need an average of much more than 5 qr. to the acre to supply our wants. Such a yield, of course, is beyond what the fertility of English earth will supply." I have a higher opinion of the capabilities of the soil of England than the writer I have just quoted, for Mr. Mechi has told us over and over again, that on his farm, which is by no means conspicuous for its natural advantages, he grows from 6 to 7 qr. of Wheat an acre, and of good quality. Mr. Mechi is no conjurer, and what he does is free to all to go and do likewise. He has efficient drainage with deep cultivation, and those operations have secured to him the use of a natural force, which is as ceaseless in its action as it is beneficial in its results. I also anticipate that the day is not far distant when public men will hesitate to say that the corn growing lands of England, under proper management, are not equal to the growth of 5 qr. of Wheat an acre. *P. Mitchell, Rainham, Essex, Sept.* 8.

Farm Agreements and Land Improvements.—At p. 1116, "H. H. O.," says, "we dare not farm high under the present system of landholding in England. Many farmers would be willing to lay out their money in steam tackle and manures if they were certain that their outlay in improving their farms would still remain their own property." Now, a single grain of experience is worth an ounce of theory, and this remark of his comes desperately contrary to what happened to myself only yesterday. One of my tenants occupies 485 acres of land, for which he pays me the handsome rent of £1,150. Once this farm there are about 250 acres in a state of pasture, a large part of which needs draining and fencing and liming and laying it into cultivation. Now, my tenant holds (like every one else in this quarter) on a yearly tenancy, and it is not to be expected that such a man would lay out money on his landlord's land. Knowing this, and knowing also that I have myself the means of laying out money, I made him a proposal to execute and drain and lime for him each year for some years to come a field of from 25 to 35 acres, according as the ground suited,—the whole expense of draining and fencing and liming to be paid for by me, and in return I was to receive 5 per cent. interest to the rent, so much per rod for drains actually put in, and so much per rod for fencing actually put up, and so much per ton for lime actually drawn and laid down upon the land. The price I asked for draining and for fencing he was quite willing to pay, therefore I need not go into them, but what I asked him for the lime would not listen to at all. Now let us go into figures. Lime costs 17*s.* per ton laid down on the land, that is to say 10*s.* at the railway station and 7*s.* for cartage, and I asked 3*s.* rise of rent for each ton of lime which I laid down upon the land. I also offered, if he would cart the lime, to pay him the same price as I paid, but he declined the offer, and proposed that he himself should buy the lime and cart it and lay it down on the land as manure, at the rate of 3 tons per acre. I pointed out to him that if he did so he would have spent £17. 2*s.* per acre, and that he had no security whatever that he might not be turned out of the farm or have his rent raised long before he had repaid himself the outlay, and I also showed that it would be nearly eight years before the charge of 3*s.* per annum would repay me my first outlay of 17*s.* and 5 per cent. interest thereon. I then asked him this question,—Suppose you spend this money on the farm, it will take you nearly eight years to get back your money and 5 per cent. interest at the rate of 3*s.* per annum; well, do you think that if you go on spending money in that way that your rent will not be raised long before eight years pass over your head? Now this man is not the only one of that opinion. The tenant of the adjoining farm had a similar proposal made to him about 10 days ago, and his reply was just the same,—"He would rather draw the lime himself at his own cost." Can "H. H. O." explain why these men should refuse to have their land improved for them, and prefer to pay the expense themselves? To me it is a mystery, but "H. H. O.," being a tenant, can probably solve it. Let me observe, they all agree in thinking lime the best possible fertiliser. *G. A. H.*

New Plans Require New Conditions.—"There's nothing but alteration, now-a-days," said a farming friend of the old school. I have got one of the new hay and corn elevators (that carry up a load of hay or barley and deposit it on the stack in few minutes), and find that there is not room enough between the stack-frames for the horse to work it. Another finds his gateways too narrow for the great steam-cultivators and reaping-machines, and so we go on adapting ourselves to new and improved practices. I don't hear much about the new thatch-stitching machine, but should be glad to be informed if it has been a practical success. Any invention that tends to shorten hay time and harvest must be welcome for many reasons. It gives us more time for cultivating and cleaning the land, it diminishes the risk of bad weather, and it protects us in some degree from the scarcity of labour, and of too great an enhancement of its cost. The mere making of these machines absorbs a large portion of what would otherwise be, perhaps, surplus agricultural labour. Machine

makers are also adapting their machines to particular laying out of the soil, such as furrows and water-furrows. There have been several improvements lately in our reapers in this respect, and also as regards the avoidance of cutting off the ears of corn. In fact they will soon, I think, if they do not already, cut laid corn better than the scythe. I find that an iron plough, minus its breast, makes the best subsoiler; and this has been admitted by those practical farmers who have seen it at work on this farm. Landowners are rejoicing at getting rid of their barns, but they will have to provide new accommodation and shelter for the costly machinery and implements of modern agriculture. Road surveyors must bid farewell to their crazy old bridges, which crumble into ruins under the ponderous traction engines. All these changes involve the employment of labour, which is nationally a great desideratum. Plenty of room between the stacks will comfort the minds of our fire insurers by diminishing the risks of conflagration. *J. J. Mechi, September.*

Sewage Irrigation.—I am sorry that Mr. Morgan's friend, "Waste Paper," should be annoyed by this controversy, but he should remember, first, that Mr. Morgan began it; and, secondly, that the dispollution of rivers by the utilisation of sewage is, on the authority of Lord Derby, one of the most important questions of the day. As regards Mr. Morgan's decimals and his broad beds, I will merely say that I am willing to refer the points in dispute to the arbitration of Mr. Bailey Denton, of Mr. Bramwell, of either of the partners in the firm of Messrs. Easton, Amos & Anderson, of Professor Fleming Jenkin, the President at Edinburgh, of Section G (Mechanics) of the British Association, or to that of any professor of mathematics, or engineering, or natural philosophy, in any first-class college. This is not an "empty challenge," but a very definite one. Will Mr. Morgan straightforwardly say whether he accepts or declines it? *W. Hope, Pardoe, Capt.* 10. [We cannot agreed with Mr. Hope that decimals are absurdly out of place in an agricultural discussion. Even "the rule of three" under such circumstances comes to grief—simply because in agriculture there are no things of "the same denomination." We fear practical arithmetics are thus out of place in an agricultural reference —the question under discussion had better be left to the plants and crops themselves for the final decision it will one day receive from them.]

The Finger-and-Toe in Turnips.—The prevalence of finger-and-toe amongst the Swedish Turnip crops in this locality is seen in many fields this year by the plants flagging in hot sunny days. It cannot be too generally known to farmers that a good liming to the land, subject to grubbing, is a certain cure to these pests. Many years ago, the late Duke of Portland tried the effects of a good dressing of the caustic magnesian lime of the district on a large field of light, sandy land, very subject to finger-and-toe when in Turnips. One-half of the field was limed with the lime and the other without, and the portion limed and sown with Turnips that year was quite free from finger-and-toe, whilst the other part of the field was attacked as usual. In the rotation of crops, and when the limed portion of the field was in Turnips again, the same immunity from finger-and-toe marked the crop, and this I believe continues up to this time. To show the caustic effects of this magnesian lime on vegetation, no grass or weeds would grow for years on the places on the head-rigs where it had laid in heaps before being distributed. *William Tillery.*

Societies.

BIRMINGHAM CATTLE SHOW.

We reprint, from the *Midland Counties Herald*, the greater portion of its article on the prize list of this forthcoming show.

The prize lists for the next of the great annual exhibitions, at Bingley Hall—the 23d of the series—which commences on November 25, are in circulation, and will, we have no doubt, be regarded with satisfaction by every wellwisher of these important undertakings. With regard to the Herefords, there are, as before, classes with prizes of £15, £10, and £5 respectively for oxen or steers above three years and three months old, for steers not exceeding that age, and for cows and heifers, but these are now supplemented by a class for Hereford steers not exceeding two years and six months old, with one prize of £10, given by the Mayor of Birmingham (Mr. G. B. Lloyd), and one for heifers of the same breed not exceeding two years and six months old, to the best of which a prize of £10, given by Mr. J. H. Dawes, will be awarded. Prizes of £15, £10, and £5, are again appropriated to Shorthorn steers or steers above three years and three months old, to steers not exceeding that age, and to cows and heifers; while a class is opened, and three prizes of £15, £10, and £5, offered by Mr. G. F. Muntz, for Shorthorn steers not exceeding four years old, bred as well as fed by the exhibitors, who must be tenant-farmers—that is to say, persons renting 100 acres of land or upwards, not possessing more than 50 acres of their own land, and not engaged in any other business. There is likewise a separate class, with one prize of £10, given by the Mayor of Birmingham, for Shorthorn steers not exceeding two years and six months old. There are prizes of £15, £10, and £5, for Devon oxen or steers exceeding three years and three months old, for Devon steers not exceeding that age, for cows, and for heifers. There is, moreover, a class with one prize of £10, for Devon steers not exceeding two years and six months old; and another for Devon heifers not exceeding two years and six months old, the best of which will receive from Mr. Wm. Lort a prize of £10. No alteration is made as to the Longhorns, premiums of £10 and £5 being offered for oxen or steers of any age, and the same amount for cows and heifers. Scotch oxen or steers are still divided into "Polled" and "West Highland;" the former having two prizes of £15 and £10 set down for them, and the latter three of £15, £10, and £5; but Scotch cows and heifers will compete, without distinction, for a 1st prize of £15 and a 2d of £5. There is only one division for representatives of the Welsh principality, in which the best ox or steer of any age will receive a prize of £10. Cows or heifers will, however, be eligible to try conclusions with other pure breeds and cross-bred animals; prizes of £15, £10, and £5 being allotted to oxen or steers of any age, and the same sums to cows and heifers of this description. There are, moreover, two extra classes for animals the owners of which are unable to comply with the conditions as to breeders' certificates, or requirements imposed upon other competitors, £5 being available for the best ox or steer, and the like for the best cow or heifer. Besides the foregoing, the judges will have at their disposal a silver cup or other suitable piece of ornamental plate of the value of 20 gs., given by Earl Beauchamp, for the best animal, bred as well as fed by the exhibitor; a silver cup or other suitable piece of ornamental plate of the value of 25 gs., given by the inn and hotel keepers of Birmingham, for the best animal in the cattle classes; 10 gs., given by Mr. C. Ratcliff, for the best Scotch ox or steer in the Highland class, purchased at the Society, for the best Hereford, the best Shorthorn, the best Devon, and the best Scot, in any of the classes restricted to those breeds; and two gold medals or articles of plate, of the value of £20 each, also given by the Society—one for the best ox or steer of any breed or cross, and the other for the best cow or heifer of any breed or age in the exhibition.

With respect to sheep, some alterations have to be noted. Prizes of £15, £10, and £5, are offered in each of the six classes for pens of three fat Leicester, Lincoln, Cotswold, Southdown, Shropshire, and Oxfordshire wethers, not exceeding 2 years old. There are, further, prizes of £15 and £5 for pens of three fat wethers, not exceeding 23 months old, of other pure breeds; and the like for cross-bred wethers of the same age. The linen and woollen drapers of Birmingham renew the offer of four extra prizes of £5 each for the best pen of Leicester, Lincoln, Cotswold, or Oxfordshire wethers; Mr. Bromley Davenport, M.P., will give £10 10*s.* for the best pen of Southdown wethers; and Mr. Newdegate, M.P., a silver cup or other article of plate, value £10 10*s.*, for the best pen of Shropshire wethers. In lieu of their regular offer for the best pen of two-year Shropshire wethers, Messrs. Mapplebeck & Lowe will this year substitute two £5 cups, or other article of plate, for the best Southdown and the best Shropshire wether, exceeding 23, but not exceeding 35 months old. There are seven classes for fat Leicester, Lincoln, Cotswold, Southdown, Shropshire, Oxfordshire, and other pure-bred ewes, which have produced one or more lambs, with a silver medal, value £2 2*s.*, for the best specimen of each.

The silver cups and money premiums, for both fat and breeding pigs, and the arrangements concerning them, remain intact.

As regards the show of seeds:—With the exception that there are now only two classes for Peas—"white" and "blue or grey"—instead of "white," "blue," and "grey," the regulations concerning them are the same as in 1870-1 but Mr. Reed, Lyon, of Spitall Farm, Banbury, will give a five-guinea silver cup for the winner of the greatest number of prizes in this department. Should an equality of numbers occur, the judges will base their final decision upon the relative merits of the samples.

The Society does not have for some years formed a very useful and interesting section of these meetings, receive due consideration. With unabated liberality, Messrs. Proctor & Ryland, and Messrs. Sutton & Sons, of Reading, give silver cups, or other articles of plate, to the value of 5 gs., for collections—the former for the best six Swedes, six Globe Mangels, and six Swedes; and the last named firm for the best six long red Mangels, six Globe or Intermediate Mangels, six Purple-top Swedes, six green Kohl Rabi, and six green, white, or yellow Turnips. Messrs. James Carter & Co., High Holborn, London, offer a 5 gs. silver cup for the best six Purple-top Swedes, six green Kohl Rabi, six long red Mangels, six yellow Globe Mangels, six yellow Intermediate Mangels, and six white-fleshed Turnips. There are, as previously, classes for Kohl Rabi, long Mangels, Globe or Intermediate Mangels, Swedes of any variety, Turnips and Carrots of any variety, with prizes of £2 and £1 each; the first premiums being augmented in the case of the Mangels and Swedes, by £2 2*s.* from Messrs. Proctor & Ryland. To Bovinia or cattle-feeding Potatos (12 specimens), £2 and £1, will be awarded; and the winner of the 1st prize will be entitled to a handsome silver-gilt epergne, value £8, given by Mrs. Paterson, widow of Mr. Wm. Paterson, of Dundee, the raiser of this new esculent. The prize for the best three specimens of Ox Cabbage is £2, and for the 2d best £1. For Potatos there are no fewer than 17 classes; prizes of £1 and 10*s.* being offered respectively for Ashleaf Kidney, Royal Ashleaf Kidney, Gloucestershire Kidney, King of Potatos, Milky White, Flukes, Dalmahoys, White Regents, Red Regents, Victorias, and Red-skinned Flourball, of each of which three classes are supplemented by four more for any other named sorts of early kidney, second early varieties, white late or winter varieties, and red or blue late varieties: Mr. J. Matthews will give £5—£3 for the best, and £2 for the 2d best six dishes, comprising six of early kidney, two of second early, and two of late or winter varieties; and Messrs. Wheeler & Son, Gloucester, £1 5*s.* and 15*s.*, for the two best dishes of second earlies.

The principal points to be mentioned in connection with the poultry are that 10-guinea silver cups, or other articles of plate, are offered for the best Dorking cock, the best Cochin China cock, and for the best Brahma cock; and for the best black or brown breasted game cock. £5 silver cups for the best Spanish cock, for the best pencilled Hamburgh cock, for the best spangled Hamburgh cock, for the best black or white Polish cock, for the best game cock among the duckwinged, black, and brassy-winged, or white and pile. It is expressly stated that where a bird takes one of these pieces of plate, the money prizes specified as the first for that particular class will be withheld. An extra prize of £5 is offered by Mr. H. Lloyd, jun., for the best buff Cochin cock of the present year, bred by the exhibitor, who must reside within 20 miles of Birmingham. The winner of the cup for the best black or brown-breasted game cockerel will receive an extra prize of £3 3*s.* Messrs. M. Billing, Son & Co., 1, and the winner of the other cup, for game cocks, a silver medal, value £3 3*s.*, from Mr. Ottley. Mr. J. Watts will give, in addition to any other prize, £3 3*s.* for the best pair of Hamburgh hens or pullets; and a few amateurs an extra prize of £4 4*s.* for the best pen of black Indian game. The number of classes has been slightly curtailed by the omission of the following:—The 4th for partridge Cochin cockerels, the 4th for silver-pencilled Hamburgh cocks, the 5th and 6th for golden-spangled Hamburgh cocks, the 5th and 6th for silver-spangled Hamburgh cocks, the 5th for hens or pullets of the same variety, the 6th for black-breasted red game cockerels, the 6th for hens or pullets of the same variety, the 6th for brown and other red cockerels, and the 5th for duckwing or other grey and blue cockerels.

The entries in all departments will close on Saturday, October 28, and intending competitors should make application to Mr. Lythall, the secretary, for copies of the lists and regulations.

MANCHESTER AND LIVERPOOL.

THE following is the Prize List of the very successful Show at the Liverpool last week—to which we referred in our last publication :—

SHORTHORNS.

(Open for competition to the United Kingdom.)

Bulls, above 2 years old.—1st, J. Bowstead, Penrith, Cumberland; 2d, W. Linton, Sheriff Hutton, York; 3d, Marquis of Exeter, Stamford.

Bull calf, but under 2 years old.—1st, Rev. W. Sneyd, Keele Hall, Staffordshire; 2d, T. Lace, Gronaby, Isle of Man; 3d, R. Parker, Burnley.

Bull Calf, but under 12 months old.—1st, J. Knowles, Wetherby; 2d, T. Statter, jun., Stand Hall, Manchester; 3d, Rev. W. Sneyd.

Cows, above 3 years old, in milk or in calf.—1st, J. Outhwaite, Catterick, Yorkshire; 2d, J. W. Kirkham, Cadeby Hall, Grimsby; 3d, A. Dugdale, Burnley.

Heifer, above 2 but under 3 years old.—1st and 2d, F. J. S. Foljambe, M.P., Osberton Hall, Worksop; 3d, Earl of Harrington, Elvaston Castle.

Heifer, above 1 but under 2 years old.—1st, E. J. Smith, Islanmore, Limerick; 2d and 3d, Rev. W. Sneyd.

Heifer Calf, but under 12 months old.—1st, J. Farrer, Burnley, Lancashire; 2d, E. H. Cheney, Gaddesby Hall, Leicester; 3d, Earl of Harrington.

OTHER BREEDS.

Ayrshire Cow or Heifer, above 2 years old, in milk or in calf.—1st, the Earl of Crawford and Balcarres, Wigan; 2d, A. Woods, Sefton Park, Liverpool; 3d, J. Seaton, Ince.

Welsh Cow or Heifer, above 2 years old, in milk or in calf.—1st, F. W. Earle, Huyton; 2d and 3d, T. Statter, jun.

Welsh Heifer, above 1 year old, in milk or in calf.—1st, Rev. J. C. Macdona, Hilbre House; 2d, J. G. Morris, Allerton; 3d, R. Inman, Cockey Moor.

French or Channel Island Cow or Heifer, above 2 years old, in milk or calf.—1st, G. Maples, jun., Wavertree, Liverpool; 2d and 3d, the Earl of Lydiate House.

French or Channel Islands Bull, of any age.—1st, W. Brothers, Lawton, Cheshire; 2d, H. S. Woodcock, Wigan.

Kerry Bull, of any age.—1st, J. C. Macdona; 2d, Gladstone, jun.

Welsh Bull, of any age.—T. Statter, jun.

Ayrshire Bull, of any age.—1st, J. Waddle; 2d, R. Kerr.

Cow, the property of and bred, belonging to a landlord resident in the district, that was allowed to serve the cows of his tenants gratis.—The Society's Silver Medal awarded to the Earl of Crawford and Balcarres.

(Competition limited to members resident in the Society's district. Prizes for tenant-farmers only.)

Bulls, of any breed, above 2 years old.—1st, W. Tillotson; 2d, R. Barnett; 3d, J. Cheetham.

Bulls, of any breed, above 1 and under 2 years old.—1st, C. W. Brierley; 2d and 3d, J. Dickinson.

Bull Calf, above 6 but under 12 months old.—1st, J. Goolden; 2d, C. W. Brierley; 3d, H. Neild.

Cow, for dairy purposes, in milk or in calf.—1st, T. Atherton; 2d, H. Neild; 3d, J. Birch.

Pairs of Cows, for dairy purposes, in milk or in calf.—1st, J. Kenwright; 2d, T. Statter, jun.; 3d, C. W. Brierley.

Pairs of Heifers, above 1 but under 3 years old.—1st, J. Dickinson; 2d, T. Statter, jun.

Single Heifer, above 2 but under 3 years old.—1st, C. W. Brierley; 2d, J. Dickinson; 3d, W. Dale.
Pairs of Heifers, above 1 but under 2 years old.—1st, C. W. Brierley; 2d, T. Statter, jun.; 3d, J. Dickinson.
Single Heifer, above 1 but under 2 years old.—Silver Cup.—1st, W. Birch; 2d, C. W. Brierley; 3d, H. Neild.
Pairs of Heifer Calves, of exhibitor's own rearing, under 12 months old.—1st, C. W. Brierley; 2d and 3d, J. Goolden.

HORSES.

(Open for competition to the United Kingdom.)

Stallions, thorough-bred, most suitable for getting weight-carrying hunters.—1st, J. Casson; 2d, R. C. Naylor; 3d, G. Holmes.
Stallions, for getting horses for draught purposes.—1st, W. Wynne; 2d, H. Tomlinson; 3d, A. Cook.
Stallion Colts, draught breed, foaled in 1869.—1st, not awarded; 2d, R. Ashcroft; 3d, L. A. Mawdsley.
Stallions, most suitable for getting horses for carriage or road purposes.—1st and 2d, B. Mitchell.
Mare or Gelding, for draught purposes, 4 years old and upwards.—1st, G. W. Brierley; 2d, W. Robinson; 3d, J. Wright.
Three-year-old Gelding or Filly, cart breed.—1st, T. Statter, jun.; 2d, W. Brierley; 3d, J. Hampson, Wigan.
Two-year-old Gelding or Filly, cart breed.—1st, T. T. Parker; 2d, J. Wright; 3d, T. Statter.
One-year-old Gelding or Filly.—1st, J. Waterworth; 2d, W. Shawe; 3d, J. Dover.
Three-year-old Gelding or Filly, half-bred.—1st, J. Rigg; 2d, W. Eccleston; 3d, R. Beside.
Two-year-old Gelding or Filly, half-bred.—1st, T. Horrocks; 2d, T. M. Tattersall; 3d, C. Roberts.
One-year-old Gelding or Filly, half-bred.—1st, T. Horrocks; 2d, E. L. Wright, Wigan.
Brood Mares for getting hunters.—1st, T. Horrocks; 2d, T. Statter, jun.; 3d, S. Kirby.
Brougham Horse, Gelding, above 4 years old.—1st, T. Percival; 2d, W. Robinson; 3d, J. Jefferson.
Hack or Roadster, Mare or Gelding, 15 hands or upwards.—1st, W. Murray; 2d, J. Schofield; 3d, H. S. Woodcock.
Colts, Mare or Gelding, under 15 hands.—1st, F. Hollins; 2d, C. Smith; 3d, J. Williams.

SHEEP.

(Open for competition to the United Kingdom.)

LEICESTERS.

Shearling Ram.—1st and 2d, T. H. Hutchinson; 3d, J. T. Clifton.
Ram, of any age.—1st and 2d, T. H. Hutchinson; 3d, E. Riley; silver medal, G. F. Statter.
Ram Lamb.—1st, 2d, and 3d, T. H. Hutchinson.
Three Shearling Ewes.—1st and 2d, T. H. Hutchinson; 3d, E. Rice.
Three Ewes, of any age, having reared lambs this year.—1st and 2d, T. H. Hutchinson; 3d, G. F. Statter.
Three Ewe Lambs.—1st, R. Jefferson; 2d, T. H. Hutchinson.

SHROPSHIRE DOWNS.

Shearling Ram.—1st, J. Coxon; 2d, Lord Wenlock; 3d, Sarah Beach.
Ram, of any other age.—1st, W. Baker; 2d, Lord Wenlock; 3d, S. Griffiths.
Ram Lamb.—1st, T. Nock; 2d, T. Johnson; 3d, T. Nock.
Three Shearling Ewes.—1st, Sarah Beach (who also got the silver cup of £10 for the best pen of three ewes); 2d, W. Baker; 3d, Lord Wenlock.
Three Ewes, of any age, having reared lambs this year.—1st, S. Beach; 2d and 3d, W. Baker.
Three Ewe Lambs.—1st, J. H. Bradburn; 2d, S. Beach; 3d, W. Yates.

SOUTHDOWNS.

Shearling Ram.—1st and 2d, Colonel R. N. F. Kingscote; 3d, J. & A. Heasman, Angmering.
Ram, of any other age.—1st, H. S. Waller; 2d and 3d, Colonel R. N. F. Kingscote.
Three Shearling Ewes.—1st, 2d, and 3d, Colonel R. N. F. Kingscote.
Three Ewes, of any age, that have reared lambs this season.—1st and 2d, H. S. Waller.

CHEVIOTS.

Shearling Ram.—1st and 2d, R. Shortreed.
Ram, of any other age.—1st and 2d, J. Robson.
Three Shearling Ewes.—1st and 2d, R. Shortreed.
Three Ewes, of any age, having reared lambs this season.—1st and 2d, R. Shortreed.

CROSS-BRED SHEEP.

Three Shearling Ewes.—S. Davies, Eardswick Hall.

BATH AND WEST OF ENGLAND.

AT the late meeting of the Council of this Society, at the commencement of the proceedings the Earl of Cork stated that he should not be doing his duty, in the position which he occupied, if he omit alluding to the loss sustained by the Society since the Guildford meeting in the death of the late lamented Sir Thomas Acland, a man universally esteemed and respected by persons of every rank and station in life, and sincerely beloved and esteemed by his neighbours and friends. Happily they had in the present Baronet a warm and zealous friend of the Society, who, they felt satisfied, would follow in the steps of his worthy father.

The business of the day was chiefly of a routine character; Colonel Luttrell being appointed one of the stewards of arrangements, and Mr. Grenfell one of the stewards of field implements.

A copy of the Society's Journal, which has just been issued to members whose subscriptions are not in arrear, was laid upon the table, and reference was made to an important article by Professor Brown on "Pleuro-Pneumonia," especially that portion of it containing a history or summary of the legislation that has taken place with reference to the disease.

Notices of Books.

The Book of the Farm. By Henry Stephens. Third edition. In great part re-written to bring it up to the present time. William Blackwood & Sons, Edinburgh and London, 1871.

This valuable work has been cut down from three, to two volumes. We find, after carefully comparing it with the edition of 1844, that this reduction of matter has not been effected without loss. The book in its younger form was certainly wearisome in some of its details, but at the same time it was a monument of the author's industry and a mine of information upon many of the most abstruse subjects connected with agriculture. The bulk of the work was in a great measure owing to the multiplicity of its woodcuts and the amusing exactness with which the most elementary processes were described. The new edition retains these peculiarities, and we still find portraits of besoms and brushes, currycombs and corn strakes, pails and ploughstaves, trowels, sacks, spades, and milking-stools; but we miss the mathematical formulæ bearing upon ploughs and ploughing, the interesting dissertation on various kinds of draining, and the detailed specifications and instructions for the erection of farm buildings, which occupied so large a portion of the older editions. The impression which cannot fail to rest upon the mind after a careful comparison of the new with the old editions is, that the editor has been wearied of his task. The parts which required an industry and research in the editor equal to that of the author, have been too often suppressed, while the mere generalities of practice have been preserved. Neither can we allow that the editor has brought his book up to the present time. This is much to be regretted in a work which has enjoyed a considerable reputation, and which, under proper management in those days of age, might well be viewed with leniency. The progress of agriculture has, among other things, been marked by the application of steam to the cultivation of the ground, and yet something short of three pages—less room than is given to broadcast sowing by hand—is all that Mr. Jefferson has to this subject. Agricultural implements have been wonderfully developed of late years, although, judging from the woodcuts in the work before us, we should hardly have suspected it. Great changes have been effected in harvest operations, and yet we have seen and still have devoted to a mindful description of the sickle and its uses, only two are allowed to the reaping-machine. We are still more surprised, perusing this scant allowance of information, that Bell's, Hussey's, and M'Cormick's, as they appeared in 1851, are the implements introduced to our notice. Surely there would not need Hussey's name in preference to M'Cormick's," a not very valuable record of experience when both implements in their original form have disappeared from the arena of competition, the original Bell's reaper being now a curiosity in South Kensington Museum, where it is placed side by side with "Rocket," one of the earliest of Stephenson's locomotives.

In the details of cultivation we learn with surprise that Turnips are often sown broadcast in England, that farmyard manure should be twice turned for Turnips, and that Wheat is usually pickled with "chamber ley" (par. 839, vol. i.). With all due deference, we sincerely hope that Scotch farmers will avail themselves of sulphate of copper in the stead of the above liquid, as an equally effective material, besides being pleasanter to work with.

We are expressly told in the preface that the author regards this as an "educational work." It is scarcely necessary to state that in educating the young we cannot be too careful in giving them the best and newest information, and it is probably best to leave to others the task of imparting knowledge upon subjects with which we are only partially acquainted. The atmosphere, according to Mr. Graham (par. 28, vol. i.), is an explosive mixture, containing 23.32 of oxygen, and 1.03 of hydrogen. The chemical information is of the oldest and most faulty character. The analyses are mostly from Johnstone, and the earlier papers of Way and Ogston. The editor is apparently also acquainted with the recent work of "How Crops Grow," in which new and accurate figures of the roots of plants are drawn from life. Liebig, Johnstone, Voelcker, and Way have done much for agriculture, but a teacher on agricultural chemistry should not ignore the recent works of French and German chemists. In treating of flax, for example, we should certainly have expected the researches of Bouchardat and Commaille to have occupied a prominent place.

Take, as an example of the chemistry of "The Book of the Farm," paragraph 151, upon organic and inorganic matter. "The class of substances," we are told, "entirely dissipated by combustion is called organic," according to Professor Johnstone (for this antiquated authority is still to be the mouthpiece of English agricultural chemistry), "because they generally exhibit a kind of structure visible to the naked eye—as in the pores of wood and in the fibres of hemp, or of the lean of beef—and are thus readily distinguished from inorganic matter in which no such structure is observable. But in many substances of organic origin also no structure can be observed. Thus sugar, starch, and gum are found in plants in great abundance, and yet do not present any pores or fibres." The feculæ of starch, with their hila and strixe, have long been interesting microscopic objects, and yet we are told in an educational work that they are destitute of structure. Apart from this, however, it is curious to note how the editor bandies with his subject, and quarrels with his definition of the word organic, simply because he has not thought fit to draw the distinction between organic and organised. All matter is either amorphous, crystalline, organised. Gum, acetic acid, and alcohol, as products of vegetable growth, are organic; but starch and vascular tissues, having a definite symmetry and arrangement of particles through the force of life, are organised. Instances of similar errors might be multiplied *ad infinitum*.

The entomology is faulty, chiefly in its nomenclature. Thus, what was formerly spoken of as "Cataphagus," is now "Agriotes," and what is named by Mr. Stephens "Ceuterohyncus" is properly written "Ceutho-rhynchus." The "Turnip fly" cannot now be called "Altica nemorum," as this old species has been split up into nine new ones, each possessed of distinctive characters. The genus is now named Phyllotreta, and the farmer's enemy is P. undulata, a much commoner species than P. nemorum. It is ridiculous to quote the 6th volume of the Royal Agricultural Society's Journal for information on the Wheat eel, which Mr. Stephens continues to name Vibrio tritici, although our knowledge of this singular animalcule has been so seriously modified by M. Davaine, and its name has long been changed to Anguillula (or Tylenchus) tritici.

The cryptogamic botany is shaky, and yet this difficult subject is approached with no lack of confidence. Many of the Fungi are designated by names now abandoned; thus the Potato Fungus, Peronospora infestans, is named Botrytis infestans; and among other now antiquated appellations we find Uredo caries given for Tilletia caries, the common "bunt," whose blight which is commended by Mr. Stephens with "smut," or Ustilago carbo, a Fungus affecting the ears of corn and grasses.

The idea of Wheat being infected with mildew from the Berberry is scouted, and we are told "there is no possibility of transmitting the one species into the other;" although that possibility is now, we believe, accepted, and which is quite in accordance with the singular dual forms of so many Fungi.

In concluding these remarks on the new edition of the "Book of the Farm," we can conscientiously state that we hailed its announcement with pleasure, but having gone through it with great care, we are compelled to declare ourselves disappointed. As a book of reference upon agricultural practice, it has still a certain value, inferior to that of the older editions; but as a book of reference to the physical sciences, in their relations to agriculture, it is not to be depended upon.

Farm Memoranda.

HAMPSHIRE.—The worst fears and strongest apprehensions of the farmers as regards the Wheat crop are now being realised. The unerring test of the threshing machine proves that the yield of Wheat, both in quantity and quality, is one of the most deficient since the harvest of 1854. A few fields yield 8 to 10 sacks per acre, the weight up to 62 to 63 lb. per bush.; but the larger portion of the crops give only from 12 to 16 bush. per acre, the weight being from 56 to 58 lb. per bush. The crop must, therefore, be considered at least one-fifth under the average. This deficiency has arisen from two causes — the cold, ungenial summer, and the loss of plant by frost in the winter; and it is generally admitted that a thin plant of Wheat should be re-sown, as it does not, when injured by frost, fill up and tiller like a thin plant arising from other causes.

Barley is a bulky crop as regards straw, and will be probably an average in quantity of grain, but the quality is again disappointing, and a large portion will prove unfit for malting. This irregularity of the quality arises from several causes—a constant repetition of the crop, its following a root crop consumed on the land by sheep, and late sowing. All these causes are, however, under the control of the farmer, except when he is bound to cultivate under the four-course rotation.

The Oat crop has never been more bulky, or likely to yield more corn, especially where sown after roots fed off, for which purpose it is well adapted in consequence of its early ripening. The heads, too, is abundant, and of excellent quality, being well saved, which will go far to assist in economising the short and damaged hay crop.

Beans, both winter and spring varieties, are not so good as were expected, and will not exceed an average crop.

The second - cut Clover and late meadows have yielded a good produce, which have been pretty well secured during the fine weather in August. Although the harvest is not completed, yet it has been favourable on the whole, and fortunately the weather has allowed a great part of the Leut corn (in many instances overgrown with Clover) to be secured in excellent condition.

Since our last report the root crops have continued to progress with every prospect of turning out one of the most abundant ever grown in this county, and it is generally admitted that our stock of sheep and cattle are so short that one-fourth of the root crop cannot be consumed in the usual way, and it has become a matter for discussion how it can be best disposed of, and, without doubt, hundreds of acres will be ploughed in rather than purchase sheep and cattle at present high prices.

This is the best time for sowing Trifolium. The seed being cheap, and the season fine, a large breadth will be sown. The plan of mixing a portion of broad Clover or Cow-grass, say 16 lb. Trifolium and 6 lb. Clover seed per acre, is recommended where the land is clean

and not intended for Turnips to follow, as the Clover is found to give a good cut in the autumn months.

The main crop of Potatos yields well, but fully one-third of the tubers will be lost by disease. The quantity of sound ones for winter use will, however, reach an average.

The value of sheep and cattle is likely to continue high, for not only is food abundant, but the price of mutton and beef is exceedingly high, and it must be a long time before supplies can be equal to the demand.

The price of grain, especially Wheat, would run high if we were dependent more upon our own resources, but the world's market being open to us, will certainly hold prices in check. *Joseph Blundell, Southampton, September 6.*

NORTH RIDING OF YORKSHIRE.—The maturing of the crops was accelerated in a wonderful degree by the brilliant weather of August. A considerable acreage has now been cut, and in some of the earlier localities a few stacks carried. The great bulk, however, is yet unsecured, and we require a full fortnight of fine weather to accomplish it. A closer acquaintance with the crops unfortunately confirms our opinion, already given in your columns, that the yield of the Wheat crop will be a short one. Thin on the ground, beat down with storms of July, together with the unfavourable season while in bloom, has rendered the crop deficient both in quantity and quality.

The Oat crop varies, being much the best where grown after Clover, but over a considerable acreage, where grown after Turnips, the crops are bad; suffering from grub in June, they never recovered, and are now very unsatisfactory, ripening at different stages. The sample will be bad, and yield very deficient.

Barley is the best crop of the season, but a shake wind during the last week in August did much damage, and will bring down the nett yield to a bare average one. The late rains have improved the Turnip crops, and the prospect of very large crops are good.

Pastures and aftermaths are also good, so that presently and prospectively cattle food is abundant.

Cattle and sheep, fat or lean, maintain unprecedentedly high prices. Mutton from 9*d.* to 10*d.* per lb. Beef from 8*d.* to 10*d.* per 14 lb.

Potatos are good crops, but complaint of disease is made from various farms.

Foot-and-mouth disease is prevalent, and seems to be fast spreading in this district. It is well known that it is not near so contagious as the rinderpest, and surely this close supervision by the local authorities it ought to be stamped out. The reverse, however, holds good, and it looks like sweeping every farm in the district. *W. J. M., Sept.* 10.

WEST GLOUCESTER: *August.*—The beautiful summer weather of the last month has enabled us to clear up the hay in good condition. Had the hay season ended as it commenced, the results must have been most disastrous, for, as is well known, young grass will stand a far greater amount of bad weather than old without getting such a bad colour, or losing so much of its quality. We have rarely seen heavier crops of grass, especially the late cut.

The bright sunshine and very drying winds have proved of the greatest benefit to the grain crops, some of which, though not long since they showed a very dark unhealthy straw, have now ripened off a much brighter colour than we anticipated.

Harvest hereabouts has become general. Peas are cut, and, in most cases, stacked. We have a bulky crop of straw, but the yield will not be equal to last year, as many of the pods have not filled, while others have but very few Peas in them. Oats are very good; the early sown are secured in good condition. Wheat, it is feared, will turn out very middling; the crop is in many instances very thin upon the ground, and badly scrawled, owing in a great measure to the season having been more than usually favourable to the creation of the forces of our innumerable farm pests, as well as to the extraordinary winter which the autumn-sown Wheat had to encounter. None has yet been threshed in this neighbourhood, therefore the produce yields cannot yet be stated, but, judging from the handling of the sheaves, there appears to be a great deficiency compared with average seasons. The stubbles are unusually foul.

Barley is very good in general, and much of the early-sown has been well secured.

All root crops look most promising, and at present quite free from mildew.

Potatos are badly diseased: in some cases scarcely a sound Potato can be found at a root.

Food for stock is abundant, and cattle of every description retain a high figure.

Beef is realising 80*s.* to 84*s.* per cwt.; Mutton, 9*d.* to 9½*d.* per lb. *J. W.*

Obituary.

IT is with unfeigned grief that we have learned the death of MR. ROBERT RUSSELL, of Pilmuir, near Leven, Fifeshire. He was a frequent and valued contributor to the *Agricultural Gazette* many years ago, when, with his friend the late Mr. Haxton, another Scottish farmer, he was an active and most efficient member of a small body of agricultural writers, to whom our own and other columns have been very greatly indebted. Mr. Russell was an independent laborer and thinker in the science of meteorology—had observed and travelled widely with special reference to meteorological and agricultural subjects—was quite one of the leaders of the agricultural world in the North—an active member of the Council of the Highland and Agricultural Society, and for many years Editor of their Transactions. But it is the loss of a friend by his death, even more than that of one who, in the very prime of life, was serving his generation so well, that will be generally felt and mourned. We quote the following from the columns of the *Scotsman*:—"The agriculturists of Scotland will learn with deep concern, and all of his many friends with no common grief, that Mr. Robert Russell died at his farm of Pilmuir, Leven, on Sunday last. Both as a practical farmer and as a writer on agricultural subjects, Mr. Russell (long known as "of Kilwhiss") was held in high estimation all over Scotland, and beyond it. Of late years, too, he had directed much of his attention to the subject of meteorology, to the literature of which he made several valuable contributions, most of them appearing first in our own columns. From 1860 to 1866, he was Editor of the Transactions of the Highland Society, to which he also contributed papers on various agricultural matters. He was appointed a director of the Highland Society in 1867, and held that position till his death. In 1854, he visited the United States, Canada, and Cuba, and gave the results in a large volume, "On the Agriculture and Climate of North America," which the late Mr. J. R. M'Culloch, an excellent judge and no lenient critic, pronounced to be the best and most solid book ever written on its subjects. It was whilst absent on this tour that a vacancy occurred in the Edinburgh Chair of Agriculture; and his friends hesitated to put him forward, without his knowledge, for an appointment for which he was eminently fitted, and which he otherwise would have had a good chance of obtaining. During the discussions on the Irish land question he published a pamphlet, proposing a scheme of his own which obtained much attention and approval amongst those most conversant with the subject. After leaving the farm of Kilwhiss on the Lathrisk estate, a few years ago, Mr. Russell entered on the fine farm of Pilmuir, near Leven, belonging to the Standard Insurance Company, and which he held for several years, as extensive sheep-farm on the Duke of Montrose's estates at Loch Lomond. He attended the late meetings of the British Association in Edinburgh, and was then in even more than his usually robust health; indeed, his apparent vigour was so great as to draw the remark—the first that strikes painfully on the memory—that, in a pretty large private company assembled during that visit, he was indicated by a physician as the man likely longest to enjoy health and life. A few days ago, one of his children was seized with scarlet fever, and died. He caught the infection, and, notwithstanding his strength, succumbed after two or three days' illness. He was a man of good heart and temper, as well as of excellent head; and his removal in the midst of his days and the prime of his strength, whilst leaving a public place unfilled, will bring heavy sorrow to a wide circle of his friends and acquaintances." [From another source we learn that it was not scarlet fever that was fatal to Mr. Russell, but that he died heart-broken at the death of his only daughter.]

— MR. JOSIAH PARKES, whose name and writings were familiar to agricultural readers in the early days of the English Agricultural Society, has lately passed away, at a great age. The following notice of his life and labours has been sent to us for publication:—Mr. Josiah Parkes died a fortnight ago, in his 78th year, without, as far as we could ascertain, a single line of notice in any of our daily papers, or even in those possessors of universal knowledge, the *Saturday Review* and *Pall Mall Gazette*; yet Mr. Parkes, whose later years were passed in cynical seclusion, did more for the progress of practical civilization than any one world than any man of the present generation, not forgetting Baron Liebig, whom on one important question he signally discomfited. Mr. Parkes, who followed the occupation of a civil engineer before that profession—out of the mining districts—had advanced much beyond the rank of a land surveyer in the pre-railway times, first came before the public through his attempts, which were quite unsuccessful, to apply steam-power to the cultivation of a peat-bog of the same character as Chat Moss, which he had drained for Mr. Heathcote in Lancashire. His observations of the effect of the deep cuttings on the bog led him to make experiments, and by these experiments he discovered the principles of agricultural drainage, which were previously not only unknown but misconceived. The vulgar idea was, and is even with educated persons, that we never thought about the subject, that agricultural land suffers from rain falling on the surface. Mr. Parkes found that a deep drain began to run after wet weather, not from the water above, but from the water rising from subterranean accumulations below, and that by drawing the stagnant moisture from 3 or 4 feet of earth next the surface it was rendered more friable and porous, easier to work, and more easily penetrated by the rain, which carried down air, which is full of ammonia and manure, made it much warmer, and therefore more genial to the roots of the various crops. Without drains a retentive soil is saturated with stagnant water, which remains until evaporated by a warm season, and then leaves the soil hard-baked. Mr. Parkes came to the conclusion that 4 feet, which left a sufficient layer of dry warm surface earth, after allowing for the rise of the moisture by capillary attraction above the water level of the drain, should be the minimum depth. This is now the universally accepted opinion of the best agriculturists in England, France, and Germany. Smith, of Deanston, a very clever man, almost a genius, who never succeeded in anything, had previously devised a system of shallow drains, made of broken stones in the gridiron shape. But he missed the principle; he devoted his ingenious mind to devising expedients for getting the surface water into his drains. After a few years of contest the Deanston plan was entirely superseded by the Parkesian plan. In 1843, Mr. Parkes gave his evidence before a committee of the House of Lords on agricultural distress and its remedies. He was warmly supported by the Earl of Lonsdale, whose experience as a commissioner of highways had proved the soundness of the system; but nothing could be done without drain-cutting tools and pipes. A Birmingham manufacturer, on Mr. Parkes' suggestion, produced, in 1844, the first set of drain-cutting implements, which have since been brought to such extraordinary perfection. A cheap conduit was still a difficulty. Stones choked up in many soils, and where they had to be broken and carted to the ground, their cost became enormous. At the Derby show of the Royal Agricultural Society in 1843, Mr. Parkes showed Lord Althorpe a cylindrical clay pipe, saying, "With this pipe, my lord, I will drain all England." This pipe had been made by wrapping a piece of clay round a mandrel by John Reade, a self-taught mechanic, inventor of the stomach-pump, who was a gardener by trade, and used these hand-made pipes for draining his hot-beds. The Council of the Royal Agricultural Society awarded John Reade a silver medal for his pipe, and a first prize in the drain-pipe class for a pipe-making machine. This prize was won by John Scraggs, at the Shrewsbury show, in 1845, and was, we believe, the only prize offered by the society, in an existence of 30 years, that ever produced a useful original invention. Drain-pipes can now be manufactured more cheaply than kilns can bake them. In 1846, Sir Robert Peel, as an aid to the distressed and frightened agriculturist, passed an Act by which four millions sterling were advanced in loans charged on lands to be drained under Government inspection, on the Parkesian principle. The first loan was nearly entirely taken up in Scotland. A second loan of four millions was granted in 1856; but these eight millions only formed a small proportion of the amount invested in systematic deep drainage by the private enterprise of landowners and of companies formed for the purpose. Hundreds of thousands of acres of stiff clay soils, previously condemned to poor pasturage or uncertain crops of corn and Beans, have been rendered friable, fit to grow roots, carry sheep, and fall into regular rotation. In Yorkshire, Mr. Parkes, for Lord Lonsdale, at an expense of from £4 to £20 an acre, converted such land not worth a rent of 1*s.* an acre, and raised its value to £2 an acre. Increased fertility of soil was not the only result. Systematic drainage led to general agricultural improvements; hedgerows and useless timber were cleared away, undulating ridges were levelled, roads made, and buildings erected to accommodate the production of meat as well as corn. It is also in evidence that the idea of pipe instead of brick sewers was first taken from the operations of Mr. Parkes in a Gloucestershire village to which he adapted the principle. One of the numerous inventions during the introduction of the Parkesian, or scientific system of deep drainage, was the virulent opposition of that able chemist, Baron Liebig, so malignantly prejudiced against everything English. The Baron, about the time of the introduction of Mr. Parkes' principles and plans, introduced his patent universal manure, which proved so complete a failure, and seriously damaged the fortunes of the Liverpool chemists who undertook its manufacture. In order to push the sale of the patent manure, Dr. Liebig wrote a letter in its puffs, and at the time would have warned English farmers that deep drainage would reduce their lands to permanent sterility, by driving into the drains the principal elements of fertility. This ridiculous theory he has since, we think, with a very bad grace, retracted. Mr. Parkes, like other men of original genius, had his foibles. He had not the art of managing men, and consequently a good deal of his early work on sound principles was very badly executed, and brought his system into disrepute. He was intolerant of advice, and jealous of opposition, and consequently never adopted the improvements introduced by Mr. Bailey Denton and others, who took advantage of the natural porosity of any tract of soil to diminish the cost of the series of uniform gridiron drains, to which Mr. Parkes adhered to the last. He would never admit that any improvement on his original plan was possible. Still, it must be admitted, it was a great triumph to introduce an entirely new system, to be executed with entirely new tools and machines against the stubborn prejudices of the farmers, within the short space of 13 years,

Mr. Parkes, for his services, was elected an honorary member of the Royal Agricultural Society; he was also a member of the Institution of Civil Engineers, but although he made immense collections of notes on experiments, he never contributed to its Transactions. At one time he had upwards of 1000 men in his employment in drainage contracts, but he lived alone and apart—the only conversation he understood was a monologue. He was the brother of the late Mr. Joseph Parkes, a famous attorney politician in the days of the first Reform Bill, and the uncle of Miss Bessie Rayner Parkes, who has some reputation as a poetess, author, and advocate of the Rights of Women. Certainly, a portrait of Mr. Josiah Parkes, if extant, ought to adorn the walls of the National Portrait Gallery and the Institution of Civil Engineers. We take the substance of this memoir from an article in the "Quarterly Review" of April, 1858.

Miscellaneous.

Agricultural Education. — Notice has been given by one of the members, that he will bring the subject of agricultural education before the Scientific and Journal Committee for the purpose of eliciting some opinion as to what the society can do to promote the same. Special instruction in the principles of husbandry is much needed in this colony. It is more needed than in Europe, where agricultural experience is the heritage of thousands. There sons succeed to the occupation of farms that have been in the family probably for many years, and follow the rules observed by their immediate predecessors, modified or improved by such lights as science and practice have thrown upon them. Yet even in England, where the practice of agriculture is most advanced, the importance attached to special instruction is great. It is considered that a gentleman should do such things, not because their fathers have done them, but because they are correct in principle. This involves a knowledge which is only to be obtained by a careful comparison of the results obtained by experiment, in various departments of this branch of industry; and the end is well in the main inasmuch as certainty in the investment of energy and capital is substituted for uncertainty, by those who proceed upon knowledge. The choice of a wrong season, of a wrong soil, of a wrong manure, of a wrong grass, of a wrong remedy in disease, amounts to an opportunity thrown away, in which not only the individual, and the community to which he belongs, has lost so much capital by his blunder. If there existed nothing to guide him in his procedure, his failure will not be regarded as a loss. It is merely a contribution to experience, and resembles a coast sounding, and the institution of a warning buoy. But if the experiment had been made before, and repeated in ignorance of this fact, it is clear that loss has been sustained, since it is just to suppose that the person who made it a second time would not have done so had he known the result of the first. All knowledge consists of the aggregation of the results of past experience, and this experience it should be the desire of all to possess who wish to make an economical use of the means placed at their disposal for the production of wealth. Agricultural education consists, of course, of the acquirement of this knowledge, which resembles very much the legal precedents with which the lawyer works. The agricultural colleges of America and England have been productive of the most decided benefit. With respect to the Cirencester College many thousands of acres in Great Britain are farmed by the students thereof, many hundreds of thousands more being under the control of former students who now hold land agencies. There are attached to the college a well-furnished agricultural museum and spacious laboratories, a botanic garden, and a veterinary hospital. The students have, by special arrangement, ample opportunities of learning practical agriculture on a farm of 500 acres, contiguous to the college. Instruction is given by the principal and a staff of professors in practical agriculture, and in chemistry and chemical analysis, geology, entomology, botany, veterinary medicine and surgery, surveying, and in architectural and mechanical drawing. The worth of this institution, although some doubts were entertained about it twenty years ago when it first started, is now well established. The young men, there boarded, trained, and instructed within its walls, are qualified to fill high positions as tenant-farmers, or to undertake the agency and management of landed estates. Every year adds to the number of collegians filling situations of importance and of trust, and the college diploma has long borne a high value as a test of knowledge, ability, and character. The attempt to establish such a college in New South Wales at the present time might be considered unseasonable. But there are many ways of promoting agricultural education without going the length of a college. We must be content to do what we can before attempting to do what we would like. Our noble president, Lord Belmore, has shown one way of promoting improvement. He offers a gold medal to the Senate of the University on the condition that an agricultural bearing is given to three branches of study —chemistry, mineralogy, and geology, in the hope of winning students thereto. Some one else might endow a Chair of Practical Agriculture, following the example of Scotland, or might give a prize for proficiency in certain subjects to be named by the Senate, that body merely appointing examiners. Or there may be other modes of attaining the same end, all of which it is well for a society to discuss whose aim it is to encourage agriculture. *Extracted from a letter in the Journal of the Agricultural Society of New South Wales.*

The Foot-and-Mouth Disease. — From the weekly returns forwarded to the Clerks of the Peace throughout the country, in accordance with the provisions of the Contagious Diseases (Animals) Act, it appears that foot-and-mouth disease is rapidly spreading in all directions. So long has it been a pest, and so steadily has it kept a hold upon our stock, now disappearing only to reappear in an aggravated form, and this in spite of all existing precautions and stringent regulations, that we are led to look narrowly into the causes of its continuance. Undoubtedly, many animals are imported with the disease in an incipient state, defying detection by the most experienced and able men, and many change hands in a similar condition at fairs and cattle markets, but after giving full weight to this, it must be confessed upon reflection that the *bonâ fide* cause or causes are to be sought elsewhere. In the first place, the farmers of England are inclined to treat this epidemic with too great levity. It lacks the terrors of the cattle plague proper; the number of deaths bears a small percentage to the large number of animals attacked. In numerous cases cleanliness and mildly astringent applications to the mouth and feet effect a fictitious cure. There may be a slight inconvenience through the prohibition of removal for sale, and a decrease in the products of the dairy; and thus the agriculturist, lulled into a false state of security by the absence of immediate loss, becomes utterly careless. The loss, however, though not immediate, is nevertheless real. Any one who has had opportunities of seeing animals while affected with this unfortunate disease, must have noticed the gains an advantage at the onset. It is cheering to know that both these classes of delinquents meet in some measure with a due reward—that is to say, are heavily fined; but it may be fairly questioned whether the magistrals who inflict these fines have not more at the interests of so many should not be still more severely handled. Another point upon which much more caution might be exercised, is the thorough disinfection of all places in which infected animals have been. I can speak from experience of the difficulty there is in this respect. Inspectors should not only give orders, but should see them carried into execution. Of course there are some inevitable modes of propagating the disease, and disaster may reward man's best endeavours; but it is an undisputed fact that, as a rule, the dimmition of disease is in direct proportion to the amount of care exercised. While, however, much may be traced to the agriculturists themselves, more is to be referred to the inefficiency of inspectors. Of the duly qualified men nothing need be said; their diplomas are presumptive evidence of their ability, and in the great majority of instances they do not disappoint the confidence placed in them. There is, however, another class—the unqualified inspector. Again and again, totally illiterate, unpossessed of any knowledge of animals, of the causes, prevention, and treatment of disease, except what has come within the glimmering twilight of Nature, men of this class rush in with the utmost assurance where men of science, well trained and practised in their profession, venture but with diffidence. Apart from the ordinary effect of ignorance, it is not difficult to see what may and does occur in another way; the office of inspector is a powerful lever, and in the hands of the unscrupulous may become an instrument of evil. Still, these men are not altogether to be blamed. So long as an inspectorship is to be obtained by mere application, right, and interest, so long will it be difficult to encourage this kind of thing are the really culpable persons. And who are these? Men who might be expected to appreciate better the difference between science and quackery; men who from experience in other pursuits can witness to the increased power attendant upon diligence and practice—in a word, the local authorities. Strange as it may appear, some of the gentlemen constituting these necessary and generally useful boards do not or will not understand the distinction between "farrier" and "veterinary surgeon," and in cases where both have applied for the same office, have been known to appoint the former in preference to the latter. An instance of this came under my notice some 18 months since. And here I may observe that my remarks are not elicited by self-interest, but by the necessity of reform in a matter of public moment. The importance of the subject is patent to every one, and has been acknowledged by Government, who have done and are doing much by legislation; but the good which might result is thwarted by deficiency in detail, and nowhere more than in the appointment of unqualified inspectors. Suppose unprofessional inspectors of horses to be appointed; they would not be tolerated. The cases are analogous, and need no further comment. The constitution of the local boards themselves so as to obtain the maximum of good affords a fair field for inquiry. Of this, however, more hereafter. Foot-and-mouth disease is on the increase; the county ratepayers, who have already unavailingly paid thousands of pounds for the prevention of the spread of contagious diseases, will probably have to pay many thousands more; the interests of the agricultural community are involved, and, through them, those of the community at large; and, this being so, nothing should be encouraged having a tendency to check the effect of salutary measures. *B. A., Higher Broughton, in the "Times."*

Brown's System for Watering and Utilising Manure.—This system has been in operation on the property of Mr. E. J. Coleman, Stoke Park, near Windsor. It was laid down in the end of August, 1870, upon 20 acres of pasture land, with a soil chiefly composed of a silicious clay, slightly calcareous, but from a want of loam-mould liable to become crust-bound in dry weather; it is, however, rich in the mineral constituents of productive soils, and may be classed with that of the well-known brick earth of Slough. On September 5, with temporary engine-power, watering was commenced, the land was top-dressed, and irrigation was continued at night until the end of the month. Notwithstanding the lateness of the season, the dried-up soil, and the destruction of vegetation since the previous June, yet on the twenty-third day after watering, a very thick-set growth of about 9 inches of superior feeding grass was produced, and by the middle of October it became a large crop, which was cut, and given to stall-feeding cattle, and the land after was successfully grazed with sheep until the end of the year, while the adjoining pasture—unirrigated, and in every other particular the same as that over which the irrigation had been conducted—remained unproductive, although rain to some extent had fallen during the autumn. The value of the cut grass and the grazing upon the irrigated land may be estimated as equal to that of an average crop of Turnips, as such grass, weight for weight, is equally rich in beef and mutton constituents, or its money value may be fairly put at £5 per acre for this autumn crop. In the spring of the year 1871 a delay in connecting the engine and pump now upon the irrigated land, operations were not commenced until the last week in March, and from five to six weeks of the best spring weather for watering and utilising manure were lost in consequence, yet a very large crop of hay, chiefly perennial Rye-grass, was fit for cutting by the second week of May. It was estimated by practical judges to yield 2½ tons per acre, and from its having been secured in fine condition without getting any rain, it became the best description of good horse hay, and at the present high prices it is valued in London at not less than £7 per ton, as hay not equal to it has been sold during this and the last month from £8 to £9. On cutting this crop, a portion of it on the same day was removed and made into hay with that upon the unirrigated land, which gave facilities for at once watering the ground from which it had been taken. This had the effect of producing a second crop of perennial Rye-grass of a large growth, which was fit for the scythe in the second week in July; such a result is, as a rule, unknown to agriculturists. A portion of the ground on which the first crop grass weighed gave a yield of 12¼ tons per acre, or about equal to 2½ tons of hay; while the unirrigated land, which had its first crop cut on the same day as the irrigated, only gave one-fourth of this weight as a second crop, although much rain had fallen during its growth, in the absence of which a large portion of this would have been the result; proving that even in a season such as 1871, the coldest and wettest (from April to August) there has been since 1862, that this system of irrigation has a threefold advantage over any ordinary means pursued by agriculturists, in the cultivation of grass or hay. This arises from the facilities given by the system for tempering the soil, and utilising manure by the necessary moisture for promoting a perfectly developed and large growth; and from the operation of watering being conducted during the night, at which time the most favourable moisture is secured by its application from March to November. The successful results obtained at Stoke Park by the British Rivers' Irrigation, since last September, undoubtedly warrant the step just taken by Mr. Coleman in extending it over the whole of the pasture-land upon his estate to the east of the 20 acres just down last autumn. The underground system of the paterlee has been adopted over the whole of it, and is one which recommends it to all for every description of cultivation. Its distribution of moisture is that of a perfect rain shower, according to the power used, over several acres simultaneously; and hundreds during the night, by the superintendence of an engineman and a tap-boy, can be perfectly watered even during the hottest weather. *Quoted from a Published Paper.*

The Week's Work.

SEPTEMBER 16.—*Bean and Pea Stubble Fallows* for Wheat sowing, if not finished last month, should be so early in the present. Heavy clay lands, if clean, as they always are under good management, may be smashing up to the weather by steam. If ploughed it should be narrow and deep, assuming that the land has hitherto been deeply cultivated, otherwise plough the depth hitherto gone, and subsoil so as to get the land cultivated to the proper depth. By such means a suitable seed-bed for Wheat will be obtained without crossing or running the risk of poaching the land in the event of being overtaken by rain before the work is finished. Light land, full of Couch and annual weeds, is not well adapted for Wheat; but if to be sown with Wheat along with from 3 to 5 cwt. of guano, scuffle or broad-share, and gather off the weeds, and then harrow once or twice to braird the seeds of weeds shaken out by the harrow and scuffler, before it is ploughed for the seed-furrow. Some burn the weeds in small heaps on the land, but the more advisable plan is to cart off, and convert them into compost by lime, guano, or liquid manure, &c., as it effects more successfully the destruction of the seeds of weeds, and secures at the same time manure to the land.

Wheat seed-time, owing to the greater breadth of root crops now grown on Wheat soils, extends over a greater length of autumn than it did under the old bare fallow system. But a very large proportion of the Wheat crop is still sown during the latter half of September and the first half of October.

Newly-threshed Seed is to be preferred to the old-threshed, the quality in other respects being equal. The best Wheat on the farm should be selected during harvest for seed—crisp, plump corn, grown on clean, flinty straw; and if such cannot be had at home, it should be obtained from some other place. Some soils and climates are defective one way and another in the growth of Wheat, so that annually it loses less or more constitutional vigour, according to the season, consequently a change of seed is desirable every year. Some, however, only change every second or third year; but, unless under exceptionally fine seasons, the practice involves a much greater sacrifice than is generally imagined. It is easily known in harvest if seed Wheat can be selected at home up to the maximum standard, and if not, the more advisable course is to change the whole of the seed for the ensuing crop.

Pickling Wheat is a very diversified practice, partly owing to opinion, and partly perhaps to the peculiar kind of Wheat sown, and Fungi with which it is infested. Thus the smooth thin-skinned varieties of Wheat, and also samples of any variety that have fine bran, are more easily washed and acted upon chemically than the thick hairy-skinned varieties and coarse bran samples; and with regard to Fungi, the spores of bunt adhere more closely than do those of smut. Some use ¼ lb. of blue vitriol (sulpate of copper) dissolved in two gallons of warm water to a sack of Wheat, so as to wet the surface of the grains equally; others use half a pound; others a whole pound, and even as soon as the grain has absorbed the moisture. Others wash the Wheat in water and skim off the light grains that float before they use the above pickles; and as the pickle is applied whilst the Wheat is wet with some 4 to 6 gallons of water, the stronger pickles may be used with safety, and so on. Another and very common mode of pickling is to wash the Wheat in brine sufficiently strong to float a Potato. Stir and skim off so long as anything rises to the surface, and then dry by sifting hot lime over the washed Wheat spread thinly on the floor, mixing rapidly until the surface of the grain is wholly coated over. Whichever of these plans is adopted, no more Wheat should be pickled at a time than can be sown.

Kind of Seed is determined by climate, soil, and cultivation. The different varieties take their names from various sources: (1) the person who selected them, as Hunter's, Shirreff's, and Hallett's Wheats; (2) the place where first grown, as Essex Wheat; (3) the colour, red Wheat and white Wheat; (4) the period at which they are sown, as winter and spring Wheat, and so on. Some are more hardy than others, and better adapted for this or that soil, climate, and management, so that trials on a limited scale should be made to ascertain whether new varieties can be grown with more profit than the old ones.

Thick and Thin Seeding is a question of experiment which every Wheat grower should solve. From 4 to 6 pecks per acre are sown in September, and from 2 bush. in November.

Wheat Sowing is generally done by seed and manure drills, less or more manure being now applied along with the seed. The coulters are placed from 8 to 12 inches asunder, the hoeing kept down by a weighted lever to the proper depth.

Renovating Grass Land is sometimes more profitably done about this time than in August, in very dry seasons. The carting, harrowing, and rolling, are more easily done than in spring, and do infinitely less harm to the land. Ant-hills, Tussack-grass, and weeds should be dug out and carted off. Some throw the ant-hills, as it is technically termed, thus spreading the ants abroad as in winter, but we prefer getting rid of the ants on the former plan, for in mild autumns they are apt to establish themselves in safety before the killing frosts of winter come. If necessary the surface should be well harrowed before the compost is applied, and after it is spread it should be well harrowed into the roots of the old grass. The grass seeds should then be sown with a broadcast machine, and lightly covered with a bush or chain harrow. If the supply of compost is limited, it is preferable to do a part well than to half do the whole, top-dressing the remainder next year. Grazing stock should be kept off, as they not only do harm with their feet before the compost is washed in and consolidated with rain, but also pull up the young grass with their mouths. Should mild weather set in, so as to force up a too luxuriant growth, it is better to top in time with the scythe or mowing-machine, as in flagging Wheat, than to turn in stock. Instances have occurred of a light crop of hay having been harvested, but it is better to consume the grass green for soiling, leaving a good long stubble, and carrying the rake high.

Notices to Correspondents.

RUNNING TO SEED: *R. H.* The Carrots were probably sown too early for the season. This is, however, no doubt, a very imperfect answer to your question. Will any of our correspondents give us their experience of the circumstances which promote the running to seed of root crops?

RYELAND BREED OF SHEEP: *G. F. O.* Undoubtedly it is still in existence. Apply to Mr. T. Duckham, Ross, Herefordshire.

THE SEED PRODUCE OF A SINGLE PLANT: *The Earl of Essex* asks if any correspondent can say what is the amount of seed which will be produced by a good Drumhead Cabbage plant and a good Mangel Wurzel plant, properly protected? We have made inquiries, but in the meantime publish his lordship's request.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Sept. 11.

We have a much smaller number of Beasts on offer than on Monday last; choice qualities are scarce, and consequently are rather dearer, otherwise there is not much alteration in the trade. The supply of English Sheep is very short for the time of year; prices are higher for them, and an early clearance is made. Choice Calves are scarce and dear. Our foreign supply consists of 3100 Beasts, 14,780 Sheep, 190 Calves, and 25 Pigs; from Ireland there are 190 Beasts; from Norfolk and Suffolk, 30; and 1530 from the Midland and Home Counties.

	s. d.	s. d.		s. d.	s. d.

			Pigs	3	8—5 0

Beasts, 4780; Sheep and Lambs, 23,600; Calves, 230; Pigs, 90.

THURSDAY, Sept. 14.

We have a few more Beasts than on last Thursday, but the demand is good, and Monday's quotations are well maintained. The supply of English Sheep is very short; they are consequently readily disposed of, at fully late rates. There are a few more foreign; these also sold dear. Choice Calves are still in demand, at high rates. Our foreign supply consists of 530 Beasts, 8700 Sheep, and 342 Calves.

HOPS.

BOROUGH MARKET, Sept. 14.

Messrs. Pattenden & Smith report that there is an active demand for the few small parcels of new Hops which have arrived at market, and prices have advanced considerably on the opening quotations:—Mid and East Kent, £9 to £12 12*s.*; Weald of Kent, £7 to £9 9*s.*; Sussex, £6 10 to £8 8*s.* per cwt. The quality of these early sorts is extremely good. The Continental advices speak of the Hops coming down very short, which is also the case here. Prices abroad rule very high. American reports are also unfavourable, and according to the latest advices their crop will not be sufficient for their consumption.

MARK LANE.

MONDAY, Sept. 11.

The supply of English Wheat from Essex and Kent to this morning's market was again moderate, and brought an advance of 1*s.* per qr. upon the prices of this day se'nnight. There was a fair attendance, but only a limited demand for foreign, at an advance of 2*s.* per qr. upon American and Russian, and 1*s.* per qr. upon other descriptions. Barley was in good demand, at full prices. Beans and Peas without change in value. Oats must be quoted 6*d.* per qr. higher. Flour was inquired for, at an advance of 1*s.* per sack and barrel. Several sales of Essex white Mustard seed were effected at 9*s.* 6*d.* per bushel.

WEDNESDAY, Sept. 13.

There was a thin attendance of millers here to-day, and the business doing was on a less extensive scale; prices, however, were without material change. English Wheat came to hand sparingly, but from abroad the arrivals were good. The demand for both red and white produce was less animated, but in all sales effected the full rates of Monday were realised. Barley was in fair request, at previous currencies. The show of Oats was liberal, and the inquiry was limited, on former terms. Beans and Peas changed hands quietly, at late rates. In Flour there was little passing, but prices were unchanged.

LIVERPOOL, Sept. 12.—The market was well attended, and sellers were firm, but the advanced rate checked transactions of any consequence, and only a moderate business was done, at an improvement of 2*d.* to 3*d.* per cental on Friday's rate. Flour was in considerable request, at 1*s.* per barrel and 2*s.* per sack advance on the week. Beans 1*s.* 6*d.* and Peas 2*d.* per qr. dearer. Oats and Oatmeal sold more freely. Indian Corn passed rapidly, at an advance of 2*s.* 6*d.* to 3*s.* on the week.

SEED MARKET.

Our seed markets have been fairly attended during the past week, but the trade has been generally very quiet. Small orders come to hand for Trifolium incarnatum. In Clovers and Trefoils there is nothing passing. Ryegrasses are unchanged in price: the Irish crop is said to be a fair one, but from Scotland bad accounts reach us. We have a fair inquiry from France for seed Wheats. There is some business passing in large blue Peas. White Mustard seed is quiet but firm. New sowing Rape seed must be quoted 2*s.* to 4*s.* per qr. dearer. Winter Tares being in improved supply are now obtainable on somewhat easier terms. For Hemp and Canary seed the trade is slow. Other articles unchanged.

JOHN SHAW & SONS, Seed Merchants, 16, Water Lane, London, E.C.

ENGLISH WOOL.

After a temporary lull the market is again firmer, and with good reason, since stocks are extremely low, and staplers are aware that directly manufacturers have worked up the parcels bought some weeks since, they will not only be obliged to pay present rates, but probably even much higher ones.

COALS.—Sept. 13.

M. DECAISNE	W. J. LOCK, F.R.S.
G. F. WILSON, F.R.S.	JAMES MCNAB, of Edinburgh.

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Gardeners' Chronicle

SATURDAY, SEPTEMBER 23, 1871.

THE FLORAL COMMITTEE of the Royal Horticultural Society would not have done its duty had it not taken the first opportunity of publicly expressing its regret at the decease of its late Chairman, the Rev. JOSHUA DIX. His love for, and his knowledge of, flowers; his sympathy with all those with similar tastes to himself; his catholic spirit, impartial judgment, and genial good-fellowship, rendered him eminently fitted to preside over a large body, the members of which have not unfrequently conflicting interests, and of course, varied and sometimes fixed predilections. To keep so heterogeneous a body in good humour, and to secure fair play to all, is no light task, but it is one which we believe everyone who knows the circumstances will agree with us in thinking that the late Chairman fulfilled admirably well. It is therefore with very great pleasure that we learn that steps will be taken to provide by public subscription a portrait of our late friend, to be placed, with those of other workers in the same field, in the Council-room of the Royal Horticultural Society.

Such a recognition can, of course, do the deceased Chairman no service, but it will be an agreeable thing to his immediate friends, and a stimulus to others who, without thought of fee or reward, devote their energies unselfishly to the general benefit of horticulture and its chief representative body, the Royal Horticultural Society.

At the same meeting it was announced that the Council (with whom the appointment rests) had appointed Mr. W. MARSHALL as successor to Mr. Dix in the presidency of the Committee. Those who have had the opportunity of witnessing Mr. MARSHALL's exertions in the cause of Horticulture and of the Society will, we believe, commend the wisdom of this appointment. Few among the Council have been more

energetic and more useful than Mr. MARSHALL in promoting the objects of which the Floral Committee, *par excellence*, may be taken as the representative; and we have every confidence that those qualifications which have rendered him so useful a man of business on the Council will be turned to even more profitable account in his new position as Chairman of the Floral Committee.

From his experience of the proper mode of managing exhibitions, and his knowledge of plants, and of those who exhibit them, we look forward with well grounded hope that the new Chairman will strain every nerve to discountenance the undue multiplication of certificates which, without some control, such as a Chairman having the confidence of the Committee can alone exercise, bids fair to become an evil, and to render the certificate of the Floral Committee about as valuable a decoration as the ribbon of the Legion of Honour! Mr. MARSHALL will do good service if he sedulously endeavours, without injuring the interests of any individual, to check any tendency towards a reckless indiscriminate issue of certificates, which should be esteemed primarily as horticultural trophies, not as commercial puffs. Again, it is highly desirable that any one who has the power of influencing for good the deliberations and awards of the Floral Committee, should do his best to secure fair play and due attention to meritorious plants, even if the interest attaching to them be not immediately of a mercantile nature. The Floral Committee is not a body constituted to determine what plants will pay best to sell, but what plants, as there exhibited, are most deserving recognition, whether from their utility, their interest, or their beauty. We would not entirely exclude commercial considerations in the judging of plants brought before such a body, inasmuch as a large number of plants submitted to it for adjudication are of such a character that they can hardly be judged by any such standard, but, at the same time, there are other subjects which not unfrequently come before the Committee, and which cannot be judged by such a standard; they are not in the trade, nor likely to be so to any extent; but that circumstance offers no good reason why they should be passed over by the Committee. At least they are as much deserving, often far more so than the subjects to which the Committee awards somewhat freely its diplomas and certificates. We do not wish to add to the difficulties which the new Chairman of the Floral Committee is sure to encounter, but we should not be doing our duty as horticulturists if we did not call attention to the points already mentioned.

POTATOS AND PRIMROSES. There is at least as great a similarity between these two words as between Scott and Monmouth, and we now associate the two with a view of ranging on our food producers the necessity of applying the same persistent energy in introducing novelties of sterling worth that is manifested by our florists. We would not be misunderstood. We recognise and thankfully appreciate all that our Potato growers have done for us in selecting and hybridising, but still we assert our opinion, that they are willing to work in one groove. Some Potatos are earlier, some later; some far more robust than others; their inner qualities, so to speak, vary as much as their outward semblance. Nevertheless, an examination of the exhibitions, year after year, only confirms us in the idea that the variations and differences we see are kaleidoscopic—the same materials worked up in different ways. Now, in view of the Potato disease also—apart from the desirability at any time of securing another string to our bow—we believe that the great want of our times, in the matter of Potatos, is an entirely new strain. We go on breeding in-and-in — ringing the changes on one set of bells, and they of no great compass, and we wonder that the bells get cracked and out of tune; and, when the blight comes, we wring our hands and deplore the fate which we have done comparatively little to avert. We plant in autumn, we lift early, we eschew animal manures, we do this and do that —the this and that being often contradictory that one to the other, but we do not go back to the fountain-head and introduce new blood. There is as good fish in the sea as ever came out of it; there are other tuberous Solanums, which we have mentioned again and again (see p. 1253, 1869), which should at least be tried, either by themselves or crossed with the Potato. These have never been tried to our knowledge. The vast majority of growers do not even know of their existence. They would go on for ever bewailing their fate, and never attaining what at least affords a reasonable chance of success. Of course time is required, but ask Mr. FENN, or any other Potato grower, whether time and patience are not required to produce such samples as were exhibited on Wednesday last at the Royal Horticultural Society. It is perhaps too much to expect private individuals to go to the expense, and suffer the long delays and disappointments which would probably have to be encountered in introducing a new breed of tuberous esculents; such is work for a body like the Royal Horticultural Society. Among its members are those who know what kinds might be sought for with a fair chance of success; among them are those whose influence could secure a supply of the plants in question with comparatively little difficulty; among their officials assuredly there are those who, if they had the materials, would know how to turn them to good account.

What greater service to the community could the Royal Horticultural Society do than introduce some other species of Solanum (or other plant), and sedulously test its capabilities as an adjunct to, or a substitute for, the Potato? What sort of Potatos were those, we wonder, which RALEIGH (if it were really RALEIGH) introduced? What would our growers say to them could they see them? No matter if the new introductions we propose were at first unpromising looking, that is the case always at first. Plants to be useful to mankind on the large scale, must be cultivated and improved. This has been proved again and again. On the other hand, it has been proved equally often that improvement may be carried on till it ends in degeneration. This seems paradoxical, but every breeder, be it of plants or animals, will realise our meaning, and own the necessity for the introduction of new blood to counteract the tendency to decline in vigour of constitution which happens when breeding in-and-in is too long and too continously persevered in.

We do not always favour fanciful or preposterous schemes, such as grafting Potatos into Artichokes, or *vice versâ*: such things may be left for psychic spiritualists, or whatever they call themselves. We confine ourselves to recommending steps in consonance with all that we know either of sound practice or of botany and vegetable physiology, and we say that in this matter no sound progress can be made unless we work in the right track, as pointed out by the physiologists.

But what has all this to do with Primroses? This much: the same amount of energy and skill which have been devoted to securing the magnificent hardy Primrose, of which we offer a portrait in another page, would secure to us, at least, in the future, a new esculent as valuable as the Potato now is. If men of commerce will not or cannot undertake to do this, our public gardeners—directors of botanic gardens, superintendents of colonial establishments, and the like, should do so, and earn the gratitude of their own and future generations.

—— A MOVEMENT has been set on foot, at the instance of the Rev. H. H. DOMBRAIN, to perpetuate amongst horticulturists the MEMORY of the LATE Rev. JOSHUA DIX, by obtaining his portrait in oil, to hang in the meeting-room of the Royal Horticultural Society. It will be seen from our advertising columns that the matter has already taken a definite shape. Mr. MARSHALL has undertaken the office of Treasurer, and Mr. THOMAS MOORE that of Secretary, and a Committee has been appointed to communicate to the artist to be employed to execute the portrait.

—— In reference to IRISH SAXIFRAGES Mr. W. ANDREWS exhibited during the summer session of the Dublin Natural History Society specimens of Saxifraga Andrewsii, supposed by some to be a hybrid, and accompanied by a statement that he had lately given Mr. A. G. MORE the exact locality of this rare form, and fully expected that in the course of this summer Mr. MORE would be able to verify its distinctness; he himself believes, judging from the structure of its ovaries, that this species has strong affinities with S. nivalis. Mr. ANDREWS at the same time exhibited some very remarkable specimens of S. stellaris, closely resembling in form S. leucanthemifolia, a plant which Mr. JOHN BALL appears to regard as but a variety of the former. A coloured drawing by the late Mr. DU NOYER was also shown of a remarkable variety found at the Great Blasquet, in which the flowers presented a glandular disc surrounding the base of the pistil.

—— The MAXIMUM TEMPERATURES of the AIR during the week ending September 16, ranged from 78°.6 at Blackheath to 62°.6 at Aberdeen. The mean for all English stations was 71°.9, there being only two places in which the temperature was less than 70°, viz., Hull and Newcastle-on-Tyne. In Scotland the mean was 65°.6, thus being 6°.3 lower than England. The MINIMUM TEMPERATURES of the air ranged from 52°.5 at Blackheath to 41° at Leith, the mean for England being 48°.2, and for Scotland 43°.9. The MEAN TEMPERATURES ranged from 62°.6 at Blackheath to 52°.5 at Newcastle-on-Tyne. The mean for all English stations was 58°.2, and for all Scottish, 54°.6. Very little rain was recorded as having fallen, the greatest in England occurring at the most southerly station, Portsmouth (0.33 inch), the mean fall for the southern country being but 0.07 inch. In Scotland the greatest fall occurred at Dundee, viz., 0.50 inch, and another of 0.36 inch was recorded at Leith, the mean for the whole country being 0.14 inch. (See Mr. GLAISHER'S Tables, p. 1235.)

—— Those who are admirers of LILIUM AURATUM —and who is not?—should see a grand bed of upwards of 5000 of them, now in full bloom, at Mr. A. WATERER'S nursery at Knap Hill. The plants are seedlings of home growth, and are remarkable for the grand size, fine form, and rich marking of their flowers, while they are also exceedingly diverse. Those with red bands, and those with crimson spots, are plentiful amongst others, and some are most intensely and superbly spotted. Mr. WATERER would, we have no doubt, gladly show them to any one interested in Lily culture.

—— Among the different plants, the cultivation of which for Fodder has been recommended, the CORONILLA VARIA seems to merit special attention. MILLER, in 1760, gave the following account of experiments which had been tried with it, which may be of interest:—

"This plant was formerly proposed to the curious in agriculture as a proper food for cattle; and a few persons did make trial of it: some of whom found by experience that it might be cultivated with great ease, and become very beneficial to the farmer; but it was never extended very far. I have for the most part known as many other valuable things are neglected, only because they were not cultivated by their predecessors. I remember to have seen a large spot of ground planted with this at Deepdene, near Dorking, in Surrey, at a time when the honourable Mr. HOWARD, who, although it had been been neglected for some years after his death, yet was growing so rank as to spread over and get the better of all the rank weeds, Brambles, &c., which had been permitted to grow among the plants; and I measured some of the branches which I cut off, and found them upward of 5 feet long, and very tender their whole length, so that a small spot of ground will afford a good quantity of fodder for cattle, especially as it will grow fast enough to be cut five or six times a-year; and in dry seasons, when there is a scarcity of other herbage, this will be found an excellent plant to supply that want. The cattle I have tried with this herb green were horses and cows, both of which seemed to eat it greedily, and there can be no doubt of its being a better food for any cattle than the common Vetches, which are sown for that purpose, and, as this is an abiding plant, it is much preferable to any which require to be renewed every year. The only objection of any force which I have yet heard made to the culture of this plant, is the difficulty of extirpating it when it is once planted, for it does spread much more than Grass in the ground. But as the plant will last for ever, so it should be always planted where it may remain; and upon such land as is too dry to produce other herbage, this may be a very profitable plant."

New Garden Plants.

PRIMULA JAPONICA, *A. Gray; Memoirs of the American Academy of Arts and Sciences (On the Botany of Japan and its Relation to that of North America)*, 1859. New series, vol. vi.

Undique glabra, foliis oblongis spathulatisve obtuse argute sæpius duplicato-denticulatis in petiolum alatum brevem attenuatis membranaceis venosis efarinosis (sed juvenilibus subtus atomiferis); scapo angulato (1—13 pedali) multifloro; floribus verticillatis; pedicellis phyllis linari-subulatis subæquantibus integerrimis, pedicellis multo brevioribus; calyce ovato-campanulato, lobis 3 angulari subulatis tubo intus farinifero æquilongis, corollæ purpureæ tubo pluries brevioribus; lobis corollæ obcordatis; capsula globosa vertice nuda demum irregulariter rupta.—*Hakodadi.*

"A showy species, which manifestly belongs to Duby's section, Sphondophylla, although the involucre is not foliaceous."

The above is the technical description by the learned American botanist of a plant whose praises are now in every one's mouth. It will do much to redeem the prejudice felt against "New Plants," and engendered by the introduction in some cases of plants having no other qualification than that of novelty. In this case, however, there need be no fear; the plant is superb, and it is hardy. It was introduced to Mr. Bull's establishment by the instrumentality of Mr. Fortune, who found the plant in Japan some ten years since, but was not successful in introducing it to British gardeners till the present year. Mr. Fortune obtained the seeds from W. Keswick, Esq., of Hong-Kong, and Messrs. Walsh, Hall & Co., of Yokohama, which gentlemen he observes, have the honour of introducing a very lovely plant to English gardens. We subjoin a few notes made on it during the season:—

FIG. 277.—PRIMULA JAPONICA

A vigorous, hardy, herbaceous perennial, stemless, with bold, oblong-spathulate, rugose, sharply-toothed (biserrate or sublobate) leaves, 6—8 inches long, and about 3 inches wide. Scape erect, stout, smooth, 1—1½ foot long, bearing successive whorls (4—5 in number) of showy flowers, 10—14 or more in a whorl; pedicels smooth, 1 inch or rather more in length, each in the axil of a subulate bract. Flowers about 1 inch in diameter, of a lively magenta colour, with a small dark zone around the eye, and scentless, strongly suggestive of those of the richly-coloured varieties of Phlox Drummondii. Calyx small, purplish at the base, campanulate, with five short triangular acuminate lobes or subulate points. Corolla 5-lobed, the lobes roundish, obcordate, bipartite, or emarginate, with a small mucro in the sinus, distinct in some vars., overlapping in others; tube ¾ inch long, swollen just below the flatly expanded limb, with a zone of maroon-crimson around the mouth of the tube. Stamens five, almost sessile, inserted at the mouth of the tube on the swollen portion. Stigma capitate, about as long as the tube; but, as in other Primroses, sometimes projecting beyond the stamens, and forming a pin-eyed flower. Already several varieties have appeared, of which the following appear to us to be perfectly distinct:—

lilacina, whitish at the edge, flushed with rosy-lilac

towards the eye, which has a zone of orange-red ; very delicate and beautiful ; a large flowered sort.

alba, white flowers with a zone of golden-yellow at the eye ; smaller than the type.

carminata, carmine-red with crimson-maroon marking at the eye ; smaller than the type.

splendida, more stocky in habit, large-flowered, the colour a very bright glowing magenta with brighter crimson zone, and broad open eye showing the yellow interior of the tube.

rosea, flowers lilac-rose, distinct.

The plant has been figured in recent numbers of the "Botanical Magazine" and of the "Florist and Pomologist."

SEEDLING FRUITS.

THERE is a fascination, if I may so term it, in raising new kinds of fruits from seed, which grew with my growth and has strengthened with my decline. I have been led into this train of thought by the wonderful variations I have seen in fruits raised from seeds ; their history would, in the hands of a novelist, fill a volume. A few days since I looked over a plantation of 400 Jefferson Plums, raised from the stones of this sort in 1865, and I found a great number of them full of fruit, but all were purple—it is well known that this is a large yellow Plum ; no two were alike, nearly all were round—the parent is oval ; and all were more or less good, but not of a superior quality. One promises to be a rich reward, for it is longer than its parent, ripens a month earlier, is oval, purple mottled with red, its flesh transparent, like that of the Pine-apple, and of the most exquisite flavour. In the same batch of seedlings, of the same age, are 100 of Reine Claude de Bavay ; all those that have borne have given purple fruit, more or less oval—how different to the parent stock !—yet they seem to inherit the Green Gage flavour. There are many hundreds in this plantation, raised in 1865, and all of great interest—to the raiser—as the origin of all is given. It will be some few years before all these trees bear fruit, but every season will give hope, and then disappointment, which one does not seem to feel, it is so often the lot of the fruit-raiser. It is only to-day that I saw on a young tree in the orchard-house one enormous fruit, measuring 12 inches round ; it was the third generation from the White Nectarine, was quite white, and from its colour I judged it to be of the finest racy flavour. I cut it, and, alas! found it to be a Pavie, very sweet, but flavourless.

I must return to Plums, which are so useful, and every season, owing to our exports of preserves, becoming of greater value. It is true, as some few possibly, 50 years since—I think I have told the tale, but *n'importe*—that my attention was attracted to some grand old Plum trees, planted by my grandfather between 1770-80. Their name, I think, was the Early French Plum. I soon found that the proper name was Précoce de Tours. These trees, now in their 90 or five years or so, bore good crops ; in other seasons a mere sprinkling of fruit. By a sort of intuition it struck me that this tender but early Plum might be acclimatised by raising seedlings from it. Accordingly I sowed some stones, and raised some young trees. These were planted on a corner, and nearly forgotten. I was then immersed in Rose culture. After some eight or 10, or 12 years had elapsed, these trees commenced to bear fruit ; I was struck by the precocity and goodness of one, and the great fertility and goodness of the other. They were at first distinguished by their numbers, and were simply No. 1 and No. 2. After a few years the former was named the Early Favourite, a dessert Plum, and the latter the Early Prolific—at present the most popular of all Plums, not only for its earliness, for it is at market by the end of July, but for its excellent flavour, as a preserve. It is, when well grown and ripe, far superior to any other early Plum, even as a dessert fruit. For the last 20 years it has so increased in popularity, that from 15,000 to 20,000 trees are sold here annually, and some thousands of young pyramids are planted out 6 feet apart for bearing, under market garden pruning. By raising this sort—creating it—one feels to have benefited one's species, and, like growing the extra blade of grass, the feeling is one of gratification.

Another seedling Plum has given me much gratification. As it will, I think, be a pleasant memento, shall I give its history ? [By all means. EDS.] Well, at this rate I could fill a volume about seedling Plums.

About 25 years ago, when full of Rose love and Rose lore, I happened to be at Bellevue, a charming height near Paris—now, I think, devastated—on a visit to M. Laffay. In the midst of our Rose talk he said, "You are so full of Roses, but look here—taste." He then gave me a large mottled Golden Gage, with a most excellent and distinct flavour, superior, I then thought, to the old Green Gage. I think so still. This was Reine Claude Diaphane (now the Diaphane Gage), because when fully ripe you can see the stone plainly. A few years after this time I received some trees, but they seemed so disinclined to bear that I despaired of them ; their shoots were so glossy and vigorous, and their leaves the same, that no blossom buds would form. This went on till the hot summer of 1857, I think, when some fine fruit ripened in September—how large and excellent they were ! I was not, however, satisfied with the habit of the tree, it was too vigorous, and to a certain extent shy in bearing ; my success in acclimatising the Précoce de Tours came to mind, and I had hopes. Some stones were sown, some young trees raised, and two years ago I had the pleasure of seeing a Plum of my own creating likely, in a humble way, to immortalise my name (*ut bene fi*). This seedling is a marvellous likeness of its parent as regards the colour, quality, and size of its fruit, but it ripens fully a month earlier and is a great bearer, but, above all, instead of having smooth, vigorous shoots it has stout downy ones and rugose leaves : a more complete departure from the parent I have never witnessed. One day this Plum will go to the London markets by thousands of bushels, and its raiser or creator may be remembered.

Among our numerous seedling Plums my attention has been directed to fine culinary sorts, so as to have a large size, deep colour, and fine flavour. One seedling from Prince Engelbert bore for the first time this season, and promises well, being large, and of the same size and quality as its parent, with this remarkable difference—it ripens at the end of July, or three weeks before its parent. Another Plum for the people is a seedling from Belle de Septembre, of the same size, or nearly so ; this ripens the middle of August, and is a prodigious bearer — it bears up the stem, so that it can be cultivated as a close pyramid in small gardens. These market Plums will, when known, supersede the useful but insipid Plum, the Victoria, now so largely grown.

With regard to seedling Pears, there are some three or four thousand here, many from hybridised sorts, as are many of the Plums ; they are full of interest, but almost hopeless—it is so difficult to raise a fine Pear from seed. Many have been raised here. There are, as we know, too many really good Pears ripening in September, October, and November ; but good Pears ripening in March and April are still rare. There are some scores of Pears raised here from seed now full of fruit ; they have been raised from esteemed sorts, and which seem quite hardy, but not good enough to name, except one, a variety of the Louise Bonne, and like it in every respect, except in ripening a month or so after its parent ; still the vagaries of my seedling Pears are productive of amusement, and the hundreds that have not borne, of hope.

With Apples raised from seed I have had but little success, for I placed the Ribston Pippin as a test, and not one could surpass or even equal it ; and so my seedlings, with the exception of two or three surface rooters, which have made valuable Paradise stocks, were all grafted and sent away.

My seedling Peaches and Nectarines are so numerous, and their origin and qualities so valuable, that I could fill a small volume in narrating their history. I will only at present mention one, most remarkable for its beauty and excellence : more than one of our best judges declare it to be the finest, handsomest, and best Peach in the world, and yet this is only one remove from that uneatable Pavie (clingstone), the Pavie de Pompone. I ate one of these Peaches to-day (September 15) ; it is the Princess of Wales, and certainly I never saw one larger or finer looking, and with the richest colour and most handsome, nor ate one so rich. This is most encouraging, still with Peaches hybridised there is something more to be done, for, as Sir John Sebright said of his bantams, "they can be bred to a feather." I can only illustrate this by saying that a seedling Peach tree will not bear this season a single perfect fruit. The tree was raised from that original Chinese sort, the Honey Peach, the blossom of which was crossed with the Albert Nectarine. The result is a perfect hybrid, with a skin nearly as smooth as the Nectarine, and with a combined flavour—the luscious sweetness of the Peach, and the brisk, brisk Nectarine flavour. It may be asked why these things have not been submitted to the Fruit Committee ? Well, I know the members to be good and honest, but—shall I say it ?—rather deficient in, in—must I say it ?—prudence. Some of them are better lovers of their judges of fruit, and so it has happened that errors have been committed, not so much, perhaps, from want of judgment as from haste ; for, in my opinion, every variety of fruit should be exhibited at least for three seasons (giving it commendation, if deserved, each time it is shown) before a first-class certificate is given. The habits of the tree should be looked into before judgment is passed ; in fact, the committee should have a peripatetic branch of, say, three good men to closely observe the origin and habit of a seedling fruit, and then wait. If this can be done we should not have a late Peach certificated as an early one, or a Grape certificate returned, or a Pear as a supposed seedling exhibited only once and certificated, putting sundry guineas into the pocket of the exhibitor. With Grapes, commencing with the Golden Hamburgh, we have much to lament, for many guineas and much labour have been wasted in the endeavour to disappear as the price of our new fruits, and that we shall soon be glad to dispense with it : depend upon it the three years' trial and the peripatetics will stop it. I have written as above after much talk with fruit-loving friends, forgetting in my old age that I am a member of the Fruit Committee, and have been mixed up with all its doings till 1870, since which I have not been able to attend ; so that I have helped it in its small errors with golden and other Grapes ; and as it is never too late to mend, I have now endeavoured to lend an amending hand, for which I trust the committee, if it do not thank me, will at least consider kindly.

I may at some future time, if permitted, give my experience in raising seedling Peaches and Nectarines, commencing some forty years since. It would, I flatter myself, form a chapter not devoid of interest. *Thos. Rivers.* [The history of our correspondent's experiments would be most valuable. EDS.]

BATONEUS POPULI.

A MITE INJURIOUS TO THE ASPEN IN SCOTLAND.

AT the end of May last, Mr. George Norman, of Forres, a gentleman well known as an ardent and successful cultivator of Scottish entomology, kindly sent to me a batch of curious Aspen galls, accompanied by a note that they were growing in vast profusion on Sir A. Gordon Cumming's estate near Shiel, on the banks of the Findhorn, and that the branches of the Aspens were covered with them in all stages of growth. My correspondent also informed me that the Aspens were probably of natural growth—quite wild, and, in reply to my inquiry, I learned that none of the galls were seen near to or on the roots.

It is the first time that British specimens of these galls have come under my notice, but I have long been acquainted with their occurrence in Bohemia, as detailed by Herr L. Kirchner in the following note, of which I think it serviceable to give a literal translation :—

"But the most diversified works I found on the Populus tremula, L., of our woods, at the young shoots of 4—5 years' growth, amongst which there are, however, individuals, nearly twenty years old, and which from the want of sun continue a stunted vegetable life in a cripped state in the thicket of old Pine plantations. Most remarkable of all are the gall-like deformations similar to tuberous growths, which are attached near to the root, and half imbedded in the soil, from the size of a Hazel-nut up to that of a man's fist ; their outside is of a fine reddish-green, their shape and look that of a raspberry,* their interior full of small cells, nearly 100 in number, each of which has the size of a Hemp-seed, and is tenanted by 10—15 mites in the larval state (Batoneus populi, mihi). Only twice I was so lucky as to catch altogether five old females which were just busy [laying ?].

"This gall formation, which is quite peculiar in construction, and which is undoubtedly the work of a mite still undescribed, I have subsequently found on 11 different crippled shoots, always only near the root, fixed to the bark, half above ground, and half imbedded in it." *Lotos*, xix, p. 44.

With the description here given of the Bohemian specimens, my own Scotch ones quite agree in every particular,—in size, colour, and internal structure. I was in particular struck by the rich, downy, reddish-green hue of their covering, by the loose, granulate texture of the outer layer, which could be easily broken up by hand, and by the fibrous, woody, hard mass around and within which the numerous cells of the mites were located. In my opinion each of these galls springs from a bud, transformed into a short, deeply-imbedded foot-stalk, within which the parent mite had deposited her eggs. Hence I would lay special stress on the fact, so much insisted upon by Herr Kirchner, that the galls occur only near the roots. On a future occasion I hope to be able to supplement this notice by an account of the development of the makers of these excrescences. In the meantime I wish to direct the attention of foresters and arboriculturists to the fact, how injurious these galls, "in vast profusion," must be to the trees, and what an enormous quantity of sap they must divert from its legitimate channels.

Those who value healthy growth, I would, therefore, recommend, not to use their pruning-hooks tremblingly, like *Æ*sculapius's "Aspen o'er a brook," but firmly, and mindful of the circumstance that if the operation is to do any lasting good, these excrescences should not remain on the ground, but should be collected and consigned to the fire. *Albert Müller.*

ENGLISH LOCAL FLORAS.—V.

IN 1825 appeared a second edition of "An Essay on the Geographical Distribution of British Plants through the counties of Northumberland, Cumberland, and Durham," by Mr. Winch ; it first appeared in 1819. This is of importance as being one of the earliest papers directing attention to geographical botany, and will be perused with great interest. It contains a careful enumeration of the more interesting plants of the district, arranged under ten heads, including such as reach their north limit in this part of the kingdom, and such as here find their south limit ; and two lists of introduced plants, the latter from the ballast hills of Tyne and Wear, being interesting as recording for the first time the occurrence of species which have since put in an appearance in other parts of the kingdom. There are two appendices—the first containing a monograph of the Roses of the district, of which 14 are enumerated ; and the second, observations on temperature, &c. In a brief review like this, it would be impossible to give anything approaching a complete

* Similar deformations are found on the trunk of Populus pyramidalis, perhaps also below, as in this case.

notice of such papers as these; and this remark applies even more forcibly to the works of Mr. Watson, which, however, it would be equally impossible to pass unmentioned.

"A Catalogue of Rare or Remarkable Phænogamous Plants of South Kent," by the Rev. G. E. Smith, published in 1829, is the next work which claims our notice. It is arranged on the plan of the English Flora, and embraces a district of much botanical interest. In careful and critical observation, this catalogue is in many respects an advance upon most of its predecessors; it contains 246 species—a good number, considering that the commoner are excluded. Among the most interesting of these is the Statice, here published as cordata, which was subsequently described by the author, in the "Supplement to English Botany," as S. binervosa. This plant, although described and figured by Lobel and Gerarde, and localised by the latter and Ray, was long overlooked by subsequent writers, and a full description is here given. In the "Student's Flora" it is placed as S. auriculæfolia. Many detailed descriptions and critical notes are scattered through the book; the observations upon the species and forms of Ophrys, which, as is well known, are especially abundant at Folkestone, will be read with interest. The form known as O. fuciflora appears to have been plentiful about this time, as our author speaks of having seen "more than 200 specimens" from the neighbourhood of Ospringe. He came to the conclusion, which subsequent writers have confirmed, that it could not be separated from O. aranifera. Careful figures of this and some other of the more interesting of the plants enumerated are given.

In 1829, also, Dr. George Johnston published Part 1 of a Flora of Berwick-upon-Tweed. This contained 248 pages, and was confined to the Phanerogams, arranged according to the Linnæan system, the nomenclature being that of Smith's "English Flora." There is an introductory essay on the geology of Berwickshire. The number of species enumerated is 608; these are briefly described, with short notes of general interest, and full lists of localities for the rarer plants. A coloured figure is given of Veronica Buxbaumii, under its synonym of V. filiformis. According to Dr. Johnston, this had not been previously noticed in any work on English botany, although Mr. E. Forster had observed it "several years" before in Sussex. Its rapid spread throughout the country need only be referred to. Another plate is that of the Luzula, which we mentioned as having been figured by Purton, and which has been given as L. sudetica. Part 2, published in 1831, contains the Cryptogams, extending over 268 pages, and several appendices on the additional species and localities observed since the publication of Part 1. There is a detailed description of Hypnum Hypnoides, for which M. sylvaticus had previously been erroneously recorded; also a figure and description of Lathræa Squamaria. There is also an arrangement of the plants according to the natural system, and a complete table of the Phanerogams and Ferns of Great Britain, with some general remarks upon the produced names, founded on the catalogue published by the Rev. J. S. Henslow two years before. The plants, which reach respectively their north and south limit in Berwickshire, are enumerated. There is a sketch of the botany of north Durham and Berwickshire from the earliest records to the date of publication, stating the principal additions made to the flora by various observers, somewhat upon the plan recently adopted in the "Flora of Middlesex," noticed in these columns at p. 1067, 1869. Dr. Johnston was evidently a careful and painstaking botanist, and well known not only in that capacity but also as an accomplished physician and a learned zoologist. We shall refer later on to another of his works.

In 1832 appeared a work by Mr. Hewett Cottrell Watson, printed for private distribution, entitled, "Outlines of the Geographical Distribution of British Plants." This may be considered of especial interest, not only from its being among the first works which directed attention to geographical botany, but also from its having been the earliest botanical work of the author, and the pioneer, so to speak, of the invaluable "Cybele Britannica." It is divided into two portions; the first containing outlines of the conditions influencing the distribution of plants, of the climate and physical aspect of Britain, and of the topographical and geographical distribution of British plants. The second part is devoted to the particular distribution of species, arranged according to the natural system. In this the range of each species, both in Britain and abroad, is given, under its proper heads of habitat, topography, and geography. Under topography, Britain is divided into six districts: the first four including respectively the south-eastern, south-western; north-eastern, and north-western counties of England; the fifth and sixth the southern and northern counties of Scotland. Then follows a reference to the various local floras in which the species was recorded, and then the counties in which it was reported to grow. Indications of supposed introductions are given; and under the head of geography, the extra-British distribution of the species is traced.

In 1833 Mr. Winch's "Contributions to the Flora of Cumberland," which had appeared a few years before in the "Newcastle Magazine," was "republished with numerous additional habitats of scarce plants in consequence of the appearance of" Mr. Watson's work. This contains a critical examination of the claims of certain plants to be admitted to the flora which had been recorded on the authority of Hutton, a Lake guide; and justifies the rejection of many which had appeared in the "Botanist's Guide." A list on the Linnæan system, with localities, follows, in which the Mosses, Lichens, and Fungi are included. In 1837, a similar catalogue of addenda to the flora of Northumberland and Durham was published by the same author, apparently in the Transactions of the Newcastle Literary and Philosophical Society, from which it was subsequently reprinted. *James Britten, F.L.S.*

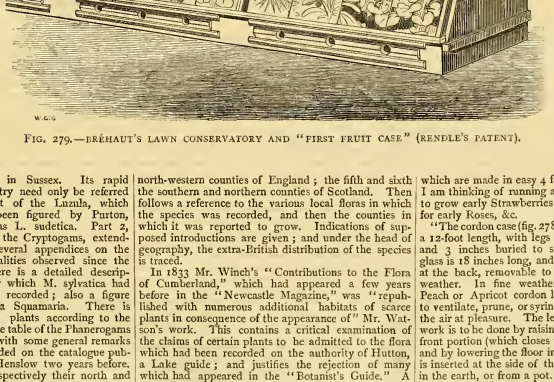

FIG. 279.—BRÉHAUT'S LAWN CONSERVATORY AND "FIRST FRUIT CASE" (RENDLE'S PATENT).

BRÉHAUT'S "LAWN CONSERVATORY" AND "CORDON CASE."

AT the Nottingham Exhibition of the Royal Horticultural Society Mr. Rendle, the patentee of the admirable inventions above named, exhibited examples to which we directed attention at the time, as being a decided step in advance of anything in their way which has been introduced to the notice of the public. We are now enabled to furnish the annexed illustrations (figs. 278, 279), and to add a full description from the pen of the inventor, the Rev. Th. C. Bréhaut:—

"The Lawn Conservatory and First Fruit Case (fig. 279) partly represents a 12-foot length, 3 feet 6 inches wide at the base, and about the same in height. The glass removes at pleasure, and so does the whole of the front and side shutters, and also lower down to water, shift pots, &c.,—in fact, every part is movable. This gives immense ventilation, and ventilating slides for winter are provided. The case stands on a single row of bricks, so that the flowers may all be readily seen when the case is used as a conservatory, the back flower-pots being raised at pleasure. On a lawn the effect is very good.

I have since added iron spikes along the ridge for a stout curtain to be drawn over the glass in stormy or cold weather. I have a 20-foot length 6 in. higher, and the same wider than the 12-foot here shown. But the smaller size is handier to transport, which, by sliding out the glass, it is easy to do. Thus we carried one and placed it over a Vine which had been trained on a wall, and at present it has this Vine running under the top, with Zonal Pelargoniums filling the floor beneath, both doing perfectly. Next winter and spring I intend filling this floor with Strawberries in pots, and replacing these, when ripe, with Roses or show Pelargoniums, which succeeded wonderfully in them this spring, being the finest in the island. This is using the case as a "first fruit" (Mr. Rivers gave the name) propagator; indeed, any early vegetables would thrive in it. If made cheaply, this is one important use it is destined for, being a miniature plant and fruit house, with glass placed to admit the direct morning and mid-day sun rays and ventilation at command.

"The leading idea of this case is that no shifting or lifting of glass lights occurs in it, the whole of the work being done by removing the back and side shutters, which are made in easy 4 feet lengths for this purpose. I am thinking of running a flue under my large cases, to grow early Strawberries for the markets, or to use for early Roses, &c.

"The cordon case (fig. 278) also illustrates a portion of a 12-foot length, with legs of 10 inches above the soil, and 3 inches buried to steady the case. The front glass is 18 inches long, and there is a half hip of wood at the back, removable to ventilate and prune in bad weather. In fine weather, the floor on which the Peach or Apricot cordon lies, is lowered to the earth to ventilate, prune, or syringe, and expose the cordon to the air at pleasure. The leading idea is, that the whole work is to be done by raising this floor to the level of the front portion (which closes up the case) in bad weather, and by lowering the floor as the cordon grows. The cordon is inserted at the side of the case, and may be planted in the earth, or from a pot. Vines are well suited for this case, which is also approved of by Mr. Rivers, and, being very portable and cheap, might be used for many other purposes, such as Strawberries or bedding plants."

The many uses to which cases of this character can be put, will no doubt commend those which Mr. Bréhaut has invented, to the favourable notice of cultivators generally.

Home Correspondence.

Philodendron crinipes.—The Philodendron we have here, under the name of P. crinipes, is at the present time in bloom. Is it an unusual occurrence? I attribute its blooming to the fact that the stem was severed just above the soil last winter, its only means of sustenance being by means of the air roots, the which are quite at home among the Lycopodium growing on the wall. *William Lees, The Gardens, Penrhos, Holyhead, September* 16.

The Potato Disease.—I have read with the greatest pleasure the article by "H." in your impression of the 9th inst., giving a synopsis of the papers of Dr. Kühn and Herr von Schultzenstein. When the disease appeared this year, I was profoundly ignorant of the whole subject, and I could not hear of any careful scientific researches on it, which, moreover, my friend Dr. J. H. Gilbert explained to me, had been discouraged by the clergy in the days of the Potato famine, on the ground that the disease was a scourge sent by God, and that to attempt its cure was impiously to oppose the designs of the Almighty. I was therefore thrown on my own resources, and having about 30 acres of Potatos, growing in different kinds of soil, and under very varied conditions, I had ample opportunities for making observations. I first of all asked all my workpeople what they knew, observed, and believed about the disease. From them I heard of course a vast number of surprising theories, but I found that they were all agreed—though coming from different parts of the country—on one point, viz., that it began in the haulm. Here, then, was a first point, susceptible of comparatively easy proof or disproof. Accordingly I made a number of observations, and found that the haulm was visibly affected long before the tubers were. I then collected some affected leaves, and found that when powerfully magnified, they revealed the existence of a Fungus growth beyond any possibility of mistake. I then traced the gradual extension of this growth, accompanied by a more or less active decomposition downwards through the stem of the haulm to the tubers; and I observed this so frequently, as to leave no doubt in my mind as to the course of the disease. So it happens that I have devoted a good deal of time to the study of the origin and spread of infectious diseases in the human subject, and among domestic animals; and, although the origin of disease is generally so obscure as to defy observation, yet the means by which contagia are spread are susceptible of close observation and direct experiment. The result has been to make me a thorough believer in the "germ theory" of disease. It is true that no one has ever actually seen the "germs" of any contagion in animals, even through the most powerful microscope, and I was taunted with this at the recent meeting of the British Association, but many things can be proved to have a material existence, which have yet never been actually seen. No one ever saw the wind, pigs excepted (if I may be allowed an Irishism), yet houses have been blown down by the material effect of this invisible agent. If, therefore, we proceed upon the "germ theory," to treat the disease chemically, instead of the patient medically; and if we succeed, as an invariable, or almost invariable result, in killing the disease, instead of the patient, the actual material existence of the "germs" is, to the impartial mind, proved just as conclusively as if they had been seen through a microscope. This is the *rationale* of what is called the "antiseptic treatment." "Curing," "pickling," "salting," "smoking," are all antiseptic processes, and nothing else. They succeed because they are all destructive of low forms of life, whether vegetable or animal, while they are not entirely successful, it is because the antiseptic agents have been applied diluted with water in the case of salts, with air in the case of smoke, or because sufficient means have not been taken to ensure the penetration of the antiseptic agent throughout the entire mass to be acted on. To act directly upon the particular disease-growth by an inorganic chemical agent, whose action we understand and can control, with the object and certainty of producing a definite result, is assuredly much more scientific and much more hopeful than to attempt to act upon it indirectly by administering to the subject attacked some empirical nostrum, sometimes organic, sometimes inorganic, sometimes a thoroughly unscientific "mixture" of both, whose action no human being pretends to understand. Accordingly the "germ theory" is much the most hopeful theory of contagia, and it is not surprising that it gains fresh adherents every year among the most scientific of our medical men, as the best explanation of the spread of contagia even where no germ can be detected by the microscope. In the case of Potato disease certain germs invariably accompany, and, according to my observation, which appears to coincide with that of Dr. Kühn and others, precede the development of the disease in the tubers. At all events on this point I prefer the evidence of my own observations to what appear to be only assertions, and unsupported ones, of Herr von Schultzenstein. Therefore I came to the conclusion (and see no reason to change my opinion), that it is in the direction of antiseptic treatment that we must look for a cure of Potato disease. But coming to this conclusion does not, unfortunately, advance us very far, for to apply antiseptic treatment to a parasitical disease in a growing plant, the valuable part of which is below ground, is obviously a problem of maximum difficulty, which is still further enhanced by the necessity of avoiding all agents which would communicate a disagreeable flavour. For some time I could not see my way through the difficulties of the case at all, and should much have preferred not writing on the subject until my experiments were much further advanced. But if they are successful this would be like locking the stable door after the steed is stolen; therefore as the disease will not wait, I think it my duty to give publicity to my views without further delay. It appeared to me at first that it would be hopeless to make any attempt to treat the Potatos before they are taken up, because I was informed, on reliable authority, that even if the haulm were cut off the disease would not be stopped; and it is at least evident that if this were done when the tubers were quite immature, the cure would be as bad as the disease, and the same argument applies to any very powerful antiseptic treatment. I therefore directed my attention to endeavouring to prevent the spread of the disease among the tubers after they are lifted. For some time I could not see my way to any process which would not give them a disagreeable flavour, but at last I thought of fumigating them with sulphur, and was delighted to find that, as I anticipated, this gave them no taste whatever. This is a great point gained, for I have difficulty in believing that the germs of the disease can resist the searching and penetrating action of sulphur fumes. In my experiments the Potatos were shut up in a tin-lined box for two hours, being supported near the top of the box on a grating, and the sulphur being thrown on hot charcoal at the bottom of the box and the lid immediately shut down. It does not appear that this process is very easily and cheaply be applied on a large scale to Potatos piled up in any small building on an artificial floor 3 or 4 feet from the bottom, composed of wire netting, with suitable supports. A number of little heaps of charcoal (or cinders) should be made, a small measure of powdered sulphur hastily heaped on each, and then the operator should escape precipitately, and fasten up the door. This operation might be repeated several times. Unfortunately I cannot yet say whether the process would really be effectual, but so far as my experiments have gone, it would appear to be so. But I would recommend under this head the cautions should be taken in storing the Potatos. The earth in which they are "clamped" should be as dry as possible, and it should be mixed with them as well as thrown over them, so that they may be as much as possible separated, in language, "isolated" from one another, and a little powdered sulphur might usefully be dusted in between the layers. Another experiment that I am about to try with some late Potatos is, when the tubers are approaching full growth, to cut off the haulm, and throw a handful of chloride of sodium (common salt) on the side of each stem (chloralum), upon the bleeding stem. I propose to try this on about 4 acres, in alternate rows, leaving other rows untreated. I venture to think that, in the above remarks, I have indicated the only direction in which a cure for Potato disease may be looked for; and although I cannot yet fully fail, I have every reason to work who have more time for experimental research than I have, and some good may result, in which case my object will have been gained. *W. Hope, Parsloes, Sept.* 19.

Slugs.—The account of the Potato disease in the *Gardeners' Chronicle* of September 9 was very interesting, as giving the opinions of two learned men, who have made it a particular study; but it is singular that they should have arrived at exactly opposite conclusions. My object in writing now is to support the opinion of Herr von Schultzenstein, whose theory of the disease is, I believe, correct. Dr. Julius Kühn states that the cause of the blight is a parasitical Fungus (Peronospora infestans), whose spawn penetrates the substance of the tubers, and communicates the disease from tuber to tuber. Herr von Schultzenstein, on the other hand, takes a different view, and states the cause to be a withering or dying off of the cellular tissue and the vessels with their contents, and that it is only along with the chemical decomposition of the decayed parts that the Fungus makes its appearance at a later stage of the decay. Now this, I believe, from close observation, to be the correct theory of the disease. It is very rare indeed, if ever, that Fungus upon any healthy living vegetable substance is the aggressor. It always follows upon any diseased or suppressed action in the cellular tissue, occasioned by sudden atmospheric changes, drought, excess of moisture, or peculiarity of soil. There are no circumstances under which the Potato disease has not occurred, and therefore the difficulty of finding a remedy is proportionately great. In fact, no specific, I think, will ever be found, as the disease is inherent, and discovers itself at a certain stage of growth, whether the Potatos are planted early or late. The disease may perhaps be the result of over cultivation, and it is in the nature of many plants as well as animals to become in the course of time degenerate and even extinct. It way be a wise ordination of Providence to prevent the human race depending almost wholly upon a vegetable not adapted to their constitution as primary food. However this may be, it is a fact that a disease has appeared in Potatos which admits of no remedy; and as long as such an enormous quantity is cultivated, a proportionate quantity will necessarily be diseased. Therefore the only alternative that offers is materially to lessen the cultivation, and, if necessary, look out for a substitute. There may then be a chance of the Potato assuming its former healthy condition. *W. H. Rogers, Red Lodge Nursery, Southampton.*

Parsons' Mignonette.—I will not encroach further on your space than to observe, in reply to the adverse criticism respecting "Parson's new white Mignonette," that it will be again exhibited at the spring flower shows, where many persons will have an opportunity of judging for themselves. Either the variety is distinct or not, and we have the authority, in the form of First-class Certificates of four different bodies of metropolitan judges, in our favour. *H. Hemsley, Manapler, Nurseries, Hassock's Gate.* [We have several letters favourable and several adverse to this new Mignonette. Our readers must draw their own inferences. We have seen it good in places. EDS.]

Torch Pruning.—In connection with the subject of torch pruning let me offer some further instances in which it will be found the only means applicable for controlling the rampant boughs of trees injurious to more valuable neighbours. As this method of working is new to most readers, it may be allowable to repeat that nothing more is required by way of instruments than a long light rod of Bamboo cane or the like, which when held in the hand will reach to a height of 30 feet. To its end should be tied firmly two or three wires, each as thick as strong whipcord, and about 18 inches long. Let these be spliced to the rod, then twisted together, so as to make a metallic termination for retaining the torch, which may be secured to the hand the rod. The torch itself is merely a bunch of linen or cotton rags, dipped in oil, and set on fire when used. Such an implement as this will be found very useful indeed to the many country gentlemen who attend personally to the details of the thinning of their own plantations, and who, at this charming season of early autumn, take especial delight in going into the woodlands, armed with knife and hatchet, to mark the trees which, after the fall of leaf, must fall under the axe. There is no time than the present for this important preparatory work of decision on the owner's part, accompanied by his faithful woodman, and perhaps by some experienced friend, well-known for skilful management of his own sylvan property. In the North of England, as throughout Scotland, such a task is occupying a bright autumnal morning or afternoon is very common; and it is full of interest from the ceaseless exercise of judgment which it requires, and the brilliance of the tints of foliage. Yet in mixed plantations, consisting mainly of hardwood trees such as Oak, Ash, Birch, Sycamore, and Wych Elm, we are continually forced to condemn a beautiful Ash, or Elm, not because it stands absolutely too near to an Oak, but because it is unluckily on the windward, that is, the westward, side of one; and consequently, the leeward branches of the Ash (which in our stormy, northern climate are always the longest) are continually encroaching on the neighbouring Oak to his detriment. "Then why not send a lad aloft with a saw to cut off these leeward limbs?" All very good if we had but a few such cases to deal with, but what if we have hundreds? Nothing, in truth, is more perplexing and more discouraging than to stand surrounded by such difficulties, and yet to have no remedy save a too free and prodigal resort to the felling-axe, thereby causing a premature fall of trees which we are conscious ought to have been spared for some time longer, if any less violent remedy could have been applied. It is impossible to exclude Ash from our plantations. Nature has given them an extensive and valuable habitat of Oak. The Wych Elm, again, cannot be shut out by any inexorable rule. It is most valuable to the planter for numberless moist and springy spots on hill sides, and in succulent bottoms of denes, gills, and ravines, affording also timber in continual demand; nor is there any northern tree more beautiful and thoroughly characteristic. But wherever it stands within arm's-length of an Oak, it must be controlled with fire and sword; in other words, with torch, axe, and saw. Now, if we are prepared to make a timely use of flame to scorch the extremities of offending side-branches of Ash and Elm whilst the foliage is upon them, we may often postpone the felling of the trees themselves for some time. Nor will they be sensibly disfigured by the operation. The balance and symmetry will generally be improved by such curtailment of long leeward branches of the Ash, or rampant extremities of Elm, which are prone to wander in various directions, to leeward or otherwise. That so simple an agent as the torch has not been before advocated and largely called into activity in the interior of hardwood plantations, is certainly owing merely to the fact that it is only applicable during the summer half year; whereas plantations are thinned mostly during the wintry months, while the trees are naked. Nothing can be done in winter except with knife, axe, and saw, hence the torch was never thought of. Next to the Ash and the Wych Elm, the Birch is the most likely tree to need being curbed by flame, and this because in stormy

climates, where westerly gales are very prevalent, it is prone to lose its balance and incline very much to the eastward, at the same time obtaining a greater stature than its neighbours, and so overhanging them. When this happens, the leeward spray of its head may be very properly curtailed by the lambent flame. In the secluded interior of a plantation, no eyesore will be produced by the pretty free application of the tool, wherever it is really needed. These remarks are all chiefly made with reference to the North of England and to Scotland. Our northern woodcraft has to contend with difficulties unknown in the south; and I trust this consideration may explain the length of the explanations which the novelty of the torch in forestry has suggested. *R. Carr Ellison.*

Orchid Cultivation.—In my last letter on this subject, which you kindly published at p. 1070, I gave an extract from Professor Dyer's lecture (at p. 771), in which he is reported to have said: "There is no inherent disposition common to all plants to hibernate during the winter." He then goes on to explain that this hibernation, when enforced, is due to the want of one of two conditions needful—either heat or moisture. I need not again give you the whole extract, but I wish to draw your attention to the misprint in my letter where you make him to say, "There is *an* inherent disposition." I gave the quotation that I might hear what your correspondent, "Ex-Cantab," had to say upon this subject, as being so contrary to his theory, that all plants having distinctly formed pseudobulbs require a season of rest (see p. 515); but, as he does not appear to have noticed the quotation, I must draw his attention to it, and beg of him to set upon the Professor to explain away that he takes to be a mask. I am unable to argue out my own views to his satisfaction—in fact, he whips me very hard at times, for my not being equal to him in discussion—so I was on the look out for some bigger and better man to take him in hand, and, if they will only come to wordy blows, I can look on with perfect calmness. "Ex-Cantab," in my mind's eye, as a tall man, accustomed to look down upon most other men, and I am rather short, and used to being looked down upon by those that are taller; but I did think that, after I took so much pains to show him I had answered his questions, he would have explained how it was he arrived at that letter; and, also, that he would have regretted that he had made me say what he could not find in print. He asks me for examples of cultivation, but he forgets that our plants are picked over each year and the best ones only produced on specimen heads, but were only able to retain it with great difficulty. As for the general collection, if it had not been a credit to us he may be quite sure he would have heard of it. Those who know me personally, and they are not a few, give me credit for trying to obtain and convey information upon Orchid cultivation, and for that, as he represents me, only intent upon forcing my own particular crotchets upon Orchid cultivators. I assure him I shall always take a genuine interest in any success he may attain in cultivating Orchids that the cool system suits, and I am as anxious to hear of one which they are. I may also add that I shall joke him, if I can, when he gets unreasonably cross, as I think he is in this last letter, when he says I am, as usual, defending my theory by extracts from a work upon tropical climates. That description was confined to two sites where Orchids were found, and I certainly took the description of the place where O. Alexandræ was found is rather tropical, but that is not my fault; it is the plants that must be excused, for not knowing that they should have been up at Bogota, with 8000 feet of altitude, instead of where they were: We must pass over a little upon their part, as they are first-rate Odontoglossums, and it won't do to offend them. And then there are the citrosmums and grandes, and the little Phalænopsis, and others, but they must speak for themselves, I cannot make excuses for them all. That they grow in New Grenada I can vouch for as to prove they must want the same treatment; for in New Grenada you can bathe in a river with a temperature of 100°, and, when you come out, you may shiver in the shade at 90°, and be obliged to dress in the sun at about 120° to 125°. You may be on the Parana, penetrated with cold by day and night, and be in danger of bursting your thermometers if they won't indicate over 130°. You may be in Bogota, where it is so dry that fires are not used for warmth, though it may freeze any day in the year, and salt is always shaken out of a box of pepper-box; while, at intermediate altitudes, sugar melts because it is so damp, and is a fit home for the most tropical of all tropical vegetation. I must try, I suppose, to maintain that New Grenada plants must all be treated alike, be it the Odontoglossum, that grows at the top of a tall tree that it may be dry, and have plenty of light and air; or the Cypripedium, that likes the shade, and grows in the water that runs at the bottom. Now come, Mr. "Ex-Cantab," is there not room for both of us? You keep us informed of those that your treatment suits, and, if we find some that we can both grow, blow the plants up for being such fickle jades, but don't come down upon me so heavy; I am flesh and blood, and can feel it, if I am only a little man. When Odontoglossums were first imported, our hothouse engineers did not understand the use of pipe-heat as they do now, and we still have this difficulty with evaporating pans fixed on the pipe—should we depend upon them for the moisture required—that, if the pipes are hot enough to evaporate much water, the part of the pipe not covered with the pans is drying the air, and thus undoing what the pans effect; therefore, I am not sure that it was the heat alone that caused the failure. Mr. Anderson tells us that a hot, dry temperature, if long maintained, will be sure to kill them. Does any one know of an Orchid that is a native of such a climate? I think we are prepared with the treatment when they are forthcoming, and it should be reserved till then. If any one is especially anxious to know what my favourite theory is, I am not ashamed to explain it again. In all cases where Orchid cultivation is successful, there must be sufficient means of generating the moisture required without the agency of pipe-heat, and that the plants must live upon the food conveyed to them by precipitation. That I am an enemy to cool treatment is not correct; I have left others to advocate it most certainly, that I might hear what it can do. Every Orchid has its own requirements as to temperature and duration of rest, and the best gardener is he who, by means of heat and moisture, can get the most growth out of his plants during the year without endangering his crop of flowers—that is, having in direct proportion to the strength and maturity of the growth secured. I certainly do not thoroughly differ with your correspondent "M. M.," at p. 1135, in his opinion that it is better to keep the temperature down by shading than by giving air. *G. H.*

The Weather at Aberdeen during July, August, &c.—In a previous number you were kind enough to insert a note on the temperature and rainfall here during the past six months of the present year. You will, perhaps, consider the matter of sufficient interest to give room for a note on the weather from July 1 to the present date (September 18):—

	Mean Temperature.	Difference from Mean of 15 Years.	Rainfall.	Difference from Mean of 15 Years.
	Deg.	Deg.	Inch.	Inch.
July	58.2	+1.0	3.056	+0.771
August	59.2	+2.8	2.598	−0.449
Sept. 1—18 ..	56.2	+2.1	0.493	−1.207

The consequence of the fine weather since the middle of July is that green crops generally in this quarter are in excellent condition, and harvest has come about a fortnight earlier than most people anticipated. I never saw the Turnips looking fresher and healthier; blight has, however, appeared among the Potatos. A month ago I recognised the smell of what I considered the disease, during close, foggy, sunless weather, and however unwilling we may have been to admit it, there was no denying the evidence afforded latterly by the state of the tuber. One or two fields present a melancholy spectacle, but as yet the proportion of diseased tubers does not appear to be very large. *B.*

Bedding Pelargoniums.—A comparison of the opinions of flower gardeners on the merits of bedding Pelargoniums would form a place or position not able at the close of every season, and I was very pleased to see lately "R. F.'s" letter ant ent them. I was still more pleased when I saw that it has brought out that unimpeachable authority in gardening matters, the Rev. C. P. Peach. I endorse all that Mr. Peach says about Violet Hill Gem—splendid habit and colour. To my taste it is not bright enough; it is a dull dead red, and I do not know what it will mix with to make a pretty bed; it will be some time, however, before we are able to try it to any extent; for it is, as Mr. Peach says, a very, very shy grower. As far as I am concerned, and I have tried it pretty well over many years, I have brought the best of Pelargoniums to grow for effect down to a very few—very few in comparison with the vast quantity now grown. I'll tell you what they are. To begin with the brightest of scarlets, I retain Lucius Grosvenor. There is nothing to equal this in brightness of colour, prolificacy of bloom, and dwarfness of habit. The next shade of scarlet is the one which signalises Waltham Nosegay,—not Waltham Seedling mind, for herein, in this matter of naming these two very excellent Pelargoniums, I think Mr. William Paul errs in giving the name of his place to each, as it makes sad confusion in many peoples' minds about them; indeed, I have found gardeners who held that they were one and the same variety, and if you said, "I like Waltham Nosegay," they would answer, "Oh! I have got it," but, they would add, on looking more closely at it, "Yours is a different shade of colour to mine." Well, it is Waltham Nosegay I mean, one of dear old Donald Beaton's seedlings, and it would have rejoiced his heart if he could have seen it; it is dwarf in habit, spreading out well over the ground, profuse in bloom, many trusses, and many pips in a truss continuously opening, so that the flowers rarely look shabby, and bright, tellingly bright in colour, one of the greatest acquisitions to the flower garden ever sent out. Added to its other excellencies, it has a plain leaf without any visible zone in it. I hold (it's perhaps heresy to say so) that a zone in a leaf in a Pelargonium grown for its flowers is a detraction rather than an attraction; the zone seems to bother, disturb the eyes when you are looking at a bed of heavily zoned plants, and thus robs you of that enjoyment that otherwise you ought to have. The next shade of colour, getting to crimson now, is in a seedling of Mr. Pearson's, of the Chilwell Nurseries, called Bayard. We used to grow Waltham Seedling for this shade of colour, but we have now let the seedling "slide," and are growing Bayard, and a still more recent seedling of Mr. Pearson's, which he calls Douglas Pearson. They are both (or so nearly that you cannot detect the difference) alike in colour, a rich scarlet-crimson; Douglas has more zone in the leaf, and so we prefer Bayard to Douglas. Bayard has a very close and low growing habit, is a constant bloomer, and has a sound and vigorous constitution; it is a treasure, and though many of my friends think differently, I really conscientiously believe that Bayard is better in all ways than Douglas Pearson. As a rosy-lilac or the Christine shade of colour, we grow one raised in our neighbourhood, called Cleopatra. It is a sport from that excellent old variety, Trentham Rose: it has the same habit as Trentham Rose, and is as profuse in its blooming. That will be recommendation enough to many people, and the colour is deeper, brighter, and warmer than Christine; it is a charming thing, and the admiration of everybody that has seen it. We have sent it to the Royal Horticultural Society's trial of Pelargoniums, and are anxiously waiting for the judges' report about it. For a white-coloured Pelargonium, we have none found to beat Madame Vaucher, and as a golden-leaved one, nothing with us is better than Golden Chain, or, as I prefer to call it, E. G. Henderson is our best yet; and as tricolors we shall retain Lady Callum and Sophie Dumaresque. As a creamy-leaved variegated Pelargonium we shall keep Flower of Spring until we can get up a stock of Mr. Pearson's Pearl, and then Flower of Spring will have to give way. That is all I can think of at present about Pelargoniums, and as my contribution I send it. *N. H. P.*

Fruit Showing.—The suggestions which I made in your columns last year on the subject of vegetable showing, were carried out so well at Nottingham that I venture again to trouble you on the equally important point of fruit showing. At the exhibition just alluded to, my friend, Mr. Miles, of Wycombe Abbey, certainly exhibited some fine examples of good gardening, and so did Mr. Simpson, of Wortley; but the fruit was scattered over the table so thinly as to make anything but a satisfactory display. In the first place the green baize employed was of the most disreputable description, and a disgrace to the surroundings. For this I would recommend the substitution of white cotton or sheeting, which should be washed every time it is used. To make the fruit show a success, the first thing wanted is more exhibitors, and to get them greater inducements must be held out. I would suggest that we have three classes for fruit, viz., for 8, 6, and 4 dishes respectively, with £2 10s for 8, £1 6s for 6, £1 2s for 4 dishes, to be divided into three prizes. These sums amount to £48, which I would suggest should be subscribed for on the condition that subscribers only are allowed to compete, I am happy to say that I have several promises of support. Subscriptions need not be restricted to gardeners. I should like to see the idea supported by the purses of all or any of our horticultural friends. A new or improved method of showing should form part of the scheme, upon which point discussion should be invited. *R. Gilbert, Burghley.*

Preserving the Fruit of the Mountain Ash.—Put a quantity of the berries into a stewpan, with sufficient cold water to cover them. Boil them to a pulp; strain the juice through a canvas bag. To every quart of juice take 2 lb. of loaf sugar, and when it boils, let it boil for 10 minutes. This will make a beautiful preserve, but no amount of sugar will remove the slightly bitter taste which the fruit possesses. Rowans are a favourite food of fieldfares. Three large trees in this neighbourhood, covered with fruit, were stripped of every berry in a few days by flocks of these birds. *A. H., Dumfries.*

Picea lasiocarpa.—I have just measured my best specimen of Picea lasiocarpa; it is 19 feet 10 inches high, and 15 feet 2 inches through the branches. It is very robust, and full of foliage. This tree was planted where it now grows in the early spring of 1859, and was then about 5 to 18 inches in height. It is a very handsome tree, and well deserves all the praises which have been bestowed on it. I think it was stated some short time ago in the *Gardeners' Chronicle* to have coned in the Knaphill Nursery; my tree this spring was covered with small cones, but it has not yet produced any perfect ones. I received it from Messrs. Veitch & Sons of the Exeter Nursery, under the name of lasiocarpa, and at the same time I also received from the same source two smaller plants under the name of Picea grandis, which have, so far as I can judge, turned out to be the same as lasiocarpa, and I call them all three by that name. Some time after them I purchased a plant as the true Picea grandis of the late Mr. Veitch of Chelsea, and which I have every reason to think is correctly named; but if so, and if the plant your correspondent describes as doing so well in the nursery at Great Berkhamsted (p. 1129) is also the true Picea grandis, it must do very much better at Berkhamsted than it does with me. My specimen is 8 feet high, but it looks very shabby, and now (September 10) is almost as bare of foliage as a deciduous tree in the begin-

ning of winter, just before the last gale of wind that clears it of leaves. I have also noticed the same shabby appearance of this tree in other places, and have been told that it looks much the same in the neighbourhood of Exeter. Grandis, so far as my experience goes, is hardly an appropriate name for it. There was some short time ago some confusion about the names of the Piceas, arising from lasiocarpa and what is now called magnifica being sent out under the names of grandis and amabilis. Whether Mr. Gordon was in any way responsible for this I will not take upon me to say, but that the confusion existed I think no one will deny. The best specimens of the true Picea grandis that I have ever seen were at Elvaston Castle, where there were two specimens growing in one of the Pinetums, both of which I believe are now dead; but Mr. Barron, who was then gardener at Elvaston, and who has now a nursery at Borrowash, near Derby, has, or had a year or two ago, plenty of this tree for sale, raised by cuttings from the two plants I have referred to; but the seed was also reintroduced there were no seedlings of it in the country. It is a fine tree where it does well, but I do not think any great improvement on the common Silver Fir. The true Picea amabilis I have never seen of any size anywhere but at Elvaston, though I believe there is a fine specimen of it at Dropmore. Picea nobilis is well known, and is a very general favourite, and very deservedly so. I suspect Picea magnifica, sent out as I have said as Picea amabilis, but to which it bears no resemblance, will turn out to be only Picea nobilis about which I have seen specimens of it, one of which I believe to be the finest in Europe; it is 16 feet 8 inches high. Another Silver Fir, a great favourite of mine, is bracteata; I have only one specimen of it, but that is very handsome, distinct, and robust. Bracteata is not so general a favourite as it deserves to be, it is well worthy a place in the most select collection of Coniferæ. Nordmanniana and Finsapo I need not allude to, their beauties and merits, great as they are, are fairly appreciated; not so, however, with Picea cephalonica, which is really a very handsome tree, and should be more generally planted, though it "spins" tender when small, frequently starting into growth too early in the season. When it gets older and bigger it acquires, or seems to acquire, as Mr. Weller would say, "wisdom with its width, and has more patience." I have a fine specimen of it here, which is robust and handsome, and which is generally admired. Not long ago a lady, the daughter of the gentleman who first introduced it into England, did me the honour to come and see it; she knew it directly, and had the whole story of its introduction off by heart, and quite correctly, as told by Mr. London in the "Arboretum Britannicum." *C. F. P., The Grange, Kingston, near Taunton.*

The Trial of Boilers.—Respecting Messrs. Weeks' offer to test their boiler against others, I do not consider their first condition, viz., "that the size of the boilers should be determined by their water contents," to be a fair test, as a tubular of the same water capacity as a saddle would be much the larger of the two, and larger than most boilers of any other form than the tubular. I consider in a test that the size of the boiler is not of so much consequence; as, if a competitor were to fix a boiler of disproportionately small a length of pipe (which should be the same for all the boilers tested), he would be the loser in the amount of fuel consumed, which would be greater than it ought in both cases, were the boiler too small or too large—unless he were to sacrifice time in keeping with the smaller boiler, which would that way cause him to be a loser. In system B I should wish to see it clearly stated if there was to be any descent from the lowest part of the boiler to the heating apparatus or pipes, as if not, the condition of a descent of 3½ feet to 4 feet from the end of the boiler to the pipes would be altogether in favour of the conical form of boiler (including Weeks' tubular), as that descent would still allow the lower part of the boiler and the inlet to be at as low a level as any part of the pipes. I should much wish to see the question of the most suitable kind of fuel for boilers discussed in your columns. It appears to me that a boiler with numerous passages or flues, such as Cannell's for one, would lose half its advantages if heated with anything but coal, and that coke or culm would not be any way suitable for it; while the latter kinds of fuel would be the most suitable for the tubular, seeing that in the latter the passages around the tubes and the half of the tube from the fire quickly become coated with soot and rust, and that the tubulars rapidly lose their heating capabilities by becoming so coated: they certainly ought to be cleaned and scraped every season before commencing the winter's work. A fair and impartial trial of boilers, held, say, under the auspices of the Royal Horticultural Society, could not but prove to be most interesting and profitable to the horticultural community. *W. B. Smale, Barton Nursery, Torquay.*

The Belle Beauce Peach.—The early sort seen by Mr. Earley at Chiswick (see p. 1130) could not be this, for it is late rather than early, and ripens ten days after its relative, the Grosse Mignonne. Although the Belle Beauce has been in the French catalogues for many years, it is, and always has been, difficult to get true to name. I have many times received the Grosse Mignonne instead. It is a grand old Peach. There is no Plum called the "Black Diamond," unless in the Borough Market. The Diamond Plum was raised in Kent, at Brenchley, by a man named Diamond; it is terribly acid when cooked, but very large and handsome, and in an orchard-house, when dead ripe, is not to be despised. *T. K.*

Hardy Succulent Plants.—Severe indisposition has prevented me giving the information which your correspondent, Mr. Croucher, at p. 1165, very properly requires, and perhaps my unhappy experience may be of advantage to others of your readers who may be hesitating as to the best method of building their glasshouses. All my little collection, with the exception of two specimens of Opuntia Rafinesquiana, was kept in a small span-roofed house admirably adapted for them, but unfortunately, when I first erected it, I was persuaded that I should save an immense amount of trouble, with an infinitesimal increase of cost, if I heated my boiler heated by gas. Now, this article is charged 5*s.* 6*d.* per 1000 feet, which brings the cost up, according to my calculation, about from three to four times the price of coke; but that was the lesser evil of the case, for not unfrequently every light in my house will suddenly disappear, and during the late severe winter our supply was entirely cut off by, I presume, water getting into the service pipes and there freezing. If succulents generally, and more especially Cactaceæ, are kept entirely dry, say from the end of September until March, they will bear a considerable degree of cold. Of course there are some few exceptions, as Pereskia aculeata; and from what has been reported from Paris, we may also expect that the Epiphyllum truncatum section will not hurt if we can wait until the spring for the bloom instead of looking for them at Christmas. I offer my apology in first troubling you with an account of my miseries was to endeavour to induce amateurs to take an interest in this really beautiful and interesting class of plants, for we may indeed say, with the poet, that they are "things of beauty and joys for ever," easy of culture, and not difficult to keep dry, even with limited time or means. Many can freely and germinate readily, and this is a great advantage if you wish to increase your stock, either for the purposes of exchange or, what is perhaps pleasanter still, to give away to your neighbours, in the hope of introducing a similar taste in them. With respect to the hardy Mammillaria, I am sorry to say I have not been successful in raising any of the seed which I procured; but of Cereus pumilus, said also to be hardy, I cannot speak in too high terms of the beauty of the two plants which I have managed to raise from a shilling packet of seeds. They were procured from a nurseryman in cactus in and from California, and with the additional advantage of being a fine esculent. Any grower having a surplus stock of hardy Mammillarias would confer a very great obligation by forwarding ever so small a plant or cutting to *John E. Daniel, The Terrace, Epsom.*

Blue Apron.—In reply to your correspondent "N. H. P.," the "shalloon" of which the gardeners' "blue" aprons are made, is only to be had from one manufacturer in Scotland that we know of, but we always keep the aprons in stock; so that, as your correspondent suggests, our customers may have them when ordering their seeds or bulbs. We shall be very pleased to supply "N. H. P., or any of your readers, with one or more aprons of blue, at 2*s.* 6*d.* each. *Downie, Laird & Laing, Stansted Park Nursery, Forest Hill.* [Messrs. J. Tremble & Son also write to say that they can supply it. EDS.]

Plants for Seaside Planting.—Residing at Southport, and only protected from the seashore by an embankment of sand, I am desirous of ascertaining what are the most suitable plants for my garden, which consists, as to a greater part, of sand mixed with such soil as can be procured in the neighbourhood, and manure. The plants in the vicinity of the house, where quite protected from storms, thrive admirably, but it is at the north side where the difficulty is felt. To give you an idea of the climate, I may say that where not exposed to the storms Fuchsias and Myrtles grow nicely, and the various kinds of vegetables are procurable with a little care. Unfortunately my flower garden, lawn, &c., is surrounded by raised banks or beds, which are indispensable, and sometimes plants are blown out of the ground, and such things as Pelargonium bloom spikes cut off; therefore anything to furnish mass of leaf and strong growth is my advice will be duly esteemed by *An Old Subscriber.*

Lilies.—We have had many discussions at South Kensington as to the Tiger Lily varieties. I held that Mr. Van Houtte had sent over a flower which he had named splendens, and which had large spots, and was more beautiful than any of the known varieties; but that the tigrinums exhibited as splendens were undistinguishable from Fortunei. At a recent discussion at Reigate, Mr. Crawford proposed bringing over a flower from a bulb he had received from the Continent. This I have carefully compared with all the tigrinums we have in bloom, and again find the much larger spots and more showy flowers. I think the mistake has been in claiming more than these distinctions for splendens. I have just measured a tigrinum with the usual sized spots, which I will therefore call Fortunei. It is grown singly in a Rhododendron bed of deep peat, and had a mulching of very old manure in autumn. Its height is 7 feet; the two lowest branches have each four flowers, and each extend 14½ inches from the main stem; the flowering part of the stem is 2 feet 3 inches in height; the stem is woolly. These dimensions, I need hardly say, are fully double what the old L. tigrinum would have reached under similar treatment. I would therefore suggest that the L. tigrinum varieties now consist of the old Tiger, of comparatively dwarf growth, blooming three weeks the earliest; L. tigrinum Fortunei, and splendens, similar in growth, but the latter having the great advantage of large-spotted and more noble flowers: and that this is practically as yet unknown in this country—that which has been exhibited by myself and others, and received as splendens, being Fortunei; and the beautiful L. tigrinum flore-pleno, which will, I hope and believe, from large bulbs, equal Fortunei in growth. *George F. Wilson, Heatherbank, Weybridge Heath.*

Storing Potatos.—Mr. Bennett's remarks on the storing of Potatos (p. 1194) are worthy the attention of all growers that store them in quantities for keeping well. For the last three years, owing to the dryness of the summer, the disease did not affect the general crop of Potatos to any great extent; but this year it is the reverse, and great care will have to be taken in picking out the affected tubers and storing the sound ones in small quantities. I usually store from 20 to 30 tons of Potatos here every year in narrow ridges, and in December, when the disease sets in, I found charcoal dust more effectual than quicklime in preventing the diseased tubers from affecting the sound ones. In the woods here a great quantity of charcoal dust is found in the places where charcoal has been burned, but this is no doubt the case in other places. Where this charcoal dust cannot be procured, the dust sifted from coal ashes will be found an excellent substitute for answering the same purpose. In trying quicklime for mixing with the heaps of Potatos, I found it hardened on the tubers when it got damp, and was no more useful in drying up the rotten ones than the charcoal dust. The quicklime used here for the purpose was made from the magnesian limestone of the district, and is of a very caustic nature. The ridges of Potatos here are all made on the surface of the ground, and instead of covering them with earth, I use coal ashes and charcoal dust mixed. This covering repels the frost better than earth, and keeps the Potatos drier in the ridges, thus preventing heating. In severe frosts some litter is always at hand to cover the ridges, and is taken off when the weather gets milder. In the spring, however, this litter must be kept from the ridges as much as possible, leaving the ridges and making the Potatos grow; but the best way is to pick them all over, and store them away in dark outhouses or sheds for keeping out the season. *Wm. Tillery.*

Water Weeds.—In reply to the letter of "W. E.," in your columns of September 9, in reference to my former communication, I beg to inform him that the lakes I referred to would not exceed 2 acres in extent; the depth of the lake would average 6 feet, and the deepest part of the other is about 8 feet; so these lakes will bear no comparison to the extensive lake mentioned by "W. E.," but, nevertheless, they abounded with weed. A couple of swans and some ducks were procured, and they lived upon nothing but the weed, and thoroughly exterminated it. Gold fish supplied —being only fed in the winter during severe weather. I think that the number of swans "W. E." states he has got will, in due time, have the desired effect, and perform their work effectually. If from the depth of the water the weed is beyond the reach of the swans, they cannot possibly clear it. If the lake is stocked with fish, it would not be policy to eradicate all the weed, as fish always thrive best where there is an abundant aquatic vegetation; they are much less healthy where the lakes are denuded of water plants. By lowering the water about a few yards from the margin of the lake, and allowing it to dry for some days, great quantities of the weed in the shallow part might be cleared, along with all decayed vegetable matter, which would form good manure when rotted. *Thomas Campbell, 11, Thurza Street, Chorlton Road, Manchester.*

The Premature Bolting of Seedling Plants.—Heat and its constant attendant, aridity, it is that, as we generally surmise, incites young seedling plants to "bolt" prematurely; here is a fact, however, which, to my mind, singularly upsets this theory or preconceived idea: Large breadths of Cabbages, and Purple Sprouting Broccoli in particular, peculiar to extensive market gardening districts, have already this season shown an unwonted tendency to flower prematurely. Now this is not usual with either, particularly with the Purple Sprouting Broccoli. Hence it occurs to me that the fact of its being common this season deserves attention. What influences are at work to produce this effect it is hard to say. We have had a cold, wet, and, consequently, backward spring, unless such an one, in fact, as would be highly likely to be favourable to the development of succulent leaves and kindred growth, and one quite adverse to the promotion of a flowering tendency. Even late-sown Celery plants show an unwonted precocity in this way. Nor do I see how these facts are to be accounted for by the generally accepted aid of vegetable physiology. For not only do I perceive here principles, I might say, in anta-

gonism with our generally accepted notions, but, if we accept this fact as it is forced on our view, we find ourselves opposed to ideas not at all consonant with the views upon which much of our practice is based. Every true gardener "pins to his apron" the belief that there is in Nature something which influences the formation of the abergrowth of plants long before the time arrives for the secret to be unfolded. Take Cucumbers and Melons for instance. Is it not patent to every true gardener that a high moist night temperature will assure the formation of an excess of male blossoms, and these often exclusively in dense clusters? That these are induced by a preternaturally high temperature our practice goes far to prove. Now take the opposite side. Reduce the night temperature, and the chance is that, by keeping it as low as possible, consistent with healthy development, female flowers only, or nearly so, may be produced. These facts, looked at superficially only, would tend to point out that a reduced temperature has been the influencing agency which causes the premature bolting described. I have but stated this much to show in what subtle manners natural causes may act, in a direct and immediate form, upon vegetation. A cool, moist period will exert an undue influence upon any form of tropical vegetation, requiring naturally a maximum temperature for its proper development, even to the forcing of a heavy crop of blossoms exclusively, as witness the dense crop of Gherkins and Cucumbers ridged out in the autumn months, with but little growth in the matter of leaves, stems, &c. Not so is it with plants natives of colder temperatures, as the Broccoli and Cabbages before alluded to. These grow vigorously, comparatively speaking, during cold weather—the long, cool nights of early autumn, for instance, when swathed in heavy dews. In such a season as the cool moist period experienced during April and May of the past spring, such plants may be said to have had the most felicitous conditions for growing. With all these such circumstances into consideration, the question arises how did they progress in growth as they habitually do under the conditions described, in which no repose could exist for them, and an excessive leafy or succulent growth alone seemed possible, and yet "bolt" immediately, without any inducement to do so, such as the more tropical plants above alluded to possessed. I think I have said sufficient to show how deeply I pin my faith on the fact that cool nights are to all intents and purposes suited to the wants of all vegetation whose primary aim is early productiveness apart from strong succulent growths. Since writing the above, I have seen, near East Ham—a place renowned for its market gardens—a field of Carrots, which I had taken to be planted for seed, so dense was the forest of huge flower-heads some 4 feet high. My surprise was greatly heightened on being told that no manure subsequently commencing at one end to take up the crop, and on learning that the plants coming into flower were only "rogues;" thus to some extent confirming my previous observations. Still, the point which I cannot settle in my mind, is as to the reason why such plants as young sprouting Broccoli show this remarkable tendency, whilst all around the most suitable conditions to a further growth-development abundantly exist.

William Earley, Valentines, Ilford.

Foreign Correspondence.

OUTSIDE PARIS IN 1871.—"And now, M. Rivière, I place myself under your direction. I want to see something of the desolation that has taken place, not merely generally, but especially to horticulturists." Such were my smiling orders, as on the morning after my arrival in Paris we came out from the Hôtel du Louvre. I had of course early sought the able and intelligent *jardinier en chef* of the Luxembourg; for it is known to the readers of the *Gardeners' Chronicle* that, when the French Horticultural Relief Fund was started, a committee was also formed for the Société Centrale d'Horticulture, of which M. Rivière was named president. I had had a good deal of correspondence with him, and found him what I had imagined from his letters,—most courteous, ready to give every information in his power, and not at all to trouble that he thought was necessary; and, as I knew he had been deeply interested in all that concerns the losses that had been experienced, I felt that I could have no better guide in the explorations I wished to make.

On passing on the Rive Gauche through the parts that suffered marvellously little from the bombardment, it having been almost entirely encased), you at once see before you the scenes of some of the most desolating periods of the whole siege. How often, during the two months of the Commune, were we reading about Neuilly, Point de Jour, Passy, Auteuil, Ternes, the Porte Maillot, &c. It was on this side that the struggle took place, the Germans held the north forts, and so that part of Paris was quiet; but all along, from Charenton to those places which lay directly between Mont Valerien and the city, the fighting raged; and if any one wishes to see what the desolations of war are, what the progress of the science of destruction can effect, they can have no better idea of it than that which is afforded by these well known places. The destruction occasioned by the shells is of course much greater than that by cannon balls. Here for instance, in the Avenue de Kreil, is, or was, a house, No. 50. It was evidently a villa residence, with its well tended garden attached to it; there is literally not a stone of the house left standing, not a tree in the garden that has not been cut down by shells, not a portion of the ground on which you cannot pick up balls of all kinds and large pieces of shells; and as you walk round it you wonder what must have been the feelings of the owners when they returned and found it thus. And this is but a sample of many others. Here, for instance, is a small street; on one side the houses are nearly all down; on the other the walls are pitted, as if pock-marked, with balls,—the fact being that the insurgents held the houses on one side, the Versailles troops the other. The slaughter that took place no one knows, or ever will know. As you drive down the Avenue de l'Impératrice (now, with that babyish propensity which characterised the movement of September 4, changed to the "Avenue du Général Uhrich"), you see what was last year the prettiest of all the outlets for the Champs Elysées (in fact, the Rotten Row of Paris), a complete scene of desolation,—houses knocked about, gardens torn up and destroyed, lamp-posts broken, trees snapped across or cut down. On all from here to the Bois de Boulogne, and you at first ask, Where is it? All that portion which was immediately close to the *enceinte* was cut down at the commencement of the first siege; the inner portion round by the lake, &c., has been preserved, but it will take years before it ever it can be as it once was. The scene of desolation at the Porte Maillot passes all belief; there is not an atom of it left, and the same may be said of the station at Auteuil, while all along the route that we took you saw the baneful results of a civil war, in which the leaders on one side marched under the banner of "Liberté, Egalité, Fraternité."

In writing of the losses of horticulturists I do not think I shall be violating any sense of propriety if, in order to make the case more plain, I mention the names of some of those whose places I saw; the owners made no secret of it, and I am sure it is the best way of making an appeal for them (some at least do not need it), it will, I think, be better so to do. Most of us who have to do with gardens know well the name of Lierval, the raiser of the many fine varieties of Phloxes which have come over to us for many years. I remember a most interesting day going to see him, with Mr. Standish, at Ternes, where he was then living; besides his Phloxes he was growing Cannas extensively, and getting up an extensive collection of stove and greenhouse plants: his place was poor and mean, but he was evidently doing well, and was proud to show it to us and contented with this poor external appearance until he could do better. Well, some five or six years ago he left his old quarters, built a new house at the Rue de Villiers aux Ternes, not far from his former residence. Here he had expended the whole of his savings of many years, had built a very handsome range of iron houses, besides several wooden ones, had accumulated a large collection of stove and greenhouse plants, Palms, Ferns, &c. When the siege begun he was left alone with his boy, of about 14 years of age. As it dragged on, fuel became scarce, diseases ran rife, and by now, until small-pox carried off poor Lierval early in December, a man of feeble frame, worn out with present anxiety, and full of gloomy forebodings for the future, with insufficient nourishment (although at that date famine had not begun to press so heavily on the inhabitants), he succumbed under the combined effects to that fearful malady? The report has been spread that he died of starvation. Sad as his end was, I am thankful to say it was not from absolute want; doubtless the insufficient nourishment had something to say to it, but anxiety and disease, coming on a weakly frame, did their work. After his death his son-in-law endeavoured to do his best, but fuel became more and more scarce, the large plants were removed into the dwelling-house, some placed in cellars, but all to no purpose: a winter more severe than any experienced in Paris for many years, and such a winter as could not be unable; and now you may go into this butely admirably arranged nursery, and find the tall rank weeds—the more rank from the care bestowed on the garden—now forming a tangled wilderness, through which you have to brush your way to get to the houses. Through the windows you see thousands and thousands of pots—not absolutely empty, but with the skeletons of the plants they once held, telling their woful tale; and of all the fine collection of plants, but one solitary specimen of Chamærops remained. After this it were vain to count the shells from one to Valerien fell thickly about—some smashed the houses; and one can readily believe, that had the poor old man lived on, he would have died of a broken heart. We sometimes feel vexed when, through our own carelessness, or that of our gardener, a plant or two is lost; but imagine what this must be to see your whole collection succumbing to frost, and no possibility of saving it—to go out to your houses, and find a scene of desolation where all was lately beauty,—and can you conceive anything of loss more distressing than this. Madame Lierval is left with two children, with hardly any means of living. The collection of Phloxes is safe, and I hope that many amateurs will this year endeavour to give the widow a helping hand, by ordering sets of the new ones. If any are so disposed, I shall only be too happy to receive their orders, and transmit them. Probably there will be some compensation by the Government by-and-by, but it will be difficult to obtain, and tardy in payment; and in the meantime we must try to do something to alleviate the present distress. "Never," said his son-in-law, "shall I forget the sensation of joy we experienced when we heard the Versailles troops coming up the avenue at the double; for then we knew that the worst was over." Such is but one picture out of many that might be drawn. Messrs. Thibaut & Keteleer, with a far more valuable and extensive collection, have seen it all perish. And such is war. No wonder that those who know it speak, as our own great Duke and Sir C. Napier, hated it. Would that France herself might learn to hate it, and instead of dreaming of a vengeance that can never be realised, would quietly submit to circumstances, and endeavour to utilise her vast resources for the common good. I hasten useless to detail the scenes of desolation at the other villages which I have named; it was a harrowing scene, and made one feel more than ever that no enlightenment, civilisation, or learning are of avail against the natural evil of the human breast.

M. Rivière had kindly volunteered to go with me to Bourg la Reine, but news that I received of the increased illness of a beloved relative hurried me home; however, I was determined not to miss my visit, and as early rising is a habit with me, I started off for the railway at 6, and got down to Bourg la Reine at 7, got my cup of coffee, and then found out some of my old friends. What Rose grower does not know the name of honest old Margottin, the raiser of Jules Margottin?—and most fruit growers know Jamain, formerly a partner with Durand, and, I may add in passing, the raiser of the Strawberry, Vicomtesse Héricart de Thury, which of late has taken a prominent position with Strawberry growers. [For many years one of the best varieties grown at Chiswick. EDS.] Let me then say how I found my friends. Bourg la Reine was early occupied by the Germans, and many of the inhabitants left their houses, among them the Margottins; their house was occupied by Bavarians, and such havoc as they made—uselessly, wantonly made! The garden had had deep trenches cut through it; the walls had been broken down for the passage of guns and cavalry; embrasures and loopholes had been made in many; and now, poor old Margottin, one used to see large quarters of standard Roses and beds of seedlings, were to be seen only beds of Cabbages, Haricot Beans, and suchlike produce. Well, this may have all been necessary in a military point of view, and war respects nothing, but the desolation in the house was abominable; doors, wooden chimney-pieces, cupboards, and even staircases, were torn to pieces to burn, filth allowed to accumulate, handsome mirrors dashed to pieces, clocks pocketed, and packed off to Germany (it is said that they looted 1,000,000 clocks in France, which they packed up in chests of drawers and any available thing, and sent off); and all this, as Margottin solemnly affirmed to me, notwithstanding that when he came back he found that there was still a pile of 200 faggots left in the garden untouched. What wonder that my old friend was indignant—that, amongst his losses, he should talk loudly of vengeance, and threaten himself to march against them. His collection of Azaleas, Camellias, and other plants, was also gone; and now, instead of retiring, as he talked of doing, he goes to work again. By-the-by, his intelligent son-in-law Jules has lately married, and has taken a nursery for himself, where he has a very nice collection of plants and Roses, which have happily been untouched by the Germans. A prettier lot of standards I have rarely seen. "But," said my friend, "we have not suffered so much as poor Jamain." Well, I thought, his must be bad enough if it be worse than this. It was only last year that he, honest fellow, went with me and showed me over his new house and garden—his model garden, where he had been for years arranging his collection of Pears; and I well remember the pride with which he took out to me his fine specimens of trained trees. Alas! the Germans made short work of all of them. They cut down the Pear trees, and tore up the stout iron trellises on which they were trained, for the purpose of making fascines and gabions; they cut deep trenches backed down by the walls; the larger garden, too, they had committed a like damage; and here it was that he had tried, and successfully tried, to reunite his Pear trees when they had been cut nearly in halves by the German adzes; and many of them seemed to be doing well. After the peace of Frankfort poor Jamain thought he might return to set his *penates* in order; but then came the Commune, and his house stood directly in front of one of the insurgent batteries at La Haute Bruyère—the Government troops having now taken the place of the Germans in the neighbourhood of Bourg la Reine; and so down came the shot and shell, to complete that which the Germans had begun. And completed indeed it was. And yet withal, there was a calm and quiet dignity in the way in which my poor friend spoke of his losses that no one that knew him would be surprised at, but which is very different from the excited manner in which many speak of the devastation occasioned by the war. None of those persons of whom I have written are what is called in Ireland "little men" (had poor Lierval lived he might have repaired his losses in time), but these are samples of the destruction that has been made; and if scrious to them, what must it be to the host of small nurserymen who live about

Vitry, Villejuif, and the neighbourhood? I hope shortly to give some statistics as to the aggregate losses sustained; and, in the meantime, let me assure those brothers of the spade, amateur or practical, who have contributed to the Relief Fund, that, small although the aggregate amount is, it has called forth an expression of gratitude on account of the sympathy shown, which ought to tend to bind more closely together the horticulturists of both countries. *D., Dead.*

Societies.

ROYAL HORTICULTURAL: *September* 20.—W. Marshall, Esq., in the chair. The usual preliminary business being concluded, the Rev. M. J. Berkeley stated that since commenting upon the specimens of Trifolium cœruleum, recently introduced by Messrs. Carter & Co., he had seen the plant growing at Chesterfield, and had been asked whether it was a Trifolium at all. An examination had confirmed the surmise that it was not a Trifolium, but the Trigonella cœrulea of De Candolle's "Prodromus," which name it ought now to bear. The plant is common enough in Southern Europe, and generally grown as Melilotus cœruleus. EDS.] After alluding to a case of monstrosity in a double-flowered Pelargonium, Mr. Berkeley remarked that at the next meeting prizes were offered for Fungi, which included a series for a collection of poisonous and edible Fungi to be shown in separate groups; for a collection of edible Fungi only; and for six cultivated edible Fungi, distinct. He (Mr. Berkeley) would also call occasional attention to anything likely to make on the Potato disease, and would show that the Potato mould produced resting spores, which come forth again in the following year.

Floral Committee.—W. Marshall, Esq., the newly appointed Chairman, took his seat for the first time. In opening the committee it is desirous of paying its deep regret at the loss it has recently sustained by the death of its much-esteemed Chairman, the late Rev. Joshua Dix, whose genial and kindly disposition and universal courtesy attached each member personally to himself, and whose business-like habits, in conjunction with his knowledge and love of floriculture, pre-eminently fitted him for the post he filled. Moreover, devoting as he did a part of his time, energies, and purse to the untiring zeal to the advancement of floriculture, and to the maintenance of the usefulness, popularity, and honourable position of the Royal Horticultural Society, his loss will long be felt and deplored, not only by the committee over which he so ably presided, but by all connected with the institution."

This resolution was unanimously assented to without being put from the chair. It was further ordered to be recorded on the minutes of the meeting, and it was agreed that a copy should be at once sent to Mrs. Dix. Subsequently an informal meeting was held, at which it was resolved to open a subscription to provide a portrait of the late Chairman of the Floral Committee, to hang in the Council-room, in company with those of Mr. Rivers and of the late Dr. Lindley and James Veitch.

The meeting though fairly good was not one for the season, was productive of no very decided novelties, neither did the prizes offered for Begonias, Pentstemons, Celosias, Stocks, and Helichrysums, bring forth any competition. Mr. Rollison was the only exhibitor of Begonias distinct, in pots, and these were deservedly awarded the 1st prize. Double Zinnias were fairly represented by Mr. G. Wheeler, Warminster; Mr. T. Bray, gr. to E. A. Sandford, Esq., Newchapel Court, Wellington; and Mr. Porter, gr. to Mrs. Benham, Sion Lodge, Isleworth, who took the awards in the order named. The last named was also the only exhibitor of 12 distinct Pentstemons, taking the 1st prize for them. Mr. S. Thorn, gr. to E. Buckingham, Esq., Hampstead, had a 2d prize for three very ordinary feathered Celosias. First-class Certificates were awarded to Mr. Green, gr. to W. Sowerby, Esq., for a new silvery-leaved Bromeliaceous plant, named Hechtia argentea; to Messrs. Veitch & Sons for Vriesia brachystachys, another handsome member of the same natural order, and for Begonia roundula; to Mr. Turner, gr. to Lord Londesborough, for Pescatorea Wallisii, an interesting Orchid, which will be found fully described by Prof. Reichenbach at p. 370 of our volume for 1869; to Mr. Knight, Floral Nursery, Hailsham, for a fine new climbing perpetual Rose, pinkish blush, named Princess Louise, a nice-shaped flower and a vigorous grower; to Mr. Parker, Maiden's Green, for Dahlia Admiral, a showy Fancy of a creamy white colour, striped with purplish-crimson; to Mr. Turner, for Dahlias Mrs. Waite, Mephistopheles, Yellow Standard and Livonia; and to Mr. Eckford, gr. to the Earl of Radnor, Coleshill, for Verbenas Lady Gertrude, Mauve Queen, and Lady Braybrooke; Certificates of the 2d class were voted to Mr. Turner for Dahlias Ranunculus, Master M'Grath, and Bucks Lass; to Mr. G. Rawlings, Romford, for Dahlias Mrs. Bennett, lilac-rose, a large flower, and Golden Beauty, a fine yellow but rather flat; and to Mr. G. Parker, for Dahlia John Batten, deep maroon. Mr. William Paul sent eight fine boxes of cut Roses, and received a Special Certificate. The same award was also made to Messrs. Veitch & Sons for a nice group of Orchids, Agaves, &c.; and for a well-grown specimen of Lasiandra macrantha floribunda, which was just coming into flower; and to Mr. Denning, gr. to Lord Londesborough, for a choice group of Orchids, which included nice specimens of Dendrobium chrysanthum, Vanda cœrulea, Oncidium macranthum, Epidendrum dichromum amabile, Miltonia candida, &c. An extra prize was also awarded to this collection. Messrs. Carter & Co. exhibited a showy new dwarf Capsicum from Brescia, which was bedded out last year in the public gardens in Milan, where, on account of its very dwarf habit and free bearing capabilities, it is said to have attracted much attention. Messrs. Cripps & Son sent two new Begonias, and examples of Impatiens macrocarpa, Tippia, and Lasiandra elegans in good form, but the specimens were too small to form a correct judgment. From Messrs. Osborn & Son came cut flowers of several forms of the beautiful hardy Hibiscus syriacus. Mr. Russell, Mayfield, Parkstone, sent one of the handsomest spikes of Saccolabium Blumei Dayanum that has ever been seen, and the committee recommended it to the notice of the Council as deserving the award of a medal.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. According to previous notice given in these columns, the "tatie" growers had a grand field day in connection with this meeting. First came Mr. Fenn, the noble tuber's greatest champion, with a batch of seedlings and graft hybrids of the most promising description; followed by the Brothers Dean, of Bedfont, with a choice collection of the best varieties, not the largest in size, it is true, but with quite the largest share of the points which in this locality are named "Fenn's Perfection;" then came Messrs. John & Charles Lee, Hammersmith, and Messrs. Sutton & Sons, Reading, with collections comprising about 50 varieties in each, of all shapes and sizes, and of all colours, from the purest white to the deepest red, down to the more handsome Cobbler's Lapstone and Early Emperor. In Mr. Fenn's collection were nine forms of graft hybrids, the best of which appeared to be a white kidney named "Fenn's Perfection," the result of grafting Yorkshire Hero into Fenn's Onward, specimens of both of which were also shown. It is of fair size, very smooth in outline, and, unlike most of its fellows, clear skinned, and is, moreover, a handsome tuber to look upon the garden, were Cricket Ball, round red, second early, and recommended as a good variety for cottagers; English Rose, early second early, a very smooth and good kidney; Victoria Regent, very handsome, but rather a light lent late keeping sort; Fenn's Bountiful, second early red kidney, a great cropper and recommended for cottage gardens; Cottagers' Blush, a good early second early variety; Fenn's Improved Purple, a purple kidney, pleasing to the eye; Eliza Fenn, first early, fine shaped round, very smooth and a great cropper; John Fenn, a pebble-shaped early round, capital for summer use; Fenn's Goldfinder, a handsome yellow kidney, a large cropper and good keeper, and excellent variety; Rector of Woodstock, a smooth round late keeping variety, to which the Committee awarded a First-class Certificate on a former occasion; and Mayor of Woodstock, a good-shaped early round, rather deep eyed, but recommended as a good sort for hotel purposes, and which has also received the highest honours that can be bestowed upon it. Messrs. Dean showed twelve varieties of Potatoes, a medium sized round variety; Excellent, a long smooth kidney, well adapted for first early frame work; and Early White Kidney, a late-keeping, late-starting, white-skinned kidney, of excellent quality which is also quite hardy, and resists the disease. For winter culture in pots, Mr. Fenn had Multum in Parvo, a small flat variety, possessing excellent qualities; Little Gem, a nice smooth kidney, also a capital variety for pot culture; and Prizetaker variety, not over large, but smooth in outline and good in quality. With these also came six new seedlings of great promise, raised from seed sown this year. A Special Certificate was awarded to No. 1, which kidney, also to Mr. R. Dean, seedsman, Ealing, was grown by his brother, at the seed grounds, Bedfont, and comprised good examples of the Waterloo Kidney (Dean), which is regarded by Mr. Dean as the best variety of the Waterloo sort, distinct in character, a fine cropper, and first-rate in quality; Cottagers' Red, a very heavy cropper, of good quality; King o' Potatos, second early kidney, handsome large tuber, but not of such high quality as Veitch's Lapstone, one of the best of the type; a long unnamed smooth kidney, a graft hybrid between Yorkshire Hero and the Fluke; Eureka, a late pink kidney, fine in quality, and a heavy cropper; and Early Emperor, a fine kidney, mons, a longish kidney, brought from the Mormon territory by Mr. Robinson; Early Emperor, second early round pink, a handsome looking variety, of good quality; Fenn's Betsy Ann, second early, handsome, blood-red, and with purple, a seedling of great promise; Wellington, late, round, small, but handsome in shape, and a good cropper; and Red Breadfruit, second early, of fine shape, and a heavy cropper, but poor in quality. A Special Certificate was awarded. In the collection of 50 varieties grown on light soil, shown by the Messrs. Lee, the handsomest was Birmingham Prizetaker, a pebble-shaped round of attractive appearance. It does not, however, follow up these great points, being both a poor cropper and poor flavoured variety. The examples of Paterson's Victoria were very fine, fully confirming the high character of this variety as one of the best for light soils. It is of the first quality, and a great cropper. Other varieties well represented were the Beaconsfield Kidney, Lapstone (said to be true); Bresee's Prolific, large and smooth; Lee's Hammersmith Early Kidney, a new variety, not yet sent out; Dunbar Regent, Mona's Pride, Coldstream, Bresee's Climax, Milky White, and Wood's Scarlet Prolific. A Special Certificate was awarded. Messrs. Cutbush' collection contained many well-grown examples, but many of the varieties were of the deep-eyed, coarse type, whose principal recommendation is their size. The most meritorious examples in point of quality were Early Emperor, Dawes' Matchless, Haigh's Kidney, Myatt's Ashleaf, Prince of Wales Kidney, Milky White, Berkshire Kidney, and Headley's Seedling Nonpareil. With these came eight new American varieties, and some new sorts sent out last year. A Special Certificate was awarded. The same award was also made to Mr. J. May, Westfield Gardens, Hayling Island, Hants, for a dozen Shallots, grown from seed sown at the same time as the general crop of Onions, and which weighed 4 lb.; to Mr. Piccirillo, Wigmore Steet, for two very fine specimens of the Giant White Tripoli Onions, weighing 7 lb., and four immense heads of Garlic, weighing 2 lb. 6 oz., grown at Ebch, near Naples, and said to be mild and pleasant in flavour; and to Messrs. Rivers & Son, Sawbridgeworth, for a collection of small pyramidal Plum trees, carrying a splendid crop of fruit, to the admiration of everyone. Mr. William Paul sent three very fine bunches of a seedling White Grape, of great promise, named Winter Muscadine, which the Committee requested to see again further on in the year; and several varieties of Pears were shown by Messrs. Sutton & Son sent a handsome brace of Cucumbers, named Marquis of Lorne, cut from plants which have been bearing fruit since last Christmas. Mr. Fenn again exhibited specimens of Blenheim Pippin Apples, which have been altered in character through grafting, and from Mr. Earley came a bunch of Black Grapes, cut from the parent plant of the old Hampton Court Vine, which is growing in the gardens of M. Inglieby, Esq., LL.D., at Valentines. The bunch shown was one of 16 grown on a rod 13 feet long, large, fine in berry, well coloured, and of good flavour, which shows that there is still plenty of vigour in the old Vine. Mr. Simpson, The Gardens, Broomfield Lodge, Chelmsford, sent tubers of what he supposed to be a graft hybrid between the Potato and the Jerusalem Artichoke, but, in the opinion of the Committee, the tubers were those of the Jerusalem and Artichoke admixture. The examples sent were said to have resulted from grafting two white kidneys into the Artichoke, the produce as shown being red kidneys of the same character as the undistinguishable from, a variety known as the Cottager's Red. The prizes offered for the best dishes of dessert Apples were taken by Mr. Gardiner, Lower Eatington Park, and Mr. Craddock, the Gardens, Compton Verney, Warwick, with Ribston Pippins, and the best dishes of Pears were of Bon Chrétien Fondante, from Mr. Bray, and Jersey Gratioli, from Mr. Tranter, Upper Assendon, Bucks. The only collection of Tomatos came from Mr. Earley, who had the 1st prize.

ROYAL CALEDONIAN HORTICULTURAL: *September* 15.—This was one of the best autumn shows held in Edinburgh for many years. We have had a better style, at least some score of them, than we are in the habit of seeing; and the fruit was a large, and, upon the whole, a very attractive exhibition; the out flowers were not so good as they usually are at this season. The Hall looked full, and the whole appearance of it, enhanced in effect by some six collections of plants from the various nursery farms in and around the city, indicated an interest that is pleasing to find is engaged in horticultural pursuits. Unfortunately, the attendance of the upper and middle class was not so good as we might have expected, and hoped to have seen, but at night the Music Hall was well filled. The show was by the best that Edinburgh and in the western division of Scotland throughout the past season, horticultural shows are more indebted for a self-sustaining support to the sixpences of the working classes than to those above them in a social position.

Coming to individual objects of interest, the first place must be voted to the plants staged for Mr. B. S. Williams' prize of £5, there were three collections of 12 plants; the 1st, gained by Mr. Paterson, gr. to Mr. Syme, Millbank, was a very uniform lot, comprising Eucharis amazonica, in splendid inflorescence, and a noble plant it was; Ixora Duffii, Dracæna Cooperi, and the new Dracæna Veitchii were also shown. Mr. Howard's fine examples at the International Exhibition of 1866. Along with this was a very well-managed densely flowered Clerodendron Balfourianum, and a good Ixora Duffii, an excellent plant of Odontoglossum grande, with at least 30 flowers; an equally good Miltonia spectabilis, with at least 40 flowers, and the whole young, fresh-looking, and captivating. They looked as if they would have been the best table upon which they were placed, and would have gained in importance and in effect under proper setting. Mr. Lees, gr. to the Earl of Haddington, had a most effective lot—larger than those composing the 1st, so even, indeed, some of them a little past. His Heaths—most, if not all of them, Turnbull's seedlings—were unusually fine; Austinians, for example, was a picture of symmetry and health, splendidly coloured, and Mr. Lees showed longer and finer coloured Bothwelliana—a Heath destined to rank in importance with Marnockiana, placed alongside of it. Another good Heath shown, but a little past, was Innocuba purpurea, a handsome, large-habited tube, a soft-growing variety, and coming in useful in autumn. Vallota purpurea was in extra style in this collection (numbering as many as 200 flowers or more), and of a rich brilliant colour; Dracæna Veitchii was also shown, but "a little past its best, as was also Vanda tricolor insignis, Mr. Paterson had a good and effective lot of foliage plants, and so had Mr. Currie, gr. to William Nelson, Esq., Saughton Grove, who showed Areca Verschaffeltii in fine style, as well as the spiny rachised Mexican Astrocaryum. These, with Yuccas and Tree Ferns, rather limited in number certainly, but what there were of them, made up an agreeable whole, taken along with the bright colouring of the numerous stands of cut flowers. Capital Ferns came from the gardens of Sir John R. Maclachop, of Niddrie, consisting of numerous Maidenhairs—all at times graceful and interesting; some good Todeas, and the neat looking Cheilanthes elegans. There seems so much cutting about the pinnæ and pinnules of this delightful species, that the eye scarcely wearies admiring its decompound fronds. As for the nursery collections, covering a large amount of table space, the prizes went as follows:—1st, Mr. Lawson & Son, Dean, to Mr. Mitchell, and to Dickson & Son. The only novelties in the plant way was an Amaranthus salicifolius, from Messrs. Veitch & Sons, a Manilla species, of remarkably elegant pyramidal habit with the leaves undulated, liguiate, acuminate, not at all Willow-like, but none the less effective from the suffusion of Indian red and green and yellow that characterised them. It is certainly a fine looking annual for individualising, and will become valuable for relieving the squatness of dumpy

flower gardening. Another subject, of a dwarf, almost uncultivatable look, was shown by Mr. Butler, Greenock; this was the variegated form of the Cornish Mouseywort (Sibthorpia europæa), growing flatly on the surface of the small pots in which it was shown. It was certificated by the judges.

The fruit consisted of collections of 20 sorts from Mr. G. Johnstone, gr. to the Earl of Strathmore, Glamis Castle. Among the best dishes were marvellously fine samples of Buckland Sweetwater, Black Prince, and Muscat of Alexandria Grapes. The Peaches were also good, and the other dishes, which consisted of Melons, Brunswick and White Marseilles Figs, Nectarines, Cherries, Strawberries and Plums, of average character. The Prince of Wales, gr. to Sanderson, Indeed, was very good, and had been well kept back. Mr. Temple, gr. to J. Balfour, Esq., Balbirnie, Markinch, had a good lot of 16 dishes. His Stirling Castle Peaches and Moorpark Apricots were very fine, and so were his Brown Turkey Figs, Bellegarde Peaches, and Downton Nectarines. Mr. James Turner, gr. to Mark Turner, Esq., Kendall, Selkirk, had also a good lot. Mr. Fowler, Tyrebeithing, had two extra well-managed fruit of Smooth Cayenne Pine, weighing from 7 to 8 lb. each; and another exhibitor, whose name we did not catch, had a couple of fine Queens. Bad sorts were the only exception, only he did not stage in the classes with that sort, showing it only in his collection. The Black Hamburghs were, as a rule, badly exhibited—great ill-finished bunches, some of them badly thinned, and others destroyed with water-spots over the surface—indeed, it is questionable whether any of the dozen of entrants should have been awarded a prize, unless it were the owner of the 2nd prize, Mr. Wyllie, gr. to Sanderson, Esq., Oaklese, Gallashiels. That exhibitor's bunches were well shown, cleanly put up; although the judges passed them for first honours, because the lot they selected were the better flavoured of the two; a point of flavour whereon there was no comparison. The prize for best flavoured black went to Mr. Temple, with Muscat Hamburgh; and the prize for the best flavoured white went to Mr. George Greig, gr. to Mr. William Christie, Craigend Park, with Duchess of Buccleuch. That exhibitor was very successful in his lots, taking 1st for Black Alicante in very good style, 1st for White Lady Downes, and 1st for well-flavoured white. The largest or heaviest bunch came from Mr. J. Dickson, gr. to J. Jerdine, Esq., Arkleton, Dumfriesshire, in the shape of White Nice or Syrian, weighing the extraordinary weight of 18 lb. 4 oz. The largest or heaviest bunch on a cord, probably, since the days of the Grapes of Eshcol. The Rev. W. P. Bushby, The Parsonage, Dalkeith, sent a nice dish of three bunches of Muscat of Alexandria of fine form, not large bunch, but well up in colour. Immense Solway Peaches, of a fine citron colour, came from Mr. Mark Kyle, Elliston House. Excellent Stirling Castle and Walkerian Admirable also came from Mr. Lees, from Mr. Johnstone, and from Mr. Price, gr. to the Earl of Rossiyn, Dysart House. There were really a grand lot of these fruits and of Nectarines, of Elruge, and of Fitmaston Nonpareil, one of the most characteristic fruit upon the table. Very good Apricots came from Mr. Cumming, gr. to the Earl of Wemyss, Arnisfield; and there were lots of Plums, of Jargonelle Pears, and, notwithstanding the absence of Apples, which Messrs. Lees, Brunton (gr. to Sir W. Kinloch), and Mr. Cumming divided the chief honours.

Cut flowers were in fair condition, especially the Gladioli; the Roses, the Dahlias, and Hollyhock blooms, but little of a class to elicit special notice. Some very good novelties in Dahlias were staged by Mr. Turner, of Slough. The following sorts were certificated:—James Wilder, a deep-shaded crimson, with the top florets shaded with blackish crimson, most novel and striking; florets fine formed, and the whole flower well raised in the centre; substance good, and making up a most distinct whole,—Second-class Certificate. Mrs. Pinkham, a primrose, with shaded white florets, much deeper and denser shaded than Mrs. Landers, and a very striking flower,—First-class Certificate. John Standish, cerise, shaded crimson towards the centre of the florets, form perfect, build firm and globular; altogether, a fine thing,—First-class Certificate. Mrs. Landers, yellow tipped with white, form a little flat, but good-turned florets, petals notched crimson, most novel and striking; florets fine formed, and the whole flower well raised in the centre; substance good, and making up a most distinct whole,—Second-class Certificate. Hope, fine deep crimson, with well-turned florets, flower well raised, and form unexceptional,—Second-class Certificate. The following Hollyhocks, from Messrs. Downie & Co., had Second-class Certificates:—John Stewart, rosy-crimson, very full of petals well packed together from the guard petal upwards, and making a full flat head of agreeable outline. Mrs. Lang, salmon-shaded pink, very full and good, and of general good parts. Mr. John M'Pherson, Aberdeen, had a Certificate of Merit for a yellow ground Pansy, with good dense eye and dark purple belting.

Vegetables were in small quantity, but what were shown were good, particularly the Onions, which were not only Spanish-like, but well matured. The Celery, and Carrots, and Beet, and Leeks, were of first quality. The best collections came from Messrs. C. Irving and A. Anderson, and the best Onions came from Messrs. D. Marshall and C. M'Farlane. Cottagers and amateurs had each separate classes for themselves, but they were not largely represented, although they showed in general very creditably.

ROYAL HORTICULTURAL OF ABERDEEN: *September 15 and 16.*—The autumn show of this Society was held in a large marquee on the Inches The show was in every respect successful. The autumn show is intended chiefly for cut flowers, fruits, and vegetables, and therefore little encouragement is held out for the exhibition of pot plants; nevertheless, the show of the latter was very good. Among these sent in for competition we observed a good plant of Lilium speciosum roseum, with about 100 blooms on it, and in the same collection very fine plants of Yucca aloifolia variegata and Lomaria gibba. The cut flowers were good, without exception, very good,—several nurserymen round the town, such as Morrison, Forbesfield; Cocker, Sunnybank; M'Pherson, Polmuir; Reid, Albyn Place, sent in fine stands for exhibition.

The display of fruit was very good. The display made by Mr. Mackie, Dunkeld; Mr. Webster, Gordon Castle, and Mr. Moir, Ury, in various classes, was remarkably fine.

The show of vegetables was also better than ever seen before in Aberdeen. Uninterested persons who had attended the recent shows at Edinburgh and Dundee asserted that the vegetables shown on this occasion were very much superior to those shown at either of those places. A new variety of Potatos, shown by Mr. M'Pherson, Polmuir, was highly commended by the judges.

As usual, the amateurs, in flowers, and vegetables, were little, if at all, behind the professionals; and we were glad to observe much improvement in all branches on the tables assigned to the working classes.

Notices of Books.

At Last: a Christmas in the West Indies. By Charles Kingsley. Two vols., crown 8vo, pp. 631. With illustrations. (Macmillan.)

If the passenger traffic of the West India Mail Company does not increase considerably during the coming winter, it will be no fault of Mr. Kingsley's. To read his volumes is a delightful occupation, for the reader is tantalising in the extreme. Instead of calmly taking pen in hand and endeavouring to give our readers some idea of these charming volumes, there is a well nigh irresistible impulse to rush off and secure a berth in the next steamer bound for the West Indies. Familiar with descriptions of tropical scenery and tropical vegetation, and not wholly unversed in the details of the latter, Mr. Kingsley's word-paintings appeal to us with a vividness and force as delightful as surprising—surprising because descriptions of tropical vegetation are often monotonous, and the botany of the West Indies in particular has been pretty well worked up by naturalists. Mr. Kingsley's descriptions have the uncommon but excellent qualification of being not only scientifically accurate so far as they go, but fluent. Too often when even a practised writer sets his hand at this kind of work, the result is wearisome to the general reader, and useless, if not unintelligible, to those who read for information rather than amusement. Again, the scientific writer is too apt to make his fishes talk like great whales, and disgust the general reader. Mr. Kingsley's graphic pen-sketches impressions made on the mind of the writer by a hurried visit to the island of Trinidad. We say hurried, because the whole journey out and home was completed within three months. Though in this place we naturally lay stress on the natural productions of the island, and especially on those deriving from the vegetable kingdom, Mr. Kingsley's scope is wider. He tells of the physical features of the islands; of their geology, not forgetting the extraordinary pitch lake in Trinidad; he glances at their history; he has much to say on their present and probable future social and commercial state; he enters at some length into the peculiarities and differences of the several races inhabiting the islands—Anglo-Saxons, Hindoo-coolies, negroes, and Chinese. In every case, what he says he says well, and his opinions will command a respectful hearing, if not always assent.

We simply must add that he surmised that had Mr. Kingsley's visit been of longer duration, and had it been made under less favourable conditions, his impressions of what he saw and heard would have been somewhat less rose-tinted than they are. However, it is quite time to let Mr. Kingsley speak for himself, and we do not think we can do better than quote the greater part of one of his chapters descriptive of West Indian scenery, merely adding that this is only one of many similar landscapes, if we may so call them, scattered throughout the volumes.

The Botanic Garden here referred to, is that of Port of Spain, under the management of Mr. Prestoe.

"You look out—would that you did look in fact!—over the low sill. The gravel outside, at least, is an old friend; it consists of broken bits of grey Silurian rock, and white quartz among it; and one touch of Siluria makes the whole world kin. But there the kindred ends. A few green weeds, looking just like English ones, peep up through the gravel. Weeds, all over the world, are mostly like each other; poor, thin, pale in leaf, small and meagre in stem and flower; meaner forms which fill up for good, and sometimes, too, for harm, the gaps left by Nature's aristocracy of grander and, in these tropics, more tyrannous and destroying forms. So like home weeds they look: but pick one, and you find it unlike anything at home. That one happens to be, as you may see by its little green mouse-tails, a Pepper-weed (Peperomia), first cousin to the great black Pepper bush in the gardens near by, with the berries of which you may burn your mouth pretty well.

"So it is, you would find, with every weed in the little cleared dell, some 15 feet deep, beyond the gravel. You could not—I certainly cannot—guess at the name, seldom at the family, of a single plant. But I am going on too fast. What are those sticks of wood which keep the gravel bank up? Veritable Bamboos; and a Bamboo pipe, too, is carrying the trickling cool water into the bath close by. Sure, we are in the tropics. You hear a sudden rattle, as of boards and brown paper, overhead, and find that it is the clashing of the huge leaves of a young Fan Palm (Sabal), growing not 10 feet from the window. It has no stem as yet; and the fan leaves have to be trimmed off, or they would close up the path, so that only the great forked green butts of them are left, bound to each other by natural matting; but overhead they range out nobly in leaf-stalks 20 feet long, and fans full 12 feet broad; and this is but a baby—a three years' old thing. Surely, again, we are in the tropics. Ten feet further, thrust all over with the huge Palmyra leaves, grows a young tree, unknown to me, looking like a Walnut. Next to it an Orange, covered with long prickles and small green fruit, its roots propped up by a semi-cylindrical bit of timber, furry inside, which would puzzle a Hampshire woodsman; for it is, plainly, a 'Groo-groo, or a Coco Palm, split down the middle. Surely, again, we are in the tropics. Beyond it, again, blaze great orange and yellow flowers, with long stamens, and pistil curving upwards out of them. They belong to a twining, scrambling bush, with finely-pinnated Mimosa leaves. That is the 'Flower-fence' (Poinciana), so often heard of in parts when . . . and wherein it harrasts itself to great orange butterfly, larger, seemingly, than any English kind. Next to it is a row of Hibiscus shrubs, with broad crimson flowers; then a row of young Screw Pines (Pandanus), from the East Indian Islands, with spiral Pine-apple plants 20 feet high standing on stilts. Yes; surely we are in the tropics. Over the low roof (for the cottage is all of one storey) of purple and brown and white shingles, that in the midst of which (for which looks (as so many do here) like a Walnut, but is not one. It is the 'Poui' of the Indians [Tecoma (serratifolia ?)], and will be covered shortly with brilliant saffron flowers.

"I turn round to look into the garden. The ground on the opposite slope (slopes are, you must remember, here as steep as house roofs, the last spurs of true mountains) is covered with a grass like tall Rye-grass, but greyish-green. This is the Guinea-grass [Panicum jumeutorum], which, introduced from Africa, has spread over the whole West Indies. Dark lithe Coolie prisoners, one a gentle young fellow, with soft beseeching eyes, and red Turkish cap, and much of his shirt, are cutting it for the horses, under the guard of a Mulatto turnkey, a tall, steadfast, dignified man; and between us and them are growing along the edge of the gutter, verdant Caladiums in the open air, and a low green tree just like an Apple, which is a Guava; and a tall stick, 30 feet high, with a flat top of gigantic curly Horse Chestnut leaves, which is a 'Trumpet-tree (Cecropia). There are hummingbirds all of them in the sunshine; but most of them are dead, from the intense drought and fires of last year. Beyond it, again, is a round-headed tree, looking like a huge Portugal Laurel, covered with racemes of white flowers. That is an 'Acacia (Acacia mermis); when full grown, one of the finest timbers in the world. And what are those at the top of the brow, rising out of the rich green scrub? Verily, again, we are in the tropics. Palms. Fifteen Cocoa-nuts, 50 feet high each, with here and there a young one springing up like a gigantic crown of male Fern. The old ones have straight grey stems, often prickly enough, and thickened in the middle; a great 'spur' leaves a long scar down, and feathering round the top, a circular plume of pale green leaves, like those of a Cocoa-nut. But these are not Cocos. The last year's leaves of Coco are rich yellow, and fall naturally. These are Groo-groos [Acrocomia sclerocarpa]; they stand as fresh proofs that we are indeed in the tropics, and as 'a thing of beauty and a joy for ever.

"For it is a joy for ever, a sight never to be forgotten, to have once seen Palms, breaking through and, as it were, defying, the soft rounded forms of the broad-leaved vegetation by the sheer force of their stems; their utter immovable pillar-stem, looking the more immovable beneath the toss and lash and flicker of the long leaves, as they awake out of their sunlit sleep, and rage impatiently for a while before the mountain gusts, and fall asleep again. Like a Greek statue in a luxurious drawing-room, sharp cut, cold, virginal; shaming, by the grandeur of mere form, the voluptuousness of mere colour, however rich and harmonious that may be. Like the Palm forest; to be worshipped rather than to be loved. Look at the drawings of the Oreodoxa avenue at Rio, in M. Agassiz's charming book. Would that you could see actually such avenues, even from Port of Spain, or anywhere else in St. Vincent and Guadaloupe: but look at the mere pictures of them in that book, and you will sympathise, surely, with our new Palm-worship.

"And lastly, that is that giant tree which almost fills the centre of the glen, towering with upright but branching limbs, and huge crown, thinly leaved, double the height of all the trees around? An Ash? Something like an Ash in growth, but with leaves? Look through the glasses (indispensable in the tropic forest), you see that the foliage is more like that of the yellow Horse Chestnut. And no British Ash, not even the Altyre giants, ever reached to half that bulk. It is a Silk-cotton tree; a Ceiba [Eriodendron anfractuosum]—say, rather, the Ceiba of the glen; for these glens have a habit of holding each one great Ceiba, which has taken its stand at the upper end, just where the mountain spurs run

together in an amphitheatre; and being favoured (it may be supposed) by the special richness of the down-washed soil at that spot, grows to one of those vast air-gardens of creepers and parasites, of which we have so often read, and dreamed. Such a one is this: but we will not go up to it now. This sketch shall be completed by the back-ground of green and grey, fading aloft into tender cobalt: the background of mountain, ribbed and gullied into sharpest slopes by the tropic rains, yet showing, even where steepest, never a face of rock, or a crag peeping through the trees. Up to the sky-line, 1000 feet aloft, all is green; and that, instead of being, as in Europe, stone or moor, is jagged and feathered with gigantic trees. How rich they could say. Yet these West Indians only mourn over its desolation and disfigurement; and point to the sheets of grey stems, which hang like mist along the upper slopes. They look to us, on this soth of December only as April signs that the woodlands have not quite burst out into full leaf. But to the inhabitants they are tokens of those fearful fires which raged over the island during the long drought of this summer; when the forests were burning for a whole month, and this house scarcely saved; when whole cane-fields, mills, dwelling-houses, went up as tinder and flame in a moment, and the smoky haze from the burning island spread far out to sea. And yet, when the fire passed six months ago, all is now a fresh, impenetrable undergrowth of green: creepers covering the land, climbing up and shrouding the charred stumps; young Palms, like Prince of Wales' feathers, breaking out 20 feet high among the charred stems of Sensitive Plants, scarlet-flowered dwarf Balisiers [Heliconia Caribæa], climbing Fern [Lygodium venustum], Convolvulses of every hue, and an endless variety of outlandish leaves, over which their troops of butterflies flow like the seeds of the plants and the eggs of the insects have been preserved, who can tell? But there their children are, in myriads; and ere a generation has passed, every dead grey stem will have disappeared before the ants and beetles and great wood-boring bees who rumble round in blue-black armour; the young plants will have grown into green trees beneath by the innumerable vital force which pours all the year round from the blazing sun above, and all be as it was once more. In verity we are in the tropics, where the so-called 'powers of Nature' are in perpetual health and strength, and as much stronger and swifter, for good and evil, than in our cold climate, as is the young man in the heat of youth compared with the old man shivering to his grave. Think over that last simile. If you think of it in the light which physiology gives, you will find that it is not merely a simile, but a true analogy; another manifestation of a great physical law.

"Thus much for the view at the back—a chance scene, which the least pretensions to what average people would call beauty of landscape. But, oh, this is not all! Turn you the view in front! The lawn with its flowering shrubs, tiny specimens of which we admire in hothouses at home; the grass as green for it is now the end of the rainy season as that of England is; the winding away into the cool shade of strange evergreens! the yellow Cocoa-nut Palms on the nearest spur of hill throwing back the tender blue of the higher mountains; the huge central group of trees —Samaan [Inga Saman], Carocas [Bignonia], Mafoura [Hura crepitans] and Fig, with the bright ostrich plumes of a climbing Palm, towering through the Mimosa-like foliage of the Samaan; and Erythrinas [Erythrina umbrosa] (Bois immortelles, as they call them), every leaf and but leafless boughs now blazing against the blue sky with vermillion flowers, trees of red coral sixty feet in height. Ah that we could show you the avenue on the right, composed of Palms from every quarter of the globe, Mexican with smooth stems or with prickly ones, with fan leaves, feather leaves, leaves (as in the wine Palm [Caryota]) like Venus' Hair [Adiantum]; some, again, like the Cocorite [Maximiliana], almost stemless, rising in a huge cone of leaves which tosses in the land breeze till the long stiff leaflets seem to whirl like the spokes of a green glass wheel. Ah that we could show you through the botanic garden beyond, amid fruits and flowers brought together from all the lands of the perpetual summer; or even give you, through the great arches of the Bamboo clumps, as they creak and sway badly in the wind, and the Bauhinias, like tall and ancient Whitethorns, which shade the road, a glance of the flat green savannah, with its herds of kine, beyond which lies, buried in flowering trees, and backed by mountains, the city of Port of Spain. One glance, too, under the boughs of the great Cotton-tree at the gate, at the still sleeping sea, with one tall coolie ship at anchor, seen above green cane-fields and coolie gardens, gay with yellow Croton, purple Dracæna, and Acalypha, son Poinsettia, and the grand leaves of the grandest of all plants, the Banana food of Paradise. Or, again, far away to the extreme right, between the flat tops of the great Samaan trees, and the dark rocks, and the wooded mountain spurs which rush down into the sea, the islands of the Bocas floating in the shining water; and beyond them, a cloud among the clouds, the peak of a mighty mountain, with one white belt of mist upon its waist. Ah that we could show you but that, and tell you that you were looking at the 'Spanish Main;' at South America itself, at the last point of the Venezuelan Cordillera, and the hills where Jaguars lie. Have you could but see what we see daily; if you could see with us the strange combination of rich and luscious beauty, with vastness and repose, you would understand, and excuse, the tendency to somewhat grandiose language which we perpetually use. Those who try to describe the tropics, and know well that they can only fail.

"In the presence of such forms and such colouring as this, one becomes painfully sensible of the poverty of words, and the futility, therefore, of all word-painting; of the inability, too, of the senses to discern and define objects of such vast variety; of our æsthetic barbarism, in fact, which has no choice of epithets save between such as 'great,' and 'vast,' and 'gigantic;' between such as 'beautiful,' and 'lovely,' and 'exquisite,' and so forth; which are, after all, intellectually only one stage higher than the half-brute Wah! wah! with which the savage grunts his astonishment—call it not admiration; epithets which are not, perhaps, intellectually as high as the 'God is great' of the Mussulman, who is wise enough not to attempt any analysis, either of Nature or of his feelings about her; and wise enough also (not having the fear of Spinoza before his eyes) to 'in omni ignoto confugere ad Deum'—in presence of the unknown, to take refuge in God.

"To describe to you, therefore, the botanic garden (in which the cottage stands), would take a week's work of words, which would convey no images to your mind. Let it be enough to say, that our favourite haunt in all the gardens is a little grassy valley, beneath the loftiest group of trees. At its entrance rises a great Tamarind, and a still greater Saman: both have leaves like the Mimosa. Up its trunk a Cereus has reared itself, for some 30 feet at least; a thick-stemmed Philodendron twines up it with leaves like 'lords and ladies:' but the glory of the tree is that climbing Palm, the Desmoncus, which is now flowering 15 from a distance. Up into the highest branches and down again, and up again into the lower branches, and rolling along the ground in curves as that of a Boa bedecked with huge Ferns and prickly spikes, 6 feet and more long each, the Rattan [Calamus Rotang, from the East Indies] hangs in mid-air, one hardly sees how, beautiful and wonderful, beyond what clumsy words can tell. Beneath the great trees [for here great trees grow freely beneath greater trees, and beneath greater trees again, delighting in the shade] is a group of young Mangosteens [Garcinia Mangostana, from Malacca—the really luscious and delightful variety has not arrived in Trinidad], looking, to describe the unknown by the known, like Walnuts with leaflets 8 inches long, their boughs clustered with yellow and green sour fruit; and beneath their leaf to the left, a young Nutmeg-tree [Myristica], with markings of orange, crimson, or blue—coming into strongest contrast with the uniform green of leaf and grass. This is our favourite spot for entomologizing, when the sun and the mosquitoes drive us from exertion. Turn with us—alas! only in fancy—out of the grove into a neighbouring path, between Tea shrubs, looking like Privets with large Myrtle flowers, and young Clove-trees, covered now with their dull red unopened buds with the cloves of commerce; and among fruit trees from every part of the tropics, with the names of which I will not burden you. Look, though, down that Allspice avenue, at the clear warm light which is reflected off the smooth yellow ever-peeling stems; and then, if you can fix your eye steadily on any object, where all are equally new and strange, look at this stately tree. A bough has been broken off from it, and the sprouts from both ends of the plants are already contending. One is a parasitic Orchis; the other a parasite of a more dangerous family. It looks like a straggling Magnolia, some 4 feet high. In 50 years it will be a huge tree, with a stout trunk, and straight air-root which it is letting down by the side of the tree bole. That root, if left, will be the destroyer of the whole tree. It will touch the earth, take root below, send out side-fibres above, and down upon the trunk it will slip, the whole bole, clasped and stifled in their embraces, dies, and rots out, and the Matapalo (or Scotch Attorney [Clusia], as it is rudely called here) stands alone on stilted roots and branches, which have taken the place of growing into one great trunk; master of the soil once owned by the patron on whose vitals he has fed: a treacherous tyrant; and yet, like many another treacherous tyrant, beautiful in his youth, down to the very edge of decay, and grand labyrinth of smooth roots, standing high in air, or dangling from the boughs in search of soil below; and last, not least, his Magnolia-like flowers, rosy or snowy-white, and his fragrant fruit-shaped buds.

"Now turn homewards, past the Rosa del monte [Brownea] bush (bushes, you must recollect, are 20 feet high here), covered with crimson Roses, full of long silky filament-stamens; and then you—as we do daily in spirit—to recollect and arrange one-tenth of the things which you have seen."

Some beautiful woodcuts are given, illustrative of tropical scenery, but they are hardly more effective than Mr. Kingsley's narrative, from which we may be tempted to make yet further extracts at another time.

—— Under the appellation of *Album Van Eedes*—a taking title!—we have received a specimen number of a periodical devoted to the illustration in chromo-lithograph of the flowers of "Dutch Bulbs and Bulbous Plants." The plate before us represents a variety of Rex Rubrorum Tulip with variegated leaves, and is most satisfactorily done. It is not stated whether descriptive letterpress is intended to accompany the plates, but if so—and if it is intended for the benefit of English readers, we would suggest that it be written in English, and not in the "double Dutch" of the prospectus addressed to the florists and amateurs in Great Britain and Ireland. Twelve large coloured plates are, we learn, be published in the course of a year, in two instalments, at a cost of 12*s.*, post free. Application should be made to MM. A. C. Van Eeden & Co., Wagenweg No. 91, Haarlem.

—— We do not suppose that many people are foolish enough to be their own lawyers. Amateur work of that description is not very profitable; however, it is often a matter of interest to the laity to know what are the rules of law applicable in particular instances, and to no class of cases is this statement more applicable than to that relating to landlords' fixtures. *The Rule of the Law of Fixtures* is the title of a little book drawn up by A. Brown, Esq., Barrister-at-Law, and published by Butterworths, Fleet Street, and which may be recommended to those concerned.

—— To sportsmen and naturalists we may safely recommend a little treatise of Mr. J. E. Harting's, entitled *Hints on Shore Shooting* (Van Voorst). The work is thoroughly practical, and the spirit of the book sportsmanlike. It tells the reader where to go, what to do, how to distinguish the several birds, and how to preserve them; and these details are interlarded with a little pleasant chit-chat.

The Apiary.

THE HIVE.—What does it matter in what kind of hive or box the bees are kept? It does not matter much during the summer months, if the bees be located in a good district for honey collecting. But we have to provide for one or two contingencies, and not a few drawbacks from the extremes of heat and cold—the sun-heat melting the new combs in wooden boxes, as happens even in the straw hives, which are the best substitute for the natural habitat of the honey-bee, because the straw absorbs the moisture within the hive in winter, and with slight protection from the summer heat and winter rains, has carried through many a stock of bees. But there is the drawback of preventing stands for the straw hives, as well as covers from the weather; and then how completely is the state of the interior condition of the hive a dead letter to the owner, while transportation for fresh pasturage for the bees is impossible. Then comes the period of smoking and driving, to save the hives of the bees at the honey harvest, if the old plan of the brimstone match has really been set aside! What a hard task has it been to introduce this "humane system," in spite of the able writings of the Rev. W. C. Cotton, with Mr. Kobard Golding's straw hives and pamphlet —or any collateral, or safer, or nadir hiving; or even the "bar-frame plan," with all the German and American adaptations of more recent dates. Nor have the frames been stopped by the skilful writings of the late lamented Mr. Woodbury, who did so much in introducing thoroughly the yellow bee, commonly called the "Ligurian bee," and which has become quite a profitable business in America and England, although the first agent, Mr. Neighbour, of London, had the "Apis ligustica" from M. Herrmann, of Switzerland, only in 1859, who called this bee "Apis helvetica." But to return to the question of hives. No hive yet introduced by hivemasters and sellers has been constructed to meet the wants of the bees, but rather the capricious fancies of bee-keepers, where the maker has to tax his skill and ingenuity to meet these wants, while every season apparently requires a new hive or a new bee to be invested on the public, whilst the true principles have been lost sight of both for economy and the right management of the honey-bee. No hive could be so easily converted, either for the usual profitable keeping of bees, or the scientific observation of bees, such as the "bar frames," by those who wish to combine the two; but they generally fail in their object by their own zeal in finding out a "perfect cure" for all the ills that bee management has to contend with, and the bee-hive seller and constructor is always ready to assist the "new idea"—such as a little piece of square pane of glass that would surely make the hive a marvel of invention! instead of taking a lesson from the simple wants of the bees. We may then sum up the history of the bee-hive with a hop, skip, and a jump,—from the Schirach suggestion to Huber, who used the leaf-hive, and the improved bar-fixed Grecian hives of Golding, made in straw and circular, to the adapted wood and straw hives of Mr. Woodbury, who introduced the system of compound bar and frame, with the adjusted bar of Mr. Golding, having guide-combs affixed, to make the bees build in a perfectly straight line; but none have attempted the first views of the "bar-frame hive," which followed on the heels of the Grecian hives, not with any view to multiply bee apparatus, bee-houses or sheds, or the necessity of stands, covers, dividers, or glass frames, except for the ladies and timid bee-keepers, but with the single object of an easy mode of inspecting each comb, and protecting the inmates of the hive, and transporting the hive and bees bodily anywhere and at any moment. *W. W. M.*

Miscellaneous.

GISHURST COMPOUND FOR MANGE.—A Scotch terrier of mine was for some time troubled with mange. I tried a variety of preparations, with no satisfactory effect. One day I was mixing a large dose of Gishurst Compound for my Peach trees, which had been dreadfully cut up with the fly during the summer, when the idea occurred to me to try the effect of it on the dog's back. I took a lump of it, and rubbed him well with it until his back was in a perfect froth, and so left him, without washing it off. I repeated the process every day for about a week, and I am happy to say that at the present time he has very little appearance of mange about him. The hair is still short, but there are no bare places, and there is no question but he has derived considerable benefit from the application. *Francis Francis, in the "Field."*

Sept. 14.—Generally overcast, with the exception of a short period in the middle of the day. Dull.

— 15.—Fine, with small amount of cloud till night; then cloudy.

— 16.—Generally cloudy but fine.

— 17.—Overcast till the afternoon, then generally cloudless.

— 18.—A fine day. Cloudy throughout.

— 19.—Overcast generally, with the exception of the period comprised between 3 and 5 o'clock.

— 20.—Very variable. A few drops of rain fell shortly after 3 P.M. A cloudless night.

JAMES GLAISHER.

Garden Operations,

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

STOVES and greenhouses should now be set neatly in order, after the blooming of the plants which have been standing out. Should there be the least danger of over-crowding—and where is there space sufficient to meet all requirements?—I advise that strong measures be resorted to, such as destroying decrepid old specimens, to make way for more creditable stuff. We are all too prone, in decided opposition to our best interests, to retain old specimens which have done good service in the past, even though they may afford but a scant supply of flowers. With a view to economise labour I generally choose a wet period to wash the pots of incoming plants, turn them over, and re-arrange them, &c. Fresh surface-soil is frequently placed over the surfaces of the old balls at the same time, to which there are objections, as I shall show. At such a period the ball of each plant is generally extremely wet, the rims of the pots are also, in consequence of the washing; it follows, therefore, that soil compressed on to a waterlashed and bedabbled surface cannot well carry out the wishes or intent of the operator. It is for such reasons as these that I advise the fresh "soiling" to be deferred for a short time—until the pots and surface soil have become somewhat dry, so that the addition be made at a time when undue cohesion is not possible, and when the aid rendered will more readily meet the requirements of the roots. Potting successional "relays" of *Primulas*, *Cinerarias*, and the forward *Herbaceous Calceolarias* must receive the usual attention somewhat by anticipation, so that the roots may be kept constantly active and the plants growing. Those desirous of an early display of bulbous plants, who have not yet potted any, should do so quickly, as it is impossible to get good trusses of blooms without first allowing the bulbs ample time to form good roots for their support. They thrive well in a generous mild yellow loam, with moderate additions of sand and good decomposed and thoroughly sweetened "spit" manure, an inch or so in thickness being placed immediately over the few crocks deemed necessary to insure an effective drainage. In potting the bulbs, first firmly press the soil into the pots, and then fix the bulbs as tightly as possible in and upon it, burying them to about a third of their depth into the fresh soil. Unless the soil is somewhat dry at the time of potting—which is not desirable, as it prevents its being made firm by pressure—they should not be watered immediately, nor, in fact, until the surface has become dried sufficiently to let the water percolate freely through without in anywise causing undue binding. To this end they should be placed in the situation where they are to be covered with ashes or coco-nut refuse, and there remain for a day or so, until the surfaces have become sufficiently dried, when the necessary watering should be given, soon after which the process of covering them over may be done. In the country generally, the family having a home at this season, every possible fuel must be made, by a concentration of all the flowering plants possible, to keep the conservatory gay. Cut back late-flowering *Ixoras* immediately the bloom is past, and place them into a nice bottom-heat, with a high, moist atmosphere, to induce them to "break" and form young shoots before the advent of winter. Withhold water gradually from *Gloxinias*, *Gesneras*, and *Achimenes*, which are going out of flower, and require now a state of rest to ripen their tubers. They ripen off better by being placed into an airy vinery, or some such similar structure, where more air can be afforded them, with a drier atmosphere.

FORCING HOUSES.

Hanging *Grapes* which are over-ripe should be very closely watched, the bunches being looked carefully into to detect any decayed berries, so that they may be removed at the earliest possible moment, as it is well known what sad havoc an individual berry so decayed will make in a bunch. The longer and cooler nights have also a tendency to induce decay amongst them. Continue constantly and evenly the use of fire-heat in moderation in connection with late Grapes, and afford the usual plentiful supply of fresh air. It is more necessary than ever now to give air betimes in the morning, as any paucity while rise in the internal temperature through external agency is certain to cause a sweating moisture to adhere to the berries and all inside surfaces, which is opposed to the real requirements of the place. Besides, the moisture which becomes deposited, if not dispelled before the sun again dominates "cloud-land," is also a decidedly pernicious influence upon all such as are fully ripened. The earliest *Vinery* may now, if the wood is well ripened and most of the leaves have fallen off, have the necessary pruning operations performed, as, with the above conditions to guide the operator, the wood will be better of being pruned if the house be kept as cool as possible. Besides, the value of early pruning to the Vines cannot well be over-estimated, in so far as the greater conservation of their strength is concerned, independently of assuring to each a much longer period of rest. In regard to *Pinerie* the same temperature of 80°, recommended last month, must now be somewhat reduced, and by this time a gradual fall of 3° should be insured below the mean before necessary for the whole 48 hours. Afford also, during bright warm weather, even more air than has been generally afforded, to harden if possible all watery parts in any formerly robust growth, and to oppose at this time the formation of any too succulent growth during the remaining days of a quick growing period. Push forward, and to delivery, by means of fire-heat, those fruiters now actively engaged in swelling their fruits; and this whilst bright summer intervals last. Upon bright, sunny days, therefore, an excessively moisture-laden atmosphere, and a high temperature, should be maintained, even to the extent of running the thermometer up to 93° or 95°, at or about 3 P.M., following the shutting-up for the day. *Figs* now ripening their second crop must have all water withheld in instances where planted into open borders only. Attend to the earliest *Peach* and *Nectarine houses* as soon as the foliage becomes sufficiently matured to part from the branches without undue violence, when they may be brushed off and the branches be loosened from their trellis supports, and the usual cleansing and dressing over with Gishurst Compound be performed.

HARDY FLOWER GARDEN.

Look carefully through *Rose* plantations, and remove all robber suckers, which often form and push somewhat freely at this time. Remove all old blooms from *Dahlias* immediately they cease to show a neat exterior. Cut away all old flower-spikes from *Hollyhocks* as soon as their work has been performed, and they cease to afford a display, so that the roots may have every opportunity of forming young shoots to carry the old stools through the winter with. Remove all the wild branches upon Roses which have been budded by shortening them in to about a foot in length, and loosen the ligatures around the buds, to afford them greater freedom for expansion. Finish transplanting all biennial and perennial seedling plants, and finish transplanting *Crocuses*, *Narcissi*, and *Snowdrops*, &c. Often a sowing made just at this time of sundry kinds of hardy annuals comes in well by way of succession to those sown earlier, or if very open weather supervene between now and Christmas, the plants are better able to stand any subsequent hard weather than the earlier sown ones, which may have become too robust. I allude to such things as *Collinsias*, *Limnanthes*, *Silenes*, *Virginian Stock*, *Nemophilas*, *Eucharidiums*, *Clarkias*, *Godetias*, and many similar kinds. Sow them on to a warm summer aspect.

KITCHEN GARDEN.

Every advantage must be taken of the first rainy period to transplant good breadths of winter *Lettuces* and *Endive*, some of the last sowings of which could not be got out before, owing to the dryness. Young seedling *Cauliflowers* intended to stand the winter will be much hardened by being transplanted out into neat nursery beds at this time, and planted out not very distant date to their more permanent winter quarters. Attend well to the thinning out of successional crops of *Spinach*; to leave them too thickly only endangers the whole crop, whilst the actual supply afforded is no better, if so good as when properly thinned out. Thin out late sowings of *Radishes*, and make another sowing in frames if a succession is wanted. Make a sowing of *Dwarf French Beans* in pots if a like requirement exists. Fully expose the fruit of *Tomatos* to the full sun by removing all gross shoots and overhanging leaves. For the rest water all lately transplanted stuff if dry weather continues, and look well to Cabbage plantations to detect and destroy the leather-coated grub. *W. E.*

Notices to Correspondents.

BOOKS: *G. L.* Mosses, Wilson's "Bryologia" (Longmans); Berkeley's "Handbook of Mosses" (Reeve & Co.).

HARDY SUCCULENTS: *J. M.* The following of those you mention are hardy:—Sedum dasyphyllum, corsicum, anglicum, &c.; Sempervivum arachnoideum, globiferum, montanum; Saxifraga liguiata, crustata. Antennaria tomentosa is hardy, but not a succulent. Sempervivum tabuliteforme and Cotyledon are greenhouse plants, but available for summer gardening.

INSECTS: *T. K.* The insects found in great numbers in your Pine-houses are an exotic and probably undescribed species of millepedes (*Julus*) sp.? They may be driven from the plants by gas-tar water, and as they feed on decaying vegetable matter they may be trapped in great numbers by laying decaying fruit about, or partially burying slices of Potatos or Turnips. *J. O. W.*

IRESINE LINDENI: *W., Inveresk.* This plant should be wintered in a cool stove, and may be propagated to any extent by cuttings, in heat, in the early spring months. It strikes freely.

LIFTING THE ROOTS OF VINES: *E. J. W.* October is about the best month to perform this operation. Keep the border free from getting into a sodden state during the winter, or the roots will perish.

NAMES OF FRUIT. *W. H. Port.* Pear, Beurré d'Amantlis. The China Winter Radish is a very useful variety.—*F. Scott.* Your Apple, named Scarlet Court of Wick, we have found to be identical with Lord Grosvenor. The Scarlet Golden Pippin and Lord Lennox Apples are unknown to us under those names.—*K. J.* Apples: 12, Ribston Pippin; 1, Gravenstein, probably; 4, Kerry Pippin; 5, King of the Pippins; 10, Hawthornden. Pear: 1, Williams' Bon Chrétien. You should send better examples, otherwise it is impossible to name them with certainty.

NAMES OF PLANTS: *Donnie, Laird & Laing.* Physgelina capensis, Meyer; native of the Cape of Good Hope, but with very much the appearance of a Penstemon. Introduced by Messrs. Veitch about the year 1855, and figured in Bot. Mag., t. 6881.—*T. S. Harrison.* *H. B.* Chrysanthemum segetum, Corn Marigold.—*J. M.* Spiræa salicifolia.—*Y. G.* Calceolaria chelidonioides.—*J. C. & Co.* Zephyranthes candida of Sims. (See Bot. Mag., t. 2600.) Native of Peru. It is the Amaryllis candida of Herbert.—*W. Foster.* Struthiopteris pennsylvanica.—*W. N.* 1, Polypodium vulgare]; 2, Nephrodium molle; 3, Pteris serrulata; 4, Pteris aquilina. We cannot name the others without specimens.—*A. B.* Sea Buckthorn (Hippophæ rhamnoides.—*T. W.* 1, Dahlia superflua, R. Br. (*alias* D. variabilis, Desf.), also known as Georgina superflua or variabilis by the older botanists—the parent of the Dahlias of our flowers; 2, Mentha rotundifolia. L.—*W. M., Ely.* Ammi majus, L.; a common weed in Egypt and the East generally, but which has only once or twice previously been gathered in this country.—*W. K.* Polygonum cuspidatum, S. and Z.; a native of Japan, now frequent in gardens.—*J. R.* Rhus cotinus, the Wig plant.—*E. W.* Gomphocarpus fruticosus.

PEARS: *G. W.* The following may perhaps suit you:—1, Doyenné d'Été; 2, Williams' Bon Chrétien; 3,

Louise Bonne of Jersey; 4, Beurré d'Amanlis; 5, Marie Louise; 6, Thompson's; 7, Fondante d'Automne; 8, Beurré Bosc; 9, Glou Morceau; 10, Beurré Rance; 11, Bergamotte d'Esperen; 12, Josephine de Malines.

PHLOXES: *F. P. A.* We should understand the class "best six perennial Phloxes, dissimilar," to mean six panicles of flowers cut from distinct sorts. If, therefore, an exhibitor shows seven panicles by tying two panicles together to be set up as one, we should decide that he does not comply with the conditions, and is disqualified.

RIDGE CUCUMBERS: *H. H.* Stockwood Bridge is a very good sort, if you can get it true; but either of the sorts named will answer well, if true.

SEEDLING PEACH: *J. S.* The fruit sent was too far gone for us to pass any opinion on its qualities. The half that remained looked well.

THE KEEPING OF A GARDEN: *R. S.* It is always a difficult matter to decide as to what amount of labour is required for the keeping of a garden from a simple description of the place. There are so many ulterior affecting causes, that none but those immediately connected can be conversant with. From your statement it seems to us, that beyond keeping a certain surface polish on the place, you can do little else with the strength allowed. The extent of glass is about sufficient for two men during the summer season, and 6 acres of kitchen garden to be cropped thoroughly would require all the strength you say you are allowed; but, as we have already stated, it is all a matter of style in keeping and requirements. It is true, also, that some masters do not care about mowing as much done as others, by properly understanding themselves when and how the work should be done. There is a deal in method and management. Do you not fail in this?

VINE *EATEN BY RATS*: *A Constant Reader.* We can gather little from your statement further than that the Vines, instead of improving, as they should do, are gradually dwindling away. There must be grave mismanagement somewhere, either in the amount of sustenance given to the roots, as regards soil or water, or in the atmospheric condition of the houses. Is the wood properly grown? and if so, is it properly ripened? We almost suspect that your houses are kept far too close and warm, and that the shoots and leaves are very much crowded together, so that they cannot perform their functions. It is absurd for any gardener to tell you that Vines that have not been planted 10 years are too old, and that young ones are wanted. They may be, and evidently are, so mismanaged, that they seem old; but, with proper liberal treatment that will recover, for no plant is more easy of cultivation; but where the actual points of failure have arisen, we cannot correctly say. If your borders are outside, no artificial watering has been necessary. Are they sufficiently drained?

CATALOGUES RECEIVED: William Knight, General Catalogue of Nursery Stock.—James Coker, Descriptive Catalogue of Dutch Flower Roots.—Downie, Laird & Laing, Descriptive Catalogue of Dutch Flower Roots.—Little & Ballantyne, Select Descriptive Catalogue of Flower Roots, &c.—James Dickson & Sons, Catalogues of Select Roses and Bulbous Flower Roots.—Dick Radclyffe & Co., Autumn Catalogue of Dutch Bulbs, Horticultural Decorations, and Garden Requisites.—George Gibbs & Co., Catalogue of Dutch Bulbs and Seeds for Autumn Sowing.—G. & W. Yates, Descriptive Catalogue of Dutch Bulbs, Flower Roots and Hardy Flowering and Evergreen Shrubs, Ornamental Trees and Fruit Trees, &c.—John Scott, Autumn Catalogue of Flower Roots.—Charles Turner, Catalogue of Choice Bulbous Roots, &c.—Fergus Farrer & Son, Catalogue of Dutch and Cape Flowering Bulbs, &c.—Robertson & Galloway, Descriptive Catalogue of Dutch Roots and other Plants, for Winter and Spring Flowering.—E. DIED,—At Wahlingen, on the 7th inst., Mr. WILLIAM BARRATT, of the St. John's and Newton Moor Nurseries, Wakefield.

Markets.

COVENT GARDEN.—Sept. 22.

The markets are very steady, and the demand and supply about equal. French produce is still largely imported, and eases the market to some extent, as good Apples and Pears of home growth are light in crop this season. Other crops are freely offered, without alteration in price. The Potato trade remains very steady, at former quotations.

VEGETABLES.

PARTNER.—By the retirement of one of the Firm, an opportunity occurs for an active Working Gardener to become PARTNER in a small Nursery and Jobbing Business, on long lease, in Islington, on very moderate terms. Apply to GEORGE RUE, 20, William Street, New North Road, Islington, London, N.

WANTED, as NURSERY FOREMAN, in a country Nursery, a good general Hand, well up in Flower Seeds, and with a knowledge of the other Stock generally met with in a good Nursery. Also an Apprentice who has been his work, and to take the head of the other men employed.—Address, stating full particulars, B. 5, Post Office, Ashford, Kent.

WANTED, a HEAD GARDENER, in Hampshire. Large Kitchen Garden, moderate Flower Garden, 30 Acres Land, Cows and Pigs. Wife to undertake Dairy and Poultry. No children. Must be steady, active, firm, and civil. Only experienced persons with first-rate character, and of Church of England, need apply. Mr. T. C., 47, White Tower Street, London, E.C.

WANTED, a young active Man as GARDENER.—Situation permanent.—CHARLES SHARPE AND CO., Sleaford.

WANTED, as GARDENER, an active, energetic, married Man, who understands the propagation in all its branches.—Address, stating wages and age, to Mr. K., The Friory, Priittlewell, Essex.

WANTED, a practical WORKING GARDENER, understanding Vines, Forcing generally, Greenhouse, and Flower and Kitchen Gardening. Wife must undertake the Laundry, Cottage Garden.—Rev. W. HOMFRAY, West Retford Rectory, Retford, Notts.

WANTED, a steady, active, young MAN (SECOND), who has had a knowledge of general Nursery Work. Budder, Grafter, and Propagator.—Apply, stating wages, &c., to G. WOOLLEY, Nurseries, Caterham, Surrey.

WANTED, an IMPROVER, in the Seed Business. At present there is an opening in the Seed Department of Mr. WILLIAM BULL'S Establishment for a respectable and intelligent young Man. Apply in own handwriting, stating age, last engaged and wages expected.—Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

Land Manager and Farm Building Resident Agent.

WANTED, in Devonshire, an active, intelligent Person, between 30 and 45 years of age, having a practical knowledge of Stock, Management of the Value and Manure of Land, including Measuring, Fencing, Planting, &c.; fully competent to prepare Plans, Specifications, and Estimates for, and to superintend the Erection and Repair of Farm Buildings. Respectability and sobriety, with practical experience required in a similar situation indispensable. Salary £300 per annum, with a residence, and £50 per annum to provide and keep a horse.—Full particulars, stating age, family (if any), and references, to be addressed to R. M., 21, Arundel Street, Strand, London, W.C.

Seed Trade.

WANTED, an ASSISTANT SHOPMAN, in a London Wholesale House. Must be experienced and quick at Counter work.—Address, stating experience and salary required, to *Seeds*, Gardeners' Chronicle Office, W.C.

WANTED, a young Man, as JUNIOR INVOICE CLERK, in a London wholesale Seed House. Salary 18*s.* to 21*s.* per week, according to ability.—*E.* AND CO., *Gardeners' Chronicle* Office, W.C.

WAITE, BURNELL, HUGGINS, AND CO. are WANTED, a JUNIOR SHOPMAN, also a JUNIOR CLERK.—Apply by letter only, Southwark, S.E.

WANT PLACES.—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen. Further particulars given on application to Messrs. J. C. D. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENER (HEAD).—Married; understands Early and Late Vineries, Greenhouse, Kitchen Gardening, and every other branch of the profession. Six years' character.—C. S., Sydmonton, Newbury, Berks.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a thorough practical Gardener.—Age 36, no family; capable of the Rearing out or making Improvements. Unexceptionable character.—P. L., Post Office, Kanturky.

GARDENER (HEAD), age 33, married, one child.—The LADY OF BLAGUERE wishes to recommend the above. Thoroughly practical, and conversant with every branch of the profession.—T. BALCOMBE, The Lawn, Whitchurch, Hants.

GARDENER (HEAD).—A Lady wishes to recommend a Gardener as steady Man, as above; master of the profession; has been Head Gardener about 17 years in three situations. No single-handed place accepted.—A. B., 13, Charles Street, Portman Square, W.

GARDENER (HEAD).—Age 36, married; a first-class Man, who thoroughly understands the profession. Has had extensive experience in Laying-out Grounds, Planting, and Transplanting very large Trees and Shrubs; also understands the Management of Plantations, Woods, and Forests in general. Would not object to the Management of Land. Can be highly recommended.—C. A. FOX, Esq., Wakefield, Warburton, Esq., Arley Hall, Cheshire.

GARDENER (HEAD).—Age 29, married; has had 13 years' experience in first-class gardens, and thoroughly understands Early and Late Forcing of Pines, Vines, Stove and Greenhouse Plants, Ferns, and Kitchen and Flower Gardening. Would be at liberty in a few days to engage with any Nobleman or Gentleman in want of a thoroughly good Gardener. Age of wife 28; no family. Can be handed place. Excellent references from late employers.—A. B., Mr. Joseph Beckett, Nursery Yard, Garston, near Liverpool.

GARDENER (HEAD, or SINGLE-HANDED).—Age 32, single.—Mr. CARLTON, Gardener to the Hon. Mrs. Howard, Ashstead Park, Epsom, Surrey, can with confidence recommend his Foreman as a thoroughly practical and energetic Man. Has been Foreman 10 years in five of the principal Establishments, where every branch of Gardening is carried out in the most complete manner, and is fully capable to take charge of a first-class place. Character will bear the strictest investigation.—Address as above.

GARDENER (HEAD, or SINGLE-HANDED).—Age 29, married, one child; thoroughly understands Flower and Kitchen Gardening, Forcing, &c. Highest personal character.—W. B., Brackett's, Bramley, Guildford.

GARDENER (JOURNEYMAN).—Age 21, single; one year's good references.—H. M., 114, High Street, Putney, S.W.

GARDENER, where assistance is given.—Age 26, single.—Mr. THOMPSON. Good character.—A. B., 10, Albert Terrace, Hornsey Rise, N.

GARDENER (SECOND, or THIRD), where five or more are kept.—Age 21, single; has had experience in Stove and Greenhouse Plants, Vines, Peaches, and Flower and Kitchen Gardening. First-class character from present situation.—L. C. SUMPTER, Head Gardener, Fring Hall, Rougham, Norfolk.

To Gardeners.

GARDENER (UNDER).—GEORGE COOPER, Rose Hill Nursery, Derby, can confidence recommend a young Man, who has been in his employ three years, as any Gardener wishing to have a good useful person, and one who is likely to make a good Gardener.—Address as above.

To Seedsmen and Fruiterers.

FOREMAN or MANAGER, in either of the above Trades.—Age 24; ten years' experience in both Trades.—H. S. 23, James Street, Covent Garden, W.C.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 26; thoroughly experienced in the profession. Eleven years' experience in establishments. Good references.—G. J., 47, James Street, Oxford Street, W.C.

FOREMAN, or FOREMAN and PROPAGATOR.—Long practice in Hard and Soft-wooded Propagating, and Plant Growing for Market. Highest references.—J. M., Mr. Ford's, 28, Rowland Grove, Wells Road, Sydenham, Kent, S.E.

To the Trade.

HOUSE FOREMAN, WOOD PROPAGATOR, and good SALESMAN.—Age 36; would not object to Grow for Market.—PROPAGATOR, 5, Cemetery Street, Biggleswade.

GENERAL NURSERY FOREMAN, PROPAGATOR, and SALESMAN.—Has a thorough knowledge of the Management of Fruit Trees, Roses, Conifers, and general stock in Nursery and Forcing Departments. Capable of taking the Management of a Nursery to any extent. Good references.—FOREMAN, Messrs. Law & Co., Clapton Nursery, London, E.

PROPAGATOR, GENERAL FOREMAN, PROPAGATOR, and SALESMAN.—Well up in Camellias, Conifers, Roses, &c., and general Nursery Stock.—X. Y., Millbank Nursery, 40, Millbank Street, Westminster.

ESTATE AGENT, or STEWARD and GARDENER. —Age 29; now leaving a situation where he has managed with success 1,800 Acres, of 600 Acres, large Gardens, Timber and Plantations, and the general Repairs of a considerable Landed Estate. Is a first-class Accountant, Correspondent, &c. References to present employer.—J. LE, Mr. Jennings, White Horse Hotel, Dorking.

FARM BAILIFF.—Married, no family; can take the full Management, or willing to Assist as Working. Wife can take charge of Dairy. Good references.—J. F., Crewmarsh Farm, near Wallingford, Berks.

FARM BAILIFF, at Michaelmas next.—Age 30, married, no family: thoroughly understands the Management of Cattle, Horses, Arable and Grass Land; also Breeding, Rearing, and Feeding all kinds of Stock. Wife has had the charge of a Nobleman's Dairy. Good references.—C. S., Chipping Warden, Banbury, Oxon.

To the Seed Trade.

TRAVELLER.—Age 37; highest references.—J. P., *Gardeners' Chronicle* Office, W.C.

WORK-MANAGER, Confidential CLERK, MANAGER of a Seed and Bulb Department, and general NURSERY SALESMAN, at Cheshunt and Waltham Cross Nurseries for the last 21 years, is now open for Engagement in any large establishment.—W. RUMSEY, Waltham Cross, N.

BOOK-KEEPER, or ASSISTANT.—An energetic young Man, desiring a practical knowledge of Horticulture, seeks an Engagement as above in General Nursery, where his time will be divided between office duties and the general work. Will recommended.—Y. Z., Post Office, Canbury, Kingston.

SHOPMAN, SHOPMAN and CLERK, Warehouse Foreman, or to Manage Country Shop or Branch.—Age 35, married; 18 years' experience in the Trade. Highest testimonials.—T. W. B., Messrs. Thos. Gibbs & Co., corner of Half-moon Street, Piccadilly, W.

SHOPMAN and general NURSERY SALESMAN.—Age 34; good knowledge of the business in all its branches.—D. R., 4, Cullum Street, City, E.C.

SHOPMAN, or COUNTER HAND.—Age 24; steady, active. Eight years' experience. Highest references.—G., 144, Caledonian Road, N.

COUNTER-MAN (ASSISTANT), in a Wholesale London Seed Warehouse.—Age 23; five years' experience.—X. Y. Z., Post Office, King Street, Covent Garden, W.C.

GOVERNESS.—A young Lady, accustomed to tuition, and who has resided some time in France, is desirous of obtaining a situation as above. Good references will be given and are expected.—B., 41, Wellington Street, Covent Garden, W.C.

IMPORTANT SALE of VALUABLE NURSERY STOCK.
MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, The Balham Nursery, Balham, S.W., on WEDNESDAY, October 11, at 12 for 12 o'Clock precisely, by order of Mr G. Edwards, a large quantity of valuable SURPLUS NURSERY STOCK, the whole of which is in capital condition for removing, and comprising 15,000 Quercus ilex, 15 to 2 feet; 1000 Aucuba Japonica, 15 to 2 feet; 800 Chinese and American Arbor-vitæ, 15 to 18 feet; 500 Portugal Laurels, 4 to 5 feet; 1000 Ligustrum ovalifolium, 500 Berberis aquifolium, Laurustinus, common Laurels; a large quantity of Ornamental Trees and Shrubs, comprising Planes, Limes, Birch, Acacias, &c.; 300 fine Standard and Dwarf ROSES, of the best varieties, by name; 500 Irish Yews and Irish Juniper, Evergreen and Flowering SHRUBS, in borders; some large Double CAMELLIAS, and PAMPAS GRASS, in pots, &c.
May be viewed two days prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers and Valuers, Leytonstone, E.

Re Mr. R. Glendinning, Deceased.
ABSOLUTE SALE.
To NURSERYMEN, SEEDSMEN, and FLORISTS.
High Road, Turnham Green, Middlesex, Hard Gate, and known as the Chiswick Nurseries.
MR. J. A. SMITH is instructed by the Executrix to SELL by AUCTION, on the Premises, as above, on TUESDAY, October 10, at 2 o'Clock P.M., in TWO LOTS, the valuable LEASEHOLD HALL, &c., of the important Business Premises and Residential Property, known as the CHISWICK NURSERIES, established in the name of Glendinning for nearly 30 years, extending over or about 4 acres of Freehold Land, in convenient plots, comprising the Residence, Shop, Offices, Warehouse, &c., and the 3-roomed Cottage adjoining; also a Range of Glass Houses, and the Nursery attractive portion of the High Western Road, and a depth of about 750 feet to the Great Western Railway. The Lease, dated 1854, per annum; and Gore Cottage adjoining, £43 per annum. LOT 2 comprises the Nursery on the West side of Chiswick Lane, with Residence held on Lease at the reduced rent of £60 per annum. The purchaser in each case may arrange to take the Greenhouses and other Erections, Nursery Stock, Utensils, &c., at a valuation, if required. May be viewed.
Further printed particulars, with plans and conditions, of W. H. MARSHALL, Esq., Solicitor, Bridge Avenue, Hammersmith, W.; and of J. A. SMITH, Esq., Auctioneer and Land Agent, Hammersmith.
NOTICE.—The ENTIRE NURSERY STOCK will be SOLD by PRIVATE TREATY about the LAST WEEK in OCTOBER. See Advertisements.

4000 Araucaria Imbricata.
To GREENHOUSE, NURSERYMEN, and OTHERS.
HILLFIELDS, BURGHFIELD, near READING.
MESSRS. HASLAM AND SON have received instructions from Mr. Gaines, Jun., to SELL by AUCTION, on the ground adjoining the Gardens of Hillfields, Burghfield, on TUESDAY, September 26, at 2 o'Clock in the afternoon punctually, in suitable Lots, 4000 ARAUCARIA IMBRICATA, raised from choice seed, specially imported by Horatio Bland, Esq., direct from Chili.
Note—The Auctioneers desire to draw special attention to this Rare and Choice Lot. They have been unsupplanted several times, and are now strong, healthy, and well-rooted, varying from 1 to 3 feet in height, and in the best possible condition for immediate removal. The whole will be sold without the slightest reserve.
May be viewed one week prior to the Sale on application to the GARDENER at Hillfields; and Catalogues had at the Office of the Auctioneers 17, Friar Street, Reading.

Primley Park Nursery, near Blackwater.
To GENTLEMEN, NURSERYMEN, and OTHERS ENGAGED in PLANTING.
MESSRS. WEEKS AND WATTS are instructed by the proprietor, Mr. Holder, to SELL by AUCTION, at the above Nursery, on TUESDAY, October 10, at 11 o'Clock (in consequence of the expiration of a lease of very long near), the whole of the thriving NURSERY STOCK upon Ten Acres, including Evergreens, Conifers, and Deciduous Shrubs, Ornamental and Forest Trees, Standard and Dwarf Roses, together with some fine Standard Rhododendrons, Clematises, and the Extensive Fruit Trees, &c.; a few Ornamental FLOWER POTS and VASES.
May be viewed the day previous and morning of Sale, and Catalogues had of Mr. Holder, York Town, Blackwater; or of the Auctioneers, Wokingham, Berks.

Periodical Sale of Pure-bred Hereford Cattle.
MR. DUNCKLEY'S NEXT PERIODICAL SALE by AUCTION will take place in the Cattle Market, Hereford, on WEDNESDAY, October 18, being the great Cattle Show Day, and the second day of the Annual Herefordshire Agricultural Society. Early ENTRIES are respectfully solicited.
59, Broad Street, Hereford.

Waresley Park, near St. Neots, Hunts.
IMPORTANT SALE of PURE-BRED SHORTHORN CATTLE.
MR. JOHN THORNTON will SELL by AUCTION, without reserve, on THURSDAY, October 26, at 1 o'Clock, Waresley Park, a valuable herd of PURE-BRED SHORTHORNS, the property of the Hon. Col. Duncombe. Bred for a lengthened period from the most fashionable strains of blood, the collection between 60 and 70 head of Cows, Heifers, and choice young Bulls, among which are many representatives of the Fame (Mr. Booth's) Finella, and Countess tribes, and others descending from the celebrated stocks of Mr. Stratton, Mr. Torr, Mr. Adams, Fawsley, and Lindsay. The Sires have always been very superior bulls of high pedigree, inheriting the Cambridge Duke (10,906), the Waterloo Duke (11,076), Wetherby (9,206), by 2d Duke of Wetherby, the famous son of the prize cow Duchess 77th, and Windsor Lad (17,823), being the last. The whole are in good condition for breeding purposes, and sound constitutions, and form a very healthy uniform herd.
Catalogues may be had of Mr. CHANDLER, Waresley Park, St. Neots; or of JOHN THORNTON, 15, Langham Place, London, W.

Smithfield Club, 1871.
THE EARL of POWIS'S PRIZE for ENGLISH ESSAYS.
A SPECIAL PRIZE of TWENTY POUNDS is offered by THE RIGHT HON. THE EARL OF POWIS, M.P., for the best ESSAY on the Use of the Steel Instrument, that shall be an efficient substitute for the Pole Axe, for Slaughtering Animals, by separating the spinal marrow from the brain. The Essay, which must be original, printed, must be delivered at the Office of the Hon. Secretary, on or before OCTOBER 1, 1871, addressed as follows:—
Mr. DAVID FULLEN, Assistant Secretary.
Corner of Half-Moon Passage, Piccadilly, London, W.

A LTRINCHAM AGRICULTURAL SOCIETY.—THE TENTH ANNUAL SHOW will be held on THURSDAY, September 28, when FIVE HUNDRED POUNDS and SILVER CUPS will be GIVEN in PRIZES for FAT CATTLE, Sheep, Pigs, Dogs, Poultry, Roots, Grain, Cheese, Butter, Implements, &c.
ENTRIES CLOSE SEPTEMBER 23, 1871, with FORMS of ENTRY, can be had on application to the Secretary,
JOHN BRADSHAW, Altrincham.

THE BIRMINGHAM CATTLE and POULTRY SHOW, 1871.—The TWENTY-THIRD GREAT ANNUAL EXHIBITION of FAT CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, ROOTS, and IMPLEMENTS, will be held in Bingley Hall, on SATURDAY, MONDAY, TUESDAY, WEDNESDAY, and THURSDAY, DECEMBER 2, 4, 5, and 6.
PRIZES to the amount of TWO THOUSAND TWO HUNDRED POUNDS will be GIVEN.
PRIZE LISTS, CERTIFICATES of ENTRY, and every information may be obtained from the Secretaries.
The ENTRIES CLOSE on SATURDAY, October 28.
JOHN B. LYTHALL, Secretary.
Offices, 39, New Street, Birmingham.

SMITHFIELD CLUB SHOW, AGRICULTURAL HALL, ISLINGTON, DECEMBER 4 to 8.
ENTRIES CLOSE NOVEMBER 1.
THE LAST DAY for receiving APPLICATIONS for SPACE for IMPLEMENTS and MACHINERY, &c., is OCTOBER 2.
Forms of Application, with Rules and Regulations, may be obtained of Mr. DAVID FULLEN, Assistant-Secretary, corner of Half-Moon Passage, Piccadilly. All communications should bear outside the words "Smithfield Club."

SMITHFIELD CLUB FAT CATTLE SHOW.—THE ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY afternoon, December 4, and four following Days.
Early ENTRIES are respectfully solicited. Special Entry Forms by the reference letters as under.
CATTLE.—A. For an OX or STEER (in any Class).
" B. For a COW or HEIFER (in any Class).
" C. For a PAIR (in any Class).
SHEEP. " D. For a Pen of three WETHERS.
" E. For a Pen of three RAMS. [Stock.
" F. For a SINGLE WETHER SHEEP in Extra
PIGS. " G. For a Pen of three PIGS (in any Class).
" H. For a SINGLE PIG in Extra Stock.
ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.
Prize Lists, Forms of Certificates, and all information, may be obtained of Mr. DAVID FULLEN, Assistant-Secretary, at the Office of the Honorary Secretary, corner of Half-Moon Passage, Piccadilly, London, W.
N.B. All communications respecting the Show must be addressed to the Assistant-Secretary, as above, and should bear outside the words "Smithfield Club Show."

The Agricultural Gazette.

SATURDAY, SEPTEMBER 23, 1871.

THE country is considerably worse off now than it was this time last year, both in respect of FOOT-AND-MOUTH DISEASE and PLEURO-PNEUMONIA. In the beginning of last autumn the number of attacks of foot-and-mouth complaint in one week did not exceed 18,000, now we may fairly calculate upon more than

20,000. Pleuro-pneumonia is not so rife as foot-and-mouth disease, fortunately for owners of stock, but it prevails more extensively than it did during the corresponding period of last year. According to the last weekly returns there are about 150 fresh attacks, against less than 100 last year. The rate of increase of lung disease bears no comparison with the more infectious foot-and-mouth disease; for example, commencing with the month of May last, we find that the cases of pleuro-pneumonia had a weekly average of less than 100; in June the increase amounted to about 30, in July there was a decrease to the May average, in August a return to the average of July. The highest number of weekly attacks reported did not exceed 150.

It is not contended that our sources of information are so complete that no chance of error exists; on the contrary, we are prepared to allow that many cases escape notice altogether; but the same thing is true of foot-and-mouth disease, and, therefore, the comparison between the two affections may be accepted as fairly correct. In the month of May we had an average of less than 1000 weekly attacks of foot-and-mouth complaints, during June there was a weekly increase of about 400 cases. In July the number was more than doubled, making a total of more than 3000 cases, as compared with 1400 of the previous month. During August the increase was still more serious; in the first week of that month the attacks reached a total of nearly 5000; in the second week 1000 were added; in the third week the total suddenly mounted to more than double that of the previous week, reaching nearly 13,000; and in the last week of the month the attacks reached nearly to 22,000. Meanwhile, it is observed, there was no corresponding increase in progress of the disease abroad, but, on the contrary, in most parts of the Continent the malady assumed insignificant proportions. Spain is still suffering from it, but the last reports from that country are favourable. Several cargoes of Spanish cattle have been detained at the outports for slaughter, in consequence of the discovery of diseased animals among them; but foreign animals generally have been particularly free from the disease, at least when landed in this country.

Allowing a full share of blame to the movement of cattle from unscheduled countries, we are sorry to be compelled to admit that there remains a very large balance of mischief to be accounted for, and, judging from our own observation, and also from the public records, we are bound to refer this balance to a general laxity in the administration of the laws of sanitary police. A very little decided action would make an immediate impression upon the diseases about which everybody, in theory, cares so much, and in practice so little; but, unfortunately, there is no such thing as an universal basis on which to discuss even the necessary measures. If it were generally allowed that foreign store stock are dangerous, feeders in this country would not buy them, and consequently they would cease to be exported; if every owner of cattle and sheep believed that infectious nature of lung disease and foot-and-mouth complaint, great care would be taken before fresh animals were allowed upon the farm, and no one having a diseased beast would conceal it, or send it to a fair or market to the injury of all animals with which it may come in contact. The fact is, farmers elect to deal with their diseased animals as they think best for their own interests; they dislike restrictions, and strongly object to have their affairs regulated for them by the local authorities.

We are told that the recent application from the Northamptonshire committee for an Order to stop fairs and markets in certain infected districts, was made after consultation with some of the leading agriculturists of the country; but had the application been granted, we can imagine how the attempt would have been met by the agriculturists of surrounding counties, the trade of which would have suffered by the prefibition, which, after all, would have been futile, because the disease would enter the district again as soon as the markets were reopened. A general stoppage of fairs and markets all over the country is simply out of the question, such a measure would be entirely out of proportion to the importance of the disease.

Farmers must, it appears, rely mainly on their own care and forethought if they desire to keep their animals free from infectious maladies; and we can confidently assure them, by way of encouragement, that strict isolation is a very effectual preventive against contagious affections of all kinds.

HAVING concluded harvest under greater difficulties than we have ever before experienced, we review our work, under the impression that we may be useful thus to others. Farming in the south-west of England, we generally have early crops; indeed only once before the present year since 1863 have we had a load of corn unsecured on the first day of September. This season, however, we have been full a fortnight later.

Our perplexities commenced in the hay field, from which scarcely a single rick has been got together without wet. We have thus been fain to make small ricks, snatching up a few waggon-loads of the fittest over night, to be ready to unload and add to next day if the weather would allow.

With every care, however, in the catching weather of this year, hay has been often put together insufficiently made, so that one had to watch for over-heating; and as we have found the rick ventilator most useful, we recommend its adoption on every farm. Failing an appliance of this kind, it may be necessary to cut a hole or two in the rick for ventilation, which is not looked upon as a sign of good management.

The Wheat we had to deal with thus has been the Talavera and the Rough Chaff White, both very delicate sorts in a damp season, so much so, that with the former we were not without evidence of its germinating in the ear before the crop was ripe, while the woolly chaff of the latter held the moisture with perplexing pertinacity. Added to this, a violent thunderstorm — and we have had three at different times during harvest—caused the sheaf butts to be immersed in water, and that, in this wet weed-growing season, made it necessary to put this crop together in "windrows" preparatory to ricking. These have kept it tolerably safe, but with mildew, weeds, and a sparse plant, half a crop has been more costly than is usual with a double one.

In one 50-acre piece, part of which was scrawled from an attack of insects, we found bagging or hewing to be best. In another part hand-reaping picked it best from Poppies and other sand-loving weeds; whilst, where it stood at all well, we have found SAMUELSON'S Eclipse Reaper a most handy and efficient implement.

These remarks upon our Wheats of this year will have told the reader that we farm light land, which, as a rule, has been this year very poor and very dirty.

We have also had to deal with 100 acres of Barley this season, 50 with young seeds, and 50 with bean stubble.

The first has been harvested with difficulty, as the crop was a very heavy one, whilst the seeds, broad Clover and Hop Trefoil, were so good as to render it difficult to cut with the reaper, which, indeed, took off the Clover too close to the ground. We have, therefore, had to mow most of it with the scythe, and to wait until the seeds had dried before we carried. This, then, had to be got in as weather would permit, and, like the hay, it has been done in bits, and we do not have every reason to be satisfied with the result, as though only seeded to the extent of less than 6 pecks an acre, we have secured a very large crop of the best Pedigree Chevalier Barley.

A neighbouring farmer, in order to utilise a large growth of Alsike Clover in his Barley, threshed out the grain in the field, putting up the seeds and straw into a rick for fodder; this we are inclined to think was no bad plan, as the Barley was over-ripe and not in bad condition.

Our 50 acres of Barley after Wheat were a good crop, and fell nicely before the machine, which we cannot extol too highly, as it easily cuts down 12 acres a day, and, unlike the mowers, does not need the many quarts of cider which they drink per acre. Indeed, all things considered, we look upon it that the cost of the machine has been saved in a single year. At present we hear of a little "rattening," and less violent opposition on the part of the men on some farms, but the time will come when they will want to borrow "master's mower" to cut down the corn in their allotments, as they do now the threshing-machine to knock out their bit of grain. With regard to the latter, in our parish, where as many as 24 flails used to be kept at work all the winter, not a single flail can now be found. And yet wages have increased and must increase, —a circumstance at which we shall ever rejoice, when we find it means better lodging, better food, and better clothing, instead of, as is too often the case, more drink.

—— THE price of Wheat somewhat declined on Monday; it was 1s. per qr. lower than during the previous week—and on Wednesday the reduction was maintained.——In the Cattle Market prices have rather advanced, the number shown on Monday being below the demand, and the demand on Thursday also being barely supplied.—In the Seed Market the tone is firm but quiet.

—— An amusing rivalry in repartee occurred the other day at an agricultural meeting at Castle Douglas, where Mr. CAIRD, C.B., proposed the toast "THE AGRICULTURAL INTERESTS;"—

"Though he was not the oldest man in the room, he could remember about 35 years ago, when he began farming; so that nobody could say he was not an experienced farmer; he had probably had as much experience as most men in the room. He remembered a meeting which was held in Wigtown in honour of the late HUGH HATHORN, of Castlewigg. Lord GALLOWAY was in the chair, and very properly praised that particular breed of cattle which bears the name of the province from which he takes his title. He (Mr. CAIRD) also had a very great respect for these black cattle, but he ventured at that meeting to say, from his own early experience, that the Ayrshire cattle, with that shape of a wedge which they possess, when once introduced to the district, would drive their way among all other breeds, the native breeds not excepted. LORD GALLOWAY replied, in a very good-humoured way, that the Ayrshires must have their horns cut off before they could act as a wedge in the way he had mentioned. It was a fact, however, that with the industry, energy, and perseverance exhibited by the dairy farmers of Galloway, the Ayrshires had done great things—the quality of the cheese produced had been gradually raised from Dunlop to Lancashire, and finally to Cheddar, which Lord GALLOWAY introduced

only to spare less than 4,000,000 for the all-important purpose of producing our daily bread? Is this justifiable or profitable? Can any excuse be found for it? I reply, none of valid worth; and I speak with the confidence of 25 years of practical experience, for while the average Wheat acres are only about 9 per cent. of our agricultural area, on my farm, since I occupied it, my average has been fully 38 per cent of Wheat acreage, with an average yield of 10 to 12 bush. per acre more than the general acreage of the kingdom, and this on land below the general average, but annually increasing in fertility. It is a remarkable confirmatory fact and coincidence that, although Mr. PROUT and myself are personally unknown to each other, and manure our farms on opposite principles, suited to the differing soils, yet we both have 38 per cent. of Wheat acreage. Mr. PROUT has 153 acres in Wheat, but no permanent pasture, and I have only 14 acres, eight of which I shall this year break up as unprofitable. The prize Oxfordshire farm had, too, only some 14 per cent. of ill-conditioned pasture. Shall we, then, be content to continue the suicidal practice of paying to foreigners annually some 20 to 35 millions sterling for that which we might produce profitably at home? The cause of this unprofitable state of things is obvious and remediable.

It is our attachment to the old pastoral age, when the acres are many and the population few. One half of the United Kingdom is occupied by permanent pasture, much of it exhausted, weedy, and nationally most unprofitable; deprived of the benefits arising from cultivation, yielding a minimum of produce and employing a minimum of labour and capital. Making due allowances for climatic peculiarities, our Wheat area and Wheat produce might be much more than doubled, as it has been on my farm, Mr. PROUT'S, and many others, and this without damage to the soil. But, then, what a change would come over the scene! Half-starved animals would no longer be permitted to wander over large areas of poor, unproductive pastures, with little fields, great timber-encumbered hedgerows, deep ditches, and every unprofitable topographical arrangement. We should then see a multiplication of our most approved and profitable models of modern agricultural improvement.

"But, before we can realise those happy results, new ideas must enter the minds of both landowners and tenants, and how painfully slow this must be! for we are all creatures of custom, and if I and my forefathers had been farmers I doubt whether I should have so greatly deviated from the old well-beaten track.

"But a change must come, and every effort should be used to make it as speedy as possible. Steam has so multiplied our power, our wealth, and our population, and so enlarged our wants, that there will be a clamour for a more common-sense and commercial use of our soil.

"But while I insist upon the necessity for breaking up poor pastures, it is not for the too common purpose of their being 'run out' by a succession of corn crops, but that they should be farmed on the best principles of modern agriculture.

"Our legislators will do well to watch the signs of the times, and adapt their land laws to our altered circumstances, or that our accumulated wealth may flow freely into agricultural improvement, and thus, by enlarging the employment of labour and capital, greatly increase our home-grown food supply.

"MILLS & SMITH, of Woolston, has 49 per cent. of Wheat, or more than five times the average of the kingdom. His own statement is—'76 acres of excellent Wheat, 26 acres of excellent Barley, 39 acres of first-rate Beans, 11 acres of roots, 11 acres of Clover, 4 acres of Potatos.' He also says:—'The heavy weight of corn, cropping 141 acres out of 166, is worthy of notice.' What will poor grass-landers say to this?

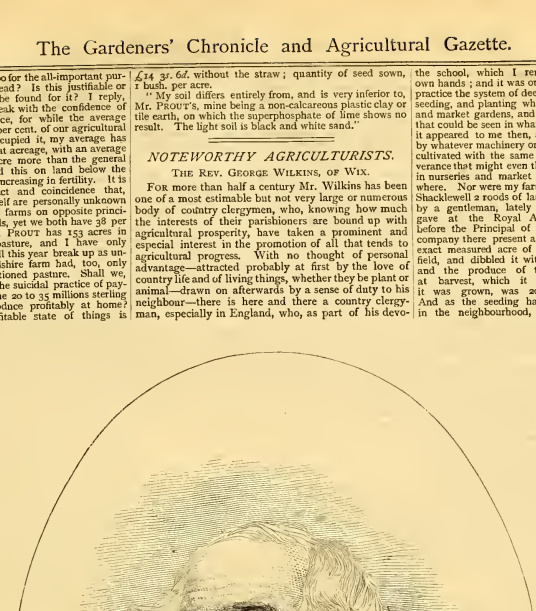
"High farming and an increased proportion of Wheat will necessitate considerable modifications in farm leases. I find that Rivett bearded Wheat succeeds well on heavy land after white or red Wheat. I have this bad year 5 qr. 2 bush. per acre after 6 qr. of white Wheat. The Rivetts weighed 63 lb. per bush., sold for 54s. per qr., and realised £14 3s. 6d. without the straw; quantity of seed sown, 1 bush. per acre.

"My soil differs entirely from, and is very inferior to, Mr. PROUT'S, mine being a non-calcareous plastic clay or tile earth, on which the superphosphate of lime shows no result. The light soil is black and white sand."

NOTEWORTHY AGRICULTURISTS.

THE REV. GEORGE WILKINS, OF WIX.

FOR more than half a century Mr. Wilkins has been one of a most estimable but not very large or numerous body of country clergymen, who, knowing how much the interests of their parishioners are bound up with agricultural prosperity, have taken a prominent and especial interest in the promotion of all that tends to agricultural progress. With no thought of personal advantage—attracted probably at first by the love of country life and of living things, whether they be plant or animal—drawn on afterwards by a sense of duty to his neighbour—there is here and there a country clergyman, especially in England, who, as part of his devotion to the best interests of his people, is to be found taking a lead in whatever tends to local, county, and even national agricultural improvement: and such an one, during almost two successive generations of us, is, and has been, Mr. Wilkins. Resident in early life where that which now is London was covered with the most richly cultivated market-garden fields, he from the first became acquainted with the merits of deep and thorough cultivation; and, whether in Lancashire, where he was for many years incumbent of a small parish near Blackburn, or in Essex, where he has long been known, both as the home-loving and warm-hearted parish clergyman, and as the outspoken public-spirited advocate of agricultural improvement, he has urged, whether in private intercourse with neighbours, or at public meetings, or in public prints, the importance of that intensive agriculture with which he thus first became familiar. And not only by word and observation, but by actual practice and example has he taught and learned. Thus in the very outset of his career, while still a master in the Hackney school, where he had been a pupil,—



THE REV. GEORGE WILKINS, OF WIX.

"There was a plot of ground," he tells us, "near the school, which I rented and cultivated with my own hands; and it was on that piece of ground I put into practice the system of deep and thorough cultivation, and seeding, and planting which I had seen in the nurseries and market gardens, and which was superior to anything that could be seen in what are designated farms,—though it appeared to me then, as it does now, that all farms, by whatever machinery or implements used, ought to be cultivated with the same science, manual skill, and perseverance that might even then, as now, be seen in operation in nurseries and market gardens round London and elsewhere. Nor were my farming and seeding confined to my Shacklewell 2 roods of land, for at the age of 16 (assisted by a gentleman, lately dead, and who will lecture I gave at the Royal Agricultural College, confirmed before the Principal of the College and the respectable company there present all I had stated) I hurdled in an exact measured acre of land in a neighbouring 20-acre field, and dibbled it with just 1 peck of seed Wheat: and the produce of this, when threshed by hand at harvest, which it was on the plot on which it was grown, was 200-fold, or exactly 2o4 pecks. And as the seeding had caused considerable interest in the neighbourhood, the field being a portion of a very large farm, many gentlemen and others were present at the threshing, winnowing, and measuring; and several of those gentlemen afterwards each dibbled his acre of land, and with equal success; but the expense and tediousness of the dibbling, separate threshing, &c., were too great to be persevered in, for there was none of the machinery to facilitate and perfect farming operations that are now seen in general use throughout, I believe, the whole civilised world.

"But I must come to my parish of Wix, the living of which I entered upon in January, 1837; and to carry out my farming views, being in the very centre of one of the finest landed districts in the kingdom, I at once determined to enter in earnest upon the cultivation and seeding of land, according to the system I had adopted and in part put into practice. For this purpose I took of a very aged man two small fields, and to them I afterwards by purchase added a third. But I will confine myself to the two first; and here is a brief account of what I did to those two fields. They were of course very full of Couch-grass and all other weeds, or what are called weeds. The first thing I did, therefore, was to commence getting rid of the Couch and other weeds, and for this purpose I ploughed my land during the first summer 11 times, going deeper and deeper every time; and by these means, assisted by the scarifier, harrow, and roller, I got out, I may say, nearly mountains of rubbish of nearly all kinds. And of this I made heaps in several places of the fields, and to these I added the huge hedge banks, which I grubbed up, and the stuff I scoured out of the ditches. 'And of course, Mr. Wilkins, you burnt the whole, as farmers would,' and writers advocate,' Mr. Observer, I did not, for I would nearly as soon set fire to dung-heaps in my farmyard; but having made the whole into heaps, by the fermentation of them, all seeds of weeds were destroyed, and then followed the destruction of the Couch and weeds also, which I used for the dressing for my subsequent crops."—These, I will here state, were, in the larger field—Wheat for 14 years in succession, the seed having been in general 2 pecks—or half a Winchester bushel per acre. In general, I write—but I sometimes had an acre or more seeded with 1 peck only, and sometimes with only half a peck, and the average yield for the 14 years was 44 bush. an acre, and one year the crop was 55 bush. an acre, the seed having been below 2 pecks; and one year, from the same quantity of seed, the yield was only 32 bush. an acre; but the average, I repeat, of the 14 years in succession with Wheat was 44 bush. an acre. And I here most emphatically state, that my land being near the village, and where two roads cross, I also got as many people as I could to witness both the putting in the seed and the threshing and measuring of the crops, which was always done by machinery, and openly in the fields where

it grew. But as some readers, perhaps, will be sceptical, I inform them that the yield of 55 bush. an acre was threshed and measured in the presence of several individuals as sceptical as themselves, and who afterwards employed a surveyor to measure the field, and not being satisfied with his measurement, they measured it themselves, and found the calculated part of the field to be rather less than it was stated to have been.

"But I must here state that, as well as so completely cultivating my land the first year I had it, I also drained it, making the mains 6 feet deep, and the branches 4 feet; and not being able to procure pipes at that time I was compelled to use shingles from the sea-shore; and I will here observe, that those drains work as well now, after 33 years' use, as they did the first year which they were made. And I will add another thing, which contributed I believe not a little to, what I consider, the unusual result of my cultivating and seeding "——

Mr. Wilkins goes on to speak of the fact that he encouraged the breed of moles in his land, which, as he contends, ignorantly destroyed by Mr. Smith, of Woolston, and other agricultural authorities. We are, however, here rather concerned with the presentation of such a portrait of our friend as may give the leading points of our agricultural indebtedness to him; and it is not necessary, therefore, to enter upon the details of his farming practice.

Mr. Wilkins has long been one of our agricultural heroes. At a great age, with all his old energy of mind, and with even more than ever of that noble bodily presence which has necessarily contributed somewhat to the great personal influence which he exerts, he retains that vivid interest in agricultural affairs which has led him for so many years to urge the principles of garden practice on the acceptance of the farmer—he still retains the perfect simplicity and lucidity of that pure Saxon English style which has always given his writings one of their chief attractions for country readers—he retains unabated that power of good-natured satire, by which, for so many years, agriculturists have been instructed and amused. He has been a welcome contributor to these columns during, we believe, all the years that we can claim for them, and we hope that he will long continue to discourse in them for the advantage of our readers.

OUR LIVE STOCK.

CATTLE.

No very high prices were given for Shorthorns at Holly Bank on the 13th inst. Sir HENRY, called May 5, 1871, got by EARL OF BARRINGTON (26,051), was purchased for 35 gs. by the Earl of Lichfield; LORD FOPPINGTON 2D, calved March 21, 1871, became Mr. Alden's at 33 gs.; and LORD DORKING, calved last February, was sold to Mr. Oldacre at 22½ gs. The remaining cattle were generally sold at from 17 to 25 gs. each.

—— On Tuesday last a large company assembled at Ozleworth Park, Gloucestershire, to witness the sale of the entire herd and flock of the late Sir John Kolt. After luncheon the auctioneer proceeded to sell 36 head of well-bred animals, which realised the fair average of £41 3*s.* 4*d.* each. Thirty females made £41 17*s.* 2½*d.* each; six bulls made £36 15*s.* each, and the entire proceeds of the Shorthorn sale was £1476 6*s.* Some of the best bred lots fell to Lord Fitzhardinge, who purchased for 50 gs. DUKE OF AIRDRIE (8,660), a nice white cow of the "Darlington" tribe, for 240 gs.; *Bracelet 7th* by GRAND DUKE 7TH (19,877), for 60 gs.; *Ursula of Ozleworth 2d*, by LORD RED EYES 4TH, of the Didmarton and Tortworth "Ursula" tribes, for 74 gs., and DUKE OF OZLEWORTH by 3D DUKE OF CLARENCE, and out of *Dora* (lot 3), a very taking bull calf, for 46 gs. *Ursula 21st* by 7TH DUKE OF YORK, was bought for 70 gs. by Mr. G. Hooper. *Annie of Wetherby* by HEIR OF WETHERBY (24,126), was purchased by Mr. Spratt for 45 gs., and *Ursula of Ozleworth* by 2D DUKE OF COLLINGHAM, was bought by Mr. Gow at 90 gs. DUKE OF FUSSBOX by 3D DUKE OF CLARENCE, dam *Fidget 6th* by 7TH DUKE OF YORK, g.d. *Fidget 4th* by 4TH DUKE OF YORK, and previously coming in a direct line from cows of the same name by DUKE OF NORTHUMBERLAND and DUKE OF 2D DUKE OF CLEVELAND, ought to be a good bull. His breeding, indeed, is perfect, and it is to be hoped his stock will be so. No doubt the bull has been worked hard, which may account for his deteriorated appearance since the Kingscote sale in the spring. His appearance is not taking, but experienced breeders considered him cheap at 105 gs., at which price he passed into Mr. Gow's hands. Among the principal buyers we may mention the Rev. Mr. Weigh, Sir Walter Trevelyan, and Messrs. W. Marsh, Knight, Griffiths, Ind, Bush, Cornwall, Vevasis, and Pugh.

—— The Hon. Col. Duncombe, of Waresley Park, St. Neots, has entrusted the sale of some valuable Shorthorns to Mr. Thornton. The sale takes place on October 19, when some well-bred animals, of good colour and character, and nice quality, will be offered.

—— We are sorry to record the death, a fortnight previously to calving, of Mr. Cheney's pure-bred Duchess cow, recently imported from America into this country.

SHEEP.

At Holly Bank, on the 12th inst., Messrs. Lythall & Clarke sold the flock of Shropshire sheep so long bred by Mr. Willoughby Wood, who is about to let his home farms and retire from farming. The shearling rams, 28 in number, made an average of £10 5*s.* 9*d.* each; 38 ram lambs made from £2 2*s.* to £6 6*s.*, or an average of 58*s.*; 130 ewes made an average of 81*s.* each, and 70 ewe lambs made 52*s.* each. Among the highest prices were 29 gs. for lot 6, a shearling ram, and £6 each for a pen of five ewes.

—— At Ozleworth Park, last Tuesday, Mr. Thornton disposed of the late Sir John Rolt's Cotswold flock. The theaves, to the number of 142, sold very uniformly, at prices varying from 60*s.* to 70*s.* per head. One pen brought 86*s.* 6*d.* per head, a second 80*s.*, a third 72*s.* 6*d.*, and two pens were sold for 57*s.* 6*d.* each. Chilver lambs sold as high as 60*s.*, and two lots made only 27*s.* and 35*s.* per head respectively—the general price being from 40*s.* to 50*s.* per head. One two-shear ram made 15½ gs., and ram lambs sold as high as 8½ gs., and as high as 4½ gs. 6*d.* each. Three shearling wethers preparing for exhibition at Birmingham and Islington were sold for £13 10*s.*

—— The Milcote Down flock was sold on the 13th inst. For many years the late Mr. Adkins had blended the best Cotswold and Hampshire blood with Oxfordshire Down as a foundation, and he at length succeeded in producing a distinct type of Down sheep. The flock sold remarkably well, 28 rams going as high as £14 14*s.* on average. Ewes made from £3 3*s.* to £5 each, ewe lambs £6 6*s.* each, and wether lambs 60*s.* each. Among the principal purchasers were Mr. Howard, of Biddenham, and Mr. Humphries, of Pershore.

RAM SALES.

THE following are the highest and average prices fetched for rams sold in connection with the meetings of the Lothian Ram Society at Warrender Park last week, and of the Border Union Society's Show at Kelso :—

Leicesters.—Mr. Simson, Blainslie (39), highest, £29; average, £8 18*s.* 4*d.* Mr. Melvin, Bonnington (102), highest, £21; average, £7 4*s.* 10*d.* Mr. Allan, Hallyne (40), highest, £12 10*s.*; average, £5 15*s.* 9*d.* Earl of Southesk (13), highest, £26; average, £10 15*s.* Mr. Lees, Marwingston (50), highest, £15 15*s.*; average, £6 3*s.* Mr. Hope, Kirkhope (40), highest, £12 10*s.*; average, £7 4*s.* 7½*d.* Mr. Smith, Castlemains (40), highest, £13; average, £10 8*s.* 4½*d.* Mr. Clark, Oldhamstocks (35), highest, £55; average, £12 12*s.* 1½*d.* Mr. G. Watson, Esperston (21), highest, £18; average, £9 10*s.* 6*d.* The Duke of Buccleuch (56), highest, £22; average, £8 14*s.* 8*d.* Mr. Dinning, Addenbrig (48), highest, £20; average, £10 18*s.* 6*d.* Mr. Wilson, Woodhorn, Morpeth (54), highest, £30; average, £9 13*s.* 6*d.* Messrs. Robertson, Pencaitland (56), highest, £20; average, £10 6*s.* Mr. Forster, Elliugham, Chathill (32), highest, £32; average, £9 7*s.* 6*d.* Mr. Bolam, Low Trewitt, Rothbury (40), highest, £18; average, £8 13*s.* 10*d.* Mr. Wilson, Haymount (55), highest, £21 10*s.*; average, £10 7*s.* 6*d.* Mr. Hardie, Harrietfield (55), highest, £22; average, £9 6*s.* 6*d.* Mr. Hall, Maidenhall (50), highest, £22; average, £11 3*s.* 3½*d.* Mr. Robertson, Springwells (55), highest, £20; average, £10 9*s.* Mr. Bell, Linton (38), highest, £23; average, £12 2*s.* 1½*d.* Mr. Simson, Courthill (30), highest, £20; average, £10 6*s.* 6*d.* Mr. Hume, Wormerlaw (22), highest, £25; average, £10 14*s.* 9*d.* Miss Stark, Mellendean (36), highest, £100; average, £28 15*s.* 3½*d.*; Mr. Hogarth, Eccles Tofts (42), highest, £23; average, £9 17*s.* 10½*d.*

For the purpose of comparison we subjoin the entries since 1861, the highest and average prices in that period, and the names of the sellers who topped the sales :—

No. of Entries.	Year.	Sellers.	Highest. Average.

Cheviots.—Mr. Stevenson, Mount Lothian (24), highest, £7 5*s.*; average, £4 5*s.* Mr. Welsh, Ericstane (20), highest, £5; lowest, £7 12*s.* Mr. Johnston, Archbank (43), highest, £40; average, £7 17*s.* Mr. Plenderleith Moorfoot (26), highest, £8 5*s.*; average, £4 15*s.* Mr. Archibald, Glengelt (20), highest, £23; average, £6 17*s.* 6*d.* Sir G. Montgomery (23), highest, £10; average, £4 12*s.* 6*d.* Mr. Moffatt, Rinleith (59), highest, £58; average, £9 5*s.*

Shropshires.—Mr. Crawford, Pitlowie (20), highest, £6 5*s.*; average, £3 16*s.* 9*d.* Mr. Gibson, Woolmet (24), highest, £8 10*s.*; average, £4 16*s.* 9*d.* Lord Strathmore (35), highest, £27; average, £4 13*s.*

Cotswolds.—Mrs. Gibson, Woolmet (18), highest, £12 10*s.*; average, £6 12*s.* 2*d.*

Blackfaced.—Mr. Gray, Harperrig (22), highest, £20; average, £6. Mr. Bryden, Burnmeadie (24), highest, £12 10*s.*; average, £7. Mr. Aitken, Listonshiels (30), highest, £43; average, £12 2*s.* 6*d.* Mr. Melrose, Westloch (40), highest, £31; average, £9 12*s.* Mr. Wilson, Crosshouse (42), highest, £24; average, £6 10*s.* Mr. Archibald, Overshiels (60), highest, £23; average, £8 11*s.* Mr. Greenshiels, Westown (46), highest, £25; average, £12.

Shropshires.—The celebrated Sutton Maddock flock, in the hands of Mr. Henry Smith, has been before the public for a term of at least 20 years; and since 1852 has acquired a high reputation from the position it has taken in the Royal, the Birmingham, the Smithfield, and other showyards. It has been universally looked upon as a true-bred Shropshire flock, and leading ram breeders have frequently made selections from it to maintain and improve their stocks. The most successful exhibitors at the Royal Agricultural Society, at Wolverhampton, viz., Mrs. Beach and Lord Chesham, owe much of their victories to the use of Sutton Maddock rams, the same has been the case this year securing a prize and high commendation. The funeral of Lady Louisa Whitmore kept all the Apley tenantry away, and consequently not more than about 120 sat down to the luncheon, at which Sir Charles Morris proposed the most generous repast was provided, the table being amply filled with game and fruit, the gifts of the respected landlord. Business was rather slack for the rams, No. 1 going cheaply to Mr. Landor, at 10 gs.; No. 2, at 15 gs., to Mr. E. Lythall, who paid that sum for the hire of him last year; No. 3, at 8 gs., to Mr. Adams; No. 4, at 9 gs.; No. 5, at 10 gs.; No. 6 being let to Mr. Nock, at 9 gs.; and others making about similar figures. Lot 5, however, made 25 gs., to Mr. Brown, of Bockton. Mr. Gardour purchased five rams, and Mr. Cooke, six, the other buyers being Messrs. Roden, Wadlow, Cooper, Jewitt, Davies, Nicholls, Hanson, Wilson, Fletcher, Webster, Hatherall, &c. The average of the 55 was £8 18*s.* 2*d.* For the ewes, than which there has seldom been a better lot offered, the competition was much brisker—Mrs. Wadlow, Lord Boyne, Mr. Jowitt, Mr. Davies, and others, being eager to secure them. Prices, consequently, ruled high—190*s.*, 115*s.*, 105*s.*, and 100*s.*, being paid; whilst only one pen made less than 72*s.* 6*d.*, bringing the average up to 96*s.* 6*d.* for 81 sheep. Messrs. Lythall & Clarke, of Birmingham, conducted the sale.

—— At the recently held Peterborough ram fair, 50 shearling rams, the property of Mr. J. H. Casswell, Laughton, were sold by auction by Mr. Lumby at an average of £17 4*s.* 6*d.* each. The best price being 40 gs.; 48 shearling rams, the property of Mr. Tom Casswell, Pointon, were sold by Messrs. Mason at an average of £16 19*s.* 6*d.* each; highest price 56 gs.

Cotswolds.—At the September sheep fair, at Cirencester, Messrs. Moore & Hill sold 10 Cotswold rams, the property of Mr. Thomas Clarke, of Frampton Mansell, which averaged £7 17*s.* 6*d.* each; and seven rams belonging to Mr. E. Holmes, of Siddington, at an average price of £7 14*s.* 6*d.* Messrs. Acock & Hawk sold 15 rams for Mr. Russell Swanwick, of the Royal Agricultural College Farm, which made an average of about £9; and 12 rams, the property of Mr. Joseph Walker, of Compton Abdale, at an average price of £11 3*s.* Mr. James Hall sold 12 rams for Mr. H. Cole, of Ashbrook, at an average of £12. (The highest price was 31 gs.) Mr. Villar also sold 12 rams for Mr. Tucker, of Soundborough, at an average of £8; 10 rams for Mr. W. Smith, of Bibury, averaged £9 15*s.*; 10 for Mr. T. Beale Brown, of Salperton Park, at a similar average of £9 2*s.* 6*d.*; and seven Cotswold rams for Mr. Vaisey, of Stratton, at an average of £9 12*s.* These were all the Cotswold rams offered by auction, but Mr. Villar likewise sold 22 ram lambs, by Oxfordshire Down rams, out of Hampshire Down ewes, for Mr. C. Hobbs, of Maiseyhampton, which made an average price of £4 12*s.*

THE HARVEST OF 1871.

[The following is a third long report on the probabilities of the past harvest. The Scotsman writes to the *Times* as follows :—]

AFTER the three weeks' brilliant weather which immediately preceded the general commencement of harvest operations, few anticipated that we should now have to record, as the most conspicuous feature of the season, a great deficiency in the Wheat crop. Such, however, is the unwelcome fact, confirmed from many districts by the proof of threshing out. From Sussex, Cornwall, Somerset, and Gloucester, from the intervening country to Kent, Essex, and Norfolk, and from districts in several of the great midland counties, as far north as York, I have obtained returns from the occupiers of land and the owners of public threshing machines, and there is no exception to a reported deficiency, varying

from 6 to 12 bush. an acre. Basing a calculation on the areas from which these returns have been obtained, and testing it by my own observations, the conclusion arrived at is that we have this year a product—not of the best quality—of from 9 to 10 bush. an acre below that of an average crop. Assuming that there were an average number of plants on the ground—which, however, was only the case in exceptional instances—an examination of the heads of various kinds of Wheat, from wide apart localities, gives the following results:—Golden Drop, blank cells, 24 per cent.; Talavera, blank cells, 22 per cent.; Browicks, blank cells, 19 per cent.; Rivetts, blank cells, 13 per cent.; Rough Chaff, blank cells, 12½ per cent. Deducting these deficiencies from an assumed average product of 30 bush. an acre, the respective residues are 22½, 23½, 24½, 26½, and 26½ bush. per acre.

In addition to these deductions for blank cells, another should be made, equivalent to one or two bushels an acre, for the smallness of the ears, which are everywhere less than in ordinary seasons. In the best districts, such as the eastern division of Lincolnshire, the damaged grain, arising from mildew, rust, and laid crops, will likewise be a serious drawback to the outcome of the crop. The restorative weather of August had a marvellous effect in matters of grain as we have now secured, but after the torrents of rain and gusts of wind which prevailed all over England in the middle of July, knocking off the Wheat bloom and laying the straw, no practical man could anticipate a better result than we have now obtained. We must also remember the ordeal through which the plant passed in the month of June—the coldest for fifty years—under a night temperature ranging from 47° to 52°, when field labourers were everywhere to be seen at work with their coats on, cattle and sheep shivering under the lee of a hedge, or in the covert at midday under their mothers' wings, and Wheat turning blue in the stem and yellow in the flag before it was out in the ear. In my letter in your columns on the 24th of that month I predicted that the change which then occurred had come too late for the recovery of the Wheat crop, though highly beneficial to the grass and green crops, and the result has proved the correctness of the prediction. Wheat generally did not break into ear until later in July than in 1860, when reaping only began in September, and ingathering was carried into November, and in very late districts into the following year. In the Royal Agricultural Society's Report on the prize farm at Sherlow, in Staffordshire, the Wheat crop is estimated at from 32 to 36 bush. an acre, equal to an average of 34; but this is only an estimate from appearances, made on July 24, and appearances this season have everywhere been found to be most delusive when tested on the barn floor. Only yesterday, in company with the owner, I saw the produce of a field on Mr. Prout's wonderful anti-stock farm, in Herts, being threshed out, and, though fairly estimated before harvest by himself, the auctioneer who sold the crop, and the purchaser, at 8 bush. an acre, it is now admitted to be yielding only 4lb. This still looks a large crop, but it is only so by comparison. In the eastern part of Essex, embracing the great Wheat-growing hundreds of Rochford and Dangie, where 44 bush. an acre is not an unfrequent average, and was counted on before harvest this year, it is found to be turning out about 32. This fact is confirmed to me by reliable reports from the owner of a number of steam threshing machines in the one hundred and an extensive corn factor residing in the centre of the other. I have no fears in inferior districts, where 3 qrs. an acre were expected, two only were obtained. On my own small farm in Surrey I have not yet threshed out any of my crop, but the harvesters report that it handles perceptibly light on the prong. I am, therefore, convinced that the Wheat crop of this year is disastrously deficient, and that we shall have to import about 13 millions of quarters, costing probably £35,000,000, or half our national taxation. The following is the basis of the calculation:—

Last year, in my letter in your columns on September 11, I estimated the area of Wheat at 3,800,000 acres, and it turns out to be 3,773,275 acres, or 26,725 acres less. The home produce I estimated at 14,250,000 qr., the consumption at 21,250,000 qr., the seed requirements at 1,000,000 qr., making 22,250,000 qr., and the foreign imports required at 8,000,000 qr., and they have been 8,017,856 qr., or 17,856 qr. in excess of my estimate. Although a considerable breadth of Wheat-sown land was ploughed up last spring for other crops in consequence of Wheat failures, I am still inclined to adopt the area of last year—namely, 3,800,000 acres—as that of Wheat this year; and taking the average produce at 21 bush. an acre, we have in round numbers 10,000,000 qr.; deducting from this 1,000,000 qr. for seed leaves 9,000,000 qr. for consumption. Seeing then that the population has increased nearly half a million, equivalent to a consumption of 343,750 qr. of corn, and that the ability to consume of three-fourths of the population has been augmented to an equal extent by increased employment and wages, we have 687,500 qr. to add to last year's consumption, making 22,000,000 of quarters; deducting from this the 9,000,000 qr. of home produce, we have a deficit of 13,000,000 qr. to be provided for by foreign importations. In 1801 our wants were represented by an importation of 500,000 qr.; in 1840 by double that quantity, or 1,000,000; during the last three years they have fluctuated between 8,000,000 and 10,000,000 qr., and now we appear to require 26 times the foreign aid we did at the beginning of the century. To those who have long hoped, and perhaps still believe, that by improved farming home produce would overtake and outrun the increase of population, and that our only safety was independence of the foreigner, the above facts must be rather alarming. If, as Lord Derby said in the other day, the land of the country is capable of producing double its present yield by the application of increased capital and facilities to draw it out, of which I have no doubt, it is evident the owners of the soil have a serious responsibility resting upon them and the occupiers a great duty to perform. Since the Repeal of the Corn Laws, now 22 years ago, the rate of importations has far exceeded the rate of increase of the population, showing clearly a decrease in the home production, arising either from a reduced yield per acre or a reduced area under Wheat. We had no agricultural statistics at the earlier date to enable us to test the latter supposition, but as we are constantly taking in commons and reclaiming waste lands, there can be little doubt that our reduced Wheat produce does not arise from a reduced area under that cereal. What steps, then, are open to us to stay this decadence? Are there any general impediments to capital flowing upon the land? Would a national tenant-right facilitate it or leases induce it? On many of the larger estates in England the latter do not exist, nor would they be appreciated if offered, as the landlords have known hereditary principles on which dependence can be placed. But those who have not hereditary principles are increasing in number every day, and necessitating legal securities for the capital that has further to develope the resources of the soil. Laying down mediocrity soils in permanent pasture is one of the agricultural necessities of the day, but who would undertake this unless he owned the land or occupied it under a compensation agreement? On the other hand, if a tenant draws unfairly upon old pastures by breaking them up or applying the scythe, or exhausts old arable land by unnecessary parsimony or incompetence, the owner is equally entitled to compensation. The old and still favourite theory of production was to keep stock, with a profit if you could, without if you couldn't; but, as manure makers, stock must be kept, and in support of this theory I at one time strenuously advocated the system of feeding all the cattle we could from the foreigner, believing that if we had the privilege of feeding all the cattle we consumed we could grow all the corn we required. If anything could modify this belief, it would be a visit to Mr. Prout's farm in Hertfordshire, which I paid in June, and interestingly reported on in your columns last November. There I yesterday walked over 450 acres of land, all under the plough, on which not a hoof or a horn has been kept for ten years, except the work horses, and even these are all but superseded by the steam-engine. In an experiment made this season, and still open to inspection, on Potatos, Mangels, Swedes, Carrots, and Maize, I have found that excessive manuring does not lead to profitable results; but on Mr. Prout's system, applied on the Bagshot sand formation, I should not have expected any crop at all. The Potato crop, which was a failure with me, is true, equivalent to £3 an acre, but his main dependence is on the soil itself and the atmosphere, in opposition to shallow tillage and the dung-cart, and already a great part of his land is laid up in the rough, imbibing atmospheric nutriment for future crops. Whether or not this great experiment will succeed in the long run, cannot yet be considered a settled question, although it has now been on its trial for 10 years. It is difficult to make up one's mind on the subject, and Mr. Prout has not made up his own. The general tendency of his mind is to be governed by the applications of bone-dust, which I believe it is, there is no reason why it should not succeed; and, if it does succeed, it will create an era in the history of agriculture on strong soil. We know that the virgin soils of America have become exhausted from continued cropping; but then we know that the occupiers have not drawn upon the atmosphere for nitrogen by deep cultivation, and restored the minerals carried off by the crops by the application of artificial manures. Inductive reason has never yet done anything directly for agriculture, and it is therefore to experience alone that Mr. Prout is looking for instruction, considering it the only safe guide to any system worthy of becoming an adopted practice. If we compare this with Mr. Mechi's diametrically opposite principles and practice, where, on very similar soils, profitless stock-keeping is the basis of all his operations, it would puzzle the most impartial to decide which system to advocate or adopt, especially when we see, as I did this season, the best Wheat crops, in both cases, anywhere to be seen. Tiptree Hall is now unassisted, and those who formerly went there to hear advanced theories propounded, may now return to see good farming practised. It requires no balance-sheet this year to prove that the farm is in a paying condition, which must be doubly satisfactory to the owner, considering how often he has been asked to prove his theories by results. Mr. Prout, possessing no theory, only offers results for consideration, and these are as follows, for this year's crops, all sold off:—

	Acres.	£ s.	£
Wheat	153 at	13 10	equal to 2066
Barley	98 "	8 0	" 857
Oats and Beans ..	90 "	8 16	" 792
Clover and Sainfoin, growing, and in hay	88 "	14 16	" 1302
	429		£5057

Some Sainfoin has been retained for seed equal in value to £50, and the horses, six in number, have been maintained off the farm. After charging the farm with rent, at the rate of 30s. an acre, interest on capital at the rate of 5 per cent. per annum; rates, taxes, labour, manures purchased, £1500; and all proper charges; the result will be a nett profit of over £3 an acre. Mr. Prout has drained nearly all his land, 3½ feet and 4 feet deep, and considers, like many other occupiers on similar soils—marl and chalk—that the annual extra produce is equal to 8 bush. of Wheat per acre.

Coming now to the less important cereal and pulse crops, my observations lead me to the conclusion that throughout England and Scotland we have a very full crop of Barley, also of Peas; Oats an average, and Beans a little under. The latter are not yet all secured, but those still exposed have suffered no injury from frost, and are now likely to be got in safe. In all cases the straw is much longer than it was last year, but in many cases it is valueless as fodder, from discoloration, rust and blight. All crops ripened rapidly and so close together that labour could not be got to reap and secure them when ready. The reaping machine was extensively employed, and was more indispensable to the farmer; and yet in more quarters than one sporting landlords were found to be as great impediments to its progress as laid and twisted crops. It appears from this as if partridges had as much claim to consideration for disturbance as Irish tenant-farmers.

All forage and stock food crops are decidedly abundant, and much beyond early anticipations. Many good second cuts of grass and Clover have been obtained for fodder and seed. The cold state in which the early hay crop was got in, and the non-solution of the saccharine matter in the stem, from the absence of moderate heating in the rick, have left it devoid of that aromatic sweetness which it usually possesses, and goes some way to account for the considerable fall in price, which is no doubt partly due to inferiority in quality, as well as the abundance of the crop. There was ample room for a fall from last year's prices, namely, £9 for Clover, £8 for meadow hay, and £3 for straw per load. Green crops are all good and regular, although the Mangel roots are not so large as usual, for want of sun and heat. Swedes are also generally good, but as they are so sensitive to the attacks of the fly and other insects in the stem, from the absence of a

extensively unemployed and indifferently remunerated, while bread was at Protection rates, and beef and mutton at war prices, and yet pauperism decreased, and the labouring people of this country continued peaceable and loyal.

Surely this is something for a country to be proud of, as it is less due to the enjoyment of physical comforts than to a tacit appreciation of equitable laws! *Thos. C. Scott*, 19, *Kings' Arms Yard, Moorgate Street, E.C., Sept.* 15.

THE GARDEN OF THE FARM.—VII.

How and with what to Furnish it.

The modes of furnishing a garden are as varied as those of furnishing a house. Some elect to furnish all at once; others piecemeal, a little at a time. Some deal in second-hand furniture, others must have all new. Again, there are those who run after cheapness only, and more wise furnishers who chiefly value quality. The first and last inquiry of the former concerning anything is, Is it cheap? the latter only query, Is it good? Finally, some furnishers decry beauty, and try to crowd it out of house and garden alike with utility; others have learned the higher lesson that utility itself is more serviceable to man when fringed round with the grace of beauty. A couch, a chair, a bed, for instance, are not less comfortable, but running through and round the whole, like golden threads. A garden without flowers is like a house with bare walls, carpetless floors, deal tables, and hard, uncovered chairs. All is hard, raw, cold, comfortless. But paper the walls, down with the carpets, drape the tables, cushion the chairs, and comfort as well as beauty come in on the heels of the finisher, and cosiness and taste take up their abode and dwell there ever after. Smoothness, order, and, above all, the gleam of flowers, effect similar transformations in gardens. Such hints to enjoyment rise from utility into the regions of taste; and the two are found to be complementary the one to the other, and to make one really enjoyable garden between them. These considerations should never be lost sight of in furnishing the Garden of the Farm. We shall, therefore, begin by ordering the utilities aright, and end with fringing the same with beauty.

One more hint or two as to the mode of furnishing, before presenting an inventory of the goods themselves. A good deal may be urged in favour of furnishing houses a little at a time. It suits the limited means of beginners, and enables them to keep pace with changing fashion. But this mode is hardly applicable to the stocking of gardens. The plants grow into profitableness, and, for that reason, should be planted all at one time, and that the earliest possible. As to second-hand goods, most wise housekeepers fight shy of them for ordinary household purposes; they know of what them. Even greater reserve is needed concerning second-hand plants. Without a special and particular knowledge of their merits is forthcoming, it is better to have nothing to do with them. If, however, you know all about them, they may be better than new, inasmuch as they have been tried and not found wanting. Mere novelty as such should be wholly ignored. Farm gardens as a rule are far too small to be converted into experimental plots, and only varieties of acknowledged merit and proved worth should find a place in them.

Again, no one should ever purchase a new or second-hand plant merely because it is rare. It may possibly turn out to have been a cumberer of the ground, got rid of because it was worthless. Better far start with maiden—that is, new plants, from a nursery. In purchasing these, deal with the best and most respectable tradesman in the neighbourhood, whose character will be a guarantee of the quality of the goods, and their trueness to name. As to cheap plants, shun them as you would a plague: a real plague of lost time, vexation, and cumbering rubbish, they will certainly prove, if, in a moment of weakness, or fit of closeness, you are tempted to let them into your gardens. Good plants are cheap enough, as I shall show by-and-by; but excessive cheapness invariably means utter worthlessness. In gardening it is even more emphatically true than in farming, that the best of everything is invariably the cheapest. Hence the answer to the questions, how and with what to furnish the garden, may be packed into a nutshell, thus—With the very best of everything; as speedily as possible.

But thousands of farmers who are interested in the matter are helplessly asking what are the best fruits, vegetables, and flowers to grow? I purpose answering these questions as briefly as possible. It may be well, however, to preface these particular replies with a few words of general advice. Whatever else you choose or discard, be sure to grow only good varieties of fruit, vegetable, or flowers that thrive specially well in your neighbourhood. This advice is especially applicable to fruits, and among these more immediately to the Apple. The varieties of this fruit are almost endless, and there are very few neighbourhoods where some local variety has not acquired, and generally deservedly so, more or less celebrity. They seem to the climate born, to take to the soil as the babe to its mother; and their quality—well, every one approves it. The same thing, to a lesser extent, is found among Plums, Pears, Cherries, which, though more limited in number and less thronged with seedlings, are yet capricious as to locality, some varieties electing, in the virtue of hidden idiocracies, to thrive in one place and pine in another without apparent reason. But these niceties of adjustment of plants to localities must not be overlooked by those who would be successful in gardening. Plants reveal their preference by results, and these should be carefully gathered and noted for future guidance. Farmers are proverbial for their keen power of observation. There is large scope for its exercise in the furnishing of their gardens. Whatever their opinion of mere book knowledge—and it is often lamentably low—they have a high estimate of all that their own eyes have seen, their own hands handled, and their mouths have tasted, of the fruits of their own experience. Well, I appeal to that first; and not till they have exhausted that store would I counsel them to take my list of fruits, &c., into their gardens.

To do this with confidence, for as wide a mountain can see further, clearer, than another in the valley, so is the experience of one who has made these matters his special business, larger and even more trustworthy than that of those who necessarily lack the time, and it may be also the power to determine with any accuracy how will find a place here that has not been tested, and found good by experience. No variety will be omitted because it is old, none commended because it is new: quality alone can qualify for a place in the Garden of the Farm. Of course, in such necessarily short lists as can be given here, much that is good must be left out, nothing bad or indifferent will be admitted. Assuming either that the garden is walled around, or that there is room for some fruit trees upon the walls or roofs of the farm buildings, I will first of all name a few varieties of different classes of fruit suitable for such trees. For of roof space there is, or may be, in most of the country is prodigious. Every kind of roof, unless it be thatched, ought to have its whole area pressed into the service of production. Any kind of rough trellissing, of wood, iron, or even boughs, laid over it, that will keep the trees from 6 to 9 inches from the tiles or slates, will do. If the branches are laid on the roof the extremes of heat and cold are too great for their well-doing, but raise them slightly above it and they are safe. Grape Vines, Figs, Peaches, Apricots, Cherries, Pears, are some of the best fruits for roof covering, and they often may be grown on the south or eastern or western roof than on a wall. Next to the roofs there are the walls of the farm, whether formed of brick, stone, compost, mortar, clay, wood, or straw, to cover with trees. By the use of slight protective expedients and the employment of riders—that is, trees with long bare wands to carry the branches beyond rubbing range of the stock—almost every farm wall might be clothed with fruit-bearing trees. And then there are the back offices, the garden walls, and the walls of the dwelling-house, which, however, ought to be reserved for flowering shrubs of sweet smelling savour, so as to intervene between the noisome farms or outbuildings a considerable amount of space for trees may readily be found or made. All the southerly and westerly aspects must be appropriated to Grape Vines, Figs, Peaches, Nectarines, Apricots, and a few of the earliest Cherries and Plums, and one or two Pears, such as the Jargonelle or the Beaumontelle, where it is expected fine, or the Uvedale's St. Germain, where monsters are wanted for stewing. The eastern and northern sides of walls and roofs of buildings may be devoted to Plums, Cherries, especially Morello Cherries, Pears, Gooseberries, Currants, or Raspberries. The three latter come very fine on north walls in hot summers, full of juice and flavour, that cannot be attained by plants in the open, exposed freely to the heat of the sun.

Every inch of bare wall should be looked upon as so much waste land to be immediately occupied. A single foot of a 4 feet wall would grow a cordon tree that might yield two dozen fine fruit for the dessert, while no space is too broad nor high for a well-trained liberally cultivated small wall-tree to occupy and cover with a luscious harvest of golden or rosy fruit. Having thus, as it were, tempted farmers by dangling a full basket of odours rich and flavours sweet before their eyes, I will now proceed to guide them in the filling thereof, by specifying what sorts to grow. To that end I will begin with the Grape Vine, the king of the dessert. The Esperione and the Cambridge Botanic Garden are perhaps the two best Black Grapes for out-of-door cultivation. They are wonderful bearers, very hardy, and of excellent quality. The Trentham Black, Ingram's Prolific Muscat, and Black Hamburgh may be added to these in highly favourable localities, such as south walls or gable ends of houses. Among White Grapes, the Royal Muscadine, Early Smyrna, Prolific Sweetwater, Early Saumur Frontignan, and Pitmaston White Cluster are the surest croppers. For wine making, Miller's Burgundy, the Black Cluster, and the Claret should be grown; the latter is also worth growing for its fine scarlet leaves alone in the autumn.

Peaches: Early York, Royal George, Noblesse, Grosse Mignonne, Barrington, Bellegarde, Lord Palmerston, Dr. Hogg, Walburton Admirable—the last being what is called an October, that is, a very late Peach.

Nectarines: Elruge, Violette Hâtive, Rivers' Orange, Balgowan, Hardwicke Seedling, Pitmaston Orange, Victoria.

Apricots: Hemskirk, Moorpark, Kaisha, Pineapple, Peach.

Figs: Brown Turkey, White Marseilles, Black Ischia; the first, which is likewise called Lee's Perpetual, is the hardiest and the surest cropper.

Plums: Coe's Golden Drop, Green Gage, and Jefferson. One of each on a south or west wall comes in before those on the east or northern sides, or from pyramids or bushes, and are sometimes of a higher flavour. For the colder aspects these three, and Reine Claude de Bavay, Royale Hâtive, Reine Claude Violette, Guthrie's Late Green, White Magnum Bonum, Kirke's, and Ickworth Imperatrice. The latter is often a shy bearer, but where it does well it shrivels on the tree, and becomes a most valuable and veritable sweetmeat for the dessert all through the latest autumnal months; suspended by the stalks in a dry storeroom it will even keep good till Christmas.

Pears: Beurré Diel, Easter Beurré, Winter Nelis, Marie Louise, Glou Morceau, Brown Beurré, Duchess d'Angoulême, and Uvedale's St. Germain, the last being a magnificent stewing Pear.

Cherries: Bigarreau, Early Red Bigarreau, Royal Duke, Monstrous Heart, Elton, Werder's Early Black, and Morello, for preserving. These do well on the coldest walls, with an outlook to the north.

Throughout all the northern parts of England, and, indeed, everywhere where wall space can be spared from the foregoing trees, the following Apples deserve a place on a wall: Blenheim Pippin, Scarlet Nonpareil, Hadick's Nonpareil, Downton Pippin, Margil, Cox's Orange Pippin, Melon, Mother, Golden Russet, Adams' Pearmain, Northern Spy, Sturmer Pippin, Pearson's Plate, and the Calville Blanche. If any wall space still remains, furnish it with such acquisitions, but trees are cheaper now and time more precious, and the world more impatient than it used to be. The first or second crop from young trees will pay the cost of purchase, and when the trees get too close every alternate one can be removed out of the way, or, better still, profitably may be kept within their allotted space by root and top pruning. To facilitate the covering of high walls two sets of trees are mostly planted: riders, that is, trees with a bare stem, of from 3 to 5 feet in height, to occupy the top of the wall; and dwarfs, that is, trees that branch out within 6 inches or so of the ground, to occupy the bottom. To these have recently been added cordons, single or double, which are either trees with one stem, single cordons, or two stems, double cordons—closely spurred in, so as to produce ropes of fruit, so thickly clustered together as to resemble ropes of bunches of fruit. The latter are admirable for filling up small vacant spaces on walls, either at top or bottom; or, trained vertically, in the unoccupied spaces between other trees. They are specially adapted for small gardens, and for producing a maximum weight of fruit of the best quality from the smallest area of space. Carried down on walls, or trained on rafters, on wires, or props of wood or iron, at distances of from 9 to 18 inches from the earth—the fruit is nourished by the vapours arising from the ground, and attains a large size. The system is specially adapted for Apples; but Pears, Apricots, Plums, Peaches, Cherries, can all be readily trained into cordon form, and successfully grown and fruited as such.

They can either be purchased in fruiting condition, or maiden plants may be had for one-third of the price, and readily converted into cordons. For a single one, lay in the young shoot full length—in a horizontal position. During the summer almost the whole of its buds, instead of rushing out into wood, will plump up into fruit buds for a crop next year. The second season a fruiting cordon is produced, without any effort or manipulation whatever. By leaving it alone it becomes fruitful, without either pinching or pruning. If a double cordon is wanted, the single shoot must be shortened back—within three or four buds of its base. Then two shoots are produced and allowed to grow instead of one, and both may be treated as above the next season, and they will fruit the following one, the same as maiden plants. This mode of growing cordons into fruitfulness is economical, saves the labour of pruning and pinching, and is most effective in forcing them into fruit bearing. We have numbers now in their third year, full of fruit, that have never been either pinched or pruned. Should, however, they make a rush woodward, every growing shoot, except the leader, should be pinched out at every second or third leaf made. This forces

the trees into fruitful ways, and if a fertile habit is established when the trees are young, they will not readily depart from it when they are old.

The oblique cordon is formed exactly on the same principle. It is slanted to allow a greater length of stem on low walls; vertical cordons are simply trained upright—either form may be carried to any length without greatly increasing the width, 6 feet long by from 6 inches to a foot wide are good proportions. Double vertical cordons have a neat appearance, and cover a gable end of a house, barn, or high wall sooner than any other form.

Single cordons can be planted from 2 to 4 feet apart, and as the roots have only one or two stems to support they make rapid progress. Of course the double cordons may likewise be trained obliquely, like the single. Among the best varieties of Apples for conversion into cordons are these:—Cox's Orange Pippin, White Nonpareil, Early Harvest, Lord Burleigh, Reinette du Canada, the Melon Apple, the Mother Apple, Duke of Devonshire, Cellini, Hubbard's Pearmain, Pitmaston Pine-apple, Court-pendu Plat, and Northern Spy. Among Kitchen Apples,—Betsy Geneviève, Calville Blanche, New Hawthornden, Lord Suffield, Small's Admirable, Cox's Pomona, Tower of Glamis, Yorkshire Greening, Dumelow's Seedling, Alexander, Beauty of Kent, and Blenheim Pippin. The Pears and Plums, as already observed, may be grown in a similar form; but specific kinds of these for cordons are hardly needed. Two of the very best Pears for the purpose are Louise Bonne of Jersey and Beurré de Capiaumont, and these may be taken as types of the more moderate growing, free fruiting sorts, that do best for this form. We have tried most of the best varieties of Plums, and found little difference among them.

The only other forms of trees admissible into the kitchen garden, are the pyramid or conical, pillar, vase, bush, and espalier. The latter is a fan or horizontal trained, in fact a wall tree backed up against an iron or wooden trellis in the open ground. All the other names explain themselves, and some of them may possibly be adverted to in our chapter on keeping the garden. *D. T. Fish.*

A PROPOSED AGRICULTURAL SURVEY.

I ENCLOSE copies of a correspondence that has passed between me and the Council of the Royal Agricultural Society. The subject has some interest at the present moment, when the manner in which the owners and cultivators of English soil have performed their duties is so loudly, and as I believe so unjustly questioned. I think the outside public will scarcely agree that the essays in the Transactions of the Royal Agricultural Society's Journal will fill the place of the national work outlined in the accompanying letter to Lord Vernon. *Sam. Sidney, Agricultural Hall, Islington, September 9.*

March 17, 1871.

1. *To the Lord Vernon, &c., &c., &c., President of the Royal Agricultural Society of England.*

My Lord,—Acting on your suggestion at our last meeting, I do myself the honour of sending you my ideas for the agricultural survey of England by the Royal Agricultural Society of England, which I have several times brought before the Council in the course of the last eight years. The object would be to ascertain what progress has been made in every branch of agriculture since the Society was established in 1839. With this view—1st. England should be divided into a certain number of agricultural districts, quite irrespective of county divisions. 2d. A series of questions should be prepared for circulation in each district, amongst the landowners and farmers. 3d. These questions would ask the progress made in each department of agriculture. For instance : Live stock, viz. :—1. Cattle ; 2. Sheep ; 3. Pigs ; 4. Draught horses. Implements, viz. :—1. Preparation of soil ; 2. Sowing seeds ; 3. Collection of crops ; 4. Preparation for market. Food purchased for cattle, as, for instance, cake of various kinds, Maize, &c. ; artificial portable manures, drainage, crops, roots (of what kinds), other new crops. In a word, the object would be to get more out of the dry bones of agricultural statistics, and to enable the Society to collect authoritative reports of the amazing progress of 30 years of English agricultural history. Then to the motto of the Society on the volumes might be added, "*Quorum pars magna fui.*"

I am aware all this would involve considerable expense, but not so much as the reports of the travelling commissioners.

The forms, which should include blank pages for "general observations" and "reminiscences," should be sent out in the autumn, through members of the Council, to those most willing contributors in each district, to be worked at during the winter. Many zealous and able assistants would certainly be found amongst the 5000 subscribers who are either able to write an agricultural article or make a speech. When returned, they could easily be digested by referring each district to one competent editor. The names of the contributors should be given with each report. I repeat, I feel the national importance of such a work. Any further questions I shall be happy to answer.—I am, my lord, your most obedient servant, S. SIDNEY.

2. *To S. Sidney, Esq.*

Sir,—I am instructed by the Council to inform you that your letter, dated March 30, addressed to the President of the Society, having been carefully considered by the Journal Committee, the enclosed report thereon was unanimously passed at their meeting on Wednesday last.—I remain, sir, your obedient servant,

H. M. JENKINS, Secretary,
Royal Agricultural Society of England,
12, Hanover Square, June 9, 1871.

Extracts from Report of Journal Committee.

Mr. Thompson (chairman) reported, that after considering a letter referred to them by the Council, in which Mr. Sidney advocated an agricultural survey of England by the Society, the committee were of opinion that the information which Mr. Sidney desired to collect, by means of a general and very expensive survey, has been to a great extent obtained in a more interesting and useful shape by means of the reports which have been published in the Journal within the last few years, viz. :—

1867. Reports on steam cultivation, giving the details of the management of 176 farms cultivated by steam, and situated in 20 different English counties.

1869. Reports of a few eminent farms, selected for the known excellence of the results obtained by the occupiers.

1870. Reports on the farms which competed for the prizes offered at the time of the Oxford Show.

These reports have been drawn up by very able writers, at a considerable cost to the Society, and will, with the consent of the Council, be continued from time to time ; and the Committee submit that no exact account of a limited number of noted farms in different districts is more likely to be useful than the indiscriminate collection of details referring to good and bad alike, and which, if faithfully collected, would be too bulky to be fit for general perusal.

This report was adopted.

PROFITABLE SHEEP FARMING.

IN the opinion of many competent judges, says a writer in the *Chamber of Agriculture Journal*, the most profitable kind of sheep-farming that can possibly be adopted is the high-feeding system applied to ewes and lambs, for the fattening first of the offspring and then of the mothers. Shrewd farmers, who find no difficulty in buying in the autumn draft six-teeth in-lamb ewes from superior flocks, often give up breeding their own stocks, and confine their attention to this branch of business altogether. Those who do so should not be induced, either by sparing of oilcake and with ordinary good fortune they may turn out their lambs about Easter in plump and fat condition, and make nearly a shilling a pound of the carcasses, while the ewes themselves will ripen into fat mutton not later than May or June. We lately rated a high-farming friend on his breeding his own stock. "I have no breeding downs," he said ; "besides which I have no occasion to breed while I can get the pick of draft six-teeth ewes in-lamb from a hundred superior flocks." Our friend had long been famous in his neighbourhood for converting the farm-crops into lamb and mutton by making free use of bountiful supplies of oilcake and other feeding stuffs. In the opinion of all the old farmers for many miles round he very much overdid the thing. "Consider the enormous expenditure," they cried one and all ; and so fully impressed were they with the one-sided view that they were unable to calculate the results the large outlay entailed. For ourselves, we never doubted. "In for a penny in for a pound," always seemed to us the proper motto for all entering heartily into the enterprise. In fattening ewes and lambs farmers are far more likely to err on the side of economy than of bountiful feeding. Besides which, our friend's luxuriant Barley crops offered standing mementos to the excellence of the system adopted. Still, we required something even more palpable to check the argument, and consequently tessed him for his balance-sheet. This we have never yet been able to obtain *in toto*, but a statement put into our hands a few days since bears materially on the point at issue, and this we deem quite important enough not only for the consideration of farmers in eastern Dorset, the part of the country in which the account more especially lies, but also for outer readers of this journal.

The draft ewes of a good flock were purchased October 14, 1870. They were 150 in number, and appeared what sheep dealers termed a thrifty, useful lot ; their breed two-thirds Sussex and one-third Hampshire, a combination of which our friend men are fond. Although warranted forward in lamb, they failed to answer expectations in this particular. 84 only yeaned in January ; 56 dropped their lambs the ensuing month ; 10 turned out barren, and were fattened off early ; these yielded a profit for their keep, but not so great as that derived from the ewes and lambs, and our flockmaster bas omitted them entirely in his statement. The artificial feeding did not commence until December 1 ; and it was confined to acorns throughout that month, the abundant yield of the fruit of the Oak last autumn causing large quantities to be procurable at about 4*s.* per sack, at which price they are, no doubt, a far cheaper auxiliary food for the flock than either cake or corn. These sheep eagerly devoured all that were given them, and were kept in sound and improving condition with such aid and the natural food of the farm until the beginning of January, when a substitute was found in cotton cake. As the ewes yeaned, they were removed from the lambing fold to the Turnip break. The roots were cut up by Gardner's cutter. Plenty of hay-chaff was provided, and oilcake mixed therewith ; in the first place cotton cake, afterwards cotton and linseed cake mixed ; and as the lambs grew big the proportion of linseed was increased, and in the latter stages of fattening it superseded cotton cake altogether. The lambs cropped down the tops in advance of the pens, and had troughs outside for themselves, plentifully supplied with meal, oilcake and pollard impregnated with Thorley's condiment, of which they soon learned to partake freely. The lambs throve to a wish, and on March 28 the first draw for the butchers took place to the number of 52, which were disposed of at 38*s.* per head. On April 21 a second draw of another 50 took place, sold at the same price, 38*s.* each. So many as 68 still remained, for there were a number of twins, and our friend had the prodigious good luck of rearing 170 lambs out of 140 ewes, or rather 136, as four died in lambing, or shortly afterwards. It testifies somewhat to his good management, moreover, that the twins were all fattened. A third draft of 50 were sold on May 20 at 36*s.* per head, while the remaining 18 odd lambs were disposed of on June 6 for a trifle over 29*s.* each, the return being £26 5*s.* The ewes were threefourths fat when the lambs were taken from them, and were rapidly forced on by the aid of oilcake to be very much fit for the knife afterwards. They were sold at 9½*d.* per lb. in their wool. The first lot of 100 were marketed on May 20, and the whole cleared off by June 27, realising by weight a nett return of £399 10*s.* But at what cost were these good returns realised? Nothing very alarming. The account has all the ordinary feeding stuffs, oilcake, corn, meal, and acorns amounted altogether to £93 19*s.* This will be deemed by no means heavy expenditure when the profits secured thereby are taken into consideration. We append a summary of the whole outlay and results :—

Cost.			
140 in-lamb ewes			£
bought at £2 each	£280	0	0
Auxiliary feeding stuffs purchased	93	19	0
Balance	334	16	0
	£708	15	0

Proceeds.			
52 lambs sold at 38*s.* each	£98	0	0
50 ditto ditto at 36*s.*	95	0	0
50 ditto ditto at 36*s.*	90	0	0
18 ditto sold for	26	5	0
136 fat ewes sold at 9½*d.* per lb. realised	398	10	0
4 skins	1	0	0
	£708	15	0

This leaves £334 16*s.* as remuneration for the natural food of the farm consumed. A perfect balance-sheet would, of course, include the cost of attendance and labour with the expenditure ; but, on the other hand, nothing is credited on the score of manure by the land being put in high condition for the Barley crop through the bountiful use of oilcake and other rich feeding stuffs.

The above account, however, is rather given as an example of what may be done under favourable circumstances in a fortunate year than as a fair estimate of outlay and profit on the adoption of the system. The flockmaster was enabled to buy in cheap and sell out dear, and had unusually good luck in suffering few losses and obtaining a singularly good number of twins. The same quality ewes be purchased last year at 40*s.* each now readily command 50*s.*, and it is not every spring that fat lambs sell at 11*d.* and 1*s.* per lb., and fat mutton at 9½*d.* Nor are there any allowances in the above statement for losses by barren ewes. A more correct general estimate of the profits to be obtained by the adoption of this system of sheep feeding may be made by supposing the ewes to be bought at 42*s.* per head ; setting down the probable sales of the lambs at about 34*s.* each, which would admit of their weights being 40 lb. each, at a little over 10*d.* per lb. The ewes might fairly be estimated to attain the average weight of 80 lb. each, and to be sold at 8*d.* per lb. ; but an death loss of 5 per cent. ought to be deemed probable, the number would be reduced to 133. Another 5 per cent. might be expected to be barren, consequently the yield of lambs, giving due allowance for twins, ought not to be estimated at more than 135. We draw a balance sheet on this basis with the appended results :—

Estimated Outlay.			
140 in-lamb ewes at 42*s.*	£294	0	0
Purchased feeding stuffs	93	19	0
Balance	197	19	4
	£585	18	4

Estimated Returns.			
135 lambs at 34*s.* .. £229	10	0	
133 ewes at 93*s. 4d.* ..	354	13	4
7 skins at 5*s.*	1	15	0
	£585	18	4

We may add that the farmer who furnished us with the statement of the outlay expended and the returns secured in fattening 140 ewes and their lambs in the past season occupies an oasis in a barren heath district. Low-lying, it possesses some depth of soil and natural fertility, but the high state of productiveness now displayed is primarily attributable to good farming. The fact, too, is particularly noteworthy that these profitable results in fattening lambs were obtained in consuming Turnips and green crops on arable land. With the exception of a fresh bite of natural grass consumed by the ewes just after lambing, they were not kept in pasture fields at all. Nor must the statement be regarded as rarely exceptional ; for although better profits were secured last winter than have been realised in any previous year, heavier weights of both lamb and mutton were produced on the same farm in the spring of 1870, but disposed of at a less rate per pound. We have the authority of the occupier in asserting that in a general point of view the average of seasons affords him larger profits than those calculated on in our own estimate ; which surely places the high-feeding system in a favourable light, and recommends it to the careful consideration of many who have not fully acquainted

themselves with the advantages of feeding liberally with oilcake, and thereby converting their Turnips and grain crops into lamb and mutton.

Home Correspondence.

The Dry Earth System.—Probably few of your readers will attach much weight to the confident assertion contained in my communication inserted in your impression of September 2,—that if the whole of the refuse of a town or village be given up to a board of management of the dry earth system, a manure may be manufactured the minimum value of which shall be £1 per head of the population of that town. Fewer persons will be disposed to procure and read my pamphlet to which in that communication I referred—"The Science of Manure as the Food of Plants,"—in order to see the principles on which that manure is manufactured, and on which my confident opinion of its value rests; perhaps, then, you will allow me briefly to state those principles. 1. It is self-evident that previous to any substances affording to a plant that nutriment with which life and growth are maintained, those substances must be reduced to an almost infinitesimal minuteness. 2. It is equally self-evident that the nutritious particles thus disintegrated and transformed should be brought into that position and circumstances in which the organs for their transmission into the sap vessels of the plant can act upon and absorb them. 3. From a very little consideration of this infinitesimal minuteness into which the nutritious particles of any manure must of necessity be reduced, it will readily be perceived that the aggregate amount of such nutritious particles requisite for the healthy growth of a given plant, or even of a given crop, must in its actual and immediate application be very small indeed. 4. In cultivation, then, whether on a small or a large scale, the main object must be the actual and immediate application of this very minute quantity of matter, and that at the proper time, to those vessels of the vegetable system through which it is to be received into each separate plant. 5. The problem to be solved (and which I claim to have solved), then, is this : since the actually nutritive portion of any manure, as distinguished from the medium through which it is prepared and conveyed, is very small indeed, how is this to be introduced into a medium of the narrowest compass, yet tangible and manageable? The compass must be narrow, that as a vehicle of transmission it shall, in proportion to the manure conveyed, be small in bulk; it must be sufficiently large to render the application of the nutriment to all portions of the crop certain and uniform. This problem, in a recent modification of the dry earth system, in its application to sink water and slops, I certainly have now more completely solved ; and in a way which at the same time will render the removal of that portion of the refuse of towns easy and profitable. Moreover the method is available in stables and cowsheds to an extent that, while giving large employment to labourers during the winter months, will save seven-twentieths of horse-labour in manuring land. All that is required to satisfy the public is a large and widely extended experiment. Forty tons ought to be tried by 40 different farmers. I should like it tried first for Wheat, because of the amount of silica which I can introduce. For each ton I ought to have £5. A farmer yesterday promised to commence the subscription by taking 5 tons. If this experiment be tried and succeed, I am ready, under a fair consideration, to throw the whole open to the public. Hitherto I have worked hard during 14 years, and have spent more money for the public good than I ought to have done. *Henry Moule, Fordington Vicarage, Dorset, Sept. 12.*

Artificial Manures.—The subject of manures is often discussed in your columns, and the Royal Agricultural Society's report, recently given by Mr. Wrightson, should open the eyes of farmers to the frauds practised upon them, particularly in guanos and Turnip manures. In my neighbourhood, superphosphate, guaranteed to contain 25 to 28 per cent. soluble phosphates, is largely used by most of the principal farmers, and it is generally admitted that another manure will produce a good crop of Turnips so cheaply. Some few have used superphosphate containing 32 to 35 per cent. of soluble phosphates, which, considering the saving of carriage, in buying so concentrated a manure, is generally cheaper of the two. It unfortunately happens that a great number of farmers are always seeking after some mysterious compound, whose effects will eclipse everything that has preceded it or that can possibly follow. They do not try to ascertain its composition—the amount of plant food—which it contains, but value it in proportion to the amount of puff with which it is introduced, which as often as not stands in inverse ratio to its fertilising properties. Farmers, as a body, can discuss with you as long as you please the breeding and feeding of stock, the different kinds of implements in use, even those recently introduced, which they will have seen at some local show, but on the subject of manures they seem perfectly at sea ; they either know nothing as to how a manure should be composed in order to furnish food for the crop ; or if they have some knowledge of chemical analysis, they are, in the majority of instances, too niggardly to be at the expense of having it tested by some experienced chemist, although the few shillings spent in this way would often, by my knowledge, be the means of saving them pounds. The 25 to 28 per cent. soluble phosphate is sold here at £4 10*s.* per ton in bags, delivered free at railway stations, for ready money.—I send you by this post a sample of manure marked No. 1, the ready money price for which by a local dealer is £6 10*s.* per ton. I have had it analysed, and give you the results :—

Analysis of a Sample of Manure.

Moisture	3.90
*Organic matters	32 10
Biphosphate of lime	2.83
Equal neutral made soluble, 4.42)	
Insoluble phosphates	17.20
Hyd. sulph. lime	20 77
Alkaline salts	0.55
Sand and earthy matter	20.65
	100.00
*Containing nitrogen	1.65
Equal ammonia	2.00

I shall be glad of your opinion of it. The dealer in question puffs his manures more than all the other vendors put together ; he secures paragraphs in newspapers, ay, and leading articles, in his favour ; and condemns alike Peruvian guano, nitrate of soda, and, as he terms them, cheap phosphates, and announces his own compounds as "the best and cheapest manures that can be used, specially prepared for all crops, under the scientific superintendence of one of our firm." The analysis I send is called nitrogenate for Turnips, and as to its scientific composition chemical analysis proves it to contain 20 per cent. of sand and earthy matter, and less than 5 per cent. of soluble phosphate. I venture to say that there is no other business but farming where those who practise it show such ignorance of the use and value of the materials they have to purchase ; yet farmers live, grumble, and save money, swindled and despised by those who are preying upon them. Prizes are offered by Agricultural Societies through the length and breadth of the land for stock, implements, &c., and no doubt much good has resulted therefrom ; but that these societies or Chambers of Agriculture, or other generally prevailing organisations take up the question of explaining and securing cheap chemical analysis, the great bulk of tenant-farmers will remain ignorant of the necessary plant food which should be contained in any material to entitle it to be called a good manure. An objection is often made to these highly soluble phosphates that they work pasty, and clog up the sort of drills which are now very much used in their application, but this dealer puffs his manure as being in such fine condition for the drill ; and farmers forget, or rather will not learn, that they have the same means of making their manures work as the dealer has, namely, by the admixture of a little sand or ashes, which they can procure for next to nothing, instead of paying £6 10*s.* per ton for them, as in the instance I have referred to. *Yorkshireman.*

Land Improvements by Tenants.—In your paper of last week (p. 1212), "G. A. H." asks if I can explain why one of his tenants prefers improving his farm, while another will not improve. I reply that I do not see in his letter why the tenant so acts ; but I can tell "G. A. H." a few instances where tenants have laid out their money freely although under the usual tenure, that is, subject to six months' notice to quit. One tenant on an estate in my county has spent more than £300 a year in improvements alone, besides artificials and feeding stuffs, and eating all his produce except Wheat and malting Barley. Another spent more than £1000 in two years in manures and feed. Most of the other tenants have laid out money in improvements. A valuer is now going over the estate. Wherever a landlord sends a valuer to look over his property, the meaning is a rise of rent. If the tenants do not like this, they can leave if they please, and other farmers will come and pay the increased rental. But the outgoing tenant then leaves his property in the landlord's hands, who increases his income in consequence of his evicted tenant's outlay. It is this which makes English farming of such a hand-to-mouth sort. If we had security, we could plaster on manure like a Mechi, and rip up our clays like a Smith. Until we get security from "felonious" confiscation, the soil of our country will not yield its proper food for the people. *H. H. O.*

Landlords and Tenants.—Much has been written, and still more spoken, upon the relative duties, business policy, and arrangements between landlords and tenants. What is their precise position ? The landlord, as proprietor of the land, is entitled to a full and equitable rent, according to the value of his land and the liberal covenant he gives to his tenant, in or by which ought to be included special reference and acknowledgment of the great improvements which British agriculture has achieved of late years ; and he is entitled in all fairness to have his land managed upon the modern principles and practice of agriculture both in the farming and grazing departments. The tenant ought to enter upon his farm with the clear understanding, that he is by his skill, capital, and industry, to cause the farm to yield the largest possible return of produce, in accordance with the nature and quality of the land or soil and climate in which it is situate. Modern agriculture demands a liberal outlay of capital in labour, in mechanical aids to culture and other farm service, in chemical manures, in artificial foods for stock, in breeding and stock management, and in the growth of the best varieties of grain, roots, &c., that can be procured. To encourage and give security to a tenant to do this, the landlord must take unusual care in selecting an intelligent and enterprising tenant, with competent capital to manage upon these modern principles ; having done this, he should be left in the free exercise of his own judgment as to his own course of management throughout, except some equitable restrictions relative to breaking up pasturage, buildings, and the condition of the farm at the termination of the tenancy. There is this certain fact for the security and encouragement of landlords, that no tenant can profitably manage a farm upon the fair, not to say expensive principles of modern agriculture, without improving his farm. He must inevitably do it, or fail. The best principles and practice of modern agriculture lie principally in the drainage and the deep effectual culture of the various soils, in the application of artificial manurings wherever requisite (and no one knows yet to what extent these can profitably be applied), to secure good crops ; for such only will pay, and must be obtained at any reasonable cost. These principles in the management of farm stock comprise this one prominent course—to keep every animal thriving from its birth to the time of slaughter ; and this can only be done by a liberal outlay in artificial foods, and very careful management. Every head of stock purchased for fatting ought to be supplied with these foods. In this way a much larger number can be fatted upon the grazing part of the farm. Farms managed after this order cannot deteriorate. It is only by this course being pursued throughout the country that the landed interest can do their duty in making the soils of the kingdom produce their utmost for the sustenance of a large and rapidly increasing population. *O. F.*

Societies.

NOTTS.

The Breeding and Feeding of Cattle.—At the quarterly meeting of the Notts Chamber of Agriculture, on Wednesday of last week, at Newark, the chair taken by Mr. George Storer, Mr. W. SANDAY, of Ratcliffe-on-Trent, formerly of Heather Hayrepont, read the following paper "On the Breeding and Feeding of Cattle :"—

The breeding and feeding of first-class stock having of late years attracted much attention, and being a pursuit in which I have been myself engaged for the greater part of my life, I felt that the result of my experience might be of use to others, and therefore, much as I dislike appearing in public, I acceded to your request to read a paper on the subject. I have endeavoured to make my remarks as practical as possible, as I have not come across any article on the subject which can be said to be of any practical use. Breeding, as the more important of the two subjects under consideration, should first claim our attention. Shorthorns, on account of their early maturity, having became more popular in this country than any other breed of cattle, I shall confine my remarks to them ; the same observations will, of course, apply with equal force to any other variety. To give you some idea of the increase of Shorthorn herd-book breeders within the last 20 years, I may mention that in the year 1850 there were 316 subscribers to Coates' Herd Book, and the pedigrees of 1127 bulls were entered ; to the last volume we find 655 subscribers, with the pedigrees of 2366 bulls. I would ask whether, in the opinion of this meeting, the number of really first-class animals has increased in proportion ? My own opinion is, that the animals bred at the present day are inferior both in size and in quality to those bred 20 or 30 years ago. Now, if this be the case, surely there must be something wrong in the present system of breeding. It is evident that but little common sense can have been brought to bear on the subject.

Deterioration of Live Stock.—I am convinced that the cause of this deterioration is the principle on which most herds are bred, viz., the fashion—or rather infatuation—of collecting from certain families, without any regard to the qualifications necessary for producing and perpetuating good animals. To follow out this plan, in-breeding must, to a very great extent, be resorted to, and the number of families on which such an experiment can be tried with the smallest chance of success is so limited, that in the majority of cases the consequences cannot fail to be ruinous. We all know the difficulty of raising and keeping up a good herd or flock ; this can only be done by breeding from the very best males and females, but the present system seems to set this rule completely at defiance ; if an animal be only of the fashionable strain, it is sure to make a fabulous price, whatever its quality. Only last year two heifers were sold by Captain Gunter to a Lincolnshire gentleman for £2500, and their produce, two heifer calves, has since been purchased by Lord Dunmore for the same sum (£2500). Should these calves breed, what price do you think Lord Dunmore will set upon their progeny ? Of course it will be a high one, totally irrespective of their quality ; should a bull be reared, doubtless he will be used, no matter what he may turn out. I have, of

course, put this as an extreme case; but similar ones are constantly occurring, and this servile adoration of pedigree cannot fail to end in disappointment, and ultimately in the permanent deterioration of Short-horns. We may have some idea of the extent of the evil if we take the number of bulls annually exhibited at our various shows, and consider how few of them are really fit to perpetuate their species, and yet the majority of them are so used, which would in some measure account for the great scarcity of good animals. Without many, a long pedigree is all that is considered necessary; but unless this pedigree be composed of really good animals the produce will probably be unsatisfactory. A well-descended bull or ram may, although not itself first-rate, produce first-rate stock; numbers of such instances have come within my own knowledge. The case is far different when the sire comes of a line of light-fleshed, delicate animals (and these, I am sorry to say, are in the present day only too numerous). Surely any of us may foresee the end of such an irrational plan, and yet it is pursued, as I have already stated, by numbers of breeders. There are two other causes which, in my opinion, must hasten the deterioration of many of our best herds, viz., first, the artificial manner of rearing calves; and second, the practice of using bulls before they arrive at maturity.—First, the artificial manner of rearing calves, especially bull calves. They are confined in small stalls, or pens, instead of being allowed to suck upon their mothers in the open pastures, where they could take any amount of the exercise so necessary to their muscular development. I am well aware of the difficulty of carrying out this plan to any great extent, but whenever practicable it should be adopted, if really first-class animals are to be produced. Second, the practice of using bulls long before they come to maturity. It will be evident to every one that such a practice cannot fail to be injurious, and, though instances to the contrary may be adduced, they are only the exceptions which prove the rule.—I am also quite of opinion that over-feeding is another cause of deterioration; but it is not likely to be discontinued at present, as, owing to the extreme difficulty of judging animals when out of condition, there are but few who will purchase them. I am well aware of the scarcity of first-rate sires, and even in the history of Shorthorns have they realised such enormous prices; but had the supply increased in proportion with the number of breeders, no such difficulty would have arisen. One advantage, however, has been gained. There is no lack of useful bulls, which may be purchased at moderate prices, and these, I think, we may fairly congratulate ourselves, have much improved the ordinary stock of the country, more especially in Ireland, as may be seen by the superior quality of the cattle brought to our fairs and markets. I am myself actually addressing myself to farmers, many of whom keep well-bred bulls, a practice the importance of which cannot be over-rated.

Selection of Sires.—Here I may perhaps be allowed to make a few remarks on the selection of this description of stock. In the first place, it should always be remembered that the male has a greater influence on the quality of the stock than the female; consequently, every female put to a good male will probably produce a better animal than herself; this rule applies to all ordinary stock put to a well-bred sire. Therefore, for a few pounds in addition, to purchase a good animal, for you may reasonably expect a handsome return for the amount expended in the improved quality of the stock. Second, with regard to the selection, the importance of which I think you will admit, I would most strongly recommend you to fix upon a flock or herd known to be descended from a long line of heavy-fleshed and robust animals, and one whose owner has a character for careful selection of his breeding stock. I am glad to say that breeders answering to this description are still to be found. By pursuing this course, the danger of getting inferior stock is reduced to a minimum. Any one who has the smallest experience in breeding knows how often the offspring of two first-class animals is not what might fairly be expected. For this reason well-bred bulls are often to be obtained at a moderate price from our best breeders, many of which, if of strong constitution, might be depended upon to produce good stock, or, at any rate, good feeders. Carefully avoid, however, herds bred from the light-fleshed, narrow, and delicate animals, so common at the present day. In purchasing a bull for ordinary stock, above all things choose a large-sized animal, with good quality of flesh; if well descended, do not be too particular about his form. The shoulders are better well open at the top, not narrow, like the withers of a horse, no matter if a little coarse, if it is a sign of constitution; the ribs should be well sprung, a most important point, but difficult to get; the hips large, even though they should be coarse; the head and neck masculine, and the horns rather thick than otherwise—a thick horn is a sign of robustness and vigour. I do not like the thin, papery hide which so many admire; you may be sure there is not much flesh under it. I think I have now given you the essential points of a useful animal, and one obtainable without any very great outlay. As there may be some amongst my hearers who are breeders of first-class Shorthorns, a few words of advice to them may not be out of place, though it must be understood that they do not in any way extend to those whom we may term "pedigree breeders." With them I have no sympathy; and though I am bound to admit that large sums of money may be and are realised by this mode of breeding, that its effects are injurious must be apparent to every unprejudiced person. What I have said in my advice to farmers will apply here, only, if possible, with tenfold force, viz., avoid any tendency to light flesh or delicacy of constitution. A cross of this kind is often attended with most disastrous results; a case in point occurred some years ago on the herd of the late Mr. Richard Booth, whose name is doubtless well known to most of you. He had for many years been breeding entirely from his own stocks, and thinking that a cross was beneficial, he was induced to purchase at one of the sales of the late Earl Spencer a bull called the Sequins. He was handsome, though neat in form, were wanting in flesh and robustness—the very characteristics possessed in such an eminent degree by Mr. Booth's, but the cross, contrary to Mr. Booth's expectation, proved a most unfortunate one, the stock from Lord Spencer's bull being decidedly inferior. Similar cases have more than once occurred in my own flock of Leicesters, and this has strengthened my conviction that, unless the male be superior, or at least equal to the female, in all essential points deterioration must take place. Let me here again impress upon you the importance of selecting a bull from a herd known to be robust, to be should, of course, be as perfect in form as possible, but the following points should be made a *sine qua non*, viz., good and heavy flesh, good looks, well-sprung ribs, and, above all, a pedigree without blot. Bear in mind, however, that a long pedigree is not necessarily a good one. Success in breeding, I am quite convinced, requires a certain amount of intuitive knowledge; it is this which enables one to see at a glance when an animal is likely to be a good stock-getter, or whether a young animal is likely to improve or deteriorate. I cannot believe that this faculty is to any extent a gift, as I have proved in the present day: if it were, the quality of the cattle brought under our notice at sales and shows would be very different. To quote an eminent authority (Mr. Darwin), "Not one man in a thousand has accuracy of eye and judgment sufficient to become an eminent breeder. If gifted with these qualities, and they are inherited, he will succeed, step by step, in producing a strain of animals, for years, and devotes his lifetime to it with indomitable perseverance, he will succeed, and may make great improvements; but if he wants any of these qualities he will assuredly fail." Before concluding this part of my paper, I must say a few words on this subject—a subject to me most interesting, and one which requires to be explicated. I feel certain that, under some conditions, the experiment might be tried with every chance of success, but these conditions so seldom occur, that it can be attempted in but few cases. The conditions to which I refer are these: If two animals be first-rate in form and quality, without the slightest appearance of delicacy, or if the male be very good in points where the female is deficient, or if it be desirable to perpetuate any particular strain, then I think you might put father and daughter, mother and son, or, indeed, any relations together, with the exception of brother and sister. Bear in mind, however, that any defects in the parents would be exaggerated, and each generation would decrease in stamina. From personal experience I cannot speak with any authority, having only tried the experiment once, and then upon sheep—the result was not satisfactory.

Feeding.—I feel some diffidence in addressing you on the subject of feeding, being well aware that there are many present who are better qualified to do so than myself. I therefore, be excused making any lengthened remarks, hoping that some one may be induced to offer a few suggestions before the close of the meeting. I shall begin by saying a few words on the rearing of calves, and their after-treatment until they are fit for market. I have always considered September, October, and November the three best months to begin rearing, that the calf may be strong enough to withstand the second winter, which is always the most trying time. Each calf should have, if possible, a loose box not less than 9 feet by 5 feet 6 inches, especial care being taken that it be well drained, any accumulation of moisture being most injurious. Each box should be provided with water-trough, manger, and small rack for hay. New milk should be given for a fortnight at least; this should gradually be supplemented by skimmed milk, and linseed cake, or oilcake ground, that as many meals as possible may be reared. A little good hay should be given as soon as the calf will eat it, and I believe that no better food can be substituted. A small quantity of linseed cake may also be given, with pulped roots and cut hay; if hay be scarce, a very little straw may be added. At the age of 14 or 16 weeks the straw may be gradually discontinued, and a little flour substituted, which may be mixed with the pulp and chop. This treatment should be continued throughout the winter, and up to the first week in May, when the calf may be turned out to grass, fetching it up at night for the first fortnight at least. One pound of cake per day should be given during the summer, and by the autumn this treatment should have produced an animal in good condition, and well able to get through the ensuing winter. The cake should now be increased to 1½ lb. to 2 lb. per day, and equal portions of hay and straw may be given chopped and mixed with pulped roots. If the stock are to be sold at an early age, which I strongly advise, a small quantity of flour should be given with the chop. I would here impress upon you the importance of keeping every young animal in a thriving state; should it once lose its calf's flesh it will take some time to restore it, and it should be remembered that time is money. At the end of the second winter the yearling ought to be in good condition, and during the next summer it may be grazed in the store pastures with ewes and lambs. At two years old those not sufficiently forward to be fed may be put into the straw folds; they should have an unlimited supply of cut straw mixed with pulped roots. If a sufficient quantity of roots can be allowed they are in my opinion preferable for store cattle to any kind of cake. The heifers intended for stock to be fed with cake, and the cake to be the best, with some of the steers, may possibly be sufficiently forward to be fed in the winter. Feeding may commence with from 4 lb. to 5 lb. of cake per day with as many roots as can be spared, and if possible a little hay; the quantity of cake must be regulated to suit the time when the animals are to be disposed of. It is a much debated question with feeders whether the preference should be given to boxes, stalls, or yards. I should place them in the following order: 1st, yards; 2d, boxes; 3d, stalls. It depends, however, in some measure on the kind of cattle to be fed. Steers will improve faster in yards or boxes, but cows, from their more quarrelsome disposition, do better in stalls. Farmers, however, have not often sufficient accommodation to admit of choice in the matter. In the foregoing remarks I have pre-supposed that the stock have been fairly bred, for it is only by this means that any quantity can be secured and at the same time I would have it understood that I am speaking of ordinary stock, and not of animals intended for exhibition. Not having any definite knowledge of the system adopted by the large dairy farmers in rearing, I cannot give any information on the subject, but beg to refer you to the interesting articles which in the Agricultural Society's Journal, where you will find some valuable hints in the account of the first prize dairy farm. I may remark that the calves on this farm were economically fed and in very good condition. With regard to the rearing and management of first-class breeding stock, I have already recommended that all the bull calves should, whenever practical, be reared upon cows in the open pastures; they should suck from six to eight months, and a few weeks before weaning should become accustomed to artificial food, as a calf so soon loses condition after leaving the dam. Exercise should be given regularly, this being also an essential point. The bull calves will, of course, receive the most liberal treatment possible until sold; the heifers only require to be kept in good growing condition, which can be done by giving a very small quantity of artificial food and good hay. They should be put to the bull at one-and-three-quarters or two years old, as, if this be longer deferred, they are likely to prove non-breeders. Stock for exhibition require the most liberal and careful feeding. Only so much should be given as can be consumed at once; if any be left it should be removed. This I believe to be a most important point in breeding. Change of food is also very essential. Linseed-cake should be given with judgment; if too much be given the animal is soon cloyed. But all these directions will be useless unless the intending exhibitor have an intelligent, persevering, and trustworthy cattle man. It must be evident to all parties to bring out the animal in show condition at the right time, which is no easy matter. Economical feeding, *i. e.*, obtaining the best results from the smallest amount of food, is of the greatest importance; but it is difficult to lay down any special rules for attaining it. I shall not attempt to give any opinion on the different feeding stuffs and condiments now before the public, my experience of them being very limited, malt, however, excepted. I am convinced that it is one of the most valuable foods known, not only as a condiment, but as a fat producer, and for exhibition we never like to be better health on malt than upon any other food, milk excepted. It is a food of which they never tire. I only hope I may live to see the day when it will be within the reach of every farmer. For further information on the subject, I must again refer you to the forthcoming number of the Royal Agricultural Society's Journal, where you will find a description of the different modes of feeding, as adopted on the prize farms, the details of which may be useful and interesting.

Discussion.

Mr. Sampey expressed the opinion that nothing would more conduce to reduce the price of meat than the use of malt in the feeding of cattle. It was invaluable as feed for young stock, and he very much agreed with what Mr. Sanday had said upon the subject. He hoped he might live to see the time when malt would be free use of for fattening purposes. He again expressed the satisfaction that Mr. Sanday had made such an allusion to the importance of malt as a feeding ingredient.

Mr. Colton said the deterioration of Shorthorns must be owing to breeding in-and-in too much. He was of opinion that the Shorthorns now bred and exhibited had nothing like the flesh they had 20 years ago. Still, they made more money than they did 20 years ago. It was to be hoped that more attention would be paid to substance, as light-fleshed animals were more liable to disease.

The CHAIRMAN said they had heard a very instructive paper. He might observe that some 40 years ago he thought of setting up as a Shorthorn breeder, and after hearing Mr. Sanday's paper he could fully realise why his anticipations were not fulfilled. He purchased some stock at the sale of a neighbour, Mr. Rose, but they had been bred in-and-in too much, and the consequence was that three or four of the heifers would not breed at all, which rather daunted him. He had a brother, however, a great breeder, but he had told him he was not much use for pedigree and too little for flesh. He recollected the remark of an excellent farmer in his locality, Mr. Bean, who said, in reference to this subject, "It's all very well, but keep beasts kind." He supposed that was an old saying, for he thought that keeping would not do it unless there was kind to start with. With regard to the paper they had heard, they had been sitting at the feet of Gamaliel; for no man could be more qualified to advise them than Mr. Sanday, and he was sure their thanks were due to him. He could not propose it from the chair, but it must be the general feeling of the meeting.

A discussion ensued as to the time of breeding, Mr. Sampey being of opinion that proceeding early conduced to regular breeding and fewer barren beasts.

Mr. HEMSLEY said he should like to know what amount of beef might be produced by farmers generally beyond what was now grown. He believed the two great points which now affected farmers most were the labour and meat questions. He should be very glad to know how they could produce more meat, as by that they would better deal with the question of labour. As far as he could see, something might be done in the way of artificial grasses. In that way they would increase the supply of beef and mutton. It is quite certain that their attention must be turned to the growing of beef and mutton more than it had been.

Mr. SAMPEY said unless they did so they would have to give way to the foreigner.

Mr. SANDAY remarked that in the matter of breeding much depended on the way a calf had been reared. If well kept, it would be ready at a year and three-quarters; if badly kept, at two years old it would only be three-fourths the size of the other. In answer to a remark of Mr. Hemsley's he mentioned one-and-a-half years as the very earliest time, but if later it would be far better. They were anxious to get produce as soon as possible; the principle was made manifest on throughout the country, and was decidedly injurious. If the animal began to breed at too early an age the stock must deteriorate to some extent. It was this gradual deterioration which had taken place that annoyed Shorthorns in the present day, but what they were 20 years ago. Of that deterioration he was quite convinced. He had the opportunity as much as most people of going from one show to another, and thus could judge of this. Some 30 years ago he had some Shorthorns at Mr. Booth's, and he was quite convinced that there were no such cows like them now. The fashion of breeding for pedigree alone had been one great cause of deterioration. There was recently a sale made by Duke of Devonshire's Shorthorns, and look what fabulous prices those cattle made. He did not see them, and therefore could not speak as to their real worth. There were no doubt some individuals amongst them that they could not all have been good ones, but must have been bought at such prices from other causes than their intrinsic value. The very dissemination of them, therefore, must have caused a great amount of harm. One cow made 2005 gs. : it might be a good one, but he doubted whether it would have been worth half the money 25 years ago. As to Lord Dunmore's sale, two heifers were there sold for 2000 gs., and he bought as cattle for the money which he thought was ridiculous. Even if they were good ones, they were very dear; but what would the end be? They would breed from them as long as they could, and fancy there was no end to it. He could get Shorthorn bulls from the markets for a tithe of the price given by Lord Dunmore and others; but they would have blood, let the consequences be what they might. There was a sale some months ago, and a cow was sold for £1000, but that was down in the catalogue as the dearest cow ever sold; but a neighbour having given £300 for one, he entered that as ten times dearer than the other. He advised them, notwithstanding, to improve the breed of their cattle as much as they could, as a well-bred animal was always in a condition to sell. He thought Mr. Hemsley's suggestion as to growing artificial grass might be adopted with the greatest benefit; but how it was to be carried out they must defer to a man who was not now a farmer.

A MEMBER suggested that they would want irrigation.

Mr. SAMPEY said that Italian Rye-grass could be grown with irrigation manure.

Mr. SANDAY said it might answer to keep their cattle up. Where he had seen as many as a hundred kept up.

Mr. GILBERT could not help thinking that there was a great scarcity of stock in this country, which he believed could be accounted for by two sufficient reasons. Last year there was a great scarcity of all sorts of provender, stock being sacrificed through a want of food; and another reason was that the cattle plague was now being felt. He thought they were greatly indebted to Mr. Sanday for the able paper he had read, and all members of the Chamber would look it over carefully when it was in print. As to the remarks of Mr. Sanday on the use of malt in feeding, he did hope that that question, which was a very large one, would be taken up by the Chamber of Agriculture, in order to see whether the heavy duty that encumbrance was either mitigated or done away with, so that they could use their produce in their own way. There were many national questions which he trusted the Chamber would discuss, we must look to the power of the country to get their opinions placed before the people. They wanted to show that it was their desire to feed the people with the best and cheapest food they could produce. With the prospect now before them, meat, and even bread, must be at a high price. He could not help observing that many farmers reaped but little benefit from high prices or stock, because they had none. He had heard it remarked by butchers, &c., that there was a great deal of grass land in the country quite unstocked. He begged to move a hearty vote of thanks to Mr. Sanday for his kindness in coming before them and reading so able a paper.

Mr. COLTON seconded the motion, and hoped they would all profit by the paper. He hoped they would continue in their endeavours to impress upon the Legislature that food was getting scarcer, and that, therefore, the malt duty ought to be repealed. He did not agree that the malt was injurious; he thought it should be taken off altogether. Let every farmer make his own malt-house, and use his Barley in the best way he could for the country at large. Making it into malt, he contended, was for the benefit of the country at large, inasmuch as if they were allowed to do so more beef and mutton would be produced. He hoped Chambers of Agriculture would not relax their efforts on this question; and they were indebted to Mr. Sanday, with his great experience, for referring to the subject in so pointed a manner.

The motion was carried unanimously.

Mr. SANDAY, in reply, said he was only too glad to give the Chamber any information he could on subjects of this character, and he only regretted that his remarks on feeding had been so meagre, though he fully expected some one would take the matter up and continue it. As to the use of malt, they might depend upon it that as to the use of Barley could say in its favour would fall short of the advantage which would be derived from the use of it. He had tried it with animals going to Royal shows, and if animals getting up for exhibition could eat malt when they would eat anything else, and would take it when cloyed by everything besides, they might be satisfied that the advantages of malt were greater than anything else. There was nothing but malt which would give unjaded, as nothing more fatness was said about it. He begged to thank them for their kind expressions towards him, and assured them that it had given him the greatest pleasure to place his opinions before them.

A vote of thanks to the Chairman concluded the proceedings.

Farmers' Clubs.

HEXHAM.

At a late monthly meeting of this club, Mr. J. J. HARLE, of West Mill Mills, read a paper "On Feeding in addition to Cropping." He said: Before commencing my paper on the subject of "Feeding in its relation to the Cropping of the Land," you will perhaps allow me to review the great advances agriculture has made during the present century. The enormous price of Wheat during the great European war caused large tracts of land to be brought into cultivation, and the comparatively low prices of sheep and cattle made farmers chiefly depend upon the sale of their corn for the production of rent and profits. At that time only a few acres of Turnips were grown on the fallowed land, and the manure produced was chiefly from straw; and farmer to grow all his fallowed land with Turnips; and these roots being consumed by the stock, along with a portion of the corn grown on the farm, the sales from off the land and the returns to it became more equally balanced. But since then we have advanced another stage. Feeding cakes of all descriptions have been introduced, and the great increase in the prices of beef and mutton has enabled us to consume large quantities of these cakes on the farm, generally with a profit, thus obtaining the rich manurial value of their residue often for nothing. At the present date, therefore, we much greater chance of keeping the land in good condition, and can bring back to the soil all the manures we sell off it in the shape of corn, &c. There is not so much necessity to slavishly adhere to the old rotations so long as we keep the sales from each field, and the returns to it in manure equally balanced. The corn crops of the rotation are generally the most profitable, at the same time being the most deteriorating for the soil, whilst the green crops, as Turnips, seldom pay for their expenses, but are the chief means by which the condition of the soil is again renovated.

Turnips being the keystone, as it were, of every rotation, I shall briefly consider the best means to render the crop profitable and increase the fertility of the soil. The too frequent growth of this crop is, perhaps, one of the chief reasons why we have now so much difficulty in getting a full plant and regular crop, for it has often been noticed how much quicker the Turnips braird and how much more vigorous is the growth on the higher lands in this district, which lie longer in grass, than on the more anciently cultivated lands in the valleys which are cropped on the four-course rotation. And, as the root crop is generally so unprofitable, we should try to keep the land clean and in good condition, with few crops of Turnips, compared with the better paying corn crops. This can be done by consuming the greater bulk of the Turnips on the land by sheep, with a liberal use of cakes, and still keeping the usual number of cattle in the yards with the remaining Turnips and cake and meal. It is frequently the practice to cart off one-half and sometimes the whole of the Turnips. If manure be applied to the Turnip crop alone, and we remove the bulk of the roots, we leave comparatively little in the land to grow the corn crops of the rotation, and the soil is never in a very good condition.

The Consumption of Turnips by Sheep.—As a general rule, where the dryness of the land allows it, it is as profitable to consume Turnips on the ground with sheep as to remove them to the buildings for cattle, and we save the cost of pulling and carting. I would suggest that two-thirds be eaten on the ground, and one-third carted off for the cattle. Care should be taken to remove the same proportion from each field; but, if any field be so distant as to cause too much expense in carting, that field should be sown with artificial manures, and the whole eaten on the ground; there will thus be a larger quantity of farmyard manure for the fields nearer home, and these will be able to stand having more roots carted off them. The extra quantity of Turnips to be eaten off with sheep would make us require a larger number of sheep than we keep at present, and our grass in the autumn would not, perhaps, be sufficient to keep them; but this could easily be remedied by placing the sheep on Turnips earlier in the autumn. One field might be sown with white Turnips early in May, which would be full grown and ready to be consumed about the end of September. I cannot see the reason why we are usually so late in beginning to use our Turnips in this district; in the south, I have frequently seen the sheep running full-cloth on Turnips in the end of August; and if, taking the chance of mildew, we can get the Turnips to their full growth by the end of September, we will surely get more benefit from them than eating them in November and December when the land is wetter. By so doing we might, at that dry season, eat Turnips on some of the strongest land, and get it sown with Wheat before the wet autumn weather commences. We have no conclusive proof that the liberal use of cake during the whole winter is a more profitable way of feeding sheep than the more common way of only giving them corn in the spring; but I think common sense shows that it must be wrong in principle to feed any animal wholly on Turnips, which contain only 10 per cent. of dry food, whilst grass, their natural food, contains 25 per cent. This is conclusively shown by an experiment at Rothamsted, where several sheep were fed on Swedes, the liberty to drink water at *libitum*—each sheep drank on an average 6½ lb. of water daily. Now an ordinary sheep will eat 20 lb. of Turnips daily, containing 18 lb. of water, so that an animal fed wholly on Turnips is obliged to take nearly three times as much water as it probably requires. This must, I think, in some measure account for the great loss annually, especially in the cold months of winter. A great difficulty is sometimes experienced in getting the boggs to commence to eat their artificial food. A very good plan is to give the ewes and lambs a little cake, for a week or two, after lambing; the lambs soon learn to eat the cake, and rarely ever forget the advantage of their early youth, and no difficulty is then found in the autumn. Supposing the hoggs to be placed on Turnips early in October, they should have, if possible, an outrake upon a grass field for a certain portion of the day, for a change of food. The shepherds on the Cotswolds have a particular about a change of food to make the sheep thrive, and very often fold their sheep on Rape for one half of the day, and on Clover aftermath during the other half. In the autumn a large proportion of the dry food should be bran, as it is a good corrective to the Turnips, and the sheep should always have access to the salt; rock salt will be readily licked by the sheep, but it will be given more regularly to the whole of them by mixing a small quantity of salt amongst the bran, cake, &c., when they are mixed together in the feeding house. The outrake for the sheep should be, if it can be contrived, grass land that is intended for corn during the next season, the manure from the sheep putting the land in capital condition for the Oats. As the autumn advances, and the grass on the outrake is consumed, the sheep should have dry fodder supplied to them in racks. Hay is the best food for this purpose, but it is too expensive; pea-straw is readily eaten by the sheep, and is very nutritious and wholesome when well won, and a very much cheaper food than hay. By the middle of January the softer varieties of Turnips ought to be consumed, and the sheep have cut Swedes given to them in troughs; and the quantity of cake and corn be slightly increased every month through the winter. From this period to the middle or end of March the sheep should be folded regularly over the Swede land, the Swedes being cut into troughs from heaps placed at equal distances from each other over the fields. By this means we consume all the Turnip land equally, and if the major part of the roots have been eaten on the land, and the sheep have been liberally fed with cake, the soil will be in very good condition for the rest of the rotation. A very important point is the manner in which the Turnip land is sown with corn. If it has been poached by the sheep during wet weather it will be soddened, and all the stirring and loosening of the soil for Turnips will be

lost. Owing to the quick growth of Barley, and being a shallow-rooted plant, it can extract little or no nourishment from clods or hard stiff soil; to obtain the maximum benefit we must therefore have the land thoroughly pulverised and loosened for this crop, taking care to keep the manure as near the surface as possible. This is done most effectively by the use of the steam cultivator, followed by the steam harrow, as by these implements the soil can be thoroughly pulverised to any depth we like, and the manure be still retained near the surface. With horses, the land should be ploughed during the winter as soon after clearing it as possible, and allowed to be weathered by frost until the sowing season, when it can either be ribbed for sowing broadcast, or drilled on the stale furrow. If the weather is very dry, and the furrows turn over stiff and in large lumps, a grub-harrowing, followed by the scrubber, will be very effective.

The Consumption of Turnips by Cattle.—The number of cattle that can be kept, if only one-third of the roots are carted off the land, of course, entirely depends on the quantity given to them daily. In the north we frequently give them Turnips *ad libitum*, and they often eat 150 lb. daily; whilst in the south of England only a small quantity is given. On the college farm at Cirencester, for example, the feeding cattle receive 30 lb. of roots per day, and no more cake and meal than we give them, but they consume large quantities of cut straw. It seems most natural and economical to give the cattle as much Turnips than will supply the animals with water, and 80 lb. per day, containing 7 gall. of water, will probably be near the mark. On this quantity 1 ton will supply each animal with roots for one month, and if we feed each animal, on the average, five months, 5 tons will be consumed during the season. If we calculate our crop of Turnips to be 15 tons per acre, and cart off one-third, or 5 tons for the cattle, then with that proportion drawn off the land we can feed one beast for every acre of Turnips, which is above the average number fattened in this district at present. The supply of meal and cake to feeding cattle is a very important point. Some Norfolk farmers give as much as 14 lb. of oilcake per day, but it is very questionable whether such large quantities are profitable. There is no doubt a great difference amongst animals as well as men, with regard to their appetites and digestive powers, but there will be a limit to every one, and if more concentrated food be given than can be digested, the excess will pass through the intestines and be voided along with the indigestible woody fibre, and therefore wasted. On the other hand, the animal requires a certain amount of food for respiration and to repair the waste in the system, and if that amount of food only be given, it will remain in the same condition. If we assume, for the sake of argument, that 4 lb. of cake be required daily to keep an animal in the same condition, and that by giving it 6 lb. daily it becomes fat in 20 weeks, then 40 stones will have been consumed in keeping the animal alive, and 20 stones in making it fat. But if we give 8 lb. daily, in ten weeks 20 stones will have been consumed in fattening the animal, and only 20 stones in keeping it alive; and if, as we may naturally suppose, the animal has become as fat or nearly so, in ten weeks, the shorter and heavier feeding must be the more economical. We cannot, therefore, feed cattle too highly, as long as the animal can assimilate the food. Besides the fattening cattle, a large number of store cattle may be kept without any profit, if we give them 3 lb. or 4 lb. of cake, with good straw and plenty of water. The manure made by them will be richer and better than if they had lived on Turnips and straw; and the cattle will be cheaper and better kept if the labour in tending and cleaning the roots be considered. And if we are once convinced that the cattle will pay for the cake, the more we use the better the condition we make the land, and we cannot bring too much of such manure on to the farm, if we can get it for nothing.

Foods.—I will now make a few remarks about the manurial value of foods. We have no certain data to show how much of the manurial value of foods goes into the farmyard manure, more especially as the quantity assimilated varies so much in different animals. Thus, in lean cattle and cows a large quantity of nitrogen will be absorbed into the system to form the muscular tissues, and phosphates to build up the bones of the growing animals. On the other hand, fat cattle assimilate a much smaller proportion of these manures for their food, and two-thirds of their increase is pure fatty matter, which is of little or no value for manure. There are only three ways that the food can go. First, the increase; second, the manure; third, for the animal heat and respiration, and to repair the waste of the body. The food used for heat and respiration is chiefly non-nitrogenous organic matter, of little or no value for manure; whilst the nitrogenous matter used to repair the waste of the muscular tissues and the mineral salts absorbed into the blood, after they have served their purpose, pass out into the manure. Thus nearly all the manure in a food that is not stored up in the increase goes into the farmyard manure. According to the experiments of Lawes and Gilbert on some sheep, only one-thirtieth of the mineral matter and one-twentieth of the nitrogen was extracted from the food to lay on the increase. We shall, therefore, be on the safe side if we consider nine-tenths of the manure in a food to be passed through the system into the farmyard manure. The value of cakes as manure is generally much higher than that of Barley, Oats, &c. Thus, the percentage of nitrogen in cakes is from 4 to 6½, whilst in Oats and Barley it is only from 1½ to 2 per cent., and the percentage of bone earth in cakes is from 5 to 7, and in Oats, &c., generally from 1½ to 3 per cent. An extreme example of this difference is shown in the comparison of Barley and decorticated cotton cake, which are generally the same price per ton in the market :—

Cotton cake, 7 per cent. of ammonia, worth £5 5s. per ton	£1 8 0
Barley, 2 per cent. of ammonia, worth £1 10s., and 2.8 of bone earth	0 7 0

If we deduct one-tenth of this value for loss, the cotton cake will be worth £6 per ton for manure, and the Barley £1 13s. 6d. From these figures it will be seen that the consumption of cake enriches the land much more than our own produce.

Modifications in Cropping Land.—When we consider that a crop of Turnips if taken off the land remove more manure than two crops of Wheat or Barley, the consumption of two-thirds of the crop on the land, along with cake, ought to put the land in a very high condition, and capable of bearing two or three crops of corn in succession. In the high districts in the south grow two crops of corn after the Turnips, with very good results; and when we consider the greater value the manure from cake is than from corn, it is easily seen that an extra crop of corn might be grown in the rotation without deteriorating the condition of the land, if a corresponding quantity of cake was consumed on the farm. And, if we could grow three average crops of corn for every crop of Turnips, our farming would be much more profitable than growing two as at present. In this district we seldom grow good crops of Wheat, as the bulk of it is sown in spring after Turnips. If we subsoiled the land after the Turnips, and sowed Wheat after the Barley, we would get it sown in October—the proper season. I have been much ridiculed for attempting to grow Wheat as a second corn crop, but if we consider that Wheat is longest on the ground, and that in spring the roots are extended more outward in all directions, we will see that it has a greater chance of flourishing in an exhausted soil than the shallow-rooted plants of Oats or Barley, which have no time to search for their food. Instead of sowing Clover and grass seeds at the end of every rotation, we should grow some other crop, as Peas, Potatos, or Rape; or, instead of these crops we might miss the Clover crop, and grow, after Turnips, two white crops, and then Turnips again, as many farmers have been obliged to do lately on account of the failure of the seeds. By so doing we are more certain to obtain a good crop of hay, if it is only sown once in eight or ten years, and the grass will probably make a good pasture for two or three years. There is no doubt that the sowing of grass seeds every four or five years has resulted in almost a total failure. On the other hand, I have several times noticed that where a second crop was not taken the field which had not been grass for eight years previously. Potatos might be grown on part of the land that should have been seeds. It is much better for the land to grow Potatos at this stage of the rotation than on the portion for Turnips, for the soil be comparatively clean, and they will be thrice cleaned during the ten years of the rotation; whereas if grown on the Turnip land, it would only receive two manurings during that time, and an extra one is requisite for this crop. Peas or Beans might be grown, accordingly as the land was clean or foul. They are generally very nearly as profitable as a corn crop, and are a change to the soil; the pea-straw is, besides, especially valuable to sheep or Turnips during winter. Tares are also a good substitute for the Clover crop, especially on land infested with weeds, as any annuals, such as Charlock, Poppies, &c., will be cut before they have ripened their seeds, and if the land be full of Couch-grass, or "quickens," it can be cleaned by a bastard fallow during the summer after the Tares have been cut. Tares are not generally a profitable crop, as the food obtained seldom pays the expenses of rent, seed, and cultivation, but they are sometimes absolutely necessary to some farmers in dry seasons, and materially lessen their consumption of artificial foods. In certain districts of the south of England, a large extent of Tares are consumed on the ground by sheep. An average crop is considered to maintain 20 sheep for one week. The land is ploughed immediately afterwards, and sown with white Turnips, but I should think these two crops will seldom pay their expenses, and are generally grown to keep light soils in good condition, and maintain the large stock of sheep which are usually kept on the light land farms in the south of England. On soils naturally poor, or out of condition, Rape might be grown instead of the Clover crop. At this stage of the rotation (being only the second crop after Turnips) the land ought to be clean, and having been ploughed in the autumn, one grubbing, and a little harrowing in the spring ought to be sufficient. The Rapeseed should be drilled in rows from 18 to 20 inches apart, and might receive 30*r.* per acre of artificial manure. This will increase the crop of Rape, and all the benefit of the manure will go to the succeeding corn crop. I believe much more produce would be obtained from Rape if sown earlier in the season. When sown about the first week of May the seed would be certain to germinate, and the crop would be ready for the sheep probably by the end of July, and would be a valuable food for fat lambs, or for the hoggs when the grass has got dry in the fall. After the Potatos come, the stems will shoot up again, and if we have an average rainfall, there would be a fair crop again in the autumn, which would be much appreciated by the breeding ewes. If any extent be grown of the crop, portions should be sown at intervals of two to three weeks, to afford a succession of meat for the sheep. All these crops, grown instead of Clover, may be sown with Wheat in the autumn, which is a great advantage, as Wheat is not found to answer after grass in this district, and the great bulk is not sown until spring. The autumn-sown Wheat is more certain and generally a heavier crop than the spring-sown; indeed, by some authorities it is considered to be heavier by 3 or 4 bolls per acre. By sowing Wheat at this part of the rotation we decrease the acreage of Oats after lea, and increase in proportion the extent of Wheat and Barley, which is very desirable; as although the Oat straw is the most valuable of the straws for fodder, yet the value of the corn is considerably less per acre than Wheat or Barley, and is more difficult to dispose of, especially since Indian meal and Beans have begun to be partly substituted for Oats in feeding horses. Another advantage of having autumn Wheat after Peas, Beans, &c., is that we are not compelled to sow so much Wheat after Turnips as we generally do in this district. Unless we have a favourable seed-time, the Wheat sown on land after Turnips, generally ploughed very dry, and which has probably been poached by sheep, is very often a thin and poor crop; but if it had been ploughed as it was cleared, and weathered by frost until spring, and then sown with Barley, the crop would probably be more remunerative, and the soil would be in a more friable state for the reception of the grass seeds. If in the combination of high feeding with heavy corn crops that produce the real profits of the farm; and it should be the object of every farmer to keep as much stock, and thus consume as much cake, &c., as he profitably can. By doing so, he will bring on to his farm substances unfit for human food, but rich in manure, and will be enabled to produce more meat and corn. It would also greatly benefit the landowner, if he enabled the tenant to farm highly, by giving him the security of a lease or tenant-right, and less restrictions in cropping his land; for the land will pay more rent if corn crops be more frequently grown, whilst its fertility will not be diminished if the artificial manures and the cake consumed be equal in manurial value to the increased quantity of corn sold off the farm.

A vote of thanks to Mr. Harle for his paper concluded the proceedings.

Farm Memoranda.

WEST SUSSEX : *Sept.* 19.—Harvest is now completed, and, on the whole, has been secured in good order. And now there are a good many samples of new Wheat in the market, and some of it is good and heavy, but the yield is said to be very bad—from 20 to 25 per cent. below last year. Much of the land has turned out very badly; the wireworm destroyed a great deal of it, and owing to the dull weather the rest did not fill up as a thin plant usually does; and as weeds come to fill up all blanks, some of the stubbles are in a very foul state.

Barley is a fair to heavy crop, and very little of it will be a good sample, and more than usual may be used in fattening, as meat is so dear. Oats will turn out well, and are already at rather a low figure.

We have abundance of grass in the fields, and lean stock are dear. The hay crop, on the whole, may be put at an average; though a good deal of the first crop was spoiled, there has been more than the usual quantity of second cut made, but some of it has been spoiled, and we do not expect hay to be very dear this winter. There is a great quantity of good oat and barley straw that will be useful for fodder, and with a mild autumn they will cost less than usual to keep.

Potatos, though a little diseased, are a good crop. The disease does not appear to be quite the same as formerly; it struck sharply during one or two days, and after that did not spread, and very few Potatos were hurt; those that were hurt had all rotted entirely before digging, and there are now no partially diseased ones, as has hitherto been the case, and they are likely to keep better. Carrots have suffered from wireworm, and there are many blanks among them; and far more than usual have run to seed. When early sown there are always a few do so, but this year a great many more than I have ever seen. Perhaps it is owing to the very changeable weather we have had,—cold nights, often with frosts in May, partly checking the growth, and then bright sunshine, with heat following, started them again. The weather is now very favourable for working the land, and Pea stubbles will be got in good order.

The root crops are not at all up to the mark. Mangel,

as a rule, are small, as they may be expected to be. Swedes are not good, and many of them are now going from the effects of grub and wireworm, and there are many blanks in the fields, both of Swedes and Turnips, so that we shall require all the extra grass to compensate for the root deficiency.

Lean stock are still dear, but sheep are not in such great demand as they were, as some fears are entertained for the supply of winter food.

Taking the season altogether, it can hardly be favourable to the cereals and grazing farmer, but rather so to the stock farmer; but many corn farmers, who are obliged to sell corn to pay Michaelmas rents, have to bring more acres into the market than usual, and by-and-by the home supply will fall off, and prices may be expected to rise. *C. S.*

The Week's Work.

SEPTEMBER 23.—*Seed Clover* is harvested about the close of the month. Wait for fine weather, as the crop should be secured dry.

Winter Beans are grown either in ridges or on the flat, and in lighter land than what is generally termed Bean soil. The cultivation and seeding is very diversified. They are now mostly grown in rows from 15 to 27 inches apart for horse-hoeing, but we have sown broadcast on an Oat stubble both with and without manure, and ploughed them in with a light furrow; or the Beans are sown broadcast on the Wheat or Oat stubble in the same way, with or without manure, but generally a slight manuring and the land ridged up with a double-furrow plough, or a bout of a common plough, which gathers the manure and Beans into a row in the centre. Where grown this way the rows are sometimes 30 inches apart, with 15 to 18 inches clear for horse-hoeing when the Beans come up in narrow beds 12 to 15 inches broad. If a light soil is set up deep, the drills will require rolling to let out the Beans equally, and on strong clays a light harrow may be needed to cover the seed. In the above examples the seed may be sown with a Bean-barrow at the back of the furrow in ridging, and in the bottom of every second furrow, where the crop is grown on the flat on lands liable to drift in winter. Another plan is to s nash up the stubble, manure and drill, or manure on the stubble, harrow and drill in one operation by stea n, and either dibble or drill in the seed by machine. But where the weather and season will permit, the more advisable course is to give the land a more thorough autumn fallow than above, in August if possible, or as early in this month as the work can be done, ridging and cleaning as for Potatos and Carrots, and then either dibbling or drilling in the seed with a machine, or the seed may be sown with a Bean-barrow over the manure, 2 bushels per acre.

Potatos.—Harvesting the main crop usually commences this month, South and North. When dug with a three-pronged fork, a man will keep two women or boys gathering with baskets. Where the Potatos are turned up by a common or double mouldboard-plough, or potato-plough with skeleton mouldboard, a man will shake out to six or eight gatherers. The Potato digger turns up and shakes out the Potatos, thus dispensing with manual labour both in digging and shaking out. A cart goes alongside the gatherers, into which the Potato-baskets are emptied, the duty of the carman being to empty the baskets so as to keep the gatherers going, and when the cart is full an empty one is ready to take its place. Potatos are stored either in barns or pits, the latter about the breadth of the cartwheels outside, so that the loaded carts can readily be backed into them. The pits are first covered with straw and an inch or so of earth, not quite up to the ridge, and when the "sweating" is over it is covered with from a foot to 15 inches of earth, with straw vents at intervals along the ridge for ventilation. Those who market immediately sort their Potatos in the gathering into three qualities; the first for sale, the second for seed, and the third for pigs. The more common practice is to pit the whole sound crop, and when sold to sort them by means of Potato-riddles, the width of the mesh being a matter of agreement. If there is any part of the field more promising than another for seed, the crop on that part should be pitted by itself, and in gathering the two extremes of unshapely large and premature small, so to speak, may be separated for pigs.

Manurings for Potatos, Carrots, Mangel Wurzel, and spring Beans and Peas, and the prior fallowing of the land, should be proceeded with without delay; and also the autumn fallowing of land for manuring for Swedes and Turnips at the time of sowing. In all such cases the land should get a thorough deep tillage, not less than 15 inches. Where it has been previously ploughed to this depth we prefer turning up the bottom to the weather by the plough, but where it has only been ploughed some 6 or 8 inches deep, smashing, subsoiling, or digging by steam is preferable, the subsoil in very few cases being perfectly sound. In late districts, where the harvesting of the Oat crop is only just concluded, the fallowing should be done at one operation, by steam in preference to horses, and if the weather will permit of manure being applied the manuring should keep close to the ploughing or smashing of the stubbles, so that when overtaken by heavy rain the work may stop until the weather breaks up, when the manuring of the newly ploughed or smashed land may be resumed; when otherwise, had the manuring of the newly ploughed land been allowed to fall behind, the carting after the rain could not be done so well, if at all. The stubbles may now be smashed and ridged for manure by steam at one operation, so that the manure-carts can go alongside the implement, the small heaps being left upon the stubbles and spread on the newly opened drills while the implement in returning is covering the manure in the last two or three drills.

The Dairy.—In our southern counties September is a good dairy month, the temperature being favourable for the operations of making either butter or cheese; but towards its close that great enemy, the moist atmosphere, begins to be felt, more especially on the west coast; hence the prudent maxim is to light the stove in time, not only to keep things dry and free from mustiness, but also to ventilate the milk-room and cheese-room when the windows are closed.

Notices to Correspondents.

POULTRY: *C. B., Charing.* Your Hamburgh hen, in all probability, was pecked or wounded by one of her companions, and as at this time of year when all birds are moulting, and consequently very tender in flesh and feather, the scar that at other seasons would have passed unnoticed assumed an importance that would not otherwise belong to it. The substance of which you speak as resembling "a cream cheese" is a pen-knife in of a tubercular nature, common to fowls and pigeons. The stoppage of the other nostril is rather a point against the health and condition of your birds. To the wound we should apply caustic, or the discharge we should commence with a treatment of castor-oil, and give a vegetable diet as far as possible.—Nos. 2 and 3: In showing silver-grey Dorkings you have no two shades of colour. As soon as a bird differs in any point from the colours laid down for the silver-grey class it would, by good judges, be disqualified or passed without notice. In breeding Hamburghs, with any idea of success, whether for sale or exhibition, the greatest care is necessary. Your idea as to breeding between the golden and silver birds would result, in all probability, in great disappointment.

SMALL STEAM-ENGINE FOR DAIRY FARM: *H. P.*, speaking of himself as the holder of a mixed dairy and arable farm, the former predominating, asks if any one has found it a paying process to buy a 2 or 2½-horse power steamer exclusively for chaff-cutting, pulping, &c., as has hitherto been unable to hear of any case where this has been done in his locality (Vale of Blackmoor, Dorset); nor can two of the local implement-makers inform him of any such case, although some cut chaff with threshing-engines.

Markets.

HOPS.

BOROUGH MARKET, Sept. 21.

Messrs. Pattenden & Smith report a steady demand for all good samples of the new growth, late rates being fully maintained. Quotations: — Mid Kents, £9 to £12 12s.; Weald of Kent, £8 to £10 10s.; Sussex, £7 10 to £9 9s per cwt. Yearlings command a fair amount of attention, at enhanced values.

METROPOLITAN CATTLE MARKET.

MONDAY, Sept. 18.

The number of Beasts is about the same as last Monday; choice qualities are, however, scarce, and realise a small advance on the average trade may be quoted about the same as last week. The supply of Sheep is unusually small for the time of year; the trade is not brisk, but choicest qualities are rather dearer. Choice Calves continue to be scarce and dear. Our foreign supply consists of 9020 Beasts, 11,270 Sheep, 311 Calves, and 10 Pigs; from Ireland there are 100 Beasts; and 1710 from the Midland and Home Counties.

Beasts, 4830; Sheep and Lambs, 20,630; Calves, 319; Pigs, 75.

THURSDAY, Sept. 21.

There are not quite so many Beasts as on last Thursday, and the demand is good; consequently Monday's quotations are fully maintained. The supply of Sheep is shorter, and choicest qualities readily disposed of at fully late rates; trade was, however, dull towards the close. Trade is not so brisk for Calves as of late, and prices are rather lower. Our foreign supply consists of 370 Beasts, 4680 Sheep, and 343 Calves.

MARK LANE.

MONDAY, Sept. 18.

The supply of English Wheat from Essex and Kent to this morning's market was again moderate, and although we do not alter our quotations, millers were reluctant buyers, and many samples were left unsold at a late hour. The attendance was fair, but only a very moderate demand for foreign, at a decline of 1s. per qr. upon the prices of this day se'nnight. Barley, Beans, and Peas were unaltered. Oats a slow sale, and rather less money was accepted for anything but good qualities. Flour not so much sought after. Mustard seed firm, at our quotations.

WEDNESDAY, Sept. 20.

The grain trade to-day presented a quiet appearance. The supplies of English grain were more liberal, but from abroad the arrivals were less extensive. Transactions were much restricted, and the tendency of prices was unfavourable. Choice Barley sold to a fair extent, at steady prices; but other qualities were dull, and in some instances easier. Malt sold slowly on former terms. The arrivals of Oats were good; the inquiry was inactive, and prices generally favoured buyers. Maize was firm, with a fair demand. Beans were dull, but prices were maintained. Peas met with a slow sale, at recent values. Flour was dull, at drooping prices.

LIVERPOOL, Sept. 19.—The market was well attended, but the transactions in Wheat were unusually limited, American and other red descriptions declining 3d. to 4d., and white 2d. per cental on the rates of this day week. Flour was without change, the extra qualities commanding full prices. Beans lost the improvement of Friday. Peas quite 1s. per qr. dearer. Indian Corn went slowly into consumption, and prices were reduced to those of Tuesday last.

SEED MARKET.

Our markets exhibit the same quiet but firm tone noted in our last; the autumn trade this year is an exceedingly poor one. In Clovers there is nothing passing. Trefoil seed excites but little attention. Winter Tares are in limited request, and are obtainable for less money. Rape seed continues scarce and dear. In white Mustard seed the tendency of prices is upwards. Bird seeds are quiet. New Rye is firm, at the recent advance. There is a fair trade doing in seed Wheats for France. Large Blue Peas are in good demand. Rye-grasses are dearer; French Italian is without alteration.

JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

ENGLISH WOOL.

Business during the past week has been somewhat limited, but solely owing to the high prices now asked, and which for the moment leave no margin to manufacturers. It is still, however, the prevailing opinion that next month will see a fresh start in the upward direction.

THE STEAM-ENGINE TRIALS
OF THE
ROYAL AGRICULTURAL SOCIETY of ENGLAND, OXFORD, 1870.

The FIRST PRIZES at this SHOW were again AWARDED to CLAYTON AND SHUTTLEWORTH, viz. :—
First Prize for Horizontal Fixed Engine of 10 H.P.; First Prize for Steam Engine, with Boiler combined.

At the previous Trials of Steam Engines, at Bury, 1867, CLAYTON AND SHUTTLEWORTH took ALL the FIRST PRIZES for ENGINES; also a PRIZE of £15 for THRESHING MACHINES, and the Society's SILVER MEDAL.

CLAYTON AND SHUTTLEWORTH have received FIRST PRIZES at all Trials of the Royal Agricultural Society of England at which they have competed since 1849.

N.B.—All the principal Makers of Portable Engines, &c., Competed for this Society's Prizes, being the only Trials in Great Britain conducted by competent and impartial Engineers, and where the capability and value of each Engine is thoroughly tested by practical experiments. C. AND S. therefore do not Compete at any other Shows.

PORTABLE ENGINES, from 4 to 25-Horse Power.
THRESHING MACHINES, Single, Double and Treble Blast, with Patent Rolled Steel Beater Plates, and all other recent improvements.

GRINDING MILLS, SAW BENCHES, STRAW ELEVATORS, &c.

☞ *CATALOGUES ON APPLICATION, OR FREE BY POST.*

CLAYTON AND SHUTTLEWORTH, STAMP END WORKS, LINCOLN;
78, LOMBARD STREET, LONDON, E.C.; and TARLETON STREET, LIVERPOOL.

GRAY'S OVAL TUBULAR BOILER.
INTERNATIONAL EXHIBITION, CLASS IX., NO. 2119.

MR. GRAY begs to call the attention of the Nobility, Gentry, Nurserymen, Gardeners, &c., to his

NEW OVAL TUBULAR BOILER.

Acknowledged by practical judges to be a great improvement on every form of Tubular Boiler yet introduced. It has proved itself superior to all other Boilers for quickness of action and economy of Fuel, doing its work with one-third less the amount required by any other.

Extract from Report in GARDENERS' CHRONICLE *of International Exhibition, May 24, 1862, page 476.*

"The upright form of Boiler is usually made on a circular plan, rather than a square, it seems feasible that the Boilers on the oval plan should bring the tubes more completely within range of the burning fuel; and this being so, the change, though a slight one, is no doubt an improvement."

☞ *They are made of all sizes, which, with prices, may be had on application.*

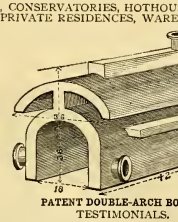
JAMES GRAY, HORTICULTURAL WORKS,
DANVERS STREET, PAULTON'S SQUARE, KING'S ROAD, CHELSEA, S.W.

J. C. & J. S. ELLIS,
HORTICULTURAL ENGINEERS,
NORFOLK FOUNDRY, SHEFFIELD,
MANUFACTURERS and ERECTORS of HOT-WATER APPARATUS
OF EVERY DESCRIPTION, FOR
HEATING GREENHOUSES, CONSERVATORIES, HOTHOUSES, CHURCHES, PUBLIC BUILDINGS, PRIVATE RESIDENCES, WAREHOUSES, &c.

The great advantages of these Boilers are :—

The fire acting directly under the flow pipe, the water begins to circulate immediately.

The Flues all being formed by a continuous water-way, the fire and all the hot gases are brought in direct contact with the heat-absorbing surface of the Boiler, thereby giving a greatly increased amount of power, and by which an immense saving of fuel is effected.



PATENT DOUBLE-ARCH BOILER.

These Boilers offer great facilities for banking-up the fire, and will burn easily from 12 to 14 hours without attention.

The arrangement of Soot-doors in the brickwork is such that all the flues can be cleaned in a few minutes.

TESTIMONIALS.

"The Gardens, Chatsworth, January 19, 1871.
"DEAR SIR,—After using your Patent Double-Arch Boiler for the past 12 months, enables me to speak with a practical knowledge of its merits; and I have no hesitation in saying, out of many Boilers, of all sorts of construction, we have in use, it is the most efficient, and I believe it to be the best Boiler extant; neither do I think there is another that exposes so much surface to the direct action of the fire. Its efficiency, economy in fuel, and the minimum of attention, renders this Boiler a valuable improvement in Horticulture, and it reflects great credit on your good sense in designing it. I shall be glad to show the one I have in use to any person calling at Chatsworth.
"Mr. Ellis." I remain, dear Sir, yours truly, "THOMAS SPEED.

"Westbourne Gardens, Sheffield, October 27, 1870.
"DEAR SIR,—Your Patent Double-Arch Boiler, that you have put down for us lately, to heat the whole of our houses, answers admirably. Its heating surface exceeds all others which I am acquainted with. The small amount of fuel required, the way it is set, and the arrangement of soot-doors, renders it the most complete and economical Boiler I have had to do with.—Believe me, Sir, yours truly,
"Mr. Ellis, Norfolk Foundry, Sheffield." "W. H. BIRD.

Horticultural Buildings.

A. SHANKS AND SONS' CATALOGUE of HORTICULTURAL BUILDINGS in IRON and WOOD, including DESIGN of GRAND WINTER GARDEN recently erected by them in Edinburgh, will be forwarded on receipt of 3d postage stamps.
Arbroath Works, Arbroath, Forfarshire; and 27, Leadenhall Street, London, E.C.

Greenhouses and Conservatories.

H. FREEMAN AND SONS' HORTICULTURAL WORKS, 106, Mare Street, Hackney, E. Established 25 years. Good sub-tantially made GREENHOUSES, glazed, ready for fixing, 40 feet long, 12 feet wide, £28; 15½ feet by 8½ feet, £38; 21½ feet by 10 feet, £55; a handsome CONSERVATORY on stand, 35½ feet by 18 feet, £110; Nurseryman's LIGHTS, 6s. per 100 feet.

Hot-Water Pipes and Boilers.

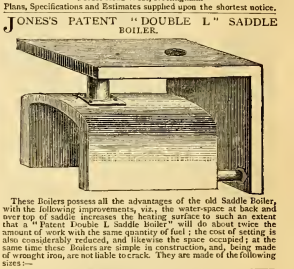
IMPERISHABLE HOTHOUSE COMPANY,
Newark-upon-Trent, Notts.
MANAGER.—W. P. AYRES, C.M.R.HS.,
a practical Rose Grower.

Plans, Specifications and Estimates supplied upon the shortest notice.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.



These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "Patent Double L Saddle Boiler" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, as the fire-brick fireside space occupied; at the same time these Boilers are simple in construction, and, being made of wrought iron, are not liable to crack. They are made of the following sizes :—

Sizes.			To heat of 4-in Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	5 0 0

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Oct.	{ Royal Horticultural (Fruit and Floral Committees), at	11 A.M.
	{ Ditto (General Meeting) "	3 P.M.

ALL horticulturists know how deeply they are indebted to the labours of BOTANICAL COLLECTORS. A glance round any garden, great or small, will at once show how large a proportion of its inmates owe their presence to the zeal, enterprise, and labour of the collector. Sadly too often has it happened that his efforts have resulted in the loss of life: yet more frequently in the sacrifice of health. There is no necessity to dwell on this—we all acknowledge it; we profit by their labours, and honour their zeal, and glory in their triumphs. We shall not be accused of any lack of appreciation of the efforts of those who have gone before—efforts not exceeded by those of any class whatever,—if we now proceed to point out sundry matters on which information is still wanted, countries still unexplored, and from which a rich harvest may be anticipated. It is natural and proper that the commercial spirit should be thoroughly manifest in these explorations, for it should be kept in check, and guided by higher considerations. Mere greed and love of gain should, under no circumstances, be allowed to prevail over the requirements of science, and the general welfare of humanity.

We are led to these remarks by the comparatively little trouble which the modern race of collectors give themselves, to attend to anything but the purely commercial element. To exterminate rare plants, to communicate wrong localities, to preserve no authentic specimens with localities attached for purely scientific purposes, to give heedlessly scientific names to plants collected without due inquiry, all this is to injure science very materially; and from a commercial point of view, sooner or later, it is equally detrimental, as the existence and history of valuable

commercial products is too often overlooked in the exclusive and sordid devotion to one object. All this is a veritable killing of the goose that lays the golden eggs. Such selfishness is opposed to the spirit of the times, and sooner or later it is sure to recoil on the heads of those who pursue or sanction it. Much that yet remains uncertain or unknown may be attributed to some such causes as we have hinted at, still more perhaps to a want of sufficient knowledge on the part of those who have the opportunity and often the will to do good service did they but know how to do it. For the benefit of such persons the late Sir WILLIAM HOOKER and other scientific men, some years since, prepared a volume published under the authority of the Admiralty, and to a new edition of which we now beg to call attention.

In the new edition of "The Admiralty Manual of Scientific Inquiry," the article Botany, originally written by Sir WILLIAM HOOKER for the guidance of those persons serving in or visiting foreign countries, in collecting plants and their products, has been revised by Dr. J. D. HOOKER, C.B. The instructions for collecting living plants for cultivation, for collecting and drying plants for the herbarium, and for collecting and preserving specimens for the museum, are brief, but quite to the purpose. The existence of this article cannot be too widely known amongst travellers, especially those whose business or pleasure takes them into those parts of the world the botany of which is at present but little known; for though of late years much of the earth's surface has been opened out, it is nevertheless quite true "that much of it is still unknown, alike to the botanist and the geographer. The interior of South America, particularly towards the sources of the great rivers; the deserts and mountain chains of Africa, all Central Asia, with the northern declivities of the Himalaya mountains, the Chinese dominions, much of Japan, and all the Malayan Archipelago, are still *terræ incognitæ* to the naturalist."

The subject of Insular Floras is one of so much interest, that every effort should be made in collecting materials for its elucidation; and for the purpose of bringing the matter more prominently before our readers, we cannot do better than quote the following paragraphs :—

"The botany of islands, and especially of oceanic islets, is of especial interest; and considering the means afforded by the officers of the Royal Navy of visiting them, it is astonishing how little has been done in bringing collections from them. Of many that lie not far from the usual tracks of ships, absolutely nothing is known, whilst of the flora of a vast majority we possess only imperfect materials. The following are especially worth exploring, and to the list is added an indication of the least explored coast lines of the great continents. As far as possible complete collections should be made, not of a family of each group, but of each islet of the group, for it is usually the case that the floras of contiguous oceanic islets are wonderfully different. Of those in italics the vegetation is absolutely unknown, or all but so.

"1. ATLANTIC OCEAN.—Cape de Verd, Tristan d'Acunha, *Fernando Noronho*, *Trinidao*, and *Martin Vas* (off the Brazil coast), *Diego Ramirez*, S. Georgia, off the African coast, Morocco, Senegal, the Gaboon, and Kamaroons, and Fernando Po; the novel flora of the Amazon coast, Cayenne, Bahia, to Cape Frio, Patagonia.

"2. WEST INDIES.—The Babamas and St. Domingo; and of the Antilles all remain to be explored, except Dominica, Trinidad, and Martinique. On the mainland, Honduras, Nicaragua, and Mexico; the Mosquito shores and Guatemala offer rich fields for botanical research.

"3. INDIAN OCEAN.—The Seychelles, *Ammirantes*, Madagascar, Bourbon, *Socotra*, *St. Paul's*, and Amsterdam Islands, *Prince Edward's*, the *Crozets*, and *Marian* groups.

"Of the East African coast no part is well explored, and from Pemba northwards it is utterly unknown botanically.

"4. PACIFIC OCEAN.—1. N. Temperate : Collections are wanted from N. Japan, and the Kuriles and Aleutian Islands. 2. Tropical : Considerable collections have been made among the Society Islands, Fiji Islands, Tahiti, and New Caledonia ; from all of which more are wanted. The *Marquesas*, *New Hebrides*, *Marshall's*, *Solomon's*, and *Caroline's*, together with all the smaller groups, may be said to be wholly unknown. Of the American continent, the Californian peninsula, Mexico, and the whole coast from Lima to Valparaiso, are very imperfectly known. Of the small islands off the coast, Juan Fernandez, and the Galapagos alone have been partially botanised. 3. S. Temperate ; Juan Fernandez, *Masafuera*, *St. Felix*, and Ambroise, *Pitcairn*, *Bounty*, *Antipodes*, *Emerald*, *M'Quarrie* Islands.

"5. INDIAN ARCHIPELAGO.—Java alone is explored, and the Philippines very partially ; collections are especially wanted from all the islands east of Java to the Louisiade and Solomon Archipelagos. Siam, Cochin China, and the whole Chinese sea-board want exploration.

6. Australia : All the tropical coasts are very partially explored."

The appendix to this useful little article is equally valuable with the article itself. It is drawn up by Mr. D. HANBURY and Prof. OLIVER, and is composed of a series of inquiries into the sources or origin of pharmacological and economic substances, about which at the present time we know little or nothing, and it is a fact worth noting that many of these articles about which we know less are amongst the most valuable of our imported products. For instance, we read that—

"Gutta-percha is, even up to the present day, little known. It is said to be yielded by several plants, such as species of *Isonandra*, *Chrysophyllum*, *Sideroxylon*, and others. Attention should be paid to the vernacular names, such as *Gutta-percha*, *Ugiato putih*, *Kotian*, *Tuban* or *Taban*, &c. Abundant and carefully preserved wet and dry specimens of the leaves, flowers, and fruits of the different kinds, the products of the same individuals from which the dried specimens were obtained, are greatly needed."

With regard to drugs or medicinal products, still less is known. Sagapenum, for instance, is occasionally shipped from Bombay, and it is presumed that it is produced in Persia. Though it has been used in medicine for ages, its botanical origin is not ascertained, but there seems to be no doubt that it is the produce of an umbelliferous plant. Little is also known of the origin or source of Galbanum, though it is more common than Sagapenum ; it occurs in trade in two varieties, which are so distinct as to lead to the inference that they are the produce of different plants. Galbanum is said to be imported into Russia in large quantities by way of Astrachan, but that which reaches England comes principally from Bombay.

It is with the hope of clearing up such doubts as these that the queries have been strung together and added to the appendix to this article, Botany, of "The Admiralty Manual of Scientific Inquiry."

We have received the following letter, on the TEMPERATURE OF FUNGI, from Dr. MCNAB, the Royal Agricultural College, Cirencester :—

"Last week I met with a number of specimens of the Giant Puff-ball, Lycoperdon giganteum, while making one of my usual weekly class excursions in the neighbourhood of Cirencester. Two of them were selected, a large and a small one, for future specimens, while a portion of a very large one was placed by me in my botanical box. Next morning on opening the box I found the contents sensibly warm to the hand, and had no difficulty in tracing the effect to its cause. The portion of Fungus was quite warm, and had communicated part of its warmth to the other plants in the box. Unfortunately, no thermometer was at hand at the time, or a careful reading and tabulation of the temperature would have been made. The smaller specimen of the Puff-ball, weighing 1 lb., was taken, and placed in a box, where it remained all night. Next morning, two readings of the thermometer were made at 8.45 A.M. The temperature was again observed at 10.30 A.M. and 11.15 A.M.

	8.45 A.M.	10.30 A.M.	11.15 A.M.
Temperature of Fungus.. ..	1. 12°.2	2. 12°.4	12°.2
Temperature of air	11°.1	11°.2	11°.6	10°.0
Difference ..	1°.1	1°.2	0°.8	0°.2

Next morning two readings were taken at 9.10 A.M., the Fungus being warmer than the surrounding atmosphere.

	9.10 A.M.	
	1.	2.
Temperature of Fungus	11°.4	11°.5
Temperature of Air	10°.5	10°.6
Difference	0°.9	0°.9

On the next morning the Fungus was found to be drying up, and the observed temperature was only 0°.2 higher than that of the surrounding air. The air outside the box, 11°.4 ; inside the box, 11°.4 ; temperature of Fungus, 11°.6. No further observations were made.

"A. DE BARY mentions (HOFFMEISTER, 'Handbuch der Physiologischen Botanik,' vol. II, pl. I, p. 228) that the temperature has been observed by DUTROCHET in five fungi belonging to the genera Agaricus, Boletus, and Lycoperdon. He, however, was only able to observe an increase of from 0°.10 Cent. to 0°.45. The greatest increase in my specimen was noticed on the first morning of the observations, at 8.45 A.M., namely, 1°.2 Cent.

"The greatest increase is evidently produced during the night, as the difference between the temperature of the Fungus and air rapidly diminished, so that at 11.15 A.M. the difference was only 0°.2 Cent.

"The difference between the morning temperatures on the first and second day of the observations—1°.2 and 0°.9—can be easily accounted for by loss from conduction, &c., but chiefly from the loss of heat caused by the evaporation of water, the weight of the Fungus having decreased from 16 oz. to 13¼ oz. during the three days the experiments lasted.

"The cause of the increase of temperature is due to the oxidation of the nutrient materials in the Fungus, a process depending on the absorption of oxygen, which sets on these nutrient materials, and causes various metamorphoses, an equivalent quantity of carbon dioxide being liberated. This metamorphosis of nutrient or assimilated materials goes on in all plants in daylight as well as in darkness, and is always associated with the taking up of oxygen and liberation of carbon dioxide, a process which is now recognised by all Continental physiologists as the true respiration of plants. In Spirogyra we can, during the day, observe the formation of assimilated materials such as starch in the cells, which contain chlorophyll. During the night the assimilated material is metamorphosed or elaborated, and the cell divides and converts the assimilated material, after it has been metamorphosed, into tissue and protoplasmic substance. In Fungi the nutrient materials are probably taken up only during the day, and during the night metamorphosis, or elaboration of these materials, takes place. Heat is the result of the oxygenation, and, from the energy of the process and size of the plant, the elevation of the temperature is very marked. All the temperatures are given in degrees Centigrade, and as the temperatures were always carefully observed by Professor CHURCH, the accuracy of the readings may be depended on."

—— Several inquiries having reached us respecting the INTERNATIONAL EXHIBITION OF FRUIT on Wednesday next, it may be useful to print the following information, which we have obtained from headquarters :—The "Collection of Apples" (Class I) is intended to include both culinary and dessert sorts. The same remark applies to the "Collection of Pears" (Class 4). The exhibitors need not, on this occasion, be the growers of the fruit they exhibit. It may, however, be a question another season whether separate classes should not be provided for growers who show only their own productions.

—— In the current number of the "American Journal of Science," we find the following note relating to the stamens of the GRASS OF PARNASSUS (Parnassia) :—

"In the 'Journal of the Linnean Society,' vol. xi., Mr. A. W. BENNETT published, two or three years ago, an interesting article upon Parnassia—its structure, affinities, and its mode of fertilisation. I am now to remark only upon its anthers, which are generally described as extrorse. Mr. BENNETT, observing that the present writer, in the 'Genera of North American Plants Illustrated,' describes the anthers as introrse, and gives a drawing of *P. caroliniana* as illustration, proceeds to say :—'I do not, however, find any other observer to agree with Professor GRAY's observation in this respect, except two American botanists, Dr. TORREY and Mr. CHAPMAN, who have probably taken their descriptions from him ; nor do any specimens which I have been able to examine of this species confirm any departure in this respect from the ordinary type of the genus.'

"It is easy to show that Dr. TORREY's observation, at least, is independent and original. In his 'Flora of Northern and Middle States,' published in 1824, p. 326, he described the anthers of *P. caroliniana* as 'incumbent;' in his 'New York State Flora,' 1843, as 'fixed by the base, introrse.' The first volume of the 'Genera N. Am. Illustrated' appeared in 1838. This season I have, for the first time, had a good fortune to look at *P. palustris* and *P. caroliniana* in flower, in the Botanic Garden of Harvard University, the former blossoming at the beginning, the latter at the close of August. The difference between the two species in this respect is obvious.

"In *P. palustris*, the anthers are certainly extrorse as to insertion ; but the line of dehiscence lateral, with introrse rather than extrorse tendency.

"In *P. caroliniana*, the anthers are quite as much introrse as extrorse as to insertion, and truly introrse for dehiscence. A transverse section removes all doubt, showing the connective or solid part to be posterior, and the anther to be as truly introrse as possible. *A. G.*"

In reference to this matter, we may refer to some correspondence in our columns, 1870, p. 147, where, in specimens sent to us from Oban (as well as many others since seen, from other localities), the anthers opened laterally, and moreover the pollen was liberated before the buds were open, though neither the filaments, nor the style, nor the ovules were fully developed ; from which we drew the inference, that the object of the peculiar palmate scales of these elegant plants was, not to convey pollen to the stigma of its own flower, but rather to retain it, and subsequently allow insects to convey it to the stigma of some other flower, thus serving much the same use as the corona of Passionflowers.

Some interesting papers have lately been published in the Journal of the Society of Arts, under the heading of the INDUSTRIAL CLASSES ABROAD. The papers are based on official reports compiled by the British Consuls in various countries, and take cognisance of the rate of wages, the state of the labour market, the cost of lodging, food, clothes, the fiscal or other restrictions on trade, manufactures, &c. The general result is that the working classes are better off in Great Britain than on the Continent, and that there are but few promising fields for the artisan in the Old World. Across the Atlantic, however, the conditions are reversed, in spite of the increased cost of lodgings and of all necessaries of life, except butcher's meat. On the farms of the West the high rate of wages for labourers, we are told, soon enables them to start a farm for themselves. Even in Louisiana, where the climate is none of the healthiest, and ill-adapted for European constitutions, it appears that in the healthy districts, by means of regular habits, industry, perseverance, frugality, and tem-

perance, it is quite possible for any ordinary individual to acquire by economy a capital after 10 or 15 years of work. "Cases," says the report of Mr. Consul Briggs, "could be cited of men who could neither read nor write 10 or 15 years ago, who now possess a capital of 8000 dols., or £1500, acquired simply in this manner, in one of the ordinary occupations of mankind—as a *gardener for instance*" (the italics are our own)—"and that without any more than the usual share of intelligence, with no extra gifts in his speciality." From the same report we learn that there is a general demand for waggon makers, blacksmiths, common engineers, horsekeepers, and men conversant with the details of a farm or garden, or for those able to manage a market garden in the neighbourhood of the inland towns. There is a significant hint that if railway and river communication is excellent, so that those who are dissatisfied with their lot in the Southern States can readily betake themselves anywhere else, as to the Western States of the Union, which open a new field of almost boundless extent. In Pennsylvania the respectable mechanic, in comparison with his British compeer, is described as "better housed, better fed, and equally well clothed', but still at a far greater expense." Admirable schools are provided at the public expense, though, *surgit aliquid amari*, "a large number of this class who ought to profit by the free education neglect to do so," and the result is that in the State there are 75,000 in Philadelphia alone 25,000 children—"who do not frequent the public schools, and who lead a life of reckless Bohemianism." Clearly, then, the American Union is not quite the paradise for the labouring classes that it is sometimes represented to be, and the Old World faults, follies, and crimes, thrive as vigorously across the Atlantic as here, and produce the same misery. To this the answer may be, that this is the fault of individuals, but so it is here; and balancing one thing with another, we think there is reason to doubt whether a workman, be his calling what it may, and who has the requisite regularity of habit, industry, and the other good qualities abovementioned, is not as well off here as in the United States. We are speaking of a first-class workman, be it understood, and one possessed of all those qualities mentioned by Mr. Consul Briggs, and which would, we presume, secure to their owner commensurate advantages anywhere, unless under specially unfortunate circumstances.

—— The Berkhamstead Nursery has for some few years had a reputation for Grape Growing, which is not likely to be lowered by its productions of the present season, the large vinery, as usual, showing an extraordinary crop of fine fruit. We, however, now more particularly refer to some splendid clusters of Muscat of Alexandra, which are well worth going to see. We believe Mr. Lane intends to exhibit some of these Muscats at the Great International Fruit Show, on October 4, so that those who cannot get to Berkhamstead, may have an opportunity of seeing some of them in London on that occasion.

—— The Maximum Temperatures of the Air during the week ending September 23 ranged from 69°.9 at Nottingham to 59°.8 at Dundee, with a mean of 63°.8 at the English and of 57°.6 at the Scotch stations. (See Mr. Glaisher's Tables.) The extreme lowest temperature in the week at the English stations was 35°.2 at Portsmouth, and was 39° at Edinburgh, being the lowest in Scotland. Generally the temperature in England rose during the day 5° to 6° higher than in Scotland, but sank lower at night on an average of 4°; the mean of the lowest in England was 39½°, and in Scotland was 43°. The mean temperature of the week varied from 53° at the South of England to 49° in the North, and varied from 49° to 52° in Scotland. The mean of the 15 stations in England was 50°.9, and of the seven in Scotland was 50°.2. The average Rainfall of the English stations was 0.2 inch, and of the seven in Scotland was 1 inch nearly. The weather was cold everywhere.

—— Mr. W. Wadsworth, in a letter to the *Sacramento Union*, strongly advocates the Manufacture of Sugar from Melons, rather than from Beet. The sugars are, when manufactured, chemically identical, and in Hungary and Italy Melon sugars are even now largely produced. Melons only require 16 feet of ploughed land, as against 50 for Beet. The Melons picked from the Vine are ready for the mill at once, whilst Beet has to be stacked and otherwise prepared. Sugar-making can commence one month sooner, and be continued as late. The Melons yield their seed each year; Beet requires a second year and careful culture to obtain the seed. Melon seeds yield 16 per cent of excellent table oil. The surplus of Beet seeds is useless. Mr. Wadsworth also states that with Melons the manufacturing processes are far less troublesome and costly. The rinds, with dry grass or straw, make good food for milch cows. The yield of sugar is as 7 per cent. from Melons, to 8 per cent. from Beet.

—— The New York publications mention a Lilium columbianum as a very pretty species. It is said to be a native of Columbia and Washington territories, to grow from 1 to 2 feet high, and to have a most graceful habit. The leaves are whorled, resembling those of L. superbum; the flowers small, with reflexed petals, orange-yellow, spotted with dark brown. The bulbs are noted to be as hardy as any of the American Lilies, and to thrive in rich moist soil.

—— To obtain Dwarf Dahlias, M. Rafarin, says the "Revue Horticole," forces the tubers in a stove, in February, and when the shoots have developed some, what they are cut off, and struck as cuttings. Another method adopted by M. Rafarin is to force the tubers as above, and when the shoots attain a height of a foot or 18 inches the end is pinched off, the lateral buds then grow out, and are pinched off at the extremities in the same manner. This continued pinching induces a dwarf habit, as might be supposed.

New Garden Plants.

Dendrobium fugax, *n. sp.*

Dendrocoryne, pseudobulbis stipitatis brevi-fusiformibus monophyllis; foliis cuneato-ligulatis obtuse acutis; floribus terminalibus subsolitariis, remotiusculis, fugacissimis; mento rectangulato, sepalo dorsali ligulato acuto, sepalis lateralibus subsequalibus, latioribus; sepalis basi unguiculatis; labello basi cuneato dilatato amplo; lacinia lateralibus antrorsis obtusangulis, lacinia media unguiculata abrupte hastata flabellata, dilatata, antice emarginata, lateribus undulatis; carina membranacea utrinque a basi in apicem unguis antice crenulato lobulato, postice integerrimo; columna brevissima.

A very curious botanical species, having stalked shining bulbs, 1 inch or less long, sheathed at the base, and giving stalked new leaves from the bulbs. The latter reach the length of 5 inches, and are nearly 1 inch broad. The flowers are yellow, with a white lip, marked with some purple and yellow. The flower is of the very thinnest structure, and lasts but a few minutes. It bothered for many years both its possessor and its grower; neither of them could, either by day or night, get to see it flowering, though they watched it with the greatest care. At length, after much trouble and anxiety, came March 14, 1871, when J. Day, Esq., was so fortunate as to catch the fugacious flower just when it was kind enough to get open. A sketch was prepared, and—*avis aux lecteurs*—two flowers were dried for the benefit of the writer of these lines. The species stands close to Dendrobium convexum, Lindl., and D. xantholeucum, Rchb. f., but the middle part of its lip is totally different, to say nothing of the two thin carinæ. I have been lucky enough to get a few flowering bulbs from the Hamburgh Botanic Garden, and expect the interesting moment when its little thin flowers will be produced. *H. G. Rchb. fil.*

Trichocentrum capistratum, *Lind., Rchb. f.*

Foliis oblongo-lanceolatis acuminatis purpuratis; pedunculis unifloris; sepalis linearibus acutis; tepalis paulo latioribus apice revolutis; labello ligulato oblongo acuto, basi in calcar brevissimum depressum pentaceras extenso; columna breviori bialata alis ligulatis obtusis, androctinio postice bidentato; anthera semilunata. hispida.

This little plant is one of the greatest curiosities I have ever seen. There are many Orchids with two spurs—the Satyria, Diplocentra, Comparettias,—there is something comparable to two spurs in Rodriguezias and Scelochilus now and then; but an Orchid enjoying five spurs at once was never seen before. Hence I looked with a certain feeling of reluctance on the small yellow flower, which was a white lip, bearing some purplish dots and spots on the sides of the wings and on the anterior side of column, and one purplish blotch at the base. I saw the plant in good health in September, 1870, in Director Bateman's establishment. Was it not a monster? This suspicion was the reason of my not publishing the plant. Now, however, the scene has changed totally. Mr. Endres, the excellent Costa Rica traveller, has found since 1867, in Costa Rica, another Trichocentrum, bearing the same most remarkable spurs, and also broad over-acute leaves, brown sepals and petals, and a rhomboid white lip, with purplish numerous spots, a shorter column, with rhomboid wings (T. calceseras, Endr., Rchb.) The T. capistratum would appear to have been also collected in Costa Rica by Wallis. *H. G. Rchb. fil.*

CONIFEROUS NOMENCLATURE.

I am always pleased to see an effusion from the pen of my old and warm-hearted friend "C. F. P.," of The Grange, Kingston. I know he will forgive my gentle touis aid in helping him out of the muddle into which the "Pine doctors" have plunged him. Were he alone in this dilemma I should not treat him so jocosely, I regret him too much for this. But seeing that he and all the Pine doctors together are in a fix, I cannot help smiling at their simplicity in keeping their patients so long in the fever hospital. My friend's article on "Picea lasiocarpa" is an odd one. I shall not waste paper in giving the various names by which this tree has been sent out (all of them wrong), but simply state, without fear of contradiction, that no species of Picea exists at present in Great Britain to which the name of "lasiocarpa" can be correctly applied. Professor Balfour named a tree "Picea lasiocarpa." This tree was raised from Jeffrey's first batch of seeds, and, as far as I know, only a very few were raised, and the only plant of it in England is in my nursery at Borrowash. In Jeffrey's second expedition he plucked our Scotch friends and others of their cash, and then cut off to the diggings, and left them in the lurch. Some years after Messrs. Parsons, of Flushing, engaged Messrs. Low & Co., of Clapton, as their agents, to sell a number of Californian trees in England, and amongst them the trees known generally as "P. lasiocarpa, Lowii, and Parsonsii." The present Mr. Low, of Clapton, sent home from America to his father, then alive at Clapton, a plant of a sort which Messrs. Parsons had to offer. The late Mr. Low sent this, with others, to me at Elvaston Castle, and requested me to give him their names. I wrote back to the effect that this species was "either P. lasiocarpa or a new species." I had not at that time had an opportunity of examining the plant named P. lasiocarpa by Dr. Balfour. In a few days after this I went to Edinburgh, and as soon as I saw P. lasiocarpa, I told Mr. McNab that it was not specifically distinct from the Picea grandis of Douglas, but only a distinct variety of that species. I also told Dr. Balfour the same when I met him in Switzerland in 1861.

Shortly after my return from Scotland, I found that Mr. Low, jun., had returned from America with the consignment of new trees; and that Mr. Bull, with all his alacrity and push with new things, had bought of them largely, and had scattered them over the country, under the name of P. lasiocarpa, upon no better authority than my qualified letter to Mr. Low, sen., saying that it was either lasiocarpa or a new species. As soon as I had an opportunity, I ran up to Clapton, and put Messrs. Low right by telling them that it was "not lasiocarpa, but a new species." The season following, Mr. Parsons and Mr. Veitch contracted unconsciously with the American Government to make a tour of Europe prior to the Park at New York being laid out. Mr. Parsons called on me at Elvaston Castle, and I told him his Picea was a new species. A few months after this he wrote me from Lausanne as follows:—

"Dear Sir,—The proof you gave me of the decided distinct character of our Picea lasiocarpa was so satisfactory to me, that I cannot doubt that your opinion must be adopted by all. In that case, what shall be its name? I do not think that either my brother or I have much right to name species we have introduced; but as we are commercial men, there are certain advantages to be derived from fathering the nomenclature of a really good thing. It is perhaps, therefore, a fair question whether we are not entitled to have this Picea called by our name. It was obtained by our enterprise and ex penditure of money. Four years ago, before much movement was made to collect seeds in California, we ordered a merchant there to send one to a man and collect seed for us, let the cost be what it may. He wrote us that he had done so, and in a few months sent us a parcel of seeds with an immense bill. From these came this Picea, which we now call lasiocarpa. Are we right, or is it fairly entitled to its name?—and would not Parsonsiana be as euphonious as Nordmanniana? Please write me what you think of it, as you are an authority in this, because Backhouse and all others still call it lasiocarpa. *S. B. Parsons.*"

It was then published in my catalogue as Picea Parsonsii. Some time after this, Mr. Gordon brought it out in his supplement as Picea Lowii, in compliment to Messrs. Low, who were only agents for its sale.

Seeing that that it has not any connection with the so-called Picea lasiocarpa of Dr. Balfour, and that Picea Parsonsii was its first legitimately published name, it will be well for the future, to avoid confusion, that all misnomers be put under ground. Picea magnifica, poor thing, has also been woefully abused by the libellers. It has been vended as Picea amabilis, P. nobilis robusta, P. amabilis robusta, and numerous others. Any worthy friend thinks it will turn out a nobilis after all; and well he may, as most of the doctors say so. Doctors are only like other men—seldom guilty of extensive, sound, pathological knowledge; hence the patients must suffer. Here is a fact worthy of their consideration.

Picea nobilis belongs to the longi-bracteata section. The bracts quite cover the scales; whereas Picea magnifica (a good name) belongs to brevi-bracteata, having its bracts entirely hid within the scales. This week I went to Dr. Lindley's to see one of P. magnifica with a branch; also a good cone of P. nobilis, in order that he may fulfil the promise he made me when last here, viz., that if I would send him a cone and branch he would name it with authority. This I have no doubt he will do.

Picea grandis is well worthy of its name, whatever locality or mismanagement in any way may have done to establish a contrary opinion. There was only one tree of this species originally raised from David Douglas' seeds. I was quite familiar with it, and its true history, 36 years ago. As I believe I may fairly take credit for conserving to our country this noble tree. When my friend "C. F. P." favours me with a visit, I shall be pleased to drive him to a piece of that tree, well worth a journey from Taunton to Derbyshire to make the *amende honorable*, and to acknowledge its grandeur by a significant bow of admiration! Unless certain conditions are fulfilled in the procreation of trees, a progeny of worthless seedlings will be the result. But when these conditions are duly observed, and the nursing or after management is in strict accordance with the requirements of a healthy and vigorous constitution, all diligent attention bestowed on them will be amply rewarded. Who ever saw a healthy and fully developed Abies excelsa, canadensis, Pinus Cembra, or Picea grandis as an isolated tree, fully exposed to the four winds of heaven? I never did. Why, then, so place them? All four are proof

against a lower temperature than we ever experience in this country. Shame upon our teachers, who have never failed to collect their fees! and for what?—only to find us, as a nation, the laughing-stock of those who have far outstripped us in useful knowledge.

Excuse my blunt axe in so roughly hewing these knotty trees. *William Barron, Elvaston Nurseries, Borrowash.*

MILTONIA WARSCEWICZII.

Those who purchase imported Orchids have had abundant facilities offered them for becoming acquainted with this plant (fig. 281), it having been introduced in large quantities from Peru, and sold at Stevens' sales under the provisional name of Oncidium Weltonii. It is also known as Odontoglossum Weltonii, and Oncidium fuscatum of gardens. A capital figure will be found at t. 5843 of the "Botanical Magazine." When not in flower the plant is easily recognised by its long, flat, ancipitate pseudobulbs. The flowers are borne on a panicle, and on imported flower stems, scarcely a foot long, as many as 20 pedicels have been counted; so that when it becomes fairly established in our collections we may expect it to be a profuse bloomer. The sepals and petals are ligulate, their margins being reflexed and beautifully undulated, of a warm brown colour tipped with golden yellow. The larger part of the lip is of a dull purple, the bilobed apex being creamy white. The plant was discovered by Poeppig, and since collected by Warscewicz, Welton, and others; while the honour of first flowering it in Europe belongs to Mr. Linden, of Brussels. Like many more Orchids it sports into several varieties of more or less merit from a cultivator's point of view, and it must be considered as one of the most charming acquisitions of late years.

Miltonias generally are characterised in our collections by their pale yellow, or what might be designated sickly-looking foliage; but this peculiarity, although in some measure natural to the genus, may, to a great extent, be obviated by good cultivation. These plants should be grown in shallow pans, using fresh fibrous peat, to which may be added a little coarse washed river-sand and a few broken crocks, the whole being neatly surfaced with fresh living Sphagnum. Drain the pan well, and then, when the plants are growing freely, they may be deluged with tepid rain or river water, and under this *régime* will be found to lose much of that sickly appearance, so objectionable to the practised eye of a good cultivator. *F. W. B.*

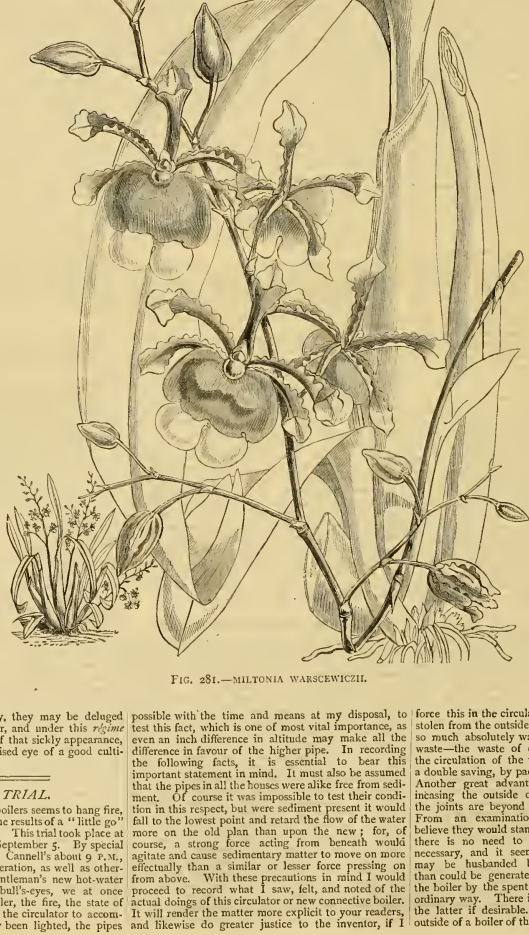

Fig. 281.—Miltonia warscewiczii.

A BOILER TRIAL.

While the great trial of boilers seems to hang fire, it may be interesting to note the results of a "little go" of considerable public interest. This trial took place at Woolwich on the evening of September 5. By special arrangement I arrived at Mr. Cannell's about 9 P.M., the object being to see the operation, as well as otherwise test the doings of this gentleman's new hot-water circulator. Furnished with bull's-eyes, we at once proceeded to examine the boiler, the fire, the state of the pipes, and the work given the circulator to accomplish. The fire had recently been lighted, the pipes were barely milk-warm, and the arrangements for a fair trial found perfectly satisfactory.

The boiler was placed well under, and in the centre of its work, behind the block of houses to be heated. The main flows and returns proceeded along the centre of a glass ridge that connected blocks of houses over 50 feet long, and which proceed at right angles to the right and left of the centre. Those nearest the boiler were given up to be heated on the new principle—that of converting the lowest pipe into the flow. Those furthest from the boiler had the hot water sent along the highest pipes first in the usual manner.

I was assured that the pipes in all the several houses—six or eight—were on a level, but found it impossible with the time and means at my disposal, to test this fact, which is one of most vital importance, as even an inch difference in altitude may make all the difference in favour of the higher pipe. In recording the following facts, it is essential to bear this important statement in mind. It must also be assumed that the pipes in all the houses were alike free from sediment. Of course it was impossible to test their condition in this respect, but were sediment present it would fall to the lowest point and retard the flow of the water more on the old plan than upon the new; for, of course, a strong force acting from beneath would agitate and cause sedimentary matter to move on more effectually than a similar or lesser force pressing on from above. With these precautions in mind I would proceed to record what I saw, felt, and noted of the actual doings of this circulator or new connective boiler. It will render the matter more explicit to your readers, and likewise do greater justice to the inventor, if I classify my remarks under two headings—the heating capacity of the new boiler, and the potency and worth of its reversing powers.

First, then, does the boiler heat well? It does. It is scarcely possible to conceive of any contrivance that would heat with more facility, in less time, with less fuel. From an hour from the time of first examining the boiler nearly all the pipes were hot, and during the whole time of trial there was no great fire, but all that there was seemed to be thoroughly utilised and sent in through the iron into the water. By substituting a thick piece of glass for an iron door, so as not to interfere with the draught, the action of the fire as it hugged the boiler plates and leaped from storey to storey of the boiler could be seen. Literally the tongues of flame licked the metal all round and darted along the roof in red-hot haste to warm another dual layer of metal and water; and so on, until, exhausted of caloric, they reached the chimney, and the comparatively cool products of combustion were swept out by the draught into the air. The bottom of the chimney immediately above the last storey of the boiler was almost quite cool, a pretty conclusive proof that the caloric had been exhausted on the metal and its all-embracing water-jacket, and not on the bricks that receive the fire as it leaves its iron-girt flue, the boiler. The boiler is so constructed as to absorb all the heat of the fire. There are no solid bars of iron, no absorbing masses of brick to compete with the water for the absorption of caloric. The fire impinges upon metal wrapped round with water at all points. Having thus arranged to get a maximum of caloric into the boiler, every precaution is taken to keep it there. The boiler is insulated from all conductors of caloric; radiation is likewise checked from the outside; within fire is coiling through it in all directions, like writhing serpents, wriggling along its sides, leaping along its many crowns, and gliding over its fiery bottom; without, a packing of dry hair and sand, from 5 to 7 inches in thickness, envelopes all, and is kept in position by dry boarding. So effective is this in keeping the heat in, that you can scarcely feel the boards warm. The heat can only escape in one way—into the water that flows through the houses. This layer of non-conducting material also keeps the two sides of the boiler-plates, the outside and the in, almost at equal temperatures,—an immense economy of force this in the circulation of the water. All the heat stolen from the outside of ordinary boilers is not only so much absolutely wasted, but it involves a double waste—the waste of caloric and of motive-power in the circulation of the water. Mr. Cannell thus effects a double saving, by packing and insulating his boiler. Another great advantage arises from this mode of incasing the outside of the boiler. The whole of the joints are beyond reach of the action of the fire. From an examination of these leakless joints I believe they would stand fire with perfect safety. Still there is no need to expose them to it if it is not necessary, and it seems probable that more caloric may be husbanded by packing in this novel way than could be generated by enveloping the outside of the boiler by the spent products of combustion, in the ordinary way. There is, however, no difficulty in doing the latter if desirable. But ready accessibility to the outside of a boiler of this kind must be an object. The

capacity of these boilers is meant to vary with their work. Is that work heavy, on with another storey or two; is it light, off with two or three. Either can be done in a few minutes, and there is no danger of leakage.

A very moderate fire was made up about 12 o'clock at night, and I examined it and the houses about 4.30 in the morning, and found fire and temperature all that a stoker could wish. The fire would have lasted many hours more, as the temperature of the pipes, considering the limited amount of fuel consumed, was most satisfactory. In fact, I have no hesitation in placing Cannell's hot-water circulator in the very first rank as a hot-water boiler, distinguished by economy of fuel, time, and labour, and by great efficiency.

I come now to my second question—Does the boiler reverse the ordinary mode of circulation? My answer to this question must be Yes and No. In certain of the houses at Woolwich there could be no question about the reversing,—indeed, I have not denied that it is possible. The hot water may be compelled to take the lower road first; and that with most other boilers, as well as Mr. Cannell's, the conversion of the flow-pipe into the return is a mere matter of pipe arrangement, and not an affair of boiler, —though I admit that, possibly, Mr. Cannell's boiler is better adapted for this mode of circulation than most others.

I must likewise acknowledge that at Woolwich most heat was thrown into those pipes in which the circulation was reversed. It must also be stated that the houses heated on the usual principle were bad examples of that mode of heating, for from some cause the return-pipes continued cold throughout their entire length in some of them. The whole were heated from Mr. Cannell's boiler, and the valves, &c., as far as I could learn, were equally favourable to the houses heated on the old and the new principle. I have no hesitation in stating that at Woolwich the new plan seemed to have the best of it. Whether there were any two currents through the pipes, could not with certainty be tested. But that there was more heat in the houses heated from beneath than from above was undeniable. I have the less hesitation in making these admissions for the following reason. Mr. Cannell attaches comparatively little importance to these examples. He was content to rest his case on a larger illustration in the neighbourhood of Forest Hill, near Sydenham; and for this new scene of trial we were in motion by 5 o'clock in the morning. Here we found a nice block of houses, part of a dwelling-house, and an attached conservatory, heated on Mr. Cannell's reversing plan by a convert to his system, who had converted the return-pipes into flows, and was perfectly satisfied with the result. The boiler was not one of Mr. Cannell's, but a powerful double saddle, one of Jones', I think. The houses were good, the pipes almost all cases, and the arrangements for the experiment admirable. The fire was speedily got up, and the experiments began. All the flow and return pipes passed through the stokehole, within feeling range, before they entered and as they returned from the houses. This afforded rare facilities for testing. Within a nice block of houses the main flows and returns were carried along the centres, and diverged to each side under the shelves or stages. From the very first there were differences of temperature between the pipes, alike in the stokehole and more still inside the houses. On one side, throughout the experiments, which were continued for four or more hours, the highest or flow-pipe in the ordinary mode of heating was the hottest; and the other, the return—that is, the flow under this arrangement—coldest. More marvellous still, in several cases the upper became the hottest pipe on each side also, and obviously the hot water was ill at ease, and trying hard to take the natural, that is, the highest, road for it. Again and again the fire, the damper, stopcocks, &c., were regulated, but with similar results; and I think Mr. Cannell will allow that this great demonstration proved virtually a failure. The water did exactly what I asserted mouths ago in the *Gardeners' Chronicle* it would do. It bounded up the return-pipe, and sent a current of hot water down to meet and master and turn back, the one being driven up by the sheer lifting force of colder water. In justice to Mr. Cannell, I would further state that in this case the back action was favoured by the fact that the bases of the return pipes rested on the fire flue outside the boiler. The absence of this sheet of flame outside Mr. Cannell's boiler, when set in Woolwich fashion, will give it an advantage in this respect, as I have already hinted; but where is the benefit of reversing the circulation? Doubtless it can be done. Shut up the hot water to the lower road, and it must perforce travel thereby; give it a choice of ways, and it will choose the higher road, unless compelled by blocks or extra pressure to take the lower. Such were my views before the trial, and they are rather confirmed by what I saw. I am, however, still open to conviction, and went to Woolwich half or more expecting to be convinced. In my paper on the *rationale* of heating, which I hope you will find room for, I pointed out that by reversing the circulation we should work against natural laws and consequently lose force. I adhere to that statement. It is just as natural for the hottest water in a heating apparatus (no matter how heated) to take the highest route first, as for the highly heated water at the Equator to float away on the surface of the ocean, while the colder waters of the Arctic regions press back to their natural warming place at lower depths. All the driving force in the world, the sum total of its caloric, would fail to reverse this circulation; and if it could our cry then, as now, in regard to the small matter of our boilers, would still be, *Cui bono? D. T. Fish, F.R.H.S.*

ON THE VARIOUS TINTS OF FOLIAGE.

ALTHOUGH we cannot yet say—

"Far, far o'er hill and dale green woods are changing,
Autumn her many hues slowly arranging,"

still it may be interesting to put together certain facts with reference to the tints of foliage which have recently been acquired to science.

Up to the present time I have been able to distinguish several dozen colouring matters in the leaves of different plants, and far more in the petals and fruits, and no doubt further inquiry will very greatly increase this number. The subject would, therefore, be quite unmanageable, if we could not divide them into well-marked groups by means of their optical characters. This is still more important when, as on the present occasion, it is desirable to give a concise summary of the leading facts. I shall, therefore, not attempt to describe the individual colouring matters, or to explain how they may be distinguished or identified by means of their spectra, either in their natural state or after being acted on by re-agents; but merely point out the general relations of the various groups, and refer to my published papers for illustrations of the methods employed in the inquiry.* The colours of these groups are not only related to one another optically and chemically, but also have a very similar connection with the growth of the plants, and thus it is possible to give a general explanation of the very various tints of foliage, without entering into technical details. For a more complete account, I beg to refer to a paper on this subject, just published in the July number of the "Quarterly Journal of Microscopical Science."

One of the chief difficulties in analysing the colours met with in plants is, that they are often mixtures of quite distinct colouring matters. Sometimes these may be easily separated, for one may be soluble, and the other insoluble, in such reagents as water, alcohol, ether, or bisulphide of carbon; but in many cases they are so closely related, that anything like a complete separation is perfectly impossible; even then, however, it may be possible so to effect a partial separation, that the presence of two different substances may be recognised, and with proper care a very good opinion may be formed as to their general properties. Nature, also, herself effects a partial analysis by investing different plants, or the same in different states, may furnish particular colouring matters comparatively pure, or so variably mixed that the character of the mixture may be recognised.

For the purposes of the subject before us, I have found it desirable to divide the different colouring matters into the following groups:—

1. The *Chlorophyll* group is distinguished by being insoluble in water, but soluble in alcohol and in bisulphide of carbon. There are three or four species, giving well-marked spectra, with several narrow, dark, absorption-bands, one or more of which occur at the red end. The mixed chlorophyll of ordinary green leaves may be obtained in a tolerably satisfactory state by heating in alcohol dark-green Holly leaves previously crushed so as to insure rapid solution, and then, when cold, agitating in a test tube with bisulphide of carbon. The latter takes the bottom, holding nearly the whole of the dark-green chlorophyll in solution, whilst nearly all the xanthophyll remains dissolved in the alcohol. Leaves having an acid juice must not be used, for that would change the normal chlorophyll into another modification, nor should the solution be left long in contact with them, for then the separation is much less perfect.

2. The *Xanthophyll* group also contains several distinct species, but only two are common in leaves, one being more, and the other less, orange. They are characterised by being insoluble in water, but soluble in alcohol and in bisulphide of carbon; and when dissolved in this latter their spectra show two not very distinct absorption-bands at the blue end; but the red, yellow, and yellow-green rays are freely transmitted. They may be obtained from yellow leaves, by the use of alcohol and bisulphide of carbon.

3. The *Erythrophyll* group comprises a number of colours soluble in water, in alcohol, and in ether, but insoluble in bisulphide of carbon. Those met with in leaves are more or less purple, made bluer by alkalis, and redder by acids; and thus sometimes plants containing the same kind may vary more in tint, owing to a variation in the amount of free acid, than others coloured by entirely different kinds. The erythrophyll may be obtained, free from chlorophyll and xanthophyll, by heating the leaves in alcohol, evaporating to dryness, redissolving in water, filtering, and then shaking with gentle heat; but, on the whole, it is better to digest the leaves for a day or so in sufficient cold ether to dissolve all the contained water, and then to agitate with water, which subsides to the bottom, with nearly all the erythrophyll in solution, but mixed with more or less of the colours of the following group. There are many species of erythrophyll, some of which have very interesting botanical relationships, being so far found only in particular classes of plants.

4. The *Chrysotannin* group contains a considerable number of yellow colours, some so pale as to be nearly colourless, and others of a fine, dark, golden-yellow. They are soluble in water, in alcohol, and in ether, but not in bisulphide of carbon. Their spectra show a variable amount of absorption at the blue end, usually with no bands when in their natural state, but sometimes with one or more sufficiently distinct when they are oxidised. They may be obtained free from chlorophyll and xanthophyll by processes similar to those made use of in the case of erythrophyll, and leaves should always be selected which are as free as possible from colours of that group. Some of the chrysotannin colours strike a dark colour with ferric salts, and constitute the tannic acid sub-group, of which there are at least six different kinds, whereas others do not give any such reaction, and constitute the chrysophyll sub-group. In both sub-groups the intensity of colour is usually greatly increased by partial oxidisation, and they are thus altered into colours of the following group.

5. The *Phaiophyll* group comprises a number of more or less brown colours, insoluble in bisulphide of carbon, and of very variable solubility in water or alcohol. The spectra usually show strong absorption at the blue end, extending over the green, often the red is very dull, and sometimes there are definite absorption bands, when the solution is acid, neutral, or alkaline. On the whole, they are in that state of oxidisation which has a maximum intensity of colour, and are simply decolorised by further oxidisation.

The very numerous tints of foliage depend almost entirely on the relative and absolute amount of the various colours of these different groups, but much remains to be learned before we can explain all their relationships. The colour of green leaves is mainly due to a mixture of chlorophyll and xanthophyll, and the variation in the relative and absolute amount of these easily accounts for the darker and brighter green. The tints are also much modified by the pressure of colours of the erythrophyll group, which, according to circumstances, may give one to lighter or darker browns, greens, or to black or to red. Healthy unchanged leaves also contain various substances, belonging to the chrysotannin group, but in many cases when these belong to the more typical kinds of tannic acid their colour is so faint that they have little or no influence on the general appearance of the leaves.

The relation of these groups to one another is still somewhat obscure. There are facts which seem to indicate that chlorophyll may in some cases pass into xanthophyll by oxidisation, and xanthophyll into chlorophyll by deoxidisation, but neither point can be considered to be established. There is manifestly some connection between the formation of chlorophyll and erythrophyll; and those conditions which are favourable to the production of one are unfavourable to the development of the other. In the present state of our knowledge it seems most probable that chlorophyll is formed when the vital functions of the leaves are very active, and erythrophyll when they are less active, but not destroyed. Exposure to light also appears to be necessary, and we often see rough natural photographs of superjacent leaves produced in this manner. As I have already stated, there are several different kinds of erythrophyll, giving very different spectra, but the most prevalent are two which are related to each other in an interesting manner. One of these is more especially found in very young leaves, and when slightly oxidised artificially it passes into the other. The more oxidised kind is found in the greater number of leaves which are dead in autumn. Both are completely decolorised by further oxidisation, and most probably this occurs in leaves themselves when their red colour is lost. Since many contain erythrophyll in early spring and lose it as the season advances, whilst it still continues to be present in the leaf-stalks, I am much inclined to believe that its disappearance is due to the ozonised oxygen given off from the chlorophyll, which is developed to so much greater an extent in the leaves than in the stalks, and that its reappearance in autumn in many leaves is characteristic of the period when they are not dead, but have more or less ceased to give off ozone.

On the approach of autumn, before the leaves have withered, we have thus in the foliage of different plants an exceedingly variable mixture of chlorophyll, xanthophyll, and erythrophyll, with the different members of the chrysotannin group, and it is to the changes which occur in some or all of these substances that the very variable tints of autumn are due. The most striking of these depend on the alteration of the chlorophyll. So long as it remains green the production of bright reds and yellows is impossible, but when it disappears the yellow colour of the xanthophyll is made apparent; and, if much erythrophyll is present, or contemporaneously developed, its colour, combined with this yellow, gives rise to a scarlet or red. In many cases, however, the chlorophyll does not disappear, but is changed into the dark olive modification, easily prepared artificially by the action of acids on the more green, and when this is present, only dull and unattractive tints can be

* "Proceedings of the Royal Society," vol. xv., p. 433; "Philosophical Magazine," vol. xxxiv., 1867, p. 244; "Quarterly Journal of Microscopical Science," vol. ix., 1869, pp. 43 and 358; "Monthly Microscopical Journal," vol. iii., 1870, p. 299; "Quarterly Journal of Science," new ser., vol. i., 1870, p. 1.

produced. We may thus easily understand why the special tints of early autumn are yellows and reds, or dull and dark greens. In these changes the various pale yellow substances of the chrysotannin group remain comparatively unaltered, and even sometimes increase in quantity; but they soon pass into the much darker red-browns of the phaiophyll group, whilst the erythrophyll fades; and thus later in the autumn the most striking tints are the brighter or duller browns, characteristic of the different kinds of plants or trees.

As already named there are many different species of colouring matters belonging to the chrysotannin group, both of those which are, and of those which are not, closely related to the more typical kinds of tannic acid. So far I have not been able to ascertain whether there is any one particular artificial oxidising process which will in each case give rise to the exact products naturally formed in the leaves themselves; but on the whole there is such a close correspondence between them that we cannot hesitate in concluding that the rich brown tints of autumn are mainly due to the oxidisation of the previously-existing more or less pale yellow colour of the chrysotannin group—a conclusion fully borne out by various independent facts. The difference in kind of tannic acid, and the absence or presence of any considerable amount of a chrysophyll substance, explains in a very satisfactory manner the difference in the tint of the leaves of different trees. Thus, for example, the quinо-tannic acid found in a comparatively pure state in the yellow leaves of the Beech is changed by oxidisation into the fine red-brown colour of those leaves at a later period. This kind of tannic acid also occurs in the Elm, but is there mixed with more or less of the chrysophyll, which turns to a duller brown; and thus we find the leaves of different Elm trees vary in tint, and are often of very dull brown colour. The leaves of the Oak and Spanish Chestnut contain gallo-tannic acid, and this, when oxidised, gives rise to a dull tint, like that seen in the faded leaves of those trees; and similar principles hold good in other cases.

As far as we are able to judge from the various facts described above, we must look upon the more characteristic tints of the foliage of early spring as evidence of the not yet matured vital powers of the plant. In summer the deeper and clearer greens are evidence of full vigour and high vitality, which not only resists but also actually overcomes the powerful affinity of oxygen. Later on the vital powers are diminished, and partial changes occur, but the affinity of the oxygen of the atmosphere is nearly balanced by the weakened but not destroyed vitality. At this stage the beautiful red and yellow tints are developed, which produce such a fine effect in certain kinds of scenery. Then comes more complete death, when the affinity of oxygen acts without any opposition, and the various brown tints of later autumn make their appearance, due to changes which we can imitate in our experiments with dead compounds. This may not be a pleasing way of treating an otherwise charming subject, but I think we must all admit that it is substantially true. *H. C. Sorby, in "Nature."*

GRAFTED SEEDLING.

FOR the illustration given (fig. 282) we are indebted to the ingenuity of that clever experimentalist, Major Trevor Clarke. It is to him that our Indian friends are indebted for many valuable crosses, obtained by pollen-fertilisation, of various breeds of Cotton, with a view to insure better staple, hardier constitution, and varieties better suited to varying conditions of climate, soil, &c. These experiments have much scientific value, while their practical importance, though still under trial, may yet be pronounced to be very great. The present case, however, is of a different nature, and has a less directly practical value, though it is not without interest to the practical man. It will be seen that Major Clarke has succeeded in engrafting, on a stock, a seedling plant, so young as still to retain its cotyledons, or seed-leaves, and the result is that the seed-leaves have assumed a more permanent character than usual—they have at once taken their place amongst, and fulfil the same functions as, the ordinary leaves. Dr. Dickie and others have caused the seed-leaves of the Castor-oil to become permanent by repressing all the other leaves as they appeared; hence it is abundantly proved that the seed-leaves have in such cases no essential diversity from other leaves. We have ourselves succeeded in producing a miniature Ash tree, such as a Chinaman or a Japanese might delight in, by a similar repression. The principle is acted on by our fruit growers, and is probably capable of greater useful application than at first sight appears. At any rate, it is certain that by engrafting an annual plant on a perennial stock the duration of the graft may in some instances be prolonged; and numerous experiments of this kind may be successfully performed, which the practical man may at some time or another find it worth his while to avail himself of.

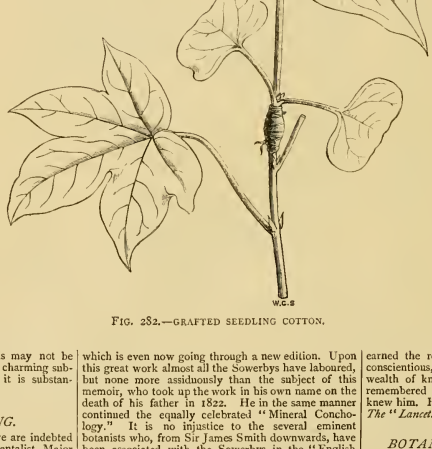

FIG. 282.—GRAFTED SEEDLING COTTON.

JAMES DE CARLE SOWERBY, F.L.S.

THE career of a working naturalist must always be a subject of interest to the medical world. Scarcely any botanical name is more literally a household word than that of Sowerby. For three generations members of this family have taken a conspicuous part in popularising—using the word in its best sense—a knowledge of botany and other branches of natural history. Combining with rare felicity the feeling and skill of the artist with the rigorous accuracy of the scientific naturalist, they have enriched our libraries with delineations of plants, shells, fossils, and minerals pre-eminent for beauty and truth. The most accomplished of those who have borne the name, and one who, perhaps, achieved the greatest amount of work, is James De Carle Sowerby, who died on August 26 last, at the age of 84. He was the eldest son of James Sowerby, the founder of the scientific race of his name, and himself the descendant of an old border family. His mother was a De Carle, who belonged to a French family settled in Norwich. James Sowerby, the father, is the real author of the "English Botany," a work which for more than half a century has had no rival, and which is even now going through a new edition. Upon this great work almost all the Sowerbys have laboured, but none more assiduously than the subject of this memoir, who took up the work in his own name on the death of his father in 1822. He in the same manner continued the equally celebrated "Mineral Conchology." It is no injustice to the several eminent botanists who, from Sir James Smith downwards, have been associated with the Sowerbys in the "English Botany" in furnishing the literary descriptions of the plants, to say that the great and enduring scientific merit of the work consists in the figures. These, in fact, not only reproduce the plants as they appear in Nature to the uninstructed eye, but they exhibit all the chief structural details which the scientific naturalist demands. These remain for ever, whilst descriptions and classifications are doomed to change. So well are these figures appreciated, that those enterprising authors and publishers who find it convenient to annex the labours of others are constantly borrowing from this never-failing source.

The life of James De Carle Sowerby was spent from boyhood in intimate association with scientific and literary circles. As a lad, his passion was chemistry, and he enjoyed the friendship of Faraday as a fellow-student. He was received as a favourite in the houses of Dawson Turner, the Hookers, Dr. Woollaston, Sir Joseph Banks, and many other distinguished naturalists. At an early period of his life he conceived the idea of founding the classification of minerals upon their chemical composition. He believed that chemistry might offer a better basis of classification than the forms of the crystals. In carrying out his scheme, he analysed the minerals, the description of which was published in his father's "British Mineralogy," and "Exotic Mineralogy." From 1823 to 1850 he contributed papers, principally relating to fossil conchology, to the "Philosophical Transactions," the "Zoological Journal," and the Transactions of the Linnæan and Geological Societies. He named, arranged, and described the fossil shells for Professor Sedgwick, Sir Roderick Murchison, Dr. Buckland, Dr. Fitton, Mr. Dixon, and Colonel Sykes, all of whom gratefully acknowledge the assistance thus rendered them. In 1840, the "Woollaston Fund" was awarded to him by the Geological Society, to facilitate the prosecution of his researches in mineral conchology. The prize was presented by Dr. Buckland, who took the opportunity of paying a graceful tribute to the merits of father and son as accurate and enthusiastic observers of nature. He observed that the modern "rapid advance in geological knowledge, arising from the introduction of the evidences of mineral conchology, was largely due to the publications of the Sowerbys."

In 1846, Mr. Sowerby was appointed Curator and Librarian to the Geological Society. These offices he was soon obliged to resign, owing to the increasing demands made upon his time as Secretary to the Royal Botanic Society. This society, with which his name has been identified from its institution in 1839, was founded by his cousin, Mr. Philip Barnes, F.L.S., who naturally sought the aid of one whose scientific reputation and connections were so well calculated to promote the success of the scheme. Mr. Sowerby was also associated with that of his cousin, the Earl of Albemarle, Colonel Rushbrooke, and others, in the first charter granted to the Society. In this office much of his time was necessarily absorbed in administrative labour, so that he found little leisure to continue his scientific pursuits. The Society is better known for its floricultural and fashionable displays than for the cultivation of botany. But still the influence of the secretary was always steadily exerted to promote the scientific utility of the gardens. These contain departments devoted to the natural classification of plants, to medical botany, to plants used in arts, &c. In the working out of the scientific element he was warmly assisted by Dr. Frederic Farre, Professor Bentley, Mr. Marnock, the first curator, Mr. P. Edward Barnes, the assistant secretary, Mr. Bushell, and others. It is here especially that the medical profession is indebted to Mr. Sowerby. It is greatly owing to him that the collections of plants are so freely thrown open to students. The students of the Pharmaceutical Society, as well as students of medicine, are admitted at certain hours, courses of lectures in illustration are given, and the lecturers on botany at our medical schools are liberally supplied with specimens for instruction as far as the resources of the garden will admit.

A year or two before his death Mr. Sowerby retired from his office on a moderate pension, and was succeeded by his son, Mr. William Sowerby, whose character and services as assistant-secretary had well earned the respect of the Council. Gentle, earnest, conscientious, ever ready to help others out of his wealth of knowledge, Mr. Sowerby's name will be remembered with affection and reverence by all who knew him. His was truly a blameless and a useful life. *The "Lancet."*

BOTANY FOR BEGINNERS.—XV.

THE grain of Wheat and the acorn have this in common—that they are neither of them seeds. Most people unversed in botany would class them as such, but this is one of the many vague and incorrect notions which the botanical student has to rid himself of. Both invest and contain the seed, but are themselves no more to be considered the seed than the case of a watch is to be held as a timepiece. The acorn, as previously explained (p. 1197), is the seed-vessel. The outer skin of a grain of Wheat or other cereal in like manner is the seed-vessel. In botanical language, the "fruit," or "seed-vessel," is that which immediately contains or invests the seed—it is, in fact, the pistil or ovary of the flower, more or less altered in character during the ripening of the seed. By referring to the description and illustration of the Wheat (fig. 283), this statement may the more readily be comprehended. To see for oneself the structure of a Wheat grain, which is what every one should do who wishes to have a clear knowledge of the subject, a few grains should be soaked for some hours in water; or, better still, they should be induced to germinate, and all the stages of the process watched.

We have already mentioned how this can be done in the case of an acorn or a filbert suspended in a bottle, and we may now commend to the notice of those of

our readers to whom it may not be known an equally simple method of growing their own Wheat on the chimney-piece, where it will form an object of great interest to the young folk, and a pretty ornament during the dull season. All that it is necessary to do is to secure some ears of Wheat, with a portion of the straw to serve as a stalk, and to plunge these stalks into some sand or moss placed in a vase or bowl, so that the ears project above the surface of the sand. The sand should be kept constantly moist, and the vase should at first be placed in a dark cupboard till the germs begin to sprout, when it may be moved on to a mantelpiece or into a window —anywhere, in fact, where it will get a moderate share of light and warmth. We once had a bowl of this description with a dome of sand in the centre, which, when covered with the green sprouts of the Wheat, presented so much of the aspect of the odd-looking ornament on the top of the monument near London Bridge, that we were almost tempted to suppose the architect took his idea from a mass of germinating Wheat grains in a bowl! To revert to our Wheat grain. Let the pupil take one that has been duly soaked, or which has only just commenced to grow, let him slice it in half lengthwise, as has been done in fig. 283, A B C. He will then see that the great bulk of the seed is made up of a floury mass, at one end of which is a little body, the embryo, fig. 283, B C, which wants a little looking for on the part of a beginner unaccustomed to use his eyes, but which may be recognised by its different texture and colour, and which, as growth proceeds, will force itself into recognition by the importance of the changes it undergoes. The floury mass is the *perisperm*, or albumen, and is the inner portion of the seed; its "floury" character is due to the circumstance that it contains a quantity of starchy material, stored up in anticipation of the wants of the swelling plant.

Comparing this arrangement with that of the acorn, it will at once be seen that the seed proper in the Oak contained no store of nutriment corresponding to the albumen of the Wheat, and the embryo plant filled up the whole of the seed, instead of occupying a little notch at one end. The seedling Oak is thus independent of the seed from the time it begins to sprout, even as a young chicken asserts its independent existence almost immediately after it is liberated from the eggshell. The seedling Wheat is not so precocious, it is more like a helpless kitten, and is dependent on its mother-seed for its supplies for some time. Of course this analogy must not be pressed too far. The fact is, the necessities of the seedlings in the two cases are equally well provided for, the one is no more really independent in its early stages than the other. The difference between them is merely this, that in the Oak the food for infants—true farinaceous food—is stored up in the tissues of the seedling itself, which thus, as it were, lives on its own resources, while in the Wheat the nutritive matter is contained in the seed and not in the seedling. After this explanation it is easy to see why the seedling Oak has such sturdy proportions almost from the first, while the seedling Wheat, on the contrary, is so tiny in its dimensions.

In order clearly to see the parts of the seedling Wheat, and to trace its mode of growth, it is advisable to take a grain that has not merely begun to swell, but one which has begun to germinate, as has been done in the case from which fig. 283 D was taken. Now compare this seedling with that of the Oak, fig. 274, p. 1197. In the Oak is a central stem or axis bearing, one on each side of its centre, the seed-leaves, and terminated above by a bud, the *plumule*, which thus emerges from between the seed-leaves, and ending below in a well-marked radicle or root, which tapers gradually from above downwards. In the Wheat there is a similar central axis, but it is comparatively very short. It bears on one side a single seed-leaf (*the cotyledon*), see p. 1197, concealed within the seed, the lower part of which forms a sort of very short sheath around the stem, and out of which the first bud or plumule emerges in such a manner as to appear to spring from the side of the seed-leaf, instead of from the end of the stem, as it does in reality.

Below the seed-leaf the stem scarcely tapers at all, neither does it perceptibly lengthen. The true root, then, is by some supposed to be absent in these cases. Probably it would be quite as correct to say that the root of a monocotyledon does really exist, but that instead of lengthening, as in the case of a dicotyledon, it is subjected to an arrest of development. Whether this be so, or not, the fact remains that a tap-root, such as we see in the Oak, has no existence in the Wheat, and that in the latter case the office of the root is filled by a number of fine hairs, which gradually emerge from the root end of the seedling Wheat, fig. 283, D E, pushing before them the skin, and ultimately breaking it so that each root fibril passes through a sheath—a circumstance very characteristic of the root of monocotyledons, but very rare in those of dicotyledons. These root fibres of the Wheat rapidly branch and subdivide, so as to be able to avail themselves, so to speak, of every particle of soil, or rather of every droplet of water intervening between these particles. Thus every provision is made for rapid growth, rapid feeding, and rapid reproduction. The *rôle* to be played is quite different in this respect from that which has to be enacted by the acorn, where deep anchorage, slow growth, and firm wood have to be secured years before it becomes necessary to produce acorns. This question of root-growth is one of the most important that can occupy the attention of gardeners and farmers, but it is one that has not been sufficiently attended to. Intending to confine these remarks to structural points chiefly, we merely indicate this matter as one deserving the fullest consideration of practical men, and may ourselves revert to it on a future occasion. We have now indicated the differences between a dicotyledonous and a monocotyledonous seedling, and we have shown (p. 1197) how these differences are associated with so many others as to render it possible to group all flowering plants—barring exceptional instances too small in number to be worth considering here, this particular point of view (though in themselves most worthy of attention)—into the group of monocotyledons to which the Wheat, the Tulip, the Hyacinth belong; and dicotyledons, under which the Willow, Poplar, Ash, Daisy, and other plants that have been illustrated in these articles, may be grouped. The main structural features, however, on which we would lay stress, in the case of the seedling Wheat, are these—the *alternate* arrangement of the leaves, as manifested from the very first in the single cotyledon, and the definite growth of the root (or at least of the root-end of the stem). It is worth while calling attention to these principles of growth as here shown in a simple condition, in order the better to understand the

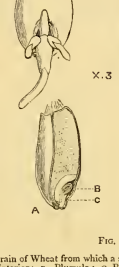

FIG. 283.

working of the same principles in their more complicated manifestations in the course of the growth of the tree or shrub.

THE ACTION OF FROST.

WE have frequently recurred to the interesting subject of the effects of frost upon vegetation, and we now give some extracts from Dr. Goeppert's article in the Botanische Zeitung on the degree of cold which plants will bear. Nobody, perhaps, has devoted more attention to this subject than the author, who published an important work, containing his earlier observations, some 40 years ago:—

Our knowledge as to the actual degree of cold which plants will bear without injury is still far from complete, on account of the general disregard of modifying conditions. At Ustjanks, in Siberia, 70° 55′ N. lat., the mean winter temperature is —38°,* and that of the coldest month, January, —44°, whilst at Jakoutsk, although 8° further south, in 62° N. lat., the mean is even —38°.9, owing to peculiar conditions, and the lowest —48° in December, the coldest month, during which on 19 days the thermometer did not rise above —40°. For 12 or 13 weeks the mercury is constantly frozen at the latter place. Even as far north as 75° N. lat., in the Polar Sea, Parry found the coldest months several degrees warmer than it is at Jakoutsk; but in West Greenland, 78° 37′ N. lat., Kane experienced —43°.5, McClure even —47°; and the latest German arctic expedition, on the east coast of Greenland, in 77° N. lat. registered, as the greatest degree of winter's frost, and that in February only —32°. Kane still found, even in these high latitudes, a somewhat luxuriant vegetation; and at no part did the snow line descend to the sea level. Hence there can scarcely be a doubt of the existence of vegetation even up to the north pole.

The cause of this remarkable phenomenon must be sought for in the protection afforded by the covering of snow, which prevents radiation, and, as a bad conductor of heat, the penetration of frost, thereby ensuring a more uniform and less fluctuating temperature. For the first observations on the temperature of snow at different depths we are indebted to Saussure ("Voyage dans les Alpes," t. ii. § 1002, p. 459). On one of the peaks of the Great St. Bernard, called La Chenalette, at an elevation of 8413 feet, with a temperature of +8° in the sun, the snow immediately beneath the surface showed freezing point, and the same degree at a depth of 3 feet.

The first connected observations, with reference to vegetation and the temperature of the snow and ground, were made by Goeppert in the Botanic Garden of Breslau, from January 22 to February 15, 1830.

The ground where solid was frozen to a depth of 12 inches, and where tilled to a depth of 16 inches. On January 22 the mean temperature of the air from three daily observations was —20°, on the 23d —16°.4; and the temperature beneath the 4-inch covering of snow —6°.5. On the 24th, with a mean air temperature of —8°, the snow, now 8 inches deep, showed only —2°.5; from the 27th to February 2, with a mean temperature of —2° to —3°, between —0°.4 and —0°.8, at a depth of 8 inches. On February 4 the snow attained a depth of 12 inches, and continued so until the 15th, on which day a thaw set in, followed by frost again on the 17th. The mean temperature of the atmosphere of this period, from February 4 to 15, amounted to —8°, and that of the snow at a depth of 12 inches during the coldest days, on three days only, —2° to —2°.5. The temperature of the ground corresponded to that of the overlying snow at a depth of 1 or 2 inches only, rising gradually to the freezing point at a depth of 12 to 16 inches. Of course, all the roots of perennials were frozen stiff, and they remained so below a depth of 1 or 2 inches during the rapid thaw of February 15 to 17, whilst the upper green portions, that had been sheltered by the snow, began to vegetate.

On the 17th, in the afternoon, the temperature again fell to —2°, and the snow froze so hard that in some places one might walk over it without breaking the crust, and on the same day there was another slight fall of snow, forming a new layer about an inch thick. Beneath this, on the 18th, the green part of plants were not frozen; and the temperature of the snow, at a depth of 5 inches, remained at freezing point, although the temperature of the air throughout the day fluctuated between —5° and —4°. On the 19th, after a night temperature of —8°, and —4° at noon, the snow registered —2° in 5 inches, and in 3 inches —3°.5, and all the green vegetation was again frozen. On the 20th, the temperature rose from —9° in the morning to freezing point towards mid-day. The snow was now colder, —1°, at a depth of 5 inches than the atmosphere; whilst nearer the surface it ultimately established an equilibrium with it. On the 21st, when the thermometer did not rise above —4°, and did not fall below —5°, the lowermost layer of snow answered to that of the previous day, and the uppermost came nearer to that of the air, viz. —2°.5. On February 22 and 23, with a mean temperature of +2°.4, the snow disappeared almost wholly in many places, and nowhere was there sufficient left to institute further observations on its temperature; notwithstanding which, however, the ground under vegetation remained frozen to below 3 inches deep. Amid alternating frosts and thaws the ground was not free from frost a foot deep until March 14. In spite of this apparent obstacle, vegetation began to develope, and Holosteum umbellatum and Draba verna flowered. Not before the 20th had all traces of snow on the ground disappeared.

Goeppert's observations in February, 1870, in the same place, led to similar results. During the preceding month of January, according to Dr. Galle's observations at the Breslau observatory, the mean temperature was —7°.03. The coldest days were the 8th, 9th, and 10th, with +4°.33, +4°, and +3°.67; the coldest, the 26th and 27th, with the mean temperatures of —7°.87 and —7°.60.

The snow which fell towards the end of December thawed on January 6, as also the slightly frozen ground, and snow covered again on the 7th, and remained about the same thickness—4 inches—until the 11th of the following month, and was very little increased before the thaw on the 19th—a very rare circumstance at this time of year, but just what I wished for my observations. The moderate frost of the latter part of January increased to great severity on February 1, and for about 12 days the cold was more intense than has been known for such a period since 1791, excepting the winter of 1830, when the above-mentioned observations were made.* The average temperature of these 12 days and nights was —7°.60, and that of the six days, from the 5th to the 10th inclusive, even —16°.03; the coldest mean for the 24 hours was —17°.63, on the 6th. On three days (the 6th, 7th, and 8th) the thermometer fell in the morning below —20°, and the minimum registered was —20°.5, on the 7th, at 6 A.M. In the morning, of the 11th, a thaw set in, towards the cold was less severe, and it thawed during the last five days of the month, with a maximum of +5°.3 on the 28th, and the warmest mean daily of +3°.1 on the 27th.

* The degrees are of Reaumur's thermometer, which, it will be remembered, has its zero at freezing point, and the boiling point at 80°. A degree of Reaumur's scale is equal to 2½ of Fahrenheit's. The degrees are reckoned plus or minus, according as they are above or below the freezing point.

* It is a remarkable fact that in England (Blackheath) the temperature did not fall below freezing point in February, 1870, until the 9th, though we had experienced very cold weather in January. We then had a period of about six days' severe weather the lowest temperature recorded being 19°.4 F., equal to about —6° R., on the 11th. Breslau is in about the same latitude as London.

The mean temperature of the whole month of —7° is 6° lower than the average rate. The greatest fluctuations of temperature from one day to another occurred—

Jan. 31 to Feb. 1	—6°.8
Feb. 5 to Feb. 6	—7°.9
Feb. 12 to Feb. 13	+5°.5
Feb. 15 to Feb. 16	+4°.1
Feb. 20 to Feb. 21	—5°.2
Feb. 23 to Feb. 24	+5°.9

Goeppert's observations on the temperature of the snow, which was 4 inches deep, began on February 4, and terminated on February 16.

On Jan. 29 the mean temperature was			— 7°.25

The ground itself was frozen 15 inches below the snow, and on the very cold day of February 5, at 2 inches deep, it was only —1°.

Two series of observations upon nearly the same spot in our garden agree so well in results, and show the use of the snow as a protective agent for vegetation.

At the 2 inches' insulation similar observations were instituted in several other parts of the province, the layer of snow being quite uniform throughout, and the results obtained corresponded to my own, with slight modifications, due to the nature of the soil and the presence or absence of woods. It was also ascertained, that not only does but also a thin layer of leaves, 2 or 3 inches thick, affords an extraordinary amount of shelter to herbaceous plants. According to a statement by H. and G. Schlagintweit, Boussingault ("Economn. Kurale," ii., p. 250) appears to have made observations on the temperature of snows, but I have not seen his work. Kerner's observations are, however, known to me, and coincide with mine. The temperature of the air showed a fluctuation of 23°, and that of the ground little more than 1° (A. Kerner, "Kultur de Alpenpflanzen: Innsbruck, 1864, p. 150).

The snow covering exercises an equally favourable influence in the highest northern latitudes. Kane, to his surprise, and formerly our own, found luxuriant vegetation of perennial plants in 82° N. lat., and in 78° 50' N. lat., with a surface temperature of —27°.5, at a depth of 2 feet in snow —17°, at a depth of 4 feet —7°.5, and 5 feet —2°.6, only few degrees below freezing point, about 6° Fahrenheit. Middendorf, * it is true, instituted no observations of this kind, but he furnishes a very decisive example of the effects of snow in an observation that the actual northern limit of the Fir tree in Taimyrland is 1° north of its forest limit. That the Fir is reduced to an intermediate stage between root and stem, which does rise above the snow covering. All shoots protruding through the snow are yearly killed back, so that it is entirely dependent for life upon the snow. We must not be astonished, therefore, at the appearance of a luxuriant vegetation there, because the lowest temperatures of —40° to —50° never reach it, and possibly it never has to bear more than a few degrees below freezing point.

The stony ground of our Alps is early clothed with a thick, abiding layer of snow, and thus it is seldom frozen to any considerable depth, and rarely has to bear more than —2° of frost—about 27° Fahr.—according to Kerner. Under less favourable circumstances most plants would succumb. Roots of Helleborus niger, H. viridis, and Valeriana Phu perished when out of the ground, at a temperature of —15°, and those of Cicuta virosa at a still lower, about —10°. Julius Sachs discovered that the roots of Myosotis palustris possess a very slight power of resistance against the cold. In return, many roots in the ground will bear an extraordinary degree of frost for a lengthened period without being killed, which I proved by direct observation during the remarkable winter of 1829-30. They remained frozen without injury from November 20, 1829, until February 9, 1830, during which time the temperature never rose above the freezing point. In East Siberia, on the ice-bound ground, the roots of plants are always frozen in winter, and entirely independent of the mean temperature of the ground, which is far above the freezing point. The roots freeze hard and stiff, and do not penetrate the underlying ice stratum, about a foot below the surface, but turn away as though they had encountered an impervious stone. Goeppert, however, doubts whether this torpidity could continue for several years without injurious influence, especially in the case of flowering plants; less so with Lichens. Charpentier, Ramond, Veultz, and Thomas, cite instances in which different plants, including Phanerogams, such as Trifolium alpinum, Geum montanum, Cerastium holosum, &c., have remained under the ice of the glaciers for years without injury. The presumed growth of plants under the snow scarcely deserves serious refutation. It rests merely upon incomplete observation. The flowers of such plants are so far developed during the preceding autumn as to need little weather to open perfectly. According to Von Vogt, Galanthus nivalis will flower at a temperature of +2°.42, Hepatica nobilis, +4°.77, &c. (Dove, in the "Monatsberichten der Berlin. Akadem." 1850, p. 214.)

This premature development of the flowers I observed beneath the snow in 1829 and 1830, in 236 (chiefly alpine) plants, belonging to 42 families.

True winter flowers are rare with us, with the exception of some annual plants already alluded to. Bellis perennis and the cultivated Helleborus niger only belong to this category. Their flowers stiffen with the cold, but grow again with the return of thaws, though the same portion of the roots remains frozen. Towards Christmas, when the weather previously has been only moderately cold, Helleborus niger is in full bloom, and Bellis is much the same throughout the year. Bellis withstood the cold of the winter of 1870, when snow improved its warm cloak covering, but the leaves and flowers of Helleborus niger perished, though not where sheltered by the snow.

Under these circumstances the full severity of the frost is only experienced by the parts of plants above the snow, and the Mosses, Lichens, and Fungi growing upon the trees, &c., not only in the arctic regions, but likewise in our own latitudes. And to the absence of an abiding snow layer we may ascribe the loss of many polar and arctic plants in our gardens. Thus trees and their parasites alone experience the extremes of temperature given at the beginning of our article, and especially the Siberian Larix Larix sibirica, Led. This forms, according to Middendorf (*l. c.* p. 1662), a forest even up to 72° 30' N. lat., in Taimyrland, which it is the highest northern forest limit on the earth. It attains here a diameter of 4 to 6 inches, and a height of 3 to 4 German fathoms, with an average annual growth of only nine or ten weeks. Associated with this are:—Picea obovata, Led., which reaches 67° to 69° N. lat.; Pinus ajanensis, Fisch., 70°; Abies sibirica, Led., 67°45'; Pinus sylvestris, 64°; Pinus Cembra and Betula alba, on the Lena, according to Trautvetter, up to 71° 5'; Alnus incana, to 69° 5'; Alnus fruticosa, to 70° 45' and 71° 45''; Populus suaveolens and tremula, to 69°; Prunus Padus, to 70° 5'; Sorbus Aucuparia, 71°, and beyond; Juniperus nana, at least to 71° 5'; and the same with Betula nana and the Willows as the most northern—the latter rarely rising above a span in height, with underground branches 5 to 6 feet long, like our Salix herbacea, &c.

In European Russia the tree-line is much farther south. The Birch appears as a bush only in 70° N. lat., on the Kolan peninsula of Russian Lapland in the Mountain Ash, also only shrubby in 70°. In Norway, as trees, Pines and Firs up to 70°, and the Aspen and Mountain Ash perhaps a little farther. In arctic America, according to Richardson, Pinus alba, together with Populus tremuloides, balsamifera, and Betula papyracea, forms the tree limit, 60° N. lat., on the country of the Mackenzie; and Pinus microcarpa, P. Banksiana, P. nigra, Alnus viridis (20 feet high), Salix speciosa (12 feet high), Juniperus virginiana, shrubby, reach no higher than 68° 5'. In the valley of the Mackenzie, Seemann saw a wood of Pinus arctica, in 66° 44' N. lat.

The strange assertion by the otherwise trustworthy Schacht, to the effect that the bark of trees prevents the ingress of frost, may be disproved any winter. Krutsch investigated this point in 1853, and found, with the temperature of the air at —23°, that of living trunks of Pines, &c., to be —20°.9.

Cryptogams, especially Lichens, are found up to the extreme limits of vegetation, and are capable of withstanding a greater degree of cold than any other class of plants. Even Fungi were found by Middendorf on the Larch in 71° N. lat. The number of Lichens found growing on trees and shrubs in the arctic regions is considerable, amounting, on the authority of Prof. Körber, to 68, of which, however, only 10 belong exclusively to high latitudes.

It is estimated that the lowest temperature borne by Lichens in exposed positions, such as the faces of rocks, &c., where no snow can protect them, is not beyond —24°, equal to 22° below zero Fahrenheit. *H.*

* "Sibirische Reise," iv., p. 608, the most complete German work on the Arctic Regions, extremely rich in observations on the biological and morphological relations of plants.

Home Correspondence.

The Potato Disease.—There is nothing very singular in the fact of two learned men—Dr. Kühn and Herr von Schultzenstein—arriving at opposite conclusions respecting the nature of the Potato disease. As this mysterious visitant is now known to be atmospheric, philosophy and learning are equally impotent to teach us more than we already know of its nature, or how to cure it. We must try, however, to grow the noble tuber at whatever cost, for there is no root known in our climate ever likely to be a substitute for it, and I believe the great bulk of the population would rather go without bread than Potatos as an auxiliary for their dinners. Your correspondent (W. H. Rogers, p. 1228) is for lessening the cultivation of Potatos, and to look out for a substitute. This is the old panacea promulgated by the Potato commissioners when the disease first appeared, but the substitute has not been found yet, nor is it likely to be. In the dry years of 1868, 1869, and 1870, as good crops of Potatos were grown, both as regards quantity and quality, as in any year before the disease first appeared. Even in this year, although June and July were such wet and ungenial months, the great bulk of the early and second early sorts, showed capital crops, and where fully matured before the beginning of August they were free from the disease, and when lifted and stored have kept well till this date. Another correspondent (W. H., p. 1228) is hopeful that he has found a remedy for destroying the germs of the Fungus in the tubers by fumigating them with sulphur. As he says he was profoundly ignorant of the subject of curing the Potato disease until this year, he may not be aware that others have been trying this, and found to be of little benefit as far as regards preserving the diseased tubers. At Welbeck, in the years when the disease first appeared, a series of experiments were tried, and, amongst them, sulphur was used, as well as chlorine gas. An old Mushroom-house was closed up, and filled with open shelves, and the diseased Potatos spread on them in thin layers, so that the fumes of sulphur and chlorine gas could penetrate all round the tubers. After repeated fumigations, the diseased Potatos were stored in the usual way, but they rotted, or dried up, as bad as those not operated upon. The theory of electricity having something to do with bringing the disease on is, I think, only tenable in one way, namely, the first attack of it is often seen in August, during sultry, moist weather, either preceding or after a thunderstorm; but the weather then is favourable for the development of the germs of Fungus, like electrical effects. On purpose to set the disease at defiance in seasons like the present, early and second early varieties, of good keeping properties, must be found out, and planted for the main crops. It might likewise be worth while to try very late planting, so that the Potatos may arrive at a state of ripeness by the end of October, when the cold weather would check the mildew from appearing—heat and moisture being its foster-parents. Our great Potato authorities have now a splendid opportunity of raising early seedling Potatos of good keeping properties; and consumers would do well to support little finances in trying to resuscitate the noble tuber from its present degraded condition. *William Tillery, Welbeck.*

——— I have just finished getting in and storing my Potato crop, and have again, for the nineteenth time in the last twenty years, to record with thankfulness my exemption from the disease by disease. This favourable result of my labour is the more important as again in the present year, as frequently on former occasions, it is so different from that which many of my neighbours have experienced. For example, the percentage of loss in one field, called Early Perfection, which in my case is 1 in 30 perhaps, is 60 or 70 per cent. in the case of a neighbour, to whom I gave some of my seed from the same lot. These opposite results cannot then be attributed to difference in the liability to disease of different kinds of Potato, although I strongly incline to the belief that such difference exists. It cannot be attributed to difference (apparently) in the nature of the attack, for my Potatos were affected in the haulm at the same time and in the same manner as my neighbour's, yet when we come to the harvesting, my crop (the bulk of it) is safe, and his is lost. Now in the sight of this startling difference, illustrated in the present season by comparison of my crop, not alone with that of one of my neighbours, but of many—illustrated also by similar comparative differences during many years, and in several different counties of England and Scils in which I have grown Potatos—I have some right, I think, to claim, under God's mercy, attention to the mode of treatment which has been attended with such uniform exemption from the destructive effect of this disease. I find my poor neighbours willing to listen to me, not only because my loss is so slight in comparison with their

own, but because my crop is so abundant, and that without my possessing any extraordinary resources for enriching my poorish soil, and so accounting for that abundance. It is, in fact, the simplicity of the means adopted, and which are so successful in their results, which enables me to recommend to poor men the same mode and principles of culture. The same facts may justify me in publishing these things, and seeking to impress them, through the pages of your excellent paper, on the minds of those who have suffered serious loss. It is the more due from me to do this, because many of the ideas were originally published to you from the pages of the *Gardeners' Chronicle*, though added to by my own observation, and the whole systematised in the course of years. In answer to Mr. Fenn's question, I can only say that I cordially wish him God-speed in his attempts at improving the kinds of Potato, and in advocating progress in the mode of cultivation. I cannot, without much more convincing proof, accept of his electrical theory any more than I can feel confident that the mould theory, to which I incline, is the true one. One thing, however, I would observe in reply to him in relation to wet or dry system of treatment. I should not expect a crop, or freedom from disease, by drying up the soil; nor should I expect attacks of disease from the action of rain, either artificial or otherwise. The Potato must have a considerable amount of moisture for the promotion of vigorous, and therefore of, in one sense, healthy growth. Stagnation of water about the roots, or of vapour about the plants, is, I think, the condition of extreme danger, so far as water is connected with it; and every precaution must be taken to prevent this. Having given in a previous communication some of the most important of my rules in Potato planting, I will now recapitulate them shortly, adding some previously omitted:—1. I plant those kinds, both early and late, which are in repute as the most healthy and profitable kinds. 2. I always choose good-sized and perfectly shaped Potatoes for seed, and keep them so that they shall not be heated or subjected thereby to premature sprouting. 3. I cut all Potatos into sets, retaining but few eyes (often only one), in order to produce a tree-like growth, *i.e.*, with one stem. 4. I plant early, *i.e.*, in February or March, the former in preference. 5. I plant the sets so that when earthed up (very moderately) they shall be 7 inches deep. 6. I subsoil my Potato ground most thoroughly, and if I suspect that the land requires draining, I plant in beds so raised above the general level of the ground that the sets lie upon the original surface level; nor would I ever plant Potatos on such land if I could help it; *i.e.*, until thoroughly drained. 7. I act upon this as an essential principle, that every plant shall have ample room to expand its foliage to the genial influence of sunshine, light, and air, and so that the rays of the sun may penetrate to the surface of the soil beneath, and that thorough acration may take place, maturing the foliage, producing short, stiff, and hardened stalks, and dissipating the vapours. 8. In manuring, which I do abundantly, I take special care to secure all the liquids as well as solids of the stable, stall, or sty; and if I could only have one of these I would not hesitate to choose the former. My attention was directed years ago to the exceeding healthiness and excellence of a crop of Potatos grown on old garden ground and manured the previous autumn with the contents of a building occupied by pigs; and, by a rough application of chemical analysis, I came to the conclusion that the large quantity of saline matters contained in urine, and likewise so characteristic of the Potato, indicated the value of the former as a manure for the latter. There appeared to me then, and ever since I have perceived the same effect, that the growth of the Potato thus fed is peculiarly healthy, and the produce uniformly excellent; and, on the contrary, from hot dry stable dung, such as is used in making hotbeds, I have observed rankness of foliage, distortion in the tubers, hollowness in the centres of the larger ones and coarseness in quality. From the time of making that observation I have never grown a coarse quality, though occasionally I have had many very large Potatos. Now certainly if we would have a plant resist disease, we must aim at producing the most healthy state possible to meet the attack. In thus seeking to avoid the attack, I therefore aim at the best possible mode of resistance. 9. Keeping the crop clean, and cutting off the whole of the haulm as soon as it is so far gone as to be useless to the promotion of growth to the tubers, complete my series of remarks. Cultivators, and especially cottagers, frequently sow seed Potatos, and in order to secure largeness of yield overcrowd the plants. This temptation must be resisted, and one of the most powerful motives to depart from the custom is that it does not attain its object. The abundant room which ministers to healthy growth increases the yield. I have dug 3 lb. of Potatos this year from one plant of Rivers' Royal Ashleaf; and the yield of Paterson's Blues has been in some places prodigious, many tubers weighing over 1 lb., and though the haulm was badly affected, and the sickly odour of the disease in it very perceptible, not more than 1 in 20 (near the shade of a belt of trees) proved diseased, and more generally not more than one or two to the bushel. Walking yesterday evening among the cottage allotments, I noticed a labourer digging Red Regents. The produce would have been unsaleable for want of size. He told me there had been a fair quantity of larger tubers, but that they were all rotten. The drills were 21 inches apart, with here and there a row of Broad Beans, and no extra room allowed for their growth. The Potatos were close to the surface. The ground had been dug with a spade used in a sloping direction, and not penetrating more than about 7 inches. The subsoil had never been stirred. The result was miserable failure. I hope to see better cultivation, and the introduction of the better sorts of Potatos among the labouring class; and trust that this long account may be of some value to some of your less experienced readers. *Y. M. Taylor, Scar Green Vicarage, near Beaconsfield.*

— Plato, in his "Phædon," says, "If what I am about to advance appear to be true, embrace it; if otherwise, attack it with all your might." I say the same. Let us argue, not for victory, but for truth. We frequently mistake effect for cause. A man's head aches, and the wife, mother, or sister, rings the bell for vinegar and rag, and bathes the temples. As well might she blister a horse behind his ears for spavins in his hocks. The seat of the ache, or primary cause of it, are the offended nerves of the stomach, with which the brain sympathises. Correct the cause, the stomach, and the pain in the head will cease. I never could detect Peronospora infestans with such glasses as I have. Probably they are not powerful enough. Let us then for a moment suppose there is Peronospora infestans to be found on the damaged stalks and leaves of afflicted Potatos. Is it the cause of, or the consequence of lesion? At present I agree with those who consider it to be a consequence, and not the cause of the malady. As long as a Lemon or Orange is sound in the skin, you will see no Fungus, but cut them in half, and the mould will soon form. How often have I seen in a decayed place in a lofty Elm tree a mighty Fungus, bigger than the crown of a hat, and looking like baked batter pudding? Well, I do not believe the Fungus caused the decay in the bark, but that the bark decayed, and the Fungus spore found a suitable pabulum. The decomposing juices of the tissues of the stalks and leaves of Potatos, suddenly stopping the inspiration and respiration of the plant, and that the juices of this member of the Nightshade family poisons the progeny, more or less, according to the more or less advanced state of

which are deposited in the young pod, and eat the seed as it matures. This is especially the case with Leguminous plants. The Cabbage Tree (Nuytsia floribunda), one of the commonest and most showy of the flowering trees, and which produces annually sheets of golden orange flowers, thicker than the leaves, so that the bush looks a blaze of gold, has never been known to produce a single seed from all this display." How many centuries since the present stock were sown we cannot tell, but the only increase is by underground suckers from the roots of old trees. *W. T. Thiselton Dyer.*

Trial of Peas at Seaham Hall, Sunderland.—The following is the result of a trial of Peas at Seaham Hall, 1871. All the varieties were sown on March 4. The trial embraced 56 varieties, supplied principally from the firm of Messrs. J. Veitch & Sons, Chelsea. A word of comment is due from me, namely, to say how satisfactory it is to find what care and attention is taken by the trade in keeping the sorts so select. I find, out of so many kinds, scarcely two Peas that resemble each other. Those marked with an asterisk (*) I can recommend, and those with two (**) I can highly recommend as the best useful kinds. I may say I have had six practical gardeners to assist me in deciding their merits. All the kinds grew so tall with the wet season that the extreme height cannot be taken as a

NAME.	In Flower.	Height.	Ready.	Average Peas in a Pod.	Remarks.
		feet.			
Auvergne	June 27	6	July 30	5	Good.
*Advancer	June 18	3½	July 19	6	Good.
*Carter's Leviathan ..	July 3	7	July 26	6	Good tall variety.
*Blue Scimetar	July 1	4	July 27	4	Good useful variety; the best variety in a dry season.
Bishop's Longpod	June 12	3	July 26	5	Good dwarf variety.
*British Queen	July 3	7	July 28	6	Very good, tall variety.
*Champion of England ..	June 22	6	July 20	6	Very good.
*Carter's Invicta	June 3	5	July 7	5 and 6	Very good, new sort.
*Competitor	June 3	8	July 23	5 and 6	Tall variety; large Peas and good flavour.
*Climax	June 10	4	July 19	5	Very good useful sort.
Champion of Scotland ..	July 2	7	July 26	5	Cannot recommend this sort; bad flavour.
*Dickson's Favourite ..	June 19	6	July 6	5	Good early kind.
Dwarf Sugarloaf	June 26	3	July 20	6	A useless variety.
*Dickson's First and Best..	June 14	4	July 6	5	One of the best early varieties.
Eley's Essex Rival	June 18	7	July 23	..	Good.
**Easter Kentish Invicta ..	June 5	7	July 31	6	Very good new sort.
*Evershed's Marrow	June 20	7	July 23	6	Good.
"Epicurean	June 8	6	July 23	5	Good.
*Fortyfold	June 22	7	July 23	..	Good useful kind, and a good cropper.
*Glory of Cassel	June 22	6	July 19	6	Good.
Grotto	July 23	7	July 20	..	Tall late variety.
**Hundredfold	June 27	8	July 30	6	One of the best.
Harrison's Glory	June 16	3	July 21	5	Good, but not one of the best.
*Huntingdonian	June 18	8	July 23	6	A good tall variety.
*Hallett's Large	June 19	7	July 29	5 and 6	A fine tall variety.
Imperial Green Marrow ..	June 27	7	July 21	5	A good useful Pea.
Imperial Wonder	July 2	8	July 29	..	Too large to be recommended.
King of the Marrows ..	June 29	8	July 24	..	Too large to be recommended.
**Little Gem	June 8	2	July 10	5	Can highly recommend this for general use; the cheapest
*Laxton's Quality	June 8	7	July 12	5	Good sort. [Pea grown.
**Laxton's Quantity ..	June 8	7	July 23	5	Good; rightly named; one of the best.
*Laxton's Alpha	June 7	6	July 12	5	Good.
**Laxton's Supreme	June 27	7	July 30	5	Very good; highly recommended.
Maclean's Wonderful ..	June 28	3½	July 23	5	Good.
Mammoth Dwarf	June 28	3½	July 30	5	Good.
*Maclean's Prolific ..	June 22	5	July 20	5	Good.
**Maclean's Premier ..	June 30	3½	July 14	6	One of the best.
Mumstead Marrow	June 30	7	July 28	5 and 6	A good tall variety.
Nonpareil Marrow	June 30	8	July 22	5 and 6	Good tall variety.
Nelson's Vanguard	June 11	3½	July 15	..	Very good.
**Ne Plus Ultra	June 30	8	July 24	5 and 6	One of the best for general use; highly recommended.
Paradise Marrow	June 27	8	July 30	5 and 6	Good.
*Prizetaker	June 18	8	July 26	6	Very good dark green variety.
Peabody	June 1	2	July 28	4	A useless variety.
**Princess Royal	June 27	3½	July 26	5	Highly recommended.
**Ringleader	June 3	5	July 6	5	Good early variety; one of the best.
Surprise	June 22	7	July 26	5	Good.
*Sangster's No. 1	June 6	5	July 10	5	Very good early kind.
**Sutton's Early Champion	June 5	5	July 8	5	Good.
**Taber's Perfection ..	June 6	3½	July ..	..	Good useful kind.
Tom Thumb	June 11	3	July 26	..	[warty at this season, also in Grotto.
The Australian	June 12	8	Aug. 3	6	Too tall, and very late for general use; the pods are
**Veitch's Perfection ..	June 27	3½	July 28	5	A good useful Pea, of fine flavour.
*Waterloo Prolific	June 30	7	July 28	..	
**Waterloo Dwarf Branching	June 11	3½	July 30	5	One of the best; very prolific; very highly recommended.
**Yorkshire Hero	July 28	4	July 30	5	A good useful sort.

standard. As to flavour the trial was made in the raw state, which I think is not a good criterion to judge by. Although some are inclined to judge the quality in this raw state, I have failed as yet to get master of this part of judgment. I must highly recommend to the notice of gardeners Maclean's Little Gem; I consider it the best and cheapest Pea to grow, as it requires no sticks; a good flavoured, early, productive, and can be grown in rows 1 foot 6 inches apart, and the produce is equal to, or more than, that of the tall varieties—taking into consideration the same space of ground; the latter should be trenched 2 feet deep, and manured well. *Robert Draper, Gr. to Earl Vane, Seaham Hall.*

The Floral Committee and its Awards.—I was much pleased with the observations on this subject contained in your leader at p. 1223. It is a matter that I have thought much about of late, and I have come to the conclusion that, if the Floral Certificates are to be respected as of value, a fixed standard of merit ought to be made, and that when a Certificate is awarded, the particular merit of the plant should be mentioned. For instance, a plant may be especially useful for table decoration, bedding out, or for stove or greenhouse decoration; or again, it may be adaptable in a young state for winter work. At present the Certificates do not specify the qualities for which they are awarded, but are merely given for the plant; but it would, I think, be to the benefit of the public if this were otherwise, for it is the public, and not the traders, the Society should help and encourage. That the traders are the principal importers of new plants is true, and when such are exhibited they should receive their due reward, but that they should be favoured is not the right thing. It appears to me that a plant should not be valued according to its propagating qualities, but according to its permanent beauty, and in some instances, its rarity. This would much help to refine the taste and improve the standard of amateurs, for though some good collections of such plants as are not generally called florists' flowers, the majority are apt to be influenced by the Society, and go in for the most gaudy. When we benighted individuals have the presumption to show plants of beauty out of the common line, we hear that worn-out phrase, "they are very interesting, but more curious than beautiful," and are looked upon as strange fish; which feeling is in danger of spreading. Knowing Mr. Marshall's love of plants, I trust that under his guidance the danger of certificates losing their value may be avoided. That the Committee have acted always with the best intention, I believe; but when the stream runs strong one way, it requires a strong man to face it; and as plant fanciers are not men devoid of goodness of heart, they are apt to err through charity. I think the Committee have it in their power to help the public out of old ruts, and should be glad to see them trying to do so. *F. Croucher, Gr. to F. T. Peacock, Esq., Sudbury House, Hammersmith, W.*

Extirpation of Heath, &c.—I have lately enclosed a common, and I find the Furze and Heath are coming up very strongly. To plough it up would destroy my crop of grass; to draw up each rootlet will be a very expensive and tedious operation. Can you suggest any other course, so that I may destroy the Furze without getting rid of Heath? I have run the paring-machine over the surface, but the Furze only grows thicker; and I shall be glad to hear the experience of yourself and that of your numerous correspondents. *Rusticus.*

Trees and Shrubs for Sea-side Planting.—I may be able to assist "An Old Subscriber" in this matter. Plants that will grow by the sea may be divided into two groups:—1st, those that will face the bluster of direct exposure to stormy sea wind, and, 2d, those which rejoice in the immediate neighbourhood of the sea, but are the better for some slight protection. From my own observation I will enumerate the two:—1st group: Scotch Fir, Pinaster, Juniperus macrocarpa, Abele Poplar, Tamarix, common Yew, Ailantus glandulosa, common Alder, White Willow and Goat Willow, Quercus Ilex, Gorse, Elder, Spartium junceum, Chenopodium fruticosum. 2d group: Norway Maple, Sycamore, common Beech, Fig tree, Myrtle, Arbutus, Sweet Bay, common Hydrangea, Bladder Senna, common Rhododendron. No doubt many might be added to those lists, especially the latter, and I hope some other correspondents may send contributions. Let me add some remarks. The whole of the first group may be added to the second. They will do well though quite exposed, but probably a little protection would help them, especially at first planting. The Scotch Fir is better than the Pinaster in very exposed situations, it gets less battered and broken. That most beautiful of our fastigiate Conifers, Cupressus macrocarpa, very much loves the neighbourhood of the sea, and flourishes gloriously in the southern counties thus situated; but, whether it would do well so far north as Southport, may be questionable. The White or Abele Poplar is also very tenacious of life under sea exposure, but it, as well as the Ailantus, Alder, and the two Willows, should have moisture. The Spanish Broom (Spartium junceum) grows surprisingly well near the sea. I have seen it flourishing in the most vigorous health, perfectly exposed to the east, growing in mere sand close to the waves. *S. F. A. S.*

Carbolic Acid: Fungi: Insects.—I notice that my paste, to which two or three drops of carbolic acid is added when made, never produces mould; but the acid does not seem to be injurious to the larve of a small crimson-eyed fly which breeds in the paste in swarms. If your entomological referee should not recognise the fly by my description of it, I will send him some specimens both in the larva, chrysalis, and perfect states. *W. Marshall.*—Our correspondent should send a specimen of the insect to Prof. Westwood, Oxford. Carbolic acid is now used in the herbarium at Kew to prevent mould on the dry plants. EDS.]

Irish Saxifrages.—The paragraph in the last number of the *Gardeners' Chronicle* suggests my asking whether any of your correspondents can state with whom originated the opinion that Saxifraga Andrewsii is a garden hybrid? Babington speaks of it as such; and Hooker and Arnott, in the 7th edition of their "British Flora," say, "From what we have learned, this supposed species is a garden hybrid, between S. umbrosa and S. ligulata." Does anyone know on whose authority these statements are made? And can any of your correspondents throw light on the origin of Saxifraga Guthbiensa, a plant which is much more vigorous in habit than, Saxifraga Andrewsii? It exists in many collections, but I can find neither name nor description in any botanical work. Saxifraga Andrewsii occurs in the collection of the Jardin des Plantes, Paris, under the name of Saxifraga stratifolia, and in that garden I have seen quite a specimen stated to have come from the Alps, but without any name or exact record of locality. The history of such a plant ought not to be hidden in obscurity, and I hope some of your correspondents will take it up, and decide at once and for ever whether or not it is a garden hybrid, as has been stated. If it is known to be a hybrid, the particulars of its birth and birthplace are probably known also. Some 18 years ago, long before I took to the cultivation of Saxifragas, I found a Saxifrage on the Great Isle of Arran, Galway, somewhat after the habit of Saxifraga cæspitosa, but with thick, fleshy, reddish leaves. Can any of your correspondents help me to a name for it? My herbarium specimens are labelled Saxifraga hirta. *Geo. Maw, F.L.S., Benthall Hall, Broseley.*

Scott's Pommier de Paradis.—Examples of this stock I have sent, to show how hardy it has proved amidst the almost general wreck of other kinds. The fruit should be tasted soon after gathering. The extreme hardiness of this as a stock, I should think, would tend to the healthy development of more tender sorts. Some young trees worked upon it this season have made extraordinary growths, and I now feel satisfied that no other stock can equal it in hardihood, let the seasons be what they may. We had it last summer (1870) as dry as it could well be; we had the thermometer 5° below zero (Fahr.) in January (1871); and now we have had one of the most disastrous springs for fruit trees that any of us have ever known; yet this hardy Apple has braved all weathers, and is in every sense in luxuriant health, and that, too, within a few yards of a river in low, rather damp ground. The branches and fruit are two years taken from a tree planted under the end of a water shoot, and will speak for themselves. *J. Scott.* [We are not sensible of any general wreck amongst the Apple stocks this season. We have looked over several quarters, and find almost all other sorts than those of our correspondent's in the most vigorous condition, equally so as in the examples sent, which were very good. It would be enough, we think, for our correspondent to state that he finds his variety of stock the best suited for his purposes, and best adapted for his soil and locality, and without entering into a general condemnation of all others, which have been proved to succeed elsewhere. EDS.]

Leptosiphon roseus. — The Godetia Whitneyi, introduced by me last spring, has received, both in your journal and other publications, abundant recognition of its value, but, unfortunately, I am not aware that any special reference has been made to

the beautiful little plant, introduced at the same time, whose name heads this note. I, therefore, crave a small space to call attention to its great value as an early bloomer, especially when sown in autumn, feeling confident that all who may make trial of it will be more than content with the result. Whether sown in early spring or autumn, it will never fail, in proper soils, and with proper treatment, to amply reward the cultivator for his trouble; but, as might be inferred by all who have grown the leading Californian annuals, this will be more especially the case when plants of the maximum size and vigour are obtained by autumn sowing, and which will yield their flowers before the heat of summer comes on. Sown early in September, in pans, pricked out when an inch or so high, and transferred to the beds or borders, either prior to the winter or about the middle or end of March, it will produce its bright rose-coloured flowers in great profusion, the beds presenting, when in full bloom, a sheet of colour to the eye. As may be supposed, the finest plants are obtained by planting out the seedlings early in autumn. If sown late, it will be better, after pricking off, to winter them in a cold frame. In conclusion, I would observe that those who will persist in the practice of thick-sowing, compelling, as often happens, 500 seedlings to develope themselves within limits barely adequate to the support of one, have only themselves to blame if the results do not realise their expectation. *W. Thompson, Ipswich.*

Mixed Bedding Plants.—In the remarks on the "bedding-out" in Hyde Park, contained in your issue of the 16th ult., my attention was drawn to the not altogether satisfactory introduction of Viola cornuta amongst some of the variegated Pelargoniums. Allow me, therefore, to recommend in substitution thereof Ageratum Imperial Dwarf Blue, which, I opine, would prove highly suitable, if I may judge by an example I lately saw in the unique "Nestlecroft" parterre at Weston House, Shipston-on-Stour, the seat of Sir G. R. Philips, Bart., composed of Pelargonium Manglesii mixed with the Ageratum in question, producing, as they signally did, an effect of the most exquisite loveliness, infinitely more so than preceding combinations of Manglesii with Verbena venosa or blue Lobelia, which, however, were very telling. From what I have seen of that new acquisition, Viola Perfection, I think it would also prove a gem for the purpose indicated. *William Gardiner, Lower Eatington Park.*

Foreign Correspondence.

ST. HELENA.—The following report on the progress of the Government plantations in St. Helena, recently drawn up by Mr. J. C. Melliss, the surveyor of crown lands in that island, will, we are sure, be read with interest.

Since the years 1808–1814, during which General Beatson accomplished so much for the improvement and extension of the vegetation of the island, no public effort for its further development was made until the importance of such work, strongly urged by Dr. Hooker, C.B., the director of the Royal Gardens at Kew, and supported by the governor, Admiral Sir Charles Elliott, resulted in the selection of Mr. Chalmers as a Government gardener for this island. He was accordingly sent out from Kew in the year 1868, with the express object in view of improving and extending the vegetation generally, and establishing a Cinchona plantation on the high central ridge, near Diana's Peak. It is now 31 months since Mr. Chalmers arrived here, and it becomes highly desirable to record under each of these heads what amount of work has actually been done up to the present time. A cottage in Plantation Grounds was appropriated as quarters for Mr. Chalmers, and a forcing house for raising Cinchonas and other plants erected. The land deemed most suitable for the cultivation of Cinchona being in the hands of private persons, an arrangement was made for securing possession of 5 acres of the land called "Newfoundland," situated on the south and windward side of the main central ridge, near Diana's Peak, at an elevation of 2600 feet above the sea. A cottage was also obtained adjacent to this plot of land, and a man placed on the spot to take immediate charge of the proposed plantation; a small forcing-house was also erected on the land. Several Cinchona plants, including some raised from seed a year or two previous to 1868, were placed out in different parts of the highlands—secluded spots, safe from the tracks of cattle, amongst the native vegetation, being selected for them; and in the following year (1869) the general planting of the 5 acres commenced, sufficient young plants by that time having been raised by seed, given to the island by Dr. Hooker. At the present time the plantation presents, in a healthy thriving condition, 500 trees of Cinchona succirubra and 300 of C. officinalis, numbering in all 800 plants; the tallest of these is a plant of C. officinalis, raised by Mr. Melliss, and planted out on the high land on October 14, 1868. It now measures 7 feet 2 inches above the ground. The next tallest tree in the plantation is one of C. succirubra, planted out in May, 1869, and now measuring 6 feet above the ground. About 300 of those first put out average a height of 4 feet 6 inches, and the remainder vary from that down to 2 inches. The cultivation of the species C. Calisaya and C. Pahudiana has not been continued, because it was found that in St. Helena they do not grow so well as the other species.

The nature of the ground forming the plantation is very steep and rugged, which prevents it from being planted very thickly. It is incapable of containing more plants, and the fact of the surrounding land being in the hands of private persons, who do not as yet see the advantage to be derived from the cultivation of this valuable plant, is the chief reason for the non-extension of the plantation. The actual cost of these 800 trees, exclusive of Mr. Chalmers' salary, and such outlay as could not be fairly charged against a limited number of plants, has been £244 19*s.* 3*d.*, or very little over 6*s.* a tree.

The work done for the general improvement of the island may be reviewed under three heads, viz., the propagation of those plants which were introduced by General Beatson and others; the interchange of plants and seeds with other countries, and the successful introduction of new plants.

With reference to the first, it may be remarked that a few years ago only eight Norfolk Island Pines (Araucaria excelsa) were growing on the island. Mr. Chalmers has, during the past year or two, set out at "Plantation" 38 fine healthy young trees of this beautiful and valuable species, which have been raised from the seeds of those few trees planted in by General Beatson 50 years ago, and which now have attained a height of over 100 feet. Several of the Norfolk Island Pines, as well as some Bermuda Cedars (Juniperus bermudiana) have been planted by the direction of his Excellency the present governor, Admiral Patey, in the hospital enclosure, as also in the castle gardens in the town, where they are now growing, and the lower land appears to suit them well, and they promise to become objects of great ornament to the town. A large number of young plants raised from seed, about 1000 in all, including Pines (Pinus Pinaster), Cape Cypress (Cupressus horizontalis), Gums (Eucalyptus diversifolia), Acacia (Acacia longifolia), and wild Olives have been, chiefly during last year, planted out in the grounds at "Plantation." There is still, however, room for a continuation of the important work of propagating those plants which already grow in the island. There are Helena,

International meetings of the present year under the name of T. Morreniana. It forms a dense tuft of elongate subulate-filiform leaves, which are erecto-divaricate, plane above, convex beneath, and from the centre of which tuft rises a lax panicle, not much exceeding the leaves, of small pale blue flowers, having reflexed petals. Primula japonica (t. 13) is copied from the plate in the *Florist and Pomologist*. This brings the publication up to June, 1871. We note that in the account of the show at South Kensington on June 7, Professor Morren erroneously attributes the display of American plants to "Messrs. John Waterer & Sons, of Bagshot," instead of to Mr. Anthony Waterer, of Knap Hill.

The numbers before us of the **Gartenflora** (August, 1870—Jan., 1871) contain the following plant portraits:—Amaryllis pardina *β* rubescens (t. 658), a narrow-petaled form, with the flowers suffused with red. Rhododendron Falconeri (t. 659), one of the Sikkim species, with large blunt leaves, rusty beneath, and dense heads of small white flowers. Lepidozamia Peroffskyana (t. 660), a very elegant Cycadaceous plant of Australia, with a stout trunk, and pinnate leaves, consisting of numerous leaflets, decurrent at the base; it bears, according to Dr. Regel, amongst other synonyms, Fischer's Cephalotaxus Denisoni, Encephalartos Denisoni, M. Peroffskyana, M. Macleayi, M. gigas, and Catakidozamia Macleayi. Cypripedium caudatum (t. 661). Rhododendron macrosepalum (t. 662), a Japanese species of the Azalea section, forming a low sub-deciduous shrub, with dull rosy flowers, spotted with purple on the upper portion of the corolla. Clarkia Riedeliana (t. 663) the fine orange-flowered species figured in the *Botanical Magazine* (t. 5829), under the name of C. macrophylla. Lythrum flexuosum (t. 664, fig. 1—3). Lilium Maximowiczi *β* tigrinum (t. 664, fig. 4), a handsome slender Lily, with scattered linear-lanceolate leaves, and orange-scarlet nodding flowers, spotted with dark purple, and having recurved segments. Mimulus Tilingi (t. 665), an erect-growing and free-flowering hardy herbaceous perennial with terete stems, 2 feet or more in height, oblong-ovate leaves, and a profusion of smallish yellow flowers, the throat of which is dark. Rhododendron Metternichii (t. 666), a Japanese species of the Azaleastrum section, growing 2—3 feet high, with elliptic, coriaceous, subdeciduous leaves, and small lateral rotate greenish-yellow flowers, apparently of no beauty. Lilium Roezli (t. 667), a pretty slender-growing Lily, found by Roezl on the Rocky Mountains, and nearly related to L. superbum; it grows 4 feet high, and has narrow linear-lanceolate leaves, the lower of which are scattered, and have about two flowers which are nodding, with recurved segments, orange-red, marked towards the base, with a few yellow and dark purple spots. Dr. Regel suggests that, if it should eventually produce, as L. superbum does, a paniculate inflorescence, it might be called L. superbum *β* Roezli. Gilia linifolia (t. 668), a pretty annual plant, from California, with branching stems, palmatisect leaves, and rather large white flowers. Coleus umbilicatus (t. 669) is the Colea Commersoni of gardens, a robust stove shrub, with whorled pinnate leaves, 2—4 feet long, and fascicled racemes of moderate-sized, rosy-lilac, Bignoniaceous flowers. Rubus leucodermis var. Golden Cap (t. 670). Vriesia corallina (t. 671), the Enchilanthus corallinus of *Lindley's Botanical Register*, a tropical American Bromeliacea, is a distinct-looking plant, with a tuft of concave, oblong-ligulate leaves, glaucous beneath, and a scape clothed with crimson bracts, and bearing a distichous spike of refracted flowers, which are yellowish-green, with the closely-pressed bracts much half their length. The scape, rachis, and bracts, are purplish-crimson. Dieffenbachia alliodora (t. 672) is a neat-growing plant, with long-stalked, oblong-lanceolate, bright green leaves, and a much shorter shining green spathe. Oxycoccus macrocarpa (t. 673). Tetratheca ericifolia (t. 674). Cordyline Haageana (t. 675), a green-leaved, New Holland Dracæna, with oblong-elliptic stalked leaves, and terminal panicles of small white tubulose flowers.

The eighteenth volume of **L'Illustration Horticole** (Jan., 1871), the second volume of the third series, opens with a plate of a noble Tree Rose, Rosa Regeliana (t. 47), a low bushy shrub, with tomentose branches furnished with numerous slender, straight, unequal, pale-coloured spines, broad stipuled pinnate leaves, tomentoso-canescent beneath, and terminal many-flowered corymbs of large single crimson flowers, measuring sometimes as much as nearly 4 inches across, and looking more like single Pæonies than Roses. It is a hardy shrub, introduced from Japan by M. Maximowicz, and is cultivated by M. Linden. Epidendrum Frederici-Guilelmi (t. 48) is a fine Orchidaceous epiphyte, from northern Peru, with tall, leafy stems, broadish oblong leaves, and terminal ovate racemes of large, deep rosy-crimson, narrow-petaled flowers, with a white lip, and attached by long rosy-purple ovaries to the dark purple rachis. Hæmidictyon? refulgens (t. 49), a stove climber from Eastern Peru, very like what Mr. Bull calls Bignonia Roezlians; the leaves (the few lower ones at least) are in opposite pairs, ovate, oblong-acuminate, of a rich velvety bottle-green, with slight silvery markings along the course of the veins, and having throughout a rich flush of violet-purple, the under surface being of a reddish-violet tint. In Clematis hybrid. vel var. Crippsianæ (t. 50), are represented the three varieties of tunbridgensis, Star of India, and Lady Caroline Nevill, raised by Mr. Cripps, the figures being copies of the plates issued by Mr. Cripps, and noticed by us on a previous occasion. Carica erythrocarpa (t. 51) is a curious little fruit-bearing tree, with a simple erect fleshy stem, upwards of a yard high, surmounted by a head of bold trilobed leaves, the flowers small, white, produced from the upper part of the trunk below the leaves, and succeeded by scarlet fruits, which are as large as a hen's egg, oval, pointed, and with a distinct suture on one side; the fruit is succulent, and said to be edible, but it is described as leaving a very nasty agreeable after-taste, and the plant is therefore recommended as chiefly an object for its Palm-like habit, its fine lobate foliage, and its brilliantly coloured fruit. Camellia Vessillo dell' Arno (t. 52), an Italian variety, of fine imbricated form, represented as a blush-white with carmine stripes, but described as a magnificent scarlet-red, veined with deeper lines. Dudcorea multicolor (t. 53) represents six varieties of a very beautiful climbing plant, the leaves of which are variously marked with shades of green, copper colour, bronze, silver-grey, &c. The leaves are more or less distinctly cordate. They are—chrysophylla, rich golden bronze, mottled and spotted, and having a golden-yellow midrib and margin, a silvery grey, with the veins marked of an emerald-green; melanoleuca, deep or bottle green, with broad central silvery band, and irregular blotches disposed along the line of the two lateral veins; metallica, deep olive or coppery green, with salmon-tinted central band; picta, green, with irregular white blotches and longitudinal bands, having their margins irregular; prismatica, rich deep green, with a central silvery band, the lateral ribs and transverse veins marked by narrow silvery lines, the surface shot with a rich purplish hue. They are all very handsome plants, especially the two last-named varieties. Dendrochilum cheetes (t. 54), a Fan Palm, represented by us at p. 697 (1870), and remarkable for the black spines of its stem. Geonoma Schotteana (t. 55), an elegant, slender-leaved, pinnate Palm of Brazil, with something of the aspect of Cocos Weddelliana. Odontoglossum Wallisii (t. 56), is a pretty New Grenadian epiphyte, described at p. 104 (1870); the flowers are tolerably showy, the sepal's chestnut-red bordered with yellow, the yellow petals blotched with chestnut colour along the centre, and the lip white towards the base, chestnut-red bordered with white in front. Plumieria lutea (t. 57), copied from the figure in the *Botanical Magazine*. Odontoglossum Halli (t. 58), a handsome figure of a now well-known and very ornamental Orchid, with large flowers, fine in colour and in marking—yellow with deep purplish brown on the sepals and petals, and white-veined with purplish red on the tip. Lonicera Periclymenum aureum (t. 59), is a hardy Honeysuckle with the leaves striately banded and blotched with yellow. Gloneria jasminiflora (t. 60), is a fine new Rubiaceous stove shrub, of erect branching habit, with leathery ovate-oblong entire leaves, and compact terminal trichotomous panicles of long-tubed white flowers. Gongora portentosa (t. 61), is a handsome Orchid of a genus now somewhat neglected, the pendent spikes being furnished with flowers of large size and of a yellowish hue finely dotted with brown. Wellia regia (t. 62), is a fine and rather novel Palm, of which we published a figure of a young plant at p. 764 (1870). M. Linden's figure is more advanced, showing a more decidedly pinnate leaf, with several pairs of pinnæ, and there is also a reduced sketch of a matured plant, in which the pinnate character is very strongly developed. The genus is mainly distinguished from Geonoma by the much more numerous stamens and staminodes.

THE WEATHER.

Sept. 21.—Very variable throughout. Slight fog and haze at night.
22.—Cloudless in the early morning and at night. A little cloud present during the day. Very fine.
23.—Foggy in early morning. Cloudy throughout. Rain fell more or less heavily from 3 P.M. onwards.
24.—Rain fell very heavily during the early morning, and partly till noon. Overcast and cloudless generally afterwards.
25.—Overcast throughout. Rain commenced falling about 3 P.M., and continued throughout the evening.
26.—Overcast till 3 P.M.; generally fine afterwards. Rain fell throughout the morning almost continuously till a little after noon.
27.—Generally overcast throughout; very frequent showers of rain.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

THOUGH it is desirable, and, in fact, necessary, for the future well-being of all plants, to reduce the artificial heat in stoves and Orchid-houses proper at this time, care must be taken not to permit the temperature to decrease too much or too suddenly, so as to prevent the plants from receiving a check. In doing this, we should aim at ensuring a decline of temperature more uniform, and with less decided fluctuations, than is externally experienced. In other words, though a slight decline must be insured, it may be necessary, on occasions, to maintain rather more artificial warmth than is at all advisable at other times, to counteract the influence of a too sudden fall of the external temperature. Water must now be given to all plants more carefully than heretofore, and especially to *Ericas*, *Epacrises*, and *New Holland plants* in general. Those who possess *Indian Azaleas* which flowered late, and are from that or any other cause backward in the matter of growth, should now hurry them on in a nice genial warmth, that the necessary growth may be perfected before the comparatively cloudy months of October and November arrive. These remarks are not inapplicable to those *Camellias* which flowered late in the past season, or such as are required in bloom at an early date. Promote, by every possible means, the further growth of such popular subjects for early winter blooming as *Epiphyllums*, *Begonias*, &c., stopping fast-growing plants of the latter, when required, and placing all such, and kindred subjects, upon shelves, or in other elevated positions, where the greatest possible amount of sun and light may reach them. *Rochæa*, *Kalosanthes*, and *Cactuses* of the *Epiphyllum* type, should also be well exposed to the influence of the now declining sun, thereby to insure that the wood may become well ripened, as the only true precursor of abundant bloom in the future. Some kinds of Orchidaceous plants, such for example as *Dendrobium nobile*, *Cypripedium insigne*, and many cool Mexican varieties may now be gradually introduced to greenhouse, their season's growth having been completed. Here they rest better, and frequently flower more abundantly afterwards than they do when wintered in higher temperatures. In some instances it may happen that *Agaves* (Aloes), which have been placed out-of-doors for the summer, may require to be shifted into new tubs, before they are removed to winter quarters. In all such instances, therefore, let due attention be given to such matters, for though some Mexican or American varieties will stand a little frost, it is not advisable to run too great a risk of injury; them. Attend to and forward the work of finally staking *Chrysanthemums*. Too few stakes cannot possibly preserve a natural contour. Those of course who "go in" for stiff table-topped specimens of Pompons, or any of the extreme forms which an emulative system of culture seems to give birth to, must make their final tyings by performing the three

usual contortions practised on the unfortunate branchlets. *Climbing Plants* must have all the young growths possible removed as they successionally go out of bloom, that every ray of light may be the better afforded to the plants beneath. By a gradual cessation of root-watering, all climbing plants must also be induced to cease growing rampantly, and to go to rest for the winter.

FORCING HOUSES.

The ordinary forcing-pits, or houses attached to any, or every establishment, should now be finally got into order. Where artificial bottom-heat is afforded by means of fermenting materials, these should be procured and made ready. Flues or pipes having tanks of hot-water attached, should also be attended to. This done, first thoroughly fumigate, then lime-wash all internal surfaces. Stir the bark-beds around fruiting *Pines*, watering the surface well; and by these, and every other means, keep up a nice surface growing heat. Though, in regard to these, a high temperature is desirable by day, let it be somewhat moderated by night, now that the hours of darkness are becoming so long. Excess at such a time is likely to produce weakly growth, which will not come to maturity as it should do. Be very particular to give the freest possible circulation of air to those *Vineries* intended for starting early, say in November, more especially to such as are in process of being, or are already, pruned. Constantly and persistently stop the young lateral shoots which continue to push upon the next earliest Vines, as is frequently the case at this season, owing to the fact that the Vines are denuded of their crops, yet are not gone to rest, and so are making a too free use of what should be a store of strength and vigour. To permit these to grow unimpeded at this time is to shorten to a great extent their legitimate period of rest, which, if not checked with a firm hand, will tell against them at a future day. *Pot Cherries* intended for early forcing, and which have been plunged out in the open borders, should now undergo an examination, and have a good surface mulching. *Cherries* may also be taken up from the open ground, and carefully potted forthwith, if they possess plenty of bloom-buds, with every hope that they will, under proper treatment, carry a good crop of fruit next year. No plant that I know of is more adaptable in this way, for such a purpose, than the Cherry. *Tomatos* grown in houses or heated pits for the winter supply, as they are in some gardens, must now have abundance of air, to impart to them the necessary robustness. Be careful to keep the stock of young *Dwarf French Beans* for the early successional supply free from red-spider, which, if existing upon such when removed into forcing structures, is likely to infest everything else, and prove a great source of annoyance all the winter. Attend well and finally to all *Cucumber* and *Melon pits* requiring aid from linings. To let the heat decline materially at this time is to check the plants beyond recovery.

HARDY FLOWER GARDEN.

By gradually withholding water from *Auriculas* at this time, a kindly rest will be insured to them, more favourable than such as is forced upon them through the increasing coldness of the weather. Preliminary to this, however, they should be placed in their winter quarters, where greater immunity will be experienced from the fluctuations of the natural elements. Real earnest winter is already foreshadowed by the falling of leaves, necessitating much labour, for if we would keep the places around mansions as tidy as it is desirable, we should collect periodically such as fall for the next five or six weeks. At this season fresh plans for the improvement of gardens are made, and these must be entered upon and carried out vigorously a few weeks hence. It may suit some to transplant shrubs in an early date, as at the end of the present month approaches this work may safely be commenced.

KITCHEN GARDEN.

With the past rain, all who were properly on the alert made good progress with the necessary transplanting of a variety of subjects, which, owing to the want of it, they had been unable to plant before. Pits and frames which can be spared should immediately be filled with young *Lettuces* and *Endives* intended to come in about Christmas, and to succeed such as will be taken up full-grown and transplanted into other pits at the first approach of frost. Other batches of these salads must likewise be transplanted to sunny southern borders, where, even though none of the more kinds of plant protectors now in use are supplied, there will be some chance that they may withstand the severity of winter. Autumn-sown Cauliflowers should likewise be transplanted permanently under the customary handlights or into an empty frame. Where saladings are largely used, it would be advisable now to make a sowing of *Lamb's Lettuce*, subsequently placing the useful *cloche* over the seeds. Attend to the necessary permanent earthing-up of *Cardoons* before hard weather sets in, and continue earthing-up successionally rows of *Celery*, according to the requirements of the establishment. Thin out further successions of *Spinach*, and where the "cutting down" of *Parsley* has been neglected so long, let this be done forthwith, if a future supply is at all valued or must be forthcoming when wanted. Make up the rows in *Cabbage* plantings where insects have done mischief, as I find it too generally the case this season. Remove the decaying leaves from around the base of *Brussels* and other *Sprouts* and the stock of green stuff generally, not only to insure a neat appearance, but that the air may exert to its fullest extent its useful hardening influences. *W. E.*

TOWN GARDENING.

One of the most useful plants in town gardens is the *Golden Feather Pyrethrum*, cuttings of the shoots of which put in, eight or ten in 48-sized pots, at once, and wintered in a cold frame, will make nice early plants for spring, and be far in advance of seedlings sown now. But where a great quantity is required, the seed should be sown at once in pans, and be placed close under glass. When the plants grow enough to handle, prick them out in light soil in a cold frame, protecting them from frost, and giving them all the air possible in fine weather. *Echeveria secunda* and *E. glauca* make very pleasing edgings, are of easy culture, and can be kept well through the winter in a cold frame. They make offshoots very freely, and these should be taken off the old plants, and be potted singly into 60-sized pots, at the same time putting the old plants in small pots, in light, sandy loam. The *Cerastium tomentosum* makes a pretty margin, and stands well in town. The above, if judiciously planted in the spring with *Coleus Verschaffeltii*, *Centaurea ragusina*, *Cineraria maritima*, and *Dell's Dwarf Beet*, make charming beds; and in my opinion are more fitted to make a display through the summer in confined gardens than Pelargoniums, Calceolarias, and such-like bedding plants. The beds intended for the above should be got in as soon as possible, and having had a good dry dressing of leaf-mould and sand dug in, should be left rough to sweeten till the roots are planted. A few early *Hyacinths* should now be placed in glasses filled with soft water, so that the base of the roots only may come in contact with the water. But this must be in a place free from about a month, when they may be brought out, and with a soft brush remove any decayed matter, which generally accumulates about the roots. At the same time change the water, and remove them to the light, always observing to change the water when it becomes foetid. For cultivating in pots, they should have a compost consisting of one-half loam, and the other half equal portions of leaf-mould, rotten dung, and sharp sand; with this fill 48-sized pots rather firmly, place the bulb on the surface, with a little sand under and about it, then press them in the soil, leaving the crown of the bulb above the surface, give them a good watering, and place them in some snug corner on slates to keep the worms out; and as soon as they have become dry, cover them with about 6 inches of fine ashes or cocoa-nut fibre, there to remain till they have made a growth of about an inch, when the ashes should be carefully brushed out of them, and the plants be placed in a close frame for a few days. They may then be removed to the rooms, and some may be turned out of their pots into baskets filled with damp Moss, where they will make pretty feature for the sideboard and table when in bloom. Where it is intended to winter *Pelargoniums* and *Fuchsias* indoors, turn them out of their pots, remove the old crocks, put in fresh, remove a small portion of the surface mould, place the plants back, adding a little fresh soil, trimming off all straggling shoots, and well water them. Keep them out of the frost, and give them as much light and air as possible in fine weather, using water very sparingly during the winter months. *J. D.*

Notices to Correspondents.

BEETROOT. With any experienced correspondent oblige by satisfying an inquirer from Australia, if Sugar Beet can be grown near the precincts of the sea, without injury to its manufacturing qualities. The inquiry has reference to a large investment of capital.

BOOKS : *A Fresh Subscriber*. Grieve's "Ornamental Foliaged Pelargonium."—*Perth*. Thompson's "Gardener's Assistant" (Blackie & Co.).—*Old Subscriber, Fenwerton*. The Rose Preceptor, or Rivers's "Miniature Fruit Garden" (*Journal of Horticulture*).

BORROWING AND PURCHASING FOR EXHIBITION PURPOSES : *A Gardener*. No doubt this is a very reprehensible practice. If you have good evidence in support of your assertions, you should bring it under the notice of the Committee. The professional feelings must be sadly weak where such practices prevail.

COARSE SULPHURIC ACID : *C. W. H.* Any druggist or dealer in cattle medicines ought to be able to supply you.

CYCLAMENS : *G. Y.* A friable soil, of a rather loamy character, well enriched with decayed cowdung and leaf-mould. The Royal Vineyard is not a big-class Grape. It should hang late, and requires considerable heat.

FIGS : *F. A. C.* Fig trees produce two crops of fruit in one season. The first crop is produced on the shoots of the previous year's formation, and show themselves a little in advance of the leaves; these ripen in the open air in this country. The second crop is produced in the axils of the leaves of the growing shoots, and seldom ripen well in the open air through want of heat. These are those you speak of; they are too late to ripen this season, and are of no use for the next.

FRUIT SHOWING : *Y. Pearce*. We cannot possibly decide the question you raise. A good Queen Pine, weighing 3 lb. 5 oz., in an amateur's collection of eight dishes should have had some influence on the award; but you admit that your opponent's Grapes were better than yours, and you say nothing of the rest of the collection. In default of further information, we can only suppose that the judges knew what they were doing.

FRUIT TREES BARKED BY RABBITS : *Charles Asprey*. The best thing you can do to save your trees which have had the bark eaten off the stems, is to first give the stems a good coating of clay or soil and bind them round with thick bagbands as far up as the broken bark extends. This will encourage the formation of young bark. Do this at once, and keep the bands moist.

FUNGUS ON GRAPES : *H. Munro*. There are two common moulds on your Grapes, Penicillium glaucum and Polyactis vulgaris, neither of which is the cause of mischief. Your Grapes are probably spotted, or, as it is commonly called, scalded; and the moulds are developed on the affected spots. *W. J. B.*

FUNGUS ON WILLOW LEAVES : *H. Munro*. Your Fungus on Willow leaves is Lecythea epitea. *M. J. B.*

GOSSYPIUM BARBADENSE : *C. P., Manchester*. Yes.

Reply to No. 2 next week.

HEATING A SMALL GREENHOUSE : *J. H.* Trotman's gas stove will answer your requirements.

INSECTS : *G. Y.* Give repeated syringings with Gishurst Compound, washing the plants alternately with clean water. Use the syringe vigorously. Of course you can do little with plants in flower, and must wait for the resting period.

KEEPING GRAPES : *S. E.* See p. 1282 of our last year's volume.

MUSCAT GRAPE : *A. O.* Very seldom have we seen a more deplorable example of Grapes than those sent by you—diseased, shrivelled, and dirty to a degree bordering case of neglect and mismanagement. The border being not drained is probably the cause of one evil, viz., the shanking of the stalks, combined with over-cropping. The dirtiness is caused through syringing them with dirty water, and rust through cold draughts of air, &c. Purchase and study "Thomson's Practical Treatise on the Vine," which will enable you to grow good Grapes.

MELONS : *C. D.* On examining your Melon branch under the microscope we find that you have been using flowers of sulphur, mixed with the globose particles of which we find abundant spores like those of a Gleosporium. Specimens, however, are not sufficiently in a sufficiently good condition to say to what species they can be referred. It is curious that this genus seems to be doing mischief everywhere, and unfortunately we know of no remedy. *W. G. S. & J. B.*

MUSHROOM : *A. Boyle, Whitland*, writes :—"I have this morning found a Mushroom, Agaricus campestris, of what appears to me very uncommon dimensions—weight, 4 lbs., circumference, 2 feet 6 inches. It was perfectly bright, and salmon-coloured in the gills, so must have been the production of one, or at most two, nights."

NAMES OF FRUITS : *J. S.* The Apple named Golden Court of Wick is simply the true Court of Wick, not Golden Wick, as stated at p. 1235.

NAMES OF PLANTS : *Fair Play*. Rhus Cotinus, the Wig plant; *D. Coyle, Loughlin Lodge, Ayster*. Impossible to say; smashed in the post.—*J. Bartlett*. You have sent more than we profess to name at once :—1. Asplenium marinum; 2. Lastrea Filix-mas; 3. Scolopendrium vulgare monstrosum; 4. Adiantum pubescens; 5. Polypodium vulgare cambricum; 6. Polystichum angulare proliferum; 7. insufficient; 8. Doodia media; 9. Lastrea Filix-mas cristata angustata; 10. Polystichum angulare cristatum; 11. Polypodium vulgare; 12. Cystopteris fragilis dentata; 13. Cystopteris fragilis.—*A. B. C.* Cephalotaxus drupacea. *A. M.—J. D. & S.* We must decline to attempt to name Willows from their leaves only. *F. A.* 1. Adiantum trapeziforme; 3. Polystichum aculeatum. *Old Subscriber*. Saponaria officinalis.—*C. D.* 1. Sempervivum aizoides variegatum; 2. Œnothera riparia; 3. Francoa ramosa. *Mrs. C.* 1. Lastrea glabra; probably 2. Rhodochiton volubile; 3. Aspidium trifolium; 4. Adiantum trapeziforme, var. pentadactylon.—*H. Mills*. Polystichum angulare—probably not permanent.

PEACH TREES DYING : *One in Trouble*. We have carefully read your statement with regard to the condition of your Peach trees, &c., and have examined the shoots, portions of root, soil, water, &c., sent. The water contains a considerable amount of lime, as what is termed "hard" water. Such water may, as you say, be injurious to Azaleas, and is certainly not by any means so good as rainwater, yet we cannot subscribe to its use the failure of your trees. The soil is heavy, more clayey than we should prefer to use, but we have seen Peach trees do well in soil of a similar nature. The roots are tolerably healthy, but a good deal of lime adhering to them. The shoots were weak and very badly ripened. It is very likely that your border may have become soddened, but more through the quantity than the quality of the water used. Is the drainage perfect? Being in the condition they are, it would no doubt be beneficial to take them up and replant in fresh soil. Lastly, you state that the trees are planted against a brick wall, and there is a Vine every 6 feet in front overshadowing them. Now if these Vines are allowed to make any shoots at all, they must almost completely shade the Peach trees, and Peach trees will never succeed well under the shade of Vines. Peach trees require the freest exposure to the direct influence of the sun to ripen the shoots thoroughly. It is here, we take it, that the great cause of your failure has arisen.

PEACHES : *J. W. B.* There is no difficulty in raising Peach trees from Peach stones. Plant them now: they will grow up in due course. You should read Mr. Kingsley's book on Peach culture.

POTATO AND ARTICHOKE GRAFTING : *T. S.* As we quoted your statement wrongly, we insert your correction : "The tubers were said to have resulted from the grafting the Artichoke into the Fluke, and the White Regent into the Artichoke; the produce being both round and kidney-shaped tubers." You have now made your statement and shown your specimens, and if you have failed to convince the committee, the fault is not ours. For our own parts we think you are labouring

under a very great fallacy, and we must decline to insert any further communication on the subject.

PRICE OF SEEDLING FRUIT TREES: *X. Y. Z.* Not being dealers in novelties among fruits, we really cannot answer your question. Apply to some respectable firm, and you will get the answer you want.

THE NEW VINE DISEASE: *Richard Shore.* A large reward, something like 40,000 £., is offered by the French Government for a certain cure for the Phylloxera. Under these circumstances communications will naturally be sent to head quarters should any really valuable information be obtained. *M. T. B.*

THE KEEPING OF A GARDEN: *K. S.* We are not aware that, in replying to your questions on this subject in our last issue, we at all "pooh-poohed" your suggestion—on the contrary; we are glad, however, to have your disclaimer, and to be informed that you are well "posted up." We may say that we agree in the main with your remarks, if not with the spirit. Employers do want a great deal done, and "for the least possible cost;" and quite right too: that is, simple value for value. We repeat our observation again, that "there is a deal in method and management"—the management of your difficulties, if you will,—the making of much out of little. What makes one man a better gangger over a lot of labourers than others?

VINE CULTURE: *Vitis.* We are always willing to assist, yet we can scarcely enter into the details of Vine culture, which would take up many pages of the paper to make ourselves intelligible to you. It is a subject which is in itself a liberal education, and constant study, and every week in the Calendar of Operations, so that we can but refer you to our pages, or to consult any of the cheap and extremely practical treatises on the Vine, which can be procured usually at one or two shillings.*

For a small viney, such as yours, we would not recommend you to raise the border more than 12 or 15 inches above the surrounding level; make it about 2½ feet deep, and drain it well. Plant the Vines outside. Soil good turfy loam, with the addition of about a bushel of ground bones to a cubic yard of soil, and a mixture of bricks and lime rubbish, to give it porosity. Treat them as liberally as you would if they were the first year or two. To allow of plants growing underneath, the Vines should not be planted at less than 6 feet apart. Azaleas and Camellias will do very well in the shade of Vines. The best sorts of Vines for that use plant, are the Black Hamburgh and Royal Muscadine,

WASP TRAP: *A. B.* Your letter was mislaid. The dimensions are as follows:—Height, 12 inches; diameter, 4½ inches. Length of horn, 4 inches; diameter of large end of ditto, 1½ inch; small end, ½ inch. The collar is merely a fold of the tin horn, contrived to prevent it slipping into the bottle. They may be had of various sizes.

COMMUNICATIONS RECEIVED:—J. M. B. P.—J. T.—J. C. A. R.—J. E.—G. L.—T. C. B.—W. H. S.—E. H.—W. A. M. —T. S.—R. & J. P.—H.—H. N. Ellacombe.—G.—Q. R. —Old Sub.—J. C.—Subscriber, Leek.—S. R.—T. W.

Markets.

COVENT GARDEN.—Sept. 29.

The home markets are unusually dull, but large quantities of goods are being sent to the northern ones, such as Plums, Apples, and French Pears, of which we are now receiving very large supplies. Rough produce in vegetables is about sufficient for the demand, and hothouse Grapes, Peaches, and Nectarines remain at last week's quotations.

FRUIT.

	s. d.	s. d.
Apples, per ½ sieve	2 0 to 4 0	
Cobs, per lb.	0 6 — 1 0	
Figs ..	0 6 — 1 0	
Filberts, per lb.	0 6 — 1 0	
Grapes, per lb.	1 6 — 5 0	
Lemons, per 100	8 0 — 12 0	

VEGETABLES.

	s. d.	s. d.
Artichokes, per doz.	4 0 to 6 0	
Beet, per doz.	1 0 — 2 0	
Brussels Sprouts, p. half sieve ..	3 0 — 3 6	
Cabbages, p. doz. ..	3 0 — 3 6	
Capsicums, p. 100 ..	1 6 — 2 0	
Carrots, p. bunch ..	0 6 — 0 8	
Cauliflowers, p. doz.	2 0 — 3 0	
Celery, red, p. bun.	1 6 — 2 0	
white, do. ..	1 0 — 1 6	
Chilies, per 100 ..	1 0 — 2 0	
Cucumbers, each ..	0 6 — 1 0	
Endive, p. doz. ..	1 0 — 1 6	
French Beans, p. lb.	0 4 — 0 6	
Herbs, per bunch ..	0 2 — 0 4	
Potatos (good samples), New Round, 5*s.* to 6*s.*; Kidneys, 5*s.* to 7*s.* per cwt.		
Melons, each ..	2 0 to 5 0	
Nectarines, per doz.	4 0 — 8 0	
Oranges, per doz.	2 0 — 3 0	
Peaches, per doz.	2 0 — 8 0	
Pears, per dozen ..	2 0 — 4 0	
Pine-apples, per lb.	2 6 — 6 0	
Horse Radish, p. bun.	3 0 to 5 0	
Leeks, per bunch ..	0 2 — 0 4	
Lettuces, per score ..	2 — 3 0	
Mushrooms, p. pott.	1 0 — 2 6	
Onions, per bunch ..	0 4 — 0 6	
Parsley, p. bunch ..	0 2 — 0 4	
Peas, per quart ..	1 0 — 1 0

Shallots, per lb. ..	0 8 — ..	
Spinach, perbushel	2 6 — 3 0	
Tomatos, p. lb. ..	0 3 — 0 6	
Turnips, p. bunch ..	0 4 — 0 6	
Vegetable Marrows, per doz. ..	1 0 — 2 0	

WANT PLACES,—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen, on application. Lists given on application to Messrs. HENDERSON and SON, Wellington Nursery, St. John's Wood, N.W.

To Gardeners and Bailiffs (Head, Foremen, or Under).

JAMES CARTER AND CO. having many applications for first-class Gardeners that those WANTING SITUATIONS will send NAME, ADDRESS, and COPIES of TESTIMONIALS, for ENTRY in their FREE REGISTER, by which means they can attend to unquestionable references need apply.

Any Lady or Gentleman requiring GARDENERS or BAILIFFS may rely upon having them sent to CO. adopting the most strongest regulations in reference to testimonials as to ability, honesty, &c.

JAMES CARTER AND CO., Nurserymen, &c., W.C.

GARDENER (Head), age 32.—F. CLARKE, Gardener to the Dowager Lady Knatchbull, Provender, Faversham, Kent, is open to engage with any Lady or Gentleman requiring the services of a good Gardener. F. C. can produce good references as to abilities, and satisfactory reasons for leaving.

GARDENER (Head), age 32, single.—Mr. CARLTON, Gardener to the Hon. Mrs. Howard, Ashtead Park, Epsom, Surrey, can with confidence recommend his Foreman as a thorough practical, energetic Man, having been Foreman 10 years in five first-class establishments, where every description of Gardening is carried out in the most efficient manner. No Single-handed place accepted. Character will bear the strictest investigation.—Address as above.

GARDENER (Head).—Age 37, married, no incumbrance; well skilled in all branches of the profession. Good reference.—C. M., 3, Standard Road, Bexley Heath, Kent, S.E.

GARDENER (Head).—Age 29, married, one child; would like an engagement either in Lancashire or Cheshire. Satisfactory character as to ability and integrity.—A. B. A., 3, Chapple Street, Liverpool.

GARDENER (Head).—Age 33, single; thoroughly acquainted with Gardening in all its branches. Has lived in some of the best places in England and Scotland.—A. B., Clapton Nursery, Upper Clapton, London, E.

GARDENER (Head).—Has had many years' experience in Fruit, Flower, and Kitchen Gardening, both in England and on the Continent, and is bearer of the most satisfactory testimonials.—J. S., Wellington Hill, Leeds Road, Bradford.

GARDENER (Head).—Thoroughly understands the Forcing of Fruits, Flowers, and Vegetables, and could Manage Land and Stock if required. Good recommendation.—T. BALCOMBE, The Lawn, Whitchurch, Hants.

GARDENER (Head).—A Scotchman, who has a first-rate knowledge of the profession in all its branches. First-class testimonials from last and former employers.—J. S., 9, Blythe Hill Terrace, Lee, S.E.

GARDENER (Head).—Married; understands Early and Late Vineries, Greenhouse, Kitchen Gardening, and every other branch of the profession. Six years' character.—C. S., Sydmonton, Newbury, Berks.

GARDENER (Head).—Age 32, married; thoroughly practical. Has had great experience in Growing and Forcing Stove and Greenhouse Plants, including Orchids, Ferns, the Forcing of all sorts of Fruit and Vegetables, keeping the Conservatory gay all the year round, and the Laying Down Gardens of Fruit, Flower, and Kitchen Gardens, and all the requirements of a Gentleman's establishment. Testimonials of the highest order, and reference to late employer.—J. D., 4, New Street, St. John's Wood, London, N.W.

To Noblemen and Gentlemen.

GARDENER (Head).—Has had much experience in the Propagation and Cultivation of Hardy and Exotic Plants, Early and Late Forcing of Vegetables, Planting and Flower Garden Ornamentation, and the usual requirements of a large establishment. Can Manage Home Farm. Garden Formation and Alteration, Draining, Ornamental Planting, Road-making, and Land Improvement preferred. Satisfactory reference.—Foreman, 2, Five and a-half years with a Nobleman.—HORTUS, Lilac Cottage, York Street, Harbourne, Staffordshire.

GARDENER (Head), where two or more are kept. —Age 29; can Lay-out new grounds, also understands Vines, Fines, Early and Late Forcing, and Grass Land and Stock. —J. H., The Gardens, Ingestre, Stafford.

GARDENER.—Age 24, single; thoroughly understands all classes of Plants, Forcing, and Fruit, Flower, and Kitchen Gardening; best references.—B., Gloucester Villa, St. James' Road, Tunbridge Wells.

GARDENER.—A LADY will have pleasure in recommending a Scotch Gardener to any Gentleman requiring a first-rate Man, who is competent to take charge of a first-class establishment.—Apply by letter to VERITAS, 1, Cobden Terrace, Canterbury Road, Forest Hill, S.E.

GARDENER (under a Foreman), in a Nobleman's or a Gentleman's Garden.—Age 21; five years' good character.—A. C., 19, Potter Row, Somerleyton, Lowestoft, Suffolk.

GARDENER (UNDER).—Seven years' good character. —B., 19, Bridge End, Warwick.

GARDENER (UNDER), in a Nobleman's or Gentleman's Establishment.—A Steady, respectable young Man, with good character.—A. B., 5, St. John's Cottages, Penge, Surrey.

GARDENER (UNDER).—A LADY wishes to recommend a Scotch Gardener for a Single-handed place.—G. B., Bearhurst, Dorking.

FOREMAN, in Fruit and Seed Trade.—Age 25; ten years' experience.—T. H. S., Post Office, King Street, Covent Garden, W.C.

PROPAGATOR (GENERAL), or GROWER for Market.—Age 26, single; good Salesman.—For particulars, apply to T., Jones' Rents Nurseries, Ashley Road, Bayswater.

PROPAGATOR and GROWER of Soft-wooded Plants. Nine years' reference in the London Trade.—A. B., 13, Hill Street, Dalston, N.W.

JOURNEYMAN, under a good Gardener, where he could further improve himself in the Houses.—Age 20; three years' experience in good gardens, with a little knowledge of Nursery Work. Excellent character.—J. M. MCRAE, Mrs. Tyson's, White Lodge, Upper Norwood, Surrey, S.E.

IMPROVER, in a Gentleman's Garden.—Age 18; four years' experience. No objection to pay a small Premium. Good character from present employer.—E. J., The Gardens, Pitchford Hall, Shrewsbury.

NURSERY MANAGER.—Upwards of 20 years' practical experience in first-class Nurseries, both in Scotland and England. Thorough knowledge of the value of Stock, the Propagation of Conifers, Roses, Rhododendrons, Evergreen and Deciduous Trees and Shrubs, and Greenhouse Plants, &c. First-class recommendations.—A. B., Downie, Laird & Laing, Forest Hill, S.E.

ESTATE AGENCY, &c.—Age 29; has had 14 years' practical experience on some of the largest Estates in the country; thoroughly understands the Value and Management of Timber, Game, Fisheries, Roses, Rhododendrons, Evergreen and Deciduous Trees and Shrubs; also all kinds of Estate Work, including Fencing, Draining, Levelling, Land Surveying, Preparing Plans, Specifications and Estimates for Sale of Land, &c. Salary moderate. Best References to present employer.—J. H., Mr. Dennis, White Horse Hotel, Guildford.

To Noblemen and Gentlemen.

STEWARD or BAILIFF.—Has had extensive practical experience in the Management of Stock; and being thoroughly acquainted with the various duties required on a Home Farm and Estate, Woods, and Repairs, desires a re-engagement as above. Good Accountant and Salesman of Stock and Crops, and would be found thoroughly useful in carrying out Plans of a Steward. Twelve months' unexceptionable references will be given. —A. B., Mr. J. Burgiss Browne, *Advertiser* Office, Andover.

To the Seed Trade.

TRAVELLER.—Age 27; highest references.—J. P., *Gardeners' Chronicle* Office, W.C.

To the Trade.

TRAVELLER.—An energetic young Man, well up in the Nursery Business. Excellent character. ALPHA, Post Office, Handsworth, Sheffield.

SHOPMAN, SHOPMAN and CLERK, Warehouse Porter, Storeman, Orange Country Shop or Branch.—Age 35; married: 18 years' experience in the Trade. Highest testimonials.—T. W. E., Messrs. Thos. Gibbs & Co., corner of Half-moon Street, Piccadilly, W.

SHOPMAN, or ASSISTANT.—Age 31; has a thorough knowledge of the Seed Trade, Bulbs, Plants, &c.—H. S., Mr. May, 39, Bevington Street, Covent Garden, W.C.

ASSISTANT, in Seed Trade.—Age 24; five years' experience.—X. Y. Z., 37, James' Street, Covent Garden, W.C.

GOVERNESS.—A young Lady, accustomed to tuition, and who has resided some time in France, is desirous of obtaining a situation as above. Good references will be given and are expected.—M., 41, Wellington Street, Covent Garden, W.C.

PAGE BOY, and to make himself generally useful, out-of-doors.—Age 14; unexceptionable references.—J. R. CUNDELL, Esq., Southwold, Suffolk.

The Agricultural Gazette.

SATURDAY, SEPTEMBER 30, 1871.

THE great increase of PAUPERISM which took place during the 16th century was the first appearance of an unwelcome phenomenon, with which we have become too familiar. As a matter of course we find nothing in history to compare with the colossal amounts now expended in the relief of the poor in England and Wales, *i. e.*, between seven and a half and eight millions of pounds in each of the last three years, and from five and a half to something less than six millions in the corresponding years of the last decade.

In the year 1601, when the first of a long succession of Acts of Parliament relating to the relief of the poor (43 Eliz.) was passed, the population of England is supposed to have been about 5,000,000. The recent census shows us that it has more than quadrupled. Neither the great statesmen nor the subjects of Queen ELIZABETH were accustomed to the large sums in social arithmetic with which modern society has to deal, and in that respect there is no parallel between the past and the present, but in other respects there is a close analogy between the pauperism of the two periods; and history undoubtedly supplies the key by which we can read and understand what is passing under our eyes.

At the breaking up of the feudal system the bond-labourers of the great barons became free labourers. Previously the poor had enjoyed few of the pleasures of liberty, and they had suffered none of its pains—they had always been certain of food. It is a natural condition of freedom that people must shift for themselves, and it is better for them to do so at some risk than to subsist on bounty as serfs, fed like animals at a master's trough. The desire of men to improve their condition is the germ of many social virtues, and of much that is excellent in the human character. But the sudden creation of a large class of independent poor was an evil for which there was no remedy. It was the signal for the appearance of a new order of society, the "sturdy vagabonds" and "valiant beggars," who were to figure so considerably in the statutes of the ensuing period. The earlier Acts were comparatively mild. They enacted that loiterers, wanderers, beggars, and idlers, when caught, should be put in the stocks for three days, "there to remain with no other sustenance than bread and water." If caught again, after having been commanded to avoid the neighbourhood, they were to be put in the stocks for six days, with "like diet as is before rehearsed."

The dissolution of the monasteries at a time when the church lands embraced one-sixth of the real property of the kingdom involved 50,000 persons in utter ruin, and this so recruited the ranks of vagrants and beggars that the Parliament of HENRY the Eighth's successor proceeded to pass a barbarous law to repress "vagabundrye and idleness." Any person "living idly and loiteringly" was to be branded with a hot iron with the letter "V," and adjudged to be the slave, for two years, of the person who brought him to justice. If he ran away he was to be branded a second time and enslaved for live, and if he ran away a second time he was to be a felon and "to suffer pains of death." Any person helping the slave to remove his iron ring to forfeit £10. So much for contemporary wisdom and appreciation of the causes and possible remedies of the increasing pauperism of that day.

Our ancestors persevered in their attempts to exorcise the demon that had appeared among them. For 200 years the most industrious people in the world were convinced that "idleness and otiosity" were the besetting sins of the nation. In DEFOE's "Giving Alms no Charity," one of the first tracts and pamphlets on this subject in the last century, it is maintained that, though "we are burdened with a crowd of clamouring unemployed, unprovided-for poor people," yet "there is more than hands enough." The real causes of poverty in England were casualty and luxury, sloth and pride. "Good husbandry (economy) is no English virtue," we are told; it may thrive here and there, but it is against "the natural temper and genius of the nation," who, "generally speaking, cannot save their money." "The profuse extravagant humour of our poor people in eating and drinking keeps them poor." "An Englishman loves to get his pocket full of money, and then go and be idle, or perhaps drunk, till all be gone." "We are the most lazy, diligent nation in the world," and an Act of Parliament is needed "to cure the sloth and luxury of our poor; make drunkards take care of wife and children, spendthrifts lay up for a wet day; idle, lazy fellows diligent; and thoughtless, sottish men careful."

This estimate of the power and province of legislation was followed by an Act which Mr. MCCULLOCH has described as a bulwark for half a century against the progress of factitious pauperism. This was the famous Act of 1723, which enabled parishes to unite for building workhouses, and gave them the privilege of refusing relief except in a workhouse, an alternative which was regarded with great and natural aversion, as it is now. A growing trade and a cycle of good harvests aided the new law, and the period which followed will always be remarkable as an era of singular prosperity. The amount raised for the relief of the poor in England and Wales in the middle of the century did not exceed an average of £750,000, which was considerably less than it had been 50 years previously.

But even Parliaments do not always let well enough alone. After the American war, and before the Revolutionary war with France, when the poor's rate was still moderate, the salutary law of 1723 was abandoned, and in 1782 GILBERT's Act provided that work should be found for able-bodied paupers at or near their own homes, and thus an active Member of Parliament succeeded in removing the checks to idleness and impostures, and in obtaining the adoption of one of the most mischievous schemes that could have been devised.

A time of trial soon came, and for many years the poor were subjected to influences calculated to destroy their self-respect and independence. At one time, when wages were partly paid out of the rates, almost every agricultural labourer in the country became a pauper, and as they were paid according to the number of children, without regard to skill, conduct, or actual earnings, imprudence, improvidence, and idleness were directly encouraged. The mischief was widespread, for war and adverse seasons crippled the resources of the country, and occasioned a rapid increase in the amount levied for the poor, till, in 1814, 1815, and 1816, it exceeded £6,000,000 a-year, and in 1817 it reached £7,870,800—Wheat being 94*s.* 9*d.* per qr. The Act of 1834, which established the existing system of administration of Poor-laws, may be said broadly to have corrected old errors and grievances, and to have effectually cleared the ground for the consideration of the causes and preventives of pauperism.

The progress and prosperity of the country, in recent times, may be marked by the following figures. From 1811 to 1834, the sums raised for poor's-rates ranged from £7,800,000 to £4,500,000, decreasing gradually; from 1834 to 1847, the amounts were from £4,000,000 to £5,500,000. The cost of the rates, per head of the population of England and Wales, which had been about 2*s.* 6*d.* per head in the middle of the 18th century, was for the following decades:—1801, 9*s.* 1*d.*; 1811, 13*s.* 1*d.*; 1821, 10*s.* 7*d.*; 1831 9*s.* 9*d.*; 1841, 6*s.* Since 1841 there was, until the last three years, a general reduction in the amount, with a regular but not extreme variation, the total ranging from 5*s.* to 6*s.*; subsequently there has been a marked rise of at least 20 per cent., the expenditure having been about 7*s.* per head in each year. The increasing pauperism of the present age has its root in the cities and trade, not in the agriculture of the country. The condition of the farm labourer has been continually progressing since the deplorable period just referred to; from 1800 to 1818 his wages were 11*s.* a week, which purchased two quarts less than a bushel of Wheat at the average price; but at the present time the wages in Kent, Sussex, and Surrey during last winter were from 12*s.* to 15*s.* Taking the lowest district and the lowest estimate of the year's earnings, the wages of day labour will be found now to purchase more than 2 bush. of Wheat per week. It may be noted that in the days of abundance in the last century the agricultural labourer was better off than he has been in any but the most recent years; from 1742 to 1752 his wages were 6*s.* per week, which at the average price of 30*s.* per quarter, purchased rather more than a bushel and a half of Wheat.

IN a recent number we drew attention to the supposition that a change was taking place in the climate of the prairie districts in the Far West of North America, in consequence of the settlements and attendant cultivation that were spreading over them. Taller herbaceous plants are said to be taking the place of the short grasses, imparting more shade to the soil, and a greater amount of rain is said now to fall, and a milder climate with less extremes appears to be the result.

It is premature to say that the amelioration in question is a reality to be referred to these causes; but, supposing it to be so, it suggests a solution for a difficult problem which has of late years occupied a considerable share of the attention of scientific men in Russia, viz., how the steppes in the south of that kingdom should be dealt with, so as at the same time to render them productive and improve the climate.

It is obvious that the barrenness of the Russian steppes has much in common with the treelessness of the American prairies. In neither is it due in the main to any defect or peculiarity in the soil. There are important and vast exceptions, but the soil of much of the steppes is the incredibly rich, deep Tschernosom, and the generality of the prairie soil, if not so exceptionally fertile, is at least of fair, if not of more than average excellence. The one thing wanted by both is water, and how to procure it is the problem. We see how it may be and is being obtained for North America, but something more is needed for the steppes. One very obvious recommendation is the gradual planting of much of the country, beginning near the rivers, where water could be obtained, by irrigation or otherwise, and gradually extending the plantations as, by their influence as a reservoir or sponge, they should enable further planting to be successfully carried on.

But this process is too slow for the Russians. They wish something more rapid in its action—something that will allow the present generation to profit by its operation—something not of a general character, but capable of individual application. We are afraid this will not be easy to find.

There is no royal road to any great success. Time, and much time, is required for every great work, and the alteration of the climate of a vast tract of country is no small one. But we have lately heard that a course of procedure analogous to the stirring of the soil of the prairies by the cultivation of new settlements has been tried with promising results. It consists in very deep trenching. The great difficulty, as we have seen, is want of water. That can only be procured either from the rivers, or from the clouds, or from the soil itself. Here the rivers are distant, and from the dead level of the country irrigation is difficult and expensive. The clouds, from want of mountains or forests, give no rain for long periods. In some districts a year or more occasionally passes without a shower refreshing the earth, and very generally not a drop falls in the whole country from the end of May to the middle of September. It rains no doubt in spring and autumn, and snows in winter, but the country is so uniformly level, and what is of more importance, the subjacent strata are so uniformly level, never having been disturbed by geological causes, that there are no means by which the water which falls at these seasons can be accumulated and stored up in subterranean reservoirs or fissures (the existence of deep springs depending mainly on the inclination of strata produced by the dislocation of beds). The surface of the ground by long baking, too, is burned as hard as a clay floor, and what rain does fall, it lies on the surface of the ground, scarcely sinking at all until the warm season comes, when it is all evaporated.

By digging deep into the soil, however, and loosening it far down, the rain is allowed to sink and penetrate beyond the reach of evaporation, and so a reservoir is formed which can be reached by the roots of any trees that may be planted. This plan of planting after very deep trenching is said to be beginning to answer.

With such large supplies of water as the Black Sea and the Caspian in their immediate vicinity, and no great mountains intervening, there is no reason why the regions which are now a waste should not be a garden; were the ground even partially clothed with timber, the whole would be changed. There is no reservoir of moisture equal to a forest. It is a sponge which soaks up an enormous quantity of water, to render it back in perennial springs and streams. Moreover, forests not only receive rain and retain it when it falls, but they attract it. We read that already a few trees planted by the engineers employed in the excavation and construction of the Suez Canal, near their temporary residences, have had the effect of attracting clouds, and that the rare event of rain falling in the land of Egypt has already taken place in their vicinity. To do the same thing in the South of Russia is obviously the true means of utilising, fertilising, and rendering productive the vast steppes in question, and an extensive system of planting after deep trenching, combined with other means which have been suggested, may fairly be expected to supply them.

—— To effect sales of English Wheat on Monday in Mark Lane, a reduction of 1*s.* per qr. on the previous Monday's rates had to be submitted to. On Wednesday the tone of the Market was quiet, but there was no material variation in prices.—At the Metropolitan Cattle Market on Monday choice qualities of Beasts did not realise a change in prices, but a decrease could not be effected in Sheep, even at lower rates. On Thursday trade was dull, at lower prices for all kinds.

—— The following letter from Mr. CAIRD, on THE HARVEST of 1871, appeared in Wednesday's *Times*:—

"As, in my opinion, some serious misapprehension is entertained regarding the produce of last harvest, I venture to offer an estimate based on my own experience as a considerable grower of Wheat, and after a very extensive observation of the country immediately before and since the close of the harvest. The acreage given in the Agricultural Returns lately published, with the addition of the figures of 1870 for Ireland and the islands,

shows a total of 3,850,000 acres. Upon this, after deducting seed, I estimate the produce available for consumption at 11,000,000 qr.

"The annual consumption may now be taken at 22,000,000 qr., which would therefore show the imports required to be 11,000,000 qr. But, owing to the comparative lateness of this harvest, the probability is that not more than eleven and a half months' consumption will be needed to meet the harvest of 1872, so that the foreign supply required may thus be reduced to very little over 10,000,000 qr.

"I am disposed to think this a liberal estimate of our foreign requirements. During the last 10 years it has only once been exceeded. For 1867, which was the worst crop of the 10, and certainly inferior to that of the present year, the import of foreign Wheat within the harvest-year was 9,293,000 qr. It exceeded 10,000,000 only in 1870, and that after an average home crop, but with consumption no doubt stimulated by the low price of 40s., which was the average of the year ending June 30, 1870. The price is 10r. higher now, and if for the current year this should be maintained or exceeded, the consumption will thereby to a moderate extent be economised.

"The price must necessarily be more difficult to estimate than the quantity required, for it is largely dependent on the crops and requirements of other countries. To a certain extent it will also be affected by the quality of the Potato crop, which is likely to be seriously deficient. The Wheat crop of our nearest neighbour, France, is said to be very deficient; but as all other crops, and especially vegetable crops, in that country are very abundant, the effect of present circumstances must impose great economy, France is not likely this year to import much Wheat. Spain is said to have had a good Wheat harvest. With regard to the more remote sources of supply in Europe and America, there is not, so far as I have seen, any reason to apprehend deficiency, and it is certain that the prices at present ruling have, during the last 12 weeks, sufficed to bring so much supplier supplies than would, if continued at the same rate, be needed to carry us in safety to another harvest. The spring corn crops of all kinds are good, and they are twice the extent of the Wheat, while the grass and green crops for cattle are in general very abundant, so that, notwithstanding the deficiency in the Wheat and Potato crops, I feel very confident that the harvest of 1871 will, when taken altogether, be of full average value."

—— The following preliminary abstract of AGRICULTURAL RETURNS of GREAT BRITAIN for 1871 has been issued from the Statistical Department of the Board of Trade:—

Extent of Land in Great Britain under

	Wheat.	Barley.	Oats.	Potatos.	Hops.
1869 ..	3,768,357 ..	2,252,480 ..	3,782,720 ..	588,211 ..	61,296.

—— On Wednesday, at the meeting of the East Cheshire Agricultural Society, Lord VERNON thus referred to the RELATIONS of LANDLORD and TENANT:

"At Liverpool the other week, Lord DERBY, in speaking on the question of the tenure of land, stated as his opinion that any tenant who was good enough to be kept permanently should have a lease if he required it. That started the whole question of leases *v.* agreements. What was the test to be applied in order to ascertain whether a tenant was good enough to keep? Was the test to be one of skill? because if it was, a tenant, after entering on a farm, might have all his powers paralysed by ill-health. If it was one of capital, he might die after he had been in possession of his farm a certain time, and all his property might be divided amongst his wife and five, or six, or more children, who might be in distant parts of the world. Therefore, he could not think that either skill or capital, or the combination of both, was sufficient test to secure a landlord's interest in ascertaining whether a tenant was good enough to keep permanently. A man might be the very best tenant in the world at the commencement of his tenancy, but, also physical and moral causes, he might very shortly after entering upon his farm be very much deteriorated in his condition, and the landlord's interest would suffer in a manner which it was not very easy to estimate. As a landlord he had had to do with both systems of letting, and, speaking in the landlord's interest, he had not observed a greater disposition on the part of tenants under lease to improve their farms than on the part of those under agreements from year and in more than one case he had had to do with farms which had greatly suffered owing to the negligence of tenants who had held leases. In the case of a very large farm he had the command of the farm himself, and he found that it would have cost £500 or £600 to put them in order. He did not hesitate to say that the present mode of letting land was not as business-like as it might be. Every landlord had a perfect right to propose an agreement which appeared to him to be the best; but, at the same time, he believed that if the conditions of letting were more liberal than they were at present, the landlords' interest need not suffer at all. Were he a tenant, he would infinitely prefer entering a farm under an annual agreement, with proper compensation clauses, to the very best lease which had ever come under his notice.

—— The *Chamber of Agriculture Journal* of last week contains an elaborate COMPARISON of the CHARACTER of the HARVEST with that of the previous season during the past 26 years, of which the figures are taken from the past 26 years' returns of the *Agricultural Gazette*. Comparing the harvest, whether average, over average, or under average, with the average temperature and rainfall of the previous August, the previous July and August, the previous June and July, the previous June, July and August, the very laborious and industrious calculator arrives at the conclusion that "the thermometer and rain-gauge together, checked by modifying accidents in the condition of the

crop which are known before harvest arrives, constitute an infallible guide to the abundance or deficiency of the yield of Wheat in England, and that an estimate of the crop, based upon this test, and published in August or September, will not be disproved by the results of actual threshing in the autumn or the winter months." We quote the above Table, as giving the substance of the facts on which the conclusion is based.

—— At the late meeting of the SOUTH TYNE AGRICULTURAL SOCIETY, the silver cups offered by Mr. HENRY WALLACE and the Rev. HUGH BROWN for the greatest improvement by a proprietor or tenant in previously unreclaimed mountain land or hill pasture, made within the 10 preceding years, and in extent not less than 6 acres in one piece or plot, were awarded: 1st, to Mrs. WINTER, Low House; and 2d, to Mr. ROBT. WILLIAM BROWN, Unthank Hall. The following is the statement handed in by the judges (Messrs. T. WRIGHT and T. P. DODS):—

"The judges, in obedience to the instructions handed to them by the committee, visited and examined the whole of the reclaimed land entered in competition for the prizes, the number of competitors being 4. After a careful consideration of the schedules handed in by the competitors, together with the notes made by them in the course of their examination, the judges had no difficulty in singling out two of the competitors as standing out from the others, viz., Mrs. WINTER, of Low House; and the Rev. DIXON BROWN. After a full consideration of the situation, original quality of the land reclaimed, and the skill with the success of the reclamation they agreed to award to Mrs. WINTER, of Low House, the 1st prize, and to the Rev. DIXON BROWN, of Unthank Hall, the 2nd prize. The judges desire to call attention to the fact that the land to which they have awarded the 1st prize was previous to being reclaimed a piece of exceedingly poor, black-topped, heath, lying at a high elevation, and that by quarrying out the stones, ploughing up, liming, cropping twice with Turnips, and sowing away without any corn crop being taken from the land, a most excellent pasture has been obtained at a cost of about £9 per acre, the value of the Turnip crops and the first year's seeds being more than equal to the whole cost. The judges very highly commend the energy and industry of Mrs. WINTER's husband in so uninviting a piece of land, and also applaud the wisdom shown in so good an example to the landlords around in so energetically carrying forward the work of reclamation. They would suggest to him that he should in the portion of the land which he has yet to reclaim adopt the Turnip crop of Turnips by a second, and sow away without taking any corn crop. Where corn is taken from a first crop it will rarely pay seed and harvesting; and from many of the pieces which the judges visited a second crop was taken before anything except lime had been applied. Where corn is taken after Turnips it is very apt to hurt the seed by getting lodged, and the judges cannot but think that wherever corn is taken from wet moor land the pasturage is less or more damaged thereby. As the occupier of a small holding the judges highly commend Mr. BYWELL, of Barnstones, for the energy and success displayed by him in reclaiming his piece of common land. They also highly commend Mr. THOMAS LITTLE for the extensive fencing, draining, and liming done by him at Far House, Knarsdale. They commend Messrs. OLIVER & SNOWDON for the manner in which, by means of draining, liming, and feeding on the grass with cake, their heath at Lees Hall is to give an impetus to the work of reclamation, for which there is still abundant room, and from which the improvers have every reason to expect a fair return."

OUR LIVE STOCK.

CATTLE.

We blame the postal arrangements for the delay of our notice of the Panton House sale, which took place on Thursday, the 14th inst. The Messrs. Dudding have long been known as the possessors of animals not only of pedigree but of excellence, and they have been for many years successful exhibitors at our largest shows. The present sale of 84 head, comprising a considerable proportion of calves of the year, realised the very fair average of £48 3*s.* per head: 71 cows made £46 7*s.* each, and 11 bulls £59 15*s.* each, while the grand total amounted to £3948. The highest prices were given for VISCOUNTESS 3rd (10,934), 33 gs., Mr. J. C. Pickin; *Countess of Wraghy* by SIR ROGER (16,991)—(dam of *Countess of Yarborough*, the 2d prize Oxford heifer, sold for 350 gs., to go out to Canada),—56 gs., Mr. Adwick; *Judith's Joy* by PRINCE ALFRED (13,484), 61 gs., Mr. J. Currie; *Joy* by COLONEL COLLING (17,587), 80 gs., Mr. A. Denison; *Agility* by WOODRANGER (21,128), 61 gs., Mr. T. C. Booth; *Hawthorn Blossom* by LORD PANTON (22,204), 52 gs., Mr. P. Brown; *Fancy 14th* by ROYAL BUCKINGHAM (20,718), 51 gs., Earl Brownlow; *Nellie 24th* by COLONEL COLLING (17,587), 50 gs., Mr. Cruickshank; *Lady Bird* by ROYAL BUCKINGHAM (20,718), 81 gs., Mr. Yarborough; *Ruby Rose* by FEUDAL CHIEF (21,740), 87 gs., Mr. J. D. Lister; *Rosebud 2d* by RAVENSHOPE (22,681), 50 gs., Mr. Taylor; *Amelia* by RAVENSWOOD (22,682), 51 gs., Capt. Pratt; *Ruth* by RAVENSWOOD, 52 gs., Earl Brownlow; *Venetia*, by do., 85 gs., Mr. Yarborough; *Heber 77th*, by do., 42 gs., Mr. Cruickshank; *Prize Flower*, by do., 51 gs., Captain Pratt; *Fancy 18th*, by do., 70 gs., Mr. J. Bentlie; *Summer Flower*, by do., 86 gs., Mr. G. Bland; *Amelia 3d*, by do., 62 gs., Capt. Pratt; *Virginia*, by do., 95 gs., Capt. Pratt; *Attraction* by ROBIN (24,968), 70 gs., Mr. T. Pears; *Royal Bridesmaid* by ROBIN, 51 gs., Mr. Knapton; *Pretty Maid* by ROBIN, 51 gs., Mr. Denison; *Lady Grace*, by do., 81 gs., Mr. J. Slatter. In the bull sale, STANDARD BEARER by RAVENSWOOD was sold to Captain Pratt for 81 gs.; BRITISH FLAG by ROBIN sold at 155 gs. to Captain Pratt; LORD HAWTHORN by ROBIN became Mr. H. Minter's property at 51 gs.; ADJUTANT by ROBIN, was sold at 87 gs. to Mr. J. R. Ealand; and FANCY STUART by THE STUART (27,650) was secured at 50 gs. by Mr. W. J. Gilliat.

—— The fourth biennial sale at Brailes House, on Thursday, the 21st inst., conducted by Mr. Strafford, resulted in a general average of £91 18*s.* 7*d.* over 38 head: an average of £112 9*s.* 5*d.* over 26 females,

and of £47 8s. 6d. over 12 bulls. The grand total was £3493 7s. The accompanying price list will show that some high prices were given, the demand being principally for animals of the *Lally* by EARL OF DERBY (10,177), "Chinchilla," or "Furbelow," and *Asia* by GRAND DUKE 2D tribes. The Darlington cow by DUKE OF GENEVA (19,614), some descendants of *Lallis* by CALIPH, *Polydora* by EARL OF DUBLIN, and *Cathleen* by CALIPH, also sold well :—

—— On Tuesday, October 3, Mr. Thornton will sell Mr. W. Angerstein's pure-bred Shorthorns at Ashby Lodge, near Rugby. The herd comprises between 30 and 40 head of cattle from the Studley Park and other good Booth stocks, as well as several heifers descended from the Kingscote herd.

—— Mr. Thornton announces the sale of the Lillingstone Dayrell Shorthorn stock for October 4. The stock comprises 40 to 50 head of bulls, cows, and heifers, about half of which are of the much-admired "Seraphina" tribe; the others being of the "Buttercup" and "Duchess" families, carefully bred for the last 40 years, and latterly crossed with Bates bulls.

AGRICULTURAL REFORM.

[The following correspondence has appeared in the *Times* since Mr. Mechi's letter, given in our columns last week.]

IN the letter which appeared in the *Times* of yesterday from my good friend Mr. Mechi, several important topics are touched upon, on one of which I entirely agree with him—viz., that our land laws and land tenure should be adapted to the altered conditions of the country brought about by our accumulated wealth, our increased population, and the introduction of costly machinery, and greater capital in farm operations. The course, however, which Mr. Mechi recommends to the country—in the breaking up of grass land, the growing of Wheat after Wheat, in adopting the example set by Mr. Prout, in Hertfordshire—is one which I think few men will endorse who have considered what is involved in the whole question.

The increase in our home supply of Wheat is undoubtedly an important one, but by the side of the question of an increased supply of meat, as I showed in my little work on "Continental Farming," it is really an insignificant one. We can draw our supplies of corn from the ends of the earth. England, indeed, has become, under free trade, the great granary for the surplus grain of all other countries, but the area from which we can draw our supplies of animal food is at present limited very nearly to the countries near to our own shores.

Mr. Mechi informs us that he has grown this year 42 bush. of Rivett Wheat (the coarsest kind) on the same land which last year produced 48 bush. of white Wheat.

Now, in addition to such a practice being unsound in principle and opposed to the scientific rotation of crops, what has been gained? By growing Wheat after Wheat, Mr. Mechi has simply sacrificed that portion of his root crop. Had the land been sown with a restorative crop—for instance, Mangel—the result, judging by the statements given of the Tiptree crops, would probably have been a produce of some 30 or 40 tons of roots per acre. These would have furnished food for a large number of bullocks and sheep, a ton of Mangel producing some 18 lb. of beef or mutton. Were any considerable number of farmers to pursue the course recommended by Mr. Mechi, the result would be a considerable increase in the already high price of meat, while the influence upon the Wheat market for the increase in our home Wheat crop would be infinitesimal. Suppose the country were to adopt the system of Mr. Prout, who, I believe, crops the whole of his land every year, and, being near London, sells off the whole of his produce, straw included, few or no animals being kept upon the farm. Why meat, under such a course, would very soon be at famine prices; and, as Mr. Prout's system requires very little labour (scarcely any in winter), the poor would soon lack employment. I think, further, that Mr. Mechi's advice as to ploughing up poor grass land is equally unsound. I should say—top and improve it. No land sooner yields to remedial measures and generous treatment than pasture. Some ten years ago my farm manager strongly urged me to break up a piece of poor grass. I objected, and instructed him to drain it, to harrow it well two or three times a year, and to give it to animals kept upon Mangel, corn, or cake, &c. This field is now as nice a piece of pasture as any in the neighbourhood. Again, every practical man knows that, to breed successfully, a certain proportion of permanent pasture is necessary, if not indispensable, and that more stock can be raised upon three acres of laying some 20 per cent. of grass land than on farms exclusively arable. With our ever-increasing population, the people are to be fed, more animals must be bred. The prices of store stock are so enormously high, that many farmers are actually deterred at the present time from buying stock to fatten during the winter, for fear of increasing their money again, and yet Mr. Mechi recommends a course which would infallibly lead to a diminution of our live stock. I can only account for the erroneous notions my friend has put forward, by supposing that he has always pursued the plan of "buying in" instead of breeding his cattle at home.

Mr. Mechi has recommended others "to watch the signs of the times," but the reports he quotes of Mr. Sanderson and Mr. Scott appear to have, for the time, obscured his own, usually, clear vision. *James Howard, September 21.*

I am glad to see in the columns of the *Times* of the 23d inst. the lively ebullition of my good friends in favour of a more abundant production of meat; for that has been, all along, the key-note of my practice, as these gentlemen must have seen or heard had they read my book, or noticed on my farm.

More fat meat to produce more manure, and more Wheat, has ever been my motto, for my annual production of meat for every acre of my farm has been fully £5 per acre, in addition to nearly £6 10*s.* per acre of corn, hay, &c., sent to market and sold for money. The average produce of the kingdom per acre is, according to the best English and foreign statisticians,* only £3 15*s.*; so that mine is more than three times that amount. In round numbers, the farmed area of the United Kingdom, 45,000,000 acres, at my average of £11 10*s.* per acre, would give £508,750,000; whilst by the rate at £3 15*s.*, £168,750,000; balance in favour of my practice, £348,650,000.

These are not imaginative figures, but based on actual facts.†

I have reason to believe that our 22,500,000 acres of pasture only make a miserable return of about 45*s.* to 50*s.* per acre of produce. Break them up, cultivate and manure them well, and they would much more than double the yield, and, concurrently, employ more than double the labour and capital. I could give ample evidence on this point, but your readers need only refer to the pages of Morton on Soils, and Mr. Woodward's case, vol. 9, p. 54, Royal Agricultural Society's Journal, to be convinced that in England, and even in many parts of Ireland, the continuance of poor permanent pasture is a great national loss and mistake. My own opinion is decidedly in favour of keeping up the fertility of the soil by feeding animals mainly with cake and other produce not grown on the farm, as well as by some of the farm produce—thus making meat and growing Wheat concurrently, using, of course, much deeper cultivation than the ordinary 5-inch agricultural pie-crust.

I have reason to believe that our £3 per acre per annum of artificial manures, and very deep steam cultivation, and of course must be the best judge of what suits his own peculiar soil, but I prefer for many reasons the concurrent production of meat and Wheat.

Your correspondents are mistaken in supposing that I do not breed stock. My success in farming depends upon making a large quantity of meat, and consequent manure. Without this I could not make a profit. Although I grow so much Wheat and other corn, I make as much or more meat per acre as those who have grass land only.

I this year bred 120 lambs from 77 ewes. This is my usual practice, and I sell the lambs as fat mutton at one year old, price from 52*s.* to 63*s.*

For many years I reared 30 calves annually, and sold them as fat bullocks at two years old, price averaging about £22 to £25 each. I only changed my practice in this respect owing to the cattle plague, but I shall now resume it. It is a great mistake to suppose one cannot raise and fatten stock without pasture. There is no difficulty in doing this when you grow great crops of Tares, Clover, Rye-grass, roots, and corn, and purchase plenty of cake, and grow plenty of straw, the latter, especially bean-straw, when properly chaffed and prepared, and mixed with richer food, such as cake, corn, &c., renders us independent of hay. A crop of standing green Beans in July and August affords more food than any pasture, the crop being passed through the chaff-cutter. In some parts of Norfolk sheep are folded on green Beans.

By deeper cultivation and more abundant manure one acre may be probably made to produce as much root crop as two under the ordinary plan. *Y. J. Mechi, Tiptree Hall, Kelvedon, Essex, September 25.*

THE DERBY CHEESE FACTORY.

THE Derby factory, originally a cheesefactor's warehouse, is 60 feet long by 30 feet wide, and consists of three separate floors. It adjoins the Derby canal and Mr. Roe's timber-yard, the ground on one side being on a level with the first floor. The basement, being an excavation, insures an equable temperature, which is conducive to uniform quality in the cheese. A width of 6 feet on the east end, embracing the whole width of the building, was partitioned off and excavated to the depth of 4 feet, lined with blue bricks laid in cement, and converted into a whey cistern capable of holding 3500 gallons.

The evening's milk having arrived at the factory, it is weighed and run directly into the vats in the make-room, which has already been fully described in a former number of this journal.* When the morning milk has all been received, and run into vats along with that of the previous evening, the cold water is stopped, and by opening a tap in the bottom of the vat the whole of the water contained between the outer and inner vats is run off and steam turned on. The space immediately fills the space previously occupied by the water, and the temperature of the milk is raised from 82° to 86°, according to the natural temperature of the atmosphere —the lower in hot and the higher in cold weather. Every experienced cheesemaker knows that coagulation takes place much quicker when a milk is set at a high than at a low temperature. A most important point is to have the whole of the milk in the vat of one uniform temperature throughout. By closely covering the vat with a thick cloth, the loss of heat by evaporation is prevented. Inequality of temperature produces curd of different kinds, the greater heat causing the action of the rennet to be more decided, consequently the curd becomes tough. It is no uncommon occurrence to have one part of the curd in the same vat tough and the other part free and open; this difficulty will, however, be readily overcome, as the system of applying heat is capable of great improvement. When the milk in the vats has been raised to the desired temperature, the annatto is added, if colouring is used, and the whole mass well stirred. The quantity of annatto will depend on the shade desired: this once settled, the rest will be easy; the same quantity being always known, the colour can be regulated accordingly. The rennet is now put in and the milk again well stirred and the vat covered over, as before described. Good rennet will coagulate 1500 times its own weight of milk; its action is more rapid when the milk is slightly warm. When the milk is set the whole operation should be performed more quickly. The thicking process is accelerated with the increased temperature up to 120°; at 135° it becomes inoperative and loses its vitality. The quantity of the rennet causes more diversity in the taste and flavour of the cheese than anything else. In America filtration has been tried successfully. I have tried some experiments on a small scale: by passing the liquid through woodcharcoal, placed in a flannel bag, the active principle remains unimpaired. I think the adoption of some such simple means may lead to important results. Under ordinary circumstances the curd will be ready to cut in from 30 to 40 minutes after the rennet is added. In many English dairies the curd is still broken by hand, instead of being cut, as is now universally the case in all the American factories. The best time to perform this operation is when the curd has obtained sufficient consistency to break smooth, without whitening the whey and before it becomes tough. The cutting should be done as carefully and evenly as possible, with despatch, but with as little motion as may be. It is first cut into prisms from bottom to top;

* M. Léonce de Lavergne, in his valuable book, the "Rural Economy of England," published by Blackwood in 1855, and ably translated by Mr. Hope, has Scotch farming out of account, and gives the produce—England, £4 15*s.* per acre; Lowlands of Scotland, Ireland, and Wales, £1 17*s.* 6*d.*; Highlands of Scotland, 8*s.* 4*d.* His total agrees very nearly with mine, £164,000,000. He estimates the arreable produce of France at only half the above amount, although he considers their land as good as ours.

† Extract from my books, year ending December 31, 1870:—Wheat sold for money, £870 7*s.*; hay, &c., sold for money, £228 8*s.* 6*d.*; corn and hay of our own growth sold to live stock, £240 7*s.* 6*d.*; ditto to farm-horses, £146 12*s.* 6*d.*; meat made and sold, £759 5*s.* 9*d.*; wool sold, £11 18*s.* 6*d.*; poultry and eggs sold, £30 4*s.* 3*d.*; meat made in 1870, but not sold, £200.

* Journal Royal Agricultural Society, and Series, vol. vi., p. 519.

it is then cut parallel to the surface, dividing the prisms into cubes. The knives used for cutting the curd are of two kinds; in the one the blades are vertical, and in the other horizontal. In America there is considerable difference of opinion as to whether the curd should be cut into large or small pieces. Coarse curd invariably gives a greater quantity of cheese from a given quantity of milk, as less casein and buttery matter pass off in the whey during the process of making. The objection to coarse curd is its liability to produce open and uneven texture, and inferior flavour, from a portion of whey becoming hermetically sealed in the centre of large lumps of curd during the process of cooking, and thus setting up a fermentation, or an acidity, which greatly deteriorates the flavour. Fine curd insures a more perfect separation of the whey.

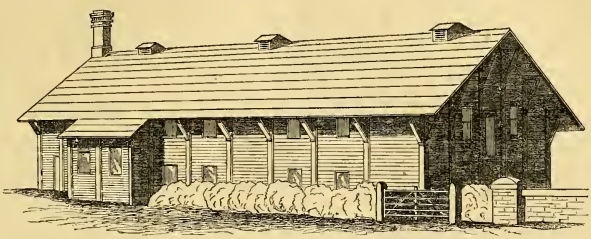

FIG. 284.—NORTH-EAST VIEW OF THE LONGFORD CHEESE FACTORY.

might be constructed that would show the exact acidity: such an instrument would be of great value in the hands of even the most experienced maker. The system of heating the milk in the vats, as is generally practised in America, and now in use in the Derbyshire factories, calls loudly for improvement. The great desideratum is to have the whole of the milk in the vat as near the same degree of temperature as possible. With the present arrangement this cannot be accomplished; but at a small additional outlay the difficulty can be overcome. In America what is claimed as an infallible test of acidity is the application of a hot iron to a lump of curd. The iron should only be searing hot; the whey is pressed with the hand from a piece of curd, which is held on the hot iron until it adheres, when the iron is pulled gently away from the curd: if the curd is raw it will break short away from the iron; as the acid becomes developed the curd will pull out into long threads, often 6 or 8 inches in length before it breaks; it is claimed that the proper degree of acidity is that at which the curd shows the finest and most numerous threads. It is possible to construct a simple instrument that will show the acidity with the same unerring certainty and precision that a thermometer does the temperature. When the exact degree has been attained, the short leg of a syphon is introduced into the vat, and the whey is run off into a pipe which conveys it direct to the whey-cistern. The curd is then transferred into what is called the dry vat: this vat is 16 feet long, 3 feet 10 inches wide inside, and 1 foot deep, having a wooden rack or perforated false bottom, over which a cloth-strainer is spread to facilitate the thorough draining of the curd. The salt is now applied and the curd turned carefully over by hand several times, and the larger lumps broken. In order to insure the salt being distributed as evenly as possible through the mass, some makers apply the salt as soon as the curd is dipped or put into the dry vat; others endeavour to reduce the temperature by turning over several times before salting. The former method insures the most even flavour, but it requires the use of a greater quantity of salt, as a portion is drained off in the whey. The quantity of salt used is 2¼ lb. to each 100 lb. of curd when the curd is cold, and 3 lb. when hot. Old cheesemakers, from practical experience, have long since discovered that the salt of one district is much better than that of another, and certain salt, they cannot make good cheese. This question of salt is one of vital importance to the interests of the cheese-producer; the quality of the cheese may be sufficient

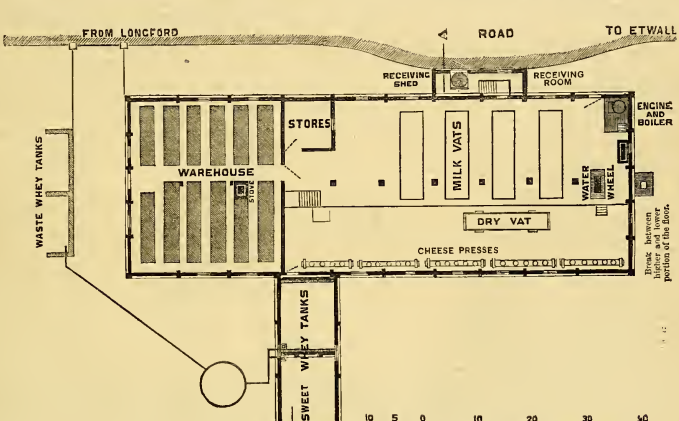

FIG. 285.—GROUND PLAN OF LONGFORD CHEESE FACTORY.

The quality may be slightly reduced, but the flavour and keeping properties are greatly improved. In England some makers advocate the grinding of the curd: this is quite unnecessary, if not actually prejudicial to the quality of the cheese. The blades of the knives used for cutting the curd should not be more than one quarter of an inch apart. When the curd has been cut it should be allowed to stand for a few minutes for the whey to separate; the heat is then turned on slowly and gradually until the temperature is raised to about 98° to 104°, which must be regulated by the condition of the milk and state of the weather. If the milk is old or has already begun to turn sour, the temperature should be raised as quickly as possible. As soon as the acid in the whey has become sufficiently developed to be perceptible to the taste the whey is run off. The exact degree of acidity is a matter of vital importance, and at present can only be approximated, the maker being entirely guided by the senses of taste and smell. A simple and inexpensive instrument suited to their purpose than, in fact, by using

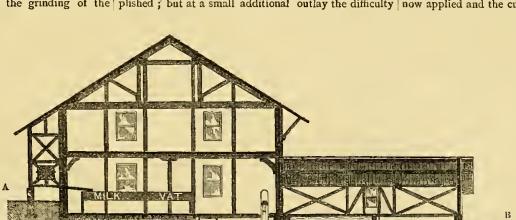

FIG. 286.—TRANSVERSE SECTION, FROM POINTS A TO B IN GROUND PLAN.

to satisfy the most fastidious, yet if the flavour be rank and strong it is at once ignored, and its value in the market depreciated accordingly. Curd cannot be dissolved by the action either of cold or hot water; but add a portion of soda, and it immediately returns to its liquid state. Salt contains a greater or less quantity of free soda; this soda, acting on the curd, sets up a chemical action which permeates and taints the whole mass, and to this cause may also be attributed the flecked or spotted appearance so often met with in coloured cheese. In all industrial occupations the first element of success is to produce an article suited to the ruling taste and fashion of the customers. With the cheese-eating public the present taste is for mild clean flavour: to accomplish this the whole of the salt used in curing cheese must of necessity undergo a chemical purification; afterwards there can be no objection to using it in a liquid form. When the curd is salted and cooled it is put into the hoops: these are open at both ends; they are 15 inches in diameter and 20 inches deep, and are made of strong galvanised iron in order to resist the great pressure to which they are subjected. A square movable board fits on to the bottom of the press, this board, when first put on, is supported in front by two legs, whilst the back rests on the bottom of the press; upon this the hoop is placed, and a square of thin cloth placed over it. The cloth is about 2 inches wider than the diameter of the hoop; the curd is now filled in by means of a filling tube, and carries the cloth with it to the bottom of the hoop; and when full a similar cloth is placed on the top, under the bed or follower; and the board, with the hoop now filled, is slipped into its proper position in the press without the hoop being moved. The pressure is then applied—slightly at first and increasing by degrees for about the space of two hours, when a pressure of 3 to 4 tons is attained. This solidifies the curd and insures sufficient cohesion to enable the maker to remove the cheese from the hoop and put on the permanent bandage, made of a thin cloth called tiffany, in width about 2 inches more than the depth of the cheese. A length sufficient to encircle the cheese is cut off, and the two ends are joined together by an overlay seam; they are then slipped on to the cheese, and the spare inch at each end is carefully turned over the top and bottom. The cheese is then returned to the hoop and the pressure again applied, this time amounting to from 4 to 5 tons. This pressure having been continued from 18 to 20 hours, the cheeses are then taken out and at once conveyed to the curing-room. For the first two or three days after the cheese has been removed from the hoops it should be daily rubbed over with fresh whey butter in a hot state. If this is neglected, sudden changes of temperature cause the rind of the cheese rapidly to contract, leaving it full of unsightly cracks and fissures, forming a birthplace and nursery for flies, skippers, and a whole host of insect enemies. It is of great importance that the curing-room should be kept at a uniform temperature, and to obtain fine quality considerable attention should be given to insure free ventilation. The cold air should be admitted only at the level of the floor of the curing-room, and a passage should be provided at the top of the building for the egress of the vitiated and heated air. All operations should be so constructed as to be entirely under control and capable of being regulated at pleasure. For the first six weeks the cheese should be kept in an even temperature of from 70° to 75°; it should then be gradually cooled down to 65°, at which temperature it should remain for a fortnight; and if clean and well made, it will then have attained that stage of mild flavour so generally appreciated by the best customers. Both in the Derby and Longford factories the heating of the curing-rooms has been accomplished by the use of stoves. This, though the cheapest, is not the best means; for by the use of hot water the heat is more evenly distributed through the room, and the degree of temperature is more easily regulated. The boiler used for generating steam to raise the temperature of the milk during the process of manufacture might also be connected with a system of pipes in which a continuous circulation of hot water is kept up, sufficient of itself to heat the curing-room. *Mr. G. Murray, in Journal of Royal Agricultural Society.*

[In connection with the subject of cheese factories, we give woodcuts illustrating the buildings at Longford; fig. 284 being a view of the factory, and figs. 285 and 286 a ground-plan and longitudinal section respectively. Mr. Murray, in his paper, says:—"At Longford, the Hon. Mr. Coke not only devoted his time to practical details, but also laid a large sum of money in the erection of buildings, and in conveying water from a long distance through underground pipes, in order to insure a low and equable temperature. All the internal fittings are on the most improved principle of the best American factories, so that nothing is wanting to give the movement a fair and unbiassed trial. The results have exceeded the most sanguine expectations, and attained a complete success."]

RECENT RESEARCHES IN AGRICULTURAL CHEMISTRY.

UNDER this head we propose to give our readers from time to time, some account of those chemical investigations which have a direct bearing upon the science of agriculture.

It is now many years since George Fownes showed that phosphoric acid was a constant ingredient of igneous rocks. Previously to his investigation it was supposed that phosphoric acid was only to be found in those rocks which contained the remains of animal life, and that the vast masses of primitive rocks which underlie the fossiliferous strata were practically destitute of this substance. The subject was of considerable importance, since it is clear that only rocks containing an appreciable quantity of phosphoric acid can yield fertile soils by their disintegration.

Dr. Constant Kosmann has recently taken up this subject.* He has examined various granites, porphyries, and syenites from the mountain range of the Vosges. In all of these rocks he finds phosphoric acid, amounting in some cases to nearly 2 per cent. The phosphoric acid is said to occur as vivanite, a mineral ferrous phosphate, generally found more or less oxidised. Dr. Kosmann has at the same time examined the metamorphic grauwacke of the Vosges, and the limestones of the trias and of the oolite. In all cases phosphoric acid, potash, magnesia, lime, and the other essential ash-constituents of plant food were found in most cases in considerable quantity. It appears, therefore, that the rock masses of our globe may be regarded as capable, without exception, of affording inexhaustible supplies of fertile soil.

An important investigation has lately been made by Dr. Fittbogen, of the experimental station at Dahme, upon the growth of Barley in Water Culture.† He has determined, with great care, the composition of the plant in various stages of its growth. The Barley was sown on April 30, in pots containing an artificial soil, chiefly composed of quartz sand, manured with known quantities of phosphate of potassium, chloride of potassium, sulphate of magnesium, nitrate of calcium, oxide of iron, and silica. The crop was taken up in five portions:—On May 22. 2. On June 2. 3. On June 16; the tops of the awns were then coming out of the sheath. 4. On June 24; blossoming was then over. 5. On July 16; the Barley was then fully ripe. The composition of each of these portions was carefully ascertained by chemical analysis.

The Table which follows exhibits the results, calculated so as to show the composition of 100 Barley plants, roots included, at each of the five periods:—

COMPOSITION OF 100 BARLEY PLANTS.

	1. On May 22.	2. On June 2.	3. On June 16.	4. On June 24.	5. On July 16.
	Grams.	Grams.	Grams.	Grams.	Grams.
Organic substances	17.979	60.752	129.604	166.823	175.726
Ash..	3.860	5.139	6.230	6.436	6.693
Total dry substance	21.839	65.891	135.924	173.259	182.419
Potash	0.978	1.116	1.114	0.847	0.809
Soda	0.163	0.180	0.214	0.227	0.203
Lime	0.855	1.257	1.512	1.649	1.777
Magnesia	0.183	0.288	0.309	0.312	0.339
Oxide of iron ..	0.074	0.074	0.134	0.136	..
Phosphoric acid ..	0.413	0.655	0.799	0.776	0.870
Silica	0.243	1.332	2.130	2.190	2.416
Chlorine	0.252	0.299	0.249	0.215	0.138
Nitrogen	1.134	2.043	2.204	2.254	2.252

In discussing these results it will be well to bear in mind the earlier investigations on this subject. Mr. Lawes refers in his paper "On the amount of Water given off by Plants during their Growth,"‡ to a series of experiments made by him on the Field of Wheat. Dr. Anderson, in his paper "On the Composition of the Wheat Crop at Different Periods of its Growth,"§ has gone into the same subject at great length. We shall see that the results obtained in these earlier investigations are for the most part abundantly confirmed by the present.

It appears very plain that the formation of the ear is a turning point in the life of a cereal plant; this period, in the experiments before us, corresponds pretty well with the third harvesting, that on June 16. Up to this point the increase in the weight of the plant has been very rapid. The Barley gains twice its weight of dry substance in 11 days between the first and second period, and more than doubles its weight again in the following 14 days. But after this critical period the gain in weight is slow. Moreover, it will be observed that the increase which indeed take place after the formation of the ear is mostly an increase of organic matter, the mineral ingredients of the plant (ash) increasing only to a small extent after that period. Still further, it will be remarked that the amount of nitrogen contained by the plant is after this period all but stationary. So that the gain in weight of the plant, from the formation of the ear to perfect ripeness, is practically a gain in carbonaceous organic matter.

This very important conclusion is amply supported by the earlier investigations of Mr. Lawes and Dr. Anderson upon the Wheat crop. Mr. Lawes says, "There was no appreciable change in the amount of the nitrogenous compounds upon a given area of land after the time of flowering, yet the amount of non-nitrogenous vegetable substance accumulated after this time had been very great." Dr. Anderson's experiments gave 65 lb. of nitrogen per acre on July 23, when the Wheat was in blossom, and 66 lb. of nitrogen on August 27, when the pair was well formed. He obtained, however, some increase of nitrogen in his final interval to September 25, and at the same time a notable increase of ash, chiefly silica. The harvest that year was however much prolonged through wet, and the conditions of the concluding period were far from normal.

The mineral ingredients of the plant undergo but little change after the formation of the ear. We observe in the Table a distinct gain in the silica, and a smaller increase in the phosphoric acid and lime. In Dr. Anderson's experiments with Wheat the phosphoric acid and silica largely increased after blooming; the other ingredients were comparatively little altered in quantity.

We must now look at some other changes which occur in the life of the Barley plant; changes due to the transference of matter from one part of the plant to another. Dr. Fittbogen has separately analysed the roots of the Barley at each of the five periods at which the crop was examined. The roots gained in size and weight as the plant grew, but while gaining in organic matter they kept losing in ash constituents. They contained, in fact, more mineral matter in the first period than at any subsequent time, although they afterwards increased to more than three times their first weight. The roots here act as the first storehouse of the plant. They appear more especially to accumulate potash, magnesia, and phosphoric acid in the early stages of the plant's growth, and then give them up again as the plant developes. Up to the fourth period the roots decreased only in the mineral ingredients just mentioned, but between the fourth and fifth period, during the process of ripening, there was a general transference of matter from the root to the upper part of the plant. The root loses at this time organic matter, nitrogen, and silica in considerable quantity.

In the last two periods of his experiment Dr. Fittbogen analysed the grain separately from the straw, leaves, and chaff; he thus shows the transference of matter from the body of the plant to the grain. His figures are as follows:—

COMPOSITION OF THE GRAIN AND STRAW OF 100 BARLEY PLANTS.

	Period IV. June 24.		Period V. July 16.	
	Straw, &c.	Grain.	Straw, &c.	Grain.
	Grams.	Grams.	Grams.	Grams.
Organic substances ..	99.596	41.230	80.308	76.654
Ash	3.563	2.000	3.767	1.388
Total dry substance ..	103.459	42.250	84.075	76.042
Potash	0.459	0.229	0.495	0.235
Soda	0.112	0.009	0.104	0.012
Lime	0.980	0.058	1.045	0.067
Magnesia	0.137	0.065	0.168	0.149
Oxide of iron ..	0.035	0.022	0.137	0.131
Phosphoric acid ..	0.295	0.384	0.159	0.566
Silica	0.642	0.249	1.603	0.308
Chlorine	0.148	0.028	0.102	0.001
Nitrogen	0.951	0.661	0.732	0.937

It is seen that a considerable transference of organic matter and of nitrogen takes place from the straw to the grain, and that among the ash constituents the straw parts chiefly with phosphoric acid and magnesia. Many other points of interest are to be found in the Table.

We have dwelt on only a part of the important observations detailed in Dr. Fittbogen's paper; it will well repay a careful perusal. One practical bearing of the facts established is very obvious. The nourishment of the Barley plant is clearly limited to a very short interval of time. And this is more especially true in respect to its assimilation of nitrogen and ash constituents; the whole of which are practically taken up during the few weeks of actual growth which precede blooming. The farmer has here a caution against applying his spring dressings too late. If manure is to be turned to economical use by the crop, it must have become thoroughly incorporated with the land by the time the active growth of the plant has commenced. Moreover, as the feeding time is so short, the soil must necessarily be in a fine state of division to allow of the largest possible growth of root in the time at its disposal. With Wheat the roots have a far longer time for accumulating plant food, but in other respects the crops are very similar.

THE FOOT-AND-MOUTH DISEASE.

By J. MOIR, V.S., ARMAGH.

As the above-named disease has become prevalent in many parts of Ireland, I trust it may be considered opportune to present your readers with a brief sketch of its history, nature, causes, and symptoms.

Though calling it a visitor, for the sake of convenience, we cannot, nevertheless, attribute to it a foreign origin, as we would to a cholera, which constantly smoulders or bursts out on the Russian steppes; sometimes, as of late, overstretching its native boundary, carrying its ravages to the western parts of Europe. It may truthfully be said of aphtha to be as often an occasional visitor of Great Britain as that of any other country, leaving us in most cases quite unable to say with any credible amount of certainty whence it came, how it goes or spreads; notwithstanding, though we have been favoured with much showing of its contagious properties, its conditions of existence

* "Archives des Sciences Physiques et Naturelles" [2.], xl. 152.
† Versuchsstationen Organ. xiii. 81.
‡ Journal of Horticultural Society, 1850.
§ Transactions of Highland Society, 1862.

and propagation in the majority of instances can only be attributed to spontaneous generation, epizootic, and to unknown causes. Doubtless, there still exists a great diversity of opinion as to its contagious or non-contagious properties, even among many eminent veterinarians; not only those employed by governments to report on its contagious or non-contagious nature, but also by others who have had ample opportunities afforded them in their ordinary professional capacities of studying its character. One thing (remarkable enough), that though it is a disease peculiarly of an eruptive nature, all attempts to communicate it by direct inoculation to another sound animal of the same species have failed. Yet we occasionally hear of people and other animals contracting the disease by the use of the milk of infected cows. Inoculation in these cases can only take place per the mucous membrane of the mouth or digestive caoal. But a circumstance I may here mention, that may go some length in explaining the already mentioned division of opinion with this and some other epizootics, is, that the diseases of cows or agents are endued at birth with complete vigour, by which period we may be able, seemingly, to note many striking instances of infection and contagion; but as their attacks multiply they gradually get benign, which is attributed to the expenditure of their forces, and with foot-and-mouth disease, in proportion to its decline of vigour, leaves to discover but few or no traces of its contagiousness. Again, in looking at the placards of contagious diseases we cannot but infer from them that the disease is a most infectious one; and to preserve cattle in the shade of immunity it is necessary to bury the carcases of those dying from the disease far under ground, and to have their bones and hides boiled entire; or otherwise the plague, like the phœnix, will rise from its ashes, take wings, fly to and fro, discharging its darts right and left, and lastly, being only brought to bay by an armed cordon of police, be quietly consigned with its victims to its last resting-place, being chained down by a heavy load of clay till again called into being by some evil influence or medium.

It is the duty of every loyal subject to aid in supporting sanitary measures that are productive of good to the country; but it is equally the privilege of the writer to check ignorant notions or pernicious ideas from incorrect premises. It has never yet been shown satisfactorily that the disease is infectious, or that by experiment it could readily, in the form of gas, be conveyed to another animal; finally, it resolves itself into this, that at most it can only do so by an immediate connection with the spring of infection. Let any one consult some of the most enlightened veterinarians in the world (the French); they will inform you that it is not a disease, like rinderpest, that can by a sanitary police be stamped out, but one calling for their non-interference, and bidding defiance to their efforts of control. Certainly, if a district or country were to be proclaimed as an infected one, and put, as it were, under martial law, all cattle trading and exporting of them stopped, such rigorous measures would not only be disastrous, but quite uncalled for, as they could not have the desired effect of arresting the disease; for, just as it acts independently of topographical and the known atmospherical causes which exercise an influence on epidemics, so will it act in opposition to the present repressive measures in force. It is beyond all contradiction that the causes which give birth, feed and multiply its existence can be clearly investigated, brought forth from obscurity, before any mode of action could with reason and intelligence be brought to bear on its extirpation. In proceding to describe the symptoms of this eruptive or exanthematous disease, we usually may note four well-marked periods or stages. First period: Symptoms of general disturbance or febrile excitement; the animal is dull, hangs his head, off his feed, or if he eats, it is just as if he had parted with his teeth and taste; extends his neck, pokes the muzzle out, rests the head on the manger or trough; the mouth is hot, dry, and injected; grinds the teeth, twitches the lips, the skin is hot, slight tremors with muscular contractions. In a milk cow the udder is hot, with suppression of milk, the breath in some cases has a fœtid odour, back arched, feet hot and tender, with lameness; keeps lying, and feels disinclined to walk; but an allowance must be made, as not to cast objects these symptoms with an equal intensity in all animals. The intensity of the malady, and the place it selects to to make its grand attack, has a leading influence which can only be one of the three following: the mouth, feet, and mamme. If one of these organs is severely attacked, the other two, by an inverse ratio, are but slightly implicated. The duration of this period is from one to two days. The same train of symptoms may be observed in sheep; in the pig slightly different: he lies and gives out a pained, dull grunt. Second period is ushered in by an abatement or complete moderation of the previous phenomena with the appearance of vesicular eruptions on the muzzle, inside of lips, gums, side of mouth, on the surface of the tongue, rarely on the roof of the mouth. When the vesicle is solitary it is about the size of a small pea, and where the outer skin is fine it has a regular circular outline; but on the muzzle, and where the epidermis is thick, their size and outline vary; they contain a serous fluid, which gradually turns opaque; when let out it is of a stringy and sticky nature. When these are thickly studded on any surface they coalesce, and are said to be confluent, in which case we have large bladders or blotches formed. In all cases the surface beneath the outer pellicle is red and raw-looking. The surface of the tongue, owing to its thick outer coat, presents a bosselated aspect. When the disease has been partially severe in the mouth the vesicles are very plentiful, and about to burst, a happy change of health and rapid recovery take place, but not so with the feet or udder, if severely affected; the symptoms are aggravated, and restoration to their functions more tedious; the feet are swollen, with an eruption between the digits in the spaces in front, and sometimes around the top of the nails, also behind, extending upwards to the fetlock. The tissue between the hoofs bulges out, is of a bleached colour, and very painful when touched. In some cases the teats are swollen, and if much diseased will not admit of the milk being drawn. In the third period the vesicles rupture, and exhibit raw surfaces, which secrete a samous-like fluid, the cuticular covering peels off in a large slough, as if steeped in boiling water. The patient constantly munches. When the nose has been affected, she keeps touching it with the tip of her tongue. A rusty, frothy saliva flows from the mouth, and commissure of the lips. In bad cases, when the ulcers are large, deep with ragged edges, they cicatrise tardily and unwillingly, but in ordinary cases they readily heal. The feet, generally speaking, are the organs that suffer most, and are longest in recovering; the dermic covering between the hoofs sloughs out, exposing an irritable, raw, and cracked-like surface; lameness increases. Frequently the sole and a portion of the horn is detached; in some instances the whole hoof is cast; but in benign cases the parts unite to each other, and the lameness disappears. There are exceptional cases, where not only the hoofs, but the soft tissue and bones, have sloughed off. The last stage is the healing of the ulcerated surfaces, which is effected by the sores getting covered over with a scale, which dries and falls off in flakes. Local treatment is very simple, from the fact that none of the internal organs are implicated by the eruption; except in some rare cases, when the constitutional disturbance is very intense, causing a great amount of functional derangement in them, which, if not promptly attended to, may result fatally. In ordinary or benign cases without any complication, little treatment is required: give light food easy to be masticated, drinks acidulated with a little nitric or acetic acid; when the mouth gets raw, dress it with a lotion composed of 1 pint of vinegar and 2 ounces of acetic acid, or in place of the acid, dissolve in it 1½ ounce of alum; keep the feet dry, and clear of dirt; if the slough is tardy in coming away, apply Venice turpentine to loosen it; when accomplished, dress with a weak solution of chloride of lime or carbolic acid, remove detached horn, and cover with Archangel tar. In complicated cases have recourse to professional advice. *Irish Farmers' Gazette.*

TURNIP GROWING.

IT is under 100 years since Mr. George Henderson, then farmer of the Burgh Muir of Linlithgow, Bonnyman, and Wester Bonhard, tried to grow Turnips in the fields. His plan was to sow them in rows on the ground, thin them afterwards, draw up the earth about them with hoes (for there were no ridging-ploughs then), the same as is now done with Potatos. He could not get them to grow to please himself; but through a three days' visit to this intimate acquaintance, Provost Clark, of Linlithgow, who was a Dutch merchant, and was often upon the Continent, he was informed how large they grew the Turnips in the fields in Holland, and advised to go over to Holland and learn their method of rearing them. Mr. Henderson took the Provost's advice, and went over and ascertained the Dutch method of growing Turnips in ridges, and when thinning them to take away the earth—the very same way as is done at present. In other words, it was Mr. George Henderson who introduced the proper way of growing Turnips in the fields to perfection, as now generally practised over this country. At that time farmers came from far and near to see his new method of cultivation. Some came too soon, when he was thinning the Turnips, and declared he never would have Turnips by taking away the earth from them as he was doing; but when they came a second time, they saw his new plan in a different light, and highly approved of it, and it soon afterwards became general.

> 'Man and his labours pass away,
> But Nature spurns thy power, Decay."

I shall now endeavour to give my experience and observations of field Turnip growing for the last 30 years. At that time Mr. David Roughead, of Haddington, was known in this district to be an eminent grower of Turnip seed, which he obtained only from selected roots, selling only such as he knew to be of the best kinds. All his seeds turned out magnificently, as far as came under my notice. I also knew some farmers who picked the best and largest of Turnips, and transplanted them early in spring in a suitable place for producing seed for their own sowing; indeed, all the seed at that time was produced as above described, and there was no such trouble and defects in growing Turnips then as now. I have seen the green-top Aberdeen and purple-top Aberdeen grown upon my own farm, some of them weighing 26 lb. imperial per Turnip; and all the Turnips at that time that came under my observation for miles distant grew well—scarcely one field being defective, unless too late of being sown. I am quite aware there are some soils more suitable for growing Turnips than other soils. For instance, they all grow both easier and larger upon a light soil than upon a heavy clay soil; and no such difficulty is felt in getting them sown at a proper time upon a light soil as there is of getting them sown at a proper time upon a heavy soil, owing to the difference of seasons, over which man has no control. But that is not what I intended clearly to bring out. I have been asking some farmers if they had any idea of what was the reason that their Turnips did not grow now as formerly, and if they could account for the change. Some thought that there had been Turnips too frequently upon the same ground; other farmers say that some land will not produce healthy Turnips. There are some who will not offer for a farm unless they get a guarantee that the land will not produce diseased-rooted Turnips. Under these circumstances it is becoming a most important matter to have the problem here involved fully inquired into, and, if possible, set at rest. The evil is, in the first instance, injuring the farmer, but ultimately it will extend its influence to all classes in the country. It is only about 18 years back that the root disease commenced to be observed by me in this district, and I have noticed its progress since to be very rapid, and I am of opinion I trace it to its true origin. I will, in the first place, describe the Turnip how it is affected. When it is about the size of an Apple it begins to split up from the bottom about one-third of its size upwards on the right angle, and throws down four small roots, one at each angle (when a healthy Turnip should only have one strong root so far down till it branches out into numerous smaller fibrous roots). The diseased Turnip thus lingers in misery for a time. I have known a field of 16 acres imperial per Scots given in the autumn to be not worth not a twentieth part of what would have been their value had they been good Turnips. I know the disease so described by me goes under different names in different localities. I will, however, continue to call it by the root disease.

In the second place, I entirely blame the seed as being the cause of this root disease. If we condescend to examine the way the Turnip seed is now produced, and compare it with the description of the mode pursued 30 years ago, as above stated, we will have no difficulty in seeing that it is the real and only source from which sprung the failure of the Turnip crop.

In the third place, I give you a true account of how a large proportion of the seed is now produced for field Turnips. Fields of hay are cut down, hurriedly ploughed, and sown with Turnip seed broadcast. They are neither hoed nor cleaned in any way, but allowed to grow as they will, and run to seed when they like the following year. These Turnips are never the size of Apples. How can they be expected to produce proper seeds when there are not the proper juices in themselves? I see this method of raising seed for Turnips is followed in many fields even between Linlithgow and Edinburgh, as elsewhere. My experiments have been very numerous, and the whole of them give the same results; therefore, I do not now scruple to offer my humble opinion that I am right.

I now give you an account of the appearance of the good and bad seed when examined with a powerful magnifying glass. The good seed is larger, darker in colour, and glossy. The bad seed is smaller, of a brown colour, and wants the gloss; but this is too fine an observation to depend upon for buying the seed by. If a magnifying glass of sufficient power is placed to show every Turnip seed the size of a large Blackberry, the farmer will plainly see that by sowing some seed (such as I have got samples of) he cannot expect a crop of Turnips, but ruin himself by purchasing the trash referred to; and it must be no joke to a farmer to have no Turnips to feed his cattle when he expected to have an abundance.

I would suggest as a proper method of putting an end to this practice, for the agricultural associations to take up the case and acquaint all sellers of seeds that no farmer would buy any Turnip seeds without a guarantee that it was entirely from full-grown Turnips, and that they would hold the sellers responsible. This would make all the growers of the inferior seed give up growing it, for they would not get it sold. *Mr. John Buncle, of Springfield, Linlithgow, in the "Falkirk Herald."*

Home Correspondence.

Farmers' Ills.—Your paper contains, from time to time, remedies for almost all the ills the lands and crops are heir to, but in my frequent perambulations amongst farmers I have noticed the frequency with which they and their farm-labourers suffer from boils. These, I notice, occur most frequently in the spring of the year, and are, no doubt, the result of exposure to wet and cold weather in winter. Very few doctors appear to possess the proper remedial means for curing boils, and, seeing that on most farms the victims to them have the cure growing, perhaps you will kindly make it known. I have recommended it in

scores of cases, and have never yet known a case of failure. Take a handful of the herb known as Horehound, a similar quantity of Wormwood, and a third of common garden Rue. Pour on to those half-a-gallon of boiling water, and take half a tumbler of the tea so made previous to retiring to bed, and the same about an hour before breakfast in the morning. This should be accompanied by a generous diet, as the old method of "starving" boils is now exploded. This, taken in the early spring and autumn, is a sure preventive; and the patient will also, in all cases, be astonished to find the wonderful improvement in his general health. *F. R. R.*

Societies.

MONMOUTHSHIRE.

Compensation to Tenants for Unexhausted Improvements.—At the annual meeting of the members of this Chamber of Agriculture, the following discussion took place on this subject. The President said that when they met at Usk, Mr. Stone had suggested that Mr. Fletcher's paper on this subject should be thoroughly discussed in different parts of the county, and that then a committee should be formed for the purpose of gathering together facts and information as to their requirements in connection with unexhausted improvements, and that the committee should frame some scheme and lay it before a general meeting of the Monmouthshire Chamber in order to elicit the views of all the members, and that they should act in accordance with what the meeting decided. He now asked Mr. Fletcher to resume the discussion on the subject of his paper.

Mr. FLETCHER said his paper had now been in their hands for some time, and therefore he thought he should be promoting their interests if he adverted but briefly to the principal heads of that document. He had already, at Chepstow and Usk, gone through the paper, probably in a more detailed form than they would think it necessary for him to do that day, because it had been before them in the public prints. Mad he had no doubt they were all familiar with its contents. It was a fact that agriculture had taken such vast strides within the past few years, that they, as occupiers and tenants, had arrived at a climax in many ways. He spoke as to the breed of cattle, the application of artificial manures to the soil, the improved method of cultivating their land, and the wonderful and powerful machinery which they brought to their aid in their various operations. Land drainage had improved their poor pastures and arable land—the rough and bard work which had been common to farmers was now exchanged for a life of almost comparative ease and refinement; and they had come to a period when it was necessary to ask, "Is it not time that we should establish among ourselves a system of remuneration for conducting our operations as farmers?" The Chairman of the Scottish Agricultural Society, the Marquis of Tweeddale, had said that agriculturists had now arrived at the top of the ladder in many respects; and that the period had now arrived when they must devote themselves to the improvement of land with a view of producing more animal food for the purpose of sustaining life. He was told there were proprietors who would the feelings of the Chairman with jealousy. There were those in charge of tracts of land in this country who doubted very much the usefulness of these meetings; and, he doubted, there were tenant-farmers who lacked energy and interest in the work of the day. But he had no fear; because, as representing a large and another part of England, he had had an opportunity of seeing the necessity for a well-devised and well-arranged rational scheme to do justice to the outgoing and the incoming tenant, and also to the landlord; and that was his ground for now appearing before them. He was sure of one thing, that in asking them to consider the subject, and come to a decision, he was advocating the interest of the landlord. Now, he would briefly allude to the chief points of his paper; and he hoped he should elicit remarks from gentlemen present which would enable them to arrive at some conclusion. The necessity which existed for recognising the acts of the outgoing tenant was so familiar to them, that he did not think he need go into that question. A man in trade or business, if he embarked his capital for the improvement of his landlord's property, secured himself in the event of death or any other casualty, so that his heirs, or those who succeeded him, should derive the benefit. That being the case, a farmer had every reason to expect to get the same right extended to him. It was impossible, as he had remarked in his paper, for a man to advantageously farm in the present day unless he put his hand in his pocket; and he must, therefore, have security that he would get back again a fair and proper interest on what he had laid out. At the present moment that was not secured to them in this county. But it was perfectly feasible for them to devise and carry a measure of the sort he indicated. In Lincolnshire the thing had been common for many years; and it was possible to reduce it to a system, and to be made of use to them without flying to their landlords, or without resorting to leases. If men in Lincolnshire could farm highly under six months' notice, surely men in Monmouthshire could do the same. He had before him the Lincolnshire customs. He would not go through the whole of them, but he would read to them what really was the state of things in that county. Yearly holdings, at six months' notice to quit, were the rule, and leases the exception; and where there was no contract to the contrary, custom allowed the outgoing tenant compensation for unexhausted improvements. He would not go into the items embraced in the schedule; but the chief thing to prove was that men farmed highly, and up to the mark, under six months' notice, with the existence of customs. The value of the respective operations and treatment of the soil he need not go into; but he might simply tell them that was the state in Lincolnshire. At some future time they would probably have the opportunity of acquainting themselves more particularly with the matter. They now came to the hindrances to that state of things in this county. There were various causes of hindrance. The hindrance arose in some measure, in the first place, from want of confidence on the part of the outgoing tenant that any operation or investment of his would ever be returned to him. In the next place, it arose from an undoubted dislike to parting with money when they embarked in a new holding, before knowing what advantage before them. There was a degree of uncertainty about valuations, which he knew full well made a man doubtful. And he was not surprised at it when he had seen what a man had to put down on going into a farm. They knew it was very natural for a man to feel that he was going to lose sight and see and feel. That was one of the difficulties of their case. To be asked to pay £4 an acre for "condition," which they had no earthly evidence to prove was in the soil, was sufficient to make a man hesitate. That was one of the points they would have to consider. He would not adopt the method of estimating that fact; but they knew it was one of their chief points—the feeling that mere "good will" generally was paid for, something they could neither see nor touch, but yet something that was there; and if they had a system of compensation throughout, that must be considered one of the chief points to them. They might have every confidence in their landlord—in his undoubted feeling towards them, and in his wish to do what was right; but they were not at all confident as to what might arise in the event of the landlord's death, nor were they aware what might be their widow's or children's state: as case they themselves should die. It was a serious matter for a man to spend £200 or £300 on bones or artificial manure, and put that on his land, and then to ask himself the question, "In the event of death, will my widow or children be paid for this?" They must therefore consider they had reasons for their apprehensions; and he hoped he should succeed in proving that the matter was more between themselves as tenants than between tenant and landlord. Landlords were not all practical men; but they were always accessible through their agents, who ought to be practical men; and if they, as occupiers, should meet one another each other, he had no fear with regard to a scheme properly and deferentially placed before them, but that it would be accepted by them. The point was, first of all, that it should be accepted by themselves as tenants. Now, that was one point which the Lincolnshire men had agreed upon as the basis upon which, at meetings, in Lincolnshire, were held, and on which they changed hands. He had given in his paper, and he would now briefly refer to, what were the customs throughout England. In fact, there were no general customs. There was that common phrase, or agreement, which, he believed, millions of bargains had been made, "Go in and out as you found it." Probably they must cultivate and amend their farms according to the custom of the country and the improved state of agriculture. That might be well in one locality, but in case circumstances occurred, and they had to change their holding, how did it affect the farmers? Probably the Lincolnshire men were migratory, and were totally opposed in its customs, or there were no customs. How, then, were they to get over the difficulty? It could not be done in a moment. But if they recognised the necessity for it, and if they followed in the shoes of the Lincolnshire men, and established a system of valuation, this county, and other counties were watching Monmouthshire, and knew that it was not sleeping—if Monmouthshire took the course indicated, and other counties followed in its footsteps, the system might be made general. From Northumberland to Monmouthshire, taking the country throughout—from north to south and east and west, with scarcely an exception—there were no two counties possessing the same customs or systems in changing holdings. Every one, as far as his memory served him, who had spoken on the subject in Monmouthshire, had agreed in this—that there was a necessity for a change; but at the present moment they did not see their way clear to effect that change. They knew the state of feeling of the man who received notice to quit his farm. While he could he got out every atom of good that lay therein. And why? Because he had no guarantee that he would be compensated for what was there. And the hardship which, in many ways, arose from the absence of a recognised custom or practice of compensation, fell on incoming tenants as well as outgoing tenants. Many men going out of their farms abused their farms. What did they do? They found opportunity for distributing over the land rubbish and other material, which they expected to be paid for as manure. Material was removed to every available spot, that the valuer might take cognisance of it, and his successor pay for it. That was simply an act of robbery. It was requiring them to pay for goods which were of no use. Far better would it be for the incoming tenant to pay for that which was of some good to him. It was better for him to say he would rather pay for going into a garden than go free into a wilderness. He repeated, that it was more a question for the tenants than the landlords. It was very much the practice to fix the responsibility on the landlords, but he would never fall into an idea of that sort, because he believed it was for the tenants to settle this matter, and then to ask the landlords to endorse their decision. He asked them whether they wanted more evidence? whether they wanted more facts? or whether they wanted more argument? If not, then commence the work at once; and let them be able to state a year hence that Monmouthshire had found its way to the system in existence in Lincolnshire. Let them improve upon that system—and he thought that they could—and then their work for the present would be at an end. Let them adopt a scheme that would have for its results the maintenance of the fertility of their soils—let them feel that they had achieved a scheme that would preserve the "condition" a man had put into his land, benefiting and rewarding him—his labours likewise benefiting the country to which he belonged.

Mr. HENRY WILLIAMS had listened with pleasure to Mr. Fletcher's address, and he would first touch this point—namely, that the question under consideration was principally a matter among themselves, as tenants. It was a matter which involved great deliberation; and one upon which they should be unanimously agreed before they asked the landlords' sanction to any scheme. It was of no use for one man to go to his landlord and ask, "Will you sanction this idea of mine?"—if by asking that sanction he sought to get on his side something which the man who might succeed him might think unfavourable to his interest. It would then be a one-sided matter, and the landlord, who would naturally be asked to sanction it, would give his sanction unless the scheme was one which would be satisfactory to both parties—outgoing and incoming tenants. Hence he held, with Mr. Fletcher, that in any scheme of this kind they must arrange among themselves what would suit both outgoers and incomers; and, provided it was not prejudicial to the landlord's interest, he had no doubt they would get the landlord's sanction. He thought the more the question was considered the more would it be seen that the discussion tended to promote the interest of the landlords as well as of the tenants. When they looked round and saw the great improvements in Monmouthshire and other counties, within the last few years, in the cultivation of land, how, it might be asked, was that improvement done? To a great extent by companies, who took and carried out the work as a matter of speculation. They said, "We will do this or that for you per cent. per cent. for so many years." Now, he held, if they could go to their landlords—and he was sure they could—and say, "We will do these things at a considerably less cost to you than these companies will do them for, we will take less time to exhaust our interest, and we are willing to take less percentage, and we are willing to do all the overlooking" (which costs you a great deal of money as part of our ordinary work)—he held, under these circumstances, that the interest of the landlords consisted in encouraging the tenants to do these operations, instead of having them done by other parties, who had not the same interest that the tenant had in doing the work. He spoke now of improvements usually done by landlords. He was aware that many persons held that there was no improvement needed in that respect, but he could not agree with them. The persons referred to said, "If you go to your landlord to get their sanction, you can do the work." But he knew the difficulty was to go to the landlord, and to get his sanction. The landlord did not see the matter with the same eyes that they did; he was not so deeply interested in the *minutiæ* of things as was the tenant; and the matter overlooked. And, in short, the system was that the tenant was allowed to do these things provided that he had the sanction of the landlord in writing. That was one of the most difficult things with which they had to deal. If the tenant got the permission of the landlord to do certain things at an estimated cost, unless he were forbidden by the landlord to do them they would have a great alteration; and he thought such an arrangement would be very feasible, for in his opinion very few landlords would give a prohibition in writing. But that which looked so feasible—but which was in the province of the Chamber—was the increasing the fertility of the land by manuring. That was a difference which was caused by the difference in the relative value of manures. But he did not deny that a committee might arrive at some decision on that point. There were some manures which would increase the fertility for many years; and there were others which were rather deteriorating—which acted simply as stimulants, just in the same manner as if they gave a glass of grog to a man to get extra work out of him for the time being. That was one of the most important parts of the question with which they had to deal. The decrease and the advantage would be

easily settled by a committee; but he did not think that under any circumstances they could lay down a hard and fast rule, which should guide a valuer—or that they could have a system by which valuers were to go over a farm and value simply what they saw.

Mr. R. Stratton said it appeared to him that there were two distinct elements in the question under consideration. First, there were the permanent improvements; and he would say that this question of permanent improvements was a thing that concerned landlords and tenants. Then there was the question of "cropping," and of compensation for unexhausted improvements—in common phrase, the custom of the country, and that concerned simply the tenants, incoming and outgoing. The first question he did not think they could do much with; as to permanent improvements, that must be a question between landlord and tenant. It was not likely a man would spend money in draining without consulting his landlord; or, if he did, it would be ridiculous to ask his landlord to compensate him. What a tenant called permanent improvements, the landlord might not; and therefore he thought the question of permanent improvements, such as building, draining, cropping, hedging, and that kind of thing, was simply a question between landlord and tenant. It was not a thing on which they could lay down a regular rule, and recommend landlords to adopt it as a system. They must deal with landlords as cases turned up, and must be guided by peculiar circumstances. But what he thought was the point they had particularly to deal with was the question of cropping—the question of unexhausted improvements—in short, the custom of the country. He thought they would agree with him that what they wanted established was a good sound custom of the country—a system which would tend to increase the produce of the land—a system which would encourage high farming—a system by which any man, either by being turned out or giving notice to quit, might leave his farm at a six months' notice without incurring the loss of a penny piece. He maintained that it was not only to the interest of the tenant, but that it was to the advantage of the landlord, that such a system should be established; and he hoped landlords would deal with them so that they would all see, as a great many already saw, that they would not be a means to oppose these Chambers of Agriculture were in the slightest degree opposed to the interests of landlords. Perhaps he had peculiar ideas of his own about cropping and leaving. However, he did hold this—that vexatious restrictions were simply abominable. He thought that a man should be allowed to crop his land as he liked. Some of their landlords and their agents were practical men, others were not; and why should they, as tenants, be obliged to put so many acres of Wheat, and so many acres of anything else? If a man chose to grow Cucumbers, let him grow Cucumbers. It was to the interest of the landlords to allow the tenants as much latitude as possible. The more a tenant could get out of the land, the more was it for the benefit of the landlord. He was opposed to absurd restrictions, and he hoped that the committee to be formed would be able to recommend some scheme which would lead to high farming, and to tenants cropping as they liked. He thought something might be done in this way. Some people were very tenacious about selling straw or hay. He had an opinion that an arrangement might be made after this wise: Let no tenant be allowed to sell hay under a certain price—say £4 a ton. He simply mentioned £4 as a hint. Then, as to straw, let them not sell under, say, £2 a ton. But he thought a tenant should be allowed to sell as much hay and straw as he liked above £4 and £2 a ton respectively, on the understanding that he should expend the whole amount of money so realised in artificial manure, or in feeding stock. That he believed would be fair to the landlord and tenant. Then they knew there were certain farmers who mowed their farms year after year, keeping no stock, but always selling for hay, whatever the price might be. He thought it fair to say that a tenant should not mow his land every year, but that he must manure his land or graze his cattle. They must not look at the question from a purely tenant's point of view. His original proposition at Usk was to form a committee to draw up a system which they could recommend to the landlords of the county. He now proposed that a committee of eight be formed—five farmers, two agents, and one landlord.

Mr. Culverwell seconded Mr. Stratton's motion. He was of opinion that compensation to tenant-farmers would supersede leases. A man might have a farm on lease, and he could not leave unless he got some one to buy him off, or the landlord allowed him to go. Moreover, compensation was better than lease, because a tenant might farm well for some years, and during the last four or five years he might do worse to recoup himself for any outlay, and leave the farm in a worse condition than he found it.

Mr. Williams (Wernymellen) paid a high tribute to the worth of the landlords in Monmouthshire, and added that he was a great deal more afraid of the gamekeeper than he was of either the landlord or the agent. The gamekeeper was the greatest cause of discord in Monmouthshire between landlord and tenant. It was no difference what they cultivated—rabbits consumed it, and there was that to be witnessed about their farms which was disgraceful to be seen. They would do very well if gamekeepers and rabbits were out of the way.

The President thought they were all agreed upon one thing—that this discussion should be brought to a close. Likewise, they would all agree that they had nothing to do with permanent improvements—it was for the individual tenant to agree with his landlord whether he would put up buildings or construct drains. Classing himself among tenant-farmers, he held that the landlords should agree upon some system whereby, when the tenants were turned out, or left by accident, they should not leave their property behind them. What they agreed upon was this—that it was a good thing for an occupier to leave his possession in a better condition than that in which he found it. It was good for his successor; it was good for the country at large. Make it to their interest, and depend upon it the farmers of this county would act upon that principle. All that a committee would have to do would be to ascertain among their neighbours how it could best be made to their pecuniary interest to leave their farm in an improved condition—improved from what they found it. The farm would then go on improving as each tenant left, if they could find out how best to recoup the tenant for his outlay. He thought all they had to do was to encourage one another, under a certainty that they would be recouped for the unexhausted improvements that they left behind. He and Mr. Stratton had spoken of leaving a farm at six months' notice, and that it was indifferent on a system of compensation whether they left at a six months' notice or not. As to the money question, it might be indifferent whether they left it at a six months' notice or a twelve months' notice, or left at any other peculiar business. A farmer who lost his farm could not go into another business without loss of time. And it was a serious thing to a farmer, who had no prospect before him, to be turned out at the mere whim of the landlord, or of the agent, at a six months' notice. It was a system to which had come in his mind for many years; and he was glad to find that the farmers were beginning to feel—that the yoke began to gall—and that they were calling on the landlords of England to promote the interests of the tenants, as they expected the tenants to look after the landlords' interest in the management of their farms. When it was looked at in this way, they would get rid of one of the great causes of short notices—they would get rid of—(and he hardly knew how to use a term sufficiently strong without being offensive)—but he meant the political power that was wielded by many of the landlords' hands, and which they could not use without having the power of the short notice. But landlords need not fear that they would lose influence. Tenants, as a rule, would go with the landlords, whether or not they had short notice to quit. He was sure that landlords, in giving up short notice, would not give up any political influence they desired to possess. These remarks were almost foreign to the subject; but they were so mixed up with it that he could not help giving utterance to them. He himself preferred leases, but compensation would do away with many evils. The President concluded by moving—

"That four members of each division form the committee proposed by Mr. Stratton, and (—) landlords and (—) agents, selected by the Council, be invited to join it." (The number of landlords and agents to be included in the committee, to be determined hereafter.)

Mr. Fletcher seconded the resolution, which was carried.

Mr. Fletcher said he should not like it to go forth that he was in favour of a six months' notice. He had not intended that his words should bear that construction. He simply stated what was done in Lincolnshire. But if they had compensation for unexhausted improvements, it would not much matter what was their holding. When there was compensation they would get their rights, which was all they wanted. But let him not be understood as advocating a six months' notice, for he deplored it.

CASTLE DOUGLAS.

At a recent agricultural meeting here Mr. J. Caird, C.B., proposed the toast, "The Agricultural Interest," and in doing so said he had heard to his astonishment that although this was an agricultural county, and although there were a great many agriculturists round the table, there were very few farmers present—scarcely any. This was a circumstance worthy of note. There were agriculturists who were landowners. In his own county of Wigtown there were very few landowners who were not farmers. Always, or very often, there were men of very large property who depended for success in life, not upon personal exertion, but upon property. In the Stewartry it was different, but he was sorry that there were not more present of that class of agriculturists who had nothing to depend upon but the exercise of their own skill and the proper employment of their capital. In regard to the subject of his toast—the success of agriculture—it depended upon the success of the country in general. It was because the consumers were ever flourishing, increasing, and getting richer—it was for that reason that British agriculture flourished. So long as that continued they might hope for agricultural prosperity, and that would probably continue so long as coal and iron and the means by which our great manufactures were maintained continued to exist. A Royal Commission had lately reported that our coal supply is not so endless as at one time it was thought to be; it would probably prove sufficient, however, for two or three or even four generations longer, and they might hope that by that time the wit of man would have discovered something to supersede or come in the place of it. That was a very remarkable fact which the census had lately told them—a fact upon which the prosperity of agriculture in this country materially depended—that within the period from 1801 to 1871 the population had exactly doubled. In 1801 it was 16,000,000; in 1871 it was 32,000,000; and the remarkable fact was this, that the agriculture of the United Kingdom, combined with the operation of those measures of free trade which had become law, had made the pressure for subsistence on the part of these 32,000,000 considerably less than it was on the part of the 16,000,000—that was to say that the 32,000,000 now existing were much better fed than when there were only 16,000,000 of a population. They might hope that state of things would still go on. And let them remember this, it was not at the expense of the consumer that agriculture was prospering. The great staff of life—meal, Wheat—that upon which beyond all others in Scotland now, in England entirely, and in Ireland to a great extent, the great mass of the people depended, had, within 20 years of free trade, actually diminished in price, as compared with the price before free trade was established. Therefore, if agriculture had prospered, it had not been at the expense of the consumer so far as the price of bread was concerned. As to the agriculture of the West of Scotland and their own district, there was this to be said, that it was because they could grow more and better grow Turnips well, feed stock well, and produce those articles which could not be very well brought from abroad, that agriculture with them had flourished as it had done. Though he was not the oldest man in the room, he could remember about 35 years ago, when he began farming, that the Ayrshire breed only could be an experienced farmer: he had probably had as much experience as most men in the room. He remembered a meeting which was held in Wigtown in honour of the late Hugh Hathorn, of Castlewigg. Lord Galloway was in the chair, and very properly praised that particular breed of cattle which formed the staple of the province from which he takes his title. He (Mr. Caird) also had a very great respect for these black cattle, but he ventured at that meeting to say, from his own short experience, that the Ayrshire cattle, with the sharp wedge which they possess, when once introduced to the district, would drive their way among all other breeds, the native breed included. Lord Galloway remarked, in a very good-humoured way, that the Ayrshires must have their horns cut off before they could act as a wedge in the way he had mentioned. It was a fact, however, that with the industry, energy, and perseverance exhibited by the dairy farmers of Galloway, the Ayrshires had done great things—the quality of the cheese produced had been gradually raised from Dunlop to Lancashire, and finally to Cheddar, which had largely increased the returns of the farmers, and had been a great increasing their expense. In another matter, the cultivation of the land by steam, agriculture had made a great improvement. There were many physical impediments to its introduction into that county, and these would probably limit it to localities where there were large farms and many steadings. These steadings, it had a great effect in improving the product of the land, by increasing the workable depth of the soil, and thus increasing the crops, and enabling a man with less capital to conduct the operations of agriculture. He therefore looked forward with great confidence to the future prosperity of agriculture. He felt, after the experience of upwards of 30 years, and after an experience of 20 years of free trade, when they had seen all the gloomy foreboding by which that policy was accompanied—the fears that were held that British agriculture would be ruined by foreign competition—when they had seen these foreboddings and fears completely falsified, he felt there was no reason to entertain any alarm for the prosperity of British agriculture. The imports of grain so much apprehended had proved to be for the benefit not only of the consumer, but of the British agriculturist, who now used a great deal of foreign grain for the purpose of feeding his cattle; and, though there had been large imports of meat, cheese, and other food supplies from foreign countries, it was now becoming evident that the people of these countries themselves were themselves becoming prosperous, and were beginning to find that they could use up more of these commodities than hitherto they had been able to do. Therefore, the British farmer might feel assured that his products would always command a ready market.

Mr. Biggar (Chapelton) was sorry there were so few agriculturists present, but he begged to thank Mr. Caird for the very handsome manner in which he had proposed the toast. Agriculture was at once a healthy and retired branch of industry. Often after visiting on business some of the large and busy towns of England, where you can scarcely thread your way for smoke and fog, or hear the sound of your own voice for the constant roar and din of traffic, he had felt thankful to find himself again at home and find everything as quiet and peaceful as a Sabbath morn. It had been said that the great cities were supplied with their bone and sinew

by the agricultural districts, and he believed that to be true, but they also found that Scotchmen who had made fortunes in these cities had a hankering for farming in their own country, and brought large amounts of capital, but without much practical experience, to compete in taking farms with men who had little but experience to help them. After alluding to the scheme of the International Association for taking possession of all the land in the country and farming it by joint commission—in which event he did not think the Government would be troubled with the collection of much Income-tax from farms, and more steamships would be required, because he thought the greater part of our bread would have to come from abroad—he alluded to Mr. Caird's remark about the Ayrshire breed of cattle with their narrow shoulders driving out the Galloways. He had no doubt what Mr. Caird said was perfectly true, but not because the Ayrshires were wedge-shaped. He remembered a dairy farmer once telling him—"We can make more money at dairy farming than you Galloway farmers can do;" to which he replied—"I doubt that; you may pay higher rents, but I don't believe you live better; you dairy farmers can live on curds and whey, while we Galloway farmers like a piece of roast beef." It was a long street that had no turning, and he thought a change was not very far distant. He found that cheese was not bringing the same price in the market that it used to bring; beef and mutton, on the other hand, were increasing in value, and he hoped the time was not far distant when the Galloway breed of cattle would resume its old position in public favour.

Mr. CAIRD requested the indulgence of the meeting for a moment, because he had had the great misfortune to be misunderstood. Mr. Biggar had in the most proper, and he really thought excellent manner, stood up for the Galloway cattle. Long might he have plenty of roast beef. He was sure he could not have too much of it. He (Mr. Caird) had not a word to say against the Galloway cattle, but simply told an anecdote about himself as a young man beginning farming many years ago. Before coming there their worthy Chairman had put into his hands an excellent letter published by his grandfather in 1811, describing the state of agriculture in the Stewartry for the preceding 90 years. Now, with regard to Galloway cattle, he thought Mr. Biggar would confess that a change had taken place in the value of that breed of cattle as well as in the value of Ayrshire produce. In the letter referred to, Mr. Maxwell mentioned that a Mr. Anthony M'Kie of Netherlaw sold at the Bridgend of Dumfries, in 1736, five score of 5-year-old Galloway cattle in good condition to an Englishman for £2 a-piece. He (Mr. Caird) wished to know if his friend Mr. Biggar would not like to get more than ten times the money for the same kind of stock? So conscious was he of the great increase in the value of cattle, that in his argument he had gone on to show that in this west country, with the abundance of grass and turnips, their great business was the growth of beef, cheese, and butter, rather than the cultivation of corn, which could be brought from abroad.

Notices of Books.

The History of the Improved Shorthorn or Durham Cattle, and of the Kirklevington Herd: *from the Notes of the late Thomas Bates, with a Memoir.* By Thomas Bell, of Brockton House, Eccleshall, Staffordshire. R. Redpath, *North of England Farmer* Office, Newcastle-upon-Tyne.

There were capital herds of shorthorned cattle in the Teeswater district long before the veterans of the Shorthorn Herd Book received their names, and any one who should collect the scattered notes and anecdotes, and even the gossip, of the pre-herd-book period was sure to command the large audience who are now interested in the fortunes of what was once little more than a local breed. Mr. Bell, the author of this little volume, states that Mr. Bates, of Kirklevington, had intended to make such a collection and write a history of this kind, but, he adds,—

"Mr. Bates' time was so much occupied with his herd, and in receiving and paying visits, generally in connection with Shorthorns, that he made little progress with his history, and he never reduced it into any regular form. My connection with Mr. Bates brought me into constant conversation with him, and I was familiar with all the transactions relating to his own herd, and was generally present both at sales of cattle and at the times he was talking of Shorthorns. From these advantages, I had long been familiar with all the facts stated, and events referred to by Mr. Bates, and, indeed, he often asked me to write the intended history from his dictation."

The object which Mr. Bell has had in view throughout the preparation of his book is declared by himself to have been—*1st*, to give Mr. Bates' own statements relating to breeding as nearly as possible as they were written from his dictation; *2d*, to state such facts as he had himself collected, to support Mr. Bates' statements; and 3*d*—

"To give some details to prove what the Kirklevington herd really was, and what it has been, and now is, that Shorthorn breeders may all see how far Mr. Bates's opinions and predictions have been justified by the experience of above 20 years since his death."

The result is a chatty and agreeable volume, full of anecdote and gossip, with occasional weightier letters, chapters, judgments, chiefly the production of the veteran breeder, who to his many other accomplishments added that of clever literary composition.

From such a collection of fragments as has been thus accomplished, it is hard to select passages for illustrative extract: we take, however, the following pieces, naming the authorities from whom they are quoted:—

In-and-in Breeding.—"The great obstacle to the improvement of domestic animals seems to have arisen from a common prevailing idea amongst breeders, that no bull should be used in the same herd more than three years, and no tup more than two; because (say they) if used longer the breed will be too near akin, the produce will be tender, diminutive, and liable to disorders; some have imbibed the prejudice so far as to think it irreligious; and if they were by chance in possession of the best breed in the island, would by no means put a male and female together that had the same sire, or were out of the same dam. But, fortunately for the public, there have been men, in different lines of breeding, whose enlarged minds were not to be bound by vulgar prejudice, or long established modes, and who have proved by many years' experience that such notions are without any foundation.

"'Mr. Bakewell has not had a cross (from any breed that his own) for upwards of 20 years; his best stock have been bred by the nearest affinities; yet they have not decreased in size, neither are they less hardy or more liable to disorders; but, on the contrary, have kept in a progressive state of improvement.

"'This mode has also been frequently practised in breeding the best dogs and game-cocks. A certain gentleman, who produced the best pointers in the North of England for shooting, never bred from any other than his own, because, he said, he could not find better to cross them with; and I am informed, from good authority, that a breeder of game-cocks, who was very successful, never would allow his breed to be contaminated by crossing with others, and to this precaution he attributed all his superiority.

"'But one of the most conclusive arguments that crossing and changing is not necessary to secure size, hardiness, &c., is the breed of wild cattle in Chillingham Park, in the county of Northumberland. It is well known these cattle have been confined in this park for several hundred years, without any intermixture; and are, perhaps, the purest breed of cattle of any in the kingdom. From their situation and uncontrolled state, they must indisputably have bred from the nearest affinities in every possible degree; yet we find these cattle exceedingly hardy, healthy, and well formed, and their size, as well as colour, and many other particulars and peculiarities, the same as they were 500 years since.

"From these instances it appears there can be no danger in breeding by the nearest affinities, provided they are possessed in a superior degree of the qualities we wish to acquire; but if not possessed of these, then we ought to procure such of the same kind as have, in the most eminent degree, the valuable properties we think our own deficient in. It is certainly from the best males and females that best breeds can be obtained or preserved.' *George Culley.*

Mr. Bell adds:—

"In the following pages I hope to point out how Mr. Bates, from his youth to and connection with Mr. George Culley, became imbued with his spirit and maxims, and how he succeeded in realising all his anticipations respecting the breeding of cattle and the improvement of the Shorthorn breed."

Portraits of Live Stock.—"A painter, without principle, may make the worst of animals to be all perfection to appearance on canvas, when the animal itself is the very reverse of anything good whatever, and only the result of breed breeding, which to the eye of a real judge shows the deficiency to be altogether the more glaring." *T. Bates.*

Let us add to this, that the portraits (lithographed) with which Mr. Bell illustrates his volume are failures, as we undertake to say nearly all cattle portraits, except those based on photography, have been.

It is, unfortunately, considered in the gossiping character of Mr. Bell's performance that he has inserted a silly letter on the conduct of the late Lord Ducie at the Kirklevington sale, which owed so much to his lordship's enterprise and pluck, and it appears that Mr. Jonas Webb was associated with his lordship in the transaction referred to. The writer never thought that any English nobleman, much less one of Lord Ducie's character, could be a party, &c., &c.; he had alway looked upon Mr. Webb as a man who would not lend himself, &c., &c.; nevertheless, with Mr. Bell's permission I will tell a story against myself. I was, unfortunately, concerned in the sale of all the other anecdotes in this volume are equally trustworthy, then nine-tenths of its lines are trash.

Farm Memoranda.

THE YARMOUTH WORKHOUSE LAND.—Having for a long period taken your paper, and read it weekly with increasing attention, I send you a report of the doings of the Workhouse Land Committee, which has appeared in the *Yarmouth Independent*, and which may or may not be of interest. The land in cultivation is about 5 acres. We had this year, on about 1¼ acre, 8500 Drumhead Cabbages and Savoys. I have, this day, sold 2500 of the Cabbages for £5 per 1000, reserving the remainder, with the Savoys, for the use of the workhouse. The Cabbages would be worth more for consumption in the workhouse, but, even at wholesale, you will agree that it is a paying crop. *John L. Cufisude, Great Yarmouth, Sept.* 16.

"The Workhouse (Yarmouth) Land Committee report that the sea-sand and sea-beach enclosed by the workhouse walls having been in a comparatively short period of time converted, by the admixture of river mud, an infinitesimal amount of clay and marl, and heavy manuring, into land capable of growing superior crops of roots and vegetables, the time has arrived when it may be desirable, for the information of the guardians, the rate-payers, and the poorer cultivators of small gardens in this neighbourhood, the mode and course of cultivation in practice; and which resulted in the first prizes being given at the late horticultural show held in the Park on August 31, to the Potatos, the Cabbages and Savoys, and the kitchen Apples produced on the land. The guardians cultivate root crops and green crops of the most exhaustive kind on the land, and aim at producing three crops on the same portion of the land in every two years. To begin with Beet, which is grown exclusively for sale to townspeople, and carted away by the purchasers. The guardians manure very highly for this crop, with manure purchased in the town. The manure is of inferior quality, being made from lean cattle and mixed with sand, but no better is to be had. The Beet sells readily at from 8*s.* to 9*s.* per 1000. Last year's produce was at the rate of about 32 tons an acre, and was of very fine quality. Potatos are the next crop. The guardians manure for Potatos with the manure made at the workhouse exclusively, and have been successful for many years past. Although there is a portion of sand in this manure (and sand is not desired for the workhouse land) the manure is valuable from causing humus in the soil—a substance essentially necessary to vegetation, and usually observable in old gardens, giving the dark colour to the land. Vetches succeed Potatos, and are planted as soon as the land can be prepared for the purpose. No manure is used for this crop. The Vetches in 1871 yielded from 12 to 24 tons per rod, and are in great demand. Cabbages and Savoys follow, the land having been first heavily manured with purchased manure. The guardians having taken the first prize for Cabbages and Savoys, and for Potatos, and averaging little more than 2*t* inches in depth (of more or less good quality) resting on sea-beach, the climate not very favourable, and in an exposed situation, the Workhouse Land Committee introduce in this report the mode of cultivating the land, as the exhibitors were many from the adjacent districts in Norfolk and Suffolk, and elsewhere, it is hoped that the hints offered may prove advantageous to small occupiers. The guardians will keep the land preserved, and used to grow prize vegetables, and this report speaks only of general crops. The course pursued, however, is the result of observations and experiments. The guardians make a great point of having the Potato seed of the best kind. The variety in use must be early, or medium-early, so that Vetches may be planted in September; and, if that were not so, the guardians would plant similar varieties in order to secure a fine healthy growth, good seed crop, and the variety almost refusing to take disease. As these were the prize takers, the guardians need not further enlarge on the size, beauty, and quality of the tubers; and as to the produce, four sacks his year produced, on the first lifting, and without going a second time over the land, 79 sacks of Potatos into the warehouse, of fine quality, and fit for consumption. The guardians planted the sets (Potatos) as they were when boiled, about the size of small hen's eggs, and part cut portions of Potatos (whole sets are preferable). These sets were planted in trenches cut by the spade up to a line, to the depth of about 6 inches, the bottom of the trench being then slightly flattened, so that the sets lay on a level surface, with the view to prevent drainage. The top of the Potato when set would be about 7 inches from the level of the land. Manure, artificial, was applied lightly on lands of deeper and better quality of soil resting on clay or similar substratums, it is the better plan to dibble or plant in a hole made by a stick, so as to secure drainage; but the guardians have too little depth of soil and too much drainage at present. As soon as the Potatos appear above ground they should be kept clean, all weeds destroyed, and hoed until the growth of the haulm prevents further cultivation. The committee recommend that on land such as described the crop should be grown upon the flat, and the land should not be ridged. It is believed that Potatos so grown are far less likely to take disease than those ridged up. The guardians plant the sets in rows, 3 feet from row to row, and 16 inches apart in the trenches. With regard to manuring the Potatos, it is a vexed question, but the committee are assured that at any rate on such land as the guardians have, the rubbish, and the scrapings and rakings of gardens will be found beneficial. The guardians this season planted, in addition to the Dalmahoy, the Prince of Wales and Dawe's Matchless Kidney varieties, and a round variety. All these varieties were fully ripened and warehoused by September 5, and this warehousing would have been accomplished some days earlier, but from lack of labourers. The committee report that the produce of an acre and a quarter of land, 151 sacks of good Potatos, free from disease, have been warehoused. About 11 sacks of seed Potatos, on the whole, were planted. With reference to the disease, Dawe's Matchless suffered far the most, next Prince of Wales, then Fortyfold, and Dalmahoy comparatively hardly touched. The varieties were planted on adjoining patches of land. The guardians also cultivate Celery, a small quantity of Onions, and a large quantity of Leeks, for improving and flavouring the soup supplied to the inmates. The guardians formerly cultivated Onions only, being unaware of the superiority of Leeks as

a general crop. The committee report that Lecks (a certain crop) are far superior for the above purpose to Onions (a very uncertain crop)—that one well-grown Leek, the green part being used as well as the blanched, will go as far as two well-grown Onions, and Leeks thicken and greatly add to the texture of the soup. The Leek should be cultivated much after the manner of Celery, well manured, and watered in dry weather, when, and after, being planted out; and blanched in due season. The Leek defies frost. Occupiers of small gardens may greatly improve their land by cultivating Leeks; as, from the manuring, trenching, and exposure, such portions of the land as have been used for this crop will be much increased in fertility, and, in time, the whole garden, if so planted, improved. The Leek is far less cultivated in this neighbourhood than the esculent deserves. Well-grown Leeks would probably sell well in the market. Cabbages and Savoys to succeed on the workhouse land, must be planted early, and manured heavily with purchased manure. The prize Cabbages and Savoys were far superior to those shown by any competitors. They were not forced or grown for show, and there are plenty of similarly fine specimens on the land. They weighed respectively about 11 lb. or 12 lb. per Cabbage or Savoy. The seed was placed in the seed-bed on March 3, and the plants set out on the land on June 9, in rows 3 feet row from row, on a plan about 1 foot by 1 foot 6 inches. Kitchen Apples.—The Lord Suffield is a splendid variety, and took 1st prize. A free grower of the largest size, in season from August to Christmas, and producing freely at two years old. The prize Apples were trees that were planted in the workhouse land on October 31, 1870, scarcely then a foot and a half high; price of each was 9d. They were planted at about the depth they had stood in the nursery, in sandy loam, and, as they are to be dotted carefully extended on all sides, and afterwards mulched with some long manure, to protect them during the winter. The trees should be bush trees on the Paradise stock. The committee would observe that although the workhouse land has been reclaimed at considerable cost, it has already proved a successful speculation, and is yearly increasing in value. Moreover, the now well cultivated inclosure is not only ornamental to the north side of the town, but affords airing grounds for the imbeciles, and enables the guardians to afford instruction to the boy inmates in agriculture and horticulture. The boys are taught to dig and to cultivate land, quite remunerative likely to be of advantage in after life. The committee, in conclusion, report that they are fully sensible of the care and attention given by the schoolmaster and the industrial trainer to the outdoor education of the boys; and to Charles Rushmer's successful cultivation of the workhouse land."

Horton Kirby, Kent.—Messrs. Robert and John Russell, of Horton Kirby, have enabled me to give an example of the farming of the upland chalk. Their farm, including 300 acres of wood on the hill and 30 of pasture, consists of 2500 acres, lying partly in the shallow valley of the Darent. It commences on the south side of the railway viaduct at Farnhigham Road station, and ascends the hill gradually in a narrow belt that stretches from the river side to Kingsdown, at a distance of five miles. The lower half of the farm is adapted for the fattening of sheep in winter; the upper portion is only favourable for grazing at other seasons.

Soil.—The land in the valley is deep, and due to the rock, without flints. In gradually ascending the hill, the thin loamy covering merges into a heavier soil, with flints, and the land on the hill consists of from 2 to 20 feet of stiff clay: 450 acres on this part of the farm have been drained at 8 rods apart. The drains were first ploughed to a depth of 1 foot, then dug 2 feet deeper and 1 foot wide, and filled in with flints. At 8 rods apart, every 20 rods of draining completed an acre, and took all the flints that could be collected on an acre: the cost was 5*d.* a rod for digging, and 5*d.* for gathering flints and filling in, or 10*s.* 6*d.* an acre, exclusive of labour. The flints sometimes to be collected in tanks, which have reduced the cost of carrying water to the flock.

There is one large field of 450 acres. Generally the farm is laid out in fields of 20 acres, divided by narrow quickset fences. On a sheep farm the yard accommodation need not be great. There are outlying barns and yards, a homestead at Kingsdown, and another near the river. To the latter spot a large quantity of Wheat is brought, in order that about a thousand pounds' worth of straw may be dispatched annually to the London markets. After harvest, a grand row of stacks (Russell Row) marks the site of this extensive holding.

Cropping and Cultivation.—On so large a farm, where the soil passes gradually from a light chalk into a stiff clay, various means of arriving at the same end must be adopted to suit village requirements. I shall, however, simplify my account of the fallowing for roots by giving the two systems that prevail—the one on the heavy, the other on the light land. The three courses of cropping to be noticed are:—

A 4-course rotation on light land: 1, roots; 2, Barley; 3, seeds (Trefoil and red Clover); 4, Wheat.

A 6-course rotation, on heavier land, obtained by extending the former succession, with Peas and Wheat in the 5th and 6th years. And a *7-course rotation, on the strongest and best land*, viz.: 1, roots (Mangel and Swedes); 2, Oats; 3, seeds; 4, Wheat; 5, Beans (with Turnips between the rows); 6, Wheat; 7, Barley.

Tillage.—The lighter Turnip land is broadshared with the Kentish plough after harvest, ploughed afterwards with three horses, and merely harrowed in spring and drilled on the stale autumn-ploughed furrow, at 12 inches apart. The deeper light land is steam-cultivated in spring, instead of being dressed by horses, and in other respects is treated in the same way. On the light chalks moisture is retained by this process. The cleaning is effected by horse-hoeing. On December 1 all the heavy land in preparation for Swedes and Mangel was in ridges, 27 inches apart, the stubbles having been ploughed immediately after harvest. 8 inches deep, and the land ridged with the double-breasted plough. Early in spring the ridges will be split after sowing 5 cwt. per acre of superphosphate of lime broadcast; they will be levelled with a 1-horse roll and drilled with Mangel and Swedes early in April, with the Suffolk corn-drill, covering three ridges and depting over 12 acres a day. The work is arranged so that the splitting and drilling are completed on the same day: 5 lb. of Mangel and a quart of Swedes are mixed with a bushel of dry sawdust, enabling them to be drilled together. A crop of Swedes or Mangel is tolerably secure. Supposing a plant of each to be obtained, sufficient Swedes would be left, in singling, to manure the land by folding them after the removal of the Mangel.

Peas.—The Wheat stubble is dunged, ploughed, and 3 bush. of seeds drilled, at 27 inches, in November. The land is horse-hoed three times during the spring and sown broadcast with a mixture of Rape and Turnip—2 quarts of seeds, containing half-a-pint of Turnip seed. The mixed crop is folded after harvest by sheep, changed to and from the Sainfoin rowens. On the heavy land Beans are substituted for Peas; but the same green crop is sown, and is afterwards folded, and thus on all the soils an excellent tilth is obtained for the Wheat which follows. Peas for early podding, to be picked green, are drilled after Barley, about December 1, and are followed by white Turnips, after ploughing the land once.

Wheat.—The usual breadth is 500 acres; 3 bushel per acre of White Rough Chaff or Red Browick are drilled in October, after pressing the furrow with either a common presser, or by means of the wheel of a cart loaded on the side next the ploughed land. This is the custom in Kent; and, if the wheel answers the purpose as well as the presser, it has the advantage of having so many implements the less on the farm. Wheat is heavily rolled, and it seldom needs hoeing. With respect to the thick seeding common on the chalk, the crops of some young men—as well as the contents of their pockets—have been seriously diminished, when they have been induced to try experiments on a large scale by the gentlemen who recommend thin seeding, and do not farm on the chalk hills.

Barley.—Three bushels of Chevalier. Oats: one sack of black Tartarians. I may notice here the winter Barley, which is largely grown on the heavy land, and has proved exceedingly valuable under proper treatment. It is sown early in September (3 bush.), eaten off by fatting lambs in spring, up to May, and then allowed to stand for a corn crop. As an instance of the vigour of this plant, a field of winter Barley, eaten off in wet weather late in spring, and left in bad plight, yielded 7 qrs. 2 bush. through the weeks' drought followed the folding-off. It proves far more productive under the management described than when it is sown later and not eaten.

Sainfoin.—Eighty acres of the common sort is the usual breadth. It lies four years, and is then sown with Oats after one ploughing. The land is not ploughed and sown with winter Vetches, and after folding these the land is fallowed during the summer, and roots follow the year after. The two years' fallow cleans the land and destroys the wireworm which would trouble the after crops, though the first crop (Oats) generally escapes. Sainfoin can be repeated on the same land after 14 years. Trifolium may be repeated after four years, and red Clover after eight years. Rye-grass is omitted in the mixture of seeds, in consequence of the injury it does the Wheat crop.

The above has been the system followed by Wheat on the better land: according to a practice general in Kent on all good land, though formerly condemned as being "contrary to science." Wheat sometimes follows Oats on this farm, with good results; for example, if Turnips are eaten on the ground with oilcake, and the Oats follow the Sheep, the land not being in store for Clover, the Oats may be followed by Wheat, unmanured, after ploughing once. But it is a matter of practical observation that a good crop of corn of any kind cannot be grown on a Barley stubble.

Stock.—A flock of improved Hampshire Downs was established on this farm because, as I was told, they could not afford to keep two generations on a hill farm in the month of May. There is certainly no need to do so now, for on December 1, when I saw the lambs which were yeaned in February, their fleeces had been sold at 2*s.* 6*d.* each, and many of the best lambs then weighed from 9 to 10 stones.*

One flock of 440 ewes had reared 620 lambs. These are some of the home qualities of a flock that has taken prizes to the value of more than £550 since Messrs. Russell "went into" improved Hampshire Downs in 1854. There are 800 ewes. About half of the average crop of 1000 lambs is fattened in May, on Rape grown on the heavier land; the rest, except those required for stock, are fattened at a year old on the roots growing on the lighter land. These and the ewes are summered on seeds and Sainfoin rowens. When the root crop is an average one, 300 or 400 lambs are bought during the autumn for fattening; there is also a flock of 100 Kentish ewes, whose progeny (half-bred Cotswold) are fattened at a year old. On this system the seeds are chiefly grazed, and the Sainfoin is cut for hay; Pea-haulm is greatly relied on to save the haystacks in winter. The heavy land, which did not formerly get the benefit of sheep, and where winter folding would be injurious both to the land and to the sheep, is now made to carry the ewes and fatting lambs in spring, by means of late-sown Rape, winter Barley, and Trefoil, and by sowing a large breadth of Mangel and Trifolium, which are eaten together by bringing the roots to the fold.

The flock is close-folded on the fallows, as usual on the Downs, in order to prevent "blown," to which the ewes are particularly liable when on Rape in gusty weather with a west wind, they are fed with dry food before leaving their fold. Stock sheep, which are not fed with cake, are less liable to "blow" when they enter the Rape ear y in the morning, before they are hungry.

Cattle.—Thirty cows are kept for suckling. Pigs: about 100 are bred on the farm, and are fattened to 20 or 30 stones.

Horses and Steam Tillage.—There are 60 horses, and this is one of the few farms where the common iron plough is used with two and three horses, instead of the Kentish plough, and three or four horses. The steam tillage consists of about 200 acres ploughed immediately after harvest and 100 acres cultivated in spring.

Cake and Corn Bill and Manures.—The following are the usual payments annually in this department:—Cake, £1000; London dung, £1000 (about three-fifths of the sold); superphosphate of lime and blood manure, £1000. The produce of about 100 acres of Peas, Beans and winter Barley, besides all tail corn, is also consumed on the farm. Nitrate of soda must be called a mischievous manure on this farm, and generally in the district. It causes great luxuriance in the corn, and an inevitable blight before harvest. Even a piece of late corn, spurred up by a light dressing, will certainly be blighted at harvest. *Mr. Evershed, in the Journal of the Bath and West of England and Southern Counties Agricultural Society.*

* Eight sheep, at 23 months old, realised at the Smithfield Club Show, 1870:—

Seven sheep	.. .. ..	..	£56 0 0
One sheep	.. .. ..	..	6 10 0
Value of the second prize	.. ..	..	15 0 0
Value of the third prize	.. ..	..	5 0 0
			£82 10 0

The average annual receipts for "mutton and wool" during the last 10 years, after deducting the cost of cake and shepherd, have been about £1600.

This year some of the fat tegs, under a year old, have been sold (January 27, 1871) at £4 each.

Miscellaneous.

The Foot-and-Mouth Disease in America.—The following report on the disease as it now prevails in the State of New York was recently presented to the United States Board of Health by the Sanitary Inspector, Mr. Morris:—

"In this State the instructions to the Assistant-Commissioners have been explicit, from the first knowledge of its presence, both in cattle, as to giving the most minute attention to the symptoms which may be found sick, and at the same time to prevent the sending of milk to the city from the dairies where the cows are so affected, and as to liberal use of disinfectants in cars and yards. These precautions, it was thought, might prevent the further spread of this disease among cattle, and at the same time protect the public health in the use of unwholesome milk. This has been done to a very considerable extent, as informed, by the Assistant-Commissioners, by Dr. Gurnsey in Dutchess County, and by Mr. Dayton in Queen's County. In Dutchess County the doctor informs me he has already quarantined over 2,000 head of cattle, a large proportion of which were dairy cows. At Albany, being a central point for the distribution of stock eastward, the Assistant-Commissioner, Dr. Stimson, has endeavoured to prevent the further spread with great care in watching and quarantining whatever could be discovered passing through it. In our own cattle-yards this disease has been discovered among beef cattle and cows on sale for dairy purposes. The rule has been to allow animals to be killed unless they were badly diseased, as there is as yet no evidence which proves that their flesh is unhealthy as human food; but cows or other cattle are not allowed to leave quarantine to continue disease in other herds after they have entirely recovered. Advices received this day inform me that the disease is subsiding in Dutchess County. No milk is allowed to be sent from dairy cows suffering with the disease for 30 days, affording ample time for complete recovery. The symptoms of this disease, as given by Professor Low, of Cornell University, are so obvious, that any person may be able to recognise it at once. An infected animal appears dull and listless for a day or two, with loss of appetite, and in cows, a falling off in the quantity of milk; hot, dry mouth; grinding of teeth and drooling; tenderness of the udder, teats, and feet, producing a lameness in walking; frequent shaking of the feet, as if to get rid of some irritating matter; on the second or third day abundant frothing at the mouth, smacking of lips, and tongue-lameness, and the formation of blisters of various sizes up to an inch or more across on the mouth, udder, and teats, and between the hoofs. In one or two days more these blisters burst, leaving raw sores and shreds of loose skin inside the upper lip, on the roof of the mouth, the tongue, on the teats, and between

the hoofs. These discharge an irritating fluid for some time, then scab over and heal up, in favourable cases, in from 10 to 15 days. The sick beasts should be well nourished with soft mashes and gruels. Cooling, but not purgative medicines should be given, and the sores washed with some mild carbolic acid preparation, or with a weak solution of sulphate of zinc (white vitriol). The discharges from the mouth, sores and scabs from the udder, teats, and feet, are the sources of infection, therefore the stable, yards, and fences, where sick cattle are kept, should be constantly cleansed and disinfected with heavy oil of coal tar and lime-washing."

The Week's Work.

SEPTEMBER 30.—*Corn Harvest* is seldom finished in late districts of the North, and in elevated and late districts of Wales, before the beginning of October, and in late seasons much corn is often abroad towards its close. The current season has been favourable to most late backlying crops, so that corn harvest is now concluded with very few exceptions.

Michaelmas Entries.—Changes of tenants are not frequent in England, but when they do take place entries to farms at this season is favourable for carrying out improvements of a permanent character, as drainage, breaking up poor pasture land to aeration, and such like. And even when no change takes place, but where the yearly tenancy runs from Michaelmas to Michaelmas, it is a favourable period for giving up old plans of farming and entering upon new. The farmer's year, too, very generally begins with October, which involves the setting of accounts and the balance of the books. Where old-fashioned tenants give up, it is not so easy selling the dead and live stock to the incoming tenant as it was in the olden time, the interest of the latter being to avoid purchasing what is out of date unless at a price sufficiently low to enable him to sell without loss. It may, therefore, be advisable for the outgoing tenant to sell by auction, but in many cases, if not the majority, the old plan of "creeping in at little money" is still the rule, the incoming tenant taking the stock of his predecessor at a lump sum. There are, however, more objections to this plan than formerly, for tenants who enter with limited capital have it in their power in most places to hire contractors to do both field and barn work, and to let their Turnips and strawyards to graziers. On the contrary, nothing is more expensive than teams and implements out of date, or more profitless than stock that will not pay their keep. It is seldom advisable, however, to start with the most expensive live stock and implements, such being in too many instances the reverse of profitable. When changes are determined on, it requires the exercise of the highest skill to purchase what will prove most profitable under the peculiar management of the purchaser. Much depends upon the state the land is in.

Farm Servants in England very frequently change places at this term, and those who do not change renew their terms. Much has recently been said relative to the management of this class, more perhaps than is consistent with the liberties we enjoy and exercise. There is not a worse plan than to treat servants with a morbid philanthropy, as if they were continually at the mercy of their employers, for the first duty of the latter is to teach the former to stand upon their own feet, which all good servants never fail to do. That there are bad masters and bad servants is a totally different affair, and for either most philanthropic remedies are about the worst that can be prescribed; and yet the man who has neither head nor hands must live, but certainly not on the same terms as the others; and the farther we progress in improvement the more difficult will it be to reconcile the two extremes to the satisfaction of political economists. Our own plan has always been to have nothing to do with bad servants, employing only good hands, who can take care of themselves and families. They cost more wages, it is true, but they are cheaper in the end, more ways than one.

Wheat Sowing continue as root crops are removed and the land got ready. Pickle and drill as directed last month, using rather more seed. October was once counted Wheat seed-time, but thorough drainage, and the growth of root crops, Beans, and Peas on land that used to lare followed, is extending the sowing over a greater length of time. Thus far the season has been favourable for getting Clover, Bean, and Pea stubble ready for early seeding, but it may be otherwise in many places with the harvesting of root crops in the South, should the weather continue favourable and growing; but the threatening aspect of an early winter may induce the early harvesting of root crops also. The season has been exceptional in many respects, so that the prudent course is to watch the weather, and store the Potatos, Carrots, Mangels, Kohl Rabi, and Swedes in time, no less for their safety than for the getting of the land ploughed and the Wheat sown with a favourable season. Avoid working in wet weather, as ponching land after roots does immense harm. In fine weather the best plan is to keep the harrows and seed-drill close up to the plough. In Ireland, where a great breadth of Potatos is grown in lazy-beds, the tops are pulled by the hand and removed, when the Wheat is sown broadcast, and covered by the operation of digging the Potatos. A good braird is generally obtained, but at the expense of a considerable sacrifice of seed, *i. e.*, the land requires to be thickly seeded, as much of it is buried too deep. The more economical plan would be to harrow the land after digging the Potatos, and then either dibble or drill in the seed.

Live Stock.—A very serious loss attends the keeping of stock too long at grass, more especially our improved breeds. Even in fine seasons in the South cattle of every kind should have a dry bed in a house to eat from in the pasture become wet, for when caught lying on a wet bed by a frosty night or morning, the consequences, in the form of inflammatory attacks, black leg, braxy, and so on, are often fatal. Even the hardy Kylo looks out for shelter in his native glen, with a dry bed of long heath; but our lowland herds have no such choice. Sheep folding on Rape, Coleseed, or Turnips, attend to; if the green tops of the latter are consumed more chaff and ground corn will be required than when the roots only are eaten in troughs. In Sussex, Hants, Dorset, and Devon this is early lambing season, and if Italian Rye-grass and Clover seeds are insufficient for ewes, as will be the case in too many instances this year, Belgian Carrot is preferable to Turnips. Put the rams to breeding ewes for lambing the latter week in February or beginning of March. In our highland sheepwalks flocks begin moving down towards their winter quarters in the lowlands. *W. B.*

Notices to Correspondents.

CABBAGE SEED: *E.* writes as follows:—"Will any one be so good as to state the average amount of good seed which is produced from a good Drumhead Cabbage, and from a good Mangel root well protected." [A quarter of a pound of seed might be taken from a plant of Drumhead Cabbage; and half a pound from a plant of Mangel Wurzel, if grown exceptionally well. The seed tends upon those stems as well as upon the space in which to grow. In some seasons the plants will grow as large again as in others. Such a question is very difficult to answer, and any reply might be misleading, so much have circumstances to do with such matters.]

FLAX STRAW: *Cor.* In answer to your question, on behalf of one of the leading farmers near Carlisle, who has a small field of flax grown as an experiment, we are unable to name a likely market for the straw when harvested, put on rail there. Probably the notice of his case may procure him a customer.

Markets.

MARK LANE.

MONDAY, Sept. 25.

There was a moderate supply of English Wheat to this morning's market, but to effect sales it was necessary to submit to a reduction of 1*s.* per qr. upon the prices of this day se'nnight. Foreign was held firmly for last week's rates, at which a fair amount of business was transacted. For Barley there was a good demand, at the extreme prices of this day week. Beans and Peans were unchanged in value. Oats were rather dearer. The Flour trade was steady, without change. The few sales of new white Mustard were made at 9*s.* 6*d.* per bushel.

WEDNESDAY, Sept. 27.

A quiet feeling pervaded the Corn Exchange to-day. The supplies of both English and foreign Wheat were tolerably good; transactions in both red and white produce were restricted, but prices remained without any material variation. For Barley a fair inquiry prevailed, at fully previous quotations. Malt was purchased cautiously, at about late rates. Oats were in large supply and limited demand, on former terms. Beans were not active, but prices ruled firm. Peas sold quietly, at previous prices. Flour was dull, but unaltered in value.

LIVERPOOL, Sept. 26.—To-day's market was well attended, and a good consumptive business was done in red American Wheat, at an improvement of 2*d.* per cental on the week. White Wheat was held for an advance of 1*d.* to 2*d.* per cental. Prime Flour realised 6*d.* per barrel and 1*s.* per sack more money. Beans are 1*s.* per qr. cheaper. Peas maintained the improvement of Friday. Indian Corn is dull, at a reduction of fully 6*d.* per qr. on the week.

METROPOLITAN CATTLE MARKET.

MONDAY, Sept. 25.

We have a considerable increase in the number of Beasts, but the average quality is not very good; consequently choicest qualities are not much lower. There are a few more Sheep, and the weight of mutton is much larger; prices are lower, and it is difficult to effect a clearance—indeed, this is not likely to be accomplished. Calves are not so plentiful as of late; the demand also has decreased; prices on the average are lower. Our foreign supply consists of 3350 Beasts, 10,970 Sheep, 99 Calves, and 10 Pigs: from Ireland there are 150 Beasts; and 2020 from the Midland and Home Counties.

Beasts, 5520; Sheep and Lambs, 22,520; Calves, 139; Pigs, 154.

THURSDAY, Sept. 28.

The number of English Beasts on offer is much smaller than last Thursday, but there are a few more foreign; trade is excessively dull, and a clearance cannot be effected, although lower prices are submitted to. The total number of Sheep is larger than last week, but the excess is in foreign; there are very few buyers at market, and the small amount of business transacted is on lower terms. Calves are also lower. Our foreign supply consists of 430 Beasts, 8000 Sheep, and 179 Calves.

HOPS.

BOROUGH MARKET, Sept. 28.

Messrs. Pattenden & Smith report an active demand for all descriptions, prices being about 10*s.* per cwt. dearer since Monday. There is already a great scarcity of choice Hops, and the crops generally fall very short of what was anticipated.

SEED MARKET.

The position of the seed trade shows but little alteration since the date of our last report. All descriptions of Clover seeds continue to be almost quite neglected. Trefoils are firm, without, however, much business passing. Trifolium meets with a retail demand, at the low rates now current. Winter Tares are cheaper, and are in limited request. New Rapeseed experiences a good inquiry, at the recent advance. Mustard seed is without alteration. There is a good trade doing in seed Wheats for France. Sowing Rye is scarce, and must be quoted 11*s.* per qr. dearer. Blue Peas meet with a ready sale.

Works on Botany, by Dr. Lindley.

SCHOOL BOTANY; OR, THE RUDIMENTS OF BOTANICAL SCIENCE. In One Volume, 8vo, half bound, with 400 Illustrations, price 9*s.* 6*d.*

DESCRIPTIVE BOTANY; OR, THE ART OF DESCRIBING PLANTS correctly, in Scientific Language, for Self Instruction and the Use of Schools. Price 12*s.*

MEDICAL and ECONOMICAL BOTANY; or An Account of the Principal Plants employed in Medicine or Domestic Economy. In 1 vol. 8vo, with numerous Woodcuts, price 7*s.* 6*d.*

THE ELEMENTS of BOTANY, STRUCTURAL AND PHYSIOLOGICAL. With a Glossary of Technical Terms, and numerous Illustrations. 12*s.* cloth.
This completes the series of Elementary Botanical Works by Professor LINDLEY, of which "SCHOOL BOTANY" and "Vegetable Kingdom," form the other parts.
The first two parts of the ELEMENTS OF BOTANY, comprising Structural and Physiological Botany, and a Glossary of Technical Terms, are published in one octavo volume, price 12*s.*
The third part, containing a complete Botanical Glossary for Medical and other Students who have made themselves acquainted with the Author's "School Botany."
N.B. The Glossary may be had separately, price 5*s.*

THE VEGETABLE KINGDOM; OR, THE STRUCTURE, CLASSIFICATION, and USES of PLANTS, illustrated upon the Natural System. In One Volume, 8vo, cloth, price 36*s.*, with upwards of 500 Illustrations.

EXTRACT FROM THE AUTHOR'S PREFACE.
"The Vegetable Kingdom contains, among a large quantity of plants of no importance, all that the student may wish to acquire previously to medicine, the arts, or in the many branches of domestic economy. The principal part of the book which can be learnt from practice in Europe under the notice of students, or which, from their great importance, ought to be among the earliest objects of study, are mentioned in the following pages, where they are arranged in the manner proposed in the VEGETABLE KINGDOM" of the author, with the sequences of character deprived from one to the other, when it was believed that the convenience of younger students would be consulted by doing so. It is to be hoped that this selection will be found to have been made in such a way that all teachers who possess reasonably extensive means of illustrating their lectures, and all Botanic Gardens, may furnish the larger part of the species which are mentioned. A small collection will suffice for the beginner. A greater work would have been beyond the reach of the majority of purchasers; and secondly, because experience shows us that those who have a large collection before them are unable to bring together to concentrate their attention, in the first instance, upon a limited number of objects."
London: BRADBURY, EVANS, AND CO., 11, Bouverie Street, E.C.

THE NEW METHOD of GROWING FRUIT and FLOWERS. By the Rev. JOHN CHARLESWORTH, Southcrce, Brandon; being a practical combination of Vinery, Pine-pit, Hothouse and Conservatory, as now worked in a New House erected for the purpose at Brandon. Third Edition, price 2*s.* 6*d.*, or 30 stamps to the
"Journal of Horticulture" Office, 171, Fleet Street; or to the Author.

THE FLORIST and POMOLOGIST for OCTOBER (Price 1*s.*) contains a Coloured Portrait of PRINCESS BEATRICE; Illustrated Articles on Palms, Begonias, Irises; Figures of the new Chrysanthemum Mrs. Dix; the new cut Pelargoniums, No. V.; Mr. Challis and Mr. Webster on Strawberries; The Dahlia and Fruit Shows; Mr. Turner's Seedlings; Mr. Tillery on Fuchsia Kicardtoni; Mr. Powell on Profitable Fruit Gardening; Mr. Williams on Bees; Novelties of the Season; Garden Gossip, &c. Published monthly at
Office, 4, Fleet Street, London, E.C.

THE GARDENER. Edited by DAVID THOMSON, Author of "Handy Book of the Flower Garden," &c.

CHRISTMAS QUINCEY, Seedsman, &c., Peterborough.

Orchids.

JAMES BROOKE AND CO. beg to invite attention to their splendid stock of ORCHIDS, adapted for supplying a regular succession of the most exquisite cut flowers. The singular beauty, and the long continuance of cut Orchid blooms, recommend them as better suited than any others for high-class ornamental purposes, including use by ladies; and there is no reason why a skilful gardener should not have abundance of them almost always at command, and with little more trouble than is required for select Dutch Bulbs.

Messrs. BROOKE AND CO.'s stock includes all the best sorts for cutting, the Bulbs are well matured, and they are certain to yield plenty of blossom.

16 and 18, Victoria Street, Manchester. Nurseries: Fairfield, near Manchester

MAURICE YOUNG, Milford Nurseries, near Godalming, Surrey.

An Inspection of the Stock is respectfully invited.
MAURICE YOUNG, Milford Nurseries, near Godalming, Surrey.

PLANTING SEASON.

ANTHONY WATERER

INVITES THE ATTENTION OF INTENDING PLANTERS TO

THE FOLLOWING SUMMARY OF HIS STOCK,

WHICH MAY BE SEEN GROWING IN HIS

NURSERY, at KNAP HILL, near WOKING, SURREY.

The Plants referred to are in the very best state for removal, every one, without exception, having been recently transplanted. Purchasers will find at Knap Hill the most extensive and varied assortment of EVERGREENS and ORNAMENTAL TREES of large size to be met with in any Nursery in the kingdom, the safe removal of which, if they are properly treated, is guaranteed. The advantage of from 20 to 30 years' growth may thus be secured at once, by selecting plants of the bulk and quality here referred to. An inspection of the Stock, which is earnestly solicited, will show that there is no exaggeration in these statements; and A. W. pledges himself that any one favouring him with a visit will find that both Plants and Prices will compare favourably with those of any other house of standing. The Railways now offer such facilities that goods can be sent from Woking Station to almost any other station in England or Scotland, without the expense of packing, and at through rates. Plants will be delivered in our own waggons within a radius of 30 miles of the Nursery, by agreement.

AMERICAN PLANTS.

American Plants are a most important feature at Knap Hill, upwards of 60 acres being devoted exclusively to their cultivation; there are borders miles in length, the plants being of all sizes from 2 feet to 8 or 10 feet high, and it is believed that the stock of Rhododendrons and American Plants generally, in the Knap Hill Nursery, far exceeds anything of its kind to be found elsewhere.

RHODODENDRONS.

The Rhododendrons will be supplied in quantities at the following rates. The plants, are, many of them, raised from layers, and are as sturdy, healthy and bushy as can be desired.

The ordinary PONTICUM, for game preserves, at £10 to £15 per 1000.

Varieties, for mixing, comprising white, pink, spotted, and other colours, from 50s. to 63s. per 100 and upwards.

Good named varieties, of all the most brilliant colours, from £5 to £10 per 100.

The best HARDY RHODODENDRONS known to A. W. will be supplied at from £15 to £20 per 100; 42s. to 60s. per dozen.

STANDARD RHODODENDRONS.

At Knap Hill will be found the largest number of the finest specimens to be met with in England. The large Standard Rhododendrons planted in Rotten Row during the last few years, were, with few exceptions, all from Knap Hill, where there are many still finer plants remaining. Ordinary sized Standard Rhododendrons will be met with in large numbers, and at fair prices.

HARDY AZALEAS.

HARDY AZALEAS, ordinary kinds, of mixed colours, at 30s. to 100s. per 100.

AZALEAS, all the finest varieties, at from 18s. to 30s. per dozen, and upwards.

Large and most magnificent AZALEAS, from 3 feet to 6 or 8 feet high, are grown at Knap Hill in great numbers.

KALMIA LATIFOLIA, good plants at £5 per 100; larger, 18s. to 42s. per dozen. Some very large specimens, 5 feet to 7 feet high.

HARDY HEATHS.—A selection of the finest and most popular kinds known, at from 30s. to 50s. per 100.

ANDROMEDAS, and all other AMERICAN PLANTS, will be found in large quantities.

The American Plants exhibited annually in the Royal Horticultural Gardens, South Kensington, are from ANTHONY WATERER.

HOLLIES.

Hollies alone occupy at Knap Hill many acres of land, and comprise thousands of Plants of all the finest variegated and green-leaved varieties, varying in height from 3 feet, to 5, 6, 8, 10, and 15 feet. These plants have been so constantly removed, that with fair play not one in a thousand would fail. It is perfectly true to state, that the stock of Hollies in this Nursery is not approached by anything of the kind in Europe.

GREEN HOLLIES, common kind, 3, 4, 5, 6, 7, 8, 10 to 15 ft. high. The

Yellow-berried,	Scotica,
Lanæfolia,	Hodgins',
Myrtle-leaved,	Shepherdii, &c.,

Are green-leaved Hollies, and are admittedly some of the most desirable and beautiful of Evergreens. A. W. has together thousands of these from 3 feet, to 5, 6, 8 and 12 feet high.

VARIEGATED HOLLIES, of the ordinary kinds, many thousands of splendid plants, from 3 feet, to 4, 5, 6 8, and 10 feet high.

WATERER'S HOLLY.—This handsomely marked variety originated at Knap Hill, and our plants of it are the admiration of all who see them. No adequate idea of their beauty can be formed without an inspection. There are hundreds grawn as Pyramids, from 3 feet, to 4, 5, and 6 feet high, and measuring from 12 to 15 feet in circumference; also as Standards, with fine symmetrical heads.

GOLDEN QUEEN HOLLY.—Large numbers of magnificent plants, from 3 feet, to 5, 6, and 8 feet high; also beautiful Standards of this handsome variety.

SILVER QUEEN HOLLY.—An immense number, from 3 feet, to 4, 5, 6, and 8 feet high.

WEEPING HOLLIES.—Splendid specimens, with 10 feet and 12 feet stems, and magnificent weeping heads, from 15 feet to 30 feet in circumference, and covered with berries.

CONIFERS.

Conifers are extensively grown, and the Stock comprises many of the finest specimens to be met with in Nurseries. The following are especially referred to:—

PICEA NOBILIS, 4, 5, 6, to 10 feet high.
" LASIOCARPA, 4, 5, to 10 feet high.
" MAGNIFICA, 3 to 5 feet high.
" NORDMANNIANA, 3 to 10 and 12 feet high.
" PINSAPO, 3 to 4, 5, 8 and 10 feet high.

All have been constantly removed, and our stock of these together, comprises hundreds of very fine specimens.

ABIES DOUGLASII, 5 to 10, and 12 feet high.
" ORIENTALIS, 3, 4, 5, to 10 feet high.
ARAUCARIAS, 4 feet to 8 or 10 feet high.
CEDRUS DEODARA, 8 feet to 12 and 14 feet high.
" ATLANTICA, 8 feet to 10 feet high.
CEDAR of LEBANON, 8 feet to 10 feet high.
CUPRESSUS LAWSONIANA, 6, 8, 10, to 12 feet high.
CHINESE JUNIPER, 4, 5, 6, 8, to 12 feet high.
THUJA AUREA, 3, 4, 5, to 6 feet high, 12 to 15 ft. in circumference.
" GIGANTEA, 6 feet to 10 feet high.
" LOBBII, 6 feet to 10 feet high.
THUJOPSIS BOREALIS, 4 feet to 8 feet high.

CONIFERS.

WELLINGTONIA, up to 8 feet and 10 feet high, in splendid condition for removal.
COMMON YEWS, 4, 5, 6, 8, 10, to 15 feet high.
GOLDEN YEWS.—An immense number of all sizes up to 10 feet high, as Pyramids, Globes, and Standards, and we believe that our stock affords a choice of sizes and varieties not to be found in any other Nursery.
IRISH YEWS, up to 20 feet high.

ORNAMENTAL TREES for AVENUES, &c.

ANTHONY WATERER invites special attention to this part of his stock, as comprising a splendid lot of well-grown Trees adapted for Avenues or Groups in Parks and Plantations.

LIMES.

LIMES, by the thousand, 10 feet, 12 feet, to 15 feet high, and girting 4 inches to 6 inches in the stem at 4 feet from the ground. The stems are straight, and have well-balanced heads, and are splendidly rooted. It would be very difficult to match these anywhere.

ORIENTAL and OCCIDENTAL PLANES.—Splendid plants, 10 feet to 15 feet high, straight in the stem, with nice heads, and finely rooted, by the 100.

These Trees are similar to those planted along the Thames Embankment, all of which were supplied by ANTHONY WATERER.

COPPER and PURPLE BEECH.—Thousands, 5 feet to 6, 8, and 10 feet high; some fine specimens, 12 feet to 18 feet.
COMMON BEECH, 8 to 10 feet high.
SCARLET AMERICAN OAKS, 8 feet to 12 feet high.
SPANISH CHESTNUT, 10 feet high.
HORSE CHESTNUT, 10 feet and 12 feet high, girting 5 inches to 7 inches in the stem, at 4 feet from the ground.
SCARLET HORSE CHESTNUT, ditto ditto.
NORWAY MAPLE, 10 feet to 15 feet high.
VARIEGATED ASH-LEAVED MAPLE, 6 feet to 8 feet high.
SYCAMORE, 10 feet to 18 feet high.
PURPLE-LEAVED SYCAMORE, 8 feet to 10 feet high.
ELMS, 10 feet to 16 feet high. | WALNUTS, 10 feet high, fine trees.

WEEPING TREES,

Of a very ornamental character.—The following are particularly recommended:—

WEEPING SOPHORA JAPONICA.
" ENGLISH OAK. | WEEPING TURKEY OAK.
" BEECH, 10 feet to 15 feet high.
" BIRCH, on 8 ft. and 10 ft. stems, with fine drooping heads.
" LIMES, splendid trees.
" ELMS, several kinds. | WEEPING ASH, several kinds.
" DECIDUOUS CYPRESS, 8 feet to 15 feet high.
" KILMARNOCK WILLOW.
" AMERICAN WILLOW.
" POPLAR, most beautiful.

All these and many others may be seen as handsome well-rooted specimens, and such as are rarely met with in Nurseries.

The **KNAP HILL NURSERY** extends over more than 200 acres of land, and contains an enormous supply of all ordinary EVERGREENS, such as AUCUBAS, BOX; LAURELS, both Common and Portugal; YEWS, PHILLYREAS, BERBERIS, &c.; and of Deciduous Flowering Shrubs, ROSES, FOREST and FRUIT TREES, &c. These will be found of various sizes, and are charged at a special rate to large purchasers.

ANTHONY WATERER'S CATALOGUE of AMERICAN PLANTS, ORNAMENTAL TREES, &c.,

Priced and Descriptive, and containing Illustrations from photographs of Waterer's and Golden Queen Hollies, as standards and pyramids; the Weeping Sophora, the Weeping Deciduous Cypress, the Weeping Beech, Standard Rhododendron, and Cupressus Lawsoniana erecta viridis; will be forwarded on application in return for 12 stamps, or the same Catalogue without the illustrations for 6 stamps. With reference to this Catalogue A. W. has the satisfaction to state, that he has received at least a hundred unsolicited testimonials of a highly complimentary character. Amongst others Mr. H. G. Bohn, whose knowledge of such matters gives authority to his opinions, writes as follows:—"I am delighted with your new Catalogue; it is a great advance upon all that has been done before." The *Gardeners' Chronicle* and other gardening publications have also made frequent allusion to it, as one of the best Catalogues ever issued. The Illustrations have been freely copied, both in this country and in America.

ANTHONY WATERER, KNAP HILL NURSERY, near WOKING, SURREY.

ROYAL HORTICULTURAL SOCIETY, SOUTH KENSINGTON, W.

SHOW of FRUIT, FUNGI, &c., OCTOBER 4, 1871.

AWARDS of the JUDGES.

CLASS 1.—Collections of EDIBLE and POISONOUS FUNGI, arranged separately.

(PRIZES OFFERED by W. WILSON SAUNDERS, Esq., F.R.S.)

1st, Messrs. Hoyle & Austin, Reading, £5.

CLASS 2.—Collection of EDIBLE FUNGI. (Open.)

1st, Messrs. Hoyle & Austin, £3.

CLASS 3.—6 EDIBLE FUNGI, cultivated, distinct. (Open.)

CLASS 4.—BLACK GRAPES, Collection of. (Open.)

1st, Mr. T. Bonnerman, Gr. to Lord Vernon, Hilsfield Hall, Rugeley, Stafford, £3.

2d, Messrs. H. Lane and Son, The Nurseries, Great Berkhampstead, Herts, £2.

Extra, Mr. C. Meredith, The Vineyard, Garston, near Liverpool.

CLASS 5.—WHITE GRAPES, Collection of. (Open.)

1st, Messrs. H. Lane & Son, £3.

2d, Mr. J. Meredith, £2.

Extra, Mr. E. Morris, Gr. to H. T. Salmon, Esq., Gayton House, near Northampton.

CLASS 6.—BLACK GRAPES, Single Bunch. (Open.)

1st, Mr. E. Clarke, Gr. to J. C. Brown, Esq., Holmbush, Horsham, Sussex, £2.

2d, Mr. P. F. Le Sueur, Meadow Vale House, Grands Vaux, Jersey, £1.

Extra, Mr. W. Lynn, Gr. to Lord Boston, Hedsor, Maidenhead.

CLASS 7.—WHITE GRAPES, Single Bunch. (Open.)

1st, Messrs. H. Lane & Son, 15s.

2d, Mr. E. Morris, 10s. | Extra, Mr. P. F. Le Sueur.

CLASS 8.—COLLECTION of AMERICAN POTATOS, 6 varieties, (PRIZES OFFERED by MESSRS. JAMES CARTER AND CO.)

1st, Mr. C. Frisby, Gr. to H. Chaplin, Esq., Blankney Hall, Sleaford, Lincoln, £2 2s.

2d, Mr. J. Garland, Killerton, Exeter, £1 1s.

MISCELLANEOUS—EXTRA PRIZES.

Mr. W. Bull, Nurseryman, &c., King's Road, Chelsea, Collection of Plants.

Mr. W. Paul, Paul's Nurseries, Waltham Cross, Collection of Tea Roses in pots.

Mr. B. S. Williams, Nurseryman, &c., Upper Holloway, Collection of Fruit.

Messrs. J. Standish & Co., Royal Nursery, Ascot, Group of Plants.

INTERNATIONAL FRUIT SHOW.

CLASS 1.—The most complete COLLECTION of APPLES, 3 Fruits of each variety.

1st, Mr. William Paul, Paul's Nurseries, Waltham Cross, Gold Medal.

2d, Messrs. Baltet Frères, Horticulteurs, Faubourg Croncels 14, Troyes, France, Silver Gilt Medal.

Extra, Mr. C. Chaff, Wallington, Carshalton, Surrey.

CLASS 2.—COLLECTION of DESSERT APPLES, 3 Fruits of each variety.

1st, Mr. C. Chaff, Silver Gilt Medal.

2d, Mr. R. Webb, Culham House, Calcot, Reading, Large Silver Medal.

CLASS 3.—Collection of CULINARY APPLES, 3 Fruits of each variety.

1st, Mr. S. Ford, Gr. to W. E. Hubbard, Esq., Leonardslee, Horsham, Sussex, Silver Gilt Medal.

2d, Mr. C. Chaff, Large Silver Medal.

CLASS 4.—The most Complete Collection of PEARS, 3 Fruits of each variety.

1st, Messrs. Baltet Frères, Troyes, France, Gold Medal.

2d, Mr. C. Chaff, Silver Gilt Medal.

Extra, Mr. Sydney, The Gardens, Hallingbury Place, Bishop Stortford, Essex.

CLASS 5.—Collection of DESSERT PEARS, 3 Fruits of each variety.

1st, Messrs. Baltet Frères, Troyes, France, Silver Gilt Medal.

2d, Mr. A. Moffat, Gr. to H. Allsopp, Esq., Hamdlip Hall, Worcester, Large Silver Medal.

CLASS 6.—Collection of KITCHEN PEARS, 3 Fruits of each variety.

1st, Messrs. Baltet Frères, Troyes, Large Silver Medal.

2d, Mr. C. Harley, The Gardens, Valentines, Ilford, Essex, Bronze Medal.

CLASS 7.—Collection of GRAPES, 2 Bunches of each variety.

1st, Mr. J. Lee, Gr. to Sir J. Gibbs, Aldenham, Herts, £3.

2d, Mr. J. Meredith, Silver Gilt Medal.

CLASS 8.—The LARGEST BUNCH of GRAPES.

1st, Mr. C. Ashman, Gr. to Lord Sherborne, £2.

2d, Mr. P. F. Le Sueur, Bronze Medal.

CLASS 9.—COLLECTION of ORANGES, LEMONS, CITRONS, LIMES, &c.

CLASS 10.—MISCELLANEOUS FRUIT, not mentioned in either of the above.—Extra Prizes.

Mr. W. G. Pragnell, Castle Gardens, Sherborne, Dorset, Collection of Fruit.

Mr. W. Cowen, Gr. to Earl Vane, Wynyard Park, County Durham, 1 Queen Pine-apple.

Mr. G. C. Miles, Gr. to Lord Carrington, Wycombe Abbey, Bucks, 1 Smooth Cayenne Pine-apple.

Mr. T. Jack, Gr. to the Duke of Cleveland, Battle Abbey, Sussex, 1 Dish of Peaches.

Mr. A. Moffat, 3 Melons.

Noteworthy Horticulturists and Botanists.

NOTICE.—A SERIES of PORTRAITS of NOTEWORTHY HORTICULTURISTS and BOTANISTS is being published in the "GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE." The following have already appeared, and copies may be had on application to the Publisher, viz.:—

Dr. HOOKER, C.B., F.R.S.	Professor REICHENBACH, of Hamburgh
W. WILSON SAUNDERS, F.R.S.	Dr. MOORE, of Glasnevin
Rev. M. J. BERKELEY, F.L.S.	Rev. S. R. HOLE, M.A.
M. DECAISNE	E. J. LOWE, F.R.S.
G. F. WILSON, F.R.S.	JAMES McNAB, of Edinburgh.

Published by WILLIAM RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Gardeners' Chronicle

SATURDAY, OCTOBER 7, 1871.

IT must be a source of well-earned gratification to the managers of the EXHIBITION just closed to find that their labours have been so thoroughly appreciated. We say *the* Exhibition, because no one but the printers ever thought of giving it its full title, and, whatever other exhibitions there may have been in London this season, and they have not been few, the London International Exhibition of 1871 has, in people's minds, taken precedence of all others. Ushered in gloomily, amid devastating war, with little or none of the *prestige* attaching to former exhibitions of a like kind, encased in brick boxes of irredeemable ugliness, it has literally won its way on its own merits, and few could have ven-

tured with any confidence to predict so genuine a success. When the stranger entered the Albert Hall, he too often made the circuit of its gloomy corridors for some considerable time before he could find his way either into the Hall itself or into the Exhibition galleries proper. Once in the Hall, we imagine none but the most inveterate grumbler, and the most sluggish of perception, could experience at the first glance anything but a feeling of astonishment and bewilderment, speedily to be followed by a sense of unqualified admiration at the boldness and elegance of the lines and proportions of the building. Emerging from this, which we have before called "Scott's triumph," the visitor experienced in many cases considerable difficulty in finding the Exhibition. It was hard to believe that the oddly shaped and disconnected rooms, the floors of which were on different levels, and which were crammed with a miscellaneous assortment of everything, from dolls' houses to theodolites—dark passages lined with maps, and curved corridors filled with strips of cloth of colours manifold enough to have clothed some thousands of little JOSEPHS—really formed part of the Exhibition. It seemed rather as if these were storerooms or places of lodgment for superfluous objects not required in the Exhibition itself. And when, after much ascending and descending of stairs and traversing of glazed corridors, the tired spectator found himself at length in one or other of the picture galleries, and after revelling in its many beauties, arrived at the opposite end of the gallery—then there were more stairs to be encountered, more dark passages, byeways, and tunnels to be traversed, and so the plan which looked so delightfully simple on paper was found to be terribly perplexing in practice. We allude to these matters now, in the hope that ere another season comes round some attempts may be made to obviate the defects we have mentioned, and if a general *vice versâ*, were not necessarily troublesome and provoking. The privilege of passing from the galleries to the balcony overlooking the gardens was very highly appreciated as a grateful relief by the visitor, and if that privilege can be extended another season so as to allow of a promenade in the garden itself with a little less trouble than was the case this time, we are convinced it will be better for all parties. To be sure the Fellows of the Horticultural Society would to some extent be deprived of their rights, but compensation may be looked for in the very substantial advantages which the Society seems likely to reap from its association with the Exhibition, and in the sundry advantages which the Commissioners would no doubt be prepared to give to the Fellows individually in exchange for the loss of some of their exclusive privileges.

We are disposed to think that the exhibition that has just been closed was, so far as it went, even more instructive than any of its predecessors—take the case of the pottery, so beautifully illustrated this year. Nearly every process of the potter's art, from the crushing of the flints to the shaping of the vase, was carried on under the eye of the spectator. The raw materials were shown, the process of manufacture, and lastly, the finished products, in infinite variety, and of all degrees of utility, beauty, or the reverse, were displayed. Who can doubt that educational value of an exhibition well carried out on such principles? We have alluded to this subject, because we think that the Horticultural Society, charged as it is with the horticultural department of the International Exhibitions, may well, in the coming season of preparation, organise for next year an exhibition of a similarly instructive character. Hitherto exhibitors have contented themselves with showing results—the public come and admire, and say how beautiful! but go away as wise as before. The great fruit show of Wednesday last was a case in point. Pears and Apples were shown by the hundreds, but with no attempt whatever at classification, beyond that of their use for table or kitchen use. The public saw the multitude of fine fruits, and were duly impressed, but they learnt nothing they did not know before. People in general have no conception of the amount of labour, skill, and knowledge required to put a Rose or a bunch of Grapes on the exhibition table. The vast majority even of the educated public have no definite ideas connected with the commonest gardening processes. They know that a garden must be dug, but they have only the vaguest notion why; and as to the question what parts of a garden should be dug and which not, they are in general quite ignorant. Grafting, pruning, training, hybridisation, selection, all these are things of which the general public knows little or nothing, but, as events have shown, it is quite willing to learn if the matter to be learnt be put before it in an attractive and easily accessible form. We would suggest then that, so far as is practicable and possible, the educational idea pervading other departments of the Exhibition be carried out also in the horticultural section.

Specimens showing the various modes of grafting and pruning, illustrations showing the many processes and stages in the life of a pot Rose or of a Peach tree, as treated of in the useful manuals of PAUL and BRÉHAUT respectively, might be exhibited. Tools and implements of all kinds might be shown, and illustrations given where possible of the proper mode of using them. We throw these out merely as crude suggestions to be adopted and improved upon if it be thought desirable, and we speak of them now without reference to that more special work of the Society which we hope it will sooner or later take up in earnest—the education of the gardener and the improvement of his position. This is a large subject, not to be discussed at the fag end of an article, and it is one to which we shall hereafter allude. At any rate we hope the time is now rapidly advancing when the Society will rise to the level of its duties, and show that while flower shows, promenades, bands, and the like, may be important adjuncts, and be serviceable as sources of income, they are, after all, secondary to the main objects for which the Society was founded—the promotion of horticulture proper, and the education of the public in general, and of the gardeners in particular, in all branches of scientific and practical gardening.

THE FRUIT SHOW held at South Kensington on Wednesday last, and continued on the following day, was undoubtedly the finest display of the kind seen in London since the International Fruit Show of 1862, although the growers had but scanty notice that it would take place, notwithstanding also the generally unfavorable character of the season. The result has been such as to show that a good exhibition of fruit may always be reckoned upon at this, the natural season of the year for such a display, if only fair encouragement be afforded, as it should be, to those who are the producers of fruit. Exhibitions of fruit have been rather neglected and cut down of late years, at the only season when a good display can be made, while at the season when fruit is usually invited, at least in a collective sense, the article is so valuable that prizes of any possible amount fail to bring it together. We think there ought always to be an autumnal show of fruit, open for some considerable time, in order that all persons interested in it may have leisure to profit by the observations they may be able to make; and as at that season fruit, when necessary, could be returned without much trouble or expense, there should be no obstacle to its remaining on view for a week at the least.

Reverting to the present show, it must be gratifying to English cultivators to find that if the more sunny climes of Continental Europe enable our neighbours across the Channel to grow finer Pears than we can do, England has beaten the foreigner in Apples, while her Grapes are beyond all comparison superior to anything which has been hitherto brought here from the Continent. True, indeed, there was no foreign competition on this occasion, but even had there been, the splendid display made by Messrs. LANE was such that they would have had nothing what-ever to fear. Their Muscats, to which we alluded last week, were simply magnificent, and fully bore out all we said in their praise; and doubtless, since there are many more examples of the various kinds remaining behind at Berkhampstead, some of the visitors to London may be tempted to go and see for themselves. The strange point is that, although drainage and heated borders are deemed essential to crack Grape growing, and no doubt are in a general way useful aids thereto, yet Messrs. LANE's Grapes are grown close to, and almost on a level with, perpetually running water, with must necessarily percolate amongst their roots, and keep them constantly damp. May not shanking and shrivelling, after all, be oftener the result of root-drought than root-damp? Messrs. LANE won in a canter the gold medal for the finest collection of Grapes, as well as the medals for the best collection of White Grapes, and the finest bunch of whites, the latter with one of the noblest and most perfect bunches of Muscat ever exhibited, the variety being, we believe, what is known as the Bowood Muscat. The largest bunch of Grapes was a Gros Guillaume from Mr. BANNERMAN, gr. to the Lord BAGOT, of Blithfield Hall, Rugeley, a finely proportioned bunch, of 6 lb. weight, shown in excellent condition. There were some capital Grapes from Chiswick—especially of the Gros Guillaume variety, of the pleasant-eating stoneless Monukka, and of the Madresfield Court; the latter, it may be specially noted, having at Chiswick ripened perfectly beside Frankenthal, which was scarcely as ripe as itself, planted in one of FOUNTAINE'S houses, and grown entirely without artificial heat. Of the two there grows no more any difference, the Madresfield Court is the most matured, and is of excellent flavour—better, as it appeared to us, than when grown with Muscats. The property of ripening in a cool house will greatly enhance the value of this novelty.

Of Pears, the collection shown by MM. BALTET was wonderful for its extent and beauty. The samples were good, especially in the group shown in the class for dessert Pears. MM. BALTET of course carried off the gold medal for Pears, but the gold medal for Apples fell to the lot of Mr. W. PAUL, of Waltham Cross, who had a collection of about 170 varieties. Mr. SIDNEY FORD, of Leonard's Lee, Messrs. LUCOMBE, PINCE & Co., of Exeter, and Mr. GARDINER, of Eatington Park, also showed capital Apples, the latter staging an extensive collection on the second day, for which space could not be found on the first day. We noticed amongst them the beautiful little Fairy Apple—so charming for desserts, as well as good Kibston Pippins, and in Mr. FORD's group were some remarkably well-kept French Crabs of the 1870 crop. Messrs. WHEELER & SONS' Brockworth Park Pear, which we figured (p. 1603, 1870), was shown, very large and fine, but not so much coloured as last year.

We have to thank Mr. GARDINER for an idea as to arrangement, which we think should be insisted on in all future exhibitions, and that is to classify the sorts collected in the case of all large collections. Glancing over Mr. GARDINER'S Apples we found, for example, all the Russets set together, and, turning to other collections, we found them set down promiscuously. Now, the advantage for purposes of observation and compairson, in the case of the classified series, was so obvious, that we believe it only needs pointing out to be at once adopted in all future exhibitions.

THE First Commissioner of HER MAJESTY'S Works and Public Buildings intends to distribute this autumn among the working classes and the poor inhabitants of London the SURPLUS BEDDING PLANTS in Battersea, Hyde, the Regent's, and Victoria Parks, and in the Royal Gardens, Kew. If the clergy, school committees, and others interested will make application to the superintendents of the parks nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, in the cases of persons residing in that neighbourhood, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

—— In the recently issued part of the "Transactions of the Botanical Society of Edinburgh," in a notice of an excursion to the Island of Arran, the profuse flowering of some fine FUCHSIAS is mentioned, and one, referred to as having a stem 22 inches in circumference, is stated in an editorial foot-note to be probably the original Fuchsia coccinea. It would seem likely, however, from some observations made by Mr. TILLERY, in the current number of the "Florist and Pomologist," to be rather the Fuchsia Riccartoni, which is well known to cultivators as one of the hardiest kinds of Fuchsias, while F. coccinea is much less so. Mr. TILLERY writes:—"Some 36 years ago I introduced the Fuchsia Riccartoni, then named the Port Famine Fuchsia, to the Island of Arran. On visiting the island a few years ago, I found it growing plentifully on the fishermen's cottages. On the south side of the island, where the thermometer in the severest winters seldom registers more than 10° or 12°

of frost, I found some of these Fuchsias with stems 3 inches in diameter, and forming little trees." This Fuchsia Riccartoni is a peculiarly sturdy kind, with broad short flowers, resembling those of F. globosa, and very different from the more slender F. coccinea, which, though superseded by the modern varieties, is still to be found now and then in old gardens. We ourselves met with it during the past summer in the neglected garden of an old farmhouse in the wilds of Surrey. There seems to be some misapprehension abroad as to the usurpation of the name Fuchsia coccinea by F. gracilis, which latter Dr. HOOKER refers back to F. magellanica. The original F. gracilis, which we well remember upwards of 40 years since, before the Fuchsia became a florists' flower, was a plant with pale green foliage, and in this respect unlike the gracilis of the present day, which is the virgata of gardens, and which might be the more readily mistaken for coccinea, inasmuch as its dark green leaves have a purplish tint, which gracilis itself did not possess.

—— The value of IPECACUANHA in the treatment of dysenteryis known to be very great; and, in consequence of the partial failure, from various causes—such as the rashness and carelessness of collectors—of the supply from its native country (South America), its cultivation in India has been commenced. A difficulty, however, stood in the way, as it had not been possible to get perfect seed, so that its propagation was but slow. Mr. JAMES MCNAB, of the Edinburgh Botanic Gardens, however, discovered that by cutting the root under the ground surface, numerous young shoots could be got, and that the plant could be so propagated much more easily and plentifully. It has thus been possible to send out a number of healthy plants to India. Mr. MCNAB has also been endeavouring, with fair prospect of success, to get perfect seeds. There are now two varieties of the plant in the Botanic Gardens, one of which has been cultivated there for 40 years, and the other has just been procured from South America, through the kindness of Dr. GUNNING and Dr. CHRISTISON. It is expected, from the union of these two varieties, to get perfect seeds, and to be hoped that the result of this experiment may be as successful as that of the introduction of Cinchona.

—— We have lately met with another instances of VARIEGATION INDUCED by PARASITISM. This occurs in the nursery of Mr. W. PAUL, at Waltham Cross. The tree in the present case is the Chestnut, Castanea vesca. The variegated variety of the Chestnut had been grafted, standard high, on an ordinary green-leaved Chestnut stock; the graft took, but from some cause or other afterwards died off and subsequently a young shoot with well-marked variegation on its leaves, broke out from near the base of the stem, and was growing in all apparent health when we saw it a few days ago. The variegation is of a creamy white colour, and margined similar to, but probably rather whiter than, that of the variegated Chestnut usually met with.

—— On Thursday evening, the 28th ult., a deputation from the two London establishments of Messrs. PETER LAWSON & SON waited upon Mr. CHARLES GARDENER SIMPSON, at his house, 110, Lilford Road, Stoke Newington, when Mr. SAMUEL MCDONALD, in the name of the *employés* of PETER LAWSON & SON, presented him with an elegant marble timepiece, on the occasion of his marriage, as a mark of their respect and esteem. Mr. SIMPSON is a native of Auchtermuchty, Fifeshire, N.B., and has long been connected with the phospho-guano department of Messrs. PETER LAWSON & SON, both in Edinburgh and London.

—— In a communication to the *Field*, on the subject of FEEDING SEA ANEMONES in AQUARIA, Lieut.-Col. STUART-WORTLEY ventures "to say very decidedly that all experienced persons who say sea anemones succeed well without food know nothing of the subject of keeping aquaria. All sea anemones kept without plenty of feeding dwindle away and become wretched objects; whereas, on the contrary, with good food, they will greatly increase in size and beauty. I have had an extensive experience in the keeping and management of aquaria that I could not let such an assertion go uncontradicted. There is no better food than the one you suggest—lean beef—and it is remarkable that a meat diet causes the brilliancy of colour in some species to increase, while a fish diet has the opposite effect. As to the question of their food, all sea anemones reject by the mouth the remnants after digestion, but not till they have sucked all the goodness out of it. Large bell-shaped glasses with stands make very nice aquaria."

—— In the current number of the "Journal of Botany," Dr. SEEMANN, referring to PHYTOLACCA ICOSANDRA, states that "in Nicaragua this plant springs up on newly-cleared ground, and on the banks of the river San Juan it is called 'Calalu,' and eaten instead of Spinach. I saw the men bring quantities of it, especially the top parts of the plant, on board the steamers whenever they went on shore, and can endorse the opinion that 'Calalu' is an excellent pot-herb. If I remember rightly, P. icosandra is cultivated in the Vine-growing districts of Southern Germany on account of its black fruit, largely used for converting white wines into red."

—— During the week ending Sept. 30, the MAXIMUM TEMPERATURES of the AIR ranged from 65°.2 at Portsmouth to 52°.5 at Aberdeen and Greenock, with a mean for all English stations of 58°.9, and of all Scottish of 53°.8. The MINIMUM TEMPERATURES ranged from as 1°.9 at Blackheath to 33° at Perth. The mean for England was 38°.4, and for Scotland 36°.2. The highest MEAN TEMPERATURE was recorded at Portsmouth, viz., 50°.9, and the lowest, 44°, at Edinburgh, the values decreasing very uniformly from south to north. The mean for the southern country was 47°.6, and for the northern, 44°.8. The RAINFALL during the week over England was very heavy, several stations recording over 3 inches as having fallen, and the mean fall for the whole country was as much as 2.07 inches, which is equivalent to nearly 300 tons per acre. In Scotland the rainfall was much lighter, the maximum fall being only 0.70 inch at Dundee, and the mean for the country being but 0.58 inch.

—— The DIFFERENT EFFECTS PRODUCED upon different persons BY THE SAME PLANT are very remarkable. This is especially noticeable in the Poison Oak of America (Rhus Toxicodendron), and its effects are well known as a medicine. It is said that some dare not meddle with R. venenata whilst its wood is fresh, or venture to touch a hand which has handled it, or even expose themselves to the smoke of a fire made with the wood. He adds that the same person may be at one time proof against the poison and not at another. Dr. BLOOMFIELD, on the contrary, states that he has repeatedly tried experiments with all the above species, under various circumstances, but has failed to produce the slightest symptoms of poisoning in himself. He remarks that a friend of his was so susceptible to the poisonous influence of these plants that momentary contact, or a brush from a branch in passing through a thicket or getting over a fence, was sufficient to induce an irritative inflammation, which lasted for a week or ten days.

New Garden Plants.

EPIDENDRUM CRINIFERUM, *n. sp.*

Spathium spathis pluribus; caule subaxipiali pleiophyllo; foliis linear-ligulatis acutis; spathis pluribus apice obtusatis: floribus paucis subracemosis; ovariis longe pedicellatis; sepalis lanceolatis; petalis linearibus apice subulatis; labelli basi utrinque lateralibus semiovatis retrorsis in crines retrorsos patulosve solutis; lacinia media porrecta linear-angustissima; calli geminis a lacinia compressis antrorsis in basi.

A very interesting species in the way of the Cuban Epidendrum rivulare, Lindl. (Wright, Cuba, 644 !), that appears to be very distinct in its longer and narrower leaves, shorter bristles of the lip, and rhomboid apex at the middle part of the lip. The lateral sepals, too, are generally much more rounded and oblique. It is a very interesting fact that it nearly agrees as to colour. The flowers of Epidendrum rivulare are said to be a yellowish green, speckled with red. Our plant has the sepals and petals and column whitish outside, the former organs yellowish green inside with dull cinnamon blotches and bars, making one think of the now well-known Odontoglossum odoratum, Lindl. The lip is totally white, without any such "fine specks" as were observed by Mr. C. Wright on Monte Verdean specimens of Epidendrum rivulare. The retrorse fringes are very peculiar. The scales are very unusual both in the garden plant and in wild specimens, while they are so very equal in the Wrightian species that Dr. Lindley placed his plant in the section Amphiglottum; but I prefer to place it in the section Spathium, for the above-mentioned reason. The plant was discovered in Costa Rica, and has just flowered with Messrs. Veitch. I may add that I compared it with the Lindleyan type of E. rivulare, and found it quite identical with my Cuban specimens. *H. G. Rchb. fil.*

THE NATURAL HISTORY OF A FLOWERING PLANT.

[The following remarks are taken from Professor Thiselton Dyer's sixth and last of his series of lectures on "The Natural History of a Flowering Plant," in the Theatre of the Royal College of Science, Dublin. The subject treated upon was "The Seedling."]

IT TYPIFIES, beside details of structure of less consequence, the most important part of the ovule is a large cell, in the interior of which some of the protoplasm becomes detached in isolated portions, or corpuscles. The pollen-cell, as already explained, developes into a thread-like body, which gradually progresses downwards into the interior of the carpel, following the line of seam where the ovules are produced. Ultimately it comes in contact with an ovule, and at a part of one where the top of the large cell above mentioned is close to the surface. Some influence is in this way communicated to it, the result of which is that one of the corpuscles (very rarely more) gets a cell-wall formed about it, and, in fact, becomes itself a complete cell. It divides, and ultimately a mass of cells is formed, which gradually shapes itself into the form of the embryo plant. As it increases in size it soon fills up the small cavity in which it was produced; it obliterates this, and often all the original surrounding substance of the ovule itself as well. It may happen that there is an additional formation of cells about the embryo in which ultimately it is found embedded in the seed; this becomes a kind of reservoir of nutriment for the embryo plant. The older botanists, who were very fond of seeing analogies between plants and animals where there are often no real ones, compared it to the white of egg, which serves much the same purpose to the chick; both are, consequently, called albumen, but their chemical composition is by no means identical. The albumen of the seed is merely a mass of cells, which may contain starchy, fatty, or even incrusting woody matters. These all pass into a soluble state, and are used up in germination.

The embryo is often very minute, compared with the bulk of the albumen. It is especially noticeable in the Cocoa-nut, where a part of it is hollow, and contains a fluid—the so-called "milk." But many seeds contain nothing but the embryo plant, packed up in a small space till the time of germination. In this state—and it is the same, only more minute, in seeds having an albumen—it consists of a short stem, terminated by a bud, and bearing one or two leaves—cotyledons. The young plant requires no root, and, therefore, has none till it begins to emerge from the seed-coverings. The cotyledons are either elevated by the lengthening of the young stem above the ground when they perform the office of ordinary leaves, or remain underground, the work of an albumen, and loaded at first with nutritious matters. In any case they are merely temporary organs. An extraordinary plant from Western Africa—Welwitschia—has the unique peculiarity of bearing no other leaves than its pair of cotyledons throughout its life. Usually, only a single embryo is developed from each ovule; only a single seedling is, therefore, produced from the mature ovule or seed. The Orange is, however, an exception, as anyone may see by sowing the pips for themselves. If one kind of plant is artificially fertilized with the pollen of another, it does not differ to a degree greater than what is called specific, a cross, or hybrid, is produced. Care must be taken to prevent the presence of the proper pollen, as it has been found that this, in such a case, will overpower the effect of that which is foreign.

It is worthy of remark, that a few instances are known of the very converse of this—that individual plants of some cultivated Lobelias, for example, are more readily fertilised with the pollen of other species than with their own.

The majority of the seeds that hybrid plants produce will not germinate: this prevents the labours of insects from producing ultimately a complete blending together of every distinct kind of plant. There is no doubt, however, that this does happen with individual plants of the same species, and that small differences in this kind of way become obliterated. A great practical difficulty arises, in consequence, in growing crops of seed of garden varieties. With Turnips, for example, it is necessary to grow the seed crop of any one sort on some farm where no other kind is grown near; otherwise the seed would not come true. Naturally, the small variations which plants usually tend to get obliterated from this cause, the blending of different races compensates by adding to the vigour of the progeny. Our cultivated plants have, no doubt, widely departed from their original natural form, to which, in a great extent, they tend to revert when they run wild. They do not, however, properly return to any form precisely identical with a wild one; some of their peculiarities have become fixed in fact, so as to be retained independently of the artificial conditions of cultivation. This makes it difficult to ascertain their precise origin with more than probability. Fruit trees, Apples especially, revert almost immediately to a wilding state. Such plants are always propagated by grafting, and no attention has been paid to select those varieties with desirable peculiarities which come true to seed. This, of course, is essential in garden vegetables, which, accordingly, are propagated they are not cross-fertilised, are remarkably permanent.

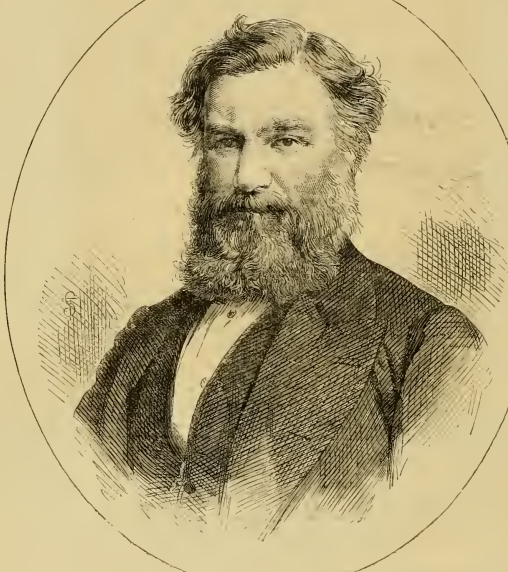
Many of our favourite garden flowers are the descendants of two or more species commingled together. The seedlings of such mixed strains often vary, as well as tend to revert to the type of their parents. Any desirable variations are promptly seized upon by a grower, who, producing the plant on a large scale, is more likely than any one else to meet with them. If they show signs of permanency they are cultivated. Particular shoots of plants, which are not of hybrid origin, will occasionally "sport away," as gardeners term it, from the true type, and such sports may be propagated by cuttings. Many varieties of rose are known to have originated in this way. Grafting is a method of implanting a portion of a plant upon the vigorous growing axis of another, so that the scion is saved the trouble of growing to a large size, and jumps into manhood at once. A portion of a seedling fruit-tree will bear much sooner if grafted than if left upon its own roots. This is not, however, the only effect of the stock; if hardy, it is found to communicate the same good effect to a tender scion. There are other cases which are more obscure, and have been attributed to a kind of hybridisation; the stock and scion are both affected, and react upon one another. Cytisus Adami is believed to have been produced by grafting the purple Cytisus upon the Laburnum; plants of it bear the flowers of both the parents, and a third kind which to some extent

combines the two. There are cases also where the scion has been variegated, and has communicated the same peculiarity to the stock, and a case is even on record where a purple hue in the foliage has been communicated in the same way.

ROBERT HOGG, LL.D.

THE occurrence of the fruit show at South Kensington on Wednesday last, and a report of which will be found in another column, affords a fitting opportunity for laying before our readers the portrait of one whose name is intimately associated with British pomology. In his capacity as Pomological Director of the Royal Horticultural Society, and one of the three secretaries concerned with the Horticultural department of the International Exhibition, Dr. Hogg has had no slight share in bringing about the successful issue of this magnificent display of fruit.

To most horticulturists at all conversant with the doings of the Royal Horticultural Society, the main facts of Dr. Hogg's later career are tolerably well known. As one of the Editors of the "Journal of Horticulture," in conjunction with Mr. Johnson, the veteran historian of British gardening, as the author of a standard descriptive work on pomology ("The Fruit Manual"), and of numerous other serviceable publications, and from his connection with the Pomological Society, and after with the Royal Horticultural Society, and specially with its Fruit Committee, Dr. Hogg has been brought into contact more or less directly with the great body of British horticulturists, and we do not overstep the bounds of good taste, when we state that his sterling qualities of head and heart have secured for him the cordial esteem and good will of his fellow workers.



ROBERT HOGG, LL.D.

At an early age Dr. Hogg exhibited a taste for the study of natural science, and especially of botany. The love of those studies induced him first of all to direct his attention to the medical profession, but his short experience of the dissecting-room, and the prospective drudgery of the general practitioner, operated as a deterrent to any great progress in that direction; still, those branches of science which were not strictly medical continued to be the subjects which more immediately roused his attention, botany being always the means by which he hoped to attain distinction.

After pursuing his "humanities" at the University of Edinburgh, Dr. Hogg acquired a knowledge of practical horticulture at the establishment of Messrs. Lawson, of that city, and subsequently at that of Mr. Ronalds, of Brentford. Here the taste for pomology showed itself, and here, in particular, were the foundations laid of that interest in, and knowledge of, the subject which have since proved to be the most important features in Dr. Hogg's public career. The intercourse with Ronalds, at that time engaged in the publication of the magnificent "Pyrus Malus Brentfordiensis," gave the impetus to that study which may be said to have become the most absorbing pursuit of his future life.

After remaining for some time at Brentford, Dr. Hogg proceeded to France, stopping for a short time at Kew, where the fruit garden was then under the management of the well-known Dubreuil, and which still remains a monument of that pomologist's skill and sagacity. From Rouen the subject of our notice made his way to Paris, where he completed his botanical studies under A. L. De Jussieu, Mirbel, and other celebrities of the Jardin des Plantes. Remaining in Paris for some time, he afterwards proceeded to Germany, and passed some time at Bonn. On his return to this country, finding that science held out but little encouragement in the shape of substantial reward, Dr. Hogg turned his attention more particularly to the more remunerative field of practical horticulture, on which he brought to bear that knowledge of botany and vegetable physiology which he had acquired during his pupilage. It was about this period that he became associated with the management of what, a century and a half previously, Evelyn had termed "that great undertaking of Brompton Park." This was an immense fruit tree nursery at Brompton, extending from Brompton Church to Gloucester Road, Kensington, on the one side, and from the Kensington Road to Brompton on the other, thus including the site of the present garden of the Royal Horticultural Society, at what has been called South Kensington only since great exhibitions and museums have given the district in question an amount of public interest of which Evelyn never dreamed.

This nursery was founded in 1681 by Lukar, Field, Cooke, and London; and it may interest many of our readers to know that Lukar was gardener to the Queen Dowager at Somerset House in the Strand; Field acted in the same capacity to the Earl of Bedford at Bedford House, also in the Strand; Cooke held a similar situation with the Earl of Essex at Cashiobury; and London was the fitting servant and friend of Bishop Compton at Fulham Palace, while he was also the grandfather of the first Lord Selsey. The fortunes of the "great undertaking of Brompton Park," after flourishing for a century and a half, were however, when Dr. Hogg joined the copartnership, on the wane. Those with whom he was associated were either enfeebled by age or by want of means, or both, and he soon found himself saddled with responsibilities he had no inclination to sustain, and consequently retired after a few years, and from that time to the present has devoted himself to the literature of horticulture. The advantages of a practical kind which he had derived from his connection with "the great undertaking" were, however, of great value. It was during that time that the first form of the "Fruit Manual" appeared, which remains the text-book of pomologists and nurserymen, and it was not till after its publication that nurserymen adopted the plan of issuing descriptive catalogues of fruits. The "Fruit Manual" is probably the best and most generally known of Dr. Hogg's separate publications; but it was not the first in order of time of his literary productions, for while still a youth he published in Edinburgh a "Treatise on Annuals," with descriptions of those cultivated at that time, and he subsequently issued a "Treatise on the Dahlia, its History and Cultivation."

About 1844 Dr. Hogg commenced a work entitled "British Pomology," but the only portion ever published was the first volume, treating on the Apple. At the time this was published the present rage for the study and cultivation of fruits did not exist. No bookseller would take the responsibility of its publication, and he had to undertake it himself. As a remunerative speculation it was a failure, and, like Lindley's "Guide to the Orchard and Kitchen Garden," published 20 years previously, it was still in advance of the time. Now, we believe, the work is entirely out of print. Not discouraged by the failure of this attempt to excite public interest in Pomology, Dr. Hogg adopted other means of keeping the subject before the public mind. Early in 1853 we find him writing as follows:—

> "There is, perhaps, no country in the world where the study, and consequently the cultivation, of fruits is more neglected than in our own. In America, they have in various States pomological 'societies' and 'institutes,' which meet as regularly as our Royal and Linnean Societies, and discuss pomological subjects. Several excellent works have issued from the press of that country, and are justly popular, and it is to America that we are indebted for some of our finest varieties of fruits. In Germany, too, it is a very popular study, as the numerous pomological societies and publications furnish ample evidence of. In France it has a great measure of support, although perhaps not so great as in those countries already mentioned, but certainly far greater than in our own; and in Belgium it is found not unworthy of Government patronage and support. Need it be wondered, then, that so little is known when so little interest is manifested on the subject in this country. We trust the time is coming when the same vitality and energy will be exhibited as there was at the time when Mr. Knight and Mr. Sabine devoted so much of their attention to it."

And the time speedily came, for in little more than twelve months after this was written the British Pomological Society was instituted, with Sir Joseph Paxton as president, and Dr. Hogg and Mr. Spencer as joint secretaries, the initiative having been taken by Mr. Spencer, of Bowood; Mr. Rivers, of Sawbridgeworth, and Dr. Hogg. After several years of usefulness, and after passing through the vicissitudes which appear to be normal phenomena in the career of societies as well as in that of most individuals, the Pomological Society was merged in the Fruit Committee of the Horticultural Society, the first meeting of which body was held at the rooms of the Horticultural Society at 21, Regent Street, on July 5, 1858. Subsequently Dr. Hogg has acted as Secretary to the Fruit Committee, and latterly he has taken an active part in the practical business of the Royal Horticultural Society, being now one of the directors (in conjunction with Rev. Mr. Berkeley and Mr. Moore) of the Society's garden at Chiswick. In this latter capacity it has fallen to Dr. Hogg's lot to superintend the replanting of the fruit garden, and to select the varieties to be retained in the diminished space now available for the purpose.

Dr. Hogg's name must also be honourably associated with those who by their zeal and energy promoted the success of the London International Horticultural Exhibition and Botanical Congress of 1866. It was, therefore, a happy coincidence that Dr. Hogg should have been one of those who represented this country at the last International Horticultural Exhibition at St.

Petersburg, on which occasion, as the reception of decorations from foreign potentates, except under special circumstances, is contrary to English practice and etiquette, Dr. Hogg became the recipient of a handsome slab of malachite as a mark of the Emperor's recognition of British Horticulture and of courtesy towards its representatives.

A SUCCESSFUL ORCHARD HOUSE.

I SEND you a photograph of a new form of Orchard-house (figs. 288, 289), which gives great satisfaction. It is an elliptical quadrant, resting on an 18-inch parapet wall of polished ashlar, through which are a series of ventilators 26 by 9 inches in every 24 feet throughout the entire length of the building (172 feet). The ventilators are moved simultaneously by connecting-rod and brackets, and if required any of them can be rendered inoperative. The top ventilator when full up gives a clear opening of 7 inches, and this is found to be sufficient, the front ones not being opened more than half a dozen times in a year. This consists of fender plate-iron, and is moved by lever and screw the whole length at once. The turn-up behind acts as a gutter for any rain falling on the plate when open.

The followiog is an epitome of our management, adhered to with little, if any, variation since the house was put up in 1860-61. Sharp on the fall of the leaf the plants are turned out of the pots, all loose straggling roots being cut away from the bottom and sides. The balls are slightly reduced, and the necessary shift given till a 15-inch pot is required, when they are returned to the same, or others of the same size. The plants on the wall are then unnailed, the roots partially shortened by cutting a trench round them, at a distance of from 3 to 5 feet from the main stems. We then have it undermined—the remaining mass, or ball, being partially loosened, similar to what is done with the pots, and fresh soil given. In like manner, the compost used is two-thirds maiden earth, one-third good rotten dung from a horse, cow, and pigs—when the gardener happens to have the latter. To that portion used for the pot plants a liberal allowance of charcoal from a trash-kiln (specially prepared annually for the purpose) is added to maintain the porosity of the ball and promote the drying process of the same, which we take every means to encourage, finding that the oftener water is required the more certainty there is of well hardened wood, and consequently of the following season's crop.

This done, and the pot and wall Peaches having been carefully rubbed with a mixture of clay and sulphur, the pots are then plunged under their summer stances, mulched over to a depth of 6 inches with dung of any kind to keep them from frost. The roots of our hardiest trees are seldom found above the frost line. The main leaders of the wall Peaches are trained to their places (leaving the feathers till the flower-buds are about to burst, when they are regulated and laid in), and the Figs bundled up in mats for the winter, to protect them from frost as well. I ought to have mentioned that, previous to plunging the pots and temporarily arranging the wall trees as above, every part of the house is carefully washed with soap and water, and the walls thoroughly lime-washed, when the house may be said to be done with for the winter.

The main leaders of the wall Peaches being trained, the Figs bundled up, and the pots plunged and mulched as above, the latter are left unwatered and unattended in any way till they have set their fruits, and the average temperature of the air is above that of the media in which they have been plunged, when they are raised to the surface, top-dressed with 1½ to 2 inches of sheep dung, and watered when required, when the summer routine of management may be said to have begun, which may shortly be summed up in the few words—stopping, watering, hydropulting, and fruit thinning.

With regard to atmospheric management, entrap the sunbeam in its course, hold it fast, and don't let it go until you have the blessing therefrom in the shape of a very high temperature: for the Peach, if kept clean, will stand any amount of natural heat, and revel therein. We have had it range from 11° to 120° Fahr. within the 24 hours, when the plants were in full flower, and shedding their pollen iferous dust, and we never had a better crop.

It may be observed, we are still cultivating the same plants with which the structure was first stocked, nine-tenths of which were maiden plants, and all from the Fulham Nurseries. Like Coniferous plants in a close plantation, they have a tendency to lose their lower branches, but they stand cutting down very well, throwing out plenty of spray from which to form a fresh head. *John Halliday, Scone Palace, Perth.*

Home Correspondence.

Diseased Onions. — I have sent you specimens of the Giant Rocca Onions, which you will perceive are affected by a somewhat unaccountable disease. In the year 1870 I manured the ground with the dung from a spent Mushroom bed, and planted with Vegetable Marrows. This year I had the land well trenched, and sowed a large breadth of Onions, part being sown where the Mushroom dung went, and part where the ordinary dung went; and strange to say, those sown where the Mushroom dung went are all diseased or rotten, whereas those sown on where the other manure went are quite sound and good. Could you at all explain why they should rot upon the Mushroom dung and not upon the ordinary dung? Has the Mushroom spawn anything to do with it? as I found several Mushrooms growing from the old dung with the Marrows last year, previous to my trenching the land. The Onions are scarcely fit to pull; but I find I must do so to prevent them all rotting. *G. A.* [It is very true there is fungous spawn about the roots of the Onions, but not all resembling that of Mushrooms, which we believe are perfectly innocent of the affection. The Giant Rocca appears to be a tender variety, and certainly does not succeed everywhere. Our own experience is not in its favour, though we should not suspect that it would fail at Cowes. The truth, however, is, that many Onions this year have been in the condition of those transmitted, especially where they have been affected with Peronospora destructor, which, however, we have failed to detect on the withered leaves, though it may have existed when they were green; still we should have expected to find some traces of it had it once attacked the leaves, or at least to find some of the resting-spores. We are inclined, however, to think that there must have been some parasite, accidentally confined to that peculiar plot of ground; as, if the affection were due to the long-continued wet and absence of sunshine for many weeks, the whole crop must have been equally affected, supposing no seed to have been used besides that of the Giant Rocca. The case, however, is quite worthy of publication. *M. J. B.*]

Viola cornuta Lavender Queen. — Among the foremost of our useful bedding plants of late years, the different varieties of Violas have held an honourable position. During a recent visit to Chatsworth, I saw one raised by Mr. Speed, and which he calls Viola cornuta Lavender Queen; it is a soft lavender colour, and viewed at a distance it produces a fine effect. It was planted in juxtaposition with the old Viola cornuta, and as much eclipsed that old-fashioned, useful variety as Mrs. Pollock Pelargonium does the old Golden Chain. I have seen nothing approaching it in colour during the summer, except a bed of Verbena Lilac Perfection at the Crystal Palace, which I saw a few weeks ago. But there is a softness and a richness about the Lavender Queen Viola that is wanting in the Verbena. The constitution of the plant is good, and it appears capable of withstanding alike both dashing wind or pelting rain, and neither tropical sunshine nor long-continued drought affect it. I hope Mr. Speed will place his new Viola in the hands of some enterprising nursery-

man, and I have no doubt but that it will be eagerly sought after by those who have to produce a continuous display in the flower garden. *Quintin Read, Pleasley Vale Gardens.*

Roses from Cuttings.—In a two-light frame, say of the size 5 feet 2 inches long by 4 feet wide, 300 cuttings of Roses might be inserted in November, and by spring most of them would have struck. They might then be put out into nursery ground until autumn, when all the best plants might be put into a prepared bed; or, if it were found that they had not struck generally, then a little mould might be put round the frame, which might be lifted off for any required use. By autumn all the cuttings likely to strike would have done so. What! 250 plants from what would have been thrown away, and such plants as Mr. Frost might injure but could not kill! Sure I am that Roses will, sooner or later, be grown upon their own roots; and what could be an object of greater interest than a bush of this kind, standing on a stem of 6 or 8 inches, with a head of 18 or 24 inches over, covered with beautiful Roses? What a sight would be a bed of three dozen or 300 of such plants, all in health and vigour, and all in bloom! The stem should be placed on the cold ground, with a depth of 8 inches of soil; and with regard to the kind of soil to be preferred, it must be remembered that for some months after the insertion of the cuttings they have no roots, therefore during this time no benefit could be derived from a rich sort of soil. Good loam is considered better for producing roots than for feeding them, hence sandy soil is best for cuttings of Roses; and another thing, it parts more readily from the roots when transplanted than a more adhesive soil. It is thought that the cutting calluses through the winter, and in the spring roots are produced from the callosity by the sheer warmth of the weather; hence the use of a frame with glass over it. By no means give artificial heat if natural heat will do; the latter is steadier and better. It is said, you should never give your roses for what you do; but I have tried to place this subject clearly before others as I see it, by giving a reason for all I recommend. *R. Y.*

Water Weeds.—It may be practicable in some cases to render the work of the swans more effective by cutting off in some measure the supply of food which causes aquatic plants to grow too luxuriantly. In too many instances the streams which feed sheets of water are polluted with sewage or farmyard drainage. The extravagant growth thus encouraged may help to teach us that if we apply not things to their right uses, they will prove to us either occasionally nuisance, or worse. That which is disfiguring in an ornamental sheet of water would give satisfaction if rightly applied to the land, by promoting the growth of useful or ornamental subjects. It must not be forgotten that the excessive luxuriance of water plants indicates often a polluted state of the water, or rather a condition which would become a serious evil but for the preventive means appointed by the Creator. One cannot be surprised at the complaints which are heard from fen countries of the increase of weed growth when we know that the sewage of whole towns, as that of Cambridge by the Cam, is (or has been) poured into them, and that there is no current sufficient to scour away the foetid mass. Water will dissolve the abundant soluble matters thus supplied—hence the low value of pond mud as a manure—and being surcharged with them will decompose and become a source of disease and death instead of health, life, and wealth to man. But here the aquatic plant steps in and takes possession, turning corruption into another form of life. Surely the vegetation which renders so important a service to man is worthy of a better name than that of "weeds." However, a weed being vegetation out of place, your correspondent may rightly call these plants by that name if they are not necessary to keep his lake water pure. But if they are necessary, if the danger of pollution exists without them, they are some of the most useful plants on his property. Their removal in any case should be attended with much extra expenditure, and if only an inflowing source of fœcal or refuse vegetable matter be cut off, and accompanied by partial removal of the mass of vegetation by the agency of swans or otherwise, a gradual diminution of the annoyance would pretty surely take place. If the pollution of an inflowing stream, derived from manures gathered in a long course out of reach of the owner of the water, such stream might be made to pass first through filtering beds thrown across the stream, with holes on the upper sides, in which floating matter might settle, and in dry weather be removed. Or the stream might be used to irrigate some land, and, giving off its impurities to useful plants, enter the lake as pure as from the original spring. Such suggestions may be of use in some cases, though possibly they may not meet the case of inquiry immediately before us. *J. M. Taylor, Seer Green Vicarage, Beaconsfield.*

Cedrus Deodara Coning.—A few days ago I was on a visit to the gardens and pleasure-grounds of John Murray, Esq., Newstead, Wimbledon Park, where I was delighted to see a large Cedrus Deodara, bearing numerous young cones. As it is the first time I have had the pleasure of seeing the Deodar producing fruit, I would recommend those parties having large trees in their possession to examine them; many may have incipient cones, but the owners may not be aware of the fact, as they are not visible till the branch is bent down. They are generally arranged along the centre of the main branches, and stand quite upright, not unlike the arrangement of the young cones of the Cedar of Lebanon at this season of the year. *O. M. N., Royal Botanic Gardens, Edinburgh.*

Wheeler's Gloucester Kidney Potato.—In the lists given lately in your columns by Potato growers, I do not meet with this name. Has it other names or aliases? We here find it the best of all early kinds. It is very little behind the old Ashleaf in coming, and is certainly a much better cropper; the flavour is also good, and it will keep a long time. I have tried near a score varieties with it, and it beat them all. Rivers' Royal is the nearest to it in every respect, but we fancy Wheeler's is the earlier by a fortnight. A kind called Early May is also very like it, coming in —as also does Wheeler's—in the month of May. I have not put manure with Potatos at planting time for many years. Even with early kinds it has a bad effect, especially in wet seasons. If they are not attacked by murrain, the tubers are swelled until most of them become hollow, or of a coarse texture. *Hy. Mills, Ewys, Penrhyn.*

Orchid Cultivation.—Messrs. Brooke & Co., advertising in your columns, request Orchid cultivators to visit their establishment, and see their "plan of supplying moisture by continued precipitation." And your esteemed correspondent, "G. H.," whose letters on this subject I (in common with others, I doubt not) read with much interest, says at p. 1229:—"There must be sufficient means of generating the moisture required without the agency of pipe-heat; and the plants must live upon the food conveyed to them by precipitation." Will "G. H." kindly explain this, with more fulness of detail? I have no "means of generating moisture" in my stove here save pipe-heat and the moisture evaporating the water in the tanks and pans, and that scattered by the hand and the syringe. And I know of no mode of precipitation but that which contact with the glass produces, and what takes place spontaneously on the surfaces of the plants. But neither of these can be "G. H.'s" or what Messrs. Brooke & Co. mean; for these have been coeval with, and inseparable from, cultivation under glass. Therefore, I again respectfully ask your correspondent, what is the mode of generating moisture, and what the plan of precipitating it, that are alluded to? *P. H. Gosse, F.R.S., Torquay.*

Large Horse Radish.—I saw yesterday, in a friend's garden, a root of Horse Radish that weighed 3 lbs. 2 oz., G. H., that an unusually large size. It was straight and well grown, and all dirt washed off before weighing; it certainly was the finest piece that I have seen. *Thos. Woodford, Eastwell Park, Ashford.*

The Seaham Hall Trial of Peas.—Mr. Draper's published tabulated report of his opinions concerning the various sorts of Peas that he has this year grown at Seaham, whilst possessing considerable interest, is robbed of much of its value, not only by the fact that no two peas can be grown in the same manner, as was straight and well grown, and all dirt washed off before weighing; it certainly was the finest piece that I have seen. *Thos. Woodford, Eastwell Park, Ashford.*

The Seaham Hall Trial of Peas.—Mr. Draper's published tabulated report of his opinions concerning the various sorts of Peas that he has this year grown at Seaham, whilst possessing considerable interest, is robbed of much of its value, not only by the fact that no two peas can be grown in the same manner, as was the case of haulm, thus presenting many kinds in an incorrect form, but also because a close scrutiny of his dates and figures seems to me to reveal certain deficiencies that perhaps may not after all exist. First, then, I find that although Mr. Draper's list of peas spread over 56 kinds, including earliest and latest sorts, yet he only finds a difference of time in their readiness for gathering of 24 days, with the exception of the Australian Pea, which, however, according to his estimate, does not appear worthy of consideration. Now, my experience of Peas in a southern county leads me to believe that a much longer period should exist between the incoming of the earliest and of the latest kinds, though sown at the same time, than 24 days; and I believe this is the experience of many more of your readers. But to test the value of late Peas we should know, not so much how early they begin to crop, as the time that they will continue to produce Peas fit for table, as well as possess capacity to withstand drought and mildew. I have found, even on dry soils, that by sowing at the same time Little Gem, Advancer, Wonderful, Premier, and Prince, I had no difficulty in maintaining a constant supply of first-rate Peas for a period of six weeks—a most important consideration where late sowings were, owing to drought, too often failures. The differences that exist between the periods of "in flower" and "ready for gathering" in Mr. Draper's Table are remarkable, and indicate either some mistakes, or else the fact that period of blooming in Peas affords no real guide as to period of cropping. Thus, Competitor is marked as in flower June 3 and ready for gathering on July 29, a period of just eight weeks, whilst Maclean's Premier is in bloom June 30 and is ready for gathering on July 14—just two weeks. That such a difference of time should exist appears incredible; but the credit, if any, must certainly be given to Premier. To add to this remarkable diversity, we find that the Peabody, growing only 2 feet in height, is marked as in flower on June 1—the earliest day of all; and yet it is ready to gather only one day before Competitor, the latter growing to the height of 8 feet. Mr. Draper affixes his marks of commendation, general and superlative, to a number of kinds, amongst which are several that grow to a height of 8 feet, and yet the very finest and best keeping of all our late tall marrows, Imperial Wonder, that grows to the same height, is declared as being "too large to be recommended;" although whether he means that the pods are too large, or the haulm too gross, I should have a difficulty in apprehending, did I not on referring to a contemporary find that his depreciatory remarks are diversified, and that Imperial Wonder is declared "too tall:" but how he reconciles this declaration of opinion with his high commendation of others that are as tall, is to me matter of wonder. If 5 feet is held "too tall" for Peas, by all means let him tar all with the same brush, and I shall then not quarrel with his conclusions. I am the more struck with this apparent inconsistency on his part, because he lays such particular stress upon the merits of Little Gem, and describes it as being the best and cheapest Peas to grow, although it averages but 18 inches in height, and is of all Peas the dwarfest. I cannot comprehend the logic that so forcibly commends Little Gem, because it is so dwarf, and yet in the same breath "highly recommends" the tallest of Peas "as the best useful kinds." Hundreds of gardeners I know continue to grow tall Peas simply because they have always grown them, but there is a strong current of public favour now setting in towards the dwarf kinds, and which has been not a little accelerated during the past season by the unmanageableness to which the tall Peas have been elevated. Dwarf, good cropping kinds are the most satisfactory to cultivate in either wet or dry seasons, for if too much rain prevails the growth will not break down the sticks, and should drought prevail there is much less exhaustion of the soil before it is produced, and with the aid of mulch the tall growing kinds. It is a matter both of interest and promise to gardeners to know that whilst we have already a goodly number of dwarf kinds of Peas, there is hope that in a year or two our present lists may be increased by the addition of several new and improved kinds. Any one who, like my stand-by, unpretending Little Gem; but if we could secure a duplicate of the former that was 10 days earlier, we should then possess the best early Pea known. This would be a step in the right direction, and it is one specially deserving the attention of hybridisers. Of later kinds I the talked-of trial at Chiswick next year, should it prove a reality, may bring to light some valuable sorts; and I would here express a hope that whenever the Fruit Committee shall meet next year to discuss the relative qualities of the various Peas then growing before them, that there will be found to be little or no lack of merit to be sufficiently acquainted with Peas to be enabled to pronounce whether or not a Pea is really new when they see it; and who will also possess sufficient practical knowledge of the requirements that constitute a first-class Pea to enable them to promptly detect whether it have any merit or not with the outside gardening community. I have not found fault with Mr. Draper's published statement because I wished to discourage private trials of that character; let every gardener do the same in the case of all vegetables from time to time, if possible; but the very fact that they are published and look well proves them of that general interest and usefulness that attaches to trials conducted under the auspices of public bodies, and which are also open to general and frequent inspection. The publication of results so obtained would carry with it weight and authority, and would prove to many a safe and reliable. I trust that we shall have plenty of these Chiswick trials in the future, and that they may result in the speedy weeding out of much of the rubbish that now only serves to cram our vegetable seed catalogues. *A. D.*

Miltonia Warscewiczii.—During the time the importations of this beautiful Orchid were being disposed of at Stevens' rooms, we received several pieces here (Fernichurst), of which some have flowered, by far the most superb variety I have yet seen among them now being in bloom. It has produced a spike with 15 flowers, which are, I think, of an extra size, the lip measuring 1 inch across. The colour is also much deeper than in the others which have flowered. We grow them in the same manner that "F. W. B." mentions. I have not heard of more flowers being produced on one spike, but I should be pleased to hear if such has been the case. *C. J. W.*

The Potato Disease.—I guarded myself by saying that I had no previous knowledge of this disease, therefore I was of course not aware that sulphur fumigation had been tried. But I would point out, that whereas I propose it "to prevent the spread of the disease," Mr. Tillery seems to have tried it to "cure" "diseased Potatos." I propose it as an antiseptic treatment for prevention, as a tried medical treatment for cure. I propose to apply it to sound, but presumably infected, tubers, he applied it to diseased tubers. My operation is in every way analogous to "blue-stoning" seed Wheat, his operation is analogous to an endeavour to restore an ear of smut to the condition of grain. I venture to say that my experiment—whether successful or not—is scientific, and his empirical; therefore I shall not abandon sulphur, and I protest most earnestly against Mr.

Tillery's statement, that "as this mysterious visitant is now known to be atmospheric, philosophy and learning are equally impotent to teach us more than we already know of its nature, or how to cure it." This is precisely what I was told when I took the rinderpest in hand, yet I saved by antiseptic treatment every animal (112) that I took charge of (vide *Agricultural Gazette* of Nov. 9, 1867). Such a sentiment would stop all research, all discovery, all progress, in every department of human knowledge. *W. Hope, Parsloe, Oct.* 1.

Cool Treatment of Orchids.—At p. 1229 your correspondent "G. H." actually confesses that he is not an enemy of cool treatment. After this confession I must be more careful, for, assuredly, I have no desire to whip him; but he must allow me to say that I have no knowledge whatever of his collection of Orchids—consequently I could not forget that the best plants were picked out of it. And, again, I am not aware that I have misrepresented him; if I have, it was quite unintentional, and I sincerely regret doing so. To some of your readers it may appear "strange that such difference should be, 'twixt tweedledum and tweedledee;" but I would remind them that up to a very recent date all epiphytal Orchids, without exception, were considered stove plants—it mattered not in the least where they came from—Mexico or Borneo, Quito or the Malayan Archipelago, Guatemala, Java, Brazil, or anywhere else; if they were Orchids that was sufficient, and, stove or bark stove treatment was recommended for all. If, at the commencement of this discussion, "G. H." meant anything, he meant that we were to go back to that temperature; but I think it has been abundantly proved that for many Orchids it is quite unnecessary, and to those who love Orchids, but hate "stewpans," I would recommend a few cool Orchids. I shall take the opportunity of noticing the quotation from Professor Dyer at another time. *Ex-Cantab.*

Beetroot Sugar.—I observe a correspondent from Australia is making inquiries as to the growth of Beetroot for the manufacture of sugar, near the precincts of the sea. In A. Barrodhson's pamphlet (Lecture at the Royal Exchange), an excellent authority, we find at p. 46—"As this root takes up 3 to 4 per cent. of mineral salts, lime, potash, and soda, and as the bases of these may interchange one with another, all attempts to make good sugar from the produce of bad lands, or soils too much manured, in ground recently cleared of timber, are certain to be entirely futile." He does not state in what part of Australia he intends to establish himself, but if within the limits that the sugar-cane, the Sorghum, or Chinese Sugar-cane, or what is known in Australia as the "Cane Brake Friend," will grow, I would be inclined to think they would be preferable to the Sugar-Beet. The Otaheite (yellow) cane surpasses all I have seen in saccharine matter. The Bourbon (purple) cane some think is not so liable to burn on shallow soils, but the juice or liquor, not being so rich in saccharine matter, is more difficult to work in the "tache." These two kinds supply their own fuel; not so the Beetroot. If, on the other hand, the Beetroot is the only plant he can avail himself of, no doubt sugar can be made, although deficient in quality; still we may hope the injurious effects of salt may be reduced to the minimum conjointly in the soil, quality and treatment of the plant. In his case, quantity may make up for quality, and I have no doubt the two may be combined by enlisting science into his service. *A West Indian Planter of* 18 *years' standing.*

Trees for Seaside Planting.—If it will be of any service to your correspondent, "Old Subscriber," I down send you a list of trees and shrubs which I noted this autumn as doing well at the beautiful watering place, Bournemouth, on the south coast, and exposed to the full sweep of the south and south-west winds. The soil is peat over deep sandy gravel, and in which, when broken up, most of our ornamental trees and shrubs seem to luxuriate. The first on my list are a double white and a red Camellia, to the first high and 10 feet through, in the highest health and beauty; they had formed lots of bloom-buds, and appeared to be just the kind of plant for such a place. If planted in groups through the woods they would form, with the Rhododendron, which flourish in abundance at Bournemouth, quite a charming feature in this wonderful place. Arbutus thrives amazingly both here and on the Weymouth side; Laurustinus, evergreen Oaks, all the Thujas, most of the Cupressus, many of the Junipers, and Pines. Amongst the last I observed fine plants of Pinus Nordmanniana, nobilis, Picea, cephalonica, Pinsapo, and leioclada, with Pinus insignis, macrocarpa, and sylvestris, which forms the great bulk of the woods here, mixed with that ugly and useless tree, Pinaster. I observed that a great many *P. austriaca* had been planted, and this is of all trees *par excellence* a seaside one. I observed that Atriplex halimifolia, Tamarix gallica, Frankenia pulverulenta, Spartium junceum, and evergreen Oaks are the best calculated to brave the fury of the winds, and are admirably adapted for advanced guardsmen, with Sea Buckthorn as their captain. Inside of these anything can be made to grow that the nature of the soil will admit of: Elder, in all its forms of gold and silver leaved, cut-leaved, and the handsome green and gold forms of racemosa; Mountain Ash here is truly a lovely plant, quite at home in hundreds of places; I saw many handsome trees of Araucaria, from 10 to 12 feet high and dark as night in their coats of mail; double Furze, the two single sorts for outsiders,—they will not bear shade; Aucuba, Laurel, and Holly, under other trees, are pleasing to the eye, the last has its home here at a place called Middle Chine, where, from some peculiarity in the soil, said to be alum shale, the tree luxuriates, and many large and handsome trees have existed from time immemorial. Euonymus, of sorts, are at home here, so is Thujopsis borealis, and Thuja gigantea, Escallonias, Mahonias, Berberis dulcis and Darwinii, with Planes, Sycamore, Laburnum, Beech, purple and other; Turkey Oak is a fine seaside tree, especially on light soils; Gymnocladus and Robinias, Wych Elm and English, also the Canadian sort, are all adapted for seaside planting. Here at Swanage and Weymouth, also all places with very different soils, and with their own especial botanical treasures, plants adapted to the varied conditions of each place, it is curious to note the difference of the three floras. I made ample notes of the generality of the species found at each place, and if you think they would interest any one I will send you the lists. Among the trees and shrubs about Bournemouth I noticed Hydrangea hortensis and japonica in several gardens, both with fine blue flowers, the last with the outer ray white and the centre blue. The blue tint, I believe, is induced by the iron ore found plentifully in the soil here; I never found any difficulty in changing the pink to blue by planting the bushes in soil impregnated with iron. I may just mention in finishing, that Portugal Laurel and Bay are amongst the most conspicuous shrubs here. I am afraid I have been a little too rambling in my list, but I give it as I made it from time to time. *John Scott, Merriott.*

Mixed Bedding Plants.—Had Mr. W. Gardiner paid a visit to Heckfield Place during the past summer, he would have been satisfied to a surety of the great usefulness of Viola Perfection as a "mixed bedding" plant. Mr. Wildsmith had there produced charming effects in some of his beds by using for centres Flower of Spring, silver-edged Pelargonium, edged with Iresine Lindeni, the Pelargoniums being dotted here and there with strong plants of the Viola. The flowers of the Pelargonium were all kept pinched out, thus making the dots of deep mauve-coloured flowers amidst the silver foliage all the more effective. I have an impression that dots of colours for contrasts are much more effective in beds or borders than are regular mixtures, the one above nothing could be more pleasing and less obtrusive than the carpet of silver with dots of deep mauve and edged with maroon-crimson. Ladies with an eye to tasteful colouring in dressing might take a hint from this combination. I agree with Mr. Gardiner in his estimate of the value of Ageratum Imperatum for a similar purpose, but this combines badly with nothing does the silvery blue of its flowers better assimilate than with the delicate pink tints of the blooming Manglesii; still it is effective and most useful in almost any company. Fortunately for the gardeners it comes perfectly true from seed, both in appearance and colour; so that a stock of almost any extent can be raised in a little heat in the spring without the necessity of keeping large stores of it in pots all the winter. *A. D.*

Leptosiphon roseus.—This would be a little gem if the colour of the flower was not so evanescent; opening a bright rosy pink, they too quickly change to a dirty dull pale hue. During the early part of the summer it grows in several large clumps, both in the country, exposed to the glare of the sun, and in town, shaded by a brick wall—all were equally dingy. I also saw Godetia Whitneyi, some of the plants being tall and bushy, whilst others were dwarf and spreading, the latter having much the brightest spots. *H. Skelton, Fulham.*

"General Wreck" of Apple Stocks.—What can Mr. Scott mean? (See p. 264.) I have been to the east, north, and south of London, and the Crab and Apple stocks of all kinds more healthy. As the "general wreck" seems to have occurred in Somersetshire and Devonshire, there must be something unfavourable in these counties to the growth of Apples, as may be observed in the orchard trees, so different to those of Gloucestershire and Herefordshire, which are full of trees with a shiny bark and grand foliage; while in the two former counties the poor damped mossy trees look as if they were tasting of death. Byethe-by, why have we retained that unmeaning foolish word "Paradise" for the Apple stock? "Paradise" is equally without meaning. These surface-rooting stocks, called Pommier du Paradis, like our English Codling and the Burr Knot Apple, all have a tendency to form roots near the surface; and from these roots being under the influence of sun-heat, they give a premature maturity to the tree, like the Quince to the Pear, or an "oft removed tree" of the Plum. There are many of these dwarfing Apple stocks, and among them two or three varieties of the French Paradise which in France survive so well in tenacious soils; for if planted in light soils, as they may be here, their roots are so near the surface as to become smoked, and the trees unhealthy. I have watched these stocks with some interest, and I find their proportions as follows: An Apple tree on the French Paradise, at three years old, is 2 feet in height, while an Apple tree on the English Paradise, or on a variety of the Doucin—the French name for a stock giving more vigorous growth than the former—is 3 to 3½ feet; but both are equally fertile. Mr. Scott's stock is a good variety—not better than many others—of the Doucin. My trees on his stock are this height, as are others on English Paradise stocks. The latter is the most useful of all, and is likely to lead to a great change in Apple culture, for every cottager may grow his Apples on trees not larger than a Gooseberry bush—planting them 4 feet apart, without having his ground shaded, as is the case with standard Apple trees. Nothing struck me more forcibly, in my last journey through Kent, than abundance of standards and the absence of dwarf trees in the gardens. This is also the case in the North and other parts of England, where standards are planted in the gardens, thus shading valuable ground. A few years since Mr. Robinson told us that our market gardens would be covered with low, lateral cordons, trained to iron wires. Your readers would, I think, be glad to know where these gardens are situated, so that they may see the fruits of his prognostication. *Malus.*

Lord Palmerston Peach.—I have gathered from a young tree of Rivers' Lord Palmerston Peach, seven Peaches weighing 4 lb. The tree has been planted on the north wall of my cottage orchard-house. This is a grand Peach; and, according to my experience, seems to be a good bearer. *F. Bell, The Gardens, Weston Hall, Towcester.*

Grafted Potatos.—In the year 1868 I spoke pretty freely in these columns against the folly and waste of time in trying such absurd and useless experiments as Potato grafting, and I must say after my visit to South Kensington a short time since, where these said grafted Potatos were exhibited in larger than one disciple, I am more fully convinced that the practice is worse than useless; and I am more than surprised that the report that appeared in these columns respecting them, should be allowed to pass over without some comment from the numerous readers and contributors. You do not believe in the Potato and Artichoke grafting, of course, Mr. Editor. [No.] Neither do I. You believe in Potato grafting. [To some extent.] So do I; but not with the view of procuring new varieties. I should as much believe in the Potato grafted into the Artichoke producing new varieties, as the Potato producing new varieties when grafted into another. Now I admit Potatos can be grafted, having tried the process; but as I can get a Fluke without grafting it into a Regent, and *vice versâ*, why should I bother myself with grafting? If I want to produce new varieties, I sow seed, and in one season I have tubers larger than my first, and from a packet of seed I have red and white rounds, red and white kidneys, &c. What more could I wish for? Potato grafting will not do this; then why try to make people believe the moon is made of green cheese? Some tubers may believe, but other folks know it is all gammon, and you don't grow one. My last grafting experiment was tried in pots: the pots were half filled with soil, and the grafted tubers placed on the top and not covered, so that I could watch the process thoroughly. As the eye of the graft pushed forth, the pots did the same, nearly to the soil. Alma was grafted into a Regent, I had Alma Potatos. In lifting up some of the sets, or stocks, that I thought I had taken all the eyes out of, I found some growing as well as the graft; here I had Almas and Regents. I might have fancied otherwise, but not having facts I could not believe. Alma grafted into a Carrot produced Alma Potatos, Red Regent grafted into a Turnip produced Red Regents, the same when grafted into a Parsnip. Potato grafts are very accommodating, they will grow grafted into almost anything a little moist, but they are still the same all that, and nothing more. Now, if you really want to get a new variety by the grafting process, graft the stems of two opposite varieties together, and when they are properly united, cut them in two, as you would make a cutting, through the centre of the united part; strike it and plant it out. You may thus get a variety for your pains. I am told by those who follow the tuber grafting, the result is to be seen more in the growth of the haulm than the tuber. Now this is a very poor consolation, and not at all encouraging to experimentalists. No doubt these few remarks will lead to some discussion on the subject of the utility of grafting Potatos; very few believe in it, whilst thousands believe it is all a farce. I reserve some other comments and facts which may be brought out on some future occasion; I merely throw out this hint that some of our friends may enlighten us on the subject—both *pro* and *con*. *Edward Bennett, Enville Hall Gardens.*

Trees for a Porous Soil.—What sorts of trees would you advise planting where the soil is loose and gravelly—and where the subsoil is nearly all gravel? Elms seem to do better than Limes, as Limes shed their leaves so soon—some trees at the present time are almost leafless—and what sort of Elms? How would Scarlet Chestnut and the common do? Will Austrian Firs do better on the above soil than Scotch Firs? My opinion is, that Austrians maintain a better outline than the Scotch—am I right? *J. T.* [To this Mr. Ingram, Belvoir, kindly replies as follows:—Your correspondent's description of the soil in which he wishes to plant trees is too general to permit any very precise information. Sandy and gravelly soils

vary in character and fertility when derived from primitive rocks, and the gravelly and sandy particles are irregularly broken and dispersed, and more or less decomposed. He may rely on satisfactory results in planting Oak, Elm, Ash, Lime, and Coniferæ. The accumulations of the sands and gravels of the Bunter conglomerate characteristically spread over parts of Sherwood Forest, Notts, are less favourable than the foregoing, but nevertheless good timber may be found on the light lands of this formation; and if your correspondent has land of this character to plant, he may try all the ordinary deciduous trees common to English plantations, as well as Pines both Scotch and Austrian, Larch, and Spruce. The poor siliceous sands and gravels of the Bagshot sand formation are infinitely less satisfactory than the foregoing, and if the land to be planted is of limited extent, and upon this formation, and a healthy and rapid growth desirable, the ground had better be dressed with clay and the peaty accumulation generally found on the surface, and the whole trenched in two spits in depth, he may then plant two kinds of Elm, the narrow-leaved and the Wych, Spanish Chestnut, Sycamore, Horse Chestnut, and Turkey Oak, and both Scotch and Austrian Pine. A glance at neighbouring plantations on similar soil to that alluded to by "J. T." will help materially to assist him in the selection of trees for the locality in which he resides. *W. J.*]

Foreign Correspondence.

INDIA: HYLAKANDY DISTRICT.—*A Combination of Diseases in Tea.*—From daily observation the following are the several forms and stages of these diseases. The trees when first showing symptoms have somewhat a spotted mildew-like appearance on the old leaves; on others of intermediate growth the margins are tipped with a brown tinge, which rapidly extends over the surface of the leaves to the axils, and forms a brown and blackened mass. The spots in some instances, on the older leaves, on examination with a lens, are found to be brown Fungi, the black or the spores of Ferns when ripe; on the same leaves is a crustaceous substance, resembling white scale or Lichen; others having a blotched and blistered appearance, which ultimately perforates them and destroys their vitality. I have found the same to occur where the plants have a free circulation of air, and the soil is well stirred about their roots, and in those in jungly or shaded situations; also in plants naturally sickly, and in those healthy and strong,—other plants growing alongside them looking the picture of health, by which it seems that situation is no criterion whatever. I also have followed the roots down to their extremities, thinking they might have come in contact with a subsoil detrimental to the functions of the plants, and that from this cause they were not able to supply a due amount of sap for the maintenance of the foliage. The constitution of the trees being impaired might have resulted from the above causes; but, on examination, I assign any reason, the roots being in perfect health, and the soil of desirable nature. By shaking badly affected trees most of the leaves will drop, leaving them nearly skeletons, the young growths remaining only on the top of the trees, and of stunted character; plants so treated do not fully recover themselves until after the ensuing season's pruning.

Another distinct form from the foregoing attacks the young succulent roots and leaving buds, sprinkling the leaves over with tiny dots, which eventually so contracts them as to give them the appearance of Fuchs or mammilated Tea—this being the most destructive. Some seasons when this epidemic prevails, the manufacture is completely stopped in some parts of the country until a new growth is obtained. On one occasion I was forcibly struck on noticing several trees on a teclah, an eastern aspect; the front parts were brown, dauntless, and exposed to the full back green and healthful: it would appear that they had received from that quarter a blast. On minute examination, I could not find any insect to which to attribute these results, therefore I am under the impression they are the results of atmospheric causes I am unable to define,—probable excess of moisture combined with lack of sunshine and fluctuating temperature, which seems to be favourable to its spreading. In some parts of the country, where rain has fallen more abundantly, this epidemic is more prevalent than in this locality. *Scientific Tea.*

[Various productions or conditions occur on or in the Tea leaves which have been submitted to our notice.

One of the most common is that peculiar condition of Lichens belonging to the genus Strigula, which has been described under the name of Cephaleuros, and of which a figure will be found in Berkeley's "Introduction to Cryptogamic Botany," p. 392. On the same leaves occur one or more of the species of Meredera. These Lichens in general occur only on old leaves or those which have been slowly developed, and in such latter cases intimate a want of vigour in the plant.

Certain detached thin white gregarious patches, occasionally presenting a fructifying disc, appear to be the stylophorous condition of some Lecanora, perhaps L. epiphylla, Fée. The sporophores are delicate and filiform, bearing thread-like stylospores two or three times their length.

The orbicular white spots with a dark hard border sprinkled with minute black specks, are due to the obscure genus of Sphæroïdæe, Depazea. It frequently happens that the spots are developed without any fructification, or it does not arrive at perfection. This appears to be the case in the present specimens, as no sporidia or asci have been detected.

Besides these are several forms of disease, for the most part depending neither on Fungi nor insects.

On the underside of some of the leaves are raised pustules indicated above merely by a little discoloured speck. These pustules are composed of brown distorted cells, showing the condition which is so common in vegetable diseases where the cellulose is discolored with ulmates or humates. On other leaves are orbicular spots equally varied, on either side of the leaf, and perfectly flat. In some cases they are confluent, and form brown patches of an irregular outline. These, like the former, consist of diseased brown cells, but more closely packed.

Another form consists of paler thin patches which penetrate to the under surface, where they are more deeply coloured, but only very slightly, if at all, prominent. This, however, may be merely an incipient condition of some Depazea, for in one of the specimens we find myceloid threads.

In another leaf, of which only a fragment was sent, there are subelliptic spots, which are transparent by transmitted light.

We have besides leaves with broad brown patches which extend further on the underside than on the upper, which may be due to water resting on the leaves, and lastly, leaves in which the cuticle is detached in broad patches, very much after the fashion of Holly leaves when they are eaten by larvæ.

Such are the various appearances presented by the leaves; the cause in most cases can be determined, if at all, only where the plant is grown. *M. J. B.*]

Societies.

ROYAL HORTICULTURAL: *October* 4.—Major Trevor Clarke in the chair. Among those present were M. Andrè, delegate of the Central Horticultural Society of France; M. Gillekens and M. Spruyt, delegates from the Federation of the Horticultural Society of Belgium. At the termination of the usual preliminary business of the meeting, Mr. Berkeley called attention to the two varieties of Avocado Pear (Persea gratissima), which exactly accorded with the two types in the "Botanical Register and Magazine," where it is stated that the more delicious variety came from Mexico. He also explained that the large Gourd sent as a sort of Vegetable Marrow, was in fact a Bottle Gourd, the poisonous qualities of which are notorious, insomuch that when the ripe fruit is used for bottles it is necessary to wash them well with vinegar before they are used. He then called attention to sonic of the wonderful specimens of Fungi, which exceeded far in number and interest any previous exhibition, owing to a Gessler visit from the gardens at Castle Ashby, which appears to be quite new. After announcing the awards, he gave a short lecture on the Potato disease, illustrated with numerous figures. He referred especially to the nature of the mould, the two modes of germination of the spores, the rapidity with which the mycelium penetrates the most intimate tissues, whether divided immediately from the spores or from the mycelium, the extraordinary power in decomposing the cellulose not only in immediate contact, but with that of neighbouring cells; proving incontestably that the well known brun of the diseased cells is due to the action of the Fungus. He then explained the nature of the resting spores in various species of Peronospora, and stated that probably the Artotrogus of Montagne, figured in the Journal of the Horticultural Society in 1846, is the resting spore of *P. infestans*. Major Clarke then pointed out a splendid scarlet-flowered hybrid which he had produced from Begonia Pearcei and B. cinnabarina.

The International Fruit Show was held in the large conservatory, and, considering the shortness of the notice given, it was a great success, nothing having been seen in London like it since 1862, on which occasion the show of fruit was more extensive than this, and the fruit, on the whole, was of a better quality. Nevertheless, on the present occasion, there was ample variety for the gratification of seeing that all our best well known fruit growers sent immense collections of the best they have, and the foreign element was exceedingly well represented by MM. Baltet, of Troyes, who held their own amongst their English competitors most successfully. A large collection of fruit was also sent from Belgium, but, unfortunately, it did not arrive in time for exhibition—on the first day, at all events. We say the first day, because the show was open almost at the last moment to keep the show open on Thursday, the principal exhibitors heartily co-operating in this direction. To give some idea of the size of the show, we may state, on good authority, that there were nearly 1500 dishes of Apples, the same of Pears, and 220 bunches of Grapes, to say nothing of a very large miscellaneous class, which included some excellent Pines, Peaches and Nectarines, Figs, Melons, and Cob Nuts. Amongst the International section of the show first, we had in class 1, which was for the most complete collection of Apples, three fruits of each variety, an extensive and very spirited competition between Mr. W. Paul, MM. Baltet frères, Messrs. Lucombe, Pince & Co., Exeter; Mr. Sidney Ford, gr. to W. E. Hubbard, Esq., Leonardslee, Horsham; Mr. Webb, Culham House, Reading; Mr. Moffat, gr. to H. Allsopp, Esq., Hindlip Hall, Worcester; Mr. Chaff, gr. to A. Smee, Esq., Carshalton; Mr. Carmichael, Sandringham; and Mr. E. Spivey, Hallingbury Place, Bishop Stortford, &c.; and the prizes were adjudicated, after a long and careful examination, 1st to Mr. W. Paul, 2d to MM. Baltet frères, an extra prize being awarded to Mr. Chaff. Mr. Paul's collection consisted of 171 of the best culinary and dessert kinds, and gained, as it deserved, much praise, on account of the nice size, cleanly grown, and fairly well-coloured examples staged. Looking over the other collections, which were too extensive to be particularised in the short time which was available, but of great credit to their owners, we noticed that the following were the kinds most often shown, and appear to be the leading varieties in their different classes:—Kerry Pippin, Dutch Mignonne, King of the Pippins, Waterford Nonpareil, Harrow Pippin, Hoary Morning, Blenheim Pippin, Warner's King, Manx Codlin, Adams' Pearmain, Alexander, Rymer, Mère de Ménage, Reinette du Canada, Golden Winter Pearmain, Calville Saint-Sauveur, Rhode Island Greening, President Dufays Dumonceau, Wadhurst Pippin, Belle Dubois, Fenouillet Gris, Belleffleur, Calville Rouge d'Hiver, Reinette Baudoc Antoine, Borsdorffer, Alexander, Tower of Glammis, Cellini, Lord Derby, Calville Malingre, Dredge's Fame, the pretty little Lady Apple, Margil, Forans' Pippin, Lord Suffield, Bess Pool, Winter Hawthornden, Ribston Pippin, Dumelow's Seedling, Beauty of Kent, and Pott's Seedling. In the next class, which was for the best collection of dessert varieties, Mr. W. Paul and Mr. Webb tied, 2d, the former with a collection of 60 dishes of very fine fruit, and Mr. Webb with a similar collection of 50 varieties. Mr. Scott, Merriott, sent the immense number of 200 varieties; and capital collections were also contributed by Mr. Ford, Mr. Spivey, Mr. Pragnell, gr. to D. W. Digby, Esq., The Castle, Sherborne, and Mr. Moffatt. The best collection of culinary Apples came from Mr. S. Ford, Mr. Chaff being 2d. The former had 80 varieties, all well grown examples, and the latter had 50, his specimens not being quite so large as he usually has them, but very good for the season. Very creditable collections also came from Mr. W. Thomson, Clavedon, Ilford; Mr. Lydiard, Bathenston; Mr. Spivey, and Mr. Stephenson, gr. to T. C. Barker, Esq., Leigh Hill, Essex. The 1st prize for the most complete collection of Pears, three fruits of each variety, was taken by MM. Baltet frères, who put forward 150 sorts—probably the most complete collection ever seen. Many of the fruits were magnificent in size, but a great number were much smaller than usual. The most noticeable kinds were Calebasse Grosse, very large; Beurré Diel, Beurré Clairgeau, Prince Impérial, Theodore Van Mons, a different Pear from the one grown under that name in this country; Thompson's; Beurré Superfin, very distinct; Passe Colmar, also another variety of this name; Lieut. Poitevin, fine in size, but not in shape; Urbaniste, Bergamot d'Esperen, De Tongre, not unlike a large Beurré Bosc; Passe Colmar Musqué, quite unlike the Passe Colmar form, being nearly round; Emile d'Heyst, Beurré Rance, Souvenir Vaisse, like a large Knight's Monarch; Doyenné Gonbalt, very fine; Marie Benoit, fine; Belle de Septembre, large and good; Beurré Diel; and Louise Bonne d'Avranches, of Jersey, the same as the old variety. Of certain new varieties of MM. Baltet's raising we shall speak next week. Next to MM. Baltet came Mr. Chaff; an extra prize being awarded to Mr. Spivey, both contributed capital lots. The competition in this class for second honours was very strong, the exhibitors being Mr. W. Gardiner, gr. to E. P. Shirley, Esq., Lower Eatington Park; Messrs. Lucombe, Pince & Co.; Mr. Windsmith, gr. to Viscount Ivery, Heckfield Place; Mr. Pragnell, Mr. Carmichael, Mr. Webb, Mr. Stephenson, Mr. S. Ford, and Mr. Lydiard, Batheaston; the best varieties shown being Louise Bonne of Jersey, Beurré Magnifique, Huyshe's Prince Consort, Beurré Gansel's Bergamot, Duchesse d'Angoulême, Beurré de Rance, Beurré Clairgeau, Seckle, Beurré Diel, Knight's Monarch, Foretle, Prince Albert, Huyshe's Bergamot, Hacon's Incomparable, Délices d'Arenberg, Beurré, Beurré Bachelier, Triomphe de Jodoigne, and Beurré Hardy. The best collection of dessert and kitchen Pears also came from MM. Baltet Frères, the first-named being very good indeed display. For culinary kinds Mr. Moffatt, and for kitchen sorts Mr. Earley, were respectively 2d, with first-rate collections. G. F. Wilson, Esq., Mr. Chaff, Mr. W. Thompson and Mr. Stephenson also exhibited.

Of Grapes there was a very good one, and though we had no strikingly sensational examples, those shown both for the International and the Society's prizes were first-class. Messrs. Lane, of Great Berkhamsted, in a collection of four

Chancellor, Barrington, and late Admirable Peaches, from Mr. Jack, gr. to the Duke of Cleveland, Battle Abbey, Sussex; a splendid collection of Late Peaches and Plums from Mr. Tillery, gr. to the Duke of Portland. Welbeck; a nice dish of Guavas (Psidium Cattleyanum), from Messrs. Lucombe, Pince & Co.; a very nice miscellaneous collection of fruit, including good Melons, Peaches, Plums, Cherries, and nuts; examples of Belle de Fontenay Raspberry, a very excellent, free bearing, and late variety, from Mr. Turner; a dozen very fine Salway Peaches from Mr. Colborne, gr. to J. Blyth, Esq., Woolhampton; a beautiful basket of Coe's Golden Drop Plums, from Mr. Record, gr. to the Marquis of Salisbury, Hatfield House; a very fine collection of 21 varieties of Nuts from Mr. Jeffery Wehb, Calcott; a dozen very handsome specimens of the new Brockworth Park Pear, from Messrs. J. & C. Wheeler, of Gloucester; some good Plums and Cherries from Mr. B. Porter, gr. to Mrs. Bonham, Isleworth; and a very large and interesting collection of Apples from Messrs. Rivers & Son, Sawbridgeworth; a large and very good collection of Pears from Messrs. J. & C. Lee; and a smaller one, of superior quality, from Mr. Cadger, gr. to J. Shaw Leigh, Esq., Luton Hoo.

Exhibition of Fungus.—Year by year these exhibitions undoubtedly gain in interest and value, and the display of Fungi on Wednesday last was better than that of any of its predecessors. One always finds something new at these exhibitions, and either in the shape of an addition to the British Flora, or in the form of some advance made in the science of mycology. Out of such a vast collection of Fungi, as exhibited on Wednesday, it is almost impossible to note all the novelties, but probably the most valuable really new to our lists was the undoubted Agaricus clypeus of Fries; the specimens exhibited were found by Mr. Plowright, of King's Lynn; but lately this species has been quite common about the north of London and Epping Forest. The next object of interest was, perhaps, the large group of Coprinus atramentarius, Fr., grown from spores planted in the spring of this year by the writer of this notice. No other competitor appeared under class 3 for cultivated edible Fungi. As this is probably one of the first efforts made in this direction, the following particulars of the experiment may have some interest. This species was selected as being because it commonly comes up in garden beds, and because all the Coprini are of very rapid growth. The spores were planted in a common sunny garden bed, near a place where some pots of a warm temperature stood, this position being selected because the plant in question frequently grows about decayed wood; the spores were deposited by merely placing some ripe plants, gills lowermost, upon the earth. The spores quickly germinated, at once, for during the present September an abundant crop of Fungi appeared, of the same species as the one placed upon the bed, and in the exact spot where planted. I have elsewhere written at length upon the habits of this species every year, one in May, the other in September. Some other species of Coprinus are very readily grown; for instance, C. radiatus, Fr., will appear in a day or two after laying spores have been placed on moderately fresh horse-dung. An account, too, has been published elsewhere of the artificial production of Agaricus Lovcianus, B. Three species of Geaster were exhibited, one a magnificent specimen, referred to G. mammosus, Vitt., found amongst Rhododendrons at Castle Ashby. This has been exhibited here before, but it is a singular fact that neither of the two new species of Lycoperdon exhibited last year were shown again this season. It is also remarkable that the fine Lactarius controversus, P., has at last appeared in the London district, and is now met with in Epping Forest. Hitherto it had only been sent from Hereford and the adjoining districts. It seems quite possible that on these plants being transmitted from one place to another the spores may get disseminated and grow in the new districts. Several striking instances might be cited in support of this; for instance, two years ago we had specimens of the rare Agaricus popinalis sent us from Bath; it had never been hitherto detected in the London district, but now it has become quite a common plant about Bath. We never saw the rare and highly coloured Peziza radiculata, Sow., till a year or two ago, and after bringing some fresh specimens to London, a large bed of it grew shortly after, almost close to our door. A great many other equally curious instances might be given if we had space at our command. Three specimens of Sparassis crispa, Fr., were shown, good specimens of Polyporus intybaceus and P. giganteus, and plants of P. lucidus from an Elm, and P. squamosus from an Elm, of unusually gigantic proportions. Two enormous groups of Agaricus jumosus, var. pollus, were at one end of the room. It is probable that such extraordinary groups of this species were never seen before; they were each about 4 feet round. There was but one poor specimen of Fistulina hepatica exhibited, showing how impossible it is to depend with any certainty on the appearance of certain Fungi in certain seasons. For our own part, after making every effort, and showing the contents of seven hampers full of Fungi, we could only get one Agaricus nebescens, and no one had Hygrophorus virgineus at all. A splendid plant of Thelephora multizonata, Berk., was exhibited by Mr. English, from Epping Forest, together with Polyporus Schweinitzii, Agaricus (Flammula) sapineus, Fr., the latter incorrectly labelled a Agaricus conissans. This species (A. alnicola) was exhibited last year, and made out with much care by Mr. Berkeley. It is common in Epping Forest and elsewhere. Mr. English also had Polyporus imbricatus, Bull, which is new to our lists, but we had it at the Horticultural Society last autumn. The exhibition of Boletus castaneus and of a Cordiceps on a wasp, by Mr. Michael Terry, deserve a line of record, as does Agaricus porrigens, from the grounds of the Duke of Argyll, at Inverary, and the beautiful specimen of Cortinarius armillatus from Reading: this species was very striking, as the stem was banded by a large vermilion zone, bright in colour, like a collar of arterial blood. Some beautiful specimens of Agaricus Tatarus were forwarded by Mr. Broome, and we observed Agaricus vaccinus and A. obturatus in the room.

It was altogether a most successful and very instructive exhibition, as nearly all the edible and poisonous Fungi, with many plants of great botanical interest, were shown in a living state. The visitors showed the greatest possible interest in the plants exhibited, and it must be conceded by all that the Fungus exhibition is one of the best attended of the year. Fungi at length begin to be appreciated according to their deserts, and are no longer set down as the favourite food only of a mere few famous but fanatical fungologists, and as not fit to take a foremost place in the autumn fare of ordinary people. The weather had been anything but favourable for Fungi for many weeks previous to the exhibition, but the success of the show, and the many species and specimens displayed, were somewhat unlooked for. The fine sunny weather of harvest time made the hearts of fungologists sink, and their expectations fall to zero. They asked themselves and each other where would Fungi be after such a wretchedly dry and brilliant September. With depressed and despairing faces they scoured the country, to find nothing but melancholy fields of ripe corn. Even the deep woods were speckled with flecks of exasperating sunlight, and the delightfully dank, wormy, and vaporous places of old, were dried with the prolonged drought. Fairies were fain to drop and hide their mortification, till at last, and just as all the harvest had been gathered in, the rain came down in one continued outpour, but almost too late for the feast. *W. G. Smith.*

As regards the prizes awarded for Fungi, we may say that in the class for a collection of edible and poisonous Fungi, the exhibitors were Mr. English, Epping, Mr. W. G. Smith, and Messrs. Hoyle & Austin, Reading; and the prizes given by W. W. Saunders, Esq., were in the first instance withheld by the judges, as the feast-standard; but, through some informality on the part of these exhibitors, the 1st prize was afterwards given to Messrs. Hoyle & Austin, who also staged the best collection of edible Fungi.

Floral Committee.—W. Marshall, Esq., in the chair. This was a very small meeting, nevertheless it was productive of a few plants which were thought worthy of First-class Certificates — Desmodium pendulifloruni, a rather new Japanese shrub, with crimson-lilac leguminous flowers, from Mr. Bull, through which is twined Akebia and Macrozamia spiralis, a very handsome Cycad, which has been in cultivation in England for some years, and was certificated on this occasion as a good old handsome greenhouse plant. From Mr. R. S. Williams, Mr. Green, gr. to W. W. Saunders, Esq., exhibited a most interesting series of Terrestrial Orchids, from Trinidad, St. Catherine's, New Grenada, and Rio de Janeiro; and also a plant of Miltonia Moreliana, on which were five of the most magnificent flowers we ever saw. A Special Certificate was awarded. Several collections of plants were shown in connection with the fruit show in the conservatory, and amongst these were a showy group from Messrs. Veitch & Son, which included a specimen of Oncidium macranthum, with eleven flowers; a fine specimen of Zygopetalum maxillare, and flowering examples of Vanda Benasoni, Vanda Morelli ana, Vanda coerulea, finely bloomed; Pleione lagenaria, and a nice specimen of the new Vriesia brachystachys, &c. Mr. W. Bull and Mr. B. S. Williams also contributed choice groups of Orchids, Palms, and other flowering plants. Messrs. Standish & Co. exhibited a nice group of plants, including some fine new Gladioli, hybrids between G. brenchleyensis and G. cruentus, of which latter beautiful plant the writer gave a flowering specimen. T. W. Paul exhibited a dozen of exceedingly well flowered Tea Roses in pots, which attracted a great amount of attention, in such fine condition were they shown for this late season. To most of the above prizes were awarded.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair, though a great number of new subjects were brought before the Committee on this occasion, only two awards were made,—Special Certificates to Mr. Cox, Madresfield Court Gardens, for a handsome dish of Seedling Grape strongly resembling Mrs. Pince's Black Muscat, but superior to that variety in flavour; and from Mr. Bannerman, gr. to Lord Bagot, Blithfield, Rugeley, came a Grape stated to be a seedling, and which the Committee considered to be the Mill Hill Hamburgh. Mr. Wildsmith, gr. to Lord Eversley, sent a large bunch of Black Hamburgh Grapes grown on a Vine 30 years old, and which supplied the dessert every month for Mr. W. Taylor, Southbrook Road, Lee, Kent, came examples of Chenopodium Quinoa, which is recommended as a substitute for Spinach. From Mr. Gardiner, Eating-House Park, Sussex, a collection of Potatoes was sent, and Messrs. Carter & Co. sent a fine lot of Onions, including Nasby Mammoth and Nuneham Park, which the Committee considered to be very closely allied; also Nuneham Park Tree, which Messrs. Carter also have White Intermediate and Bedfordshire Champion, considered to be identical. Mr. Hepper, The Elms, Acton, sent fine examples of his Giant Tomato, and Mr. Wildsmith also exhibited some very fine specimens of Veitch's Autumn Giant Cauliflower. Mr. Evershed, Munsted Gardens, Godalming, had a collection of vegetables, consisting of Cauliflowers, Peas, and Vegetable Marrows. Mr. Gribble, gr. to Sir T. Lloyd, Bart., Ashe Park, Clifton, Warwick, exhibited examples of a seedling Grape, which produces sometimes white, sometimes black, and at others variegated bunches,—the Committee considered it to be the same as the Aleppo or Variegated Chasselas. From Mr. Pearson, Chilwell, came several seedling Grapes of great promise, one named Abram Bass, a large black berry, like Alicante, with a Muscat flavour, being considered highly promising. From Mr. Wells, Southend, came some examples of Grapes grown in ground Vineries, not, however, of such good quality as in former years; the varieties were Golden Champion, Black Hamburgh, Muscat of Alexandria, and Muscat Hamburgh. Mr. Parsons, Ranelagh Nursery, Leamington, exhibited specimens of the Abercairney Grape, which is the true Alicante. Messrs. Lucombe, Pince & Co., also sent a white seedling Grape, having large bunches and oval berries, sweet in flavour. Mr. G. Cardnell, gr. to H. J. Sewell, Esq., Cheddington, Edenbridge, Kent, had some good specimens of Late Admirable Peaches, and some fine examples of Walburton Admirable Peaches also came from Mr. Poulton, gr. to C. S. Dickins, Esq., Coolhurst Park, Horsham. Messrs. Veitch & Sons exhibited a large and interesting collection of Beets, with examples baked and boiled, including Nutting's Dwarf Red, Whyte's Black, Dewar's Dwarf Red, Veitch's Crimson, Dell's Crimson, Pine-apple, Egyptian Turnip-rooted; also the Improved Silver or Seakale, and the Red Brazilian for decorative purposes, and some very well-grown Endives. Mr. Bland, gr. to Earl Kilmorey, Gordon House, Isleworth, sent a fine basket of Mushrooms; and from Mr. F. Dancer, Chiswick, came dishes of Belle de Septembre and Sandall's Prune, both valuable late Pear varieties. Messrs. Carter & Co.'s prizes, offered for a collection of 6 varieties of American Potatos, were taken by Mr. C. Frisby, gr. to H. Chaplin, Esq., and Mr. J. Garland, Killerton, Devon.

Notices of Books.

Hardy Flowers: *Descriptions of upwards of Thirteen Hundred of the most Ornamental Species, and Directions for their Arrangement, Culture, &c.* By W. Robinson, F.L.S., author of "Alpine Flowers for English Gardens," &c. London: Warne & Co.

Whatever the causes, and they may be various, there can be no question that the class of plants known as hardy perennials have for some years been neglected by cultivators in the search for materials for the decoration of the flower garden, except in those instances in which particular genera or species have been taken up as florists' flowers. That our gardens were thus losing much of the interest which should attach to them was becoming evident; and not all the attractions of masses of brilliant colours, albeit though sometimes arranged with a high degree of skill, could ward off the inevitable charge of sameness and monotony, while in too many cases the want of skilful arrangement laid the flower garden open to the additional charge of meretricious vulgarity. These facts being patent, and the public taste being ripe for change, our horticultural seamen, and none more sedulously than the author of this book, have set themselves to endeavour to bring about a revival of the taste for hardy flowers, and not without a considerable amount of success.

The book now before us is written in aid of this object, and, as we have said, is a work, not been hastily thrown together, but is the result of study and application over a considerable period. Moreover, it is a subject upon which his own personal experience has specially assisted him—a vast advantage even to the most prolific book-makers. Hence we are disposed to regard the bulk of the more than 1000 books its writer has produced, and we may at once specially point to one of its features which will, no doubt, be of especial value to many of those who consult its pages, namely, that of indicating the positions for which each of the plants described is best adapted. These plants comprise, as the author says, "the cream of all the ornamental, hardy herbaceous, alpine, and bulbous plants, at every elevation, from sea-shore to snowy peak, that are now to be had in cultivation."

After an introductory page or two, we come to the first part of the book proper, which comprises chapters on the mixed border for hardy flowers, on the mixed shrubbery border, on beds and groups of hardy perennials, on the isolation of hardy plants, on hardy perennials and alpines as bedding plants, on similar plants in the rock garden, the wild garden, in water, and in boggy ground, on hardy florists' flowers, on hardy flowers in the spring garden, on the culture of hardy flowers, and on the propagation of hardy flowers. We take a passage from the chapter on spring gardens, to show how this part of the subject is handled:—

"The garden depends as much for its beauty in spring on hardy flowers as the spring does for its life on the sun. How the earth is embellished with plant beauty at this season must be apparent to all who can get a glimpse at her where yet even a little free. For countless ages the flowers of spring have been the joy of the year. From the time of our first great poet, Chaucer, who forsook his book and his devotion to walk in the mead to see the flowers 'against the sunné spread,' to Milton's 'vernal flowers,' and Gray's 'violets dim, but sweeter than the lids of Juno's eyes, or Cytherea's breath,' 'pale Primroses,' 'Lilies of all kiods,' and the 'Flower de Luce,' their beauties have been sung by our greatest poets. But beautiful as are our own wildings, we may enjoy a host of continental, American, North Asian and other plants, which, being as hardy and as easily grown as our own, would make the margins, so to speak, of our garden paradisiacal scenery more highly beautiful. How many a snowy white, how thoroughly hardy, and how pretty and useful even as tiny evergreen shrubs, are the fberises!

How they live on or in anything—thrive on rockwork, and luxuriate on the level ground, even if wet and heavy enough to kill some of their pretty allies! Many and beautiful are the spring-flowering plants of the same order, which would thrive if only granted a spot in some outlying half-shift place, and would doubly repay in one spring day the very slight trouble of obtaining and planting them. Where will the Aubrietias not thrive if let alone? and what more beautiful? The numerous beautiful Narcissi—strong, delicate, too—how lovely are they, and how effective in Spring! How sweet is odorus, how pale and graceful tortuosus, how golden and showy maximus! Is there any spring flower that can surpass in beauty or interest poeticus or ornatus, which is very like to poet's Narcissus, but a week or two earlier in flower? These will all grow in the wildest of shrubbery margins, if only permitted to develope their leaves in peace. In many other orders are those things of beauty suited for the sort of gardening I am advocating: however, it is needless to mention the many plants that may be used in the spring and early summer garden, as that is done in the borders of the week. But is there any of this beauty to be seen in eight out of ten of the gardens of England—of the beauty of either choice British or hardy exotic plants? Very little! A chance spray here and there has escaped the tasteless of the Vandals in the borders, people write and talk a good deal of spring flowers and spring gardening, yet, speaking generally, there is no such thing as spring gardening to be seen in English gardens. I do not call the display of a few Tulips, Hyacinths, Wallflowers, &c., that we in autumn to produce a few faint and abortive flowers in spring, and, perhaps to be torn up before they have time to open them fully, 'spring gardening.'

"Lately there have been hardy subjects introduced into botanic gardens during the last 20 years, where are the Anemones of sorts, the double Rockets, the pretty double white Ranunculus, the fine double Wallflowers of sorts, and the numerous good things that our forefathers used to make a garden pleasant during the sweetest months of the year? Frequently thrown away, or so neglected that persons with large gardens, and who spend much money on them, look during the summer months of the year, not half so many floral charms around them as the peasant who happens to live in a good wild flower district!"

Here is one of the several examples of grouping hardy flowers in beds :—

"No 2. This shall be a grand bed of Lilies. Unhappily, the finer kinds of Lilies are anything but as plentiful as they should be, though in a free rich soil they increase readily enough. Few may have them sufficiently plentiful for some time to make beds of them, but when once possessed know how truly fine they are when seen well-arranged in a large bed in an isolated place, they will hardly rest content without such glorious garden ornaments. With such kinds as Lilium testaceum, and tigrinum Fortunei in the centre, surrounded by the queenly candidum, burnished croceum, spotted canadense, pomponium, colchicum, vivid chalcedonicum, and gradually worked down to the edge with dwarf but beautiful kinds like excelsum, longiflorum, and tenuifolium, a large circular or oval bed might be made on the grass, in some isolated spot, which, for the highest beauties of colour, form, and fragrance—for, in fact, almost every quality by which variable beauty endeavours itself to excel—will be surpassed by any arrangement of indoor or outdoor plants. The only precaution that need be mentioned is, that to grow Lilies well they should have 3 feet, or nearly that, of free loamy earth, with a good dash of vegetable mould to it. Even now, such kinds as L. tigrinum, longiflorum, candidum, croceum, bulbiferum, &c., are to be had pretty cheap—although the chief thing that gardeners have been doing with the hardy Lilies for some time past has been to throw them on the rubbish heap, to make way for such glorious 'stuff' as the yellow Calceolaria and the red Geranium."

The second part, which forms the bulk of the book, is devoted to an alphabetical arrangement of the most ornamental hardy flowers, and comprises descriptions of the plants, with brief notes on culture, and observations on the positions for which the different kinds are best suited. An example will best show the character of this part of the book. We select that relating to Spiræas :—

"*Spiræa Filipendula* (Dropwort).—A rather common native herb, with pinnate leaves and erect stems, 1 to 2 feet high. Flowers, in summer; yellowish-white, often small, freely produced in long spikes forming a terminal panicle. Leaves, tripinnate; leaflets in 3 or 4 pairs with an odd one, about 2 inches long and about 1 inch broad, oblong, acute, serrate; the terminal one ovate. Europe, Asia, and America.—Associated with the more vigorous herbaceous plants by wood-walks or banks, &c., and also grouped with the finer herbaceous plants having fine foliage. Division.

"*Spiræa Filipendula* (Dropwort).—A rather common native herb, with pinnate leaves and erect stems, 1 to 2 feet high. Flowers, in summer; yellowish-white, often small, freely produced in long spikes forming a terminal panicle. Leaves, tripinnate; leaflets in 3 or 4 pairs with an odd one, about 2 inches long and about 1 inch broad, oblong, acute, serrate; the terminal one ovate. Europe, Asia, and America.—Associated with the more vigorous herbaceous plants by wood-walks or banks, &c., and also grouped with the finer herbaceous plants having fine foliage. Division.

"*Spiræa Aruncus* (Goat's-beard S.).—A vigorous perennial, 3 to 5 feet high. Flowers, in summer; white, small, finely produced in long spikes forming a terminal panicle. Leaves, tripinnate; leaflets in 3 or 4 pairs with an odd one, about 2 inches long and about 1 inch broad, oblong, acute, serrate; the terminal one ovate. Europe, Asia, and America.—Associated with the more vigorous herbaceous plants by wood-walks or banks, &c., and also grouped with the finer herbaceous plants having fine foliage. Division.

"*Spiræa Filipendula* (Dropwort).—A rather common native herb, with pinnate leaves and erect stems, 1 to 2 feet high. Flowers, in summer; yellowish-white, often small, fre

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

WHETHER *Caladiums* have ceased to be ornamental or not, they should now be collected from cool conservatories, greenhouses, &c., and taken into drier and warmer quarters, so as to ripen their bulbs properly before they enter their season of rest, which, in the case of early grown plants, has already arrived. The first symptoms of a tendency to ripen the leaves must be the sign to withhold water and to give but very little afterwards. These remarks also apply to the requirements of *Gloxinias*, *Achimenes*, &c., the risk of repeating suggestions given two or three weeks ago, I advise that all *Heaths* be examined minutely, to detect at the earliest moment possible any symptoms of mildew, which forms and spreads so quickly now. The small winter-blooming *Ericas*, such as *E. Willmoreana*, *E. hyemalis*, *E. grandinosa*, and *E. gracilis*, should now be placed in as light and airy a position as possible, elevated upon pots turned upside down or otherwise, so that the blooms have every opportunity to form freely and well. With regard to watering, though it is needless to state that none should suffer, such as these need, if anything, even more attention than others whilst actively engaged in flower-bud formation. Bring pots containing bulbs of *Tropæolum tricolorum*, and any other of the section, into the full light of an exposed greenhouse shelf. Those who grow any of the winter blooming varieties of the old *Tropæolum Lobbii*, should shift them at once into their flowering pots, and place them in their winter quarters, so that they may get a good start before winter sets in. With the necessary amount of judgment as to soil, a bright but uniform gradation, the temperature in Orchid-houses. The temperature in the Cattleya-house should now be reduced to a mean of about 60° by night, with an increase, when by artificial means only, of 5° or 8° by day—the *Vanda*, *Saccolabium*, or *Aerides* houses being kept at an increase of 10° or 12° beyond this. Purchased bulbs of the pretty *Sparaxis*, *Ixias*, and clumps of the indispensable *Hoteia japonica*—so useful for forcing—should be potted immediately they come to hand, and be well "watered in" when the outer or two subsequently to each pot is filled around it. It will be observed that many plants immediately they are "housed," or brought in from the outer air, will begin to ripen off previous to shedding many of their leaves, some varieties of course more than others. More attention will therefore be needed for some weeks to come in regard to keeping the structures free from too marked symptoms of decay. I deem it of some little importance, however, not to remove too violently or quickly such ripening leaves upon any kinds of plants which are at all valued. Rather permit them to ripen off as far as possible naturally, so that their natural functions are not interfered with. The buds upon *Chrysanthemums* may be thinned out as soon as they have made sufficient progress to enable the grower to discern well which should remain and which be removed, especially in instances where fine blooms are desired. In practice I could never see any real benefit gained by the thinning process. The few blooms left become larger, certainly, and are all very well where home decoration is sacrificed for the purposes of exhibition; not so otherwise, with the single exception of the new narrow-petaled Japanese varieties. The petals upon these are so long that the necessity for thinning may sometimes arise to obviate one bloom being unduly mixed up with others, which certainly destroys their individual beauty.

FORCING HOUSES.

Give the necessary attention to pot *Vines* intended for early forcing by removing them to a place where they can be kept perfectly dry, by way of a preliminary to pruning, &c. Where proper coverings are not afforded for outdoor Vine borders, especially those the Vines in which are forced, the best kind of temporary or makeshift protection should be made use of. Bracken Fern being light, and admitting the air with moderate freedom, makes a good base when placed about a foot thick; a proper thatch of straw may be given, which would make all watertight. Next to this, simply straw or stable litter, or both, used as above, should be requisitioned. *Pines* generally will now need much more caution in the matter of watering. Strictly speaking, each plant should now be tested, and watered or not according to its own individual wants. Finally and expeditiously make all right for the winter in regard to the tan-pits, and the materials used to cause the necessary fermentation. Fruiters must, when the fruit has almost finished swelling, be kept in a dry, high temperature, as by these means, aided by as free as possible a supply of fresh air only, is good flavour to be insured, especially at this infelicitous season. Pot *Figs* and all others which cease to produce fruit should be kept as cool as possible, to induce them to assume a state of rest, by laying the former upon their side under a wall or other such sunny position. Where late *Melons* are still growing, maintain a somewhat dry heat to insure good flavour to the fruit. Wherever vacancies occur in *Peach*, *Nectarine*, or *Fig houses*, these should be made up forthwith by removing the most promising young trees of proper growth from the outside walls.

HARDY FRUIT GARDEN.

Remove now decisively all young summer or late autumn growths from the wall fruit trees, to stop the activity of the roots, and to admit the light and air more freely around the older shoots which are required to remain. Preparation may be made at any time now for planting young *Fruit Trees* against walls, by properly preparing the border, as well as adding fresh loam and a moderately good supply of wholesome manure. Those who are intending to plant young *Apricot trees* would do well to add a little chalk to the other soils collected to grow them in, if the natural soil of their district is not of a calcareous nature.

HARDY FLOWER GARDEN.

Lilies of the Valley may now be taken up and repotted for forcing, as well as a first batch of flowering shrubs for a like purpose. Any of the hardy annuals moderately small and fit to work, *Anemones* may be planted into the open borders. The scarlet Turban and other *Ranunculuses* may likewise be planted into the border prepared previously. Be careful to plant with the root "claws" downwards, and not more than 2 inches deep, or less if the ground has been recently worked, and is likely to settle down at all. Prune immediately all pot *Roses* intended for winter forcing. Do not cut any fine strong shoots upon "Teas" too severely, but, by leaving three or four eyes upon such, endeavour to secure fine growths and blooms. I have alluded recently to the small, yet flaunting hardy bulbs early, and may refer to such as *Crown Imperials*, *Gladioli* of the hardy border kinds, *Fritillarias*, tuberous *Irises*, &c., in addition to those mentioned before. I would proffer another timely warning, *i. e.*, that all plants of any value be protected from frost and severe rain after protection. The time is already short to prepare the roots for winter, independent of the risk run if left out-of-doors any longer.

KITCHEN GARDEN.

I need add little to the suggestions of the past week or two in this department. The rain has come liberally, and the empty spaces are now filled with such subjects as are in demand throughout our trying winters. If available space still exists, by all means fill it with more *Lettuce*, *Endives*, *Cabbages*, *Cauliflowers*, &c., even at the risk of having an excess. A poor supply exhibits a weakness on the part of the cultivator, whilst superabundance is never found fault with. Sow a good batch of *Australian* or *Golden Cape* upon a warm southern aspect, as well as more *Turnip Radish* seed. *W. E.*

Miscellaneous.

ENGLISH GRAPES.—Our own country is noted for producing some of the finest Grapes in the world, and the fame of the great Vines at Hampton Court and Cumberland Lodge, Windsor, is great. On one occasion George III. was so pleased with a performance at Drury-lane Theatre that he gave orders for a hundred dozen bunches of Grapes to be cut off from the Hampton Court Vine, if so many could be found upon it, and sent to the actors. The gardener presented his commission, and informed his royal master that he could still cut off as many more without stripping the tree. *Food Journal.*

Notices to Correspondents.

APPLE SKINS BECOMING LEATHERY: *J. J. S.* It is not uncommon for Apples when stored to turn of a dark colour, the skin becoming leathery. On such individuals Sphæropsis malorum sometimes occurs, but whether it is the cause or consequence of the change it is difficult to say. *M. J. B.*

ARAUCARIA IMBRICATA FRUITING: *F. E. T.* Yes, several times, at Bicton, Kew, and elsewhere.

ARTICHOKE GALL ON THE OAK: *W. W.* You will find an article on this gall at p. 1162.

BOOKS: *J. S.* Mr. W. Paul's "The Rose Garden," or Mr. Cranston's "Cultural Directions for the Rose," will meet your requirements.

DIPLADENIA: *Yorkshire.* Much the finest we have seen. The colour is a clear carmine, as deep on the outside as within, and the clear white sharply defined base of the tube is a distinctive feature. We should be glad to be favoured with your address.

DISEASES IN TEA: *G. L.* See p. 1266.

FIGS: *Sub.* Figs "gape" or split open through too much humidity surrounding them whilst ripening, either too much water at the roots, or too damp an atmosphere in which they are growing. The best sorts for general culture under glass are White Marseilles, Lee's Perpetual, and the carpaccotte Grise, the best of all Figs. There is no good manual on Fig growing yet written.

INSECTS: *Y., Balham.* Blatta americana, small variety. Sink two or three earthenware basins up to the rim in the ground among the Orchid beds, and fill them with bread crumbs. They will scramble in and can't creep out. *I. O. W.—M.G., Brigg.* Caterpillar of Geometra (Odontopera) bidentata of Stephens; dentaria, Hübner. *J. H.*

LONDON AGENT: *F. M. Bilton.* We really do not know whether Mr. G. Classens has an agent in London or not.

NAMES OF FRUITS: *J. E., Dublin. Pears*: 1, not quite certain; 2, Urbaniste; 4, Flemish Beauty; 6, Beurré de Capiaumont. *Apples*: 1, Sops of Wine; 4, Hick's Fancy; 5, Dutch Mignonne; 6, Emperor Alexander; 7, Keswick Codlin; 8, Kerry Pippin; 9, *Apples*: 1, Oslin; 2, Warwickshire Pippin; 5, Herefordshire Pearmain; 6, Sturmer Pippin.—*J. C. & Co. Apple*: Cellini Pippin.

NAMES OF PLANTS: *G. D., Newry.* The common Soapwort, Saponaria officinalis.—*J. S. B.* Clematis tubulosa, Turcz., a native of N. China.—*J. S. J., Aberdeen.* Your Heaths are—2, the fine-leaved Heath, *Erica cinerea*; 3, Kerry Pippin variety of the same. 4, *E. cinerea alba*; 3, the cross-leaved Heath, *E. Tetralix*; 4, the common Ling, Calluna vulgaris.—*J. G.* The flower and leaves both belong to Mutisia decurrens—a very ornamental plant, frequently grown as a greenhouse climber, and originally introduced from the Andes of Chili.—*C. B. 1*, Lastrea patens; 2, L. aristata; 3, L. decomposita.—*J. C. 1*, Cheilanthes odora; 2, A very pretty and novel variety of Pteris serrulata, which we will take an early opportunity of noticing again.

NEW GRAPE, ROCKWOOD SWEETWATER: *J. Woodthorpe.* Is this anything else than an abortive sample of the common Sweetwater, or Black Muscadine, having ripened early in consequence of having produced no seeds? There is nothing new in it, or crushed seeds of Elais guineensis.

PALM-OIL MEAL: *C. P. Manchester.* The Palm-nut meal, used for feeding cattle, is the crushed seeds of Elais guineensis.

PERIWINKLE: *F. L., Southport.* If you are anxious to have your banks of this plant green all the winter, you must not cut down until it shows signs of making new growth in spring, and then it is best only to thin it out.

SELECTION OF KITCHEN APPLES: "*Stewbly, Bucks.*" We would recommend the following:—Lord Suffield, Keswick Codlin, Hawthornden, Beauty of Kent, Tower of Glammis, Waltham Abbey Seedling, Blenheim Orange, Mère de Ménage, Alfriston, and Dumelow's Seedling.

STEWING PEARS: *Ibid.* Catillac.

VINE-LEAVES: *J. D. & S.* They are in a very bad condition. The raised spots on the under-side are extremely common, and are not injurious, but the larger brown spots, which in some cases destroy half the leaves, have arisen from water resting upon them. In one case we find an undescribed Phoma on them, but we do not suppose this has anything to do with the condition. The roots must be in a very bad state, or there must be some other cause which can only be estimated on the spot to account for so much mischief. *M. J. B.*

WINE MAKING: *Fragility* asks if some of our readers will furnish him with vessels are required to make Grape wine from unripe Grapes, with and without their leaves, of which many, like himself, will have a large quantity this year. He would also be obliged for a recipe for making both still and effervescing wines; quantity, 18 gallons.

CATALOGUES RECEIVED:—George Such (South Amboy, N. J.), Catalogue of some Stove and Greenhouse Plants, including Orchids, Palms, Ferns, &c.—Joseph Tremble & Sons, Catalogue of Dutch Bulbs and other Flower Roots.—Richard Dean, Catalogue of Hyacinths and other Bulbs, Hardy Bedding Plants, Seeds, &c.—Butler, McCulloch & Co., Autumn Catalogue of Dutch and Cape Bulbs, Flower, Vegetable, and Agricultural Seeds, Plants, &c.—Ewing & Co., Catalogue of Dutch Flower Roots.—Harrison & Sons, Autumn Catalogue of Selected Dutch and other Flowering Bulbs.—Wood & Co., Catalogue of Bulbs for 1871.—W. MARRIED.—On the 28th ult., at Selhurst Congregational Church, by the Rev. N. T. Langridge, GODWIN MOGINIE SHAW, of 56, Cannonbury Park South, and Mark Lane, E.C., third son of John Shaw, of Northumberland Park, Canonbury, to ELIZA CHRISTIANA, elder daughter of the late WILLIAM FREDERICK FARWIG. No cards.

Markets.

COVENT GARDEN.—Oct. 5.

A large consignment of foreign produce has reached us during the last few days, comprising Pears and Apples and some late Peaches—the latter, however, very inferior. Home-grown fruit, consisting of the same varieties, has been also more plentiful; and good late Peaches, such as Barrington and Late Admirable, are making better prices. Coe's Golden Drop and Magnum Bonum Plums are both coming very good.

FRUIT.

Caution to Gardeners.—When you ask for

SAYNOR'S CORKS which received the PRIZE PRUNING and BUDDING KNIVES, see that you get them. Observe the mark SAYNOR, also the Corporate Mark OBTAIN LATELY, which is on every genuine Knife.

S. & C. regret having to caution Gardeners and others, but are compelled to do so, in consequence of the sale of common quality, having been sold for the genuine one, and which has caused many complaints. They are made to them of the best steel and of their make, all of which are warranted both by Sellers and Makers.

S. AND C. CORKS and BUDDING KNIVES are the best and the cheapest in the market.

Paxton Works, Sheffield. Established upwards of 30 years.

For Double Poughs,

APPLY TO

J. AND F. HOWARD, Bedford,

or their Agents in every part of the Kingdom.

Catalogues free.

FOWLER'S PATENT STEAM PLOUGH and APPARATUS for DRAINING and WORK in every Agricultural County in England.

For particulars apply to JOHN FOWLER AND CO., 71, Cornhill, London, E.C., and at the Steam Plough Works, Leeds.

THE CELEBRATED GRANITIC PAINT. Manufactured Solely and Only by the Silicate Zopissa Composition Paint Company.

For Price Lists, Testimonials, and Patterns of Colours, apply to THOMAS CRAVEN, Secretary, 3, Parliament Street, Westminster, S.W.

THE SILICATE ZOPISSA COMPOSITION. TO CURE DAMP in WALLS, and Preserve Stone, &c., from Decay. Manufactured Solely and Only by the Silicate Zopissa Composition Paint Company.

For Particulars and Testimonials apply to THOMAS CHILD, Manager, 30*a*, King William Street, London, E.C.

HEAD GARDENER, for New England, U.S.—In consequence of the number of applications for above situation, the Advertisers have decided to appoint a person from personal knowledge. Applicants that the SITUATION has been FILLED this week.—London, October 6, 1871.

JOHN CARTER, NURSERYMAN, Keighley, Yorkshire, is in WANT of a MAN for Laying-out new Grounds, and to take the Management of Nursery Work. Also a YOUTH about 14 years old, under a Propagator of General Nursery Stock. This is an excellent opening for a persevering Lad.—Address, stating wages, &c., as above.

To Gardeners.

WANTED, for the Country, about 30 miles west of London, a MARRIED MAN, who can thoroughly undertake the Management of a Greenhouse, with a knowledge of Rockwork. Also a YOUNG MAN, to assist in Nursery Work. Gardeners' Lodging.—Apply by letter only, stating wages required and other particulars, to E. C., R. H. Smith's Newspaper Office, Great Marlow, Bucks.

WANTED, a steady MAN, used to Nursery Work, to plant Forest Trees, Graft and Grow Fruit Trees and Roses, and to take the Management of the Nursery Work. Gardeners' Lodging. A good Workman can have constant employment.—Apply, with references from last Employer, to J. W. COLE, Nurseryman, Halton Holgate, Spilsby, Lincolnshire.

WANTED, a steady young MAN, from the country, to do Jobbing Work and assist in Plant Houses. A good opportunity for one wishing to learn Plant Growing. Wages 12*s.* per week.—A. B., Mr. Lewis Baker, Upper Richmond Road, Putney, S.W.

Working Gardener.

WANTED, a single MAN, accustomed to a Market Garden, and who thoroughly understands his duties. State wages and last place.—A. B., 1 Post Office, Deptford, Greenwich.

WANTED, a Working Gardener and Wife (without children preferred), as LABOUR MASTER and MATRON of a small Industrial School.—Miss C., Beckley, near Oxford.

WANTED, a first-class TRAVELLER, well versed in Plants of every description and their value. Journeys will not be limited. If a knowledge of the Seed Trade preferred.—Z. A., *Gardeners' Chronicle* Office, W.C.

WANTED, a SHOPMAN.—Must be experienced, and quick at Counter Work; one acquainted with the Retail, and capable of taking entire Charge of that Department, preferred.—Address, stating Amount of experience, and wages required, to C. D., *Gardeners' Chronicle* Office, W.C.

WANTED a JUNIOR ASSISTANT, in the Seed Department. Must live on the premises.—THOMAS E. THOMSON, 20, High Street, Birmingham.

WANT PLACES.—Letters to be Post Paid.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Further particulars on application to Messrs. R. G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

A knowledge of Agriculture and Agriculture. No objection to going abroad. Unexceptionable testimonials, and satisfactory references.—J. JONES, 43, Fish Street Hill, London, E.C.

GARDENER (Head).—Married; thoroughly practical in Forcing all kinds of Fruits, Flowers, and Vegetables; also Kitchen and Flower Gardening. Has had extensive experience in the Cultivation of Stove and Greenhouse Plants, the Erecting and Heating all kinds of Horticultural Buildings, &c. Single-handed place not accepted. Seven years' character.—A. B., 13, Charles Street, Portman Square, London, W.

GARDENER (Head, or SINGLE-HANDED).—Age 30, single; thoroughly understands his business. Two years' good character.—A. B., 80, High Street, Hampstead, N.W.

GARDENER (Head, WORKING).—Age 30, married; understands Stove and Greenhouse Plants, Vines and Orchards, and Flower and Kitchen Garden. Five years' good character.—A. B., Post Office, Stroud, Gloucestershire.

GARDENER (Head), where four or more are kept.—Age 32, married, no family; understands Cucumbers, Melons, Stove and Greenhouse Plants, and Orchids; also Kitchen and Flower Gardening.—A. Z., Nursery, Newmarket, Cambridgeshire.

GARDENER (JOURNEYMAN).—Age 23; eight years' experience. Two and a half years' good character.—X. Y. Z., Post Office, Sunning Hill, Berks.

GARDENER (SINGLE-HANDED, or otherwise).—Age 24; single. Three years' good character.—J. J., Mr. Jones, Stationer, Post Office, Upper Clapton, E.

GARDENER (SINGLE-HANDED, or SECOND), where a two or three are kept.—Age 21; understands Stove and Greenhouse Plants, Vines, Melons, Cucumbers, and Flower and Kitchen Garden. Two years' character.—ROBERT ESTCOURT, Brownshill, near Stroud, Gloucestershire.

GARDENER (SECOND), in a Nobleman's or Gentleman's Garden.—Age 20; two years' good character.—B. A., Post Office, Twickenham.

GARDENER (UNDER).—Good character.—Mrs. SPARKES, Coleshill.

GARDENER (UNDER), or to take charge of Houses, where very good character.—Address, stating terms, F. C. A., General Post Office, London.

GARDENER, or GARDENER and BAILIFF.—Middle-aged, married, no incumbrance; has had great experience in Forcing of Fruits, Flowers, and Kitchen Gardening; also the Management of Land and Stock. Good character and references can be had.—J. B., Mr. Randall's Yard, Paddington, W.

ESTATE BAILIFF, or ESTATE BAILIFF and GARDENER.—Age 29, married; understands all kinds of Estate Work, including Fencing, Draining, Road-making, Timber and Plantations, Hedging and Ditching, Wood and Underwood Measuring for Farm Buildings, &c. Also a good practical Gardener; has had a good deal of experience in Fruit and Vegetable Growing for Sales and Pleasure Grounds. References from present and previous employers.—A. B., Ewell, Surrey, Wilts.

ESTATE AGENCY, &c.—Age 29; has had 14 years' practical experience on some of the largest Estates in the country; thoroughly understands the Value and Management of Land, Stock, Timber, Game, Woods, Farm Buildings, including Fencing, Draining, Levelling, Land Surveying, Preparing Plans, Specifications and Estimates for the Erection of Farm Buildings, Cottages, &c. References to present employer.—J. H., Mr. Dennis, White Horse Street, Chelsea.

FOREMAN and PROPAGATOR, in a Florist's Nursery, to Grow for Exhibition or otherwise.—Has a thorough knowledge of the Trade in all its branches. Unexceptionable references from late employers.—A. B., 6, Upper York Place, St. John's Wood, London, N.W.

PROPAGATOR, or PROPAGATOR and FOREMAN.—Middle-aged; well experienced.—C. A., Bootle Hall Lodge, Irlam Lane, Lincare, Liverpool.

IMPROVER, where he could gain a knowledge of the General Routine of a good Garden.—A steady, obliging young Man, who has been three and a-half years in the profession. No objection to Make himself Useful. Unexceptionable character.—W. S., Post Office, Old Beckenham, Kent.

To the Seed Trade.

TRAVELLER.—The highest references.—P. J., *Gardeners' Chronicle* Office, W.C.

To the Seed Trade.

WAREHOUSE MANAGER, or SHOP FOREMAN. —Age 30; 13 years' experience in all the Departments, and first-class references.—M., Box 68, Post Office, Chester.

COUNTER MAN.—Age 23; has been five years in one of the largest London Wholesale Houses. Understands Plants.—C. C., 2, Albert Cottages, Avenue Road, Hackney Downs, N.

To the Seed Trade.

SHOPMAN or ASSISTANT.—Thoroughly experienced, and willing to be useful in any branch of the business. For particulars apply to T. T., Messrs. Hurst & Son, 6, Leadenhall Street, London, E.C.

The Gardeners' Chronicle and Agricultural Gazette.

SATURDAY, OCTOBER 7, 1871.

THE subject of "bolting," or PREMATURE RUNNING to SEED of roots and allied plants has come so prominently before us during this exceptional season, both from correspondents and in our own crops, that we venture a few remarks upon it.

Those who observe crops, however slightly, must have been impressed with the unusual extent of this evil, especially in Cabbages, Mangels, and Carrots. Early or late sown plants have been equally affected, and it would seem that no kind of management has been able to prevent it.

In our own practice the contrast in this respect between 1870 and 1871, has been most marked, for whereas in the former year it was scarcely noticeable, in the latter it has prevailed in crops similarly treated in both seasons so as to be remarkably conspicuous.

Last year a crop of 5 acres of Cabbages, which was drilled and thinned out after the manner of Mangels and Swedes, was remarkable for nearly total absence of "bolted" plants, while from 8 acres of Mangels it would have been difficult to have collected a wheelbarrowful of these disSightly objects.

This year, in looking over crops of Cabbage, Mangel, and Carrots, the tall flowering stems at once attract attention. The following, indeed, is an estimate of the amount of this mischief:—

Crop.	Per cent. of Flowering Stems.	Extent of Crop.
Oxheart Cabbage	5	1 acre of each
Large Drumhead	4	
Small Drumhead	3	
Battersea	0	
London Market	0	
Long Red Mangel Wurzel	1	
Yellow Globe Mangel Wurzel ..	½	2 acres of each
Ditto ditto	1	
Sugar-Beet	1½	
Swedes and Turnips	0	40 acres
Rape	0	6 acres
White Belgian Carrot	7	Small plots
Green-topped Carrot	5	Quarter of an acre
Parsnips	0	

These percentages are not given as being absolutely correct, as it will be understood that from the difficulties of the case they can only be approximations, still as such they afford some points of interest to which we would now advert. The Cabbages were drilled on March 28, and many of the Oxheart had become well hearted at the end of July. At this time many of the bolted examples seem to have burst through a previously formed heart, so that the percentage of these is doubtless put at a higher rate than it ought to be. With regard to the Drumheads, they have fairly bolted to the amount stated, and we may account for this from the want of purity of sort. Drumhead Cabbages are those that have been farmed most, and as their seed is not selected with the care of garden sorts, any crop will show a tendency to run off in different directions. We have this year seen some autumn planted Drumheads very largely sported in this way, and, indeed, when we examined them the bolted specimens had nearly ripened their seed. Now upon our inquiring what would be done with these, we were informed that the seed would be saved. If, then, this is the way in which seed is grown, we need not be surprised at bolting, as we know both from theory and practice that "bolters" will beget "bolters," and a want of trueness to sort will result in a mixed crop, and it is just this want of care in the growth of seeds for the farm in comparison with those for the garden which will in a great measure account for the conditions we have been describing. That there is a difference in crops in the directions indicated may be gathered from our Mangels. Here two lots of Yellow Globe from different seedsmen differ in bolting, the one being double that of the other, and we have no doubt but at lifting other differences will be present.

As regards the Carrots, it should be noted that our garden crops have shown a disposition to bolt, but certainly not to a quarter of the extent of the field sorts, which we account for upon the same principles as those already noted with regard to the Cabbages. We have before pointed out the tendency of the Sugar-Beets to bolting, which is also accompanied by great forkedness of roots; and it should be remembered that this is entirely a field crop, for the seed of which as yet we are wholly dependent upon the foreign grower, who, in as far as we can gather, does not recognise the importance of "selected roots" to the extent that our own seedsmen at least pretend to.

But, if we inquire into this subject, we shall find that there is something more in the matter than can be accounted for from the seed, for it will be seen that it is more prevalent this year than usual. It is then to be presumed that the exceptional season has had something to do with it. Now, if we consider that the produce of our root and allied crops is the result of those cultivative processes which tend to make them so strictly biennial that the first or seeding season is in them devoted to the production of—in roots, an enlarged bulb; in Cabbage, an enlarged heart; which, again, has little to do but to produce seed the following season; if then, as in this year, moisture has resulted in a plethora of the first growth, much of the bolting complained of may be, and doubtless is, due to this cause.

If this be so, seed carelessly grown would be more liable to it than the reverse, and we may then be quite certain that if degenerate seed does not in dry seasons show its effects so readily as in wet ones, yet continuous wet, as in the past summer, will only the more clearly demonstrate to the observant cultivator that seed is not always carefully grown. Against this notion it may perhaps be urged that, judging from the list of crops above given, it will be seen that Swedes and Turnips have not bolted; but as regards this matter, it should be noted that we have heard much of these going greatly to leaf and not bulbing well. It is, however, a little too soon to judge these accurately, though we have observed a tendency to *neckiness*, which in itself is an evidence of degeneracy.

We have been particular in these few notes, on account of the importance of the matter, which has been referred to by some of our correspondents, and in the hope that they may elicit further remarks upon so interesting a subject.

TICKS—that is, the blood-sucking little insects (or crustaceans, to speak by the card), known to agriculturists as dog ticks, sheep ticks, and cattle

FIG. 291.—IXODES RICINUS—MALE.

ticks, and to entomologists as species of the genus Ixodes—have been exceptionally abundant this year, or we have been brought exceptionally often in contact with them. We have received com-

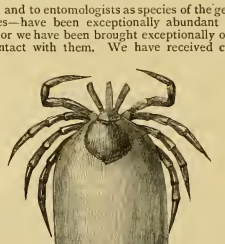

FIG. 292.—IXODES RICINUS—FEMALE.

plaints of their abundance, and specimens have been sent to us from various quarters for their names, and a remedy—a remedy not for use on dogs or cattle, but — to protect man him-

FIG. 293.—IXODES TESTUDINARIUS—FEMALE.

self from their attacks, for they do not confine themselves to the lower animals, and one of our correspondents has informed us, that the lawn where he was employed swarmed so with them as to be a serious annoyance to those making the hay; creeping up their clothes and into their hair, and fastening on them as they do on dogs—an experience which we also have made in person. Our attention has thus been, as it were, compulsorily directed to them, and as we think that an erroneous impression exists as to their habits, we shall state the result to which we have been led by our observations this year.

It is usually supposed that these ticks are parasitic on the animals on which they are found, a separate species being appropriated to each animal, and that they breed either upon them or about them. The grounds for this idea are chiefly their occurrence on different animals. Thus Dr. LEACH describes six species, as found in Britain, one from the swallow, one from the hedgehog, one from dogs, another from dogs and hedgehogs, and another from dogs (principally pointers, in autumn). The sixth which he describes appears to belong to another genus (Nycteribia, which infests bats). Again, there are accounts of vast numbers of one species being found in dog-kennels, swarming so in the chinks of the wood as to render it necessary to pull them down and burn them. Lastly, to bring together all that we remember in support of the special attribution of one kind to each animal, there is a species of Ixodes (I. flavomaculatus) described from examples taken from a boa constrictor, which is marked yellow and brown in patches so exactly in harmony with the colours of the boa itself that one is very apt to jump to the *à priori* conclusion that the one is made for the other, and, consequently, restricted to each other's society.

Notwithstanding all this, our own observations decidedly lead to the conclusion that in Britain, at least, there is no specialisation of species to different animals, and that the bloodsucking propensities or parasitism is accidental and temporary, like (although of longer continuance than) that of the mosquito or bed bug, or more analogous still to the attacks of the leech. In the first place, as to LEACH'S species, the characters which he gives do not enable us to recognise any of his species as different from the common one, they being mainly drawn from points (such as the colour of the legs) which are somewhat variable; and we have been unable to confirm the soundness of his species by an examination of his type specimens, for we have failed to discover them in the only place where they were likely to be, viz., the British Museum. For ourselves, we only know two British species of tick, which are exceedingly like each other, but which may be readily distinguished by the characters which we give below. The one we have found only in the south of England, the other in the north and in Scotland. But whichever is the species of a district, all animals are attacked by and suffer from it indiscriminately. On examining the dogs, cattle, and the sheep of a district, we have invariably found them all to be attacked by the same species of tick. Furthermore, the ticks do not reside on the animal itself. We have carefully gone over a dog before taking it out in the morning, and could have sworn that not a single tick was upon it, and on returning in the evening have found several. At first these are small, but if let alone, by sucking the blood the females gradually swell and increase in size for a day or two, when, being now completely full and satiated, they drop off of their own accord. Repeated observation has convinced us that the ticks live in herbage—what is called rough ground, and that it is only when an animal passes through it that they avail themselves of the opportunity of fastening upon it, and that it is all the same what animal passes, it fastens on all indiscriminately.

It may be said, if this be so, then on what does the tick feed until it meets with an animal on which to feed? It is supplied with an admirable phlebotomising and sucking apparatus, formed out of the converted mandibles, maxillæ, and ligula. And the question is,—for what purpose has it been provided with such a wonderful sucking apparatus for pumping up blood from warm-blooded animals if it can live without it?

To this we must reply *Scottice* by another question: To what purpose has an equally wonderful blood-sucking apparatus been supplied to musquitos, gnats, midges, *Simulia, Tabani et hoc genus omne?* Musquitos in the countries where they occur are in such countless myriads that it would take all the herds in the world to supply a minute fraction of them with blood-food. And in many places, as for example the Canadian swamps, it is only at rare intervals that a solitary

mammal intrudes into their haunts. How do they live? One fact peculiar to all the Culicidæ (musquitos, gnats, midges, and *Simulia*) disposes at once of the half of them. It is only the females that have this blood-sucking apparatus. We do not know that the cause of this distinction has ever been ascertained, but we would suggest as a not improbable explanation, that the lives of the males may be shorter. Their part of the great duty allotted to the perfect stage of insect life, viz., the propagation of their species, can be performed in a day, or an hour, after their emergence from the pupa, and Nature does not care what becomes of them afterwards; whereas the female has to mature and deposit her eggs—and that must take time—choose food, and the means of taking it, must be provided for her. Whether, in default of blood, she can feed upon the juice of plants, we have no means of knowing—it is not likely; but what is likely is, that she may have such great powers of abstinence that she can, in case of necessity, do either altogether or for a long time without food. The tick, which we see has a similar apparatus, can live for a long time without it. Prof. Westwood tells of one which he kept alive for twelve months without food, and at the end of that time it laid fruitful eggs and then died. We do not see any difference between the suctorial apparatus of the male and female ticks; we have found both on animals, but we cannot call to mind having found the male adhering with his head buried up to the eyes in the flesh, like the female; the male may do so notwithstanding, but we are sure that he is unable to take in the blood in the quantity that the female does. Her abdomen is a flexible leathern sack, which swells to many times her natural dimensions or those of the male. Four times as long, four times as broad, and eight times as deep, will give the comparative estimate of her relative dimensions when full and fasting in square magnitude, which, according to our imperfect powers of arithmetical calculation, would make the creature hold upwards of 100 times its own size. The male, on the contrary, has not a leathern bag for an abdomen, and it may be that he has the same measure dealt out to him that the musquito has, namely, no power of suction, the female permitted to revel in an unlimited quantity of claret, while he is condemned to total abstinence.

The two British species of tick that we know are—1. Ixodes Ricinus, of which fig. 291 represents the male.

It is distinguished from the next species by the scutell or carapace of the male being uniformly brown, and by its palpi being elongate and straight on both sides, and by the longer and more slender legs with an acute termination, which, however is rather exaggerated in the woodcut.

Fig. 292 shows the female when about half-full at first; and when only half-filled, her abdomen is pale salmon-coloured, when full, leaden-coloured, whence one of its synonyms (Ixodes plumbeus).—From Scotland and North of England.

2. Ixodes testudinarius (Murray).

We call this species testudinarius in allusion to the scutell or carapace of the male being marked black and brown like the colouring of tortoise-shell. The general appearance does not differ from that of the other, but its legs are shorter, flatter, and broader, and the termination more obtuse, and its palpi are shorter, transverse and flat, and obtusely angular on the external side. Fig. 293 shows the female before she has begun to suck, and represents the natural proportions of her body in this and the other species. The differences in the legs and mandibles are the same in both sexes in both species.—From Devonshire.

This may be one of Leach's species; but as, if it be, we cannot determine which, we are driven to give it a new name. *A. M.*

—— There was an advance of 1*s.* to 2*s.* per qr. for English Wheat on Monday at Mark Lane; malting Barley also went up 1*s.* per qr.; and on Wednesday, though business was limited, Monday's prices were well maintained.—— At the Metropolitan Cattle Market on Monday the average prices for beasts did not improve, and there was a difficulty in effecting a clearance of sheep, though the supply of English was small. The same report will suffice for Thursday's business.—— The Hop Market remains very firm.

—— The Harvest Festival, which commenced at the Crystal Palace on Monday last, and extended over the greater part of the week, may fairly be said to have most appropriately celebrated a harvest which, in many respects, has satisfactorily fulfilled reasonable expectations. From a cultural and strictly utilitarian point of view, the most prominent feature of the week's entertainment was undoubtedly the imposing emblem of modern husbandry—designated "The Harvest Trophy"—erected by Messrs. Sutton & Sons, of the Royal Berkshire Seed Establishment, Reading, in the northern nave. The Messrs. Sutton have before made a display of this kind on occasions like the present, but this year they have fairly eclipsed all former efforts in this direction. So large and so varied, indeed, is the collection, and so excellent in quality are the examples exhibited, that the Messrs. Sutton may fairly take credit for having placed before the public an exhibition, the like of which has probably never been seen before, and which has certainly never been gathered together by one firm. Some idea of the size of this harvest trophy may be formed, when we state that it is 50 feet long by about 20 feet broad, at either end bearing a tower 25 feet high, and in the centre an imposing mass of the plume-like inflorescence of the Pampas-grass (Gynerium argenteum), which is also again skilfully manipulated into a design representing the "Prince of Wales' feathers," proportionate in size to the structure which it helps to adorn. There are also represented over 200 varieties of grasses, a few trusses of capital meadow hay, wonderfully fine specimens of Sutton's Mammoth Long Red and other Mangels; Sutton's Champion Swedes, Pomeranian White Globe and Greystone Turnips, and Kohl Rabi; Wheat, Barley, Oats, and Beans, and an attractive assortment of vegetables. Then come several varieties of Cucumbers, which include examples of the new Chinese variety, named Sooly Qua, and of the Snake Cucumber from Central America (Trichosanthes colubrina), 75 dishes of Apples, 70 of Pears, several of Grapes, and 12 of Nuts; and a most interesting collection of ornamental Gourds. These, tastefully and judiciously arranged, and occupying a very prominent position, make the trophy an exceedingly attractive one, and one which, if the examples may be accepted as a criterion of the state of the crops, leaves ample room for congratulation. Another novel feature to be seen amongst the agricultural implements exhibited, and which for the most part are of American origin, is one of Wood's new champion self-delivery reaping machine, the novelty in which consists of its being constructed upon an entirely new principle, the motive power being acquired by the use of a wheel without any spokes, which works on friction rollers, and is supported by side plates. The gear is internal, —two shafts, two pinions, and a bevel wheel, complete the parts. The rake and gathering arms are actuated by means of a screw mechanism direct from the main shaft. This implement was exhibited by Mr. W. A. Wood, of 77, Upper Thames Street. It was exhibited at Guildford and Wolverhampton, and has been most successfully tried in several parts of the country.

—— We learn from the "Augsburg Allgemeine Zeitung" that a Permanent Agricultural Professorship has been established at the University of Giessen, since the commencement of the summer session of 1871. This section has, therefore, been placed on an equality with the other philosophical departments. Dr. Alex. Thaer has been appointed permanent professor, and he has already commenced his lectures. At the same time an Agricultural Institute, similar to the Institute of Tharand and Forest, which has already been in existence a long time, was established in the University. For founding this Institute, a fund and trial ground were provided by the States of the Grand Duchy, particularly the town of Giessen, for the trial of manures and machines and the cultivation of plants. The University provides space for the lecture-rooms and laboratory, the latter being already in operation for the benefit of agriculturists. In the botanical garden also there is an agricultural division. All remaining sections of the university are likewise within reach of the agricultural student, if he desire a general as well as technical education. There is, in addition to all this, a very excellent veterinary institute attached to the university. Agriculture is likewise made an integral and compulsory part of the examinations on political economy. As regards the practical education of the agricultural student in the neighborhood and within a short distance of Giessen by the numerous railway routes, there are farms which have been kindly offered, and upon which the student may receive practical instruction. The varieties of climate here, and the consequently various phases of agricultural life, from mountain cultivation to vineyards, from perennial pasture to luxuriant corn lands, as well as the careful breeding and manipulation of cattle in the district, indicate the great agricultural resources which it offers as a means of practical agricultural education.

OUR LIVE STOCK.

CATTLE.

At Ellington, on the 28th ult., Mr. Strafford sold 95 head of Shorthorns, bred by Mr. Ladds, for a general average of £45 13*s.* 7*d.*, and a total of £4140. Seventy-two cows made £45 12*s.*, and 23 bulls £37 13*s.* 3*d.*, each. The sale was characterised by a great uniformity of prices. Earl of Barrington 2d by Duke of Brailes, and of the *Sally* by Earl of Derby tribe, was competed for up to 150 gs., but was finally bought in by Mr. Ladds at 200 gs. Mr. Stratton bought a "J" cow by George 1st (19,848) for 62 gs., and others of the same family went into Sir George Philip's hands at 66 gs. and 69 gs. each. We append a list of prices and purchasers:—

Name of Animal.	When Calved.	Price.	Purchaser.
		Gs.	
Cows and Heifers.			
Empress 2d	1859	29	Mr. Burton.
Red Duchess 2d	1861	40	Mr. Statter.
Cress	1861	59	Mr. Fawcett.
Lady Julia	1862	40	Mr. Statter.
War Cloud	1862	40	Mr. J. J. Sharp.
Laurel	1863	35	Duke of Manchester.
Red Duchess 4th	1863	43	Mr. Banyard.
Red Duchess 5th	1863	40	Mr. Burton.
Mantle	1863	52	Mr. Methringham.
Cowslip	1863	43	Mr. Fawcett.
Sunday	1864	46	Mr. Frudd.
Lady Margaret 3d	1864	38	Mr. Burton.
Pythia 8th	1864	41	Mr. Webb.
Belle	1864	52	Mr. Cock.
Mantua	1864	36	Mr. Brown.
Bella	1864	30	Captain Oliver.
Red Duchess 6th	1864	35	Mr. Brown.
Virgin	1864	41	Mr. Statter.
Red Duchess 7th	1865	43	Mr. Freeman.
Princess	1865	35	Mr. Vipen.
Red Duchess 8th	1865	30	Mr. Burton.
Empress 3d	1865	28	Mr. Vipen.
Cora	1865	42	Mr. Fawcett.
Red Duchess 9th	1866	40	Captain Oliver.
Empress 4th	1866	40	Mr. Eady.
Seraphina	1866	43	Mr. Cock.
Linnet	1866	40	Mr. J. Smith.
Red Duchess 10th	1866	46	Mr. Armstrong.
Fennel	1866	36	Sir G. Philips.
Pythia 9th	1867	40	Mr. C. Day.
Red Duchess 11th	1867	50	Sir T. Whichcote.
Laura	1867	40	Mr. Whichcote.
Pet	1867	38	Mr. J. Milligan.
Laurustina	1867	56	Sir W. Booth.
Pythia 10th	1867	41	Mr. Webb.
Red Duchess 12th	1867	40	Mr. Heathcote.
Venus	1868	60	Mr. Smith.
Pythia 11th	1868	37	Mr. Parker.
Cuddy	1868	41	Mr. Parker.
Princess	1868	60	Mr. Jervois.
Empress 5th	1868	50	Rev. W. Young.
Red Duchess 13th	1868	42	Mr. C. Howard.
Bella Donna	1868	41	Mr. Frudd.
Coral	1868	55	Rev. S. Storer.
Red Duchess 14th	1868	41	Mr. Parker.
Lilac	1868	41	Mr. Webb.
Pythia 12th	1868	30	Rev. W. Young.
Empress 6th	1869	42	Mr. C. Hoard.
Pythia 13th	1869	41	Mr. Parker.
Matilda	1869	55	Rev. J. Storer.
Red Duchess 15th	1869	41	Mr. Parker.
Maud	1869	41	Mr. Webb.
Jessie	1869	72	Sir G. Philips.
Red Duchess 16th	1869	55	Mr. Smith.
Crocus	1869	41	Mr. Parker.
Water Hen	1869	..	
Comely	1869	47	Mr. Fawcett.
Seraph	1869	40	Mr. Smith.
Blush	Feb., 1870	40	Captain Oliver.
Pythia 14th	Mar., 1870	40	Mr. Whichett.
Jane	April, 1870	57	Sir J. Whichett.
Janet	April, 1870	46	Mr. Armstrong.
Portia	May, 1870	35	Mr. Smith.
Madeline	Sept., 1870	35	Mr. Lindon.
Red Duchess 17th	Sept., 1870	35	Duke of Manchester.
Red Duchess 18th	Sept., 1870	41	Mr. Sandy.
Red Duchess 19th	Oct., 1870	30	Mr. Wythes.
Grey	Oct., 1870	30	Mr. Cocks.
Empress 7th	Nov., 1870	23	Duke of Manchester.
Carnation	Feb., 1871	24	Mr. Fawcett.
Empress 8th	Feb., 1871	24	Mr. Russell.
Syren	Feb., 1871	22	Mr. Morris.
Pythia 15th	Mar., 1871	30	Mr. Senior.
Bulls.			
Wellesley (25,421)	1865	52	Mr. Statter.
Red Knight	1869	50	Mr. Edwards.
Volunteer	1869	41	Mr. Burton.
Marquis	Mar., 1870	35	Sir W. Booth.
Lord Burleigh	April, 1870	40	Mr. Vipen.
Pennyn	June, 1870	68	Sir T. Whichcote.
Jeweller	Aug., 1870	40	Mr. Webb.
Crœsus	Sept., 1870	36	Mr. Enfield.
Despot	Sept., 1870	34	Mr. Selby.
Laudable	Oct., 1870	36	Mr. Knight.
Viscount	Oct., 1870	61	Mr. Chaplin.
Barrington	Nov., 1870	80	Mr. Linton.

Bala	Mar., 1871	25	Mr. Gifford.
Prince	April, 1871	25	Mr. Armstrong.
Edgar	April, 1871	15	Mr. Laxton.
Rufus	April, 1871	15	Mr. Laxton.
Waterloo	April, 1871	15	Mr. Linton.
Mentor	May, 1871	22	Mr. Percival.

—— Mr. Thornton sold 28 head of Shorthorns, the property of Mr. Ashburner, at Netherhouses, Ulverston, on the 27th ult. The cattle comprised some well-bred animals of Bates blood, several of the favourite "Blanche" or "Sockburn" line that recently commanded such high prices at the Duke of Devonshire's sale, others of the "Cressida" and "Nonpareil" families, whilst a few traced to Messrs. Bell's stock, bred originally at Kirklevington for many years. The remainder included well-known tribes bred and highly esteemed in the district for a number of years, some of them having been successful prize takers at the county and local shows. The cattle were in very fair condition, and had been on grass up to the sale day. The weather was unfortunately wet, and the rain poured down in a manner calculated to damp, not only the clothes, but the spirits

of the buyers. The following are among the principal prices given: — *Fairy* by BARON WILD EYES (19,291), 47 gs., Mr. Savage; *Blush Rose* by SPORTSMAN (25,207), 36 gs., Mr. Hawkrigg; *Princess Helena* by BELVEDERE (23,405), 31 gs., Mr. Woodborne; *Orange Blossom* by BARON GENEVA (25,568), 50 gs., Mr. Washburne; *Maseo* by PARIS (20,469), 68 gs., Dr. Cranke; *Blanche 6th* by PROVOST (24,878), 33 gs., Mr. Bates; *Buttercup 17th* by MOUNTBARROW (26,931), 31 gs., Mr. Macketh; *Fairy Caroline* by STORKS (25,238), 30 gs., Mr. Parker; *Azalea* by BARON FENNEL (lot 25), 35 gs., Mr. Potter.

—— Mr. Sanday was right in so distinctly pointing out certain errors into which cattle breeders are liable to fall, and his own large experience gives his statements weight, and will insure their grave consideration. He tells us, that "with many, a long pedigree is all that is considered necessary; but unless this pedigree be composed of really good animals, the produce will probably be unsatisfactory." And, again, "there are two other causes which must hasten the deterioration of some of our best herds, namely, first, the artificial manner of rearing calves, and second, the practice of using bulls before they arrive at maturity." How truly does this bear out Mr. Bates' statement, as rendered by Mr. Bell in his history of Shorthorns. At page 184 we are told that Mr. Bates used to say, and indeed truly, "that money-making was the ruling motive that governed the breeders of Shorthorn cattle, and not the improvement of the shorthorns. Had the latter been the main object, the Shorthorn cattle might have been of double the value they then were in these kingdoms, and have spread over the whole habitable globe." Again, "Mr. Bates might have kept all his calves for bulls, and sold them at high prices. After the advent of BELVEDERE he kept more calves for bulls, but very frequently not by any means the best looking or most promising of the stock, but he frequently had ten or more bulls in his possession which he never used, and had no desire to part with, except when he considered they would improve the herds into which they were going." Also, at p. 219, we find that "from about 1830 to 1833, Mr. Bates rarely let any bulls, and kept no calves for bulls except what he thought he might require for his own use, or induce his friends to introduce into their own herds for improvement of the stock." In other parts of the volume there are sufficient indications that the system which was rigorously carried on at Halton and Kirklevington. The three cardinal points, pedigree, personal qualifications, and treatment, must be kept in view by all breeders of good stock; and we maintain that the, to a certain extent true, idea that pedigree will make up for personal demerits has been pushed too far. It may be foolish to castrate a high, "fashionably" bred young bull, but we can never believe that breeding for pedigree alone, and at the same time neglecting the rigorous selection of the best only for breeding purposes, can be followed by any other than disastrous results.

—— Among recent additions to the Siddington herd are the following:—

Gazell 24th, roan, calved January 19: by 2D DUKE OF TEGUNTER, dam *Gazell 14th*.

Gazell 25th, roan, calved August 27: by 2D DUKE OF TEGUNTER, dam *Gazell 11th*.

Mustard 3d, white ears, calved March 4, 1871: by 2D DUKE OF TEGUNTER, dam *Musical 7th*.

Ruby 4th, rich roan, calved April 21, 1871: by BATES TERTIUS (31,249), dam *Ruby*.

Siddington 9th, roan, calved March 22, 1871: by 2D DUKE OF TEGUNTER, dam *Siddington 2d*.

Siddington 10th, flaked roan, calved March 22, 1871: by 2D DUKE OF TEGUNTER, dam *Siddington 2d*.

Siddington 11th, white, calved March 30, 1871: by 2D DUKE OF TEGUNTER, dam *Siddington 5th*.

3D CAPTAIN TEGUNTER, white, calved February 1, 1871; by 2D DUKE OF TEGUNTER, dam *Gazell 6th*.

Wild Fire, red and white, calved May 10, 1871: by 2D DUKE OF TEGUNTER, dam *Wild Eyes 5th*.

COLONEL TEGUNTER, roan, calved May 20, 1871: by 2D DUKE OF TEGUNTER, dam *Gazell 2d*.

3D COLONEL TEGUNTER, roan, calved June 4, 1871: by 2D DUKE OF TEGUNTER, dam *Sybil*.

3D COLONEL TEGUNTER, roan, calved June 7, 1871: by 2D DUKE OF TEGUNTER, dam *British Queen*.

We have within the last few days visited Siddington, and were much pleased with the calves. They were looking the picture of health, and were exceedingly well haired and of good colours.

—— Colonel Gunter has sold a 3-months'-old Duchess bull for 1000 gs. to Mr. Graham, of Lancashire.

—— Lady Pigot's bull VICTORIOUS, the sire of BYTHIS and SIDUS, is dead.

THE DRY-EARTH SYSTEM v. THE WASTE OF LIQUID MANURE.

HAVING witnessed the application in a rough and imperfect, yet profitable, way of this system for collecting and applying all the refuse matters of a house and a farmyard many years ago; and having long applied dry earth in a very simple manner to my own stable, styes, &c., with great advantage both to field and garden; I may be allowed to record my testimony in its favour.

The deodorising powers of earth, and its admirable fitness for preserving the fertilising properties of manure, are well known, and cannot fail to manifest themselves in the application of this system to the farm. But besides this it offers the special advantage of keeping together the liquids and solids in a form under which their easy removal and application to land is effected by one and the same operation, and with the same implements; so that wherever manure cartage is already in operation, all is ready for the dry-earth system, and more profit will result from the labour.

The dry-earth system meets on the threshold many of the difficulties which the farmer encounters or raises in objection to the attempt at utilising the liquid manure. Being applied in the stables, the cow-sheds, and styes (with a proportion of straw), the urine is at once absorbed, and never appears in the comparatively unmanageable liquid form, and cannot become more unmanageable still by large dilution with water. It becomes at once subject to the control of the fork, shovel, and dungcart. The system may be partly (but cannot be fully) carried out where cattle are kept in open yards, especially where these are, in wet weather, little better than watercourses.

Presented to the labourer in the solid form by means of dry earth, the two forms of manure which Nature presents to man for his use (or abuse) are fully utilised with the greatest advantage to the farm or garden. The simple reason for the neglect of the liquid part no longer exists, which is this:—That liquid manure will not lie in a heap, but a man cannot take it up with a fork and load it; and that, naturally prone to run away, it soon ceases to invite removal by removing itself.

A very simple and elementary process of reasoning will suffice to show that the neglect of liquid excreta is a loss to the farm, and that the loss is not a simple one; telling as it does in more ways than one against the profits of farming.

The loss would be much greater than it is but for one redeeming feature of manure management. By folding sheep on the land, all their liquids as well as solids are rendered up to its use. No wonder that this custom of manuring is highly approved and persevered in. What would be the effect of a dressing of sheep-dung on a rotation of crops were the liquid poured into some ditch instead of upon the land?

Farmers who allow this substance to run to waste admit that it is valuable. They admit, therefore, that there is loss in one way, viz., in the quantity of manure at their disposal. But of equal moment at least, and probably of far greater, is the loss in quality to the solid manure which is saved and used.

The old idea of the antaught tiller of the soil was that manure supplied "fat" to the land. Thus the natural idea is that manure is a simple substance, and that the food of plants is a simple substance. But the first thing we learn of the constitution of a plant is that it is made up of many things, differing from each other in all necessaries of life and vitality. Therefore we infer at once that the food of plants must contain all these necessary things, and that they must all be supplied in sufficient abundance, in manuring the land for a succession of crops.

The absence of one of these things is often fatal to the plant, while in its ordinary growth, is found to contain it. Thus the old worn-out Cheshire pasture refused to produce (at one time) grass fit for profitable milk-production, until the application of bones secured abundance of phosphate of lime. Clover dies out for want of some essential. I have covered my orchard this year with Clover, without sowing seed, by giving it a dressing of manure which manifestly contained the food required by that plant. I have seen the Wheat plant in a whole field die away without any ordinary cause to account for it, leaving the conviction on the mind of the labourer that the land and manure did not contain the food it required. This was on Bagshot Heath, a soil which contains less of the food of grain crops than any other known; and which food has therefore to be supplied. The same field, without extra manure, would yield an abundant crop of Rye. It was not, then, lack of fertilising matter, but of some particular food which the Wheat plant demands in large proportion, that led to the destruction of that plant.

Now, of the many substances required for plant food, it is unquestionable that the liquid excreta contains some of them in much greater abundance than the solid. The constant draining away of this leaves that portion of manure which is saved and used, with a smaller quantity of these special substances than Nature yields for our use. Hence the danger arises that some crop shall find out the defect, and suffer severely for the deficit. How much more probable this event when that drain upon the food supply is constantly going on in the farmyard—when the stock of manure is always being robbed of the same substances? That liquid manure contains some substances in greater proportion than the solid, is to be inferred even from the difference in appearance, smell, &c., from the solid dung. It is highly probable on the outset of inquiry, it is found to be so on examination. It is also certain that these things (in which the liquid is rich and the solid poor) are necessary to plant life. That they are necessary to the food of the cattle which supply the manure to the farm is most clear; for as those cattle yield up those substances, they must needs have drawn them from the food, the grass, corn, &c., which they have consumed. The waste, therefore—the constant waste, I may say—is waste of some special things necessary to the vigorous growth of farm produce.

Now this waste is sure to be felt; the sin, the abuse of God's gifts, finds us out. We may in many cases fail to detect the true cause and apply the simple remedy; but a remedy the farmer does even in that case apply, the cost of which we shall best appreciate thus. If he went to a grocer to order something in which his stock of grocery is deficient, he would know not only the exact article, but the exact quantity of it required. He can thus supply the loss with economy. Should he, however, have forgotten the exact article required, and yet know that it was much needed, his only way of securing it would be buying a complete stock of goods, in which the special article required would be found.

Now, this is the remedy which he practically adopts, and this the heavy price he pays for the defect in his manure stock. Finding the crops inferior and unremunerative with a certain tonnage of dung, he adds to it. What does he add? The special things required? Yes; this he does indeed, but in a wasteful manner, for, as he cannot know what the exact substance of the manure is which is deficient, he can only remedy it by adding more of the whole stock; and, as this stock happens to be weak in the special things required, there must not only be addition but, therefore, larger addition of it than would be the case with such uniform draining away of such essential matters from plant food then takes this simple form, that the quantity of manure applied to the acre is much greater than it need be. The consequence of this is, that a smaller quantity of land must be manured from the yard than would otherwise be the case, and that difference in general bulk of manure for keeping up the fertility of the whole farm must be made up with large purchases of bought food or fertilisers. Such purchase can only indicate extravagance where it is the remedy for waste.

But if the liquid and the solid be preserved together, then this drain of essentials is at once stopped, and flows in upon the produce of the farm. An increase of fertility becomes visible. It soon becomes apparent that a ton or two of the quantity of dung previously employed per acre can be spared for other fields. Then so much is added to the bulk of the manure by the addition of that which before filled ditches, or formed a swamp, that a still greater acreage is benefited.

Another great practical fact in agriculture invites the principle of making the body of manure, applied for general purposes, as complete as possible in all its parts. What lesson do we learn from a rotation of crops, as commonly employed, and found so advisable as to enter into the condition of a lease? The lesson is this, that each crop requires as food the substances which the land and manure supply in different proportions, if it is a different kind of grain, or green crop. After a Wheat crop, the properties of food left in the ground are changed. They no longer exist, in ordinary cases, in that degree which another Wheat crop would require; such a crop would, therefore, starve; but a Barley or Root crop would find it supplied, and a third, differing from its predecessors, would live and thrive where the others would languish or perish. Thus, then, the object of the succession is, that deficiency in special substances shall be met by growing those things which require much less of them. Manifestly, therefore, it must be the object in supplying manure to give it all the variety of these substances in full quantity. The very fact, therefore, that liquid manure differs in certain essentials from the solid, is a very strong motive for combining it with the other. The combination of the excreta of different kinds of stock promises advantage on the above principles, how much more if the manure be only that of one animal that both kinds should be combined? There will be what is termed a "screw loose somewhere" in the agricultural machine if such waste be not remedied. And though the machine may be patched up, it is a more costly process to keep it going thus than by seeing to the perfect adjustment of parts before setting out.

Mr. Mechi, in his great tank (of which you have already made mention), combines all substances in his plant food, and this, among other important reasons, must be one which enables him to grow Wheat so much more frequently on the same land, and at the same time so abundantly. There is no fear of the food stock giving out when thus enriched at every point.

The dry-earth system has this advantage—that it can be fairly tried without costly outlay for tanks, watercarts, pumps, or even shedding for the preparation of earth, and with very little extra cartage. The cart returning empty from the field can bring back earth. If it be dry already, as in case of removal from some bank, it can be kept so by some thatched hurdles; if moist, it can be spread under an open shed to dry. The small expense of getting it may be lessened by gaining two objects from the one operation, as by digging a watercourse where it is wanted, the earth going to the farm; or sinking a reservoir for watering cattle, where that is needed. Nay, further, the staple of the soil may be gradually but most surely improved without any cost, by using clay as the absorbent of the

manure for light soil, and light earth as the absorbent for the manure destined for clay fields.

The waste of this substance obtrudes itself so often and so offensively on our senses, the means of remedying it appear on Mr. Moule's plan so simple, and the prospect of advantage so well grounded, that one may well claim the liberty of adding a few words to the general demand for improvement in these matters. *J. W. Taylor, Seer Green Vicarage, near Beaconsfield.*

INTERNATIONAL EXHIBITION.

Blake's Stone Breaker.—This machine, invaluable to those who require it, has won a greater amount of popularity from spectators than any other machine exhibited. No sooner does it begin to chump up large nodules of various kinds of stone into fragmentary parts of any required degree of fineness purchasers may request, than all who see or hear it flock together to see its simple but powerful performance. Its simplicity of mechanism, upon which its real worth depends, will readily be understood from the annexed diagram (fig. 294), which shows a vertical view of a machine at work breaking flints. The general principle of mechanism of this machine is the same in a series of machines now in use for breaking various kinds of rock for different purposes. We shall notice, firstly, its peculiar mechanism; and, secondly, its adaptation and extended use chiefly in agriculture.

The machine, it will be observed from the illustration, is actuated by a strap on a drum or pulley, two powerful fly-wheels being on the same axis. This axis has an eccentric, which actuates a pendent connecting bar or pitman, and which, by means of a double toggle-joint, gives the movable jaw a chumping action against the fixed jaws, between which are seen the nodules of flint, or fragments of any kind of rock, &c. Both jaws have a ribbed surface, the better to produce a breaking, crushing, and grinding action by the peculiar up-and-down movement of the pitman, produced by the eccentric on the common axis of the fly-wheel and motor drum, actuated by a strap from the engine, as already noticed. In the illustration this drum will be seen on the further, or outside of the fly-wheel, its diameter being about half that of the latter (the fly-wheel). The fineness of the material being broken is regulated by a wedge scen in section on the right hand side, which is screwed up or down by means of a screw-nut, shown above the crossbars of the framing. The illustration is sufficiently plain to render a detailed description of this adjusting mechanism unnecessary, for by screwing up the wedge the toggle-block fulcrum is forced nearer the movable jaw, so that the two toggles, in crossing centres, force it closer to the fixed jaw. The two toggles, or cross-bars, can be taken out, and shorter or longer ones substituted in their place, as the nature of the work requires. The form of the jaws is made different for different kinds of work, that shown in the illustration being for road metal, limestone for burning, and the like. In the diagram the broken metal is shown falling into a heap, and for road-making this is generally sufficient, as the fine mixed with the large helps to bind the two together. But for most other purposes the broken materials pass through a rotary screen of perforated zinc or iron, which separates them into three or four sorts of different degrees of fineness, the coarsest, that passes out at the end of the screen, being passed through the breaker a second time, if desirable. The different sizes that pass through the perforations of the screen are each very uniform, more so than can be done in the usual way by hand-breaking with hammers and rings, and at a small fraction of the expense. The large stones are fed in at the top by hand, those larger than the mouth will receive are broken by a sledge hammer, and as they descend between the jaws they are broken finer and finer until they pass out below of the desired size. It will be seen that every revolution of the eccentric gives the pitman an up and a down movement, the toggles crossing centres twice, thus effecting two bites against the fixed frame—250 revolutions per minute making 500 bites, and that the power of each bite is due to the momentum of the fly-wheels. Only one fly-wheel can be shown in section, but the small machine exhibited in the International and the larger ones shown at Wolverhampton had each two fly-wheels, which act more effectually than one would do, and with less strain on the axis. In breaking round metal the movable jaw recedes about a quarter of an inch at the bottom, the distance diminishing towards the top, so that the breaking power is economically distributed, whilst the broken materials cannot fall through until reduced to the required size as adjusted by the cross-bar of iron below, the hook of which forms a movable pivot or centre for the lower end of the movable jaw.

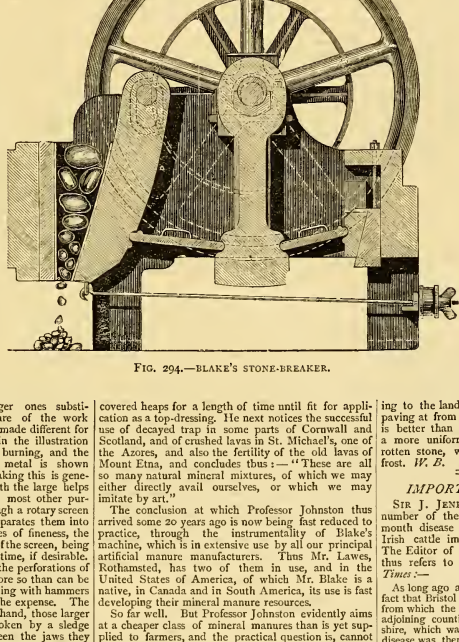

FIG. 294.—BLAKE'S STONE-BREAKER.

Blake's stonebreaker is now in extensive use in Britain, America, North and South, and the Continent of Europe, and in short in all parts of the world, in roadmaking, railroad ballasting, in breaking pyrites (firestone, &c.), sulphur-stone, emery, furnace cinder, ores, limestone for burning, rock salt, coprolites and native phosphatic rock for manure, materials for concrete, cement, and artificial stone, asphalte pavement, &c. Landowners are interested in all the above appliances—some, it may be, in only one or two, others in all, and even in a more extended use of the machine than is included in the above list. It has long, for example, been a favourite theory with some chemists to break down certain descriptions of granite, lava, &c., for the sake of the potash and other fertilising matters they would yield as manure to the land. Quoting from Professor Johnston's lectures, "It is many years since Fuchs proposed to manufacture potash from felspar and mica by mixing them with quicklime, calcined in a furnace, and then washing with water." He then goes on to notice Mr. Prideaux's proposition for mixing crushed granite with quicklime and slaking them together, and then allowing the mixture to lie in heaps for a length of time until fit for application as a top-dressing. He next notices the successful use of decayed trap in some parts of Cornwall and Scotland, and of crushed lavas in St. Michael's, one of the Azores, and also the fertility of the old lavas of Mount Etna, and concludes thus:—"These are all so many natural mineral mixtures, of which we may either directly avail ourselves, or which we may imitate by art."

The conclusion at which Professor Johnston thus arrived some 20 years ago is now being fast reduced to practice, through the instrumentality of Blake's machine, which is in extensive use by all our principal artificial manure manufacturers. Thus Mr. Lawes, Rothamsted, has two of them in use, and in the United States of America, of which Mr. Blake is a native, in Canada and in South America, its use is fast developing their mineral manure resources.

So far well. But Professor Johnston evidently aims at a cheaper class of mineral manures than is yet supplied to farmers, and the practical question is, cannot landowners look around them, and, by means of Blake's machine, supply the grand desideratum in question? The expense of breaking materials to the size of road metal is about 3*d.* per ton, and at the rate of from 8 to 10 tons per hour, or 100 tons in a day of 10 hours. About 50 machines are now in use in granite quarries, breaking up the broken chips for road metal at a cost of 3*d.* per ton, which formerly cost 2*s.* per ton when broken by hand. If put through the machine a second time, and broken finer, the expense would be double or treble, according to the degree of fineness. But granting that the crushing of the granite, according to Mr. Prideaux's process, as recommended by Professor Johnston, costs 1*s.* per ton, the expense of carting and application would remain the same. The other expenses will depend upon the expense of time and coal, if the granite is calcined, and so on, and must be left for experiment to determine; though the total expense, when ready for application, by broadcast distribution, should not cost much per ton. But the rotten rocks to which Professor Johnston refers, in Cornwall and Scotland, can be broken at 3*d.* per ton, ready for application, so that this has only to be added to the price the landowner may charge for the rock, which may be set down as nominal in the outset, like the refuse-hills of the Sheffield bone-cutters in times gone by. If found to pay, the price would rise accordingly.

Two other new uses of Blake's machines have come out during the International Exhibition, viz., the breaking of materials for artificial stone, of which there is a very fine exhibition in the building department, and machinery-in-motion department, by Colonel Scott and others, and for asphalte concrete for roads, streets, farm buildings, garden walks, &c.

For artificial stone various degrees of fineness are used, the granite in some being from 1 to 1½ inch, the cement being poured in to fill up the interstices. This is evidently an offset of the old Pictish process of building in moulds or framing, the stones being first thrown into the frame in such manner as to allow the mortar to fill up the interstices. In many of these old buildings the mortar is stronger than the stones, the latter yielding to the hammer before the former will break; and so is it in the Exhibition, the cleavage of broken bricks and cubes of artifical stone showing that the stone breaks before the cement. Two common bricks are cemented together, and are shown to break anywhere but at the place they are thus united. Large's small machine for making artificial stone or "concrete bricks" as they are sometimes termed, will turn out 5000 or 6000 in a day ready for the builder, and we believe Blake and Large have entered into arrangements for working their patents together on favourable terms; and the greater part of the work of breaking the stone fine, mixing it with the cement, damping, and weighing or measuring into the moulds, can be done by machinery.

The paving of stables and other farm buildings, including the strawyard, with asphalte concrete is now being discussed in the columns of most agricultural and horticultural papers, and were contractors who hire out agricultural implements to employ one of Blake's stone-breakers, they could break down stone at a few pence per ton to those who might employ them. Much of the gravel now used in making and repairing roads should be passed through one of these machines, which might be done at from 1*d.* to 3*d.* per ton. Chalk could be crushed as small as Peas for 3*d.* per ton for applying to the land, and most kinds of stone for asphalte paving at from 3*d.* to 6*d.* per ton; and broken stone is better than screened gravels generally, being of a more uniform quality, and free from nodules of rotten stone, which absorb rain, and break up with frost. *W. E.*

IMPORTED CATTLE DISEASE.

SIR J. JENKINSON called attention, in a recent number of the *Times*, to the extension of foot-and-mouth disease in Gloucestershire, attributable to the Irish cattle imported into Bristol, and sold thence. The Editor of the *Wilts and Gloucestershire Standard* thus refers to the same subject in last Saturday's *Times*:—

As long ago as October last I called attention to the fact that Bristol was then, as it certainly is now, a centre from which the infection was being spread through the adjoining counties, but more particularly in Somersetshire, which was at that time suffering severely. The disease was then very prevalent in the south and southeast of Ireland, and as Cork, Waterford, and in a smaller degree, Wexford, are the shipping ports of that district, from all of which there is a large trade to Bristol, a considerable number of cattle are sent over to the latter port. On their arrival they are turned out upon the quay at Cumberland Basin, and are all mixed up in glorious confusion for an hour or so before being driven off to the market, thence to distribute the disease over the adjoining counties by mixing with other cattle at the fairs which are so numerous at this season of the year. Who can wonder that Somerset, Wilts, and West Gloucester, being close at hand to receive the first favours, suffered as heavily as they did?

Much the same thing is happening now, and though

the dealers pretend that the disease is only coming from Waterford, and not from Cork, I am rather sceptical on that point. But, be that as it may, if Waterford is dangerous, Cork cannot be very safe in the case of so highly infectious a disease; and it seems to me that common sense demands that a very rigid quarantine should be imposed upon animals coming from either.

Mere inspection is a miserable delusion, and its protective value is absolutely *nil*; and for this reason, that it merely stamps all the cases that are already developed, while it passes others with a clean bill of health to carry the seeds of the disease all over the country. For example, on Saturday last the Bristol magistrates imposed a fine of £5 on a Irish dealer for exposing for sale a diseased heifer in Bristol cattle market. The man assured the Bench that he was not aware that the animal was diseased, but the magistrates, of course, replied promptly, that he had to deal with those who learn his business, and make himself acquainted with the symptoms. In this case they were evident enough, but in how many others in the same cargo was the disease latent, to be developed, in the course of a few days, in the midst of the valuable herd at Eastwood Park or else where? Sir George Jenkinson tells us of three having fallen sick of the disease out of the 12 he had just bought, and he has, perhaps, by this time found it in more. And what happened at Eastwood is happening daily in many other places. That diseased heifer which the inspector detected at Bristol Cattle Market came over from Waterford with a number of others. How many of those which were confined with her on the lower deck of the steamer are likely to have escaped the taint to which the heat and deficient ventilation, unavoidable on a sea voyage, rendered them peculiarly susceptible, and yet in a few hours' passage it had not had time to develope itself so that the most lynx-eyed inspector could detect it.

It is this that makes inspection, however carefully conducted, so useless. What we want is quarantine, if the stock is to be imported at all. It will be said that this would interfere with trade; but if trade is a means of disseminating disease it ought to be interfered with. We do not scruple to interfere with any trade which becomes injurious to the public, and this importation of diseased cattle is highly so, causing a loss of food to the nation, and of the value of that food to the owners of stock, which considerably exceeds the total value of all the foreign cattle we import. Surely it would be better to check importation should lose the sale of 12 diseased Irish steers than that they should be sent to spread infection among 100 others at Eastwood; for although foot-and-mouth disease may not be so fatal under examination, yet we cannot put the deterioration of each animal suffering from it at less than from £2 to £3. Why should a dealer inflict upon Sir George Jenkinson a loss of £200 or £300 merely in order that his cargo may not be interfered with? and as to the carrying trade, it is surely better that the Cork and Waterford steamers should bring less than their usual amount of cargo than that they should scatter disease broadcast throughout the 3,600 head of cattle in the counties of Wilts, Gloucester, and Somerset.

FOOT AND MOUTH DISEASE.

[The following is an abridgment of the reports given in Wednesday's *Times* of the progress of the disease.]

An amended return as to the cases of foot-and-mouth disease occurring in Norfolk during the week ending September 23 places the total for the week at 2239. On Saturday a return for the week ending September 30 was made up, the total arrived at being 2229, so that the disease is happily not further increasing in the county.

The returns in Cambridgeshire and Huntingdonshire up to Saturday night last are still unfavourable, as not only is the foot-and-mouth disease increasing among the cattle but it has spread to the swine, and the deaths among these latter exceed, in proportion to the number attacked, those among either cattle or sheep. Of sheep scab there are numerous cases on farms at Chesterton and Wicken in Cambridgeshire. The following are the statistics of the foot-and-mouth disease in the two counties up to Saturday night:—Cambridgeshire: Arrington Division, 17 infected farms in eight parishes. Cambridge Division: The disease exists on no less than 52 farms, and on 19 of these is the result of fresh outbreaks. Newmarket Division: Here no less than 416 head of cattle are suffering from the disease. Huntingdonshire: In the Ives Division there have been outbreaks on 11 farms; in the Norman Cross Division the disease exists on 13 farms, out of which eight are fresh outbreaks.

The disease continues to spread in the county of Buckingham. The inspector's returns sent in for the past week show an increase of 250 cases affected with the disease. Altogether in the county the disease exists on 134 farms, and 1258 animals are affected.

This disease is spreading to a most alarming extent in the fenny parts of Lincolnshire, and has in numerous instances assumed a very virulent form, producing great prostration in the cattle attacked, and reducing them almost to skeletons. A large number of cases of the foot-and-mouth disease have been reported in the parts of Kesteven during the past week, probably owing to the recent conviction by the magistrates of a farmer for omitting to report the cases that occurred upon his farm. Cases are very numerous still in Leicestershire, Notts, and Derbyshire.

There has been a considerable diminution of the foot-and-mouth disease among cattle during the last fortnight in Staffordshire. The inspector's return for last week showed that 2657 cattle, 177 sheep, and 302 pigs were suffering, against 3361 cattle, 114 sheep, and 292 pigs in the previous week. The number of places where the disease prevailed was 597, against 682 in the preceding week; but while in the latter period the disease appeared in 124 fresh places, the number of fresh places visited last week was 92.

An increased number of new cases of foot-and-mouth disease in Northamptonshire has been reported during the week ending September 29, compared with the preceding seven days, the number being 99, as against 86. The Little Bowden district, which adjoins Leicestershire, has the most cases, there being 37 reported.

In the Malton district for the past week Mr. Superintendent Metcalfe reports four new outbreaks on fresh farms at Amotherby, Huttons Ambo, and Bulmer, and the disease exists on 11 farms.

The foot, mouth, and lung disease is very prevalent in the south-eastern division of Northumberland and North Durham. It is specially felt in Newcastle and the surrounding district, the town cows which graze on the moor having suffered severely from it. Two hundred and fifty cases were reported to the county police in Castle Ward, immediately outside Newcastle, last month, and the disease is spreading very much.

During the past week 48 new outbreaks of foot-and-mouth disease have been reported in Cumberland, and pleuro-pneumonia has appeared on two farms in addition to those on which it previously existed. Scab in sheep is also reported from two farms, and 100 animals are affected. In Westmoreland, foot-and-mouth disease has broken out on eight additional farms. In the district there are now 221 farms affected with the contagion of one or other of the diseases mentioned, and 1368 animals are diseased; while 19 farms and 145 cattle are affected in Westmoreland.

Foot-and-mouth disease among cattle is very prevalent in the neighbourhood of Berwick, where it appeared on several farms last week. One cattle plague occurred on Saturday that at Haggerston a herd of 49 cattle were affected by the disease, and another herd of 39, belonging to Scremerston, were similarly affected.

The reports from the west are still unfavourable. The returns from the constabulary made up to Saturday last show that in the county of Dorset there are above a thousand animals suffering from the contagion, about 50 per cent. consisting of sheep. Equally unsatisfactory are the returns from the neighbouring county of Somerset. About 150 cattle, sheep, and swine are affected around Bridgewater, while from Ilminster 13 farms are reported. To keep the malady back from the milch cows is a difficult task, especially as such large numbers of Irish cattle bought at the Bristol market are dispersed throughout the county. From Hants nearly 800 cases are reported. No returns for Wilts are published.

This epidemic still continues to spread in the district around Bath, although the number of attacks during the past has been much less than was the case during the previous week. The police are making strenuous and, we believe, successful efforts to stamp out the disease by rigidly enforcing the non-removal system in the infected parishes. Mr. Superintendent Morgan reported to the local committee of the Western (Bath) Division, on Saturday morning, that during the week 34 head of cattle and six sheep had been attacked on eight fresh farms in the parishes of Charterhouse, Hinton, Northstoke, St. Catherine, Combend, Englishcombe, Priston, Weston, and Twerton.

The scene at the yearly meeting of the Winchcombe Agricultural Society, held on Friday afternoon on the ridge of hills 8 or 10 miles beyond Cheltenham, gave a melancholy proof of the ravages of the foot-and-mouth disease upon the farms in Gloucestershire. The farmers and visitors trampled over the drenched turf of the Abbey meadow to view only 20 or 30 cart-horses, and roadsters, and hunters. There were neither cattle, sheep, nor pigs. The weekly returns by the cattle inspectors are said to give no real criterion as to the prevalence of the disorder. At the Northleach Petty Session, Mr. William Jones, of Sirsa House, Cheltenham, a magistrate of the county, was charged by an inspector with not reporting to a police-constable that certain cattle on his farm at Pegglesworth were affected with the disease. Mr. Jones pleaded that he had been from home, and that only on the day the inspector came did he fully know that, in the opinion of some, his cattle were affected. However, he was fined £2 and costs.

Home Correspondence.

Thin Seeding.—Your readers are aware that I am an advocate of thin seeding, both of cereals and pulse; but I again emphatically state that thin seeding to be profitable depends upon deep and thorough cultivation, and keeping the land in good working order, as a man who loves his horse would keep his horse. But what is thin seeding? I and the late Mr. Piper, of Colne Engaine, grew Wheat in succession for years, and with success, from half a peck of seed per acre; and I have grown Wheat after Wheat, from a peck of seed per acre, but I would not advise farmers to do the same; and in my subsequent papers I will explain why I would not so advise them. But I here just hint, as I have stated a hundred and one times before, that I should increase or double the quantity of seed of one kind of Wheat than I should of another kind; and I should use still a great a difference in the quantity of seed between my seeding in September and November, that is, I should use double the quantity of seed in November that I should in September. But with this brief explanation I will, Mr. Editor, inform your readers a little of what I did for my last crops. This time last year I asked my churchwarden, who himself owns and farms three extensive farms in my parish, to allow me to put the seed in for him in one of his fields, and I stipulated that if the crop, the seed for which I should drill in by the drill I invented and made, should not be equal to the best crop he had on his farm, I would make up the difference in money. This was agreed to; and so on Thursday, November 24, my churchwarden sent me word that a field was ready for me about a mile from my house, and so on November 26 I went to the field with my drill, and by agreement my churchwarden met me with a man and a horse with the seed, and some of which they measured into my drill, and I myself set to acting as drillman to put the seed in; which having been done, my churchwarden, having left a man with me, returned to the field, and they measured the quantity of seed left in the drill, and which proved that I had put in just 2 pecks per acre, a fifth more than I intended, but my drill happened to be out of order at that time. Now, my attentive readers, I had never been in that field before, nor had any one of my men, nor have I or they been in it since the drilling it; but the farmer cut the crop and measured it, and what was the result? In common guess, I should be correct in saying that the season was too late for thin seeding by at least two months, and that nothing was done to the crop during the time it was growing, and yet what was the yield? My friends, the 2½ pecks an acre produced 49 bush. an acre; and let me further add, that the crop was so thick that it lodged, or, of course, the yield would have been more. *G. Wilkins, Vicarage, Wix, September* 26.

Landowners and Agricultural Labourers.—A very common complaint amongst farmers is that they cannot get a sufficient number of workmen—or at any rate skilled workmen. What is the remedy for this evil, which no doubt exists in many parts of England? It must be confessed at once that it is a question which the landed proprietors must take in hand rather than their tenants—for I think, although they may do something to help to solve the difficulty, are almost powerless, while their landlords can do (and some have done) much to benefit them in this respect. In some counties men are not scarce, but their education and training have been so very defective that they make execrable workmen; in others the labour is done almost entirely by Irishmen, who although in many instances do good work, are, nevertheless, uncertain, and are not to be depended upon; and, in some parts labourers are not to be had in sufficient numbers to meet the requirements of the agriculturists of the neighbourhood. To meet this state of things, it is necessary that in the future some different course should be pursued, if any improvement is looked for. What, then, can be done? First, I would suggest that all landowners and agents should use every endeavour to retain upon the estate the labourers' sons as a rule, three out of every five country lads find their way to the towns and cities, but if plenty of good cottage accommodation was to be obtained in the country, they would probably remain there. With a lot of boys and young men growing up on an estate, it seems reasonable to suppose that if the owner and his agent took some interest in these youths, and made it their study to retain them, or, at least, the best of them, they would in time become useful labourers. But not only do I advocate their being induced to remain on their native soil, but they should be taken of their training. If they were thus well looked after, and suitable situations found for them, in course of time they would feel themselves so linked to the estate as never to think of removing. In short, I would have every landowner look upon his cottagers and labourers in much the same light as he does upon his farmers. Let there be a feeling of dependence upon one another, and an interest shown in each other's welfare, and that will result in a true bond of friendship and respect springing up between them. Secondly, I would suggest that every cottager should hold land from the farmer who employs his master. In most cases cottages are leased to the farmers, who sublet them to their workmen as weekly tenants. This arrangement is bad, for in many cases under it the labourer feels himself a sort of slave to his master. He knows perfectly well that if he should offend his employer the consequence is a notice to quit at the end of the week. No doubt under this system many a poor man is trodden down and forced into submission. Besides, a man of any honour feels it a sort of slight to take his cottage from his master, and not from the owner. He appears as a part and parcel of the farm—a sort of machine tacked on with the holding, and, it may almost be said, partly included in the rent. Now, if every cottage was let direct to the occupier, under a monthly agreement, and the farmer to nominate the tenant, subject to the approval of the agent, an improvement would be made. A cottager would then feel himself independent, and would pride himself in keeping his place clean and

tidly, and would find himself free from the everlasting threat which in many cases now continually bangs over his head. Any man of spirit who is imposed upon is certain to kick, and I believe that a vast number of the squabbles between master and servants arise directly or indirectly from this bad system to which I refer. Thirdly, I would suggest that a good number of small farms be kept for those labourers who have worked longest on the estate. Many a labouring man has gained his aim in life if he can say he holds a farm. It would be a great inducement to labourers' sons to know that such was the reward for the respectable men that had served longest on the property. They should be encouraged to save their money early in life, and thus by perseverance and industry in course of time they would be compensated for their pains. If it was a thoroughly understood rule that the small farms were reserved entirely for the most deserving of the labourers, I believe more would be willing to become farm servants, and the general conduct of all would be influenced thereby. Fourthly, I would suggest that the general education of the families of the labourer be well looked after. The most effectual way to do this now is (provided the district is not under a school board) to insert a compulsory clause in all cottage agreements to the effect all children under a certain age shall be sent to school. This is a simple plan, and it would be a matter of no very great difficulty to see that the clause was carried out. The necessity for educated labourers appears more and more every day, and unless the landowners of the country take up the subject, and at once see means to provide more workmen, the next generation will suffer in the same manner that many farmers do now. *E. Minshall, Estate Office, Aston, Preston Brook.*

Diseased Cattle Importations.—Allow me to endorse the statement in your able *resumé* of the progress and state of cattle disease in England, "That the country is considerably worse off now than it was this time last year, both in respect of foot-and-mouth disease and pleuro-pneumonia," as also to testify to the truth of the information, that "several cargoes of Spanish cattle have been detained at the outports for slaughter in consequence of the discovery of diseased animals among them." I observe, however, that this intelligence is supplemented by an important qualification—"at least," it is added, "when landed in this country." I therefore request the favour that you will publish the fact that some cattle from the Continent, examined on landing, and passed as healthy by the Government inspectors on Thursday last, proved the following day affected with foot-and-mouth disease? Thus, another instance is added to the many that have come under my notice of the valuelessness of official inspection on the debarkation of animals as a safeguard against the constant re-introduction of contagious disease. *John Waller, Secretary, Home Cattle Defence Association, 81, Fenchurch Street, September 27.*

Disaforestry Compensated by Plantations.—I happen to have been in a part of the world where forest conservancy verges on a mania, where conservancy practically shuts out profitable enterprise, defies all the laws of political economy, and "beggs," common sense. I am one of those who believe in the beneficial effect of arborescent vegetation upon climate, and would stoutly advocate the planting of two—ay, ten trees, for every one that is felled, especially in such countries as America and India. It is the latter country, or a portion of it, with which I will more particularly deal. In some of the more populous parts much of the indigenous forest has disappeared to make way for Coffee, Tea, and Cinchona plantations, and this disaforestry has caused great apprehension in the minds of various forest officers and others as to the course of the clouds, and the ultimate inches of rain. These gentlemen do not appear to consider the compensating effect produced by the plantations taking the place of the forest, and it must be satisfactory to them to find that even bare mountains and "tall herbaceous plants" have their influence in causing a greater amount of rain to fall. But if this point be conceded, it will be easy to believe that trees such as the Cinchona, and shrubs such as Coffee and Tea (all of which impart dense shade to the soil), exert their compensating influences. It also happens that private speculators on the Neilgherries, for instance, have found it profitable to form extensive plantations of Eucalyptus and Acacia, and there is scarcely a villa residence on these hills the grounds of which are not largely planted with these and other trees—a compensating influence which has not been sufficiently taken into account. Now, it happens that comparatively treeless sites were chosen for the hill stations of Octacamund, Coonoor, Wellington, and Kotagherry, and the consequence of these places being settled by Europeans is, that there are more trees growing within the large area of the stations than probably ever existed before; and it must be gratifying to know that the rainfall has not seriously diminished—on the contrary, the extensive tree planting seems to have resulted in "most wonderful weather;" the rain that used in former days, when seasons were good, to fall (on the Neilgherries) the last 10 days of April, has visited them early in March. Such improvements, says the *Agricultural Gazette* of India, has not been experienced by that mythical person, the "oldest inhabitant." It is for the Government to inquire whether the 60 years' cycle of Hindoo belief accounts for this result, or whether compensating influences, such as I have pointed out, have had their effect. If it be the latter, then by all means let them abandon their profitless forests (they were conserved at a loss a year or two ago) in the accessible districts, to the tree and shrub planting, food-producing planter, and so stimulate the profitable opening out of these glorious hills to the compensating and improving influence of artificial plantations. For a plantation to succeed, it must be formed on good forest land, it must be in a roaded district, it must be near a market, it must have every encouragement; as a means of fostering such encouragement, let the Government considerably abate the operation of Rules I. and XVIII. of the Madras Waste Land Rules. *James MacPherson.*

Facts about Steam and Horse Power.—Said my engine-driver to me to-day (he was formerly my farm-labourer), "My eldest son is 24 years of age next November, and your engine was put up in December, 24 years ago." Well, there it is now threshing away, and likely to do so for many years to come. After 20 years' use of the original boiler, I changed it away for an 8-horse new Cornish boiler, paying the difference. The Cornish boiler is more powerful and economical than the old flue boiler. The engine is of 6-horse power. If agriculturists were to sit down quietly, and calculate without prejudice the relative cost and value of steam *versus* horses, the former would get the almost unanimous verdict. The annexed figures, extracted from my farm account-books, will give unmistakable evidence on this subject. We use our engine about two days out of three throughout the year. From October 1 to June 1 it is at work almost daily, according to our number of live stock. It is often worked long hours, or overtime when required. The facts justify the following conclusions:—That a steam-horse costs less to purchase than a real horse; that it will last more than twice as long; that its annual cost for food (coal) is less than half that of the real horse; that the cost for attendance is only one-third that of a real horse; that it will do twice as much work as a real horse; when my 6-horse fixed steam-engine rests it only costs me 4*s.* per week, or the interest on £200, the amount of its cost and fixing; when my six horses rest, they cost me £3 18*s.* per week for their food, besides manual attendance and interest on their cost; a horse works eight hours, and rests 16; a steam-engine requires no rest except for cleaning or repairing; a steam-engine gets no lameness from kicks or strains, no death or inflammation from gripes, wind, or flatulence, or the other numerous complaints and disasters that befall horses.

Manual attendance per horse per annum	..	..	£16 10 0

Three ploughmen for 5 years at £33 6*s.* 8*d.*							..	..	500
Two horses to each ploughman					..	..	..	..	£1580

Some deduction should be made from the charge for for horsemen's attendance, because they labour during harvest and at other times when the horses rest. My engine and boiler cost £170 without fixing. The engine is of 6-horse power. My horses are always stabled when not at work. They work very hard. All their food is given in the manger: straw and hay cut fine, corn ground. Mangel pulped, rock salt in the manger. Stable ventilated. *J. J. Mechi, Sept.* 1871.

Societies.

SOUTH TYNE.

[We gave last week the report of the judges on moorland improvements in competition for a prize offered by the high sheriff of Northumberland; we now publish speeches relating partly to this subject delivered on the occasion of the annual meeting of the Society.]

The Chairman, Mr. Hope Wallace, proposed "Success and prosperity to the South Tyne Agricultural Society," and in doing so lie said that an agricultural society took all classes of farmers under its wing, and gave, or ought to give, prizes for all sorts of farming, and not simply to encourage the breeders of stock. Mr. Brown and himself had given silver cups as prizes in connection with the reclaiming of land. In the South Tyne district there were thousands of acres of land that ought to be reclaimed, and which would, he believed, be reclaimed in a few years time. They should all work together, and face the matter resolutely, and have the land improved in the best way possible. These special prizes were given for two reasons; in the first place to show that the landlords of the district wished to show their sense and appreciation of the time and labour employed by not only tenants but also small proprietors, in bringing the land under cultivation; and in the second place to get the problem solved with regard to mountain land. How could two simple words often mean, indeed there were to every question—ought the land to be touched with the plough or not? Ought a farmer to drain and lime his land, then take a rotation of crops from it, and then lay it down to pasture, or ought he never to touch the skin of the land with the plough? That was the problem to be solved. He often heard people talking about the question of the day, and he thought that the real question of the day, which would come home to every one, was the supply of food; and in what way could they better increase the supply of food, and also circulate money, than by bringing land under cultivation? Cultivation would not be brought under cultivation? As a young landlord, he wished to bring a question before the young tenant-farmer, being wishful to find out what kind of a person his future tenant was to be. He expected he would be a well educated man, for he could not help thinking that times would farm much better if they had more of what was called book learning. He spoke to a considerable farmer the other day about the education of his son, and suggested that the son should be sent either to some agricultural college—there was a good one now he believed at Cramptonor to some friend who farmed in the south of England or in Scotland; and the farmer replied, "Hoots, what does he want with a better education than his father has?" That was not the question to be considered; the question was, whether that education would enable him to compete with farmers in the future. Home-keeping youth always had homely wits, as Shakspeare said, and a man of that stamp had no chance in competing with men who had been where they had seen farming in all its branches. He recommended the young farmer to get hold of standard works on agriculture and read them up at night. They generally found that an ignorant and uneducated man was a prejudiced man, and, on the first blush, was always against improvements. The rising generation of farmers, when leases fell out, should make up their minds to drive a hard bargain with their landlord, for in the long run it would answer best. If the landlord was too easy with the tenant, the latter was too hard upon the land, and it was downright injustice to the land to allow too low renting. He did not allude to rack-renting, but a fair and reasonable rent, and if the tenant and landlord should humour him, but if he was a bad one he should be god rid of at any price, for kindness to the tenant in this way was an injury to the land,

Mr. T. P. Dods, in giving "The Competitors," said—The most interesting features of the competition were the two special prizes for reclaimed land, about which he was desirous of saying a few words. There was a story told of Lord Mansfield, of a brother judge saying to him, upon his appointment to the bench, that he doubted how he would get on, and receiving the reply that if he gave decisions without giving any reasons he had no doubt he would get on very well. One reason why they were asked to write a report was that they might give their reasons for their decisions, and although it might lay them open to a little criticism, he had no hesitation on the part of himself and his friend Mr. Wright in giving the reasons for coming to the decisions which they came to. The terms in which the prizes were offered were for the greatest improvement of mountain or hill pasture. They did not interpret the

greatest improvement as being the improvement of the greatest quantity of hill land, else that would have been a simple matter of the number of acres reclaimed and returned to the secretary. They interpreted it, as they were instructed that it was the quality of the improvement and not the quantity, and Mr. Wright and himself visited 16 different parcels of ground belonging to 14 different competitors spread over the district from Chatley the head of Knaresdale on the one hand to Whiteside in the north on the other. The reason of their awarding the 1st prize to Mrs. Winter was because—looking at the land round about the improved portion which they considered fair specimens of the land which had been improved—they thought she had made the greatest improvement on her piece of land from a state of Nature to what it was now than had been made in any piece which they visited. Many of the competitors had done a great deal and gone over a much larger area, but Mrs. Winter's was the most thoroughly done, the most economically done, and the most speedily done. They commenced at the head of Knaresdale and came downwards. Mr. Bywell, of Burnstones, had made great improvement in a piece of land through a great deal of labour, and with small opportunities for doing so. He had shown great perseverance in getting up lime over a bad road, or rather no road at all, and that was the case also with respect to many places which they visited. Mr. Brown's was the last place they visited on the first day, and on talking matters over they thought it was very doubtful that they could place any before, but on going to Mrs. Winter's they had no hesitation in placing it first, as being more thoroughly done and done well done than Mr. Brown's, and being a tenant and not a landlord, if there had been any doubt in their minds they would certainly have given the tenant the benefit of the doubt; but they had no doubt about it. They then went to Mr. Nicholas, who, in the few years he had been at Whiteside, had made a great reformation there, and he was much pleased to see it. The question had been put to him—which was the best way of treating this land, whether to break it up or lime it? He replied that as to breaking it up, it would depend upon the nature of the soil. In reference to Mr. Winton's, he acted more wisely in draining and liming it, while he had no hesitation in saying that in other pieces—Mr. Brown's and Mrs. Winter's—they had done right in putting the plough into it, but he could not approve of taking white crops off poor land. Mrs. Winter had put nothing into her land and taking nothing out, and, as a consequence, Mrs. Winter had Rape and seeds. He did not know the value of them there, but in his district there would be no difficulty in getting £4 per acre for the eatage of it. His Knaresdale friends were going on not merely taking two white crops, but repeating after a Turnip crop a third white crop from this peat top sort of land; and their grass was not so good as Mrs. Winter's, who only took one white crop, as far as the schedules informed them. Some person had told him that Mr. Grieves had robbed some other land to improve the piece he had entered in the competition. He might say that by trenching, draining, and liming it he had made it a piece of very good grass, he thought worth 30s., while the surrounding land was not worth 2s. 6d. an acre. He could not give them exact information of what it cost him, but he thought it would have cost him a good deal for manure.

There was a great quantity of land in the district quite capable of being improved, and he had no doubt but that the result of this competition would be to cause a very considerable amount of improvement to start and be carried on which was not going on before; and if it had to do anything like feel the population of this island it was not ten thousand, nor a hundred thousand, but hundreds of thousands of acres which could be brought under cultivation, and a still greater portion could be made into good useful pasture which was at present lying in a state of black heath. He was glad that the chairman had called their attention to the subject of education. He did not know if they had any communication from the secretary of the joint education committee down east, but he hoped some parties had been considering the movement made to utilise—not merely for the sons of gentlemen but for the sons of small middle-class lads — the charity now doing little or nothing at Haydon Bridge. The movement commenced with a paper read by Canon Dwarris at the Hexham Farmers' Club; it was joined by the Newcastle Farmers' Club and by the Committee for Educational Purposes of the University of Durham, and the joint committee thus formed had been trying to rouse the county to do something towards getting this fund utilised. If nothing was done in the course of a year or two, he had no doubt the School Commissioners, who had entire power to deal with this matter, would interfere with this fund, and if it was not made use of in this county it would be made use of somewhere else. The great matter they desired was a large boarding-school to be established at Haydon Bridge, making use of these funds for the partial endowment of it. This school would be one where farmers' sons and those of the middle class could have a sound and thoroughly good education at a reasonable sum. He hoped the people of that district would take home the remarks that had been made on education, and that when this movement had been initiated up there they would support it with all their might.

Farmers' Clubs.

BOTLEY.

The Impediments to Agricultural Progress.—This subject was introduced at one of the meetings of this Club last winter, and we publish Mr. Blundell's paper now.

Mr. Blundell said: I propose to use as little argument as is consistent with the time at our disposal, and shall content myself chiefly with giving my own conclusions upon the various headings under which I propose to illustrate the subject, and leave for the most part the discussion in the hands of the gentlemen whom I see around me.

Leases.—I propose first to allude to the influence which leases and agreements for letting land have upon agricultural progress. It is to be feared that leases and agreements for letting land are often drawn professedly in the interest of the proprietor, but still turn out to be practically against his interest and that of his tenant also; in such cases they are very much opposed to good farming. My experience tells me that it is very difficult to bind a tenant by terms and clauses in order to prevent his lowering and impoverishing the condition of the land in his occupation, and thereby ruin the highest offer as rent. I should much prefer to take a tenant with sufficient capital, giving him a lease for eight or twelve years, or otherwise an agreement for a term, subject to two years' notice, with liberal covenants as to cropping, and compensation on quitting for unexhausted manures, chalking, &c.; thus giving the tenant an interest in farming well to the last, and the incoming tenant a favourable entry, for which he ought to be willing to pay. By such a plan the landlord will always ensure a fair rental, and there will be no, or very little diminution of production and agricultural progress. I am decidedly opposed to an annual tenancy. I have seen so many changes of tenants by six months' notice to quit, that I do not hesitate to say the uncertainty of such a holding is often the cause of bad farming. Being always at the mercy of the landlord, how can the tenant feel justified in high farming with a liberal outlay, not knowing, when he sows, who shall reap? Compensation at quitting for unexhausted manures, &c., certainly palliates the difficulty, but does not remove it, because a tenant cannot shift his residence continually without expensive alterations of house, and at great inconvenience to himself and family. The clauses of a lease cannot be too simple if they are calculated to secure the interest of both landlord and tenant, and I will allude to a few of importance. For instance, a tenant should, in my opinion, not be allowed to crop more than half of the arable land with white straw crop on the vale farms, nor more than two-fifths upon the hill or poor stock farms, simply because it cannot answer his purpose, the most practical system being an alternation with pulse crops, &c., or green feeding crops upon the stock farms. The plan of paying for hay at market price upon entry is adverse to the tenant, he having to invest more capital which lays dead and pays no interest during his occupation. Again: a tenant ought to be allowed to sell hay and straw enough to pay for his requirements in artificial manures every year, except the last, otherwise this extra outlay is a dead loss in addition to the loss of the land. Upon such farms as require it a chalking clause should be entered in the agreement, compelling the tenant to dress a portion of the land every year, the unexhausted effects to be charged to the succeeding tenant. Some arrangement should also be made for the manuring, or otherwise improving, grass land, which is usually so much neglected in this county. The four-course, or Norfolk rotation, being the only recognised system, except on the hill farms, where the five-course prevails, should be the course laid down for an off-going tenant, in order that some definite system should form a basis for quitting.

Buildings, &c.—In estate management the want of careful attention to many leading points has much to do with the loss on land farming, and in which the whole community are more or less interested. First, let us consider how insufficient are many of the farm buildings in different parts of the country, and my opinion is, that great improvements may be made by re-appropriation and remodelling rather than by new erection or expensive additions. I have seen some homesteads greatly improved by these means, costing but little more than repairing, particularly when (as they usually are) sufficiently extensive. We must not, now we are considering this subject, forget the great advantage and yearly increasing necessity for building a proper number of cottages for labourers attached to the farm, and which should be not less than two tenements per hundred acres; for the system of education now so much extending will render the labourer more independent, and more inclined to emigrate than formerly. It will, therefore, be more difficult in the future for tenants to secure and retain good labourers unless they can offer them good cottages near their work, thus affording them a more permanent home. Again: how can we expect a man to do a fair day's work unless he is situated near his labour? His daily strength is partly expended in travelling to and from his work. We do not build our farm-stables miles away from the farm, and so take work out of our horses by travelling. Why should we act otherwise with our labourers?

Another subject in connection with landed estates also demands a notice, namely, draining, for, although it has been extensively executed within the past three years, few can estimate the extent of land still requiring to be done. Mr. Bailey Denton—a sufficient authority—has stated we have in the United Kingdom upwards of nine millions of acres undrained of clay soil alone, besides which there is probably as much more of other land which would pay for being drained. Many of the improvements required upon estates have heretofore been very difficult to accomplish, more particularly in the case of entailed properties, but at the present time there are great facilities offered by different companies by loans for the improvement of landed estates, whereby the cost and charges may be spread over 25 years, and I notice more particularly by advertisement that the Right Hon. Lord Ashburton has recently applied for a loan of £25,000, for the improvement of his estates near Alresford, Hants, thus showing that there is but little or no excuse for the neglect of farm buildings, land, &c., which we see around us, and which proves so injurious to the progress of agriculture.

Any district in an agricultural area of the kingdom is necessarily opposed to progress, unless a corresponding or an increasing area can be obtained by the enclosure and cultivation of woods and wastes, &c. It is my firm conviction that we have not at present so much land under culture or grazing as we had 30 years ago. And the enormous quantity of land absorbed by railways and their stations, &c.; look at the extension of factories and public buildings of various kinds. Again, look at the increase of towns and villages consequent upon increase of population and extension of trade and commerce. Take our own neighbourhood for instance. The market gardeners are now driven away from the towns, and have absorbed large tracts of land previously used for ordinary agriculture, and I can only come to the conclusion that much more land has been taken from the plough than has been given by enclosure and cultivation of wastes. A very natural question to ask—How is more land to be made available for agricultural purposes?

If we look back at the discussion of this Club last session we shall find that there is plenty of land lying idle, or nearly so, in the country; and who is to blame for this when it is proved beyond dispute that a large portion would pay for cultivation? As before observed, money is readily obtainable by loan for the purpose, and, even if it were not, the land may be offered to adjoining tenants, who, in most instances, would be ready to occupy and bring it into cultivation at a nominal rent for a given period, and, as it often pays no rent at present, this arrangement must be a gain and advantage to a proprietor, who would receive a fair rental at the end of a term of years. I have done this myself, and found it answer my purpose and that of the tenants also. It seems an extraordinary thing, but go which way you will in this country if you find waste land or worthless irregular timber in woods, by just asking to whom it belongs, in nine cases out of ten it is found to be the property of some large or considerable proprietor. Again, where the commons have been enclosed, nearly all the allotments should have been cultivated, and many of the larger ones neglected. I forbear giving any other reason why this should be the case, except that I believe parties are blind to their own interest. Steam cultivation would also be more generally adopted if proprietors would cut the timber in the hedges, which would pay for it, and leave the money, instead of 1¼ per cent. which they are now obliged to take in the growth of timber. As it is at present, it is a loss to the owner and occupier, preventing the removal of hedges and the enlarging of fields, diminishing produce, and often totally preventing the use of steam-power and impeding agricultural progress.

Game.—There can be no doubt that the loss by game of agricultural produce, irrespective of impediments to the cultivation of the land, is enormous. As, however, this subject engaged the attention of this Club last year, I intend to confine my observations chiefly to two points, viz., the prevention of game being an impediment to the occupier of land, and the making it profitable as an agricultural production. Firstly, it is not disputed by practical men that at present game has no value, and can be rented free of the game, and probably this freedom applies only to one-eighth of the leased land in the kingdom. It therefore follows that the occupying tenants have no option, under present circumstances, but that of submitting to the reservation of game by the proprietors. The effect of this is notorious—that employment of capital in cultivation is discouraged, that large numbers of occupiers are ruined, and the produce of the land greatly curtailed by the existing state of things; and I can see no other remedy for the evil than that "game be made the property of the occupiers of land whereon it may be found," and "that by legislative enactment any agreement for the letting or reservation of pheasants, partridges, hares, and rabbits shall be null and void in law," and "that game shall be protected by the law of trespass and the same laws which now protect the occupier's poultry,

sheep, &c." Secondly, I am not opposed, nor do I believe it opposed, to the interests of the country that large heads of game may be raised with the view to both profit and sport (call it battue shooting, if you like), so long as the occupier confines the ground game by wire netting or otherwise, and the winged game by feeding and careful keeping to his own occupation. There is no reason why it should not be made profitable, afford excellent sport, and injure nobody. Assuming, however, that game shall be protected by the same means as farmyard fowls, ducks, &c., this will, no doubt, involve the repeal of the Game Laws as at present existing. Be it so. No doubt there might be some who would say that they could not move in the matter of these contracts without the interference of Parliament. I want you to notice that I have alluded to this, and that we have already instances where the Government have interfered, as at the shipping employed in former years to carry emigrants to foreign countries. They made it compulsory that there should be sufficient accommodation for each emigrant, and thus interfered in the contract which had been made between the shipping agents and the emigrants themselves. Did not the legislature interfere in the Factory Act, whereby they said that persons should work so many hours per week and no more, thereby interfering with a contract that was made between man and man? Then, again, I might point to the Elementary Education Act, the education of the children of our labourer, and which is very likely to work injurious to the labouring man in one way, as it will compel a man to give up his children—the bread earners, who are sometimes of such importance to him in that respect; by legislation they will compel that man to give up his children for so many years, in order that they may be educated. That is an interference between a contract—between man and man. Look, again, at the many clauses in the Irish Land Bill which interfere with the contracts between man and man; but yet how much good do we see done by such a proposal. With regard to the letting of game, it will be of very little consequence to the large landed proprietor, because he can take 400,000 or 500,000 acres off the estate, and have a good preservation of game, and then let off the rest of his farm free of it; but it will be with the small proprietor. I think there are several members of the Club who happen to be so situate. My proposal would deal rather heavily with the small landlord, inasmuch as by letting off the land he would be obliged to forego the sport. He would have to say that by law; but what I think is, that landlords may make a previous arrangement with their tenants whereby they might have a right to kill the game in question equally with the tenant, and I do not hesitate to say that such an understanding would more firmly bind together the landlord and tenant in the bonds of friendship than all the laws in this country. This is my justification for the proposals I have made to you. These are my opinions, and, although I now stand alone, perhaps the time will come when others will join me more friendly than they might now. However, it is my opinion, and I claim the right to express it.

Local Taxation, as now collected, must be considered so unfair in its pressure upon landed property, that, whether we view it as a landlord's or tenant's charge, it is alike adverse to the welfare and progress of agriculture. This subject has recently and still continues to attract the attention of Chambers of Agriculture and Farmers' Clubs; but I have in no instance seen the subject better handled than it was recently by Sir George Jenkinson, the member for North Wilts, at the meeting of the Kingscote Club, and in the course of his observations, he refers to the report of a committee of the House of Lords, which sat in 1850, on parochial assessments, and the sixth resolution of their report says: "That the relief of the poor is a national object, towards which every description of property ought justly to be called upon to contribute, and that the Act of 43 Elizabeth, c. 2, contemplated such contribution according to the ability of every inhabitant." Well, the question then arises, why was real property only specified, and why was not other property named at that time, as liable to be rated to the relief of the poor, and sick, and aged, &c.? The answer is obvious. No other property, such as is now designated personal property, or very little at any rate, at that time visibly existed. No funds or railways, or rich iron mines, or other such personal property then existed. All the mass of wealth which is now possessed by the numerous classes of the community has gradually arisen since the days when this tax was first imposed. Then why, I ask, as in process of time it did arise, should it not have taken upon its shoulders its fair share of the burdens of the nation? Can any person say that the wealth of the country, no matter from what source it may arise, ought not to bear its share of the relief of the poor, and sick, and aged; and, still more, that it ought not to contribute to those burdens that are more imperial than local, and, as such, concern every class of the community? As an instance I quote the charges for police, for the gaols, for militia stores, for lunatic asylums, for coroners, and other charges, to say nothing of the charge for maintaining turnpike roads, and soon for the education rate. Who can say that the fundholder is not as much interested in the maintenance of all those institutions I have named—police, gaols, militia, &c.—as the landowner? Now, I will refer to some of the great sources of wealth in this country, none of which contribute to the local taxation charges. The following condensed statement will convey an idea of this enormous capital:—

Funded and unfunded debt	..	£805,000,000
British railway shares and debentures	..	325,500,000
Indian railway shares held in England	..	26,500,000
Colonial Government securities	..	16,000,000
Indian Home Bond debt	..	6,000,000
London Joint Stock banks	..	15,500,000
Irish and Scotch banks	..	12,750,000
Bank Stock	..	14,500,000
Insurance companies	..	15,000,000
Mines—British and foreign	..	10,000,000
Steam companies	..	20,000,000
Telegraphic companies	..	9,000,000
Docks, canals, waterworks, bridges, &c.	..	30,000,000
Gas companies	..	6,700,000
		£1,388,250,000

In addition to this immense amount of property, I am of opinion that all Government property (dockyards, &c.) ought to be rated. The extraordinary increase of poor rates within the last few years is beginning to take effect on public opinion. Hence its being taken up by the Chambers of Agriculture, and hence our naming of the subject. The increase, having been something like three millions annually, is all heaped upon land and house property, the income on which has been estimated at 90 millions; whereas the income assessed by the Income-tax, and which is only half the real income of the country, is nearly 400 millions; so that, in fact, the property and income of the country were fairly assessed, the rates would be about one-fourth of what they are now. With regard to land let us look at the last 30 years, and see what has happened with regard to it. I wish to know why the owners of funded property should not be called upon to pay taxes in the same way as houses and land! Why, if we look at the newspapers, we find that banking companies in this country, or some of them, pay 15 or 20 per cent., and I want to know—and I confess I think that some of you will go with me—whether it is right for a great portion to be paying this high rate for interest, by sitting down in his easy-chair, and enjoying his *otium cum dignitate*, without paying out of it one farthing to the local taxation of this country. I believe, if you all put your shoulders to the wheel and work in the right direction, we shall not see the burdens placed so unfairly as they are now.

Farm Capital.—Insufficiency of capital employed is probably the greatest of all obstacles to progressive agriculture, but still it would be difficult to lay down any rule as to the amount of money necessary to possess with a farm to be most advantageous, because some districts require much more than others, owing to the variation of soils and situation. It must, however, be admitted that where capital is wanted great losses often occur. In such cases too little stock, too little manure, too little both of animal and manual labour is available, and, from necessity, the produce also is disposed of at the most unprofitable time—in fact, it may be said that the free-trade idea of buying in the cheapest market and selling in the dearest is very often completely reversed. Land, however, can only be made productive by means of the capital employed in cultivation being the means to an end, and that in proportion to the judicious outlay of money the productions of the soil yield profit or loss. I may also trace to the same cause the want of a well-bred stock of horses, cattle, sheep, swine, &c., which still impedes very much progress to a great extent, for although wonderful improvements have been made during the last 20 years, yet if we go into any market we meet with lots of ill-bred animals for sale which never have, and never can, yield a fair profit for keeping. I must, however, say that I think there are more bad farmers through want of means than there are for lack of judgment and practical skill.

In conclusion, I would say that there are many other causes which I could name having a tendency collaterally to impede the progress of agriculture, but I forbear, in the hope that other members will take them up in the discussion which I trust will follow the reading of this paper. I beg to suggest that Mr. Sutton should take up the subject of the loss and waste of the force of cultivation of the land through the bad construction of the implements used. We have to trust ourselves to the manure sellers, and I should be pleased to hear our worthy secretary make a few observations with regard to it, for I cannot but admit that the farmers are very often the dupes of the manure merchants, and only find out that it is bad manure after they have lost their crops. I will leave the matter in the hands of the Chairman, who will no doubt call upon gentlemen who are able to supply the omissions I have made in this paper.

Discussion.

Mr. G. Gater said Mr. Blundell, if he understood him aright, wanted to show that the market gardeners had done harm by taking away a deal of the country.

The Chairman: No, what he wishes to show is that buildings and such like in the towns have driven the market gardeners farther out into the country.

Mr. Gater could not quite understand how it was that Mr. Blundell made it appear that the property he had mentioned paid no taxes, which were paid almost exclusively by houses and land according to his theory. All he (Mr. Gater) could say was that he had got property of every description, and it all paid taxes in one way or the other. Funded property paid the Income-tax, and therefore he could not understand how Mr. Blundell could say that houses and land paid all the burdens. It might be, however, that funded property did not pay its proper proportion.

The Chairman explained that Mr. Blundell was only speaking of local and not imperial taxation. He had alluded to those which escaped local taxation.

Mr. Gater: Every man who has property pays something, but whether he pays enough or not I do not know.

Mr. James Withers entirely concurred with Mr. Blundell in the idea he had thrown forward; indeed he and Mr. Blundell's ideas were the self same. He had thought over some of the impediments to agricultural progress, and which he would repeat to them. There were many impediments to agriculture which the tenant might both plead guilty. There were some things which the landlord thinks he has nothing to do with, and the same with regard to the tenant. One thing was, they wanted more convenient farm buildings, and among them labourers' cottages was not the least. He was very badly off indeed with them himself. Then they could not remove timber, also hedges and hedgerows. He could speak of these things because he suffered from them. Then there were short and imperfect leases, and these were impediments to agricultural progress. A great deal depended on the way in which the leases were drawn, for he had known cases where they were very detrimental to the occupier, and of no benefit to the owner. Some leases were so binding that the tenant was confined to a circle, just like a circus-horse running round a ring, and thus all his energies were crushed, because the land suffered much at the end of a lease where there was no compensation for unexhausted or permanent improvements, and this was a very great clog to agricultural progress. They had not got a just law with regard to tenant-right, and if it was right to make an alteration in Ireland he also thought it was but fair and just to England that an alteration should also be made for the benefit of the English agriculturist.

Mr. John Gater thought many thanks were due to Mr. Blundell for his excellent paper. There was one point in it which struck his attention more than anything else, and that was with regard to the question of taxation. It was that part where he alluded to the insufficiency of capital employed, and this concerned both the landlord and the tenant. Taking the landlords first, he really thought there were many cases where they were not masters of their own. They saw that many estates were so encumbered as to be almost entirely out of the hands of the owners, and in such cases the owners declined to do anything for the benefit of the community. Then they had another case—where the estates were heavily mortgaged. He thought they wanted some alteration in the law of mortgage, for now a man went and mortgaged his estate recently, and wished it to be known what he had done, whereas if he had the power he might be inclined to sell it, or deal with it better than he otherwise could. With regard to leases he could not go with all Mr. Blundell had said. He thought he had spoken on one side of the question—the tenants'. He thought much fault rested on the tenants' side as well as the landlords'. It seemed to him that if a tenant was willing to give an increased rent for a long lease, there would be plenty of landlords willing to grant them. He would ask Mr. Blundell whether, as a rule, there were parties who were willing to give an increased rent where long leases were offered. He did not expect that a tenant would go out of their way and grant leases for 10, 15, or 21 years, at a low rate; for during that time they would be debarred from taking advantage of any rise there might be in the value of land. If tenants were willing to give an increased rent for long leases, he could not help thinking that gentlemen would grant them; and if they would not give more for them they were not entitled to have them. The cottages for agricultural labourers was a point of very great importance. Mr. Blundell had truly said that they took care of the animals, that they had nice buildings, well drained and ventilated, and everything to make them comfortable, while the labourer and his family were crowded together in a small house. They caused him to sleep in small rooms, with a very few cubic feet of air to breathe, and he went to work the next morning with his physical vitality so reduced that he could not do his work properly. Therefore the farmer was deprived of much of his labour, and this was one of the impediments to agricultural progress. It seemed to him that there were many questions which the tenants could settle themselves. The advantages of draining were now so well known, and had been so often alluded to, that he would not now dilate upon them. There was a large quantity of land in every county which could not be properly cultivated without being well drained. If the occupiers were willing to come forward and pay a fair percentage on the drainage —for they must remember that drains would not last for ever—that a man might have to come into a county, and that a new tenant might not like what had been done before —if they would pay a fair percentage for the draining, he thought landlords would be willing to meet them. The question of tenant-right, which Mr. Blundell alluded to, was one which might come under the inquiry as to whether a man had a right to do as he liked with his property. It was often the case where a man had the inclination to remove all the things he had on the farm, and often when he had the right he had not the will to do so. The question of game was a very old subject, and one which had been pretty well ventilated there. Mr. Blundell said that he would make any agreement between landlord and tenant as to game illegal. He also went on to say that small occupiers should lose their game, but he afterwards recommended that they should make some sort of contract with the tenant afterwards.

Mr. Blundell: I beg your pardon. What I say is, that the agreement with regard to the reservation of the game should be put an end to.

Mr. Gater: Then I would ask you in what way the small proprietor could enjoy his sport?

Mr. Blundell replied that, seeing gentlemen like the Messrs. Gater around him he would remind them that what

he said was that he would have any agreement between landlords and their tenants as to game reservation null and void in law, but that they might come to an understanding among themselves in a spirit of friendliness, so that both might enjoy the game; and he believed that would cause that spirit of friendship to exist between them and the best bond of union that could ever be made.

Mr. Gayer continued: Mr. Blundell had taken up emigration and the Factory Acts, but he did not think that they would say agriculturists were the same sort of people. He thought they had more power of taking care of themselves than the others had. The next part of Mr. Blundell's paper to which his attention had been directed was that with regard to local taxation, and he felt there was much that might be said on that point. With regard to Government properties, he thought they ought to be rated, and for this reason—that many districts were altogether free from them, while there were others which had a large portion. Where the Government property was there was sure to be poor people and distress, and other parts had nothing of it. He now came again to the insufficiency of capital employed, which was really at the bottom of all their grievances, and he had no doubt a resolution dealing with it would be submitted before the close of the discussion.

Mr. Spooner did not think they could complain of the want of latitude for discussion. He thought if the paper had been a little more direct in its aim, and it had not fired so largely, it might have brought down more game. He agreed with Mr. Blundell with regard to leases and agreements, and he thought there should be two modes of dealing with them. There should be leases for a term of years, and there should also be annual lettings, with something like two years' notice to quit, and compensation for improvements. They had one system in one part, and one in another. In Norfolk one system prevailed, and in Lincolnshire another, and he did not place everyone seemed satisfied without a lease. He thought that both plans were equally good, and that a better arrangement might be made than now existed.

Farm Memoranda.

Wisbech District.—Harvest operations being now completed, and threshing having been carried out to some considerable extent, I venture to send you an account of what is the general opinion of practical and intelligent men as to the yield of our corn crop in this neighbourhood. It is universally admitted that the yield of Wheat will be deficient, although opinions vary as to the amount of deficiency. Wherever the threshing-machine has been used the result has been unsatisfactory, the produce in few instances exceeding 4 qr. per acre, and in many not more than 3 qr. have been obtained. Mildew has injured the Wheat to a great extent; indeed, almost all those thin crops that "tillered" after the rains in June suffered severely, and the result will be that much of the corn will not weigh more than 16 and 17 stones per sack.

The crop of Oats has, however, been more encouraging to the growers; and although not many have been threshed, those who have done so are, I believe, satisfied with the result.

I have not heard of any Barley having been threshed, but, as you know, it is not much grown here; however, the few pieces I saw a few weeks ago had the appearance of a good and full crop.

Peas and Beans are, I believe, a fair crop; the former, however, must have made every good farmer's heart ache to see the great amount of weeds which grew among them.

Potatos, of which I suppose 5000 acres have been grown within six miles of Wisbech, have not come up at all well, for there the disease seized them early the affected tubers have rotted in the ground, and the others being deprived of the assistance of the tops, matured before they gained any considerable size. There are, however, few diseased ones to be taken up, as they have rotted quite away.

I will reserve my account of the Mustard crop for a few weeks, until one or two of the usual Mustard markets have been held, when I shall be better able to judge of the yield. I very much fear, however, that it will not average 18 bush. to the acre. *Nemesis, September* 29.

Miscellaneous.

Tithes: Where are the Farmer's Friends? Chambers of Agriculture! what have they done for the tithe-payer? A recent writer commenting on the Tithe Commutation Act (6th and 7th William IV.) concludes these words:—"In legislating on this subject every care appears to have been taken to guard the interest of the tithe-owner, but it is equally clear that very little concern has been manifested for that of the tithe-payer," and this is shown in various ways, a few of which may be briefly stated, and first as to the annual payments of tithe being governed by the septennial average of corn instead of a yearly average. Secondly, in registering in this seven years' average all the high prices which occur during the period and calculating the tithe average therefrom, instead of introducing and fixing a maximum limit as to price, beyond which the calculation should not extend. Thirdly, in the circumstance that corn buyers and dealers are the persons chosen to furnish the corn returns instead of the growers. Fourthly, in the Act referred to being very defective in another respect, namely, as containing sundry loopholes by which the fraudulent tenant on quitting a farm may leave half a year's tithe unpaid, may escape with impunity, and may saddle his successor in the farm with the onus of paying it, anything in any recent Act of Parliament to the contrary notwithstanding. Fifthly, in the partial and oppressive operation of the Act which admits of a tenant entering upon a farm, when tithe, previously high, is beginning to recede in amount, while the man going out has paid it at the high figure. Sixthly, in the amendment so called, of the Act of 1864, which appears to have been smuggled through "the House" unchallenged, and passed on the plea of "diminishing the expense of collection," and which abrogates altogether the farmer's right to have the corn returns calculated from the prices obtaining in 290 towns large and small as before, and restricts the number to 149, which is manifestly unfair to all the other 141 parts of the kingdom, where prices are, of course, higher than in the small towns, thus raising the averages fictitiously, and foisting on the tithe-payer a rent-charge for the payment of which he is not fairly liable. Seventhly, to objections first and second in the foregoing section, it may be remarked that another evil in connection with the seven years' tithe average is, that there is no maximum limit or other provision made to protect the tenant from the effects of high prices caused by short crops. The argument that because the low-cwt includes in its calculation all the low prices of corn, that therefore he should be allowed to include all the high prices, could only be valid in the case of the tithe-payer having the same number of bushels to sell at the high as at the low price, and this we know he could not have; it is because he has to sell the quantity at low prices, averages, should be made by the growers only. Amongst the vast quantity of printed matter which year by year is issued from the press of this country, there is, perhaps, no species of composition so involved, contradictory, unintelligible, as a new-born Act of Parliament. Some time after it has come to the light, some sage also sees strange malformations in the bantling, and forthwith comes Act the Second to amend Act the First, but the second effort not being completely successful, we have, after a short interval, Act the Third to amend Act the Second, and so on, and so on, and after some years have passed away, during which this amending process has been going on, that we at length begin to get into clear water; in other instances these defects are not observed, and the Act goes down to posterity with all its imperfections on its head. Within a few months of the passing of the Act of 1864, which altered the mode of calculating the tithe-rent-charge, it was found that a County Court judge, in deciding a case, remarked that he had looked into the Act of Parliament on the subject, but could obtain no light there; the words of the section were so obscure, and the whole so ungrammatical that he could only guess at the meaning. The Act of the 14th and 15th Vict., cap. 25, called "An Act to Amend the Law of Landlord and Tenant." It does not improve anything, however, but leaves matters rather worse than it found them. Section 4 has something to say about tithe, and runs thus:—"That if any occupying tenant of land shall quit, leaving unpaid any rent-charge which he was legally liable to pay, such next tenant may pay it, and may sue the man gone out for repayment and recovery." Yes, but how if the man gone out was not "legally liable;" what says the Tithe Commutation Act?—"Such yearly sum or rent-charge shall be payable by two equal half-yearly payments, on the first day of January and the first day of July in each year." Now, if a farmer's term on his holding happens to expire at Midsummer or Christmas, he may walk out, leaving a half-year's tithe unpaid, and it is not recoverable from him because it was not "legally due," though within a few days of it when he left the farm. A case of the following description was decided a short time since in a western county court:—The plaintiffs sought to recover £56, the amount paid by them as tithes for the farm on which they had recently entered, and from which the defendant had given up the occupation at Michaelmas. The judge said, "He must very reluctantly decide against the plaintiffs, because the defendant had quitted the farm a day or two before January 1, when the tithe became legally due. Unless by a special interposition of the Legislature, which no doubt the 14th and 15th Vict. was intended to be, you cannot claim rent or tithe until it is lawfully due, which in this case was not until January 1, as he said before. No doubt the defendant owed the money, and there was a moral obligation on him to pay it; but if he chose to act the rogue, this Act of Parliament afforded him every facility. Here was the Legislature espousing the cause of a chent, and enabling him to overreach his neighbour to the extent, in this case, of £56. The Act should be altered, and the sooner the better, for he must say he never met with a more gross case of actual injustice"—so far the judge. Messieurs the members of the Chambers, have you looked into this little matter? We have all heard of a certain place that is said to be paved with good intentions, and so no doubt our section was good intentioned, but carelessly worded. It would have been the easiest thing in the world to say—The tithe shall be apportioned according to the last septennial average, and the tenant going out of a farm shall pay up to the day he leaves. It would then have been a simple rule of three calculation—if 12 months' tithe by the last average was so many pounds, how much for the 11 months and 25 days since? So much as regards tithe. Now let us see what section 1st of the same Act of Parliament says about emblements, which we in the West of England ough to know something about, seeing that we have so many holdings with a tenure of "from year to year" in existence. The following may be taken as a short definition of emblements:—"Those who have an uncertain estate or interest in the land, which estate is determined either by the act of God or of the law between the period of sowing and the severance of the crops, are entitled to emblements, or the profits of the sown land." And so the old phrase, applied to this condition of things, was "Quiet sow, quiet mow;" but the Legislature said—Stand aside; I am wiser than thou in this matter, and the following is my decision on the subject:—14th and 15th Vict., cap. 25, section 1st.—"When the lease or tenancy of any farm held by a tenant shall determine by the death of any landlord entitled for his life, instead of emblements the tenant shall continue to hold and occupy until the expiration of the then current year of his tenancy, and shall then quit." So much for the new-born babe, which we are told is in this island as the laws." *Western Times.*

The Week's Work.

October 7.—*Threshing* and *Dressing Seed* for autumn sowing, including Wheat, Barley, Oats, Rye, Vetches, Beans, Peas, and grass seeds, is a question which has this year been differently solved in different districts, owing to the varying condition of the harvest. Newly threshed corn out of the stook is an old rule which requires to be observed in late, wet seasons, as more or less injury is sustained when the sheaves are stacked damp. This year, as yet, we have not heard much of heating in the stackyard. Smut and premature ripening are reported from some places, so that seed will require to be thoroughly dressed to as uniform a sample as possible. I must say I do not believe in seed being changed from one district to another as a necessity, as dressing machines and washing apparatus are at the command of every farmer. On the other hand, very fine samples of seed may be obtained from other places, more especially of Wheat and winter Beans, so that a change may be made by districts subject naturally to degeneracy.

Winter Beans.—If not sown, get in without delay. The plant is a large consumer of lime. Where lime is naturally deficient, the land should be limed previously to sowing. From 50 to 100 bush. of unslaked lime from the kiln is a common dose for applying to a clean Wheat or Oat stubble per acre. When slaked and spread, it should be well harrowed into the surface with a heavy harrow, before manure is applied. Wood ashes, or specific artificial manures, supply potash, of which the plant is also a large consumer. But a good specific manure for Beans, suitable for being drilled in along with the seed, is much needed; and specific manures are favourable to early maturity of seed.
