"The slowness of the process of altering strongly-rooted characters is well illustrated by Fleischmann's experiments with Merino rams, put to coarse German sheep, which he says have 5500 fibres of wool on a square inch; grades of the third or fourth Merino-cross produced about 8000; the twentieth cross 27,000; the perfect pure Merino blood 40,000 to 48,000. Hence from this experiment, it appears that even 20 successive crosses with the Merino ram did not suffice to give their wool as fine as that of the pure breed. Recognising this law of reversion, it is evident that the more inherent of family characters, rather than the accidental or individual, are more particularly transmitted from the parents to their offspring. To ensure definite results in breeding, the pedigree and antecedents of the parents must be known. In this way alone is the transmission of desirable character constantly secured. This truth is fully recognised in the breeding of horses for the turf, and of the best of our Shorthorns; but amongst the less intelligent of our agriculturists, even male animals are chosen generally on account of their moderate price, sometimes perhaps on account of their good looks, but rarely on account of their goodness of descent. Purchasers if satisfied with the general appearance and quality of their stallion, bull, or ram, and perhaps with the look of the sire and dam, seldom make inquiries regarding pedigree. This is certainly wrong, for no animal, however good and shapely himself, can be expected to transmit his good qualities to his descendants unless such qualities have by transmission through several generations become by repeated repetition indelibly fixed and stamped. So far back as in the old days of Rome, Virgil enjoins the agriculturist 'to note the tribe, the lineage, and the sire whom to reserve for husband of the herd.' In highly-bred or good-pedigreed animals, carefully selected throughout a long line of illustrious ancestors, there must exist a great uniformity of type, and the qualities thus inherited for many generations are still banded down with an ever-accumulating power and certainty. Amongst the Arabs, the most careful horse-breeders of the world, this truth is recognised. Spotless pedigree alike of male and female being regarded as so essential, that when a sufficiently aristocratic sire cannot be procured, the best mares are not bred from at all. Where such a system of combination is selected is made, the stock, like that of the best Arab horses, attains a remarkable uniformity of character, and impresses with much greater certainty its characteristics on any commoner animal with which it is mated. In illustration may be mentioned the well-bred and celebrated ECLIPSE, who, although he contended with some of the best horses of his day, never met with his equal. His power and certainty in transmitting his sterling qualities to his progeny are amply attested by the fact, that he was the sire of 134 winners, which brought their owners £160,000, exclusive of cups. Again, amongst Shorthorns, what grandeur, style, and quality have been handed down from generation to generation amongst the well-selected scions of FAVOURITE, THE DUKE OF NORTHUMBERLAND, GRAND DUKE, DUKE OF GLOUCESTER, and EARL OF DUBLIN. Well is it still remembered how once a year half the flock-masters in England crowded round the ring at Babraham to see the distribution of Mr. Jonas Webb's Southdowns,

which were so well and carefully bred that they left their mark wherever they went.

"In the production of beef, mutton, or bacon, it might be supposed that a long line of illustrious ancestors might very well be dispensed with, and that any tolerably shaped sire would answer sufficiently well. But this is very emphatically contradicted by the fact that the best beasts in our fairs, at our stock sales, and pre-eminently at our great Christmas shows, are what may be termed pedigree animals, if not on both sides, at any rate on that of the sire. Surely the grazier, the breeder, and the feeder want no stronger evidence of the practical economy of using only well-descended, carefully-selected males. At the meetings of the Royal, and at other great shows of breeding stock, open alike to all comers, blood asserts its pre-eminence, and alone possesses the symmetry, style, and quality requisite to take honours at such gatherings. At Bingley Hall, Islington, and elsewhere there is ample evidence of the value of the animals obtained by crossing Highland or Scotch polled cows with good Shorthorn bulls. Some of these superior half-breeds have themselves been reserved as sires; but usually with signal failure. They do not produce anything so good as themselves; their progeny vary greatly, and frequently call back to some of their plainest and commonest ancestors. In the successful breeding of a flock, the importance of using well-bred rams of established and fixed characters, is also now generally admitted by all intelligent flock-masters. From these premises the important practical corollary is fairly deducible—that in the production, especially of male animals, whether it be horses, cattle, sheep, or swine, descent or pedigree should be regarded of primary importance. No careful breeder should, we think, rest satisfied without securing, say three or five distinct accredited crosses of superior recognised merit."

—An important NORTH RIDING AGRICULTURAL ASSOCIATION held its ninth meeting on Tuesday, at Appleton, near Malton, under the presidency of the Rev. C. P. Peach. There were over 300 entries in the horse classes, one-third of which were hunters, and the judging lasted from 10 A.M. to 7 P.M., the weather getting up fine in the afternoon. The notable feature in the hunting classes was the competition for the special prizes, in which some of the best horses in Yorkshire competed. The president's cup of 10 gs. was carried off by Mr. T. Cattle's "Sir Roger," five years, by "Cootes," dam by "Moss Trooper." Mr. Thellusson's silver cup for 4-year-old hunter was awarded to the Scarborough winner, Mr. E. Nesfield's "Mischief," by "Fugleman;" Mr. Milner's "Captain Peel" being 2d. Mr. Cattley's cup, for 3-year-old hunter, was won by Mr. J. Cattle's "Hugo," by "Strathern." In the cattle classes, Mr. Stamper, of Highfield, took the principal award, and likewise the special cup given by Mr. Bower, of Welham Hall, for the best animal in the cattle classes, with GRINDEWALDE.

SHEEP.

MR. ROBERT GARNE's sale of Cotswold rams took place at Aldsworth on Friday last, when 54 sheep were offered (three of which were let for the season, one at 81 gs.), and realised an average of £19 1s. each.

The Cotswold ram sales commenced last week, at the hospitable residence of Mr. William Lane, at Broadfield. Fifty splendid sheep were readily sold at an average of £18 2s. 6d. each. Last year's average was £14 11s. 8d., for 54 sheep. It may be interesting to mention that this celebrated flock made an average of £20 3s. 6d. for 65 sheep, in 1856; £22 4s. 2d., for 65 sheep, in 1857; £15 18s. 10d., for 54 sheep, in 1868; and £20 3s., for 54 sheep, in 1869, being the highest averages realised in those years.

PRESENT APPEARANCE OF THE CROPS.

AYRSHIRE.—Wheat, generally thin and small in ear, will be considerably under average. Oats thick and promising, though short of straw; probably a full average. Barley average. Beans looking well; full average. Hay generally thin and light. Turnips very backward and patchy; a large proportion still to single. Mangel and Swedes backward. Potatoes: A considerable extent of the early kinds raised; crop rather lighter than usual; late kinds look very healthy and promising. *Andrew Ralston, Lagg-by-Ayr, July* 20.

BERKSHIRE.—I consider our Wheat crop much improved, and may turn out rather above an average if not attacked with blight; our Barley I never remember better when the land was well done. Oats are not a heavy crop, but an average. Peas very good, a large breadth planted. The upland hay crop never worse, except Sainfoin, and most of that spoiled with the continued wet; I never remember to have seen so much hay spoilt. The root crop promises beyond any one's expectation, a better plant or more promising I never saw (all roots). Our Potatos were exceedingly good and promising up to last Thursday and Friday, July 12 and 13; every day since they have shown the disease more and more. Our harvest cannot, I think, commence (reaping) before the third week in August. *Thos. Owen, Clapton, Hungerford, July* 20.

—— The grain crops in this neighbourhood have improved in a magical manner since the rain that fell about the middle of June. During the early spring the Wheat crops were very thin indeed, having lost plant more than I ever remember them doing during the winter. Though they have recovered wonderfully, yet on the whole I consider the Wheats thin. Whilst they were in bloom we had a good deal of wind and many heavy storms, and as a general rule Wheat does not "set" well in rough weather. Taking, therefore, the thinness of the plant, and the chance of the ears not filling well, owing to the rough weather during blooming, I shall not be surprised to find that Wheat will be a bare average crop. Barley promises well, so do Oats. Peas are well podded, but so dly. Beans look well, but I hear of blight in some pieces. Hay, which early in June promised to be a poor crop, now turns out a fairly abundant one. A good deal, however, has been spoilt by floods in the meadows of the Ouse and Ousel. Mangel a full crop, and Kohl Rabi too. Swedes are backward, but I anticipate a good crop, as there has been no "fleas" this year. Potatos are looking first-rate, but I fear disease owing to the superabundance of rain during the last four weeks. The pastures, as a matter of course, have plenty of feed in them. *W. C. D., Stony Stratford, July* 20.

BUCKS.—The crops in this neighbourhood are as follows:—Wheat very various. Some blighty, brown down by the wet and wind before or while it was in bloom, therefore is injured; some a good full crop, well up, and looks promising, yet late. Some thin ones have made up very much, and are not yet on bloom, therefore must be very late; some are a fair average crop, while some of the weak ones are a good bit root-fallen, therefore cannot be good, and some are very bad. The plough has turned some in, and Barley, &c., has been drilled amongst some, therefore we cannot expect an average crop, and harvest must be late. Barley is generally good, and will be a fair average crop, the worst got I ever remember; a lot of my own and others has been swam away by the flood. Clover was a very poor crop, as well as badly harvested. The grass fields have not turned up an average crop. *William Smith, Woolston, Bletchley Station, July* 18.

DORSET.—There is some difficulty in giving an opinion on the crops of this season. Must our verdict be satisfactory, or otherwise? We leave the decision of this question to the public generally, and proceed to the statement of the case which comes within our own notice. The hay, now mostly secured, is in bulk but two-thirds more than was the average crop. Much of it will, however, be injured with the rains. As to Flax, a neighbour tells he expects an average of 10 bush. of seed, and from 2 to 3 pecks of Flax per acre, from 36 acres, this season. Some, he admits, struck with the rust or blight, is much laid, but he trusts it generally not seriously injured. In this locality we have annual Flax sales, and the price has varied from £7 to £16 per acre. The Wheat is uneven in straw and in thickness, yet some pieces look promising and regular, while other pieces are patchy and thin. The ears appear proportionately large, and with a good set they may be an average very much below the average. We form our expectation somewhat from the older blossoms, which came out most promptly. Still very few berries are visible, and we fear the Wheat may have suffered in proportion. Certainly the weather has been anything but favourable during Wheat-blossoming. The Barley presents most promising large and long ears. These are so thick that they lean under the pressure of raindrops, to recover when the sun shines. Oats are good, but Potatos are much diseased in the stalks, which emit an unpleasant odour. The crops I can only describe as very cheering. Mangels very good; Swedes equally so, and the common Turnips most promising. *John Pope, Symondsbury.*

ESSEX.—We are still able to report the Wheat crop making satisfactory progress. All agree that there is straw sufficient for to give an abundant yield, but some think the ear is not sufficiently bold to warrant over an average crop. The admission is, that if we have a fine weather, we will commence to harvest the finest crop of Wheat which has been cut in this locality for many years. The Barley, although not so important a crop, is also good, and is just beginning to change colour. The same may be said respecting Rye and winter Oats, which are coming on out through the 24th inst. Beans have made plenty of straw, but, just as they were going out of flower, the black-fly attacked them, but does not appear to make the progress which I have seen, and may not produce serious results. Mangel, which is the root crop here, is in every respect good, and when the grower, in the face of so much wet and dull weather, was able to keep the weeds under, no doubt need be entertained about the produce. On this farm, where we have 100 acres to struggle with, it required both capital and energy to accomplish the task. *T. Mitchell, East Hall, Rainham, July* 18.

—— In a ride last week of some 50 miles on the south-eastern coast of this county (Essex), I saw very promising indications of a full crop of Wheat, Barley, and Oats. In some ears of Wheat I found upwards of 80 kernels. A little damage occasioned by heavy rains must be deducted, leaving, I think, a full average, and perhaps something more. Bad farming is concealed by the wealth of vegetable life, but there is everywhere too much of it. I can report quite as favourably of the district in which I write this (Witham). The crop of Beans is somewhat questionable; some fields look blighted, and the pods not well filled. There is, as far as I have noticed, a full crop and growth of Peas of common sorts, and the same remarks apply to the early garden varieties, but the latter sorts called wrinkled are much blighted, and the yield expected a fortnight ago must be short from 20 to 40 per cent. This is a district where these varieties are largely cultivated for the seed trade. Mangels are filling our fields with a vigorous growth, but within a few days the black aphis has made its appearance amongst them; a report about them, as well as the varieties of the Turnip, would be premature. I will add a few words about the prospects of the seed-growers, who occupy a large breadth of land in this part of our county for this purpose. The severity of last winter entirely destroyed many fields of Mangels planted for this purpose, and but few pieces escaped some damage. It must be a short crop; it is late, and I notice that the black aphis is beginning its ravages. Swedes are well podded off, and look like a good crop. Common Red Clover is a great failure. Seed is good defective in plant, and unkindly. We have not been visited here by destructive storms, such as are recorded in many parts of the kingdom. Our rainfall for the last four months is as follows:—April, 2.94; May, 1.14; June, 2.26; July, up to the 20th, 1.78. *Henry Dixon, Dorward's Hall, July* 20.

KENT.—From what I have seen I should say the Wheat crop is excellent on stiff lands; thin on other soils, yet much improved for the late rains. Barley very good on all soils that are at all well managed. Oats a bad crop generally, except the winter Oats, which are good. Peas very good indeed; free from dolphin. Beans, which promised so well, are now generally injured by the black dolphin, and this must injure the crop. Hops stand a chance to be a total blight, except in some favoured districts. The hay crop was bad for the early mowing, but for the marsh districts we are now getting a good crop. Clover and Sainfoin an average crop. *G. Witt, Tunstall, near Sittingbourne, July* 18.

LEICESTERSHIRE: *Charnwood Forest*—The crops generally in what is popularly known as the "Forest," are looking extremely well, much better, in fact, than in most places. The season seems to have suited this district better than lands which are naturally much more fertile. The Wheat and Oats are looking well, some of the Barleys exceedingly well, and others fair, and the Peas and Potatos and Turnips good. The Turnips look very promising, but the Mangels are not doing so well; they have scarcely recovered the cold of June. Cabbages are extensively grown for sheep and cattle, and are very thriving. There would have been a heavy crop of hay, but a good deal has been injured by the wet. On one farm in the Forest, where the plan of piling the hay in very large cocks, holding about two cart-loads each, has been followed, about 50 acres have been saved in capital condition, but the hay in this district is generally much spoiled. The plan of having large cocks is not advisable in fine weather, but when followed judiciously in wet and showery season, it is very useful. There have been two very heavy storms of rain, and one of hail, doing much damage—the rain by washing up the roads and the soil in the fields, and the hail by injuring the crops. I hear that the Royal Farmers' Insurance Company have acted with great liberality, and paid numerous compensations. *H. W., July* 18.

LINCOLNSHIRE.—I am glad to say that our present prospects are very good. Wheat and Oats, our principal crops in this locality, though later than the past few years will, I believe, be ready to cut by August 14, with sunny weather some days sooner, which will be about the average time of commencing the past 30 years; and upon ordinary harvesting we think can find many hours of good returns when we did not begin harvest before August 12; and if we get plenty of sunshine during the next month, I think we may have a full average crop of Wheat, and over average of Oats. The Oats never in my recollection presented so good an appearance. Other grain is grown in such small quantities as hardly to be worth notice. The Peas I have seen were very promising; Beans also. Rabi, as well as all other varieties of the Cabbage tribe, are very largely planted this season, and promising well. Mangels are not generally good, and unless our soils and well-manured, cannot be a good crop; a larger proportion than usual are running to seed. Carrots are looking well, and a very large breadth sown. Potatos are also looking well, excepting the flukes; some disease is showing, but we may have quite sufficient of a crop for human food though a third should fail. *Thos. Aitken, Keyston Rectory, Spalding, July* 20.

NORFOLK.—The last week of genial warmth and sunshine has had a wonderful, almost magical, effect upon the corn crops of this county. A few of the heaviest fields in some districts are badly laid, but generally the Wheats stand up well, are a good plant, with what appears to be a well developed ear. It is yet too early to tell how the ear is filled, but although the weather was wet, it was not cold or frosty when the Wheat was in bloom. Barleys promise well, save on the undrained clays and cold sands, and there the back-

ward spring and ungenial summer have left their mark. The hay is not so much damaged as was at one time expected, and the Turnips grow with such rapidity that it is very difficult to set them out in proper time. Mangels are a poor, patchy plant, and have not grown well till within the last few days. *Clare Sewell Read.*

——It is rather too early to form a correct opinion as to the real prospect of the growing grain crop, but from present appearance I am inclined to think that on good Wheat lands there will not be much cause for complaint, either as to quantity or quality; but still we must not look for heavy weights this year—much over 18 stones per 4 imperial bushels will, I think, be the exception rather than the rule. On poor badly-farmed land the crop will not be so good, but plenty of straw. Barley will probably be a full average crop in bulk, quality cannot determine at present. Oats promise well, also Peas and Beans; some of the latter are 6 feet high, with 40 and 50 pods on a stem, but in a few instances aphis has attacked them, and for about 6 inches on the top of the stems quite a black hue is apparent, and the leaves are dwinged up. Potatos rise well as to size, quantity, and quality. Hay a good crop; some little of upland injured by the rains. Roots are doing well, and promise an abundant crop; there is also a good prospect of a second crop of Clover, but probably not so good of a large yield of seed. Beef and mutton, although lower in price, sell well; wool is making high prices; and altogether, with the present propitious weather, the farmer's prospects look brighter than for some time past. I send you, sir, the above, and shall have much pleasure in giving you any further information at some future time, which, to be of service to the agriculturist, will be required, as with present appearances harvest cannot be general here before the third week in August, if then. *W. H. Taylor, Bank House, Wymondham.*

RUTLAND.—As far as my observation goes I consider the Wheats a full average plant, but have noticed the last few days red rust to some considerable extent, which must materially reduce the yield. Spring cropping looks very promising, especially Oats, but I consider it much too early to give an opinion as to the probable yield of any corn, as they are now just in the stage when blight would most affect them. A continuation of sunny weather is most desirable. *Conyers Peach, Stoke Dry, Uppingham.*

WARWICKSHIRE.—When I left Rugby all crops were looking well. Grass abundant. Hay crop very promising; rain has hindered the working, but the crop is above average. Wheat and Barley promised well, on my own farm never better, but the heavy rains, however, laid them flat. Mangel is first-rate, and Swedes coming away well. Peas good, Beans fine, and Potatos also. My dairy cows fed in the houses are not milking so well as usual, probably from the wet season and rapid growth of the grass. *Jas. A. A. Campbell.*

WORCESTERSHIRE.—The character of the season is a complete contrast to that of last year. Much rain has fallen during the last three months, with cold nights and but little sunshine. All the cereal crops are long in straw. Wheat in this neighbourhood is in great part thin, being injured by winter frost and wireworm, and much is very weedy; the ear is too early in stage yet to report on; it appears late in proportion to spring corn, and the yield is likely to be under average. Barley is a heavy crop and long in ear, much lodged in some places; Clover seeds, where sown amongst it, are getting high, and may injure the harvest. Oats appear fair, but are not much grown here; the straw is valuable when cut moderately green. Winter Beans very defective; spring Beans once bid fair to be very good, but are much injured by the blight, called blacks. Peas very good, with plenty of haulm for fodder. Roots of all kinds a fine plant, but foul with weeds, in consequence of too much wet hindering the hoeing. Hay a full crop, spoiled by rain. Grass and Tares plentiful, and good; the summer supply and prospect of keep for stock, particularly if straw should be well harvested, is favourable. Potatos: A prospect of heavy crop, but disease has made its appearance during the last few days. A month's fine open warm weather is now much required to bring all crops to maturity; and the final yield, as the grand result of the harvest, will much depend on it. *Stiles Rich, The Cedars, Fearnall Heath, Worcester, July 25.*

AMERICAN BUTTER.

[The following is an extract from a paper on Butter Factories in the States, vol. vii., English Agricultural Society's Journal.]

Working the Butter.—In working the butter, considerable skill and experience are required that the grain of the butter shall not be injured. The butter must have a peculiar firmness and fineness of texture, and a wax-like appearance when fractured, which an improper handling, in expelling the butter-milk and working, will destroy. Care is taken, therefore, not to overwork it, nor subject it to a grinding manipulation like tempering mortar, as this spoils the grain and renders the butter of a greasy or salve-like texture.

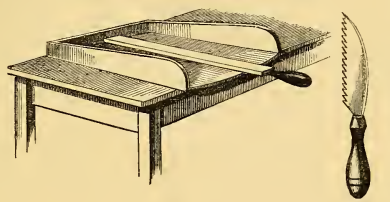

FIG. 219.—BUTTER-WORKER.

FIG. 220.—EUREKA BUTTER-WORKER.

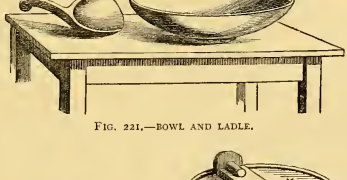

FIG. 221.—BOWL AND LADLE.

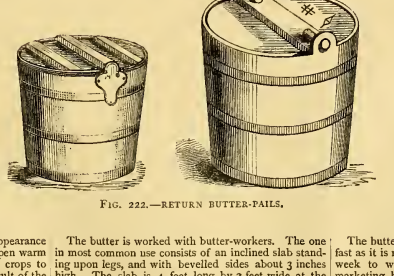

FIG. 222.—RETURN BUTTER-PAILS.

The butter is worked with butter-workers. The one in most common use consists of an inclined slab standing upon legs, and with bevelled sides about 3 inches high. The slab is 4 feet long by 2 feet wide at the upper end, and tapering down 4 inches at the lower end, where there is a cross-piece, with a slot for the reception of the end of the lever. There is also an opening at this end for the escape of the butter-milk into a pail below. The lever is made either with four or eight sides, and the end fits loosely in the slot, so as to be worked in any direction. It is quite simple, as will be seen by the figure below (fig. 219), but does good execution, and is much liked at the butter factories.

There are other butter-workers in use, and one of the more recent inventions is represented by the annexed cut (fig. 220).

A common butter-bowl is placed and held securely on a light, small stool, firmly against a solid rest (R), that protects it from breaking or springing. It may be revolved either way, at will, also easily tipped by a lever to drain off the fluids, and as readily removed from the stool as from a table, and bowls of different sizes may be used on the same stool.

The ladle (H) is attached to a pendant lever (F G) that enables a person to press directly through hard butter in all parts of the bowl without drawing or sliding it; also to cut, turn, and work it in every manner desired. It is light, strong, and simple, everything about it is practical, with nothing to get out of place or order, and it is as handily moved, washed, and dried as any butter-bowl and ladle, such as are shown in fig. 221.

The lever (E) is fastened to the slot (I) while the butter is being worked, and is raised up to discharge the butter-milk from the bowl as occasion requires.

There is a circular iron fastened to the bottom of the bowl, which slides in an iron groove attached to the lever K, and which allows the bowl to be moved round, and, when desired, to be removed entirely from the other parts of the worker.

After the butter has been washed in the trays, a batch, weighing 22 lb., is laid upon an inclined slab, or butter-worker, first described, and then spread out with the ladle. Pure Ashton or Onondaga salt, made fine by rolling, is now sprinkled over the mass and the lever applied, first from one side, until the whole is gone over. Only a few manipulations of this kind are required to work in the salt, and complete this part of the process.

As it is important that the butter-milk should be completely removed, this is facilitated during the working process by applying a slightly dampened napkin to the surface, or by the use of a damp sponge covered with a napkin for the purpose.

Packing.—The butter is packed in firkins, in half-firkins, and in Orange County pails. The pails are "return pails," that is, they are not sold with the butter, but are to be returned to the factory after the purchaser has taken out the butter. They hold about 60 lb. of butter, are of white Oak, nicely made, and strongly hooped with heavy band-iron. They have movable covers, that fit closely, and are fastened with wooden bolts or metallic clasps. The firkins are also made of white Oak, heavily hooped, and the sides neatly turned.

The greatest attention is paid to have the packages perfectly tight, so as not to permit the least leakage. White Oak is regarded as the best material for packages, and the butter factories use no other. The firkins hold about 100 lb. each. The half-firkin is simply the firkin sawed in two, and provided with an Oak head, which is nailed on the top of the package after it is filled. Fig. 222 shows the form of these packages.

The firkin is prepared for use by soaking in cold water, after that in scalding water, and then again in cold water. It is then either filled with brine, and soaked 24 hours, or the inside is thoroughly rubbed with dry salt, and left to stand a short time, when it is considered ready for use.

In packing the butter it is pressed together as solidly as may be, and when the firkin is filled it is immediately headed up, and a strong brine poured through a hole in the top head, to fill all the intervening spaces. The orifice is then closed, and the firkin is set in a cool cellar until it is ready to be sent to market. When the half-firkin is filled, a dry cloth, cut so as to entirely cover the butter, is spread over it, and covered with a thin layer of salt. The cover is then fastened on, and the package is set away in a dry cool place until it is taken to market.

The butter factories usually have orders for butter as fast as it is made, so that the consignments are from week to week. In Orange County the manner of marketing butter differs from that practised in other localities. Consignments are not generally made direct to the city dealers, but they are intrusted to "Cap-

tains," as they are called, or persons who make it a business to collect freights of this kind, and take them in charge to New York, making the sales and returning the proceeds to the manufacturer. The "Captains" go with their freight twice a week, are men of standing and responsibility, who are well acquainted with the trade, and know how and when to obtain the best prices.

They receive a commission for their labours, and find it to their interest to make good sales, otherwise they lose the confidence of those entrusting freight to their charge, and are liable, therefore, to be displaced. The captains often receive proposals for large lots of butter, which proposals are submitted to the factories, when they are accepted or rejected, as seems best to the parties interested. They supply private families and hotels, and by having a line of customers who are willing to pay a high price for an extreme fancy article, very large returns are not unfrequently made to the factories.

THE WOLVERHAMPTON MEETING.

THE Royal races at Wolverhampton are now over; you have given reports throughout; I have sat quietly at home to watch them. The first thing you gave was the "correct card" (the prize list) for the steam cultivator trials. I need not give it, for your readers can refer to it at p. 548.

The 1st prize of £100 goes to Fowler's 12-horse power double engine set. This set is strictly applicable to the contract plan, therefore that plan is looked upon as "the best application" by the Royal Agricultural Society. I do not agree with that judgment; I am quite certain that England cannot be farmed upon that plan, even in the face of the Lord Palmerston's words at p. 1240, 1864, "all farmers may not be buyers, but surely they may hire, as they do threshing." My lord understood law-making better than he did farming, or he would never have used those words, for they go against procuring the big loaf for the people, and he pretended to go for it, as a free-trader. A great free-trader told me years ago that I was the greatest free-trader that he had ever met with, for I practised while others talked. Lord Leicester, at p. 1022, 1864, goes almost as much against tackle buying as Lord Palmerston did, for he says that it would not do to buy a set on 1000 acres of light land; 500 acres of heavy land, and all, to nothing less. So much for the opinion of the big-wigs, for I do well on 166 acres, therefore I back my opinion against the big-wigs, and here is my especial reason why the contract plan cannot do it. Nearly all the work done by steam-power must be done in September and October, and Mr. Isaac Robinson says there is dead against its ever being done in those months upon the contract plan. I now offer to back my opinion by offering to farm 100 acres of heavy clay land for seven years, with the well-known tackle with which I have worked my farm for 16 years, against any farmer who will hire a set of the 1st prize winning tackle and implements, and farm 100 acres of such land for seven years, for £2000 against his £1000—the cost of the working and results to decide; and I will make a like challenge against any man who will buy a set of the cup-winning tackle to work against me.

Reports show that my opinions are receiving support. It is well known that I started off with turn-round at land's-end implements, for at Chelmsford I showed my well-known turn-round implements; Fowler came out with a balance-plough, and the year after the Chester show, in 1858, with the balance-cultivator. And I worked became manufacturers of the implements known by their own name, they came out with cultivators that did not need turning at land's-end. At that period, and for some years afterwards, the Woolston system of turning the implements at land's-end was attempted to be written down from first to last. Here is one, as a sample, I will give you the sayings of one man upon the point at p. 515, 1864. Mr. R. Ransome, in his paper read before the Suffolk Farmers' Club, said thus: "About this date (1858) Messrs. Howard, of Bedford, entered the field as manufacturers of Mr. Smith's apparatus, with which they continued associated until 1861; since then they have been manufacturing an apparatus upon the roundabout principle, with which Mr. Smith originally commenced, but further improved and developed in some of its mechanical details, especially in avoiding the necessity of turning the implement at the end of each furrow." Now we see what the attempt of Mr. R. Ransome and others at that period was worth, in trying to write and talk down the turning-round at land's-end implements, for at Leicester, in 1868, "John Fowler & Co." came out with a number of turning at land's-end implements; and now I read thus: "In spite of the disadvantage the system laboured under in being obliged to use a balance-cultivator, for such it undoubtedly is, the first prize went to the clip-drum," Fowler's, in class 2. In addition to this I read: "I am not surprised at the awards in class 1, for Fowler's improved cultivator appears to me as superior to Howards' as theirs is to the balance-cultivator." Therefore, according to the award of the judges and report, my turning cultivators are vastly superior to implements that do not turn at land's-end, whether balanced or otherwise. Time has thus overcome prejudice upon that point, and I am publicly pronounced the winner.

Here is another bit of evidence in support of my opinions. It is well known that I came out, and have always worked, upon the roundabout plan. Many have been the attempts to write and run it down. The Royal Agricultural Society's last attempt to do so, that I had anything to do with, was at the Worcester show, where they gave to Fowler's clip-drum £25, that broke to bits before it completed its plot, and never did complete it, against the roundabout (the Woolston) plan, that did its work well. Now, the grand Wolverhampton cup goes to a roundabout, a very similar set to one worked by the late Lord Hatherton, working a set of my implements, in 1858. Therefore, upon this evidence, the Woolston man has been right upon the point throughout; and as the contract plan (although puffed up by my Lords Palmerston and Leicester) cannot farm England, he must continue so upon all points. England wants the big loaf, and the contract plan cannot give it.

Poor "Sutherland!" My Lord Dunmore will now find that I did not use unjustly hard words against it, and my friend Mr. Isaac Robinson, of Wisbech, who warned me of its coming to Wolverhampton, will cool down a bit now in his expectations. Poor thing, it got in the mud in much the same time back as were told to believe that it got over a newly dug Potato field without making an impression.

The rain at Wolverhampton did no end of good, for through it the land represented autumn work much more than it had done for many years past. The ploughing done by the engine going over the land could be plainly seen. The cultivator did not like the Twitch; the plough was just in its glee, for it could well cut and turn its furrow-slice even if there was a little Twitch in it, and made quite showable work. The dirt made a nasty mess of it to all, and the farmers would be, judge as to how they would like to have their land thus messed about with road steamers.

The Royal Agricultural Society of England is a very antiquated body—its list of prizes proves it. It must and will have its old plough, so it gives the Royal prize of £25 for a ploughing and then the grand £300, and subsequent smaller prizes. Then it gives to the makers £25 for a half-bred thing, called a digger. In it there is the plough principle working upon the cultivator principle. Then it gives two prizes of £45 to the same makers for cultivators. This is getting after Smith a bit, following his teaching. It took him years to convince them of the use of that implement. Then the Messrs. Howard got £10 for the old antiquated harrow, and to make it appear that they are in earnest upon the steam question, the Council give drills £20, and they give a few prizes to the makers of the children; but the grand cup goes to the plough, digger, and cultivator, all of which must be arranged in the same frame—thus buckling old things together, *i. e.*, two ploughs and a cultivator, to keep the whole within £700. The makers know how to please them, and they get paid for doing it. Fowler's set of implements that I challenge £2000 to £1000, twice over. The combined things may have a good engine to work them, but they have no chance against Woolston implements worked by Mr. Smith's little engine upon Woolston practice, neither have the old plough and harrow, &c., worked by bigger engines upon the contract plan, for Woolston man can thrash them in practice any day. His crops now stand forth as witnesses on his side. *William Smith, Woolston, Bletchley Station, Bucks, July 18.*

THE TENANT'S RIGHT TO UNEXHAUSTED IMPROVEMENTS.

[We take the following from Mr. Bence Jones' published "Letter to an Assistant Barrister on Unexhausted Tillages and Manure under the Land Act."]

THE Land Act plainly does not put unexhausted tillages and manures under what may be called the penal jurisdiction of the Court. They are classed with permanent buildings and reclamation of waste, in all of which money (or value) has been laid out by an outgoing tenant, and remains in the land, and of which his successor in occupation will get the benefit. In fact, it is not as much part of the case that the benefit shall be in the land for the successor, as that the outgoing tenant shall have put it there. The out-going tenant may have been the best farmer in the world, but if the manures he put in the land are exhausted, he will not be paid for them. Besides, tenants ejected for non-payment of rent, and those who give up voluntarily, are equally entitled to payment for unexhausted tillages and manures under the Act. It is clear, that when a tenant leaves voluntarily there can be no reason for a penalty on the landlord. In truth, in this part of the Act, I believe, it is certain that an honest commercial dealing, equally fair to both parties, was meant. The interest of the public in unexhausted tillages and manures is, that a tenant in the last years, before from any cause he leaves a farm, should have no motive to exhaust it, which is seldom any real gain to him. An out-going tenant exhausting his land for some years before he leaves it, and the in-coming tenant restoring it again by some years' expenditure, is no gain to either, and the public loses by less produce at more cost. This compensation, moreover, is one in which, except when the owner means himself to occupy the farm, it will soon be found that landlords are not directly interested either way. The benefit from unexhausted tillages and manures is to the succeeding occupier. Should he chance to be a bad farmer (not purposely bad, but only not good), he will exhaust in the first few years whatever was left in the land by his predecessor. It is certain that in a very few years this will come to be understood, and the payment for unexhausted tillages and manures will always be made by the in-coming tenant. It is always so in England; the landlord takes no part in the question, which is settled between the out-going and in-coming tenants. For the reason I have given, it is fair and right he should pay it; and even those landlords like me, who object to all payments by an in-coming tenant in the nature of fines, purchase of interest, &c., because they absorb the tenant's capital just when he most wants it to stock and manure his land, and so hinder his success in the farm, will be obliged, in self-protection, to throw upon him the payment for unexhausted tillages and manures.

From every point of view, therefore, it is very important this question should be placed on thoroughly sound principles, and more important for the tenant class than for the landlords.

It cannot be thought the Act meant to give the tenant a right to all unexhausted manures in any way existing in the farm, as if bare exhaustion was recognised as the normal state in which tenants are justified in leaving their farms.

Plainly, the meaning must be unexhausted manures which the tenant has himself added to those that, from any cause, natural or artificial, existed in the farm when he took it. This is the meaning to which the words are always understood in England and Scotland.

This makes it needful to go into the question—What is the origin of the manures used?

Manures may be made from the consumption of plants, straw, hay, or roots, grown on the farm, with the help of previous manure made in a good way; or it may be manure from outside the farm, usually bought, as town dung, sea manure, lime, bones, guano, or superphosphate, or plants grown more or less by the help of such bought manures, or manure made from bought food.

Now this is all the teaching, both of practice and science, is, that when a farm is even well farmed without the use of additional bought manures or food, *i. e.*, with only manures made from the hay, straw, roots, and grass grown on it, the corn, and stock, and dairy produce sold off cause a slow but steady exhaustion of the land; even on good land, of course, much slower than on inferior land, because there is more to draw upon. It is often so slow as only to be perceived after a lapse of many years. The blame is often put on other causes; farmers, even good farmers, constantly deceive themselves on the matter; men of little education have no firm general principles, and often fancy they have found out some way of gaining in their particular case by what elsewhere would be a loss, and chance favourable seasons, or accidental quality of some fields above others, or insufficient observations of all the effects of their own doings, or other imperfect causes, deceive them very sure they are right, and that principle is wrong. Yet the result is absolutely certain, that when more is sold off the farm than is brought on it, there is an exhaustion in proportion. In truth, when the point is once clearly stated, common sense will show even to those who have nothing of farming, that it must be so, else—something would be made out of nothing. A man might eat his cake and have it afterward. In practice, among farmers of education, the fact is beyond question, and proofs that the result is such as I have stated can be given to any extent. In the whole foundation of the modern system of good farming, and the immense trade in manures that is growing up in Ireland no less than elsewhere. To go through the proofs that can be given on this point would take too much space; even the fertile virgin soils of America have been thus gradually exhausted.

The food of all plants comes from the ingredients of the soil, with a small addition from the rain and air. By exposure to the weather, and the action of the roots of plants, especially of grass, the elements of the food of plants in the soil are made available for other plants. Part of these are sold as corn, meat, or butter—part returned to the soil as manure. But this manure belongs to the land; it owes nothing to the tenant. In every well-drawn lease in the three kingdoms, it is covenanted that all hay, straw, and roots shall be consumed on the land, and the manure made from them returned to it. If these are sold off the land for a few years, or if the cattle grazed on it are folded on other land, rapid exhaustion soon is evident. A tenant may take these elements of fertility from one field and put them on another, but the farm gains nothing thereby. Good farming, from making all the resources of the farm and soil available, will always show better than bad, though it may even more exhaust the soil; but unless the tenant has brought additional manures on the farm, or food for stock, as oil-cake, &c. (which is the same thing in another form), he cannot leave unexhausted manure on it in the sense of the Act.

The practice of compensation for unexhausted ma-

* Hodges, Foster & Co., Grafton Street, Dublin.

nures in England and Scotland rests wholly on these principles. The tenant is only compensated for so much of the extra manure, or food for stock, he brings on the farm within a certain number of years before, as he leaves behind. It does not follow, because manure was once brought on a farm that it is there still; it may have been exhausted since by cropping, and it is simply impossible to prove whether a course of cropping many years before was or was not exhausting, or what was the quantity or quality of the manure used. It is certain that much manure that has been used becomes unavailable for future plants—whether it is consumed in mere growth without appearing in the ripened produce—whether it is washed away by the percolation of rain, or whether it forms new but insoluble chemical compounds with other substances that it meets in the soil. But it is not there for use. Custom, based on experience, has taught us how many years manures are practically exhausted—lime, seven years; bones, four years; guano and superphosphate, two years; oilcake, three years; and the tenant is paid accordingly in proportion to the number of years since the manure was used, provided it has been cropped exhaustively since, and so taken the manure out again.

In truth, the whole idea of the justice of recompensing a tenant for unexhausted manures rests on the view, that his money or labour has added a value in this respect to the land which it did not before possess. It does not include the removing the elements of fertility already in the land, from one field to another, in the ordinary course of growing hay, straw, or roots, of which the profit is got in feeding the usual stock of the farm. When bought manure grows extra food, or extra food is bought, and so more stock is fed and more manure made, the tenant's claim is very just to what is unexhausted. The only question is, in what way such compensation shall be given, and how the facts can be best proved so as to avoid frauds, to which the question is peculiarly open.

NO MORE GUANO.

This means dearer bread, scarcer meat, more paupers, heavier rates, higher rents, smaller profits; bad times, worse times, short time for labourers, more hungry and half-fed throughout the kingdom. It may mean more and worse than all this—semi-starvation to many, pinching poverty to more, more suffering and privation to all; embarrassing problems in politics, social strife, danger to order, and serious peril to our institutions. For, by estimating in the admission is, it is nevertheless largely true, that the security, happiness, stability of states rest largely on the state of their larders. Fill them with an abundance of good things, and nations wax fat and prosper, while ill-filled stomachs are the natural cradles of treason, conflagration, sedition. No monster so unreasonable as gaunt famine, gnawing hunger, and these seem barking at our heels in the no very distant future. Every day swells the ranks of the bread eaters by the thousand, while the area of production, we are told, has reached its limits, and one of the most powerful promoters of fertility is exhausted. Truly the prospect seems most gloomy. It would be intolerable but for some gleams of light athwart the gathering darkness. We are not wholly dependent for life on home supplies of food. Corn comes to us from every land, and provisions as well nigh unheeded in bringing us fresh beef from the antipodes. We have been called a nation of shopkeepers—the cotton-spinners for the human family. We should be more truly described as a nation of bread and meat eaters. Our shambles and bakers' shops cover the earth, and our deliveries in transit block up the sea. Every breeze wafts us golden grain or preserved meats. The prairie and pampas alike are but wide fields on our outlying offhand farms. But it must never be forgotten that as the food from distant lands rolls in, the gold is drained out. We are fed, it is true, but we are likewise impoverished. Foreign food blesses us but once—home supplies many times. And it would be easy to show that food is to a large extent cheap or dear—and that means to the mass of consumers plenty or scarce—in proportion to the amount and efficiency of work at home. The more bread, beef, sugar grown in England, the cheaper these commodities; the less, the dearer—free trade and its invulnerable theory of exchanges notwithstanding.

Accepting your estimate, we have reached the maximum of home production; with all the land occupied, and one of our most powerful stimulants exhausted, we can hardly expect to get more out of the land. Hallam's *dictum* seems also irrefragable. "There are but two possible modes by which the produce of the earth can be increased—one by tendering fresh land serviceable, the other by improving the fertility of that already cultivated." You assume that the first mode has been worked out. No more commons to enclose, no fresh land to be possessed. Of course the statement is meant to be wide and general. There are still many exceptions to it, a good numbers of acres throughout the kingdom that might be profitably reclaimed. How frequently we pass over barren tracks, only separated from splendid fields of corn or roots by a fence. Surely if the one could not be made as fruitful as the other, then our geological boundaries are more sharp and capricious than we are wont to believe. They are likewise wonderfully easily obliterated, for I have never seen an unsuccessful attempt made to make the one land as good as the other. But it is not of such means of getting more land that I am writing at present, for these wastes cannot be had for nothing; on the contrary, they rise wonderfully in value as soon as wanted; but my light and hope for the future is—more land without more rent. Surely in these days of struggling competition for land, when a raid is made by eager farmers on every vacant holding, that cry will be listened to. No new land laws are needed to make that land yours. How then are you to get it? Get your smashers and ploughs deeper, and it is yours. Amid all the barbarous impediments to improved cultivation stereotyped in ancient lease. I have never read among them, "Thou shalt not go down and find new gold fields," that is, fresh land beneath each furrow. There it is in every arable field throughout the three kingdoms, waiting patiently through the long ages to be possessed by the well-fed roots of the future. No fresh land to be possessed, only every inch gained in depth adds 120 additional tons of produce per acre per cent. per cent. Let us pause a moment, and try to realise the meaning of this statement. A 4-inch tilth represents a productive earth force of 480 tons, a 5-inch of 600 tons, a 10-inch of 1200 tons. I do not assert absolutely that a 12-inch tilth would yield three times more than a 4-inch, but I do affirm that the capacity of the deep tilth would be three times that of the shallow, and were they both alike rich and good in texture, the possibility is that the 12-inch would yield even more, especially of root crops, than the legitimate ratio of three to one.

It may be well also to remind your readers that these views are not founded upon mere arithmetical data, nor natural philosophy formula—thus, two and two are four, the energy of mass is apportioned to its size—but that they have been abundantly proved in practice for years of actual cropping. It is amusing to read occasionally, in the discussions at farmers' clubs, of namby-pamby farming as mere gardening, as if the practice of horticulturists was in a laggard, benighted, to-be-commisserated state. So, evidently, does not think that busy, great, and intelligent farmer, Mr. Mechi. In his admirable new letter on Liebig's theory vindicated, he points out how gardeners have long been familiar with the art of feeding the lower roots, and implores farmers to go and do likewise. And where are those lower roots to be found? On the farm, from 4 to 12 inches from the surface; in the garden, from 2 to 4 feet. Rather namby-pamby cultivation that, is it not? The wisdom and advantages of this radical treatment of the earth, this cultivation of the lower farm, is proved by the irresistible logic of such facts as these,—the increased produce and superior quality of root crops, and the higher rent of garden land. Similar good results are reaped from deeply-cultivated farm lands.

It will probably be another century at least before a maximum depth of tilth will be generally reached. Until that time come—for come it ever will—there is plenty of fresh land to be utilised. It is wholly a mistake to measure the productive force of the earth by square feet or yards. This mode of computation has led to intense competition for possession of surface only. The joint streams of capital, skill, and labour that have been poured on it run chiefly—sometimes has been a tremendous loss of productive force, and a wretched average return of about £4 per acre. By doubling the depth you get as much again land for the same rent; and surely it is almost as obvious as that two and two make four, that with as much again food, the things fed thereby—that is, the produce—ought also to be doubled. Some will doubtless cry, "I have tried it frequently; you cannot do any more than cover the surface. My crops cover the ground." Yes, but with what sort of covering? Might not these ears be longer, each filled with more grain? Might not Turnip and Mangel reach double the size? I do not affirm too much when I say, you know they might. And for the development of quality and weight the unused earth at the bottom of the furrows is as good, nay, it may be better—at least it may be richer—than that which is tilled.

But this brings me to my last point. How are you to get more out of your enlarged holdings? All your manure was too little to enrich your shallow tilths; how is enough to be provided to satisfy the deeper ones, especially as your old friend, guano, is worn out? These are vital questions, and I will endeavour to answer them briefly and fairly. The earth itself is a productive force of no mean value. This is too apt to be overlooked by the farmer; he treats the ground too much as he would a horse—so much corn in, so much work out; so much manure in, so many coombs or tons out.

But the earth can also produce somewhat without manure, and this natural force can be wonderfully augmented by aeration and admixture. This co-mingling of earths in the soil is somewhat analogous to the cross-breeding of animals. The product of the admixture of soils is a wonderful increase of growing force. Even the addition of a comparatively worthless earth to a good soil, gives, as it were, a fresh lease or a new infusion of growing power to the entire mass. That great and good teacher, Mr. Mechi, adverts to this in the letter already referred to, and I think a useful aid to deep culture might be rendered by republishing, in a cheap form, Mr. Smith's, of Lois Weedon, and Mr. Lawes' experiments on what might be called the normal productive force of the earth without manure. Again, deep tilths utilise to much more advantage all the manure applied to them. On shallow tilths it is no exaggeration to affirm that one-third of the manure is utterly wasted; it is either lifted up into the air or washed out into the water; it is not half covered, and its strength is rinsed out into the nearest ditch or blown out by the first breeze; but deep tilths hold manure tenaciously as a blacksmith's vice—the top covering is thick enough to be gas-proof, the bottom is deep and retentive of manurial juices as a sponge. There is, there can be, no loss.

But then, with a dearth of guano and more land, will not the farmer be in a worse dilemma than before? It certainly seems so at first sight, but we fall back on the common proverb, that when one door shuts another opens. We believe this will be verified in this instance to the letter, and that, moreover, the second door will prove by far the best for the farmer. While the guano store lasted it seemed useless to direct attention to other sources of enrichment, but close that door and our home guano will stand a chance of being fairly tried. Here, again, I am glad to find the views I have endeavoured to enforce for years are in perfect accord with your own and Mr. Mechi's. Both reach the same point from opposite sides: the guano deposits are exhausted, therefore recoup your fields from the refuse of your consuming centres, is your cry; deepen your tilths 30 inches, and flood and enrich them with town sewage, is Mr. Mechi's. I reiterate these cries. Possibly they may be heard now there seems no other means of getting more off the land than by recouping its productive force by the waste of our lives and the dirt of our labour. We are coming to this at last, by a process of exhaustion. All other means have been tried to enrich the earth. Battlefields have been rifled of their bare bones, islands in the distant oceans scoured for birds' dung; seeds, oils, and entire crops converted into feeding cake, and giving food for the hungry earth; and still the cry remains hungry, and it is repeated with a louder voice and from a deeper throat year by year, "Give, give."

We take more out of it, and must give it more, or break its back by exhaustion. The weakened earth revenges itself on us for our niggardly feeding by light yields; for in the matter of manure, whether it is emphatically true, as we sow so we shall reap. All the while we have been starving the hungry earth of its proper food we have been wasting it most lavishly in all directions, and filth, the proper food of the earth, has literally been cast a-begging. We begged the wind and the air to take it, and they reproved our folly by returning it in fiery fevers or the serpent trail of lingering disease. We poured it into the waters and they became black in the face with rage, and the pure water of life was transformed into the slimy draught of death to thousands. We offered it to the dogs, and he licked it up in anger, and reproved our wasteful folly by scattering its elements broadcast throughout the air we breathe.

While all this folly, waste, and wickedness—for it was all three—went on, the mute, long-suffering, ill-used earth looked on and wondered at the so-called wisdom of its masters. At last the cry arose, To the land with all excrements and waste, the filth of towns, and the dirt of the country. And the earth heard it and rejoiced, and thought that its time—the time when it should be filled with manure and fatness—had at last come. Vain hope—fond delusion. Ignorance, prejudice, habit, old saws and modern instances, even Mammon with his money-bags, blocked up the way—stood an impregnable barricade between the hungry earth and its natural supplies of food; and the year by finds us wasting more at the rate probably of £50,000,000 sterling per annum, to the impoverishment of the earth, and the wasting of the very essence alike of vegetable and animal life; for it can never be too often repeated that the food of plants misapplied, wasted, unused, is disease, suffering, death. And all this while the wisdom of Parliament is expended upon the ways and means of raising three millions more revenue, and the struggling taxpayers are crying out that 2*d.* more Income-tax will break their backs. No wonder there is all this impatience of taxation, all this anxiety to play pitch and toss with local and general burdens, while we are undermining the energy of the earth itself, the foundation of all our riches, by our wasteful extravagance of our home-made manures. The Chancellor of the Exchequer has just tried to raise a small tax from our matches and tapers, I wish he would try to lay a large one on the waste of good manure. Such a tax, fairly levied and sternly collected, would set all future Chancellors' minds at rest about ways and means for this generation, while it would enrich posterity so much that they would pay all demanded of them without grumbling. Certain it is that only by doubling or trebling the depth of our tilths, and by enriching them by all our waste, can the circle of production be completed, and the strength of the earth, represented by our harvests, restored. The nation that wastes not manure shall not want bread but there need be no hesitation in affirming that the opposite is equally true.

D. T. Fish.

Home Correspondence.

A General Invitation to Tiptree.—As it is desirable that both landowners and farmers should be enabled to judge whether poor land will make a grateful and profitable return for draining, deep and clean cultivation, and good manure, those who desire to see my farm are at liberty to do so at any time between this and harvest, which, we expect, will commence on August 13 or 14. I paid £23 an acre for this land, nearly all freehold, in 1841, and it has been heavily cropped ever since. As an instance of what such land may be made to produce, I will quote Willow Field, which produced, in 1867, a heavy crop of Clover; in 1868, 8 qr. of white Wheat per acre, sold for £23 per acre, without the straw; 7 qr. per acre of Rivett Wheat in 1869; 30 tons of Mangel per acre in 1870; and now a crop of red Wheat, which promises to be an excellent crop. Next year it will be cropped with Beans, and in 1873 with Wheat again; in 1874 (winter) with Tares, sown in October, 1873; followed by Kohl Rabi or Cabbage, transplanted in July, 1874; and in 1875 Oats sown down with red Clover. This finishes the rotation after red Clover. I then get nine years—one red Clover crop, four Wheat do., one Bean do., one Oat do., one Mangel do., one winter Tares do., one Cabbage or Kohl Rabi do. I consider the seasons very favourable for this neighbourhood. My object in giving this information in this form has been, a sincere desire to stimulate and encourage agricultural improvements. *J. J. Mechi, Tiptree Hall, Kelvedon, Essex, July 24.*

Utilisation of Romford Sewage.—The original estimate of the population of Romford, namely, 6000, was, I believe, erroneous. The real figure I believe to be about 8000; however, this we shall soon know with certainty. It will be seen, therefore, that 1100 tons daily would be more than over 50 tons yearly per head of the population, and not 67. This, then, over some such quantity—represents the sewage proper, and for all manurial calculations the adventitious addition of rainfall may be eliminated. A man becomes intoxicated in proportion to the amount of brandy that he has put into him, and not in proportion to the amount of water. But it is in vain to attempt to satisfy every "F. P." desires into a complicated question like sewage irrigation in the compass of a short paragraph. He must not suppose that he can start any new difficulty that has not been already faced, if not solved; and it is impossible for him to obtain answers to all the searching questions that he has asked, even should see he has the understanding hereafter to ask, through the medium of your columns. If he really desires to sift the whole question in all its bearings, let him begin by reading my friend Professor Corfield's "Digest of Facts relating to the Sewage Question" (London, Macmillan), and if he wants further information about my farm he will, as I said before, find it in the last report of the British Association, including analysis of the soil, sewage, and effluent water, which will be further supplemented by the forthcoming report of the committee. And, finally, after my return from the meeting of the Association, I shall be happy to meet him at the farm, and give him any additional information in my power. Meanwhile, I will ask him to accept as a fact my statement, that my farm is too small, even when supplemented by 50 or 60 acres of my neighbour's land, to extract the full value of the sewage. I base this as the result of my experience, and no further experience can affect this fact in any way. *W. Hope, Parsloes, July 23.*

The Future of the Mangel Wurzel Crop is full of interest. I have watched its growth for many years, nay, almost from its first introduction as a British root crop. It is yearly increasing in public favour, and much larger breadths are sown. It is fast becoming the most valuable of our root crops. The varieties cultivated have become established, and the Long Reds and Yellows and the Globe Reds and Yellows, the first for deep and loamy soils, the latter for thin and light soils. The qualities have been so greatly improved, that a bad or indifferent variety can scarcely be found, and we produce now grown in many districts is almost beyond belief. I have for many years been connected with a local agricultural society, which has for many years given a distinctive prize for the best 3 acres of Mangel Wurzel. It is astonishing to what extent our competitors will go in competing for this distinction, and what is more remarkable is, that the crops invariably amply repay the outlay; so that I have come to the conclusion that for the Mangel crop no reasonable amount of management and manurings can be thrown away—all will be compensated. The winner of our last year's "medal" produced 62 tons upon an acre, worth £46 "medal" the expenditure in management and manures amounting to near £20 per acre, so that notwithstanding the outlay he was well repaid. We have many competitors this year, eight (I think) having declared. These eight crops will, to all appearance, be very heavy ones, estimated to yield not less than 50 tons per acre. The manurings chiefly consists of Peruvian guano, superphosphate, blood manure, salt and fold-yard manure. The extent or quantity used is enormous, but which the growers do not readily inform us. In one instance 1 ton of Peruvian guano is said to be applied per acre; in another 1 ton per acre is used of Peruvian guano, superphosphate, and blood manure in equal proportions; and others in similar, but not such heavy dressings: all supplemented if required, according to the judgment of the grower, by salt sown between the rows. The fold-yard manurings, in addition, are in several cases very heavy. The great question, however, is—does it pay, and can such management be kept up? I fear not altogether, nor would I recommend cultivators of inferior soils to aim at such great results, although they may do much by ample artificial manurings. On useful loamy soils vast weights of these invaluable crops may be advantageously grown, and they might either be consumed upon the farms where grown, or they might open a new trade by growing them for exportation and sale to other districts, or the large towns. The fact is established, these crops can be produced. The best mode of their disposal is in the future. Landlords must permit their export. Tenants must lay out their money in buying aids to produce them. Railway companies must lower their rates of carriage for this heavy produce. In this way loamy soils of fair quality only will be made more useful and profitable than now. *O. F.*

Sewage Irrigation.—Referring to "J. M.'s" remarks, I am decidedly of opinion that nothing in the shape of storage is permissible (the word "possible" in his notice, I think, should have been "should be") tributed on the land as soon as possible. I have good reason to know this, from the fact that under the system of irrigation formerly carried out here the sewage was stored in tanks, and proved a great nuisance. Decomposition set in to a great extent, deteriorating greatly the fertilising properties of the sewage. I certainly recommend that land should be well irrigated before being sown, but I entirely fail to see how this necessitates storage, as "J. M." seems to think. Surely if there is a sufficient quantity of land for the proper application of the sewage, there can be no difficulty in doing as I recommend, and that without storage, but actually preventing anything in the shape of storage becoming necessary. With respect to the quantity of sewage per acre, it is impossible, in my opinion, to lay down a precise rule. The quantity per acre must be of the soil, the season, the crop growing or intended to be grown, and other circumstances of a like nature, combine to render this a matter for the exercise of judgment and experience, rather than of a rule of thumb. I hope at some future time to give the result of my experience as to the quantity of sewage required. I feel that this is a matter necessitating the experience of varying seasons before definitive conclusions can be arrived at. *T. G. Palmer, Town Surveyor, Rugby.*

Wireworm, Crosskill's Clod-crusher, Roller and Salt.—This implement will occasionally pay for its whole cost in a single year. Mine has a block of cast-iron (5 cwt.) on the back frame, which balances the shafts, takes the weight off the horse, and adds so much to the weight and efficiency of the roller. This spring I found the Wheat thrown out by frost, so, after the first horse-hoeing with *Garrett's* scarifier, I gave the Wheat a good Crosskilling on the heavy lands, thus giving the roots a firm foundation. When horse-hoeing a second time we were careful not to go too deep or too close to the rows. Our Wheats are inches high now to rows. On the light land subject to wireworm the Crosskill, aided by rain, ensures our crops, that would be otherwise injured or ruined. We had an especial instance of this in the spring, on a Wheat crop which followed white Turnips, fed on the land. We sowed 6 bushels of salt before ploughing; but notwithstanding this, the wireworm attacked it in spring, so we Crosskilled with cross-directions, and then sowed 8 bush. more salt per acre. This was a settler for the wireworm, which had already done much mischief. The land was consolidated, the plants branched, and now we have a fine plant indeed. It looks like a full crop acre—very healthy, although a poor sandy and silty land. Barley, too, was Crosskilled and salted, and is a capital crop after Wheat on the same sort of land. I am quite surprised to find how little farmers generally are aware of this ready cure for wireworm. In former times, in this neighbourhood, most severe losses were caused by wireworm. But see how useful Crosskill is in summer tillage; the great blocks of earth torn up by deep steam cultivation or subsoiling are at once crushed into powder or small square pieces, and a clean fallow can be made in a very short period of dry weather. I can be made in a very short period of dry weather. For old Crosskill makes an unfailing impression on the most obstinate clods, and grinds the earth away from the roots of weeds. Of course it is a dry weather tool on stiff clays. After Crosskilling, a moderate rain suffices to soften and pulverise the diminished clods. I have used salt here for 28 years, and it has done much work on many other farms. I am a firm believer in salt; I have used some 150 tons on this farm. I see that along our salt-water coast, and for some distance inland, the crops are healthy and fine. We know that in stormy weather salt from the sea-water travels a long way. I have been told that the windows of our Royal Agricultural College at Cirencester have been coated with salt after a severe gale, although I believe 30 miles from the sea. I always mix salt with the guano I sow, about weight for weight. Salted land should be drained. Liebig has explained to us how salt acts on the soil, more as a solvent than as, *per se*, a manure. *J. J. Mechi, Tiptree, July 21.*

Labourers' Cottages.—There is no doubt of the excellence of the plan for double cottages which you publish, and which Mr. Bailey Denton says that he has built in several parts of England, but I do not perceive from the plans as published in what particulars they are an improvement upon Messrs. Richardson & Ross's plan. I should be much obliged to Mr. Denton (and I think that others who are interested in the subject would be equally so) if he would point out the particular improvements upon the original plan; because, as this is perhaps the very best form of cottage for general use, it is of importance that it should be made as perfect as possible, and that every possible improvement should be carefully considered. In one respect I think that the elevations given in my book on cottages are better than the one given by Mr. Bailey Denton, in which he follows the original plan. There are objections to the double gable, because the level gutter between them is liable to get choked with snow or rubbish, and then to leak into the house. I think that some of the plans for roofing with a single roof are very decidedly better than the double gable. Whilst on the subject of cottages, I may mention that the plan No. 9 in the book lately issued on the Duchy of Lancaster Estate near Olney in Bedfordshire. Its cost is about a third less than that of such a pair as Mr. Denton's. Of course, it is not quite equal to this in point of accommodation, but I believe it to be by far the best plan of a rather cheap cottage which has yet been published; and I am no doubt that, in proportion to the cost, it gives more accommodation than any other plan. *C. W. Strickland, Hildenley, Malton, July 21.*

Small Farms.—Among the various schemes of land reform now put forward, the most intelligible and practicable is that which is based upon the supposed superior advantages of small farms over large ones. Now, for carrying out this scheme, it is not necessary that it should have secure general approval. If good on a large scale, it would be good on a small one, and assuming its proposers to be in earnest, I would recommend them to bring it to a practical proof. Instead of calling for Acts of Parliament, as the carter called on Hercules, let them set their own shoulders to the wheel, buy a farm, and divide it. For £20,000 500 acres of good land might be bought, and divided into 50 holdings of 10 acres each; an addition of £10 to the price of each holding will cover law expenses. And if there really be this great want felt by the English people for small farms, surely 50 persons may be found to purchase outright, or at least by instalments. The scheme would thus scarcely cost its promoters anything, and no theoretical argument which they can now use would be so convincing as the actual spectacle of 50 thriving and happy yeoman, forming, as the poet tell us, "their country's pride." *G. S.*

Societies.

BEDFORDSHIRE.

At the annual show on Thursday (last week), held on the day when we go to press, there were capital classes of horses, especially of agricultural horses—rather short classes of Shorthorns, and among the sheep a good class of Oxford Downs, Messrs. C. Howard, Treadwell, Harris, and Underwood, taking the prizes. At the dinner, held afterwards, in a tent on the ground—

The PRESIDENT (Mr. James Howard) said that in the course of his short life he had been called upon to occupy many public positions, but never had felt more complimented by election to office than when chosen president of this, one of the oldest agricultural societies in the kingdom. For many years he had taken a very lively interest in its prosperity, having heartily sympathised with its objects. It was founded for the purpose of raising the standard of farming throughout the county, for the encouragement of the agricultural labourer, and rewarding the meritorious. It was inaugurated at a time when there was very little public spirit or enterprise displayed in agricultural affairs. Much ignorance prevailed, and throughout the greater part of the county agriculture was carried on after a most primitive fashion, and the live stock was of the most wretched quality. How much of the great advance which had since taken place was owing to the operation of this Society he would not take upon himself to say, but that it had improved it considerably no reflecting mind could doubt. He was glad to know that the Society had better support now than at any former period, and when the benefits it was calculated to confer on the agriculture of the county were more fully known it would be supported in a corresponding ratio. Bedfordshire, from being one of the most backward counties in agriculture, had now become one of the most forward. (Mr. READ, M.P.: Hear, hear.) The member for South Norfolk said "hear, hear;" when he (Mr. Howard) was in the county of Norfolk, which had a world-wide reputation for agriculture, he came to the conclusion that we in Bedfordshire were, if not

superior to Norfolk, at least quite abreast of it. Still, we must not suppose that we have reached perfection. Far from it. Much of the soil of this country, by being deeper and better tilled, was susceptible of being made to raise a larger produce, and by the introduction of a larger amount of capital more meat could be produced. While there was such a scarcity of meat, and while we depended upon foreigners for one-third of our grain supplies, we could not look altogether with complacency on our agriculture. He believed there was not a practical farmer in that tent who would not agree with him that if all England were farmed like much of this country we should be a long way towards being independent of foreign supplies. There was one important obstacle, in his opinion, to the further progress of agriculture. He believed that until the tenantry of this country enjoyed a greater security of tenure the resources of the soil would never be fully developed. Fortunately, on the great estates of this county the relations between landlord and tenant were of a most amicable nature, but throughout the great extent of England a different state of things existed. He maintained that six months' notice to quit was altogether incompatible with high farming, and capital would never be attracted to the soil in the way it would be if the tenantry had a vested interest in the improvements they made. Dr. Liebig had long asserted, and Mr. Lawes had proved by experiment, that to exhaust the natural fertility of the soil was absolutely impossible. No amount of skilful farming could permanently reduce it, but all that could be taken out of it was "condition," a word the meaning of which was known to every man who knew anything of an animal, and this was a fact which every landlord in the kingdom would do well to ponder, and they ought not to hesitate for a moment in connecting liberal improvements with the tenantry. Mr. Harvey had alluded to the revolutionary doctrines which had recently been propagated on the land question. He (Mr. Howard) had no fear that the rights of property would be rudely interfered with if landlords did not stand in the way of progress. They knew that the feeling was very strong in favour of fixity of tenure, and now it was demonstrated that the worst of tenants could not permanently reduce the fertility of the soil, landowners would do well to consent to liberal covenants with their tenants.

Mr. MECHI, M.P., said there were two sides to many questions, and owning as he was in the House of Commons he thought he had heard it stated in pretty strong language, that the interests of landlords and of tenants were not always identical. He did not mean to say that they were always in antagonism, but wherever there were two interests there were always two views. There was, for instance, the question of leases, the reference to which had been so well received, and there was also the question of the Game-laws. Mr. Harvey had referred to local taxation, but he had heard men who were competent to reason that question out say that it depended on the rent, and that it was as broad as it was long.

Mr. C. S. READ, M.P., said, in answer to Mr. Magniac, that the question of local taxation was not a question between landlord and tenant. Both these were perfectly agreeing that that local taxation as at present levied was wrong, but the question was whether land and houses should pay the whole of the local taxation, and why all the other property of the country should go scot free. In foreign countries almost all industries, but especially agriculture, looked to the State for protection and assistance; in England there was a good saying that if we wanted to do a thing well we must do it ourselves, and his advice to the farmers was, never to go to the Government for anything they could have otherwise. As it was impossible for them as individuals to protect themselves, they therefore united in great agricultural societies, and foremost amongst these was the Royal Agricultural Society of England. Some time since, in the House of Commons, it was proposed that a department of the Board of Trade should take in hand the prevention of the adulteration of manures and feeding stuffs, but he ventured on that occasion to say that if the matter were left to the agricultural societies they could do better than any Government department, and he was glad that the Royal society had come forward and exposed the frauds to which the farmers had been subjected.

BRECON.

The Management and Treatment of Grass Land.—Some time ago Professor Wrightson read a capital paper on this subject before this Society. We here give the substance of it.

Professor WRIGHTSON said the subject would be considered under three or four sections, and the following headings appeared to him as allowing of an exhaustive treatment—1st, laying land down to grass; 2d, the improvement of already existing grass land, although it may not be in good condition; 3d, some hints on the general management of grass lands.

(1.) *The Laying of Land down to Grass.*—There was an immense difference between enjoying the possession or occupancy of old grass land and taking steps to exchange old going tillage land into a similar condition. The reason was obvious. It required time to give to old sward its characteristic verdure, vigour, and thickness of cover. The new laid was at once known to the practised eye by its sparse vegetation, want of elasticity under foot, and upstart appearance. The first question he had to answer was: "Why is this difficulty met with? How is it that land cannot be made to grow abundant grass crops as certainly as it grows corn and Clover?" He would ask them to call to mind the appearance of an old piece of grass land which had been just ploughed up. They might picture it situated in a clay arable land district, and when they made the comparison they would be at once struck with the marked difference between the newly broken up land and that which had for years been under the plough. If they looked at the land which had previously been pasture and which had been recently broken up, a peculiar black colour, an absence of stones, a friability and lightness of texture, and a large admixture of organic matter would be at once observed in contradistinction to the brick-like furrow, yellow or red hue, and stony character of the arable furrow. This black, friable, stoneless character of newly broken-up grass land was the result of the long-continued action of two or three simple forces. In the first place, there was the decay of successive generations of grass roots, which left organic matter in the soil, and which tended to render it friable. Then, in the second place, there were the untiring labours of the common earthworm, which, but for Mr. Darwin, would, perhaps, have remained unknown. The earthworm obtained its nourishment by passing earth through its body. After it had absorbed certain nutritive principles from the earth, it ejected what it had taken in the form of earth-casts. The consequence was a continual top-dressing of the land. Sometimes their grass land might take well for the first year or two, and then they, perhaps, languished, and it was then discovered they had not been aware of what was known as old permanent pasture land. This threw some light upon the difficulty of laying down arable land to pasture. Arable land, after it had been worked by the plough for many years, was apt to become very tenacious; and if grass seeds were sown upon it, they would inevitably tend to rather die than grow. Then, in the second place, there was another difficulty connected with newly-laid grass land, and that was with regard to sowing the proper seeds. It was found that various grasses were suited to various localities; and, therefore, if they went to a London seedsman and got a mixture of grass seeds, and sowed them upon their arable land about to be turned into pasture, they would probably find that there were many grasses which were not suited to the locality in which they had been sown. They might then get an improper mixture of grass seed, and if they did the young vigorous grasses would have to die out. But they might not only get an improper mixture, they might get seed of bad quality. He could not approve of that plan which had been sometimes recommended, viz., sowing the hay seeds of the neighbourhood. If they examined the Tables of the growth of grasses, in which the time of the ripening of various grasses in pastures was worked out, they would see that there was an immense difference in the time of ripening. Some grasses ripened as early as the beginning of May, while some were as late as August. How could they then expect to get hay seeds all cut at the same time of equal perfection? Some of them would be over-ripe, and some not ripened.

In the next place, with reference to the laying of land down to grass, he thought that they would agree with him that it was necessary that the land should be clean and in good condition. With regard to the tillising power, it must be clean. If it were laid down when it was full of Couch, they would find that these pernicious weeds would overpower the grasses. Then, as to the time of year at which it was best to sow the seeds. The beginning of the year was the usual time, say April 1 and 2 in some years. Many years ago he recommended that grass seeds should be sown in autumn. He was unable to give an opinion, but eminent seedsmen had held that August was a better time than the spring. Then there was a very important question which arose, viz., whether they should sow their grass seeds with a crop or without a crop. He had come to the conclusion that the plan of sowing grass seeds with a crop was the one which would be most wisely and generally followed. He thought this was the best plan on the score of economy. If they sowed land without a crop, they would have to go to great expense, and if it were done by a tenant he should be assisted by the landlord. But whether the landlord or the tenant undertook the work, he thought it was important that there should be a crop. The crop, he thought, would act as a shelter to the seed, and any exhaustion from the crop might be replaced by a dressing of manure. He thought that, theoretically, laying down without a crop was the best, but the laying down with a crop was the most likely to reimburse the sower.

Now, with reference to the best methods of sowing grass seeds. He should assume, then, that they were sown in the month of April, and either upon Wheat or Barley. One point which they ought to remember was, the delicate nature of the seeds with which they had to do. Mr. Stirling, in experiments he made, had taken great pains to ascertain the depth at which these seeds would germinate. The experiments were made upon a fine mould, which was kept moist. It was found that the large majority of grass seeds germinated at a depth of one-quarter to half an inch; only half the seeds germinated when the depth was half an inch to an inch and one and a half inch; and if they examined the Tables giving the results of these experiments they would find that few, if any, of the seeds germinated when they were buried at a greater depth. When, therefore, they were sowing grass seeds it was necessary that they should see that the surface of the land was smooth and in good condition. He would suggest that the use of the Cambridge roller would be the best previous treatment in preparation for the sowing. Then they should sow with the broadcast barrow, and bush or chain harrow. If this course were taken the surface of the soil was rendered fine, and the grass seeds were not buried at too great a depth. He should take it that a good mixture was sown.

In the next place they had to think of the after treatment of the young grass seeds when the crop had been removed from the land. This subject was one which demanded a great deal of attention. He thought it would be advisable, especially in the case of land intended for permanent pasture, that they should not stock the young seeds after the corn crop had been removed. They knew it had been much disputed whether Clover or Grass should be stocked in the autumn; but without entering upon this question, he thought with regard to pastures that they would be wise to keep stock off them for the first winter. It would be advisable to keep sheep out of the pastures for the first year, and he would suggest that the grass should be mown rather than fed for the first season. He recommended that cattle should be kept off the young pastures, because it was important that the land should not be trodden down by the passage of animals upon it, and it was important that the grass should not be eaten, especially by sheep. The horned cattle were more advisable for the laid down land than sheep, because the latter would bite closer, and therefore, were more liable to destroy the young grass. After the third or fourth year they might be more careless as to the kind of stock which they placed in the field. He had given a reason as to this theory was found in an article which was contributed by Mr. H. T. Thompson to the Agricultural Society some years ago. In laying down some land to pasture Mr. Thompson had been of opinion that sheep with the "coddling" of the best animals tended to bring a young pasture into condition. The sheep were allowed to feed over the land with a liberal allowance of oilcake. This was carried on for two years, and then it was found that the land had deteriorated in quality, and Mr. Thompson came to the conclusion that sheep should be kept out of the land, and the land be mown for the first and second years and manured to compensate for the loss. The reason of this was to allow for the development of leaf, stem, and roots, and to prevent the consolidation of the ground by the trampling of stock.

(2.) *The Improvement of Land which was already in a state of Permanent Pasture.*—Upon the point whether grass land should be broken up the landlord and tenant might have different opinions. The tenant having only a tenancy-at-will of the land might like to break up even his first-rate grass land, because he might think it would benefit him, but the landlord, looking further ahead, might be sorry to see such land broken up. But with reference to inferior grass land a good deal had been said about the propriety of breaking it up. As regarded inferior pasture, they knew that Tables could be constructed to show that it would yield much greater produce if it were arable. But increased produce was not the only thing they had to consider. He had no hesitation in saying that if the greater portion of clay land pastures of a poor kind had the capital expended upon them which would be expended in breaking them up, and applied in the form of manure they would be brought into a more remunerative condition than if they were broken up in arable land. With reference to the improvement of land which was in good heart a good deal had been written, and, considering the importance of the subject, a great deal more might be written. At the same time, in examining the essays upon this subject, he could not but be struck with the fact that there was very little to be said about it. Mr. Cadle contributed a very able essay to the Journal of the Royal Agricultural Society upon the treatment of grass land. The simple expedients set forth in this essay were draining and liberal management. This was his opinion, and he hoped they would bear him out. It appeared to him that the apparent failure of draining on grass land was simply due to the dying out of injurious grass. Drainage must, however, be supplemented by liberal treatment. The lecturer recommended a dressing of farmyard manure if it could be obtained. If this could not be obtained, guano or superphosphate would be a good substitute. He then referred to the result of the treatment of Mr. Ruck (Braydon Manor Farm). He had visited Mr. Ruck's farm, and could say that this treatment of the pasture lands had rendered them very much more valuable. The land on this farm was mole-drained, and not tile-drained. The land lay upon Oxford clay, and the mole-drain was used by means of Fowler's 12-horse engine, the whole process costing £1 per acre. That was cheap. Mr. Ruck then manured with Peruvian guano and superphosphate

and lime. These dressings were applied in the years '62, '63, '64, and '65, to which was added a very valuable compost by deepening the ditches, &c. The consequence of this was a very great improvement in the grass land. It was rather difficult for him to point out the exact improvements, but he might mention that in 1864 the land was considered to be worth 30s. per acre, whereas the land was bought in 1862, 300 acres for £4000, or about £14 fee simple per acre. It appeared upon comparing the experience of many men with regard to the improvement of grass land that the idea that draining was prejudicial to grass land must be dismissed from their minds. Draining might be followed by a certain diminution in the grass, but if supplemented by manure they would find that it would be an improvement.

(3.) *The General Management and Manuring of Grass Land.*—One of the first points in connection with this part of his subject was the collection of the droppings of cattle. Sheep distributed their manure very equally over the land, but cattle frequently dropped their dung in one place, and thus the dung was wasted. More than this, it had a prejudicial effect; for the next year in those spots were the manure had been dropped there would be hassocks of coarse grass which nothing could touch. He thought, therefore, that they ought to collect the manure of cattle, make it into a compost, and then proceed to distribute it equally over the land. The next point was one of some importance, viz., the even eating of grass land. They should not allow the grass in any part of a field to run to seed. There was nothing which exhausted the land so much as to allow grass to run to seed or to get too ripe. The grass should be eaten evenly, and if the cattle would not eat it evenly it should be cut.

Then there was another point which was of some importance, viz., that once a-year, at midsummer, the grass ought to be eaten down bare. They ought not to stock land too early in the spring, if they did, they would find that the prospects of the whole season were injured. Stock ought to be changed from a worse to a better pasture; and in buying stock, it was necessary that they should consider the pasture which they came from. As to manuring, farmyard manure, when it could be obtained in sufficient quantity, would be, perhaps, the best for improving permanent pasture, but there would probably be difficulty in getting a sufficient quantity. The lecturer then referred to the experiments which Mr. Lawes had made at Rothamsted. There certain plots of land had been portioned out for the growth of grasses under different treatments. These experiments had been carried on for a long series of years, and proved that under certain treatment the germenacious or true grasses preponderated greatly, that under different treatment the leguminous (which included Clover) grasses were produced in greater quantity, thus demonstrating that certain manures had the power of developing certain species of grass. After expressing an opinion in favour of the use of farmyard manure if it could be obtained in sufficient quantity, he referred to the use of bone manure as a means of improving grass land, observing that a few years ago a good deal of excitement was caused by the wonderful effect of bone manures upon the grass land in Cheshire and in other parts of England. They had a great effect, but they would not find that the application of bone manures, or superphosphates, was invariably attended with great improvement. The lecturer concluded his address by observing, that he hoped to hear the opinions of the practical agriculturists present upon the subject he had been speaking of.

Discussion.

From the discussion which followed the reading of the above paper, we make the following brief extracts:—

Mr. Mordecai Jones agreed with what the lecturer had said about Clover. He took a farm at Aberdare about nine years ago. Everything had been allowed to go to ruin. He tried superphosphate, and soon the land appeared all white. He was asked what he had been doing. Had he been sowing lime? "No," he replied; and he showed to his querist the beautiful white Dutch which had come up.

Mr. Overton said he could vouch for the astonishing benefit which had been conferred on the land referred to by Mr. Jones by the use of superphosphate. The land was almost in a most bleak position, but good crops of hay had been raised on it. Mr. Overton related also a case in which he had used superphosphate unsuccessfully, but said, perhaps his failure was the result of misapplication. He thought they should be cautious as to the time when they applied manure. If applied about the month of April they would be likely to get the showers which would serve to dilute and convey the beneficial qualities of the manure into the land. He must say that he felt a good deal of interest in the subject, because he agreed with the able observations of the gentlemen who had moved the vote of thanks, that the time had come when they must direct their attention to the raising of beef and mutton. The price of corn was so low that it was impossible for the farmer to grow it to advantage. In that neighbourhood they had a wonderfully good market for their meat, and the present prices were highly remunerative. They had a large mining district surrounding them, and it was important that agriculturists should turn their attention more to the growth of beef and mutton than to cereal crops.

Notices of Books.

Vere Foster's Drawing Copy Books. Marcus & Co., 67 and 68, Chandos Street, Covent Garden.

We are possibly indebted to the article on the contrast between the ideal and the real in the common portrayal of prize animals, on p. 883, for the specimen which has been sent us by the publishers of one of their series of copy-books, in which natural objects, trees, animals, architecture, man, are presented as the copies by means of which facility in the use of pen and pencil is to be obtained. The figures of cattle given as copies in the example before us, numbered 08 of Mr. Foster's series, seem to us exaggerated in an artistic sense rather than natural. The West Highlander is fairly drawn; the Ayrshire and Shorthorn, of the same size, and giving the outlines of gaunt old cows, are unsatisfactory. Neither the Devon nor Hereford, though they are better, are exactly what one wants; and the Kerry exhibits the fault of being presented as of the same size as the others. Certainly the specimens do not exhibit the fault to which our article called attention, as characteristic of the drawings of prize animals—they do not exhibit pampered monsters, of sleek and rounded symmetry.

Farm Memoranda.

A South American Poultry Farm.—I propose to describe a poultry farm, where fowls are kept by the thousand, whose proprietor counts his gains therefrom proportionately. It is situated in the southern extremity of Chili, South America, where the rainy season, of six months' duration, is as detrimental to the well-being of all fowl kind as the rigours of our own winters, and where great care and skill is very essential to satisfactory results.

Senor Don San Fuentes commenced his operations in poultry with a stock of 200 hens and eight cocks, to which he has added thereto, by natural increase from year to year, until now he has somewhere in the vicinity of 6000. Their range is unlimited, as his farm covers 3000 cuadras, equal to 7500 acres. To every 50 hens are allotted a house, each house of their own, of which there are 600 or 700 on the place. These are placed 200 feet apart, each way, thus isolating one lot from the other.

These houses are very cheap affairs, and are made by erecting two forked posts, 8 feet long and distant from each other 4 feet. On these the ridge-pole. On both sides of the centre post, 10 feet distant, a trench is dug, a foot in depth. Then small poles are placed for rafters, one end in the trench and the other tied to the ridge-pole, 2 feet apart, then another set of poles tied crossways, also 2 feet equidistant, and the framework is complete. This is then covered with thatch, which is found in plentiful abundance, and to be had for the cutting. The only framework about the house are the doors at the ends, both of which are 4 by 6, and contain each a window, pivoted in the centre of the sash, to be opened at will as the requirements of ventilation demand. Each house has its complement of 20 boxes for laying placed under the eaves, and partly concealed by bundles of straw.

Near the family residence is a large building, devoted to the storing of grain and eggs; nursery for the hens, a long room for hatching, and another for slaughtering purposes. In the sick room is arranged a series of boxes, each one large enough for the comfort and convenience of its solitary occupant, who is there placed, and treated for its malady with as much care as if its value was dollars instead of cents, and with such skill, that the ratio of deaths has been 1 in 280.

The sitting department is also provided with boxes, some 300 in number. Here all are brought from their respective coops as soon as their incubating propensity shows itself, and placed upon their quota of eggs. Food, water, and a supply of sand and ashes, are provided, and the sitting hen not allowed to leave the room until she takes her young brood with her.

The chickens are then "doubled up," that is, two broods to one hen, and the chickenless one sent back to her coop to resume her egg-laying. As soon as the young chicks are discarded by their mother they are taken to their future home, fifty in each lot, and the old ones back to their respective localities.

The fowls are fed three times per day, and their diet so arranged as to always present a variety, although Oats is their staple article of food, and always before them in unlimited quantity. To-day it will be Indian meal, made into a stiff dough, and given hot; to-morrow, Barley; next day, boiled Potatos mashed and mixed with pork scraps and bran, corn broken in a coarse mill, and so on in rotation; adding from time to time horse-flesh, or some other cheap and inexpensive animal food. Burned bones, pounded shells, and lime are supplied in profusion. These, with what they gather on their foraging expeditions, produce a wonderful supply of eggs.

During the rainy season they are not allowed to leave the coop, except the day be exceedingly pleasant, and then only for a short time. They appear to bear their confinement remarkably well, and with hardly any decrease in the quantity of eggs. While confined they are allowed an extra allowance of animal food.

The attendants requisite to the care of these 6000 fowls are one man and four boys. The houses are thoroughly cleaned once a week, and the interiors whitewashed every three months. Every morning each lot of fowls undergoes a careful inspection, and any one found moping or otherwise indisposed is immediately taken to the hospital, and cared for; and seldom is it but what the indisposition is cured, and she takes her place back again as well as ever. At evening the boys go the rounds to gather up the proceeds of the day's labours, which will average 200 dozen per day, the year through.

"Killing time" takes place twice during the year—in the spring, and again at the commencement of the rainy season. All the early chickens are thus disposed of at a good price, and the 2-year-old fowls decapitated to give room for the younger broods, as they are supposed to be past profitable service after the second year.

The profits from one year's business amounted to 11,000 dollars. The sales were 72,000 dozen of eggs, and nearly 20,000 chickens and 2-year-olds. Mr. San Fuentes expresses himself as being perfectly satisfied with the result obtained, and intends to double his stock each year, until every 200 feet of his extensive farm has its house of 50 tenants. *G. F. Pearce, of Freetown, Mass., in the "People's Practical Poultry Book," recently published by D. D. T. Moore, New York.*

Obituary.

We sincerely regret to announce the death of Sir Thomas Dyke Acland, Bart, one of the original members of the Royal Agricultural Society of England, whose bright eye and hearty manner we recollect so well at the first meeting of the Society at Oxford, where he was speaker at the banquet in one of the College squares.

Sir Thomas Acland had considerably passed his 80th year, having been born on March 29, 1787. He was the eldest son of the late Sir Thomas Dyke Acland, 9th baronet, by Lucy Caroline, Anne, only daughter of Sir Richard Hoare, of Stonehead, Wilts, and sister of Sir Richard Colt Hoare, the celebrated Wiltshire antiquary. Her husband dying in 1794, her son, the subject of these remarks, succeeded to the title and family estates when still quite a child; and the mother married, as her second husband, the Hon. Matthew Fortescue, Captain R.N., brother of Hugh, Earl Fortescue, and died in 1841. At an early age young Acland was sent to Harrow, where he was three years junior to Lord Palmerston and Lord Ripon, and about a year senior to the late Sir Robert Peel, to whom through life he was personally attached. From Harrow he proceeded to Christ Church, Oxford, where he took his Bachelor's degree in 1808, and proceeded M.A. in 1814. In 1812 he had entered Parliament in the Tory interest as one of the members for Devon, and being again returned at the general elections of 1820, 1826, and 1830, he managed to divide the representation of that important county with his Liberal antagonist, but personal friend and connection, Lord Ebrington (afterwards Earl Fortescue), whose career in the House of Commons ran very much parallel to his own, until the first Reform Parliament in 1831. He was re-chosen after the dissolution of July, 1837, as member for North Devon, Lord Ebrington being his colleague, as he had been before the county was divided by the first Reform Bill; and he continued to enjoy his seat without interruption down to the year 1857, when he retired from public life. After that time he lived quietly at his country seat of Killerton, near Exeter, occupying himself with agricultural improvements and the duties of a resident magistrate and gentleman. Sir Thomas was created an honorary D.C.L. of Oxford, in 1831, and was for many years a deputy-lieutenant for Devonshire. He also enjoyed the patronage of several livings. By his late wife, Lydia Elizabeth, daughter of the late Mr. Henry Hoare, of Mitchamgrove, Surrey, he had a large family—two daughters and seven sons; and he is succeeded in his title and estates by his eldest son, Mr. Thomas Dyke Acland, M.P. for North Devon, and formerly for West Somersetshire, who now becomes 11th baronet. He was born in 1809, and was formerly Fellow of All Souls' College, Oxford, having taken his degree at Christ Church as a "Double First" class. He has been twice married: firstly, in 1841, to Mary, daughter of the late Sir Charles Mordaunt, of Walton, county Warwick, who died in 1851; and secondly, in 1856, to Mary, daughter of Mr. John Erskine. The family of Acland, according to Sir Bernard Burke, is of great antiquity in Devonshire, tracing its pedigree through 23 generations of unbroken descent, from Hugh de Aclen or de Accalen, who held lands at Accalen, in the parish of Landkey, Devon, as early as the middle of the 12th century. John Acland, his descendant, maintained the Royal cause in Devon with great zeal and ability, and, according to Lord Clarendon, his force was at one time the only one left to the unfortunate Charles throughout the county of Devon. He was created a baronet in 1644-45; but, the original patent having been lost in the Civil Wars, he obtained in 1677 a re-grant of his title, with a special clause

granting him precedence from the former date. From him the baronet just deceased was sixth in direct descent.

Miscellaneous.

NUTRITION OF THE RUMINANTS.—I must now say a few words respecting the manner in which this highly distinctive ruminating function is accomplished. An ox grazes with its head swinging, as it were, easily, and crops the grass with each motion; the sheep grazing in the same way. The head of an ox is supported in this swinging action by a large ligament attached to the vertebral processes, and also to the occiput, enabling the animal to move its head without the slightest strain or effort. Not having any incisor teeth in the upper jaw, nor any canines, their place is supplied by a very firm, callous pad. You would think it inconvenient, perhaps, to have to crop the grass without any upper teeth; but their place being thus supplied by a hard pad, and the incisor teeth being at the same time arranged in a continuous and even series, whilst the canines are also pushed forward in such a way as to increase the breadth of that cutting surface, the act of grazing is thus carried on with the utmost ease and the least possible expenditure of muscular energy. The grass, therefore, is not bitten off, as it would be by other animals, rodents for instance, but it is simply pressed against the pad, and, the weight of the head being carried forward, the grass is merely nipped off, so to speak. This food, being thus received into the mouth in the raw condition, is rapidly carried down, in the form of pellets or boluses, until it arrives at the lower part of the œsophagus. When it has arrived there, it next passes into the great paunch or macerating tub, where it remains for a considerable time. It is acted upon by the secretions from the interior lining of this large cavity, and after it has become pretty well distended, the animal drinks, part of the water passing into the second stomach or cavity. The remainder enters this great macerating tub, and by-and-by, when the animal is resting, and generally lying down, successive portions of this raw material are transferred to the reticulum or water bag; and there, being rendered more moist, these are returned, partly by what we call a reversed peristaltic action, carried upwards along the gullet until they again arrive at the mouth. Here they undergo the process of remastication. This is technically termed, as you know, chewing the cud. Now, animals do not all chew the cud exactly after the same fashion; some generally manage moving the jaw from right to left, or from left to right, and that goes on continuously for a time, perhaps for the whole day. Whichever way the motion is originally transmitted, it remains for a considerable time in that direction. But some of the animals, instead of chewing the cud in this continuous way, alternate the action of the jaws, making a single movement first in one direction and then in another. This method occurs in the camel tribe. When the bolus has been remasticated, and is nicely soft, it goes down again; but this time, instead of going into the stomach, where it is an excito-motary agent, so to speak (acting like an intelligent person), placed at the common opening of the stomachs, to direct it where it should go, and instead of passing into the first or second stomach, it takes a turn in the other direction, and is transferred to the third stomach. How is it to perform this feat? There is a most beautiful mechanism expressly constructed for that purpose; yet not arbitrarily formed, but differentiated or evolved by a process of development. There is, in short, a little canal, which is half closed and half open; and this so-called canal, instructed, as it were, by certain reflex sensations, acts in such a manner as to ensure the passage of the bolus into the third stomach. In other words, it closes the lips of the orifices leading into the first and second stomachs. That is, I repeat, a most beautiful illustration of adaptation to a useful purpose. When the bolus has gained access to the third cavity, it is further acted upon by certain juices there secreted, and eventually passes into the fourth stomach, where, by the secretion of the ordinary gastric juice (and by the aid of other remarkable arrangements, that which we cannot now enter) it is finally reduced to such a condition as to be allowed to pass into the alimentary canal. Here the food is assimilated, being taken up by the lacteals, whence it passes to nourish the animal; and eventually, it may be added, to nourish ourselves. However, in this legitimate desire on our part to nourish ourselves at the expense of the ox we have formidable competitors, in the shape of those little animals called entozoa, which are also on the look-out to get hold of the nourishment that we think we alone ought to have. In concluding this portion of my subject, let me remark that there are many other structural features of great importance; but I do not propose to trouble you at further length with such details as belong rather to zoology or comparative anatomy than to the special object proposed in the delivery of these lectures. I may, perhaps, on a future occasion, have to point out one or two peculiarities in connection with the camels; but, in the meantime, I will only ask you to bear in mind the enormous length of the alimentary canal in the ruminants. It is twelve times the length of the animal itself in the camel and in the deer tribe; it is 22 times the length of the ox, and 28 times the length of the sheep, and about 130 feet long in the giraffe. Having dissected three of these animals, I can speak with some confidence as to their remarkable anatomical peculiarities. *Dr. Spencer Cobbold's first lecture before the Society of Arts on the Bovine Ruminants, especially in relation to the Operations of Parasites.*

The Week's Work.

JULY 29.—*Odd Jobs* bring up. To these reference was made at the commencement of hay harvest (June 17), we now bring up some working details.

Winter Beans, in our southern provinces, are generally harvested this month. In Scotland and the north of England the crop is, for the most part, spring-sown, and, therefore, later, harvest seldom taking place before September and October. The crop is sometimes pulled, but more commonly cut low with the scythe or hagging-hook, and either left in small parcels, or in the swathe, until fit for being bound up into sheaves. Beans stand wet weather better before cut than after, and therefore, in prospect of a rain, the crop should be allowed to stand until the weather breaks up, as it will be sooner in the stack-yard the one way than the other. Some allow late beans to stand till fit for stacking, so that when cut or pulled, it is carried immediately and thatched; others tie up and stack the newly cut crop. But for July harvesting, under a southern sun, neither of those plans answer unless in exceptional seasons, for if allowed to stand on its foot in roasting weather, the haulm, which makes excellent fodder, will be wasted, and if tied up into sheaves green, the outsides will be burnt to snuff before the inside is fit for the stack. The more common plan is, therefore, to leave the sheaves open and spread out, turn to prevent scorching, and then bind up when ready for carrying. At the same time, in most cases, however, something may be learned from the northern practice.

Ashes for mixing with artificial manures should be in store before corn harvest. If the work has not already been finished, no time should be lost in getting the requisite supply into store. Now that artificial manures are used for growing stubble Turnips, and for almost all crops afterwards to next harvest, it follows that a suitable supply of ashes should be in store before corn harvest commences. When old pastures have been pared and burned, ashes may be obtained from this source, otherwise the roadsides, cleanings of rivers and ditches, and the accumulation of vegetable mould or headlands must suit the supply to the demand.

Artificial Warping, where there is a command of water, and, of course, warping materials, may be more profitably done at this season than at any other in many instances. Thus meadow hay and Rye-grass stubble, poor pastures, Bean, Pea, and Vetch stubble, poor sandy and gravelly land, or fenny land about to be laid down to permanent pasture, or about to be broken up from pasture to arable husbandry, may have any desired depth of clay or other warping material spread evenly over them by means of water. In most if not all these examples the water required is not such as to warp will sink into the soil, thus leaving the warp on the surface, which mixed with the bottom, by means of the plough, will form a new soil. Practically apply the warp no faster than the soil drinks in the water to the drainage, whether the drainage is natural or artificial. Gravelly, sandy, peaty, or wasted ground, like the warp, as soon as dry, may be chain-harrowed in, and renovating grasses sown to suit the change of soil; artificial manure being applied as the case may require. Warp applied to the stubbles of corn, pulse, and forage crops will produce equally favourable results. And in all these cases the land must be observed as the water which conveys the warp supplies at this season food directly to plants which it does not do in the winter time, and that this peculiar difference turns the balance in favour of warping at this season.

Sewage Farms yield, during July, from 10 to 12 tons of Italian Rye-grass per acre, *i.e.*, 31 acre field yields 12 tons daily for live stock. Mangels, Cabbages, &c., grow equally fast—results which cannot fail, sooner or later, of convincing farmers of their practical value; and more than this, for the present month is a favourable one for laying down land, the moment hay and corn crops are removed, for irrigation, either with town sewage or doctored river water.

Sundries.—Collect materials for the drainage of land immediately after harvest; also for new roads, rendered necessary by the straightening of fences and the enlargement of fields for steam culture. Carting can be done much better now than in the winter time. Examine the homesteads and labourers' cottages, and see that roofs, walls, doors, windows, stable fittings, cattle-stalls, boxes, tillage and barn implements, &c., are as they should be. July is a favourable time for cleaning out the mill-dam and watercourses when the threshing-machine is driven by water.

Live Stock, including all kinds, require special attention this month, health being more or less affected by changes of temperature, bad smells, improper food and drink, and so on. The patience of the dairymaid is sorely tasked at times, and the cause of the bad cream, butter, and cheese—due to the exposure of the milch cows to the stinging sums, gad-flies, rank meat, and dirty water—is often very unfairly laid to her milking-pail and dairy utensils. And when the cows are brought home during mid-day, badly ventilated cow-houses are just as injurious to the milk as badly ventilated milk-rooms. Heat from the roof intercepts through current, and down draughts, proceed by the unequal heat of the sun on the opposite sides of the building, are easily obviated; and spreading dry earth over the litter and droppings will neutralise bad smells—on the principle of Moule's earth closet. Give newly weaned calves and lambs the best pastures, and see that they have plenty of shade from the sun and pure water to drink.

Scab, Lice and Ticks in sheep indicate a filthy state of the wool and skin; washing, therefore, so as to clean the wool and skin, is a rule as applicable to the flock as to the shepherd and his family. Put the sheep through Gwynne's washing cage, as they do in Australia, both before and after clipping; *i.e.*, frequent ablutions are necessary to keep sheep clean at this season.

The Fly is due to the same attractive cause—an unhealthy state of the skin, and may be obviated far more successfully by washing than by all the poisonous nostrums now in use. *W. B.*

Notices to Correspondents.

PIGS WITH WORMS: *A 21 Years' Reader.* It is unusual for pigs to suffer much inconvenience from intestinal worms. The parasites which infest the bronchial tubes are very injurious, and it is not unlikely that your pigs have them. Send some specimens of the worms in a little whiskey to Prof. G. T. Brown, 3, Princes Street, Westminster, and meanwhile give the animals five to ten grains of powdered Areca-nut every other day, in the food.

TURNIP SEED: *T. F.* We regret very much the delay of a week in answering your letter. We should not think it safe for the purity of the seed that Swedish Turnips, Kohl Rabi, and Rape be grown and seeded in the same field.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, July 24.

The supply of Beasts is shorter than last week, and we have a brisk demand, consequently prices have advanced on all descriptions. The number of Sheep is nearly the same as last week, but very small for the time of year; they are all readily disposed of at higher rates. Choice Lambs and Calves are rather scarce. Our foreign supply consists of 1630 Beasts, 10,900 Sheep, 437 Calves, and 75 Pigs; from Scotland there are 25 Beasts; from Ireland, 150; from Holland and Suffolk, 280; and 1045 from the Midland and Home Counties.

Beasts, 3130;			Pigs	3	4—5 0
			Sheep and Lambs, 14,325; Calves, 466; Pigs, 190.		

THURSDAY, July 27.

We have a considerable increase in the supply of English Beasts, the number of foreign is rather less than last week. Trade on the average is not so good, and a clearance is scarcely effected. The number of Sheep is larger than on Thursday, the excess being mainly in foreign; trade throughout was not so active as on Monday, and lower prices were submitted to towards the close of the market. Lambs and Calves are selling about the same as on Monday. Our foreign supply consists of 370 Beasts, 6500 Sheep, 666 Calves, and no Pigs.

ENGLISH WOOL.

English Wool still continues its upward course. The advance is not very rapid, but each week some small improvement is established, and apparently this is likely to be the case for some time, as everything points to a permanently higher range of prices than we have known for the last five or six years.

HAY.—Per Load of 36 Trusses.

JOSHUA BAKER.

MARK LANE.

MONDAY, July 24.

There were very few samples of English Wheat at this morning's market, and they were disposed of at the prices of this day week. The attendance was good, and there was a moderate demand for foreign Wheat at about last week's rates, excepting for Russian, which was fully 1*s.* per qr. cheaper. Barley, Beans, and Peas were unchanged in value. For Oats there was a fair inquiry, at a decline of 6*d.* per qr. upon the prices of last Monday. Flour was unaltered.

WEDNESDAY, July 26.

The anticipation of a wet harvest imparted a firmer tone to the Corn Exchange to-day, previous rates being more easily realised. There were limited supplies of English Wheat on sale, but from abroad a large quantity was sent forward; trade was not active, but prices were maintained. Barley, the supplies of which were moderate, experienced a quiet sale, at recent values. Malt was dull, but not quotably lower. The supplies of Oats were liberal, the demand was rather more active, and prices were supported. Beans and Peas were in slow request, at previous currencies. Flour was quiet, except American barrels, which being in demand for the Continent, were slightly firmer.

ARRIVALS OF GRAIN, &C., INTO LONDON BY WATER CARRIAGE.

	43,510	9720	42,260	

LIVERPOOL, July 25.—There was a more numerous attendance than usual, a good many millers appearing from the interior counties, and a healthy demand was experienced for Wheat, the decline noted on Friday being nearly recovered, and prices standing about the same as on Tuesday last. Flour did not move freely, but maintained the rates of this day week. Beans, with an increased quantity offering, declined 2*s*. per qr. for Egyptian. Peas unchanged. Oats and Oatmeal barely sustained late rates. For American Indian Corn there was a good sale, at an improvement of 3*d*. per qr. on the week.

AVERAGES.

SEED MARKET.

The last few days has been less favourable for the maturing and harvesting of seeds, which has had a hardening effect upon prices. We have had a considerable quantity of new Trifolium incarnatum on offer, which has lowered prices 4*s*. to 5*s*. per cwt.; also a few samples of fine new Rape, which sells readily at about 20*s*. per qr. less than the old realised. Red and white Clover, hardly any in offer, and with Trefoil held for a further advance of 2*s*. to 3*s*. per cwt. Canary, 2*s*. per qr. dearer. Hemp unchanged. In other articles no alteration.

JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

HOPS.

BOROUGH MARKET, July 26.

Messrs. Pattenden & Smith report a firm and steady trade for Hops of all descriptions. Choice samples are scarce, and command higher prices. The plantation accounts are of a very unsatisfactory character; vermin follow up the young shoots, which are very weakly from the exhausted state of the plant.

COALS.—June 26.

West Hartley, 18*s*.; Walls End Thrislington, 16*s*. 9*d*.; Walls End Hetton, 18*s*. 6*d*.; Walls End Hetton Lyons, 16*s*. 3*d*.; Walls End Heugh Hall, 17*s*. 3*d*.; Walls End Original Hartlepool, 18*s*. 6*d*.; Walls End South Kelloe, 17*s*. 3*d*.—Ships at market, 17; sold, 13; unsold, 4; at sea, 15.

THE BOILER PROBLEM SOLVED.

April 14, 1871. **MANLEY HALL,** MANCHESTER.

GENTLEMEN,—In reply to your letter, I have pleasure in stating that the works executed by your Firm, extending over the last nine years, have proved in all respects satisfactory. During the late severe winter the Boilers have acted efficiently and to my entire satisfaction.

I am, Gentlemen, yours faithfully, SAM MENDEL.

April 12, 1871. **ZOOLOGICAL SOCIETY'S GARDENS,** REGENT'S PARK, LONDON, N.W.

GENTLEMEN,—I have much pleasure in adding my testimony in favour of Weeks's Patent Duplex Boiler. It does its work well and satisfactorily, being both economical in fuel and labour, and, in my opinion, cannot be surpassed in heating power, the late severe season having fully tested its capabilities. I may add that the amount of 4-inch piping heated by this one boiler is about 4600 feet.

WM. PASFIELD, Clerk of Works.

April 4, 1871. **GOODWOOD,** CHICHESTER, SUSSEX.

GENTLEMEN,—My opinion of your Upright Tubular Boiler remains unaltered, as I have never seen anything to equal it during my experience in gardening. Our new works have given the greatest satisfaction.

I remain, Gentlemen, faithfully yours, GEO. CAMERON,
Gardener to His Grace the Duke of Richmond.

April 6, 1871. **CASTLE GARDENS,** CARDIFF.

GENTLEMEN,—I have much pleasure in stating that the Upright Tubular Boiler and Heating Apparatus supplied by you here has in every respect perfectly answered my expectations. Respectfully yours,

EDWARD N. COX, Gardener to the Marquis of Bute.

May 9, 1871. **KITCHEN GARDENS,** BURGHLEY.

The Upright Tubular Boilers set here two years back continue to meet my entire approval. One Boiler is doing the work which usually took *ten*. I have worked these Boilers *sixteen years* in many parts of England, always finding them there when wanted. I may add, if honours and medals were given to Hot-Water Apparatus manufacturers, John Weeks's breast would be covered with distinction. E. GILBERT,

Head Gardener to the Most Noble the Marquis Exeter, of Burghley.

April 12, 1871. **THE GARDENS,** WILTON HOUSE.

GENTLEMEN,—It is now ten years since your Upright Tubular Boiler was fixed here, and it gives me great pleasure to be able to say that during that time it has not cost a farthing in alterations or repairs. We have 5000 feet of piping attached to it, which heats 15 early forcing-houses and plant stoves. I find no difficulty in burning any kind of fuel in it, having used nothing but small cinders for some weeks past, with an occasional lump of coke when the weather is severe. During my experience I have proved nearly every kind of boiler, and can with confidence assert that yours is the most powerful and economical, and requires less attention, than any I have tried.

I am, Gentlemen, yours respectfully, THOMAS CHALLIS,
Gardener to the Earl of Pembroke.

April 10, 1871. **THE GARDENS,** SEVERN STOKE.

GENTLEMEN,—In reply to your note, I am glad to say that the whole apparatus is in perfect working order, and gives every satisfaction. I have, during the last 10 years, worked a variety of boilers, but for power and economy I have not found one to equal your Upright Tubular; and to surpass it, I am convinced, is an utter impossibility. Therefore, I have much pleasure in adding my testimony to its very superior merit.

I am, truly yours, H. ROWBREE,
Gardener to the Right Hon. the Earl of Coventry.

April 14, 1871. **THE GRANGE,** ALRESFORD, HANTS.

GENTLEMEN,—I find your Upright Duplex Tubular Boiler more economical in the consumption of fuel than the old Saddle, and does not require so much labour in stoking. During this last severe winter we were able to bank our fires up at half-past ten, and find the temperature all right in the morning.

I remain, Gentlemen, your obedient servant, ROBERT BAKER,
Gardener to Lord Ashburton.

April 8, 1871. **RUXLEY LODGE.**

GENTLEMEN,—The Upright Tubular Boiler which you fixed here, gives entire satisfaction. From my own experience in working your boilers, I have no hesitation in saying that I believe them to be the best boilers in use.

I am, Gentlemen, yours, &c., J. HOWIE,
Gardener to the Right Hon. Lady Foley.

April 11, 1871. **ASHTON COURT,** BRISTOL.

GENTLEMEN,—I am happy to state that the Horticultural Buildings erected by you here, during the past nine years, continue to give Sir Greville Smyth and myself every satisfaction. As for the Heating Apparatus, nothing can be more satisfactory, the two boilers at the Court Gardens, fixed in 1862, not having cost one shilling for repairs, and, so far as one can judge, are as sound as when originally fixed. I may further observe that during 40 years' experience as head gardener almost every description of boiler has fallen under my supervision, and without the least hesitation I impartially state that none have equalled Week's Upright Tubular. I prefer them with a safety expansion pipe, filled with rainwater, kept clean, and in constant operation. By attention to these rules, I believe they will last for 20 years.

I am, Gentlemen, yours obediently, WILLIAM DODDS,
Gardener to Sir Greville Smyth, Bart.

April 6, 1871. **LEYBOURNE GRANGE,** WEST MALLING.

GENTLEMEN,—It gives me much pleasure to inform you of the great satisfaction I have received from your New Tubular Duplex Boiler that you sent me last season. Of all boilers at present in use for heating horticultural structures there is nothing to equal the above for heating power. A boiler of such great power as the Duplex I should think offers great advantages to the successful heating of large public buildings of every description, where a certain amount of heat is often wanted within a very limited space of time. Your Duplex is the key to success.—I remain, Gentlemen, yours truly,

WILLIAM BOWMAN, Gardener to Sir Joseph Hawley, Bart.

April 8, 1871. **THE GARDENS,** DRAYTON MANOR.

DEAR SIRS,—Your Upright Tubular Boiler has successfully and economically worked our Forcing department (2540 feet of piping) for upwards of seventeen years, without a single mishap of any kind, and when examined with the view of testing its soundness, about four years ago, it was found thoroughly sound, and to all appearance equal to the like term of years again. During the late severe winter I found no difficulty in maintaining the desired temperatures, and that by banking up the fires at 10.30, as in ordinary seasons. OWEN THOMAS,

Gardener to the Right Hon. Sir Robert Peel, Bart., G.C.B., M.P.

THE GARDENS, BEDDINGTON HOUSE.

GENTLEMEN,—You are at liberty to make use of my name in any way you think proper respecting your Upright Tubular Boiler, as it has given the greatest satisfaction here. I remain, Gentlemen, your obedient servant, THOMAS PENFOLD,
Gardener to the Rev. A. H. Bridges.

April 15, 1871. **STANSTED PARK,** EMSWORTH, HANTS.

GENTLEMEN, —I have much pleasure, now that we may consider the winter past, to let you know that your Upright Tubular Boilers have done their work to my entire satisfaction; and if it were necessary for me to make a change, it would only be to substitute the Duplex Compensating for the old Upright Tubular, for I believe the Patent Duplex Compensating Arrangements have made the Upright Tubular Boiler as near to perfection as it is possible to be.

I remain, Gentlemen, yours respectfully, GEORGE THOMPSON,
Gardener to Mrs. Dixon, Stansted Park, Emsworth, Hants.

April 8, 1871. **THE GARDENS,** HOOLEY HALL.

SIRS,—Having had your New Duplex Patent Boiler in constant work for the last six months, I have much pleasure in bearing testimony to its great superiority over any other boiler that I am acquainted with. I have found it to be most powerful, quick in its action, very moderate in fuel, and so constructed that it requires very little attention.

I am, Sirs, yours truly, JOHN JACQUES,
Gardener to J. C. P. Cunliffe, Esq.

April 18, 1871. **WIDMORE LODGE,** BROMLEY, KENT.

GENTLEMEN,—It is rather out of my line of things to recommend *anything*, but in reference to your inquiry about the Upright Tubular form of Boiler, I may say I am quite satisfied with it. Giving all other inventors and manufacturers of hot-water boilers due praise for trying to meet the growing wants of horticulturists, yet, to Mr. Weeks alone, we, as *gardeners*, have to date the first steps in alleviating the midnight ordeal of young gardeners. The Upright Tubular Boiler has stood the test for years, and even now, as far as my experience goes, there is no other form of boiler equally powerful and so easily stoked.

I remain, Gentlemen, yours respectfully, PETER M'PHAIL,
Gardener to C. Telford, Esq.

April 24, 1871. **THE MOUNT,** BISHOPSTOKE, HANTS.

GENTLEMEN,—I have much pleasure in reporting upon the working of your new Duplex Upright Tubular Boiler, and feel that I cannot do better than give a correct statement of its operations. Previous to the removal of the old boilers, our average consumption of fuel was, during winter, about 10 tons per month, and with the new boiler it averages from 5½ to 5¾ tons, thus saving a little more than 4 tons per month. The quantity of piping heated is about 2300 feet. I may also add that we have a much stronger command of heat in every house and pit than we ever had with the two old boilers, which were of a large size. The whole apparatus now sets most satisfactorily, and further, I, having had upwards of 40 years' experience with almost every description of boiler, pronounce most impartially for the new Upright Tubular.

I am, Gentlemen, your obedient servant, THOS. LOWE.

April 10, 1871. **THE GARDENS,** HANBURY HALL.

DEAR SIRS,—I am much pleased to to be able to say that the Duplex Boilers you fixed here some time ago do their work well, and need as little care and attention as it is possible for boilers, doing the work they are doing, to need. We have never worked, but for trial, more than one, and that has needed nothing more than to be cleaned once a year. We have power enough to work double, or even treble, the houses we have here at present. I am, Sirs, yours truly, WILLIAM BISHOP.

April 14, 1871. **NORMANHURST COURT,** BATTLE.

MESSRS. WEEKS & CO., GENTLEMEN,—We have one of your No. 5 Upright Tubular Boilers here, heating about 3400 feet 4-in. piping, with little trouble and great satisfaction. I am, Gentlemen, your humble servant, GEO. SMITH,

---

April 11, 1871. **IWERNE HOUSE,** BLANDFORD.

GENTLEMEN,—After twelve months' trial of your Patent Duplex Boilers, I feel perfectly satisfied with them in every way, and believe them capable of doing any amount of work you may require of them; they are very simple, and easy to manage, and a great improvement on your other boilers where only one boiler is required.

I remain, yours most obediently, E. JAMES,
Gardener to Thos. Bowyer Bower, Esq.

April 14, 1871. **HALL PLACE,** LEIGH, KENT.

DEAR SIRS,—I give you the liberty of using my name in any way you please that will add weight to your testimonials. Nothing can answer better than your Duplex Upright Tubular Boilers, and I am very pleased with their operations; they act admirably. I could expatiate at some length upon the merits of your old pattern boilers, having worked them for a number of years, but have no doubt that the Duplex arrangement is a valuable improvement. I am, dear Sirs, yours truly,

JAMES KETTLE, Gardener to Samuel Morley, Esq., M.P.

For full particulars of Boilers, additional Testimonials, and Illustrated Book of Designs (12th Edition), apply to

" " small packet, 6d.

N.B.—Wherever this charming little Lettuce is grown it is a remarkable favourite. It may be obtained *true* from either Gloucester, or Mark Lane, London. We recommend everybody to try it who have not already done so.

All the above Post Free.

WHEELERS'
BROCKWORTH PARK PEAR,
10s. 6d. each.

This magnificent Pear is a cross between Williams' Bon Chrétien, and Louise Bonne of Jersey. It considerably surpasses both its parents in SIZE, fine QUALITY, BEAUTY, and FLAVOUR, ripening about the same time, viz., September and October; grown against a wall, the fruit is remarkably large and handsome, the Pears weighing about 12 oz. (¾ of a lb. each). On the dinner-table well-ripened specimens are remarkably conspicuous for their size and beauty, and their flavour and juiciness are fully equal to their appearance.

A First-class Certificate was awarded to this handsome variety last autumn by the Royal Horticultural Society, and Trees were ordered by the principal Nurserymen in the kingdom; but the demand was so great that we were Sold out of all our Saleable Plants immediately they were offered. Coloured Plates, taken from Nature, may be had at 6*d.* each.

We are now Booking Orders to be executed in November next; all Orders will be executed in exact rotation as received, as far as the Plants will go; but we expect to be Sold out long before the season is over.

The price of young PYRAMIDS is 10*s.* 6*d.* each. We have a few Plants trained for walls at 15*s.* The Pyramids will furnish plenty of buds next summer for budding Trees of other varieties established against walls. This fine variety is well worthy of a wall, and of a good aspect.

☞ **Orders are now being Booked.**

To Florists and Amateurs.

TO BE SOLD, a fine Collection of CACTI, consisting of most of the choice varieties; many of them fine specimens, of 20 years' growth. Over 200 Pots will be sold for one quarter their value, on account of the bad health of the owner, and removing into the country. The Cacti can be had in lots to suit purchasers. Also a nearly new GREENHOUSE, at feet by 9 feet.

Mr. QUELCH, 200, Albany Road, Camberwell, Surrey, S. E.

ALEXIS DALLIERE, Nurseryman, Faubourg de Bruxelles, Ghent, Belgium, begs to offer the undermentioned Plants, which will be ready for sending out in early part of August:—

100 well-assorted AZALEA INDICA, with buds, nice specimens, for 24 and 48.

100 do. CAMELLIAS, with buds, beautiful plants, 48.

100 do. do. strong plants, 28.

200 HOTEIA (SPIRÆA) JAPONICA, nice bushed plants, £1 12s.

1000 " " £14.

32 beautiful varieties of CALADIUMS, 10s. "

Also a large stock of DRACÆNAS, PALMS, FERNS, MARANTAS, and many other Ornamental Foliaged Stoves and Greenhouse Plants, the prices and sizes of which will be sent on application to A. DALLIERE, as above.

REES and CO.'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in fine condition. It is believed to be the best Artificial Manure yet produced. Its base is Peruvian Government Guano: it contains 21 per cent. of Soluble Phosphates, 5 to 7 per cent. of Ammonia with Salts of Potash. See reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Ogston, and Mr. Sibson. Delivered in 2 cwt. bags, each of which is secured by a leaden seal, bearing the Company's Trade Mark. The analysis is guaranteed so long as the seals remain unbroken.

REES AND CO., Limited, 58, Old Broad Street, London, E.C.

REES and CO. (Limited), MANUFACTURERS of the BIPHOSPHATED PERUVIAN GUANO, and other CHEMICAL MANURES, beg leave to inform their Customers, and others, that they have REMOVED from 30, King William Street to their new and commodious Offices,

POOLEY'S TOBACCO POWDER. Of all Nurserymen and Seedsmen.

"PHYTOSMEGMA," or PLANT CLEANSER, destroys Scale, Mealy Bug, Red Spider, &c., without injury to Plants; 6d. and 1s. per bottle.

THE NEW SHOWERER, for applying the above, 6d., 1s. and 3s. 6d. each.

Wholesale of T. A. FOOLEY, Sussex Wharf, Wapping, E.; and Retail of all Nurserymen, Seedsmen, and Florists.

Red Spider.

Magnified.

GISHURST COMPOUND.

Used by many of the leading Gardeners since 1839, against Red Spider, Mildew, Thrips, Green Fly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 oz. to 1 pint in a Winter Dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it.

Sold Retail by Seedsmen, in boxes, 1s., 3s., and 10s. 6d.

Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited), Battersea, London, S.W.

J. TYLOR AND SONS' FOUNTAIN JETS.

A large variety to be seen in action at THE MANUFACTORY, No. 2, Newgate Street, London, E.C.

Illustrated Catalogues on application.

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS are made in materials of great durability. The plainer sorts are especially suited for KITCHEN GARDENS, as the harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.

F. and G. ROSHER, Manufacturers, Upper Eccleston Street, Blackfriars, S.E.; Queen's Road West, Chelsea, S.W.; Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME" PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Patterns of plain or more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, &c. Grooved and other Bricks. Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds, Roofing Tiles in great variety.

Illustrated Price Lists forwarded, &c.

F. AND G. ROSHER, Brick and Tile Merchants.—See addresses above.

SILVER SAND, fine or coarse grain as desired. Fine 12s., Coarse 17s. per Ton. In Truck Loads 1s. per Ton less. Delivery by Cart within three miles, or to any London Railway or Wharf, at per Ton extra. Samples of Sand free by post.

FLINTS and BRICK BURRS for Rockeries or Ferneries. KENT PEAT or LOAM supplied at lowest rates in any quantities.

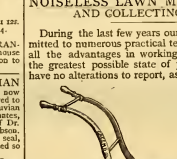
F. AND G. ROSHER.—Addresses above.

N.B. Orders promptly executed by Rail or to Wharves.

A liberal discount to the Trade

Great Reduction in Prices for 1871, OF GREEN'S PATENT SILENS MESSORS OR NOISELESS LAWN MOWING, ROLLING AND COLLECTING MACHINES.

During the last few years our Machines have been submitted to numerous practical tests, and found to possess all the advantages in working and keeping a Lawn in the greatest possible state of perfection. We therefore have no alterations to report, as they are unnecessary.



The above Machines have carried off every Prize that has been given in all cases of competition.

They are warranted to be superior to any others. We guarantee them to give entire satisfaction, otherwise they can be returned, free of cost to the purchaser. With the increased facilities we possess for the Manufacture of Lawn Mowers, we are enabled to sell them at a reduced rate on former years, as will be seen from the following Scale of Prices :—

To cut 8 inches	.. Price	£2 10	0
" 10 "	..	3	0
" 12 "	..	4	0
" 14 "	..	5	0
" 16 "	..	6	0

T. GREEN & SON have pleasure in announcing that the demand for their Lawn Mowers this season far exceeds all previous ones, and from this fact they are led to believe that the machines of their manufacture are held higher in the estimation of the public than ever.

Prices of HORSE, PONY, and DONKEY MACHINES on application.

☞ *Repairs executed with efficiency and despatch, both at Leeds and London Establishments.*

GREEN'S IMPROVED

PATENT ROLLER,

FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS, Suitable for Hand or Horse-power.

PRICES of HAND ROLLERS.

Diameter.	Length.	£ s. d.	Diameter.	Length.	£ s. d.
30 in.	32 in.	7 10 0	20 in.	22 in.	3 10 0
24 in.	26 in.	4 10 0	16 in.	17 in.	3 15 0

PRICES of ROLLERS, fitted with Shafts, Suitable for Pony or Horse-power.

Diameter.	Length.	£ s. d.	Diameter.	Length.	£ s. d.
30 in.	32 in.	10 0 0	30 in.	60 in.	15 10 0
30 in.	36 in.	11 5 0	30 in.	72 in.	17 10 0
30 in.	42 in.	11 15 0	30 in.	84 in.	19 10 0
30 in.	48 in.	13 10 0			

These ROLLERS possess many advantages over all others; they are made in two parts, and are free to revolve on the axis, affording greater facility for turning, and the outer edges are rounded off, or turned inwards, thus avoiding the unsightly marks left by other Rollers. They are manufactured of the best materials, and are got up in a manner surpassing any ever yet brought out.

The ROLLERS, 24 by 26 inches, 20 by 22 inches, and 16 by 17 inches, are also made in one part, at a reduced price; and for Rollers of that size, will be found to answer many requirements, as the handle can be reversed to either side of the Roller at pleasure.

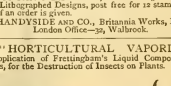
VASES and FOUNTAINS for the GARDEN and CONSERVATORY.

Illustrated Catalogue, containing prices and full information concerning FOUNTAINS and VASES, and with 30 large pages of beautifully Lithographed Designs, post free for 12 stamps, which will be allowed if an order is given.

A. HANDYSIDE AND CO., Britannia Works, Derby.
London Office—39, Walbrook.

THE "HORTICULTURAL VAPORISER," for the Application of Fretingham's Liquid Compound, or other Preparations, for the Destruction of Insects on Plants.



TRADE MARK.

By means of this Apparatus, liquids may be diffused over Plants in a state of minute division, or fine spray, in sufficient quantity to thoroughly moisten them, without rudely or disturbing the most delicate flower or foliage.

Besides these advantages, great saving of the liquid is effected. A tablespoonful applied by the Vaporiser is equal to a pint applied by means of a sponge, or the ordinary methods in use.

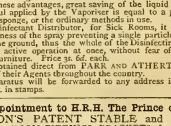
As a Disinfectant Distributor, for Sick Rooms, it is invaluable. The minuteness of the spray preventing a single particle of the liquid falling to the ground, thus the whole of the Disinfecting Liquid used comes into active operation at once, without fear of damaging the carpets or furniture. Price 3s. 6d. each.

May be obtained direct from PARR AND ATHERTON, Nottingham; or of their Agents throughout the country.

The Apparatus will be forwarded to any address in England on receipt of 4s. in stamps.

By Appointment to H.R.H. The Prince of Wales.

BARTON'S PATENT STABLE and HARNESS ROOM FITTINGS, BRACKETS, &c.



Patronised by H.H. the Viceroy of Egypt, the King of the Belgians, the King of Italy, the King of Holland, by the Imperial Nobility of the Kingdom, and adopted by the first Architects and Builders of England and the Continent. Illustrated Catalogues sent on receipt of six stamps.

For ALTERATION of STABLES a competent person can be sent to any part, to inspect and give Estimates.

THE ALEXANDRA PALACE AND MUSWELL HILL ESTATE TONTINE.

(TO TERMINATE ON THE 30th JUNE, 1886.)

This being a "Trust," Subscribers incur no Liability.

Certificates representing 850,000 Guineas (of which 1s. of each Guinea is to be appropriated to Insurance of Subscribers), will be issued at the following Rates:—

A	(or Single Right) Certificates	each £1 1 0	**D**	(or 50 Right) Certificates	each £52 10 0
B	(or 10 Right) ,, ...	,, 10 10 0	**E**	(or 100 Right) ,, ...	,, 105 0 0
C	(or 25 Right) ,, ...	,, 26 5 0		Payable on application.	

CERTIFICATES PASS TO AND ENTITLE THE BEARER:—

1. To participation in the proceeds of sale of the property if the representative life upon which the Tontine privilege depends shall be living on the 30th June, 1886.
2. To the receipt from a life assurance of the sum of 20*s.* in respect of each Guinea paid upon any Certificate, if the representative life shall die before the said 30th June, 1886.
3. To admissions to the Palace and Park, according to the number of Rights. | 4. To participation in Art Union Distributions proposed to be hereafter established.

The 2nd and 4th are explained in detail in the full Prospectus.

The acceptance of a Certificate involves no liability. The rights and privileges of Certificate holders are governed by the Trust Deed.

The whole nett Income of the undertaking, after defraying interest charges and management expenses, will be devoted to the improvement of the Property, and also (when power is obtained) to Art Union Distributions.

Trustees { JOHN CLUTTON, Esq., Whitehall Place.
JOHN HACKBLOCK, Esq., Bolton Gardens.
JOHN HORATIO LLOYD, Esq., Inner Temple.

Bankers { THE LONDON and COUNTY BANK and BRANCHES.

Solicitors—Messrs. COPE, ROSE, AND PEARSON, 26, Great George Street, Westminster.

Secretary—THOMAS DIXON, Esq.

OFFICES—5 and 6, GREAT WINCHESTER STREET BUILDINGS.

ABRIDGED PROSPECTUS.

CONTRACT for PURCHASE of PROPERTY.

An advantageous Contract has been concluded for the purchase, free from incumbrance, of the Alexandra Palace Park and Lands adjoining, situate at Muswell Hill, Hornsey, in the county of Middlesex (comprising about 470 acres of Freehold and 28 acres of Leasehold Land), and the contents of the Palace, for the sum of £605,000. Of this amount £450,000 may remain on the security of the Property for 5 years, represented by Mortgage and Debentures.

OBJECT of TONTINE.—The INSTITUTION.

The object of the Tontine is to complete the purchase and improve the property, and thus to provide for all classes of the inhabitants of the Metropolis, and especially of its northern and eastern portions and suburbs, and for the many thousands of country excursionists, a Grand Institution of healthful recreation, and elevating instruction, which will combine the solid advantages of the South Kensington Museum and Schools of Art, with the lighter pleasures and pastimes of the Crystal Palace at Sydenham, thus giving effect to the large and enlightened views of the late Prince Consort.

ART UNIONS.

In furtherance of this design it is proposed to inaugurate a series of Exhibitions, Art Unions, and distributions, in the support of which, and as soon as the necessary power can be obtained for the purpose, it is proposed that the chief portion of the profits of the Park and Palace, after making proper provision for management, improvements, and other charges, should be applied.

It is intended to apply to Parliament for power to devote part or the whole of the surplus income to Art Union Distributions, to be held every third year during the term of the Tontine, by giving to opposite a number or chance in each Distribution to every Certificate in respect of every 21*s.* paid thereon. It is estimated that the fund for distribution will amount triennially to £100,000, and the prizes will range from £500 to £2.

SINGLE CERTIFICATES MAY OBTAIN PRIZES of £500 EACH for 21*s.*

The value represented by the Prize Tickets is to be applied wholly in the selection of articles contained in the Alexandra Art Union Exhibitions, and it will be seen that it is possible for the holder of a single right Certificate to receive Five Prizes of £500 each for his investment of 21*s.*

INSURANCE of CERTIFICATE HOLDERS.

An established Insurance Company has agreed, in consideration of the payment to them of a premium of one shilling for every £1 for single right) Certificate, and so on in proportion for any plural rights certificate (*i.e.*, one shilling for each right), to pay to the holder £1 for each guinea paid on such certificate upon the death of the representative life in respect of which the Tontine privileges depend, if such death happens before the 30th June, 1886, provided such Certificate shall not have been previously surrendered, or the bearer of such Certificate for the time being shall not have drawn a prize in an Art Union Distribution in respect of the right representing such guinea. Such premium will be paid out of the Tontine funds.

TONTINE WILL CEASE JUNE 30, 1886. PROPERTY then to be DISTRIBUTED.

Upon the 30th June, 1886, the Tontine will absolutely cease; and as soon as may be after that date the whole of the property will be realised, and the nett proceeds will be distributed amongst the Tontiners or Certificate holders.

CONTRIBUTIONS INCUR No LIABILITY, and must BENEFIT.

Thus every subscriber of 21*s.* and upwards to the Tontine, or the holder for the time being of his Certificate (the same not having been previously surrendered) will, in addition to the privileges of entry to the Park and Palace as enumerated in the full Prospectus obtain the repayment, in case of the death of the representative life or lives, of 20*s.* in respect of every 21*s.* paid by such subscriber, or will have previously drawn a prize of at least £2 in the Art Union Distribution in respect of such 21*s.* subscription, and will, when the Tontine ceases, have, in respect of each of the Rights of which the representative life shall be then in existence, the right to a share in the proceeds of the Tontine property. Looking at the rapidly increasing value of Building Land near London there can be no doubt that at the expiration of the Tontine, in 15 years, the property to be then distributed amongst the holders of Certificates entitled to participate will be of enormous value.

PROPERTY VESTED in TRUSTEES.

All the landed property to be acquired for the purposes of the Tontine will be vested in the Trustees upon trust, to permit the Management Company to manage the same; and upon the termination of the Tontine (the 30th of June, 1886), or so soon after as may be convenient, to sell the Tontine property and distribute the proceeds.

DEEDS.

The Purchase Contract, the Trust Deed, the Insurance Contract, and the Memorandum and Articles of Association of the Management Company may be perused at the Offices of the Solicitors.

PROSPECTUSES.

Prospectuses (with an outline sketch of the Palace) and Forms of Application for Certificates may be obtained of the Secretary at the Offices of the Trustees and of the Brokers, and of the Bankers, and at the various Branches, as well as of the Solicitors.

Agencies for the receipt of Applications will shortly be advertised.

APPLICATIONS for CERTIFICATES.

Applications for Certificates must for the present be left with the Bankers at the time of the payment of a deposit; and no application will be noticed unless the sum of 21*s.*, in respect of each single right, or the amounts specified for plural rights applied for as above stated, shall have been paid.

If no issue is made the subscription will be returned in full.

For full particulars see detailed Prospectuses, which, with the Forms of Application for Certificates, can be obtained of the Bankers and their Branches, the Solicitors and Brokers, and at the Offices of the Tontine, as above.

The Gardeners' Chronicle

SATURDAY, AUGUST 5, 1871.

MEETING FOR THE ENSUING WEEK.

THURSDAY, Aug. 10—Royal Botanic (Anniversary).. .. 1 P.M.

WE have before us some elaborate statistics relating to the results of the EXAMINATIONS of YOUNG GARDENERS, held by the Royal Horticultural Society and the Society of Arts respectively, from December, 1866, to July, 1870. These statistics were compiled by one whose name appears most frequently on the honours list, and, we have every reason to believe, substantially correct.

During the period named 54 youths were examined by the Royal Horticultural Society. Of these, two gained the associateship, the highest honour open to them, after a special examination; 11 gained double first-class honours, *i.e.*, first-class certificates in both floriculture and fruit culture. At the Society of Arts, out of 37 candidates, eight obtained double first honours, while eight were awarded first-class certificates in floriculture only, and two in fruit culture.

Seven of the young men above alluded to managed to carry off double first honours from both Societies; 18 second-class, and 12 third-class certificates, viz., Floriculture: 11 first, 7 second, 6 third; Fruit culture, 4 first, 11 second, 4 third.

Chiswick has been represented at the Royal Horticultural Society's examinations during the period in question by 19 pupils. These 19 pupils have gained in all 19 first-class, 35 second-class, and 15 third-class certificates, thus distributed:—Floriculture: 14 first, 18 second, 4 third-class; fruit culture: 5 first, 17 second, 11 third-class; showing, as will be seen, either that the young men are much less efficiently trained in fruit than in flower culture, or that the examination in fruit culture is more a tax on the memory, in supplying lists and diagnoses of fruit, than it is a test of cultural knowledge. The 19 first-class certificates gained by Chiswick, were won by eight of her pupils.

Kew has been represented at the same examinations by an equal number, viz., 19. Of these 19, nine managed to carry off between them the 15 first-class certificates which fell to the lot of Kew men. At the Society of Arts, Kew men have gained 8 first, 14 second, and 1 third-class certificate; or in floriculture 5 first, 7 second, and in fruit culture 3 first, 7 second, and 1 third. At the Society of Arts examinations it appears that Chiswick has only sent out five pupils, but those five were good men, as witnesses the fact that they carried off between them 4 first and 1 second-class certificate in floriculture, and 3 first and 1 second in fruit culture. These Chiswick lads, all honour to them, managed to appropriate money prizes to the amount of £37, while six of the Kew men were lucky enough between them to win money prizes to the extent of £130—the small amount, as compared with Kew, being accounted for by the smaller number of candidates for these prizes, and the more frequently repeated trials made by the Kew men.

Besides the public establishments of Kew and Chiswick, 35 young men, from various private establishments throughout the country, have offered themselves for examination by one or both societies during the time under review. Of these 35 six had been at Kew, and two at Chiswick for a time.

At the Horticultural Society's examinations 16 of these outsiders presented themselves; of whom one gained the associateship, while to the rest were allotted 14 first-class certificates, 11 second-class, and 5 third-class; or, in floriculture, 11 first, 3 second, 2 third-class certificates; and in fruit culture, 3 first, 8 second, 3 third.

At the Society of Arts 24 outsiders gained 10 first-class certificates, 24 second, and 20 third; or in Floriculture 6, 12, 12, and in Fruit culture 4, 12, 8, respectively—showing either the same relative deficiency in a knowledge of fruits and vegetables, and their culture, that is observable in the young men sent up from public establishments, or a style of questioning not calculated to elicit from the candidates ready, as blind. The latter have, as might have been expected, rather a preponderance of good men as represented by the numbers of honours-men as contrasted with those sent out from private establishments, where too often the instruction given is of the "happy go lucky" order. Still the "outsiders," or eight of them, have succeeded in gaining money prizes to the extent of £80.

Some few of the young men in the list have also distinguished themselves in various other examinations, including those of the Science and Art Department, in such subjects as Botany, Vegetable Physiology (though it is remarkable how few young gardeners have studied these subjects, and how deplorably ignorant the mass of them are of the very important scientific rudiments of their craft), Arithmetic, Zoology, Animal Physiology, Political Economy, Chemistry, Electricity, Book-keeping, Mensuration, Geography. This is a rather imposing list of subjects, it is true, but it is equally true that the proficients have been very few, and that, as happens in most examinations, the man most advanced in any one subject is also pretty sure to be well up in many others.

We should greatly like to trace the career of these certificated gardeners and to ascertain whether, other things being equal, they have successfully competed for places better or worse than fall to the lot of most youngsters, who become gardeners. Our own impression, from what we know of the position of several of those who have taken honours, is, that they have commanded better positions than the undecorated youths. Six of the certificated young men at least are in India, all New men, holding good positions. Several others are known to us in this country holding considerably better positions than the majority of those who have not thus given a pledge of their industry and ability.

Considering the amount of forethought and intelligence required even by a second or third-rate gardener, we are grieved and surprised to see the comparatively low estimate in which the fraternity is held by the general public. We believe this arises from many causes, and foremost from the want of a proper healthy professional organisation among gardeners—an organisation which would bind the gardeners together in the same way that the several colleges and universities serve as a bond uniting their members—an organisation which should gradually establish an unwritten code regulating the duties of gardeners to their employers, to one another, and to themselves, in the manner most advantageous to all—an organisation which should lead gardeners to depend on themselves more and on the nurserymen less. We do not know how such an organisation could be more efficiently, though perhaps slowly and gradually, built up than by the creation of a healthy *esprit de corps* from the beginning, such a one as is naturally the result of the friendly competition in the class rooms and examination halls. We hope that in future the number of candidates for examination will be greatly increased, for it must be admitted that the numbers that have hitherto presented themselves is but small compared with the number of young gardeners dispersed throughout the kingdom. The number at the Society of Arts this year shows a considerable falling off, though one at least of the candidates has managed to gain the first prize in fruit and flower culture from the Society of Arts and the Royal Horticultural Society, and to secure an *honorarium* of £20. This should be an encouragement to others.

— WHILE adverting to the EDUCATION QUESTION it seems *apropos* to introduce in this place some extracts from a recent discussion on the subject in the House of Commons, wherein we are told that:—

Sir J. LUBBOCK moved, "That, in the opinion of this House, it is desirable to modify the new code of regulations issued by the Committee of the Privy Council, in such a manner as to give more encouragement to the teaching of history, geography, elementary social economy, and the higher parts of extra subjects in the elementary schools of the country." He observed that so far from these subjects interfering with reading, writing, and arithmetic, they would greatly promote them, and he quoted the evidence in support of his opinion. Elementary social economy was one of the subjects which it was of great importance to teach in our public schools, and the evidence of Professor HUXLEY was very strong upon the point, it being stated by him that a knowledge of social economy would tend in a material degree to put an end to strikes. The British Association and the Association for the Promotion of Social Science were also agreed upon the point that elementary education should be extended to a much greater degree than was proposed under the new code. The schoolmasters would naturally look to the new code as the guide they had to follow. At first sight the arrangement of the new code appeared to be perfectly fair. Fifteen shillings a head was the sum to be granted by the code, of which 6s. a head was to be for attendance; but he contended that the division of the money might be susceptible of great improvement. The encouragement for extra subjects under the code was really delusive. There was no encouragement offered to induce agricultural labourers to continue their children at school for a much longer period than they did. He complained of the inaccuracy of the information contained in the books used in the elementary schools, which, he said, were full of ambiguities and errors. For instance, he found it stated under the head of geography, that Ireland was in America. Under the head of botany the children were informed that sap was not black, as was generally supposed, but in the opinion of many eminent authorities of a dark blue colour. Again, under the head of vegetable physiology, it was stated that the seed of a Sweet Pea was not much larger than a pin's head, yet it contained, compactly folded up, a large branchy flowering plant. In animal physiology they were taught that fishes had no voice, except seals and whales. Insects, they were told, had their uses, and a fly keeps the warm air pure and wholesome by its constant zig-zag flight. But it was not only in matters of natural science that these books were susceptible of improvement, for some of the moral teaching they conveyed might be questioned; as, for example, the tale of the boy who, when he hesitated to rob an orchard, was induced to join in the depredation by the argument that his refusal to do so would not influence the result; and he is made to sum up the train of moral reasoning thus:—

'Since they will take them, I will go too:
He'll not be more by me though I get a few.'

He asked whether that was unobjectionable moral teaching? In another place was the story of how a boy in humble life rose to be a master manufacturer by first saving the sixpence of his godmother, his parental, £7 00, and risking it over and over again, till at length he found himself in possession of £90,000. Were the working classes to be taught that the way to get rich was by risking their sixpences over and over again? Mr. E. FORSTER inquired what series the hon. baronet referred to.—Sir J. LUBBOCK said the series issued by the British and Foreign School Society, and that issued by the National Society, which had been drawn up since the education code within the last few months. He should be glad if he could induce the Government to issue, themselves, a short series of manuals adapted for every school. In Scotland and in Ireland the plan which he advocated was already carried out; and during the late war every German soldier carried with him a map of the roads of the country in which he was engaged. The statistics connected with science and industry showed a growing appreciation of the instruction afforded in them. In the year 1860 there were nine schools of that kind and 500 students; last year there were 820 schools and 30,000 students. Year by year there had been a great increase of schools and students, and also a considerable improvement in the system of instruction. Out of 60 Queen's medals allowed after the examinations in physical geography, no less than 40 of them were gained by young people under 14 years of age. He wanted to introduce variety into education. In the American schools it was an axiom that the lessons ought to be short, many, and varied. He did not want to have the school hours lengthened. The fault of the existing system was that it loaded the memory instead of educating the mind. There was in fact too much instruction and too little education. They wasted children's time in elementary schools with the mechanical act of writing and long lists of dates, names, places, and kings, which conveyed no definite idea, and had no apparent relation to the duties and occupations in life of the children. It was more important that children should like their lessons than that they should learn them, on account of the habit of learning which liking them would tend to form. What he wanted to see taught was something about the properties of water, the processes of day and night, of summer and winter, and the ordinary phenomena by which they were surrounded; believing as he did that such instruction would create a desire for more information, open sources of the purest recreation and enjoyment for leisure hours, and, in accordance with a well-known proverb, make the man better workman and the workman the better man.—Mr. MUNDELLA believed that if some of the elements of political economy were taught, the relations between capital and labour would be much more satisfactory, and he concurred in the opinion of the late Mr. COBDEN that if agricultural labourers knew something of the outside of the world, they would not be content to rot on 8s. a week. The English working man, when a thing was brought fairly before him, was a just man, but it was almost impossible for him to judge the value of money or his own interests. A great mistake had been raised in this country about the dowry of a princess. £6000 a-year and £30,000 paid down seemed an enormous sum to an English workman who was in receipt of his 30s. a week, but that was only because he had no capacity for making comparisons, had no idea of the vast resources of the country, and had no conception of its vast expenditure. If the great masses of the working classes were to be made loyal to the institutions under which they lived, they must give them more intelligence. They ought not to be content with English education until it was as good as that of any other country in the world. Their ideas of the education which ought to be given to the working classes were altogether too low to make them useful to themselves, or appreciative of the advantages which this country and the colonies offered to them; and he did trust that something would be done to give them a knowledge of the subjects

to which his hon. friend had directed the attention of the House.—Dr. L. Playfair supported the motion, and contended that mere elementary education was not sufficient to carry a working man through life. On the contrary, it was apt to melt away in two or three years of active occupation. The higher subjects provided for by the Revised Code existed more in name than in reality; because the maximum sum could be gained for the elementary subjects, and there was no necessity for trying the higher subjects. It was true that the talented poor were always in a very small minority; but it was of the greatest importance to the State to add to its intellectual funds. The working classes of England have far less chance of educating themselves in the higher branches of learning than the working men of any other country, though no other country spent so large a proportion of the Imperial funds on education as England did. The reason of this was that while other countries made it the duty of localities to teach the A. B. C. of education, and employed Imperial funds for the purpose of inspection and the development of education into that which would be useful to the State, we had, until the recent Act, adopted the opposite course, and four-fifths of the treasure poured out upon education was wasted, because, as it appeared from the reports of the inspectors, four-fifths of the scholars forgot soon after leaving the schools the elementary learning they had acquired. Up to eight years of age the children of the poor and of the middle classes received the same education, but that which was useful in the beginning with the latter was with the former the end of their education. State education must be made much more productive than it was at present, and in that view he supported the resolution.—Mr. A. Herbert complained of the want of interest in teaching on the part of children. It was like putting a stick in the ground to grow; there was no vitality in it. If they could but teach children why tops spin, and why chimneys smoked, they would have done something useful. What was wanted was, to make the occupations of the people a means of their education. In all trades there was constant waste. If they took cabinet-making they would find a continual waste of material and time, because men did not know how to carry on their work. A want of scientific knowledge showed itself in all departments of trade.

—— The suggestion made amongst the exhibitors at Nottingham, to the effect that some mark of esteem and respect should be presented by them to Mr. George Eyles, the superintendent of the flower shows of the Royal Horticultural Society, was taken up at a meeting of some of the principal exhibitors, Mr. C. Turner in the chair, held at South Kensington on Wednesday last, when a committee, with power to add to their number, was formed to carry out the above object. Mr. John Fraser was requested to act as treasurer, and Mr. Moore as secretary; and it was determined that subscriptions to the testimonial should be limited to one guinea.

—— In England the Maximum Temperatures of the air during the week ending July 29 ranged from 76°.6 at Blackheath to 67° at Newcastle-on-Tyne and Liverpool respectively, with a mean for the several towns of 70°.8. The Minimum Temperatures ranged from 51°.9 at Blackheath to 47° at Wolverhampton, Eccles, and Hull, and the mean for the several stations was 48°.5. Rain fell more or less heavily throughout the week over the whole country; the principal fall recorded were 1.47 inch at Leicester, 1.43 inch at Manchester, 1.42 inch at Eccles, and 1.20 inch at Hull, and the mean for the several stations was 1 inch. In Scotland the Maximum Temperatures ranged from 73° at Perth to 64°.2 at Aberdeen, and the minimum temperatures from 48°.8 at Leith to 43° at Perth. At all the Scottish stations rain fell during the week, the greatest fall takiug place at Perth, viz., 1.49 inch, and the mean for the several stations 1.26 inch. The Mean Temperature for England for the week was 57°.2, and for Scotland 54°.4. The highest mean temperature recorded in England was 60°.4 at Blackheath, and the lowest 55°.8 at Eccles. In Scotland the highest was 56°.2 at Perth, and the lowest 53°.4 at Glasgow. (See Mr. Glaisher's Tables in our present issue.)

—— As regards the Gall-like Bodies on Rhododendron ferrugineum, the Rev. M. J. Berkeley writes as follows:—"The specimens sent were not on the leaves, but on the terminal bud. I could not find any trace of larvæ, but the whole of the external surface was covered with a white bloom, which resembled to the naked eye that in the young condition of Peach blisters, and under the microscope was identical in structure. Only three specimens were sent, and as these were not in a satisfactory condition, I wrote immediately to the address which accompanied the communication (Mr. R. B. Ferguson, Chester), but the letter was returned from the Dead Letter Office marked "not known at Chester." Should this meet the eye of Mr. Ferguson, I should feel much obliged by the communication of additional specimens, directed to Sibbertoft Vicarage, Market Harborough. Mr. Müller's description of the Cherry-like galls does not tally with the specimens which I received. I inquired of an Indian botanist, who has seen thousands of Rhododendrons, whether he had seen such galls, but he did not recollect to have done so. Should I be so fortunate as to get a better supply of specimens, I will make a more accurate examination, but even should I find larvæ it is not impossible that Ascomyces may coexist with them. Since the above was written, Mr. Broome has sent from Perthshire a thinner but similar substance on Vaccinium Vitis Idæa, covered with a similar bloom. There is no reason to think that this is an insect product."

—— It is stated that a jet of quartz sand blown through a pipe by steam, at 300 lb. pressure to the square inch, will make a hole in a solid block of corundum an inch and a half deep and of the same diameter, in less than 25 minutes. Corundum is little, if at all, inferior in hardness to the diamond; in the comparison, even blued steel is soft, and granite absolutely pulpy. This remarkable Mechanical Discovery is due to Mr. B. C. Tilghman, an engineer of Philadelphia, who turns upon corundum a pipe which discharges sifted sand, mixed with a furious squirting of steam, and the fine shower of particles

Fig. 223.—Asplenium schizodon.

thus flung cuts a hole equal to the diameter of the jet. The same effect is produced in anything else submitted to the process. So great a force of steam is not necessary for finer work, such as grinding or engraving glass. For this purpose, a blast of air may be employed by means of a rotary fan. The tube is fed with sifted sand, which the air-blast takes up and whirls against the glass. It will thus completely demolish a surface moving past at the rate of five inches in the minute, and the spent sand and sand-dust can be perpetually returned and re-employed. Moreover, by covering parts of the glass with any semi-elastic material, such as paper, lace, caoutchouc, or oil-paint, designs of any sort may be engraved. The particles which eat off the hard glass or stone beat in vain upon the interposed medium; and so curious is this resistance that even a green Fern leaf may be used, and the sand-shower will consume all but the parts thus covered, leaving a delicate pattern of the frond. The film of bichromatised gelatine used for photographic negatives may also be thus utilised for producing an engraving on glass or steel; and by a very simple arrangement the jet can be rendered movable, and handled with an absolutely artistic freedom.

—— At a recent meeting of the French Academy of Sciences, M. Elie de Beaumont, the perpetual secretary, communicated certain observations relative to the effects of Hoar Frost about the middle of May last. The highest intensity and destructiveness was remarked on the night of the 18th of that month, at Cissors, by M. Adolphe Brongniart; at Meudon, by M. Duchartre; in the woods around Versailles, by M. Bouquet de la Grye; the environs of Chatelherault (Vienne), by M. Moll; the Haute-Marne, by M. Flammarion; and in various other parts of France, by M. Barral.

—— The following account of the medical properties of Symphytum officinale is taken from Houttuyn's "Plantensystem:" "The root is employed as a soothing, sanative, and astringent remedy in spitting of blood, dysentery, and ulcers in the lungs and urethra. It is also employed externally in emollient and discutient poultices. The blossoms also are used in the preparation of a ptisan for colds and coughs." In some parts of the country the blossoms are collected and dried like Cowslips for making country-wine, which is supposed to have great healing powers. *M. J. B.*

New Garden Plants.

Asplenium schizodon, *Moore, n. sp.*

Fronds pinnate, coriaceous, glabrous, broadly oblong; pinnæ about three pairs with a terminal one, alternate, 3 inches long and about ¾ inch broad, obtuse, unequally cuneate, often narrowed at the base, narrowing into a distinct stalk, deeply toothed along the margin, especially towards the broadly rounded often truncated and dilated apex, which is deeply and unequally incised, the teeth usually bifid; sori numerous, narrow, linear, extending nearly from the costa to the margin, slightly curved following the direction of the once-forked veins, crowded, and hence occasionally displaced or scolopendroid; caudex decumbent, clothed with dark-coloured lanceolate scales; stipes semiterete, channeled in front.—*Hab.* New Caledonia.

This curious and ornamental Fern (fig. 223) has been known to us for the last three or four years in the collection of the Messrs. Veitch & Sons, of Chelsea, whence our most perfect specimens were obtained, having been collected by the late Mr. J. G. Veitch, in New Caledonia. Recently it has been shown at South Kensington by the Messrs. E. G. Henderson & Son, of St. John's Wood, and received a First-class Certificate, the plant in this latter case having been received by way of New Zealand, but apparently from some garden source. The fronds are evergreen, of a deep dull green colour, somewhat coriaceous in texture, and growing in a crowded manner from a decumbent scaly caudex. They have a stoutish stipes of about 3 inches long, rounded, and of a blackish-purple behind, channeled in front, and supporting a lamina of about 6 inches long, which is divided in the specimens before us into about three pairs of alternate pinnæ, the terminal one being similar to the others both in size and form, except that the auricle is wanting; the pinnæ are, including the tapered stalk-like base, about 3 inches long, broad, often dilated, rounded or irregularly-truncate at the apex, and with one or more deep clefts there, dividing it more unequally, while the margin is sharply toothed, and the teeth, especially those at the apex, conspicuously bifid. The posterior base of the pinnæ is cut away obliquely, while on the anterior side is sometimes a lobe, which is most strongly developed in the lower pinnæ. As an evergreen Fern it is well worth a place in the greenhouse, where its singularly toothed fronds will always give to it a considerable degree of interest. *T. M.*

APPLE TWIG PARASITES.

It is a fault, to which too many of us must plead guilty, to accept two or three generalisations for granted, assent to them mechanically, pass on, and take no more heed of the subject. For example, we take an autumnal or spring tour round the garden, just to see how things are going on, and an old Cabbage stalk meets our gaze, blackened with sooty patches, 2 or 3 inches in length. We look at it casually, it is not soot, it is only a Fungus of some kind or other: that is our fact, hastily arrived at, and with it we are content. Off we start on our tour, the Fungus on the Cabbage stalk does not torment us for years perhaps, and perhaps never. It was a Fungus, and a black Fungus; Fungi are plants of a low organisation, still they are plants. Curious, very! Away we start upon a more familiar theme, content with what we suppose we know about the sooty Fungus on the Cabbage stalk, and not desirous to know no more. It was not, perhaps, the result of examination of the structure that this general notion has been gained. After all it may only have been a "happy guess." So an old Apple twig, covered with vegetation of a peculiarly characteristic kind, with a very characteristic odour, excites no particular interest. The parasitic growths are so very common, that we know them as Lichens, and have known them as such for many years. Why should we know more? why

examine them more intimately to ascertain if they are indeed Lichens? Once on a time, when we were boys, it was told to us that they were Lichens, and we have gone on, and lived in the faith ever since.

This sort of superficial knowledge may, perchance, be quite enough for our everyday life. It is quite possible that more knowledge on that subject will neither add to our purse a single florin, nor aid us in growing Apples, or selling them. It might be very poetical, and very true, for Wordsworth to write—

"The world is too much with us—
Getting and spending we lay waste our powers;"

but, after all, is not the main object of human life the getting and spending? The unadorned and naked philosophy of most human hearts nowadays is of the Iago type, "Put money in thy purse." However much we may deny it with our lips, we confess it in our hearts, and prove it by our deeds, that those occupations please best which pay best; and the test applied even to scientific knowledge is but too often its market value.

Back again to Lichens, taking for granted that so much knowledge, no matter how obtained, is possessed by all who peruse these lines. A fragment of an Apple twig covered with Lichens. The object is a common one, for there seems to be an affinity between old Apple trees and Lichens. On the occasion when we made a garden stroll for the subject matter of this chapter, the twig collected carried upon it two distinct forms—two well marked species. One of these of a bright golden yellow or orange, the other of a sombre ashy grey; one spreading closely over the surface of its host, the other somewhat erect and bushy. The close affinity which exists between Lichens and Fungi is not so evident in either of these species as in some others. For the benefit of those who are somewhat acquainted with the subject, we might suggest the comparison of some Parmelias and Lecideas amongst Lichens, with such Fungi as Peziza vesca and Peziza fusca, or many graphideous Lichens, with Fungi belonging to the Hysteriacei. In fact, there are points at which the two approximate so closely that it is exceedingly difficult, scarcely possible, to determine satisfactorily whether the organism should be classed with Lichens or Fungi. The proposition by Dr. Lauder Lindsay to establish a sort of intermediate order for the reception of what he terms Fungo-lichens is evidence of this close approximation.

Let us endeavour to gain some knowledge of the structure of Lichens from the orange specimen on our twig. It is common on old posts, palings, and barn-doors, and is the same that is so often found on old brick walls. Sometimes only yellowish green, but more beautiful, and more easily recognised when of the golden hue. The "common yellow wall Lichen" (fig. 224, B) is known to many by that name, who would not dare venture to call it Parmelia parietina, or whatever generic name the "latest authority" may think fit to adopt. It spreads over the surface of the twig, closely adherent to it by its under surface, and may be roughly said to resemble a patch of puckered orange paper, with a more or less regular outline, glued down to the bark. The vegetative portion of this Lichen is the flat patch, which is called the thallus, and, whatever form the vegetative portion assumes it bears this name. It is well to examine separately the vegetative and the reproductive system of these lowly organised plants, the latter usually arising from the former, although in some cases the former seems to be almost obsolete.

The surface of the thallus is irregular, dotted over with little cups, and the margin is finely lobed and lacerated. The under surface is whitish. The little cups belong to the reproductive system, and will receive attention hereafter. In order to comprehend the structure of the Lichen-thallus, a thin section should be cut with a sharp knife or razor, and examined under the microscope in a drop of water. By this means four superimposed layers may be made out, running into each other, or blended so as to form a compact thallus. The upper or cortical layer may be regarded as a sort of cuticle. It is made up of compacted cells, subglobose, elliptical, or rather irregular, by compression; in fact the whole thallus is cellular. Below the cortical layer is a series of globular, rounded, greenish yellow cells, called gonidia (fig. 225, E), which are said to be peculiar to Lichens. In some species this gonidic layer is close to the surface of the thallus. These gonidia frequently break through under certain conditions, and encrust the surface, giving the Lichen a mealy appearance. The "conidia" of Fungi are very different,* in many cases spore-like, and developed in clusters, or singly, at the tips of branched flocci, possessing the character of what are popularly called "moulds." As far as we know, the functions of the two also seem to be equally distinct.

The term "gonidia," applied to these thalline bodies in Lichens is certainly not a happy one, and would be much more applicable to the "conidia" of Fungi. It is questionable whether two words so similar in sound should be applied to things so distinct, associated with plants so nearly allied to each other as Lichens and Fungi. In fact, so close is the alliance in some cases, that the strongest evidence which could be offered has been that the presence of gonidia in the apothecia (no thallus being developed) established their claim to be regarded as Lichens, and not as Fungi. Gonidia are sometimes so freely developed in certain Lichens that they completely alter their appearance, so as to make them recognised with difficulty, Whole genera have been abandoned as spurious, because based on

FIG. 224.—APPLE TWIG, WITH TWO LICHENS ON IT.
A, Ramalina calicaris; B, Parmelia parietina; C, Apothecium; D, Osticlum.

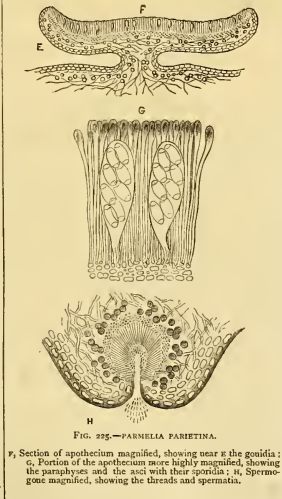

FIG. 225.—PARMELIA PARIETINA.
F, Section of apothecium magnified, showing near E the gonidia; G, Portion of the apothecium more highly magnified, showing the paraphyses and the asci with their sporidia; H, Spermogone magnified, showing the threads and spermatia.

metamorphoses caused by the excessive development of gonidia.

Lichen-gonidia possess a certain amount of reproductive power, and are in a limited sense reproductive buds. Whilst the cells of the cortical layer are compact, those of the gonidic layer are lax, each cell seeming to be quite independent of its neighbour, ready to make its way to the surface whenever an opportunity presents itself.

The third layer is sometimes called the medullary layer. It is a spongy stratum of elongated filaments, branching and crossing each other in all directions, and in some Lichens this is the lowest stratum, from whence proceed the root-like fibrils which are seen on the under surface of such species as the one commonly called "ground liverwort."

Lastly, there is in our "yellow wall Lichen" a fourth layer, or thin stratum of cells similar to those of the cortical layer, and this constitutes the under surface, which is applied to the matrix on which the Lichen flourishes, be it Apple twig, barn door, stone column, or brick wall.

A very pertinent question is nearly certain to arise at this point, when we have completed our examination of the vegetative system of this Lichen, Whence does this parasite derive sustenance? Does it grow at the expense of the tree on which it flourishes? If so, to what extent are Lichens detrimental to the trees on which they grow? These are questions which Dr. Lauder Lindsay has already answered, as far as his experience and opinion goes. Of course it is very much a matter of opinion after all, as there is but little positive evidence. Lichenologists have generally been in the habit of describing Lichens as deriving their nourishment wholly from the air, and not from the trees on which they grow. Cultivators of trees and shrubs seem to be almost unanimously of opinion that Lichen growth is injurious to the trees on which they are parasitic. Dr. Lindsay is disposed to think that the latter are nearer the truth than the former, and "that Lichens must be regarded as, in some measure, at least, parasitic, drawing the constituents of their thallus from the objects on which they grow." There is, however, so great a paucity of evidence, and that so unsatisfactory, that it cannot be regarded as settled whether Lichen growth is detrimental to trees, and to what extent.

Returning to our wall Lichen, we examine the surface of the thallus, and find it studded with little cups or discs of a rather darker colour, and near the margin of the thallus minute points or dots. These are the parts engaged in the process of reproduction. First and foremost the prominent discs, attached to the thallus by a short stem: these are the apothecia (fig. 224, C, fig. 225, F). If we make a section through one of these, and the thallus supporting it, we shall observe how intimate are the relations between them. The apothecium grows from the thallus, expanding into a flattened disc with a slightly elevated margin. In order to obtain a clean section for the microscope, it is recommended that a fragment of the thallus with its apothecia be inserted in a slit made in a cork of cork, and then sliced with a sharp penknife or razor, through both cork and Lichen. A good section may generally be made in this way, after a few failures, and the section may be permanently mounted for future examination. The great difficulty is to cut it thin enough. If cut smartly, and with a sharp instrument, it is generally uniform in thickness.

Having obtained such a section, let us endeavour to comprehend its structure under a quarter-inch objective. The margin and under-surface of the disc partakes of the cellular character of the thallus, and gonidia are also present. The rest of the disc, except the extreme margin, is called the hymenium, and contains the fruit. At right angles from the surface a mass of parallel threads are closely packed together, and mingled with them transparent, club-shaped sacs, each enclosing eight sporidia (fig. 225, G). These organs are called by the same names as in Fungi, and the structure really reminds one very much of that of the cups of a Peziza. The parallel threads are paraphyses, slender, jointed threads, more or less expanded, and club-shaped above, containing a few granules. Some say that they are barren asci, or spore-cases; others contend that they are not. Their functions, certainly, are not very clear, but there they are, and, undoubtedly, to serve some purpose. The membranous sacs, which inclose the sporidia, are the theca or asci, each enclosing eight elliptic sporidia, and each of these has a similar yellowish spot at either extremity, and are colourless in the centre. The sporidia in other species differ considerabiy from these in form, colour, size, subdivision, &c., and are in themselves excellent microscopical objects. It may be stated, in passing, that diluted tincture of iodine is very useful in examining many Lichen structures with the microscope, since by imparting a blue or brownish colour, almost invisible membranes are rendered distinct.

Beside the discs and their sporidia, contained in asci, there are other bodies concerned in the reproductive process, which are indicated by the small dot-like points, already alluded to, near the margin of the thallus. These are somewhat of sunken cells, with an orifice in the thallus, called the ostiolum. The mouth or ostiolum leads into a cavity surrounded by jointed threads, which bear at their tips minute slender, sinuous bodies in great profusion, called spermatia (fig. 224, D, fig. 225, H). It is supposed that these spermatia possess fecundative power, and represent the male element, as the apothecia enclose the female element, in the reproductive process. The details of the mode of action, and conditions of fecundation in Lichens, as in Fungi, are still unknown. Beside the spermogones, as the cells are termed which contain the spermatia, there are other organs found in some Lichens, called pycnides, but their functions are also very obscure.

* We confess to an error at p. 105, in referring "conidia" as applied to Fungi, to the same etymological source as "gonidia;" but we are still disposed to maintain that the two words have been confounded, and used interchangeably.

In this yellow wall Lichen we have a foliaceous species, with open, disc-like apothecia, and asci containing eight elliptic sporidia; these latter are supposed to be fertilised in some manner by the spermatia which are generated in the spermogonia scattered near the margin of the thallus.

Side by side with it on our Apple twig we find growing another Lichen, differing very much from it in habit, whilst agreeing in many other particulars. It is much less common in such a place than in some others, but here it is. This is a fruticulose species, having the bushy habit of a miniature shrub. The thallus is very much divided, springing from a button-like base. The genus to which it belongs is called Ramalina, probably because most of the species are found on dead twigs; and whether this is really to be regarded as a good species, under the name of Ramalina calicaris (fig. 224, A), or only a variety of another species, is of very little consequence to us. The thallus is cut into narrow, long, forked divisions, which are sometimes smooth, and at others ribbed or channelled. The apothecia are seated near the tips of these divisions or branches. These two Lichens, which we find flourishing on the same twig, may be accepted as examples of foliaceous and fruticulose species, so called from their habit, which in one instance is flat and leaf-like, and in the other erect and shrub-like. There is nothing very special to be noticed in the structure of this second species. There are spermogones, which are seated on the vein-like ribs of the thallus (or lacinia), and these contain straight, delicate spermatia. The sporidia are different from those of the yellow wall Lichen, but the manner in which they are produced in the apothecia is the same. In the present case it will be observed that the sporidia are elongate-oval, divided across the centre into two cells, and they are described as bilocular, or two-celled, and very slightly coloured.

Other Lichens are found in similar situations, but the two already described are sufficient to give a general idea of structure. It is not uncommon to find parasites on the thallus of some Lichens, consisting of apothecia only. Some of these are found on British Lichens than others. A few seem to be undoubted Fungi, whilst there are others of a character so doubtful that some cryptogamists consider them Lichens, and others Fungi. Here, as in Fungi, there is still much that is obscure, and close observers, with plenty of leisure, would find a wide field for research, and opportunities for discovery. Let no one suppose that everything is known which can be known even of the reproductive process in the lower Cryptogamia. It is true that much has been discovered of late years, but the subject is not by any means exhausted. No one has worked more closely and satisfactorily in our own country than Dr. Lindsay, of Perth, and the novice who is desirous of commencing the study of these interesting forms will find his "Popular History of British Lichens" an easy and safe guide.

Finally, there is one advantage which Lichens possess over many other low forms of plant life, that they may be easily preserved for years without alteration of form or colour, and a well-stored collection seems as fresh and natural in ten years as in ten hours. Fortunately also, little insects do not show such a predilection for them as for Fungi. Will not many readers collect and examine the common wall Lichen for themselves, and with that commence the study of these lowly organisms? All we can promise is, that if they do so "with a will" they will never repent. *M. C. C.*

THE CYPRIPEDIUM SCALE INSECT.

AMONGST the many curious forms exhibited by the different kinds of scale insects and their immediate allies, constituting together the family Coccidæ, none have surprised us more by their complete departure from the general form of the insect type than the scale insect represented in the accompanying woodcut, (fig. 226) which is parasitic upon Cypripedium niveum, and which has been kindly communicated to us by Mr. Herington, Esq., of Panty Goitre, Abergavenny, by whom a number of the plants were imported in the summer of 1870 from the west coast of Siam. Several of these plants flowered well, and in the month of January last about two-thirds of the whole were beginning to push up their flower-stems, one plant having as many as six or eight buds. Several, however, of the plants were then found to be infested with pretty little insects lying flat upon the surface of the leaves, and which had rather the appearance of minute, radiated, semi-transparent snowflakes than real insects.

The general appearance which was borne by a portion of one of these leaves is represented in the centre figure of our woodcut; whilst the figure on the right hand represents one of the scales highly magnified. The scale consists of a very minute, central, white mass, from which all round extends a most delicate, semi-transparent, white, flattened membrane, which is extremely brittle, and very difficult to move without breaking, and which is produced into eight conical points, which are thickened like the central mass, and beautifully white; occasionally these points are furnished on each side with a very minute branch, and there also runs, from the central mass to each of these points, a slender, thickened, white rib. These white lines are also to be seen on the borders of many of the more regularly formed species of scale insects, and seem to indicate the chief articulations of the body: thus the anterior point appears to represent the extension of the scale over the head of the insect, the three pairs of lateral points, the three pairs of legs, and the posterior point the abdomen of the insect.

The substance of the scale seems to be identical in its nature with the waxy secretion of so many Homopterous insects, and which varies from the hard waxy secretion of the lac insect and the white material of the Coccus Pe-la employed by the Chinese to make wax candles, to the white cotton-like covering of the American blight on the Apple, or the long thread-like filaments emitted from the bodies of the little jumping Psylla Buxi and other allied species; and which in the insect before us takes the shape of a flattened continuous scale, entirely covering the body of the real insect. Some of the more minute and younger scales were not so regular in their form, having nine or even ten points instead of eight.

On removing some of the largest of these scales, and turning them upside down, the under surface was found to be formed of a very delicate semi-transparent film, quite flat, and applied to the surface of the leaf, of an oval form, occupying the greater part of the under portion of the scale, and extending nearly to the bases of its eight prolongations. On very carefully removing this oval covering, there was discovered, lodged in the cavity formed between it and the upper covering, a regularly formed pupa of a male Coccus lying inactive in the cell, having the head small, furnished with two black eyes and two jointed antennæ, slender and extending beyond the base of the wing-covering; the head was followed by the semi-oval prothorax, having its pair of legs lying on its underside enveloped in their sheaths, whilst on the underside of this prothorax, near the basal part, or place of insertion of the forelegs, were two small black points, which may possibly be connected with the mouth of the pupa, and which may possibly be analogous to the curious mandibles of the pupa of certain Neuropterous insects which are found in a different state of development, both in the larva and perfect insect—(*e. g.*, as in Hemerobius and Myrmeleon) The mesothorax of the pupa of the scale insect before

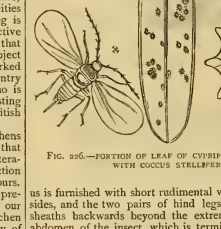

FIG. 226.—PORTION OF LEAF OF CYPRIPEDIUM NIVEUM, WITH COCCUS STELLIFER.

us is furnished with short rudimental wing covers at its sides, and the two pairs of hind legs extend in their sheaths backwards beyond the extremity of the oval abdomen of the insect, which is terminated by a small conical point, at each side of which is a minute bracticulated conical appendage.

From beneath one of the scales I had the pleasure to extract a fully-developed male scale insect, represented in the left hand figure of the accompanying woodcut (fig. 226). It is extremely minute, the natural size being indicated by the small crossed lines near the head of the figure. The head is distinct and transverse, with moderately long 10-jointed antennæ, of which the basal joint is short and thick, and the second joint very minute, the others being long, slender, and setose, gradually shortening beyond the fourth joint, which is the longest; the mesothorax has the deep transverse impression common to the males of these insects, and the scutellum is very large and semicircular, the legs long and very thin, terminated by an exarticulate tarsus, having a single apical hook or unguis. The abdomen is terminated by a single elongated style, having a small bi (possibly tri) articulated lobe on each side of its base. The wings are large and milk-white, with one strong vein towards the anterior margin and two others on the disc.

This result of the examination of these bodies has led me to the conclusion that the star-like scales are those of the males only, and that the female scale is of an elongated oval form, one of which may be observed in the central figure of our woodcut, lying close to the right side of the midrib of the leaf. This is a scale of the more ordinary form; it is clearly that of a female insect, having distinct legs, antennæ, and eyes; and on detaching one of these oval scales from the leaf several young larvæ recently hatched were found nestled beneath the body of their parent; these are minute active creatures, with six legs, and 9-jointed antennæ, of which the three basal joints are considerably the largest, and the tarsi are terminated by three long bristles.

This species of Coccus belongs to that section of the family of which the common Coccus (Lecanium) hesperidum, or scale of the Myrtle, &c., is the type; it will probably form a distinct genus in the system of Messrs. Targioni, Tarzetti, and Signoret. I shall, however, here simply indicate it under the name of Coccus stelliger. *J. O. W.*

PEACH AND NECTARINE TREES OUT-OF-DOORS.

I WAS much amused on reading in the *Sherborne Journal* "that the Rev. W. F. Radclyffe had brought down upon his head a hornet's nest!" This was accompanied by "D., Deal's," article. I regret having given so much pain to so many worthy men. The gardeners of England are, I believe, the best in the world, and certainly the qualified gardeners are generally an underpaid class. I am always gratified and surprised by their numerous and wonderful productions; still, to every qualified gardener there are hundreds of worthy men who have not had a gardener's education, and hence have not studied the "theory of vegetation and the phenomena of plant life." Against this class I have not a word to say. They do the best they can under the circumstances, and if their knowledge of arboriculture is not great, neither is their remuneration great. Till my articles appear in print (my eyesight not being very good) I cannot see what I have said. I ought to have said "the sad condition of Peach and Nectarine trees out-of-doors is, in many instances, the result of gross ignorance and neglect." It is difficult for a tailor to make a suit of clothes to fit all his customers, and it is almost as difficult to write an article on the treatment of Peach and Nectarine trees out-of-doors to suit everybody. The difference of soils, aspects, seasons, and other circumstances cause this difficulty. What may be right treatment in one soil or one season may be wrong in another. As, however, Mr. Henry Mills wishes me to say how the trees are generally treated here, I will do so; though I would at all times rather read another's article than write one myself. From the time that the late Dr. Lindley wrote to me a complimentary letter, expressing a wish that I should write for the *Gardeners' Chronicle*, up to the present, I am not aware of ever having intentionally written an ill-natured article.

There are three things that must be especially attended to, namely, the roots, the foliage, or first lung, and the skin, which is the second lung. Therefore, if the soil is swampy it must be drained. Even Willows do best in drained ground, though they like moisture. All my gardens, three in number, and lawn were tile-drained by me to the depth of 3 feet 6 inches. Before I did this, the Rose leaves turned yellow by September. Having built about 70 yards of 5, 6, and 7 feet brick wall against the cutting north wind and the violent west wind—the other points being open for miles to the south and east, the next thing to do was to buy some trees. I bought from the Blandford Nurseries some young and 21 old trees, some of which were from 10 to 16 years of age; some young trees from Mr. Rivers, and some maidens from Mr. Gray, of Brox; and so my walls were filled up. They are all healthy and vigorous trees; the aged trees are as healthy and vigorous as the young; and though some of them were naked at the base and centre, they are now nicely filled in. I pointed them out to Mr. Leach and Mr. Beck, respectively the very able gardeners of my friends Lord Portman and Mr. Sturt, a few days ago. They expressed themselves much pleased with the health, vigour, and cleanliness of all the trees, and also with the fruit, which is a good crop for such inclement spring. At the conclusion of this article I will give a list of the sorts used here, and I should say that not one of them is tender or difficult to manage, if properly attended to. It is fair to say that the trees are my "hobby," and that even a qualified gardener, with so much else and so many other things to supply in the course of the year, could not pay as much attention to them as I do. In a large garden there is usually a wide border, cropped with something or another; hence the walk is far from the trees. Here I only allow my trees an 18-inch border, and that is confined by the walks. Going in and out and down, I can see the *status* of the trees, and can easily manage them. The walls being low, there is no need of a ladder! Under the walls I keep low stools, so that I can perch under the trees and look up, and see what mischief is going on.

I carry a knife and scissors and measuring reel in one pocket, and a hammer, nails, and bast in the other, and thus I am enabled from time to time to shorten a twig or nail one in. I say from time to time, because it is not good to disturb the economy of the tree by shortening all the twigs at once. It is one of the causes of gum. I usually stop the shoots about the first week in June, a little shorter in July or August, and finally in September I stop them once more, including the terminals. I then remove all that is not wanted. Circumstances, however, may vary all this. Gardening is a matter of judgment and great experience. Instead of training in one long shoot, from 12 to 18 inches in length, I prefer three shorter shoots, from 4 to 6 inches in length, with an independent Peach or Nectarine on each twig, instead of three fruits on one shoot, from 12 to 18 inches in length. This, however, cannot always be done. Where there is a vacancy a longer shoot must be trained in for a future breeder. I like Mr. Bréhaut's alternate system, and strongly recommend his valuable work to pruners, whether they prune long, short, or alternately. I disbud less than

most people, and cut to an inch, or 2 inches in length, what others usually pull out altogether, taking care not to overcrowd the wall. Hence I have more chances of fruit, and a better chance of ripening the wood.

What we want is a fruit at the base of the twig and two successional shoots, the one to be spurred and the other to be pinched at greater length. Thus the foliage being at shorter distances and nearer home, is the more available for the depuration of the sap in the main wood; and the base and centre of the trees, instead of being bare, are well filled up. In gardens, where long pruning, and by consequence much disbudding, are practised the trees in the course of time get "naked as lances!" unless it is done by a scientific pruner. Good foliage is a matter of the greatest consequence; because, as it is true in a spiritual sense that "the leaves of the 'tree of life' are for the healing of the nations," so in a secular sense the leaves of every tree are for the healing of the tree. Moreover, without good foliage, fruit can have no flavour. The sun, last summer, struck Alexandra Noblesse and the Princess of Wales in the crux of a wall, and their fine crops were perfectly tasteless. The ripening of moderate wood of course is the grand wind in the key of success, as before cropping. In order to get my wood ripe, and the skins hardened before severity sets in, I cut off in September, or as soon as the crop is taken, half of every leaf, which allows the sun and air to have access to the twig. By the first or second week in October every leaf is off; and from that time the severity sets in the skin hardens, and the twig, instead of being soft and of a pale sickly green, becomes blood red or mahogany colour. This cutting off of leaves I can afford, because I disbud but little in the spring, and the trees are full foliaged. I do not advise this practice to trees that are sickly, or that have had bad foliage, or a short allowance of it.

There is one other matter of great importance in two such torrid summers as the two last, namely, supplying the trees with mulching, copious waterings, and constant syringing to cool the walls and refresh the parched skins. I believe the sufferings of last winter did not arise from severity, pure and simple, but from ill health previously contracted from other causes. I did not use my coping sheets at all till the buds and foliage showed signs of development. The winter had no effect whatever on the trees. An animal well fed against is well wintered, and if people want their trees to stand such a hyperborean winter as the last, and crop, they must feed them properly, according to the requirement of each tree, stop their shoots, so as to shut back the early sap upon the cambium for the formation of fruit buds, keep their foliage clean, cool the walls in torrid summers, mulch freshly moved trees, supply abundance of water to the roots, and put on a sufficient covering early, to defend the blossoms and the starting foliage. The foliage, when it first spears out, is very tender, and will assuredly blister more or less, unless you keep it dry. It is the dew that gives the first power to bite and disorganise the cuticle of the leaf, which, as it grows, assumes the form of a gutta-percha ball! When the leaves are fully expanded and hardened they rarely blister.

"D., Deal," says I keep many trees, and small: that is correct. Some of my trees are very small, and are placed at the base between two larger trees, and others are riders—more properly, I believe, spelt ryders—a parliamentary legal term denoting an additional clause to a bill; thus, otherwise useless spaces below and above are filled up. I pursue the following plan when trees grow too robust to bear: I take them up, cut their roots hard, plant them on the hard, unbroken ground, and cover the roots with a molehill; they then form fibrous roots, and make fruit-bearing wood. In the autumn they are carefully taken up, without breaking a fibre of the root, and are the subject of some other recalcitrant tree, which undergoes the same process. I have now two Bellegardes laden with fruit that were so served. I practise this on a wall facing the east.

I conclude by recommending the following Peach and Nectarine trees in the order of fruiting. They are all hardy and robust trees, and their fruits are excellent:—

Peaches.—Early York, Dr. Hogg, Early Alfred, Early Ascot, Grosse Mignonne, Noblesse, Royal George, Violette Hâtive, Bellegarde, Barrington, Nectarine Peach, Prince of Wales, Princess of Wales, Lord Palmerston.

Nectarines.—Elruge, Violette Hâtive, Rivers' White, the Old White, Rivers' Orange, Rivers' Victoria. The two last Nectarines are the finest of all, and very valuable. I took a dish of Orange and Pine-apple Nectarines to Lord Rivers last year, and the ladies had them for luncheon, and pronounced them the most delicious fruit they had ever eaten. The largest Pine-apple measured 8¼ inches, and was red as a harvest-moon. I have a capital crop of this fine Nectarine now on the trees. I have written the above just as it occurred to my mind. I hope I have expressed myself "contemplay." *W. F. Radclyffe.* [Not only blunt-spoken, but well-spoken. The truth is, that there are gardeners and gardeners, and the whole community too often has to suffer the reproaches which properly belong but to a section. It is a pity that public opinion cannot be brought to bear on the inefficient, the careless, or the dishonourable, without wounding the susceptibilities of those who fall under neither of these categories. EDS.]

Home Correspondence.

The Linnean Society's Journal.—In a recent number of the *Gardeners' Chronicle* (which I have only just seen), there is (p. 777) a notice of the last part (number) of the Journal of the Linnean Society, and the writer remarks that some of the papers were read as long ago as 1869. With regard to one of these, the title of which, I may remark, is mis-spelt in your columns, there were special circumstances which I need not detail which would account for the delay. The other of the two is a very short communication—little more than a note; and I am sure that neither the assumption nor the Fellows would make a grievance of its having been postponed in favour of papers of greater importance. *Fred. Currey, Sec. L. S.* [As our correspondent takes exception to our statement, we add the following particulars relating to the number in question, issued on May 23, 1871, and containing about one hundred 8vo pages, with one plate. The nine papers there published were read to the Society on the following dates—1, April 15, 1869; 2, June 3, 1869; 3 and 4, March 3, 1870; 5, April 7, 1870; 6, May 5, 1870; 7, June 2, 1870; 8, June 16, 1870; 9, June 16, 1870. From which it appears that in the majority of cases more than a year elapsed between the reading and the publication, and the shortest period was about 11 months. If we look further back to the zoological numbers, we find even longer intervals. We are aware that there are special circumstances which have prevented some of these papers from being issued earlier, but the general body of the Fellows, still less the outside public, know nothing of these impediments; and assuming them to be unavoidable, some explanation might well be given. The President's paper on Cassia, for instance, is looked for with much interest, but how many of the Fellows are aware of the cause of its delay? EDS.]

Dinner Table Decorations.—Some objections having been taken to the decorations which, with the assistance of several amateur friends, were arranged on the day of the Rose show at the Crystal Palace last year, I should be obliged if you could find me space for a reply to them. The principal features were the introduction of young Palm trees, the sinking of their pots through the table, and the use of tall trumpet-shaped vases with climbing Ferns, drooping from the top, and trailing around the stem down on to the cloth. The intention was to show how such tall objects can be employed without interfering with the view, or with conversation, across the table. With respect to the use of Palm trees, it has been objected that their costliness puts them beyond the reach of any one but a millionnaire. I daresay that there may have been Palms up to the value of £50 on that table, which was large enough to accommodate 30 persons. But, when it is remembered that the cost of the best dinners in London and other large places varies from 3 to 4 guineas per head, and that there are two or three Londoners who subscribe £5 each towards the collection for the occasion for £5 or £6, the objector on the score of their costliness will be obliged to acknowledge that they only affect the price of such a dinner to the extent of 3*s.* or 4*s.* per head, a trifling amount in the estimation of thousands of wealthy dinner-givers in and near the metropolis. The Palms required for such a table must be moved in one of the covered waggons used by nurserymen in taking specimens to the flower shows, and when packed for travelling only occupy one-third of the waggon. In every case of my using them, the waggon has been laid up with Dracænas, Rhododendrons, Dacrydiums, Ferns, or any other greenhouse foliage plants that the nursery could spare, without any extra charge. These, of course, are very useful for ornamenting side-tables, or for filling the angles of the room with pyramids of foliage, but contrast well with the bold foliage with that of the Palms on the table. I have paid as much as 10 guineas for a van-load of Palms only, but the effect produced by them was not commensurate with the expense. To those who reside at too great a distance from a nursery to be able to hire Palms, and who may have been frightened at the cost of purchasing them, it may be some satisfaction to learn that young plants of many species are now to be bought on much more easy terms than formerly. The next objection to which I desire to allude is the supposed necessity for cutting holes in the tablecloth and in the mahogany, to allow of sinking the flower-pots through the table, and consequently the impossibility of doing such a thing, except in large places, where the expense of providing tables and tablecloths expressly to meet this requirement would not be a consideration. I have repeatedly heard it remarked (in a tone of voice that indicated no very great belief in the sanity of the proposer of such an idea), that no one would be likely to cut a hole in his dining-table, merely for the sake of putting a flower-pot out of sight. To such objectors I would make the following reply: When your family party at dinner is likely to be increased by the advent of a few friends, you are obliged to put in one or two extra leaves to your table. For such occasions be prepared with one or more extra leaves, which any joiner will make for you, of well-seasoned deal, at a cost of a few shillings each. In the centre of each of these deal leaves describe a circle large enough to admit through it the biggest flower-pot you are ever likely to use, and with a keyhole-saw cut out this circle on the bevel, so that the circular piece cut out may be dropped into the hole, if necessary, without falling through. So far, therefore, from this plan being only available by the privileged few, the humble possessor of a diningroom 6 feet by 4 may entertain his little party of six and have sunk in the centre of his table the choicest specimens of his amateur efforts in floriculture. Again, to the objector who sees no way of managing to lay his cloth without cutting a hole in it, I would say, use two tablecloths, folding each one into half its usual length, and put one to each end of the table, bringing the folded edges close together, and ironing them down quite flat. For fear of this line across the table being disturbed by the shifting of plates or dishes, it is desirable to prevent the edges of the two cloths from coming apart by putting in two or three pins, or tacking it here and there with white thread before ironing it; and as a still further precaution, it is advisable to lay sheets of white blotting-paper, or two small white cloths on each side of the plant under the join of the two tablecloths. Having thus replied to, as I hope, have explained away, the assumed difficulties of this kind of dinner-table decoration, I will now only add, with reference to the tall trumpet-shaped glasses, that their height should be in proportion to the width of the table upon which they are used. For the centre line of a table 4 feet wide, glasses may be 18 inches high. A semi-circular wire arch, connecting two of these glasses, and covered with some climbing plant, is a very pretty decoration for the centre of a small oblong table. *W. T.*

Galls on Rhododendrons.—With reference to the question relating to the existence of galls on the leaves of the Rhododendron, if it be of any interest, I may state that having been led to closely examine the various varieties of Rhododendron nilagiricum (through having failed to collect and transmit the seed of the white and pink kinds at one time), I can almost affirm that no galls are produced on this species in its natural habitat. *James MacPherson.*

Recognition of the Services of Mr. Geo. Eyles.—I prefer putting it in this way. Testimonials have become somewhat hackneyed, and besides, they mostly succeed work, and, alas! too often close it. But in this case I trust the expression of our appreciation of many and long services will be also accepted as a pledge of their continuance for many years to come. He is still in the prime of life, his full strength mellowed by experience, and his wise plans of serving and illustrating horticulture ripened by many years of practice in two of the best and largest gardens in the country. Very few but thoughtful exhibitors really know how much horticulture owes to Mr. Eyles. For many years he has been the strong link that has bound some of the largest societies and their exhibitors together, in such a way as to keep up an unbroken succession of splendid exhibitions, of much benefit to trade, draw the public, and to strengthen and deepen the general interest in horticulture. He has even done greater and higher work than this. At the Crystal Palace especially he displayed a tact and an energy in the furnishing and management of the Palace and grounds, which will ever make him rank high among eminent and scientific horticulturists. It would be beside my purpose to advert to other labour at Chiswick and Kensington, or to cite examples of his tact as a landscape gardener, in which profession he has made an honourable position. We are not simply to express admiration and esteem of the courteous and able manner in which he has always discharged his somewhat onerous duties as manager of flower-shows. Every one who knows Mr. Eyles must be anxious to do that. His quiet, most efficient mode of management is beyond all praise. I confess that first brought into closer contact with Mr. Eyles at the Royal Show at Bury, I did not quite understand him. His unmoved manner puzzled me. Was it consummate generalship, or was it happy-go-lucky-ism? —to coin a long but most expressive word, Let his brilliant victories of perfect management answer for him. I quite envy Mr. Eyles his self command, his immobility amid scenes of trial, worry, and intense excitement. Enthusiasm—no, I won't paint a picture. But ever and anon George Eyles is found unmoved amid it all, pouring oil on the troubled waters of rising strife, smoothing down difficulties, unravelling the tangled skein of confusion, and bringing order, beauty, finish, out of chaos. Scarcely heard, but seen everywhere, he moves about like a fabled magician of the olden times, before him a medley of confusion, behind a garden of Eden. He has an ear for the complaints and the requests of all, a word of advice, instruction, or encouragement, and a kindly greeting for friends however hardly pressed. It does honour to the head and heart of those who conceived the happy thought of expressing esteem for Mr. George Eyles. I hasten to join in the good work, and I hope all will have a hand in it, that our gifts may be in some measure worthy of our esteem; and as we lay them at

his feet our hearts would exclaim, "Thus shall it be done unto the man whom the exhibitors"—shall I not write the gardeners?—"of Britain delight to honour." *D. T. Fish.* [See p. 1004].

Bickley's Mode of Glazing.—In answer to "G. A. H.," allow me to say that I have to pay nothing extra for having glass cut perfectly true and square, and that the curvature of English glass is so slight that it leaves no opening in a 20-inch length; the same also applies to 21-oz. foreign 48s, or 16-oz. 32s. I may add that the glass may be lapped ¼ inch or so, a strip of glass or felt 1 inch shorter than the width of squares used being laid horizontally on the zinc bar, under the lower edge of each raised square. For an orchard-house I should recommend good 16-oz. English sheet glass, cut true, and simply butted together at the sides; this ought to be obtained in quantity at about 2*d.* per foot for cash. The whole of the glass, 378 feet, was removed from the orchard-house which I exhibited at Nottingham, in 32 minutes, by a man and boy, and re-inserted firmly in 1 hour and 10 minutes without any breakage, or injury to the house. The advantages of this will readily be seen by those who possess orchard-houses, especially if they have to water and syringe the occupants during summer months such as we experienced the three years preceding 1871. *Thomas A. Bickley, 70, Smallbrook Street, Birmingham.*

Heilkraut.—No doubt Comfrey (Symphytum officinale) is termed Heilkraut on account of its medicinal properties. In Sussex it is cultivated in many cottage gardens, and utilised in making a cooling ointment, very much esteemed by some, and, perhaps, not to be despised by any. It is also sometimes used as a substitute for borage in making a cooling beverage called cold-tankard. *H.*

Your correspondent (p. 980) inquires why Comfrey (Symphytum officinale) is called healing herb in Germany? The root of this plant boiled with coarse sugar, in equal proportions, and strained through gauze, forms a gelatine, which is very healing, and much used for affections of the bronchial tubes and lungs. It is said to possess the useful property of restoring the necessary mucus for re-coating abrasions arising from internal inflammations. *C. B. S., Surrey, July 29.*

Lilium giganteum.—I believe it is not generally known that this Lilium is perfectly hardy. In the gardens at Ravensworth Castle, Durham, can now (July 20) be seen a magnificent plant in bloom, about 6 feet high, and Mr. Moult, the gardener, assured me that it had been there for the last two or three years without receiving the slightest protection. This is certainly a grand and noble acquisition to our hardy border plants. *William Burton, Victoria and Paradise Nurseries, Holloway.*

Caterpillars v. Fruit.—I can fully endorse the remarks of "G. A. H." respecting the use of Hellebore powder for the destruction of caterpillars on fruit bushes, but I should advise those that have never used it to wear a handkerchief over the nose and mouth, because the powder is apt to cause violent sneezing. I have found the middle of the day to be the best time for using it, especially if a hot sunshiny day, for the caterpillar does not appear so active then. It has often struck me as curious, that while lime and soot, mixed in equal quantities, will destroy caterpillars on the Brassica family, it has no effect on the caterpillar that attacks the Currant and Gooseberry bushes. *W. S.*

Grape-growing at Kingston Hall.—I have read with much interest and satisfaction the reports by your able correspondents on the condition of these Vines, and have long thought that the time required, I should fully verify the high eulogium passed on their merits. At the same time I wish to correct a mis-statement that both writers have made in asserting that there were no pipes at all in the chambers under the borders; and to do this more fully it will be necessary in the first place for me to revert to the original method adopted by Mr. Sylvester in the heating of these vineries, *i.e.*, that of placing the whole of the pipes in arches underneath. This method was a favourite one with Mr. Sylvester, and though most absurd it was carried out in all the houses then at Kingston, the vaulted passages underneath the interior of the vineries being constructed to receive the pipes, with arches between to form the beds in the interior. This was purely and simply the purpose of these vaults, and not to supply heat to the borders at all. Twelve ranges of Sylvester's winged pipes were placed along these passages, the heat from which passed to the surface by means of pigeon-holes on each side of the three paths, these apertures being so arranged as to promote the circulation of the heated air. These particulars, with a great measure exulting "F." to at once comprehend the peculiar construction and complication of the arches underneath the interior. The present system of heating was executed under my directions, and I have no doubt your correspondents will be surprised to hear that each border is separately supplied with two 4-inch pipes in chambers underneath them, which are external to the houses, there being no connection whatever with the border chamber and that underneath but by means of a small door, and the Vines are planted immediately over the chamber supplying heat to the border. I may here mention that the whole of the Vines were lifted and the soil removed during the time that I was at Kingston, so that I am in a position to give a pretty accurate statement as to the formation of the borders, &c. I quite agree with "F.," and have previously stated, that the most rational method of heating is through the rubble, the bottom being made impervious to the roots. Allow me to say, in conclusion, that I write in no carping spirit, but purely to justify what I have previously stated, as well as to show the actual state of heating, believing that neither of your correspondents would knowingly make a mis-statement. *Geo. Westland.*

Japan Radish.—I bought in the spring some highly vaunted new sort of Radish seed from Japan, about 16 in a shilling packet, said to grow to a very large size, and of oval shape, of fine flavour, and very crisp. They soon came up, with large leaves, and when I thought them ready to draw, pulled up two with a long slender root as thick as a small cow-quill, and as tough as a piece of stick. They soon sent up a flower stem, and have yielded, with a second parcel (18 for 1*s.*), a fine crop of seed. I bought a second lot, being told they required room to enlarge, but the second lot proved as worthless as the first, and I will thank any one who will tell me if they have grown any of this new Japan Radish worth eating, as I think them of no value. I shall make a sowing late in autumn, as many of these things are grown at high elevations where the temperature is very low in Japan. *Thomas Ingle.* [Does our correspondent mean the Madras or Rat-tailed Radish, the pods of both of which are edible? EDS.]

Ventilating Plant Structures.—The notes on the above subject in your number of the 24th ult., p. 906, seem to have attracted the attention of your correspondent, "A. W." who is desirous I should give some further details, so as to bring the plan within the comprehension of a country carpenter. Without diagrams, a plan of the structure intended to be ventilated, or any kind of data upon which I may found a reply, I feel I am placed in considerable difficulty. I will, in the absence of detail, assume that "A. W.'s" plant-house has a row of front lights, of the same dimensions between the sill and the top plate; these should be all attached together by iron plates fixed on the sides, and connected from one to the other by a circular iron bar, forming the back rail, which circular bar, connecting the two plates, is suspended on and in the upright bars, which form the framework of the front or side of the structure. To secure the perfect and regular working of the lights, these bars are encircled by an iron thimble. The screw which works the whole is fixed upon the front platform, immediately opposite the centre of one of the lights, the centre one being preferable, inasmuch as it equalises the strain upon the light, which, I venture to say, is little, if the fixings are properly made, the strain upon the iron work from the iron which connects the whole, and links them very firmly together. Attached to the screw, and worked by the worm of it, is a cog-wheel, with a larger wheel and a band, or line, attached to it, which, supposing the top lights to be fixed in the same manner, move the whole together, so that they may be opened one or more inches, as circumstances indicate necessary. The plan is very simple, and easy of application, but special cases will require specific details; and, however desirous a writer might be to elucidate a case without particulars, I fear he would barely be understood. *Charles B. Saunders, Jersey, July 24.*

The Potato Disease.—In reference to the Potato murrain, recently noticed by Mr. Earley, allow me to ask, has Mr. Earley, or any other of the readers of the *Gardeners' Chronicle*, tried the following plan?—When the disease (or murrain) appears in the leaves, take the stalks in your hands, and place one foot on either side of the row, as near the stalks as possible, and pull up the stalk boldly, leaving the tubers in the ground, carefully filling up the hole made by the stalks with soil. If treated in this manner, the disease in a great measure will be prevented from doing any more harm to the tubers. By so doing the tubers will not be quite so large as they would be if the stalks were allowed to remain, but I presume it is far better to have a small amount of Potato tree from disease than to have a large one that is diseased. It has been tried in a garden here for the two last seasons, with a good result. *J. S.*

The Pot Culture of Vines.—For many years past I have occupied myself with the culture of Vines in pots, and have had great success in all its phases —with pots plunged, or placed on hot-water pipes, or on borders in a common forcing-house. My attention has been called to a passage in the "Gardener," by Mr. Wm. Thomson. He says, that when Vines are grown "too thickly in an upright position in the centre of houses devoted entirely to themselves," under such circumstances "sound and fruitful growths, though strong, cannot be produced, and we would advise growers to avoid such conditions." Now, according to my experience, this is and has long been the method of growing Vines for sale in most of our large establishments; I have, however, seen 2000 Hamburgh Vines grown on dry heat and trained close under the glass. The Vines are not quite so stout as those grown as above, but their canes and roots are hard and ripe, and the buds from 3 to ¾ inches asunder. These I saw with Mr. Rivers, who prides himself in having grown on a 4-inch hot-water pipe, in a 12-inch pot, a Vine upwards of 30 feet in length, and well ripened. When the pots are plunged in tan the Vines emit roots in it, which increase the bulk and the foliage, but not soundness. *Vitis.*

Gigantic Puff-balls.—The following dimensions of a gigantic Puff-ball found by the under-butler here on the 25th ult., may be worth recording:—Breadth, 3 feet 3 inches; height, 2 feet 9 inches; weight, 7 lb. I have just seen it, and both weighed and measured it, in the presence of the butler. I may add that I never saw one at all approaching the size of this specimen. *Charles Hubbard, Gr. to Lady Berners, Keythorpe, Leicestershire.*

——I have gathered some very large Puff-balls here this season. The largest in diameter measured 17 inches, and was the best flavoured I ever ate. They grow in abundance on some very rotten manure, under some Elm trees in the park, which no doubt has been here some years. *James Martin, The Gardens, Osterley Park, Southall, W.*

Laxton's Alpha Pea.—Noticing the letter in your columns regarding this Pea, we beg to say that it has proved in our trial-ground to be second to none for earliness, at the same time having a decided advantage in flavour over Ringleader, Daniel O'Rourke, and others of the same class. Kentish Invicta, also, we find quite as early, of excellent flavour, and very distinct. Of the two dwarfs, Little Gem and Multum in Parvo, we find the latter is a larger cropper, of better flavour, and similarly early, therefore superior to Little Gem. *James Dickson & Sons, Newton Nurseries, Chester.*

Exchanging Seedling Ferns.—As I was looking over my old files of the *Gardeners' Chronicle*, I found, just now, in July 25, 1868 (p. 790), the proposal of Mr. C. W. Swaland, Hildenley, to exchange his seedling Ferns for those of other growers. Like him, I have multitudes which are constantly going to the dunghill, possibly some that he might be glad of. Besides, the matter may be worth re-agitating, for the reminding of other growers. *P. H. Gosse, F.R.S., Sandhurst, Torquay.*

The Thinning of Grapes by the Syringe.—If the communication under this heading, signed "A Practical Hand," July 15, is intended as an answer to my query, "At what stage of the swelling will Grapes be syringed to check setting?" then "Practical Hand" has mistaken its drift altogether, as his answer refers to the idea of thinning Grapes after they have set. *A. Boyle.*

Caterpillars and the Fruit Crops.—In the last number of the "Canadian Entomologist" Mr. W. Saunders, of London, Ontario, gives an illustrated life-history of an allied species of Gooseberry saw-fly (Nematus ventricosus), a most destructive pest in North America. Mr. W. Saunders says:—"The fly deposits its white eggs in long regular rows on the under sides of the leaves, chiefly on the larger veins, where they speedily hatch, and the hundreds of voracious worms resulting are soon scattered all over the bushes. Already (July 15), the eggs are very numerous, and here and there may be found a colony of larvæ. These latter, while young, feed in company, from 20 to 40 on a leaf, which is soon riddled with the small holes they at first make, but in a few days they increase in size, and, parting company, spread in all directions. By keeping a sharp look-out, picking off the stem leaves early in the season, the evil will be much lessened, but where the worms are numerous there is nothing so good as powdered Hellebore, which may be readily and economically applied by mixing an ounce (previously rubbed up with a little water to prevent its being lumpy) in a pail of water, and showering it over the bushes with a watering-pot. Many people are timid about using Hellebore, while the fruit is on, for fear of its finding lodgment there in quantities sufficient to produce unpleasant consequences when the fruit is eaten, but if applied in the way just mentioned, there need be no apprehensions on this point." Mr. Saunders, in the same interesting paper quoted above, also gives illustrated life-histories of the Plum Curculio and the Codlin moth (Carpocapsa Pomonella). Speaking of the latter insect, so destructive to Apples, Mr. Saunders informs us that "excellent traps may be made for them out of common bottles—wide-mouthed ones preferred—by partly filling them with a mixture of vinegar and water, well sweetened with sugar, and having a little rum or other strong-smelling spirit added to it. These may be fastened among the branches with wire, string, or pieces of wire. The insects, being attracted by the smell of the compound, are lured into the bottle and drowned, and thus the mischief they were about to perpetrate is nipped in the bud. Later in the season the wormy fruit should be carefully gathered, and either dipped in boiling water to destroy the grubs, or fed to hogs." Our entomological friends across the Atlantic are doing well in giving us illustrated life-histories of all garden and farm pests, through the

medium of the "Canadian Entomologist," a capital periodical, mailed free to England for the low price of 5*s.* sterling, by E. B. Reed, Esq., London, Ontario. *Henry Recks, East Woodhay, July 29.*

Societies

ROYAL HORTICULTURAL: *August* 12.—W. W. Saunders, Esq., F.R.S., in the chair. The usual preliminary business being concluded, the Rev. M. J. Berkeley announced the awards of the Floral Committee, and in doing so took occasion to remark, when alluding to a golden form of Juniperus chinensis shown by Mr. Maurice Young, of the Milford Nursery, Godalming, that such plants when grown in the shade usually reverted to the green state, and that they kept their golden colour only when fully exposed to the sun. Adverting next to a fine plant of Eonanthera coccinea, shown by Mr. Parker, Tooting, Mr. Berkeley observed that the flowers were not so deep in colour as he had seen them before, but still the plant was interesting on account of its being but rarely seen. At the last meeting a small fridaceous plant of considerable interest was shown by the present chairman, and was considered to be a species of Tritelea, but on searching for further particulars in the Herbarium at Kew, in connection with Mr. Baker, they had discovered that it very much resembled Watsonia plantaginea, and they had come to the conclusion that it was a species—and a most interesting one—of that genus. On the present occasion, continued Mr. Berkeley, the chairman had brought before them several very remarkable plants, including a plant of an unnamed Dieffenbachia, which exhibited an exceedingly curious case of fasciation, two leaves being joined together back to back, the result of the coalition of two petioles. Such an instance he had only seen once before, in a species of Ficus. Next to come under notice, and from the same exhibitor, was a pretty little species of Cyrtanthus, from the Cape of Good Hope, which he (Mr. Berkeley) thought was a form between C. angustifolius and C. collinus, the foliage partaking somewhat of that character of both, but which in the case of the first-named was green, and in the latter glaucous. The specimen of Calochortus flavus, said Mr. Berkeley, was perhaps the least showy of a handsome tribe of Liliaceous plants, and which he had never seen in such beauty in this country as he did in the early days of Chiswick, when a batch of tubers sent over by Douglas were planted in a peat bed under a north wall, in which position they throve very well that they could not have appeared more beautiful in their own country. The speaker then directed attention to Lilium Leichtlini, one of the best of the Lilies, and to a magnificent example of the old Tiger Lily, the name of which there was great doubt whether it was L. splendens or L. Fortunei, though Mr. Berkeley said he thought it very distinct from the type, since it grew to a great height, and on the plants shown there was a most pronounced woolliness on the stems, which he had not remarked on the older kind. Mr. Berkeley concluded by mentioning a remarkable circumstance in connection with some specimens of Messrs. Cripps & Sons' new Cape Pelargonium aurea that was not generally known, namely, that in the Catalpa the petioles had a solid pith, unlike all other petioles, as would be seen on comparing them with those of a near relative, the Pelargonium inquinans, which has a soft pith. The latter plant flowers early, and the former late, which he considered was a sufficient reason why the Catalpa should be the more frequently grown.

The Secretary, alluding to a singularly striking new Coleus, shown by R. Tryon, Esq., Loddington Hall, Leicester, remarked that in this instance the variegation had taken an entirely new direction, as instead of being, as heretofore, distributed longitudinally, it was banded or transverse; and this would no doubt open out other forms of variegation in a similar direction. For the Cyrtanthus, the speaker said he was indebted to a gentleman at the Cape, who had paid much attention to the flora of the district, and who had informed him that plants at the Cape assumed such differences, under different conditions, that though he thought this was distinct, he would be sorry to say so definitely.

Floral Committee.—J. Fraser, Esq., in the chair. This meeting was the series of bringing out one of the most decided novelties of the season, in the Coleus named Tryoni, in which the variegation, which has usually been distributed longitudinally, is in this instance transverse, one-half of the leaf (that near the leaf-stalk) being of a rich glowing crimson, and the outer portion of a golden yellow. It was exhibited by Mr. Guildford, gr. to R. Tryon, Esq., Loddington Hall, Leicester, and received the highest award that could be given to it—a First-class Certificate. Mr. Laxton, Stamford, also contributed a most desirable acquisition to the group of double-flowered Pelargoniums in level, a variety raised from Madame Rose Charmeux, in which the foliage partakes strongly of the Tom Thumb character, the trusses of flowers being of medium size, each pip more resembling the bud of the Fairy Rose than the flowers of a Pelargonium. It is without exception the prettiest thing for button-hole bouquets that we have seen. A First-class Certificate was awarded. Mr. Maurice Young, of the Milford Nursery, near Godalming, sent several examples of Juniperus chinensis aurea, which received a similar award. With the exception of the bright golden variegation it is in character the exact prototype of the old Chinese Juniper, from which it is a sport, of some 16 years old, during which time it has never once reverted to the green form so that it may be considered as an acquisition to the list of beautiful variegated trees for the ornamentation of lawns and shrubberies. First-class Certificates were also voted to Messrs. Kelway & Son, Langport, for three new varieties of Gladioli, named Hogarth, blush, crimson flamed; Oberon, blush, heavily flamed with crimson, and much resembling Julie; and Pictum, a large flower, resembling Adolphe Brongniart, with the exception that this has a deep maroon centre; to Messrs. Wood & Ingram, Huntingdon, for Picotee Delicata, white, and one of the 2d class for Picotee Mrs. Ingram, white, with crimson edge; to Messrs. E. G. Henderson & Son for Begonia multiflora elegans, red, and said to be a perpetual flowerer; to Mr. Fraser, The Nurseries, Lea Bridge, for a fine new Dracæna, named Fraseri, with very distinct, robust foliage of a deep bronze colour edged with crimson; to Mr. N. Nonelius, Funstead, for Picotees Miss Ingleton and Ada Ingleton, and one of the 2d class for Charles Williams, Esq.; to Mr. Green, gr. to W. W. Saunders, for a small orange-flowered species of Cyrtanthus from the Cape of Good Hope; and to Mr. J. Laurence, gr. to Bishop Sumner, Farnham Castle, for the beautiful Anæctochilus Ordianus. From Mr. Frisby, gr. to H. Chaplin, Esq., M.P., Blankney Hall, Lincoln, came a group of new Tricolor Pelargoniums of Ladelias; and Mr. Turner sent a specimen of Renanthera coccinea. Messrs. Veitch & Sons sent a stand of 10 varieties of Phloxes, and Messrs. Cripps & Son, Tunbridge Wells, sent two new Clematis, William Cripps, deep violet-purple, and Lady Marie Meade, very large and of a bright lilac colour. Messrs. Bell & Thorpe, Stratford-on-Avon, and Messrs. Rollisson & Son, each contributed well-grown examples of Ladelias; and Mr. Turner and Mr. J. Mann were exhibitors of new Zonal Pelargoniums. Messrs. E. G. Henderson & Son sent a group of Lobelias, Fancy and Tricolor Pelargoniums, and Platycodon grandiflorum. Messrs. Scott, gr. to Miss Coventry, Blackheath, sent a variety of Oncidium carthaginense. Messrs. Carter & Co. had a Second-class Certificate for Tricolor Pelargonium Prospero, and Mr. T. S. Wilson a like award for a nice collection of Liliums. Mr. Cannell, Woolwich, sent a stand of a dozen new Verbenas.

As on the last occasion, a small tent near the Council room was also filled, this time principally with the various forms of Pelargoniums. The great feature of this display was the competition for prizes offered for seedling Tricolors by Mr. R. Morris, Esq., of Deptford. The first class was for a group of seedling varieties of Golden Variegated Zonal (Tricolor) Pelargoniums, not to exceed six in number. The competitors were Messrs. Downie, Laird & Laing, Mr. Turner, Messrs. F. & A. Smith, and Mr. Laing, the 1st prize going to the latter exhibitor, and the 2d to Mr. Turner. In the 1st prize lot the plants were raised this year, and bore the names of Brightness, Blithe Hill, Flora MacNab, Decision, Stanstead Eclipse, and Gloria. The 2d prize lot also took the 1st prize for the best in class 1, so that Mr. Laing is to be congratulated on his success, this being the first year in which he has attempted to raise this class of plants. The other two classes, older, and of course quite meet the terms of the schedule. The best collection of variegated varieties was staged by Mr. Turner, and consisted of 33 named sorts, Messrs. Laing being 2d with 32 sorts, Messrs. Bell & Thorpe 3d, Messrs. F. & A. Smith also competed with large plants, mostly deficient in colour, the latter receiving an extra prize. Messrs. Downie, Laird & Laing had a dozen varieties neatly, shown in baskets, and came in 3d. The best single Gold and Bronze Zonal (Bicolor) was Maréchal MacMahon, in which the 1st prize was awarded to Mrs. Meachy, also from Laird & Laing; Mr. Keiler, New Beckenham, being 2d with Conqueror. The best golden-leaved self was Golden Circle, shown by Messrs. E. G. Henderson & Son, and that with 72 named varieties, Messrs. Laing & Mann named exhibitor had the best Golden Variegated (Tricolor), Miss Morris, Messrs. Carter & Co. being 2d with Prince of Wales, and Messrs. Bell & Thorpe 3d with Princess. The best Silver Variegated was also shown in the class for a Silver Variegated Zonal. Mr. T. Postridge exhibited Blushing Bride, and Mr. Turner, Miss Kingsbury, in the class for silver-edged varieties, Mr. Postridge's Fragrant Queen taking 1st prize. For the best double-flowered variety Messrs. Bell & Thorpe were well 1st with the beautiful Miss Evelyn, bright pink; Messrs. Carter & Co. 2d, with C. Gilpin, Messrs. Laing & Mann, Downie, Laird & Laing 3d, with Victor Lemoine. The first-named exhibitors also took the 1st prize for the best single Nosegay variety, with large well-grown plants of Charles Dickens, salmon-red, with a singular tint of white on the petals; and Mr. Turner's Lucy 2d with the profuse flowering Master Christine, pink. Mr. Mann's Triumph, scarlet, was the best Zonal, and Mr. Turner's Madame Jules Elyse stood next; the latter, however, Messrs. Downie, Laird & Laing's Lucy 2d with leaved varieties was 1st. Amongst miscellaneous subjects were, from Messrs. F. & A. Smith, a very large and fine collection of pyramidal Balsams, of various colours, many handsomely marked; from Messrs. Turner and Bennett Carnations and Picotees; from Mr. W. Norman, Crescent Road, Plumstead, a stand of 12 new Picotees; from Belle & Thorpe, cut blooms of Zonal double flowered and Nosegay Pelargoniums, and examples of a new Petunia, Single Beauty, deep purple with a faint lilac edge, habit very wiry, and likely to make a good bedder; from Mr. Hooper, Bath, large stands of Pansies, Carnations, Picotees, and Cloves; from E. Sherdon, Bennett Nursery, Biggleswade, a large white Pink, named Flower of Eden, delicately scented; from Mr. B. Porter, gr. to Mr. Benham, Sion Lodge, Isleworth, 6 nice spikes of Dendrobium Devonianum; from Mr. Cannell, two dozen trusses of Zonal and Nosegay Pelargoniums; from Mr. J. Mann, Brentwood, a similar group; from Messrs. Jackman & Son, Woking, a large collection of seedling Clematis, and 6 handsome specimen plants of Clematis in tubs, for which they received a 1st prize; from Mr. Turner, a nice group of Lilium auratum; and from Messrs. Downie, Laird & Laing, a selected group of Gold and Bronze Zonal Pelargoniums, seedlings of 1871, remarkably fine in foliage and bright in colour.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. As the season advances, so does the number of subjects sent for adjudication by this body increase. On this occasion there was a varied and interesting display, the principal feature of which was the exhibition of wonderful Gooseberries, three prizes being offered for the best collections, 12 of a kind. Mr. Turner came in for 1st honours with a very fine lot, consisting of 70 named varieties, and including all of the best show kinds. Mr. J. Sharp, gr. to W. Martin, Esq., Shermanbury, was 2d; and Mr. Beach, gr. to C. J. Herries, Esq., St. Julian's, Sevenoaks, 3d—the last named exhibitors being also 1st and 2d in the order named for the six heaviest fruit, the former with Rifleman, very large, and pale green, and the latter with Overall. From Mr. Knight, The Floral Nursery, Hailsham, came a dish of a new Peach, named Knight's Markley Admirable, raised by G. Darby, Esq., Markley, Sussex; it is a freestone of the Téton de Venus type, of good size, slightly oval in shape, with a prominent nipple on the apex. It was grown in a cold house, and the fruit possessed a particularly rich flavour, much superior to that of other Peaches. A First-class Certificate was awarded. Mr. Turner sent 3 nice bunches of the Golden Champion Grape, showing too plainly the spot to which this otherwise fine variety is unfortunately subject. Mr. Laurence, gr. to Farnham Castle, sent a dish of fruit of the Black Apricot of Siberia, Prunus dasycarpa; and from Mr. Tillery, of Welbeck, came a specimen of the Eastwell Seedling Melon, a nice-looking Melon, but past its best. Ingram's Scarlet Gem Melon, unripe, was shown by Mr. J. Meaks, gr. to R. Fowler, Esq., Petersham. It is a large, handsome, and beautifully netted scarlet-fleshed variety. Messrs. J. C. & C. Lee exhibited specimens of their Hammersmith Early Kidney Potato, grown on light and heavy land. From Mr. Gilbert, gr. to the Marquis of Exeter, Burghley, came a collection of Potatos—viz., Alpha; and Mr. Evenshed, Munsted Gardens, Godalming, also sent two very promising varieties, but the committee adhered to their former resolution not to make any awards save to novelties not shown at Chiswick. It was reported that a trial of Peas and Potatos would be made there next year. From Mr. Rivers came a collection of ten varieties of Filberts and Nuts, grafted on Corylus atrosanguinea, which it would appear that this plant induced fertility, but though the little half standard specimen bore a capital crop, it must be remembered that this is an exceptionally good year for Nuts, so that further experience must be gained on this above point before it be affirmed. Mr. D. Piccorilli, Wigmore Street, sent very handsome specimens of Giant Early White Tripoli, and Giant Rocca Onions. From Messrs. Bell & Thorpe were shown varieties of Grapes, and Mr. Portis had specimens of Rintoul's Early White Don. Prizes were offered for the best single dishes of early Plums, Mr. J. Douglas being 1st with Early Green Gage, finely grown, Mr. Turner being 2d with Kirke's Blue, and Mr. Gustave Couvreaux, of Nogent, Haute-Marne, France, sent specimens of his Sécateur, which differs from the usual form, in having larger handles, made by riveting strips of wood alongside the ordinary iron form.

DITCHLING GOOSEBERRY SHOW.—I cannot refrain from sending you a notice of the Ditchling Gooseberry and Currant show, as it is the oldest established society connected with horticultural pursuits in this part of the kingdom, and, I presume, one of the oldest in England. According to the bills, the one just past was the forty-ninth annual show, but I am convinced that it is more indicated to me that it was really the fiftieth. It was originally started by a few amateur Gooseberry growers, who met together and pitted their single berries and dozens of bunches against each other. The show has gradually increased, and now includes flowers and vegetables, but the main feature is still the Gooseberry, This is no doubt in great measure due to the liberality of a few gentlemen connected with the show, and principally, I believe, a sum of money sufficient to induce the rival growers to meet in competition. And then some of the best prizes drawn from the annual subscriptions are given for the single berries, of course so that amateurs may only be able to compete with our Lancashire brethren, as we do not grow for single berries, but for dozens. The principal prizes are offered for white, green, yellow, and red Gooseberries, and there were 15 entries this year in the amateur class was about 12 *s.* dwts.; in class B, for amateurs, a little over 10 oz.; and in the cottagers' class, about 9 oz. 8 dwts. The Currants this year were not up to the usual standard, though a dozen bunches of black exceeded 3 oz. *H.*

BRITISH ASSOCIATION.—The 41st annual meeting of the Association was inaugurated on Wednesday evening last at the Music Hall, Edinburgh, by the President, Sir W. Thomson in the chair, before a full audience. Sir W. Thomson is well known not only as an experienced practitioner, but as a bold theorist. The hypothesis he proposed as to the origin of life on the globe, is a fit pendant to his idea, formerly propounded, that the heat of the sun is due to the constant friction caused by the impact of meteors falling into it.

Our readers, who peruse the following passages, which formed the conclusion of the learned President's address, will doubtless agree with us that at present we know wonderfully little about the matter at issue. "The essence of science," said the President, towards the close of his speech, "consists in inferring antecedent conditions, and anticipating further evolutions, from phenomena which have actually come under observation." What, then, he went on to inquire, does science teach us in regard to the origin of life on the earth? Following up Professor Huxley's address last year, Sir William Thomson declared that he was prepared "to adopt it as an article of scientific faith, true through all space

and through all time, that life proceeds from life and from nothing but life."

"Did grass and trees and flowers spring into existence by a fiat of Creative Power, or did vegetation, growing from seed sown, spread and multiply over the whole earth? When a volcanic island springs up from the sea, and after a few years is found clothed with vegetation, we do not hesitate to assume that seed has been wafted to it through the air, or floated to it on rafts. Is it not possible, is it not probable that the beginning of vegetable life on the earth is to be similarly explained? Every year thousands, probably millions, of fragments of solid matter fall upon the earth—whence come these fragments? What is the previous history of any one of them? Should the time when this earth comes into collision with another body, comparable in dimensions to itself, be when it is still clothed as at present with vegetation, many great and small fragments carrying seed and living plants and animals would undoubtedly be scattered through space. Hence and because we all confidently believe this, the scientific objections which may be urged against this hypothesis, but I believe them to be all answerable. The hypothesis that life originated on this earth through Moss-grown fragments from the ruins of another world may seem wild and visionary; all I maintain is that it is not unscientific. From the earth stocked with such vegetation as it could receive meteorically, to the earth teeming with all the endless variety of plants and animals which now inhabit it, the step is prodigious; yet, according to the doctrine of continuity, most ably laid before the Association by a predecessor in this chair (Mr. Grove), all existing living on earth have proceeded by orderly evolution from some such origin. Sir John Herschel, in expressing a favourable judgment on the hypothesis of zoological evolution, with, however, some reservation in respect to the origin of man, has stated to the doctrine of natural selection, that it was too like the Laputan method of making books, and that it did not sufficiently take into account a continually guiding and controlling intelligence. This seems to me a most valuable and instructive criticism. I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Reaction against the frivolities of teleology such as are to be found not rarely in the writings of the learned commentators on Paley's "Natural Theology," has, I believe, had a temporary effect in turning attention from the solid and irrefragable argument so well put forward in that excellent old book. Paley overpoweringly strong proofs of intelligent and benevolent design lie all round us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through Nature the influence of a free will, and teaching us that all living beings depend on one ever-acting Creator and Ruler."

Notices of Books.

Artistic Cookery; *a Practical System, suited for the Use of the Nobility and Gentry, and for Public Entertainments.* With 80 engraved plates. By Urbain Dubois, Chef de Cuisine of their Majesties the King and Queen of Prussia. 4to., pp. 244. Longmans. 1870.

Cosmopolitan Cookery; *Popular Studies.* With 310 drawings. By Urbain Dubois, Author of the "Artistic Cookery." Royal 8vo, pp. 625. Longmans. 1870.

Although it is generally admitted that cooking, as a science, is better understood and practised abroad than it is in England, it is not so generally known that the literature of the subject has for many years been in a more advanced condition in France than with us. Mrs. Rundle used to be the great authority; after that, Mrs. Beeton's was, and perhaps still is, the most highly valued "Cook Book" in the vast majority of English families. In those larger houses, where foreign styles of cooking began to be practised some 50 years ago, French men-cooks have been generally employed, until within the latter half of this period, when English men-cooks have divided the best appointments with their French brothers in this art. To these English artists it was a boon, when in 1846 Soyer, the French head-cook at the Reform Club, published in good English his work, called the "Gastronomic Regenerator," which contained "2000 practical recipes, suited to the income of all classes." The only other book in English to which we need refer, as treating of the higher branches of cookery, was that brought out by Francatelli, in 1868, called "The Modern Cook," in which will be found recipes for various dishes served by the best French, Italian, and German, as well as English cooks.

The two works which call forth the present remarks are, however, of a much more elaborate character, so much so that it is difficult to convey an idea of their contents. That called "Artistic Cookery," although describing the mode of cooking a large number of most expensive dishes, is more especially devoted to the ornamentation and decoration of these dishes, of which there are no less than 391 excellent illustrations. Kitchen-maids would probably set greater store by the "pictures" than the letterpress, and would vote it a "wonderful good book about dishing-up." The author's own opinion of it is differently expressed, for we find at the top of every page, where they can be introduced, the words "Album of Classic Cookery." When we state that three-fourths of these illustrations are devoted to cold dishes, it will at once be seen that the work will be more useful to those who indulge in grand breakfasts and state suppers than to givers of good dinners. Indeed, with the exception of dishes guided a cook as M. Dubois unquestionably is, we venture to think that his enthusiasm in the application of high art and fine art to the decoration of a hot joint before he would allow his employer to partake of it, is just so much energy misapplied. There are few hot dishes which are not liable to spoil more or less rapidly for every minute of delay which occurs between the completion of their cooking and the time of their mastication, and consequently the elaborate decoration of any hot dish, after its cooking is finished, is, in our judgment, a grievous mistake. Turning from the hot to the cold dishes, one cannot fail to admire the great taste which appears in their ornamentation; for whether it be fish, meat, or game, pastry, fruit, or ices, everything is prettily and artistically arranged. The engravings give one the notion that Truffles and Cockscombs are in too great a preponderance in the ornamental part of his work; but this is only if their forms, and not colours, the red of the Carrot and the lobster-spawn, and the green of the Pistachio-nut, would have relieved the monotony of the black and white in the illustrations referred to. There is a large collection of bills of fare given, some of which are interesting from their variety, others for their choiceness, some for the selection of wines served with the respective dishes, others for their quaintness. For example, when the Sultan entertained Prince Jerome Napoleon on July 6, 1868, he gave him amongst other things, "Beureck, Quephte, Kiaq-Lokmassy, Visnali, and Ekmek." And here we must mention a point in this otherwise excellent work—it has no index, no table of contents, no glossary; and hence we are unable to find out, without reading through the whole of the book, what these curiosities are, or whether they are described at all.

Turning now to the other book, we are much to believe at first that it can be by the same author. "Artistic Cookery" is written in good English. Here is an extract from "Cosmopolitan Cookery:"—

"Butcher's meat, in its various extent, is, so to say, the nerve and soul of the kitchen. There is no fat dinner, no festival, where it does not make a conspicuous figure. By the distinction we make or by the badness of its substance the varieties of butcher's meat are alike indispensable on the table, as in the kitchen. * * * The darker sorts of butcher's meat, served at a dinner, if roasted, gain exceedingly by being carved on the table, and then handed round to the guests; all roast meat, carved previously, by this proceeding loses most of its nutritive juice. Never forget this, amphitryons."

This is a portion of one of the introductions to the five pages into which this book is divided; they are Soup, Fish, Butcher's Meat, Poultry, and Entremêts. It seems probable that M. Dubois has ventured upon doing a little English for himself in these introductions. The recipes, however, are no doubt translated from the French by the same person who was employed upon the previous work. The recipes are in this book 1288, most of them different from those in "Artistic Cookery." From the preface we glean that "Cosmopolitan Cookery" first appeared in French in 1868, followed by a second edition in 1869, and that the author is prevented by want of funds from proceeding with the publication of a similar, third work in English, to be called "School of High Culinary Art," in four 8vo volumes. The present book will be found more generally useful than "Artistic Cookery," inasmuch as it possesses an index, occupying 24 pages. One might suppose this enough for any purpose, and so it would as this is the only book in this work 1288, most of them different from those in "Artistic Cookery." From the preface we glean that "Cosmopolitan Cookery" first appeared in French in 1868, followed by a second edition in 1869, and that the author is prevented by want of funds from proceeding with the publication of a similar, third work in English, to be called "School of High Culinary Art," in four 8vo volumes. The present book will be found more generally useful than "Artistic Cookery," inasmuch as it possesses an index, occupying 24 pages. One might suppose this enough for any purpose, and so it would as this is the only book in existence across the information that they are a kind of Mushroom, known in Russia by the name of "gribouis;" but we are still in doubt whether it is an Agaricus or a Boletus that is referred to.

Nothing doubting that these two works will, ere long, find their way into the cook's room of most of the large country mansions in England, and assuming the existence of that kindly feeling and friendly cooperation between the head gardener and the head cook, which are so necessary between principal officers in such establishments, we recommend the cook to ask the gardener to take a cup of tea with him, and look over his new "picture-books," from an inspection of which they cannot fail, both of them, to obtain hints which they can conjointly use to their employer's interest, and to his increased satisfaction.

Florists' Flowers.

"How is it," said a fine old florist to me the other day, "that these beautiful SWEET WILLIAMS are not more grown?" We were looking at a bed of them in my own garden, saved from some seed sent me by the Rev. E. N. Pochin, of Sileby Vicarage, Loughborough, during the early part of last year. (Incidentally, it may be stated that Mr. Pochin grows Sweet Williams as finely, comparatively, as he does the beautiful Roses with which he wrests so many 1st prizes from many an aspiring exhibitor.) These Sweet Williams, in the size and regularity of their markings, more nearly resembled Phloxes than anything else I have yet seen. There were rich shining crimson self flowers, and there were others almost wholly white, save and except that a faint ring of pink or rose surrounded a white eye. Between these there were flowers variously and handsomely marked, some with white, some with coloured centres; some with zones, others with mingled tints, but not one undeserving of the most tender care. Planted in rather poor stiff soil, and allowed to carry the whole of their lateral shoots, the flowers were very fine; what they would have been had they been placed in light rich soil and duly thinned, cannot be imagined.

In these days, when provincial shows as a general rule provide classes for cut blooms of Sweet Williams, and when, as a general rule, also, they are but indifferently shown, if exhibited at all, one cannot help repeating the question of my old floricultural friend. It can't be that strains of good seeds are difficult of acquirement, it must be from indifference on the part of the growers, and a lack of that competition with the flower, which invariably incites to exertions to obtain the finest strain of seed possible.

In the strain under notice, the smooth edges and coloured centres with zones, and again mingled with the fringed margins and pale centres of Dean's Auricula-eyed. These characteristics undoubtedly appeared in the two strains when originally selected, but Nature is an indulgent mother, and the sportive character of the flowers soon presented a commingling of each character. What matters it if the best flowers are large, circular, stout in texture, and finely marked?

A good, light, rich soil is the one for the Sweet William. Some seed can be cast down in any spare plot in the month of March, and in October there will be an abundance of strong plants with which to form a blooming bed. The Sweet William is subject on a somewhat dry position, where the plants can be sheltered from cutting winds; excessive wet at the roots is far more injurious than hard frosts; and cutting north winds playing on the plants growing in a moist, heavy soil, will work great destruction among them. How well the Sweet William comes in as an edging shrubbery borders during the summer months, needs scarcely to be stated here. In connection with the Double Rocket, Antirrhinums, Pentstemons, Salvia patens, Foxgloves, and other things, there is secured a succession of bloom affording bright and varied tints.

It may be that the amateur desires to propagate certain finely marked varieties in his collection. To do this, the side shoots, *i. e.*, those that form the blooming wood of the succeeding season, should be pulled off, just as the plants are coming into bloom. If taken off close to the main shoots by the ground, they will often be found to have made a few short fibres, by which the work of propagation will be greatly accelerated. These, put in some fine light soil in a shady place, will soon take roots, when they can be planted out in a well prepared bed, as in the case of the seedlings.

To obtain fine masses of bloom for exhibition purposes, a bed formed of two parts of good fibry loam and one of well-rotted manure, with the addition of some leaf-mould, should be made, and the plants placed about a foot apart. Only one head of bloom should be allowed to rise, and all the lateral blooming stems should be removed as they appear. A support should be given to each stem, as they are brittle, and will readily snap when swayed to and fro by the wind; and in order that there should be a nice even face to the show trusses, there must be some careful thinning of the pips. This done, there will be seen a stand of Sweet Williams that will almost, if not quite, rival the choicest varieties of the perennial Phloxes. *R. D.*

Garden Memoranda.

ORCHARD-HOUSE TREES AND OTHER MATTERS AT THE NURSERIES OF MR. PEARSON, CHILWELL.—A charming, though necessarily brief, report of these nurseries was given by "R. D." in your number for June 24, and you specify most of the seedling Pelargoniums that I had made a note of, in the *Gardeners' Chronicle* of July 1. I can heartily endorse all that you and the special correspondent say about this splendid strain of Zonals. They exceed anything I had before seen. The season was unfavourable for judging of their full beauty out-of-doors, but that northern house, 200 feet long, filled with seedling Zonals, was a glowing mass of rich beauty worth going 100 miles to see. I should they prove good bedders—which doubtless many of them will—our gardens will be enriched with many new shades of colour, and lighted up with fine masses of beauty. But should they not prove first-class bedders, most of them will be serviceable for house work, and useful for bouquets; and these two last far exceed the first in importance. Individual excellence and fine shades of colour are lost to a great extent in a massed flower garden. But bring these qualities close to the eye in a pot plant, in conservatory or room, or in a bouquet, and it is chiefly those qualities that please. Many of the single pips of these seedling Zonals are distinguished by their great size and substance, and they are of the softest, purest, and most brilliant colours—just the thing for the floral decorator and bouquet maker to conjure with; and they will be conjured with, to the delight of many fair eyes, and the gladdening of thousands of youthful hearts of both

sexes in the future. For some of these trusses are almost large enough for a lady's bouquet, if fringed with Ferns, while one just set on a tiny leaf would suffice for a perfect bouquet for a gentleman. I congratulate the *artistes* on the saving of time that will be effected by the use of these fine sorts. Many of them seem of the *La Grande* type.

But I must rein in my hobby-horse, and write of orchard-house trees. I have never been very enthusiastic about such trees in pots; and by some strange perversity many writers and readers infer that the term orchard-house tree means a fruit tree grown in a pot. It does nothing of the kind. In fact the term orchard takes us to the very antipodes of pots, outside the garden, to a sort of half-way house, between the garden and open park, and orchard trees were originally trees as near to their natural state as might be. But Mr. Rivers has given a new meaning to the phrase, and now it is applied to all sizes and forms of trees, and all modes of training except to such as are trained on trellises. The pyramid and the bush are the most common forms, however, of orchard-house trees; at least, so I always thought until I went to Chilwell. Of course, there are obvious objections to both forms. Suitable for and easily assumed by Apples, Pears, Cherries, Plums, or Apricots, Peaches and Nectarines, do not assume the pyramid and bush form so readily; and when moulded into shape, they often try hard to get out of it. But there are much stronger objections to the bush and pyramid form. Placed thickly together in pots, or planted closely, the greater portion of the tree—the base—the best fruit-bearing part, is much shaded, and necessarily a long way from the glass. This into beautifully against quality. It is a well-known axiom among Peach growers that the nearer the glass the finer flavoured and higher coloured the fruit—hence the strong attachment of practical men to Peach-houses rather than orchard-houses. In the former the trees are trained and trellised at a distance of from 9 to 18 inches off the glass; in the latter much of the fruit is placed from 3 to 6 feet off the same.

But Mr. Pearson meets and masters this objection. By adopting the standard form and working his trees at different heights, the whole of the fruit bearing wood is brought up at the glass as the cultivator chooses, and this whether the trees are planted out or grown in pots.

The Peaches and Nectarines in the great orchard-house at Chilwell are like graduated rows of standard Roses, marshalled according to stature. The mode of training also seems well adapted to the habits of the tree. The natural disposition of a Peach or Nectarine, and indeed of most stone fruit trees on a single stem, is to throw their growth towards the top. This form meets this tendency, and turns it to account by converting that strength into fruit. There can never be any difficulty in keeping the top of a standard Peach well furnished with wood, though there is often very great difficulty in keeping the base of a pyramidal tree as well furnished or as strong as its apex.

With plenty of young wood any fruit is old or exhausted may be renewed, and standard trees could be kept in a bearing state for years, without any great increase of size, and without exhausting. No trees could look in better health than Mr. Pearson's. Most of them were well laden with fruit, and the leaves were healthy, large, and vigorous, without spot. That, artistically, such trees are very effective I never have cared for fruit trees on the dinner table; but if ever admissible, a well furnished standard is assuredly the prettiest, and most tasteful form. And Cherries, glowing with vermilion, Apricots burdened with gold, Peaches and Nectarines of choicest colours and richness, or cool-cheeked Apples, might form highly effective objects in halls, or on staircases, or even in large drawing or hall-rooms. Thus horticulturally and artistically I consider the growth of standard orchard-house trees a happy thought, and though we are not wholly indebted for it to Mr. Pearson—for I have seen such trees at Sawbridgeworth years ago—yet I have never seen anything like the number of trees grown in this style, nor the perfection of form and fruiting, that I saw at Chilwell.

Grape and Grape Vine growing here have already been adverted to; the latter were unexpectedly strong and good. Mr. Pearson seems rather sceptical about all the new Grapes but the Madresfield Court; he is also a considerable experimenter in this line, having a house for proving his seedlings. I was pleased to meet with his Ferdinand de Lesseps in good style, evidently a useful though most peculiarly flavoured early White Grape. Other sorts here are very promising, but I forbear specifying them until further proved. The man who thoughtlessly writes up a new Grape without sure and certain and repeated proof of its general and special excellencies, and the soundness of its constitution, ought to be lynched. Of this I feel certain—we shall hear again of some of these. Mr. Pearson pointed out one striking case of reversed seed—one of the choicest Grapes had run clean back into something wild and worthless. I noticed also that some varieties, as far as one could judge from leaf and wood and unripe fruit, seem to come quite true from seed.

I met with several fine old herbaceous or alpine plants, among them were the following:—Crucianella stylosa, Veronica taurica, Salvia alpestris, Gypsophila prostrata, Arenaria laricifolia, Rose Campion, Sisyrinchium bermudianum, Anthericum flexifolium, Liliastrum, Liliago, &c.

It may be added that this is a mere fragmentary notice. It would well repay any of your readers to go and judge for themselves. Mr. Pearson is one of the most genial and hospitable of men, and has many things to show and to tell his visitors that space forbids me to write of. *F.*

July 27.—A fine day. The amount of cloud increased towards night.
— 28.—Rain fell heavily in the early morning. A fine afternoon and evening.
— 29.—Fine in the morning. Between 4 and 7 the sky was generally overcast, and rain fell heavily. Fine at night.
— 30.—Very variable throughout. At frequent intervals the morning rain fell in torrents. Generally fine after noon, though a few light showers fell.
— 31.—Light clouds prevalent. Very fine throughout.
August 1.—Fine. Cloudless at night.
— 2.—Very fine day.

JAMES GLAISHER.

Miscellaneous

CRICKET.—A match was played on Saturday last between the *employés* of Messrs. James Carter, Bunnett & Peale, and those of Messrs. Waite, Burnell, Huggins & Co., on the ground of "Carter's Cricket Club," at Dulwich, which resulted in an easy victory for "Carter's."

SALE OF TIMBER.—A few of the Oak trees in Burghley Park, having shown symptoms of decay, were recently cut down, and were sold by auction. The size of the trees and the value of the timber may be inferred from the prices that were realised. One tree brought £72; a second, £61; a third, £54; and the whole, 30 in number, realised £900.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

SEEDLING plants of *Cyclamen persicum*, which were potted off a month or two since, should be kept constantly growing in an intermediate temperature. It is quite probable that at this time the young roots will be approaching the sides of the pots rather freely; so that if the latter are small in size (such as are recommended) another shift may be of much benefit to them at this time. If on the other hand they were potted off into large pots, such as the largest sized 60's, this will not altogether be advisable. In the case of these latter it will be best to apply a little weak liquid manure at alternate waterings. In potting-on Cyclamens at this season, there are certain circumstances which require consideration. For instance, as the long cold nights of autumn and early winter are approaching, it will be advisable to give small shifts only, and these again must be afforded after a careful consideration of the means at command to grow them on quickly and well. Few plants have shown a greater amount of progress in a cultural point of view, in the hands of the modern gardener, than have the Cyclamens; but it will be found that wherever the greatest amount of success has been attained there will also be found the best means for affording it. Perhaps it may be superfluous to mention that these "sweet and showy" plants cannot be grown to a tithe of the beauty they are capable of displaying amongst a mixed incongruous medley of plants, as they invariably are when large returns are expected from poor means. I should, however, state the fact that the Cyclamens delights in being grown near to the glass, and also that it prospers thoroughly only by the aid of a little bottom-heat. Those cheap low span-roofed houses, which are so much employed by the caterers of the plants for the great metropolitan markets, are not the things required to do this decorative justice, as well as to that of every 15 of all other decorative subjects. Yet all our large ducal and other establishments seem to be totally without such models of convenience. I cannot help thinking that by far too much attention, on the part of those individuals, is given to the mere ornamental element, say in filling out a certain piece of ground, or in the external appearance of any given structure, than to the internal working arrangements. The former, no doubt, is very desirable in the case of conservatories and show-houses of a permanent character, but structures of a more suitable nature, for growing stuff to furnish them, should nevertheless be always provided in fittiog positions. Those, then, who labour under the burden of inconveniences, and have not proper means, should keep their seedling Cyclamens in the same sized pots and the same shifts, and may then have some hopes of making a good advance. Pay careful attention to young seedling *Herbaceous Calceolarias*, which should now be attaining to a readily discernible size. Immediately the plants become large enough to handle well, prick them out into light, rich soil, subsequently taking care to place them in a cool, shady situation. Water them with care, so that none may be allowed to become too dry or too wet. Old plants of *Cinerarias* which have been turned out on to a cool shady border should now be taken up and divided, and the young shoots or cuttings potted off singly. Place them then into a cool frame, the bottom of which is composed of cinder ashes, under a north wall; keep them well watered and with but a moderate quantity of air for the first week or two, unless, indeed, the weather prove cool and moist, when more may be freely afforded. *Conservatories* which from any cause, such as the absence of the family, &c., may not require to be kept constantly gay, and in which large specimen plants are grown in open borders, should now have copious syringings within. This will afford a very material aid to all such inmates. Those who may have turned out-of-doors any choice plants will have to calculate a little, if the moist, dripping weather present while I am writing continues, as to whether harm is not likely to accrue to them through being constantly too wet at the root.

FORCING HOUSES.

Take advantage now of the duration of sunlight, to ensure a sturdy growth in all plants in forcing-houses, bearing in mind that these autumn days are exceedingly treacherous, and that no time should be lost in fully availing ourselves of a favourable opportunity. Give air freely, according to the state of the outer weather, but close up early in the afternoon. Feed the roots of fruiting *Pines* freely with proper manure-water, and stimulate every means the fullest possible development of each. In *Early Vineries*, the wood must now be induced to ripen off. It will be well, therefore, to remove every symptom of fresh growth, and, by gradually inuring the Vines to night air, to induce a perfect state of rest. To further these views, some means must be devised to throw off all moisture from superficial rains from outside Vine borders. Apply a moderate amount of artificial warmth to vineries in which the fruit is ripening, during all inclement weather. Keep Muscats ripening at any stage in a good high temperature, increasing it as they proceed with the final swelling and the ripening process. With Muscats it is only by a high temperature that good flavour is possible, hence it must be used with freedom. Be careful to keep down red spider upon *Peach* and *Nectarine trees* which have done fruiting; to accomplish which give a good syringing occasionally. Use other means to get the wood thoroughly ripened, that the lights may be removed boldly at the earliest possible time. *Melons*

which are ripening their fruits must neither be watered nor shaded, and all the air possible must be afforded, in conjunction with the maintenance of a good temperature within.

HARDY FLOWER GARDEN.

Hollyhocks will now be commencing to bloom, so that, where fine blooms are required for any special purpose, the points of the shoots should be pinched back, and the plants be supplied with manure-water. Thin out the shoots somewhat upon *Dahlias*, selecting those which exhibit a greater proportion of bloom-buds to remain. Fasten them firmly to the stakes, so that they may escape all danger from injury by wind-storms. Earwigs must be actively entrapped by the customary means of elevating small flower-pots containing Moss upon the stakes, or by thrusting old Broad Bean stalks amongst the foliage, which latter method is, perhaps, the least unsightly. Prick out seedling Queen and Brompton *Stocks* into sheltered seed-beds, and by these means endeavour to insure stiff, sturdy stuff, the better to stand through the future winter. Prune off all young side shoots or suckers from Neapolitan or other choice *Violets*, particularly such as are being grown on for lifting in the autumn to bloom in pots. Remove the old decaying or seedy remains from off border plants, and cut-in any kind of *Hardy Shrubs* which are unduly exceeding their limits.

HARDY FRUIT GARDEN.

Too much importance cannot be attached to the fact, that the sooner all *Strawberry plants* intended for forcing fill their pots with roots the better.

KITCHEN GARDEN.

I referred some weeks back to the desirability of sowing seeds of Rosette and Little Pixie *Coleworts*. Let the plants now be planted out thickly, or not more than from 10 inches to a foot apart, and they will be found to form nice compact heads, from the early winter frosts away into the more youthful weeks of the incoming year, often proving very useful at a time when this kind of vegetable is frequently not over-abundant. Proceed with the earthing-up of the earliest rows of *Celery*, taking care to remove all old leaves and the young side shoots, which generally form freely at their base. Make yet another sowing of *Peas* by way of a chance crop, be the variety ever so early kind. I have found the not over-early Ne Plus Ultra do well during very cold nights, comparatively speaking, and with but moderately sunny days. Remove all old *Peas*, *Broad Beans*, &c., immediately they cease to afford a supply, and plant out varieties of winter vegetables in their room without delay. In light soils, *Broccoli* and all similar crops will do better following these (giving the ground a good surface hoeing only) than they will in many cases in the same kind of soils when it has been freshly dug and manured. The same cannot be said, however, of very stiff heavy soils. *W. E.*

Notices to Correspondents.

ARISTOLOCHIAS. One of the Editors of this journal being engaged in drawing up an account of the species of Aristolochia, would feel indebted to any correspondents who will kindly furnish him with fresh flowers of any species they may have in cultivation. The flowers may be sent by post to the office of the *Gardeners' Chronicle*.

BOOKS: *W. B.* Williams' "Orchid Grower's Manual," 4th ed., will probably suit you well.

CAPER SURGREE: *Mrs. C. and others.* This is the Euphorbia Lathyris, and is of so poisonous a nature that we strongly recommend our correspondents not to try its edible qualities. We presume the name Caper has been given from a superficial resemblance of the seed-vessel to the buds of the true Caper, Capparis spinosa.

FAIRY-RING FUNGI: *A.* The only way to get rid of these is to dig out the soil impregnated with the spawn. We should be very unwilling to do so in most cases, as they produce abundant crops of Marasmius Oreades, one of the very best of our edible Fungi. They have been peculiarly abundant this year, but, strange to say, they have yielded little or no catsup, even from a bushel and a half of the fungi. *W. G. S.*

INSECTS: *H. G.* The Vine-leaf sent is swarming with hundreds of the just hatched young of the Vine coccus (C. vitis). Look carefully over the stems, and pick off all the swollen bodies of the females with their white cotton-like ovisacs, and burn them. Syringe with soap in the state of that sent should be picked off and burnt. *L. O. W.*

NAMES OF PLANTS: *H. W. C.* Pelargonium fulgidum, the parent of *P. zonales* and many other varieties.—*G., Bath.* This is not Abies Hookeriana, but Abies grandis, Auct. *A. M.—J. Lad.* The Wig Plant, Rhus Cotinus.—*John L.* Amorpha fruticosa.—*D. W.* Lastrea tenericaulis, *alias* Polypodium trichodes. — *W. R., Lanepert.* Blechnum occidentale and Aloe proliifera. *Rusticus.* Hypericum Androsæmum.—*A. G.* Ononis arvensis. Rest Harrow.

NEW PEAS: *W. Kurle.* So numerous are the new varieties of Peas, and so slight the differences between them, that we feel some hesitation in pronouncing an opinion; nevertheless we can give an excellent character of the sample of Evershed's West Surrey Marrow, the pods of which are well filled and the Peas of excellent flavour. Evershed's Dwarf Munsted Marrow is also a fine sort, but in our opinion not equal to the other.

PEAS: *C. M.* Your Pea bears a very strong resemblance to British Queen, but it is impossible to definitely name any Pea without seeing it growing, or being able to compare it with others.—*E. N.* Yours is a variety of the Sugar Pea, which, as you say, is a delicious vegetable. It is no novelty.

PELARGONIUM: *T. W.* Not equal to several already in cultivation, of which Jean Sisley and Wellington may be cited as examples.

REMOVING PLANTS: *Old Subscriber.* Strictly speaking, no, unless by special agreement, or unless you are in the trade.

COMMUNICATIONS RECEIVED: P. G.—F. W. B.—J. J. N.—J. B. Gordon.—R. F.—A. M.—J. W. & Co. (next week).—A. M.—T. D.—J. H.—J. S. (next week).—H. M.

Markets.

COVENT GARDEN.—Aug. 4.

The markets have been generally well attended during the past week, and supplies have been fairly kept up, prices remaining nearly stationary. Another large cargo of West India Pines has passed under the hammer this week, realising rather more money. The Potato trade is very heavy, and likely to be so for the next month, the disease having shown itself in Lincolnshire as well as in the west of England.

W. CULLINGFORD, Forest Gate, London, E.

Caution to Gardeners.—When you ask for

SAYNOR AND COOKE'S AWARDED PRIZE PRUNING and BUDDING KNIVES, see that you get them. Observe the mark SAYNOR, also the Corporate Mark, OBTAIN ABERSON'S, and the name and address.

S. & C. regret having to caution Gardeners and others, but are compelled to do so, in consequence of the imitation, of common quality, having been sold for the genuine one, and which has caused many complaints. S. & C. request that to those Knives they may have their make, all of which are warranted both by Sellers and Makers.

S. AND C.'S PRUNING and BUDDING KNIVES are the best and the cheapest in the world.

PATON WORKS, Sheffield. Established upwards of 25 years.

May be had of all Booksellers Price 4d. ; Stamped, 5d.
Published by W. RICHARDS, 41, Wellington Street, Covent Garden, W.C.

The Agricultural Gazette.

SATURDAY, AUGUST 5, 1871.

AN inferior crop of Wheat, a very good crop of Barley, an average crop of Oats, and crops of Beans and Peas which are promised better, but which, in the case of the former already, and in that of the latter will most probably before harvest, have disappointed expectation :—This is the report (upon the whole) of our correspondents, whose returns we publish in the following pages. Comparing them by the mere classification and addition of their returns, we have the following result :—

CROP RETURNS—HARVEST, 1871.

	Wheat.	Barley.	Oats.	Beans.	Peas.
Over-average ..	8	80	43	12	99
Average	96	116	158	92	56
Under average ..	121	12	62	52	10
Total ..	225	228	233	156	164

Comparing the above with the returns for 1870, which was not a good year, though it turned out better than was expected, we come to the conclusion that this year's produce is upon the whole inferior.
The following were the figures for last year :—

CROP RETURNS—HARVEST, 1870.

	Wheat.	Barley.	Oats.	Beans.	Peas.
Over average ..	16	12	6	4	7
Average	67	55	21	25	62
Under average ..	40	57	93	72	26
Total	123	124	120	101	85

Owing to the varying number of our correspondents in 1870 and 1871, respectively, these figures cannot be compared at a glance. We therefore reduce them to their percentage values in another Table :—

CROP RETURNS—HARVESTS 1870 AND 1871.

	Wheat.	Barley.	Oats.	Beans.	Peas.
1870.					
Over average ..	13	10	5	4	8
Average	54	44	18	25	73
Under average ..	33	46	77	71	19
1871.					
Over average ..	3	35	18	7	36
Average	43	60	55	59	38
Under average ..	54	5	27	34	6

It will be seen from these figures that the Wheat crop of the current year is decidedly inferior to that of 1870, and whereas that turned out better than was expected, this, in all probability, will not turn out so well as its present appearance leads us to expect. A wet summer—cold wet summer as we may call that of 1871—is certain to disappoint expectations of seed produce ; and that will be our lot this year.

Cattle food of all kinds promises to be abundant. Mangels, indeed, do not prosper in such weather as we have had, but Turnips of all kinds were never better, and grass is plentiful, though hay has been badly made. The wet season is producing its usual effect in an early development of the Potato disease.

It would be matter of surprise if, in this cold and wet season, there were not indications of disease in some of our cereals. At present, as far as we have observed, the Wheat is free from mildew, though there are indications on the stem which threaten an attack should mild and wet weather succeed to the present climatic conditions. We have, however, received from two sources ears of Barley attacked by a disease, which, according to the accompanying reports, seems, unless limited to a small area, likely to be very disastrous. In the first case the inside of the grain is mottled and tinged with pink, a colour which extends to the glumes, on which it is far more permanent than in the seed. This tint is not uncommon in diseased cereals ; it is often very conspicuous in Indian Corn, and is, we believe, a purely chemical change, consequent on disease from various causes. In the other case, which was forwarded to us from Northamptonshire, where the peculiar condition is said to prevail largely in certain districts, the stem is often streaked with dark lines, not caused by Fungi, as might at first be suspected, but where the component cells are gorged with brown inspissated matter—as is so frequently the case in many instances of vegetable pathology—the knots are all more or less diseased—and in consequence the supply of nutriment has been cut off, and the grain in various stages of development has perished. These knots, as far as we have seen, are not attacked by Septoria nodosum, which is sometimes destructive to Wheat. At least, if such is the case, the Fungus is not sufficiently developed to show any traces under the microscope. The glumes are brown, also the grain itself, especially where it was in an early stage of growth ; discoloured, and covered with a thin coating of mould, the threads in part being brown and belonging to some species of Macrosporium, while in part they are white, anastomosing very freely, and apparently referable to some species of Fusisporium, for we have seen scarcely any fructification. The grains appear in every case to have been impregnated, and there are abundant remains of pollen grains on the still adhering stigmas. It is quite clear, however, that these fungi have had nothing to do with the death of the plant, but are mere aftergrowth, as is also the case with what appears on the leaves under a peculiar form of the common Cladosporium herbarum, which appears in every part of the world where it is possible for a Fungus to grow. The stems, it should be observed, are quite free from any form of rust, and we can only attribute the malady to the peculiar state of the weather. We ought not to omit that the larva of Cecidonya is found within many of the glumes, but though these might impede the development of the grain, they would not cause the death of the plant. In every grain which we examined, except one, the young embryo was dead, even where it was considerably advanced, and the albumen was mottled as in the case first mentioned.

We have received from Mr. ODAMS a liberal supply of specimens of diseased Wheat ears from the neighbourhood of Plymouth, entirely deformed by the attack of a very curious Fungus, referred by DESMAZIÈRES to his genus Dilophosporium,* the cylindrical spores being furnished at either extremity with a little crest consisting of a few colourless short threads. In this case the destruction is complete, as the whole part of the ear affected is changed into a fungoid mass. It has occurred before in this country, but is very rare, and it is devoutly to be wished that it may continue to be so.

The Peronospora to which the Potato murrain is due is unusually prevalent and early, and other species of the genus are committing ravages, especially one amongst Onions. *M. J. B.*

SOME very important questions have lately arisen, respecting the influence of artificial food upon the health of stock. In our report of the last meeting of the Council of the Royal Agricultural Society, reference was made to the losses which have recently occurred among animals which were fed upon a "patent cake," supplied by a well-known maker, whose name we refrain from publishing for two reasons—first, because it is of no consequence to the question which is before us; and, secondly, because under the comprehensive clauses of the law of libel, journalists may be subjected to much undeserved annoyance, and entirely unproductive expenditure of time and money, in order to prove that no intentional injury was inflicted upon an individual whose personality was in all probability quite unknown to them.

The cake which has, or which is alleged to have, caused the death of many animals—cattle, sheep, and pigs—and which certainly did destroy the animal that was fed upon it at the Royal Veterinary College, has not up to the present time been proved to contain any deleterious ingredient, and we are aware of its having been used by stockowners for some time, without any ill-effects upon the health of their animals. There is, therefore, positive practical evidence—and, inasmuch as nothing of a poisonous nature has yet been detected, there is also negative chemical evidence—in favour of the food. Against it there is now only the fact that animals fed on it have died with unmistakable symptoms of blood poisoning.

Certain cattle belonging to the Marquis of EXETER died after having eaten the cake for some time: but pigs, which partook of it, died in a few hours. A heifer which was fed on the cake almost exclusively, the ration commencing at 2 lb. daily, and gradually increasing to 8 lb., died suddenly after eating the food for three or four weeks, apparently without suffering any inconvenience until the day before her death. Similar instances of death occurring among stock in different parts of the country are considered to be due to the use of the same kind of cake; no doubt, therefore, can exist of the absolute necessity for a complete inquiry—botanical, chemical, and experimental—for the purpose of deciding whether the constituents of the compound or any of them are essentially injurious, or become indirectly deleterious to the organism during the process of digestion.

The Royal Agricultural Society has undertaken the investigation, and with the means at its command it ought to be carried out exhaustively, not only in reference to the one variety of food which is presumed to have done the mischief, but to all kinds which are presumed to be harmless. It is at present an open question how far concentrated food—such as linseed-cake of the best quality, for example—may be given without injury to the animal organism. That there is a point beyond which nutriment, in a condensed form, cannot be forced into the system without danger, experience has clearly proved, and it would be well worth while to ascertain what are the principles which should guide the stock feeder in his proceedings.

The subject of inquiry is not so simple in its nature as it may at first appear to be. The old maxim which defines an ox or sheep as a table on which fat and flesh may be deposited *ad libitum*, is no longer orthodox. Under the high-farming system of the day, animals are looked upon as manure-making machines rather than as a means of supplying meat. The question often is, not how much cake can the animal body appropriate to the formation of fat and flesh, but what quantity can be passed through the alimentary canal for the improvement of the land. The problem is—given a piece of land that is capable of feeding one sheep to the acre, what is required to make it carry 10? The answer is universally—oilcake will do it; and both science and practice have sanctioned the assertion, and stamped it as true.

Meanwhile animals get fat, and as the pastures on which they are kept become more and more luxuriant, the whole system seems to be a great success; but by way of comparison the annals by sudden death among fattening animals are getting more serious year after year—splenic apoplexy, black leg, and all the forms of "blood poisoning" occur more frequently than formerly, and every now and then a piece of pasture that was once healthy land is found to be so destructive to animals fed upon it, that nothing short of the plough will suffice to restore the ground to its natural condition.

All these questions are mere truisms, and it will probably occur to each one of our readers that he knows already what we have endeavoured to prove; however this may be, there is no disposition to accept the conclusions which follow; any important change in the received methods of feeding stock are usually deprecated, nevertheless, if it be ascertained what proportion of concentrated food the organism can assimilate, it will be possible to devise some method of enriching the land without poisoning the animals which are pastured on it. There is no question of the absolute necessity for the employment of concentrated food, but the wasteful abuse of these compounds is not therefore admitted; the vague impression which is generally current, that the excess of aliment goes to enrich the manure, is not entirely true: an unknown quantity remains behind to undergo some changes which are not included in the process of nutrition, and the final result of which is poisoning of the blood.

The whole question resolves itself in one of quantity or quality. It is admitted that certain kinds of cake contain ingredients which are deleterious—other kinds are only highly nutritive—both are capable of producing equally fatal effects; it should be the province of science to indicate to the practical agriculturist what to take and what to avoid, and even to point out the limits beyond which the best kind of concentrated food becomes dangerous.

—— A SHORT supply of English Wheat at Mark Lane on Monday sold at a 1s. advance on the previous Monday's rates, but on Wednesday some difficulty was experienced in maintaining the rise.—— At the Metropolitan Cattle Market on Monday only choicest beasts brought previous prices, and on Thursday still further reductions had to be submitted to.

—— The Show of the ROYAL AGRICULTURAL SOCIETY OF IRELAND, under the Presidency of H.R.H. the PRINCE OF SOVEREIGN, hitherto unbroken in Ireland, was placed 2d to an English-bred bull belonging to Mr. Cooke, of Ballyneal House, New Ross, County Wexford. The highly commended card is attached to a half-brother of SOVEREIGN, who is shown by Mr. E. J. Smith, Plamore, Broom, County Cork. This bull was placed 2d to SOVEREIGN at the last spring show of the Royal Dublin Society. There was an exceedingly good class of 2-year-old bulls shown, and the judges had considerable difficulty in adjudicating in this class. Mr. Moutray, of Aughnaclay, took 1st prize with a massive bull; Mr. Meadows, of Lurgan, coming 2d with a beautiful, even, lengthy, active animal; Mr. Gumbleton, of Cork, 3d, with a half-brother of the 1st prize animal of this class. The yearlings were more numerous, but the quality of most of the animals was not very good. Mr. Maxwell, of Belfast, takes 1st prize; Mr. Chaloner, of Kells, 2d; Mr. Bland, of Abbeyleix, being commended. The class of bull calves was not well filled, Mr. Downing, of Fermoy, County Cork, takes 1st and 2d prizes. There were a few very good female Shorthorns shown amongst the young animals. Mr. Moutray, of Aughnaclay, takes 1st place, Earl Fitzwilliam, County Wicklow, 2d. Moutray is successful again in 3-year-olds and 2-year-olds. The show of Herefords, Devons, Polled Angus, and Ayrshires is exceedingly poor, some of the classes being without an entry. There is a good display of beautiful Kerrys; a native breed which is well worthy of cultivation. A very large show of sheep and some animals of rare merit are exhibited. The class of Leicesters is well-filled, a good many English-bred rams being shown. A class for Border Leicesters brings together a splendid collection. Mr. Turner, of Uppingham, takes 1st prize in aged Leicester rams, and 2d with a good shearling. Mr. Seymour Worsley, of Mountrath, takes 1st prize in shearling Leicester rams. Mr. Thomas Robertson, of Athy, is placed 1st in Border Leicesters. The class for the Roscommon breed was well filled with some very splendid sheep. This is a variety which seems deserving of care and cultivation. A type seems to have been set in the breed, and though coarse-looking to those accustomed to the finer Leicester, they seem to be a variety well suited to a damp, cold climate. The Lincolns were a poor show; the chief entries were made by Mr. Caleb Going, of Tipperary. The class "Shropshire and other Downs" struck us as well calculated to bring an incongruous assembly together. The time for better classification seems to have come, as there is character in most of the dark faces to entitle them to class for each variety. In rams, Mr. Chas. Wm. Hamilton is successful, with H.R.H. Prince of Wales, who sends some very excellent Southdowns, takes a 1st prize with a magnificent pen of 5 shearling ewes. There is a very fair show of pigs, Lord Clermont being eminently successful in Berkshires. The Horse Show, which is notably the feature of the autumn exhibition, contains 600 entries, some of the animals being very good. It is expected that a large sale of horses will be made during the show. The jumping will be an attractive affair, and very good arrangements have been made for this. The classes of horses for hunting, hack, and harness purposes, are very much in excess of those for agricultural horses. A proposition of agricultural implements is made, and visitors to the show seem to pay marked attention to this department. A full report, with prize list, shall appear in our next.

—— The annual show of the YORKSHIRE AGRICULTURAL SOCIETY commenced on Wednesday, on a portion of Bootham Stray, near the city of York. Admirable arrangements have been made within an extensive enclosure for the accommodation and display of implements and machinery, and for the exhibition of live stock. A junction siding has also been made from the York and Scarborough Railway, at which trains set down passengers close to the entrance. The central situation of York, where the meeting of this Society is held every five years, renders the show at that place unusually interesting; being equally convenient for the three Ridings; the competition is also generally large and always good. On the present occasion an unusually liberal prize list has resulted in a most numerous entry. Thus of cattle we have 124, sheep 113, pigs 107, horses 409, and wool 7, amongst which £1525 is divided in prizes and plate. The accommodation which for which we have been enabled to take, we have no hesitation in characterising the present as one of the best of a long series of Yorkshire shows which we have attended. As, however, the open judging of stock in the ring—a feature adopted by the Royal from the practice of the Yorkshire—was not completed when our report was despatched, we are compelled to delay, till next week, the publication of the full list of awards, and till that time we must also defer our report of the show in detail. We report, however, the following awards at once:—In the first class of Shorthorn bulls, GRINDELWALD, the property of Mr. Thomas Outhwaite, of Oswaldkirk, took the 1st prize, the Marquis of Exeter's TELEMACHUS the 2d, and PRINCE LEOPOLD, belonging to Mr. Knowles, of Wetherby, the 3d. In the next class of bulls, above two and not exceeding three years old, Mr. William Linton's LORD IRWIN, the Royal Agricultural Society's prize winner, took 1st, Mr. John Outhwaite's ROYAL WINDSOR 2d, and Lady Pigot's BYTHIS the 3d. The bulls not exceeding two years old were placed as follows:—1st, Sir G. Wombwell's NEWBROUGH 3D; GRANDEE, the property of Lieutenant-Colonel Keeve, Grantham, the 2d; and HORN OF PLENTY, exhibited by Mr. Wm. Foggitt, of Doncaster, the 3d. For bull calves, BRITISH FLAG, belonging to Messrs. Dudding, of Wragby, won the 1st prize; Mr. Linton's LEEMAN the 2d; and Major Stapylton's SUNDOWN the 3d. *Windsor's Butterfly*, the property of Mr. James How, of Broughton, Huntingdon, carried off the first cows of any age, the next two places being taken by Mr. Outhwaite's *Vivandière* and Mr. Emmerson's *Janey*. The prizes for 3-year-old heifers were taken by Mr. Foljambe's *Concert*, Mr. Tennant's *Daisy*, and Mr. Howe's *Vesper Queen* respectively; the 1st, 2d, and 3d prizes for 2-year-old heifers being awarded in the following order—viz., *Flora*, belonging to Mr. J. R. Singleton, of Great Givendale; *Fleur-de-lis*, the property of Mr. Foljambe, M.P.; and Mr. Howe's *Verona*. Mr. J. Borton, of Barton House, Malton, won five prizes in the shearling and aged Leicester ram classes, the sixth being taken by Mr. E. Riley, of Kipling Cotes, Beverley. For Lincoln sheep the prize-takers were Mr. T. Cartwright, of Dunstan Pillar, Lincoln; Mr. R. Wright, of Norton, Lincoln; Messrs. Dudding, Wragby; Mr. J. Pears, Mere, Lincoln; and Mr. C. Clarke, of Ashby-de-la-Launde, Sleaford. For Shrop-

* It was by a slip of the tongue that it was said on a former occasion to belong to the genus Dinemasporium.

sbire Down sheep Lord Wenlock won the 1st prize and cup, and Lord Wenlock and Lord Chesham took all the other prizes in all the classes for Shropshire Downs. The principal winners for pigs were Mr. P. Eden, of Salford, and Messrs. R. E. Duckering & Son, of Northorpe, Kirton Lindsey. Speaking generally, so far as a first day can indicate, the meeting promises to be a brilliant one. In the class of horses we have the winners from many prize-rings, Wolverhampton, Lincoln, Driffield, Burlington, all sending their "chiefs." In the racing world, no one knows the horse of the year till after the Leger; and, similarly, until the Yorkshire show is over, it would be premature to say where the best horse, hack or hunter, or the best Shorthorn, is to be found. The only thing doubtful connected with the show has been the weather. After a month of showers, confidence has not certainly been felt on this point. In spite, however, of all fears the weather, so far, has been brilliantly fine, and the attendance great and fashionable. The receipts for the first day are £315—2529 persons having paid an admission fee of 2s. 6d. each on the first day. The fact that the Royal Irish Agricultural Society's show is being held at the same time is perhaps not of much importance as far as the show itself is concerned, still there are exhibitors who would have shown at both places, and there are many agriculturists who would have liked to have seen both exhibitions. If such are inclined to scold, we beg to observe that no blame should fall upon the Yorkshire Society. From its first meeting to the present one, it has always held its show on the same day—the first Wednesday in August; yet our friends over the Channel have managed to blunder upon it on this occasion. *H.*

—— A recent visit to Fenn's Moss, near Whitchurch, Salop, deserves record here for the illustration which was witnessed there of the possibility of the profitable RECLAMATION of a GENUINE PEAT-BOG. Mr. FARDON, who has till lately been on the staff of Messrs. BAILEY DENTON, SON & NORTH, has taken 100 acres here of Sir J. HANMER, Bart., and is hopefully engaged in investing money in its cultivation. Draining it by open ditches, gradually dug, and thereafter by drainpipes—levelling it as it gradually dried and became firm, and carrying sand and gravel on it by light tramways from the edge of the bog—burning a good deal of the surface, liming, digging it over, and sowing hay seeds on it—he has obtained a rough thin pasture, consisting chiefly of Hop-grass, and therefore very poor and worthless. This, however, is ploughed under, and he gets a crop of Rye; or it receives a dressing of town manure from Chester, brought thither by canal, and this being ploughed under he gets a good crop of Potatos. Some 30 acres which have been reclaimed are thus in grass, and Rye, and Potatos. The grass is poor; the Rye would be good were it not for the way in which it has been eaten down and cut to pieces by the hares; the Potatos are capital. It is by this crop, with the aid of the Chester canal barges full of town manure, that Mr. FARDON will recover his large outlay. In ordinary seasons there seems no reason to doubt that he can obtain heavy crops of Potatos in this way, after three or four years of preliminary preparation of the original bog. Fenn's Moss is a specimen of as true a peat-bog as Chat Moss or any Irish bog that can be named, and Mr. FARDON's experience ought to excite the interest, not only of the proprietors of land, but of the authorities of towns in such neighbourhoods. We look forward, for example, to the time when the immense fertilising power of Manchester, now wasted in the pollution of the Irwell, will be brought to bear upon the bog land between it and Liverpool, and when Mr. FARDON's judgment and experience, acquired on Fenn's Moss, will be sought for and engaged in the draining, levelling, and preparation needed, before the sewage is poured on it. The land now yielding Potatos in as friable and soil-like a mould as one could wish, was, only three years ago, a tough peat, just such as is being cut for fuel close by. It is impossible to doubt that such a soil, watered with the Manchester sewage, would yield the very best of market garden produce. We have seen such peat-earth, watered with the drainage of the convict gaol at Woking, produce the largest and most vigorously grown Cabbages. We strongly recommend the Manchester people to look into the possibility of utilising their town sewage on Chat Moss, and thus convert that which is a source of nuisance and offence into a source of wholesome food and profit.

— The Council of the SOCIÉTÉ DES AGRICULTEURS DE FRANCE, at their first meeting since the commencement of the Franco-German war, on the 22d ult., expressed their recognition of the assistance which has been rendered by the agriculturists of the United Kingdom to their unfortunate brethren in France by unanimously electing Lord VERNON, chairman of the French Peasant-Farmers' Seed Fund, an honorary member of that Society. This is the highest mark of distinction which the Society can confer.

—— Some experiments have lately been conducted in India in the IMPROVEMENT of WHEAT by SELECTION. In one experiment the ears that were selected measured from 3½ to 4¼ inches long, but it has not transpired what variety was chosen. The seeds were purposely sown in quite a medium soil, with little manure, the object being to obtain a variety which should owe its increased length to Nature only, and not to high culture. They were sown with a spade, and, unfortunately, in consequence, sown too deeply, by which a great deal of the plant was lost, but of those plants which came up, none of the ears were shorter than those of the parent, but some measured 4¾ inches in length, being half an inch longer than the selected ears. Similar experiments were conducted with several varieties of Wheat, the result in each case being satisfactory; one of the most promising varieties, however, seems to be that known as Polish Wheat, which in some districts is so highly prized that great demands prevail for it. A kind of Pedigree Wheat, cultivated in Lahore, is said to be so fine that a European cultivator, writing on the subject, says, "Nothing in England could beat the Wheat here this year, length and weight of ear combined with long straw. I am going to test a great number of fields this year, by weighing the contents of the imperial bushel, and, if I mistake not, we shall find it fully up to a European standard." A more serviceable test in the interest of the cultivator would be the determination of the produce per acre.

THE PRESENT APPEARANCE OF THE CROPS.

[FROM OUR OWN CORRESPONDENTS, JULY 25.]

COUNTY.	WHEAT.	BARLEY.	OATS.	BEANS.	PEAS.	ROOT CROPS.	HAY.	DATE OF HARVEST.	NAME AND ADDRESS.

	A good bulk; much laid; yield doubtful	Heavy crop; will yield well, if not too laid	Good	....	Good	Very good	A fair crop; much spoilt	August 8	William Rigden, Hove, Brighton
HAMPSHIRE	Rather under average	Over average	Average	Much blighted	Over average	Swedes and Turnips good	Clovers short crop; much injured	August 10	W. C. Spooner, Eling Downs, Southampton
	Below an average	Considerably above an average	Above an average	Spring good, but blighted	Above average	Very good	A good crop, damaged	August 7	William Spearing, Winchester
	Thin plant; under average	Bulky crop; quality doubtful	Good	Good	Good	Very promising	Much damaged	Middle of August	Hugh S. Raynbird, Basingstoke
	Under average	Over average	Over average	Over average	Over average	Over average	Under average; damaged	August 7	Joseph Blundell, Southampton
WILTS	Good, where there is sufficient plant	Good	Good	Winter thin, but well kidded; spring bulky, but blighted	Good	Good	Good	End of August	Richard Stratton, Burderop, Swindon
DORSET	Below an average	A good average crop	An average crop	Above an average	Above an average	As good as ever known	Average; damaged	Second week in August	James Buckman, Bradford Abbas
	Thin on ground; fair head, but blighted a little	Looks level and well	Not a heavy crop, but much improved	Half crop; destroyed by black aphis	Good	Good	Light crop; much damaged	August 6	J. T. Homer, Hemsworth
	Under average	Over average	Average	....	Average	Excellent	Good; some spoilt	Middle of August	W. J. Voss, West Bucknowle, Corfe Castle
	Improved, but thin; will be under an average	Very good; an average	Very good; an average	Very few in this locality	Have heard complaints	Very promising	Rye-grass and Clovers, thin	August 10	Henry Frokes, Whitechurch, Blandford
	Under average, but too early	Over average	Average	Blighted	Blighted; may be average	Very good	Average crop	August 15	R. Damen, Dorchester
	Under average	Over average	Over average; very promising	Partially blighted	Early Peas, good	Very good	Good; not well secured	In a fortnight	John Pope, Symondsbury
	Average	Average	Over average	Over average	Over average	Promising	Sainfoin and meadow, average	August 7	John Ford, Rushton, Blandford
	Very variable; not two-thirds of a crop	Good average, but full of rust	Full average	Much blighted	Average	Never better	Average	....	T. H. Saunders, Watercombe Farm, Dorchester
SOMERSET	Under average; half a crop	Average	Average	....	....	Good plant	Average; not half harvested	End of August	John B. Collyns, Dulverton
	Average	Over average	Average	Winter, failure; spring, nearly average	Good	Good	Good; badly made	About August 10	Walter Farthing, Stowey Court, Bridgwater
	Full average crop, if not over; rust appears in spots	Improved; over an average, but deficient in quality	The few grown are good	A deficient crop, and small breadth	Full average	Generally bids fair for a good crop: Mangels good	A fair crop, but seriously damaged	In about 10 days	Richard Corner, Torweston, Wellington
DEVON	Under average	Average	Average	....	....	Very good	Good, but badly saved	Second week in August	R. W. Pollard, Blagdon
	Scarcely average crop; depends on the weather	Fair average	Spring-sown below an average	....	Few grown, those good	Full crop	Meadow middling; saved badly	Middle of August	Samuel P. Newbury, 4, Boringdon Villas, Plympton St. Mary's
	Under average	Over average	Average	....	....	Very promising	Average	August 15	P. Bawan, Barnstaple
	Below an average	Average	Above average	....	....	Very fine	Light crop; badly saved	About middle of August	Samuel Cornish, Stancombe, near Kingsbridge
	Under average	Under average	Under average	....	....	Good	Small crop and damaged	August 14	R. H. Watson, Dorsely, Totnes
	Thin most places	Pretty good	Good	Good	Good	Very good	Half crop	August and September	Lamoureux & Co., Plymouth
CORNWALL	Thin	Average; greatly improved	Average crop	....	....	About average	Barely average; badly saved	Early in August	Magor, Davey & Co., Brewery, Redruth
	Average, but damaged by rust	Under average; very thin	Average	....	....	Looking well	Various	Beginning of August	T. D. Simmons, Killiganoon
	About average	Average	Over average	....	....	Very good	Not quite average; badly saved	In a fortnight	W. M. Ware, Newham House, Helstone
	Below average	Full average	Average	....	....	Very promising	Light, and badly got	August 12	John Wills, Southpetherwyn, Launceston
WALES.									
CARMARTHEN	Not average	Good	Average	....	....	Not good	Average; not half cut	Depends on the weather	John Burnell, Penyfair, Llanelly
GLAMORGAN	Very much below the average	Very good	Average crop	....	....	Looking well	Average crop	....	Thomas Thomas, St. Hilary, Cowbridge
IRELAND.									
LONDONDERRY	Average crop	Scarcely any sown	Short; not average	....	....	Promising	Bad	About Sept. 25	Charles Pollock, Farmhill, Magherafelt
QUEEN'S COUNTY	Scarcely any sown	A fair crop; a good deal laid	Promise a good crop	....	....	Fair crop	Much damaged	End of August	Charles H. Franks, Westfield, Mountrath
ANTRIM	Average	....	Average	Very good	....	Average	Average	August 14	J. Babnick, Carrickfergus
MEATH	Very little sown here; what is sown is good	....	A great quantity, and very good	Look well	....	Turnips (late) good; Potatos good and plentiful—disease appearing	Second crop good, weather bad	End of August	John M'Collough, Chenymount, Kells
	Good	Average	Heavy	....	Very good; not much sown	Mangels fine	Abundant	September 10	John Anderson, Land Steward, Mountainstown, Navan
	Winter Wheat very good, spring ditto fair	Rather light	Very good about here	Fair	Good	Uneven, but good	Light, badly saved	Middle of August	W. A. Barnes, Westland, Moynalty
KILKENNY	Not good	Average	Good	Good	....	Late, but good	Very bad	August 20	D. C. Milward, Tullogher
	Good, but too soon to judge	Good	Good	....	....	Fair crop	Light	August 20	Patrick Grace, Trestford.
	Good	Good	Good	....	....	Good	Constant rain	August 20	John O. Sullivan, P.P. and V.G., Kenmare, Kerry
CORK	Average; much injured by continued rain	Good; little grown	Average; damaged with smut	....	....	Potatos showing disease	Under average	End of August	F. A. Twname, Bally Philip, Kanturk
	Promising, but blight is feared	Good	Under average	....	....	Under average	Average; badly saved	August 20	J. Byrne, Wallstown Castle, Mallow

OUR LIVE STOCK.

On Tuesday Mr. Strafford sold the whole of the well-known herd of Shorthorns at Farmley Hall Farm, near Otley, the property of the trustees of the late Mr. Fawkes. There was a large attendance of breeders from the home counties and from America and Australia. The bulls averaged £55 each, and the cows and heifers £46 each; the total amount being £1680, giving a general average of £48 per head. The highest price given was 150 gs., for NINTH LORD, a yearling bull by LORD DARLINGTON.

—— The Highland and Agricultural Show presents many points of interest to those who are occupied with live stock. It brings before us several breeds, of both cattle and sheep, which the English farmer but rarely sees in perfection.

In the cattle classes, Ayrshire cattle occupy an important position. These cattle are rather small in size, vary in colour from white with a little red, to red with a little white, and again from a fawn colour broken with white, to almost black and white. The typical Ayrshire cow is formed for milk. Her long, firm head, and rather upturned horns, are succeeded by a thin neck, no great depth of hosom, shoulder tops and crops narrow, well sprung ribs, and great breadth over the hooks. Again, looking at the broadside of the animal, the depth should gradually increase backwards towards the flanks, giving what is termed a wedge-like form. This is much insisted on by all the Ayrshire admirers, and it signifies the gradual thickening of the cow from the set-on of the head when the neck is light, to the base of the neck, the breast, the girth, and the still greater depth at the flank. This gradual deepening combined with the heavy fore-end and cylindrical form of the Shorthorn, and indicates milking rather than feeding properties. We took the measurements of the 1st prize Ayrshire bull and cow, and also of the 1st prize Angus bull and cow, to which we shall again refer. The Ayrshire measurements were as follows :—

Measurements of prize Ayrshire bull, the property of Mr. James Wilson, Boghall, Houston; brown and white; 4 years. Bred by Robert Wilson, Forehouse, Kilbarchan.

	ft.	in.
Girth	7	4
Length from shoulder (last cervical vertebra) to rump	5	5
Total length from poll to rump	7	3
Height at shoulder	4	8½
Width across hooks	1	9
From shoulder-point to hook	1	4
From ground to dewlap	1	4

The Ayrshire cow measured as follows :—

Measurement of prize Ayrshire cow, the property of Mr. John Stewart, Burnside Cottage, Strathaven; 5 years 3 months. Bred by Mr. David Osborne, Harelaw, Neilston.

	ft.	in.
Girth	6	ft. 0 in.
Length from shoulder (last cervical vertebra) to rumps	5	0
Total length from poll to rumps	6	5
Width across hooks	1	7½
Length from hooks to rumps	1	7
From ground to dewlap	1	6
From shoulder-point to hook	3	7

Angus polled cattle are characterised by their black colour, occasionally broken near the udder with a little white. They are low-legged, are characterised by great length, by a great width across the shoulder-tops, continued by well sprung ribs and good loins, without prominent hook-bones. The hair is short and glossy, and the skin thick and soft. We append a few important measurements of the best examples of the breed we could meet with.

Measurements of prize Angus bull, JURYMAN, the property of Sir George Macpherson Grant, of Ballindalloch; 3 years, 4 months, 14 days. Bred by exhibitor.

	ft.	in.
Girth	7	ft. 10 in.
Length from shoulder to rumps	5	1
Total length	7	0
Height at shoulder	4	0½
Width across hooks	1	10½
Width across shoulders	1	0
Width across crops	1	4
From hook to shoulders	4	1
Girth of leg below knee	0	8½

Measurements of a commended Angus bull, the property of Mr. Alexander, Mains of Kelly; 2 years 5 months. Bred by exhibitor.

	ft.	in.
Girth	7	ft. 4 in.
Length from shoulder to rumps	5	0
Width over hooks	1	7
Width over shoulders	1	0½
Girth of leg below knee	0	8

Measurements of a prize Angus cow, *Elisa*; the property of, and bred by Sir George Macpherson Grant; 4 years 6 months.

	ft.	in.
Girth	7	ft. 1 in.
Length from shoulder to rumps	5	0
Total length from poll to rumps	6	11
Height at shoulder	4	2½
Width across hooks	1	9½
Width across shoulders	1	0
Length from hooks to rumps	1	9
Shoulder-point to hook	4	0
Girth of leg below knee	0	7

Passing from cattle to sheep, the Blackfaced heath breed first claim our attention, a breed adapted for the higher situation of hill farms—wherever heather predominates. The head must be black and white, the colours being distinct and unmixed; the horns should slope back in the same line as the forehead; the back of the neck is free from wool, but is covered with goat-like hair; the wool should come up well at the cheeks; the fleece must be long, curly, fine, and free from grey hair or kemps; grey, however, is apt to appear in old sheep.

Border Leicesters differ from English Leicesters principally in character of head, which is thickly covered with white hairs, giving a dead white appearance, while the true Leicester head has a blue "tinge" on the face. Where the skin is visible at the nose near the eyes, it is black, and a pink tinge indicates delicacy. There is no wool on the forehead, but the fleece comes up well to the cheeks and back of the head. The fleece ought to be thickly set on the skin, and the curl should be bold and open. The body is long, of great thickness through the heart and ribs, and tapering towards the rumps. The back is well covered with flesh, and the scragg, or neck, is well developed.

Such are a few points which may be noted upon examining good specimens of animals of the above breeds.

THE HIGHLAND AND AGRICULTURAL SOCIETY AT PERTH.

THE opening day of the Highland and Agricultural Society's show was discouraging enough. The weather, however, cleared up towards evening, and the following day (Thursday) was all that could be desired. The Scottish show is essentially a business proceeding. But few ladies visit the ground, and the streets are unadorned with flags, arches, or any of the accompaniments of bell-ringing, and holiday appearance, which characterise our English show-times. The proximity of the Highlands, and the picturesque appearance of those who affect the national costume, be they English or Scotch, the tones of the bagpipes, and the spectacle of Highland sports, in immediate contact with the show ; the exhilarating Caledonian Blackfast there said, like their masters, to thrive where pampered Saxon breeds would starve—these, and the Ayrshire cows, and black polled cattle, all help to compensate for the missing features above alluded to, and to give a picturesque freshness to the scene. The show itself at once strikes the casual observer as being inferior in size to the gigantic English meeting, but closer inspection reveals a greater variety, and equal excellence in most of the live stock classes. Implements are of course present in considerable variety, but we miss the application of steam in its application to agriculture yearly brought before us nearer home. Twenty acres of ground are occupied by the Highland Show, and in this very considerable space there is, we confess, much more of interest than we have had opportunity to examine. We shall now attempt to convey an idea of the "stock" show.

CATTLE.

Shorthorns.—There was a good show of Shorthorns, and it must be gratifying to the promoters of this breed that it appears to be rapidly extending in Scotland as well as in England. Taking the catalogue as our guide, we find in the first place a class of old bulls of great merit. It is the custom of the Highland and Agricultural Society to award a gold medal to animals which have taken first prizes in their previous shows, and this excellent arrangement enabled us to once more obtain a view of that grand bull, HEIR OF ENGLISHMAN (24,122), bred by Mr. Barclay, and now owned by Mr. W. S. Marr—a bull of great substance, on short legs, and of great style of notice. EDGAR, the well-known "Royal" prize-taker, ought to have been present, but was for some reason prevented from putting in an appearance.—The aged bull class comprised 15 entries, many of which were very excellent. The 1st prize was awarded to Mr. Robert Arkley's ANNAN WATER, bred by Mr. Cruickshanke, of Hallhills, Lochmaben, a bull with grand quarters, a good girth, and in fine shoulders. The 2d place was awarded to Mr. James Fletcher's MICHIGAN 2D, also a good bull, with good quarters and loins, and a fair "touch." The 3rd prize was taken by Mr. James Cochrane's BARONET (25,564), an animal which, although good in many points, is certainly weak about the shoulder tops and crops, and has not the "touch" of his successful rivals ; he is, however, a useful beast, and, on the whole, deserves his place.—The 2-year-old bulls formed a class of 13, many of which were very excellent. The 1st place was awarded to a bull possessing plenty of fine hair, and of fair quality. When we mention that his crops were a trifle weak we record the only fault noticeable to us. He is the property of Mr. Balfour, of Balbirnie, was bred by Mr. Wilson, Stirling Tolbwell, and is named KEIR BUTTERFLY 7TH. The 2d place was accorded to Sir David Baird's BARON LAURIE 3D, bred by Mr. Barclay, of Keavil, a red bull, of considerable merit, although a little plain about the head, and not quite heavy enough fleshed at the buttocks. So far so good ; but we cannot concur with the judges in the case of the 3d award. This was given to Mr. Walter Scott's BARON STAPLETON, bred by Mr. Thomas Lawson, of Stapleton Grange, Darlington. We should be sorry to say a word against any good animal, and are ready to acknowledge the BARON to be such. Nevertheless he has faults which, in our estimation, should have weighed with the judges. Take, for instance, Mr. Bell's DUKE OF NORFOLK, a red and white bull, noticed by many as possessing good shoulders, crops, and buttocks, and compare him, unnoticed as he is, with BARON STAPLETON. Such a comparison will reveal that the last-named bull is deficient in all the above points, and is also not so good a "toucher." With these facts it is difficult to see the reason of the award, and this difficulty was expressed by many very competent persons. Lastly, we may mention a very neat red bull, RED ROVER, the property of Mr. Robert Moubray, of Cambus, which received a high commendation. The yearling bulls comprise 12 entries, of which Sir W. S. Maxwell's RED DUKE was declared to be the best. This decision was, so far as we could learn, unchallenged, and with the exception of too much loose hair about the rumps, he is a very straight, good bull, and not made up for show in any extreme manner. Mr. James Beattie's BARON TORR, the 2d prize animal in this class, is white in colour, has horns not very nicely put on, and is a little low in the chine. Here, again, was dissent somewhat loudly expressed, many preferring other unplaced animals in the class. The 3d prize was awarded to Mr. Bruce, of Newton of Struthers, for a gay, nice looking bull, BARON CECIL. Mr. John Lamb, of Burrell Green, Penrith, again exhibited IGNORAMUS, the 3d prize bull at Wolverhampton, a grand "toucher," and altogether a gay and truly good animal, which, however, could not get a commendation. Mr. Cruikshanks, of Sittyton, exhibited a very good red bull, unfortunately lame ; and there were other excellent young bulls in this class qualified to take honours at high-class shows.

The class was better than at Wolverhampton, and we were especially struck with the exceedingly level cow exhibited by Sir W. S. Maxwell. From her loins forward she is perfect, and in other respects it is difficult to find fault ; still, her quality, as revealed by touch, is scarcely in her favour, but taking her altogether we have not often seen her fellow. The Duke of Buccleuch took the 2d place with his *Young Cherry*, a very good cow, and Mr. Robert Arklay was 3d, with *Flecky Wear* by REPRESENTATIVE (20,666). Mr. James Beattie showed two remarkably good cows, which, although unplaced, had many admirers. The 1st Royal 1st prize cow, *Warrior's Queen*, was also present, enjoying her honours with the fresh decoration of a gold medal awarded to her as the 1st prize cow last year at Dumfries. Plain at the rump, as the old cow unquestionably is, breeding and character are strongly evident in her. The yearling heifer class for heifers calved after January, 1869, Mr. Robert Bruce, of Newton of Struthers, was placed 1st with *Raspberry*, and Lord Kinnaird took off both 2d and 3d prizes. There was a large entry of yearling heifers, in which the Duke of Buccleuch carried off both 1st and 2d prizes, and Lord Kinnaird secured the 3d place.

Polled Angus or Aberdeen.—Still following the order of the catalogue, we next find the remarkably black polled cattle of Aberdeen forming a magnificent show. To see such a grand collection of these noble animals is a novel and interesting sight to an Englishman. So, at least, we found it, and spent a considerable time among them. Three veteran prize-takers, now retired on their well-won gold medals, formed the commencement of a very good class of aged bulls, among which Sir George Macpherson Grant's JURYMAN ranked 1st. He is perfectly black, has a remarkably good soft skin, and is exceedingly level. Mr. William Dingwall Fordyce showed the 2d prize bull, MUNGUMIR, which may be spoken of as scarcely equal to the last animal in hair and quality, but as very perfect in form. He was 1st at the Aberdeen show in 1868. The 3d prize was awarded to Mr. Robert Walker's DERBY, a grand beast, with a considerable amount of white on his belly.

There was a good entry of bulls, calved since 1869. The prizes were awarded as follows :—Mr. George Brown, of Westertown, 1st ; Sir Thomas Gladstone, of Fasque, 2d ; and Mr. Robert Clark, of Taybank, 3d. There was also a very good bull exhibited by Mr. Alexander Bowie, Mains of Kelly, which was commended, and whose dimensions we found to be as follows :—Girth, 7 feet 4 inches ; length, 5 feet ; length from shoulder point to centre of hook, 4 feet ; width over shoulder blades just about 11 inches ; over hook, 1 foot 7 inches, and girth of leg below knee, 8 inches. We cannot speak more at length upon the awards in this and other of the Aberdeen classes, but refer our readers to the prize list. We may, however, mention that the general impression was, that it was a grand show, especially of heifers. The breed is considered to be more hardy than Shorthorns, and has the following characteristic points :—Colour perfectly black, no horns, not even a "scar;" skin soft, and covered with fine short hair ; carcase very long, and especially well rounded over the shoulders and crops, very level from rump to hook, and from hook along the top of the ribs to the shoulder ; shoulder fine, not heavy, neck fine, head massive, and characteristic. In walking through the Aberdeen classes we observed many animals coming up to the standard.

Passing over the Galloways we arrive at the important classes of *Ayrshire cattle*. In general, with reference to these cattle, we note that the colour is exceedingly various, passing from almost white to red and white, brown and white to almost black and white, and again to red and dark brown. Sometimes the colour might be that of a Shorthorn, and at other times it was similar to an Alderney or Guernsey. The cows are small in size compared with our large breeds, and are formed for milking. The head is free from flesh and long ; the horns, of late years especially, point upwards and outwards ; the neck is light ; the shoulders close at the top, giving a narrow shoulder-top and crop ; the carcase gradually

increases backwards till we find wide loins, prominent "hooks," and wide rumps. Looking at the broad side, the light neck, shallow breast, narrow girth, and gradually increasing depth, as the eye passes backwards, gives a wedge-like form to the animal which contrasts with the full fore-quarters of the Shorthorn race. Sir Michael R. Shaw Stewart, of Greenock, showed a typical bull, the winner of the 1st prize at Edinburgh, in 1869. We may call attention Mr. James Wilson's excellent 1st prize bull, whose girth is 7 feet 4 inches, and length 5 feet 5 inches from before shoulder to rump. Sir Michael Stewart also showed a remarkably good bull, which obtained a 2d place, and Mr. John Fleming was awarded a 3d prize. In the yearling bull class Mr. Carmichael and Lord Lorne, an almost white bull, was much admired, and secured the 1st place, and other very good specimens were to be seen among the young bulls. There was a remarkably good show of cows and heifers, a large majority of which were of the true milking type. We took accurate measurements of the 1st prize cow *Rosa*, exhibited by Mr. John Stewart, and since sold, we understand, for £100. Her girth is 6 feet, length 5 feet, and total length, from poll to rump, 6 feet 5 inches. Another feature of the show was the Highland cattle formed to withstand the boisterous and severe winters of the Highlands. There was a fair show of these, but our time was unfortunately too much occupied to do them justice. Information as to the prizes will be found in the published list. Lastly, there was a section for fat animals, in which some 30 very good cattle were exhibited.

SHEEP.

Blackfaced.—There was a very excellent show of Blackfaced sheep. In this breed, the face should be black and white, the colours, in the best examples, being clearly defined, and not at all mixed. This is what the Highlander calls good "paintings." A Roman nose is in favour, and horns sloping back in the same line as the general slope of the forehead. There is no wool between the ears, or on the back of the head and neck close to the head, but thick, goat-like hair. The wool should come up to the chin, and the legs must be fine, curly, and free from hair. As ewes become old, they are liable to grow grey, or blue, hairs along the back. The 1st prize in the tup class was awarded to a sheep bred and exhibited by Mr. James Greenshields. The black and white face markings were distinct and characteristic, and the fleece was of particularly good quality. This sheep was got by a ram of Mr. Archibald's, of Overshields. The 2d prize was awarded to Mr. Archibald for the 1st prize sheep last year at Dumfries, an excellent animal, and sold on the ground at Perth for £40 to Fleming of Keel. The 3d prize was taken by Mr. Greenshields, and Mr. Aitken, of Listonshiels, was commended for a good sheep, not quite distinct enough in the colours of his face, but with good fleece and horns. Another of Mr. Archibald's (No. 558) also struck us as a stylish sheep, with good quarters and head, but with rather straight wool.

In the class for Dinmont or shearling tups Mr. Archibald took the 1st place with a good-headed sheep, having a capital carcase and fleece, a son of the 1st prize sheep at Edinburgh in 1869. Mr. Aitken also showed a good tup with a very black face, only slightly broken with white, and Mr. Archibald took the 3d prize with a very good animal. This class may be spoken of as good, but we noticed in some cases straight, goat-like wool, and faces in which the black and white were badly defined and mixed.

Passing on to the ewes above 1-shear, with lambs, we found the 1st prize awarded to Mr. Tweedie, of Castle Crawford, for some very good ewes, in which the wool was a little too fine, and the "paintings" not quite perfect. Mr. Archibald was placed 2d for ewes and 1st for lambs; Mr. John Malcolm, of Poltalloch, was 2d, and Mr. Pagan, of Innergellrie, was commended. There was a good class of shearling ewes, in which Mr. Archibald took 1st and 3d prizes for two good pens, in which the 1st prize seemed to have been secured by better character of head, but both were excellent pens. The 2d prize sheep in this class were bred and exhibited by Mr. A. C. Pagan; and, although good sheep, they were a little-inclined to a hairy style of wool, and lacked character.

Cheviots.—There was a grand show of Cheviots; and, although Dinmonts had been seen better, gimmers were first-rate. The names of Archibald, of Glengelt, Elliot, of Hindhope, and Brydon, again appear in force, and divide many of the prizes. Among the best sheep shown in these classes we may specially notice Mr. Thomas Welsh's most excellent shearling tup as an animal of good style and quality. The 2d prize sheep, the property of Sir G. Graham Montgomery, was also a fine sheep, although a little slack in the back; and the 3d prize sheep, exhibited by Mr. James Johnstone, of Capplegill, was also handsome and well-wooled, thus attesting the general excellence of his class. The commended sheep, belonging to the same breeder as the last, were also very good, although smaller than those already noticed, and the whole class was considered a most excellent one.

The class for ewes and lambs, although not well filled, yet contained some remarkably good pens, in which Messrs. Brydon, Archibald, and Elliot, divided the honours. Mr. Elliot's sheep, although only placed 3d, were very excellent, and almost equal to the 1st. Young ewes were also remarkably well represented, the class being both large and good. Border Leicesters are a great feature at the Highland and Agricultural Show. This sub-breed is a favourite in Scotland, and is considered to excel its south country progenitor in size and hardihood. The head is white and well covered with hair, and the nose and skin subjacent round either eye, black. Where a pink colour appears at these points it is considered to indicate delicacy. The "blue" colour of the English Leicester is not considered characteristic in the Border Leicester, but it is said to be appearing too much in some flocks. There were complaints with regard to the shearing in all the Leicester classes, and we have no hesitation in saying that the so-called "shearlings" had in some cases been very gently dealt with at shearing time, whenever that might have been. The Leicester show was undoubtedly good, and the shearling rams may be mentioned as especially excellent. Taking the classes in their catalogue order, we find, first, the old tup, forming a large and good show, in which Mr. George Hope, of Fenton Barns, took the 1st prize, with a very grand, long, well-covered sheep, with a thick good neck, and great width of carcase. The fleece, too, was quite unobjectionable, and may be described as hanging of a bold, rather large, and open curl. Mr. Thomas Ferguson, of Kinnochtry, Coupar Angus, also showed a good typical sheep, which won the 2d place; and Mr. Adam Smith's 3d prize may be spoken of as a good sheep with a characteristic head.

Dinmont or shearling tups were a very first-rate class, numbering 56 in all, and headed by Mr. James Clark, of Oldhamstocks', very good and well-woolled sheep, an excellent animal, with but little wool on the cod. Lord Southesk was placed 2d, with a well-woolled and otherwise good sheep; and Mr. Simson, of Ellieslaw, made a good 3d.

Old ewes were represented by 10 entries, in which Mr. George Laing took the 1st place, with five very well formed ewes, and, with one exception, well woolled. The 2d prize was awarded to Mr. Hope, of Fenton Barns, for five large and good carcased sheep, two of which carried fairly good fleeces. The 3d prize sheep, the property of Mr. Thomas Ferguson, of Kinnochtry, were, with one exception, very good sheep.

In the class for shearling ewes or gimmers, Mr. John Lees, of Warrington, Haddington, took the 1st place with a good-headed sheep, and Mr. Jenner Clark, of Oldhamstocks, was placed 3d with some sheep carrying splendid fleeces.

Besides the important breeds already noticed, there were a few specimens of Cotswolds and Southdowns. Shropshire sheep also appeared in considerable force, from the flocks of Earl of Strathmore, Mr. Hood, of Linross; Mr. John Gibson, of Woolmet; Mr. Crawford, of Pitlowrie; and Mr. Arnot, of Glamis Mains.

PIGS.

Swine were fairly represented, especially the white breed. It is scarcely, however, in Scotland, that we look for black pigs, and we were not surprised to notice a poor show of Berkshire, some of which did not much resemble the best types of the breed.

HORSES.

There was a remarkably good show of Clydesdale horses, especially of mares and fillies; thorough-breds and hacks were by no means so well represented. There also appeared to be a considerable number of empty stalls in the horse classes, in which the words "not forward" were conspicuous.

The following is the list of the awards in the various classes of stock :—

CLASS I.—CATTLE.

SHORTHORN.

1st Prize Bull at former Shows (exhibited Aberdeen, 1868).—William S. Marr, Heir of Englishman.

2. Best Bull calved before January 1, 1869.—1st, Robert Arkhay, Dundee; 2d, James Fletcher, Rosehaugh; 3d, James Cochrane, Aberdeen.

3. Best Bull calved after January 1, 1869.—1st, John Balfour, Balbirnie; 2d, Sir David Baird, of Newbyth, Bart.; 3d, Walter Scott, Hallyburton.

4. Best Bull calved after January 1, 1870.—1st, Sir W. Stirling Maxwell, Bart.; 2d, James Beattie, Annan.

5. Best Pen of Bull Calves (Medium Gold Medal): Dumfries, 1870.—James Beattie, Annan.

4. Best cow of any age.—1st, Sir William Stirling Maxwell, Bart.; 2d, the Duke of Buccleuch; 3d, Robert Arkhay, Dundee.

5. Best Heifer calved after January 1, 1869.—1st, Robert Brice, Forres; 2d, Lord Kinnaird; 3d, ditto.

6. Best Heifer calved after January 1, 1870.—1st, the Duke of Buccleuch; 2d, ditto; 3d, Lord Kinnaird.

POLLED ANGUS OR ABERDEEN.

1st Prize Bulls at former Shows (Medium Gold Medal): Aberdeen, 1868.—1st, Alexander Morison, Turriff; 2d, James Skinner, Drumin, Ballindalloch.

2. Best Bull calved before January 1, 1869.—1st, Sir George Macpherson Grant, Bart.; 2d, W. D. Fordyce, M.P.; 3d, Robert Walker, Aberdeen.

3. Best Bull calved after January 1, 1869.—1st, George Brown, Fochabers; 2d, Sir Thomas Gladstone, Bart.; 3d, Robert Clark, Errol.

4. Best Bull calved after January 1, 1870.—1st, William M'Combie, of Easter Skeoe; 2d, W. J. Taylor; 3d, James Leslie, Blairgowrie.

1st Prize Cows at former Shows.—George Brown, Fochabers.

10. Best Cow of any age.—1st, Sir George Macpherson Grant; 2d, ditto.

11. Best Heifer calved after January 1, 1869.—1st, Sir George Macpherson Grant; 2d, Alexander Bowie, Mains of Kelly; 3d, George Brown, Fochabers.

12. Best Heifer calved after January 1, 1870.—1st, W. J. Taylor, Huntly; 2d, George Brown, Fochabers; 3d, ditto.

GALLOWAY.

1st Prize Bulls at former Shows.—John Fisher, Knells, Carlisle.

13. Best Bull calved before January 1, 1869.—1st, James Graham, Carlisle; 2d, James Cunningham, Tarbreoch; 3d, Peter Morton, Longtown.

14. Best Bull calved after January 1, 1869.—1st, James Cunningham, Dalbeattie; 2d, T. Biggar, Dalbeattie.

15. Best Bull calved after January 1, 1870.—1st, Mrs. James Graham, Newcastleton; 2d, Joseph Kerr, Dumfries.

1st Prize Cows at former Shows.—James Cunningham, Tarbreoch.

16. Best Cow of any age.—1st, James Cunningham, Dalbeattie; 2d, Thomas Biggar, Dalbeattie; 3d, James Cunningham, Dalbeattie.

17. Best Heifer calved after January 1, 1869.—1st, Thomas Biggar, Dalbeattie; 2d, James Cunningham.

18. Best Heifer calved after January 1, 1870.—1st, Duke of Buccleuch; 2d, James Cunningham; 3d, ditto.

AYRSHIRE.

1st Prize Bulls at former Shows, exhibited for Medium Gold Medal.—Sir Michael R. Shaw Stewart.

19. Best Bull calved before January 1, 1869.—1st, James Wilson, Houston; 2d, Sir Michael R. Shaw Stewart, Bart.; 3d, John Fleming, Keel.

20. Best Bull calved after January 1, 1869.—1st, Robert Kelso, Greenock; 2d, the Hon. G. R. Vernon; 3d, John Fleming, Carnbeth Hall.

21. Best Bull calved after January 1, 1870.—1st, William Carmichael, Carnwath; 2d, John Fleming, Strathaven; 3d, Duncan Campbell Willis, Dundas.

1st Prize Cows at former Shows.—John Fleming, Strathaven.

22. Best Cow, in milk, of any age.—1st, Gabriel Dunlop, Stewarton; 2d, Martin Cardross; 3d, John M'Callum, Crieff.

23. Best Cow, in calf, of any age.—1st, John Stewart, Strathaven; 2d, John Fleming, Strathaven; 3d, Gabriel Dunlop, Stewarton.

24. Best Heifer calved after January 1, 1869.—1st, G. Pender, Kilsyth; 2d, Gabriel Dunlop, Stewarton; 3d, G. Pander. The whole of section 24 were very highly commended.

25. Best Heifer calved after January 1, 1870.—1st, John Fleming, Meadowbank Cottage, Strathaven; 2, George Pender; 3d, John Fleming.

HIGHLAND.

1st Prize Bulls at former Shows.—The Earl of Seafield.

26. Best Bull calved before January 1, 1868.—1st, John Stewart, Portree; 2d, Duke of Athole; 3d, John Grant, Carr Bridge.

27. Best Bull calved after January 1, 1868.—1st, David Carnegie, of Stronvar; 2d, T. Leslie Melville Cartwright, Ladybank.

28. Best Bull calved after January 1, 1869.—1st, John Malcolm, of Poltalloch; 2d, the Duke of Athole; 3d, John Malcolm.

1st Prize Cows at former Show.—1st, John Stewart; 2d, John Malcolm; John M. Martin, Cardross.

29. Best Cow of any age.—1st, the Duke of Athole; 2d, Donald M'Laren, Callander; 3d, John Malcolm, of Poltalloch.

30. Best Heifer calved after January 1, 1868.—1st, John Malcolm; 2d, Duke of Athole; 3d, John Stewart, Callander.

31. Best Heifer calved after January 1, 1869.—1st, John Malcolm; 2d, John Stewart; 3d, John Malcolm.

CLASS II.—HORSES.

FOR AGRICULTURAL PURPOSES.

1st Prize Stallions at former Shows.—Merdo Bethune, Beauly; Peter Crawford, Strathblane.

1. Best Stallion foaled before January, 1868.—1st, Peter M'Robbie, Aberdeen; 2d, William Wylie, Whitburn; 3d, William Moffat, Kirkintilloch.

2. Best Stallion foaled after January 1, 1868.—1st, Robert Brewster, Barabath; 2d, Abram Kerr, Durrisdeer; 3d, P. M'Robbie, Sunnyside.

3. Best Entire Colt foaled after January 1, 1869.—1st, Sir Wm. Stirling Maxwell; 2d, Archd. Johnston, Marybill; 3, Peter Crawford, Strathblane.

4. Best Entire Colt foaled after January 1, 1870.—1st, A. Weir, Newhouse Mill; 2d, Jas. Love, Greenock; 3d, James Nichol Fleming, of Knockdown.

1st Prize Fillies at former Shows.—Sir William Stirling Maxwell of Keir, Bart.

5. Best Filly (with Foal at foot) foaled before January 1, 1868.—1st, Wm. Moffat, Kirkintilloch; 2d, Sir Wm. Stirling, Bart.; 3d, M. Bethune, Beauly.

6. Best Mare (with Foal) foaled before January 1, 1868.—1st, Col. Findlay, Boutrich Castle; 2d, L. Drew, Merrytown; 3d, A. Buchanan, Garscadden Mains.

7. Best Filly foaled after January 1, 1868.—1st, J. N. Fleming, of Knockdoe; 2d, Lawrence Drew, Merryton; 3d, Robert Pollock, Mearns.

8. Best Filly foaled after January 1, 1869.—1st, George Knox; 2d, L. Drew, Merryton; 3d, R. Walker, Banff.

9. Best Filly foaled after January 1, 1870.—1st, J. N. Fleming, of Knockdoe; 2d, ditto; 3d, Sir William Stirling Maxwell, Bart.

10. Best Draught Gelding, foaled after January 1, 1868.—1st, A. Weir.

11. Best Draught Gelding, foaled after January 1, 1869.—1st, George Morgan, Cyrenf; 2d, George Todd, of East Brackley; 3d, Thomas Landale, Rhynd.

CLASS III.—SHEEP.

BLACKFACED.

1. Best Tup, above 1-shear.—1st, James Greenshields, Lesmahagow; 2d, John Archibald, Stow; 3d, James Greenshields.

2. Best Tup, Shearling.—1st, Thomas Welsh, Archibald, Stow; 2d, Thomas Aitken, Balerno; 3d, John Archibald.

3. Best Ewes, above 2-shear, with Lambs.—1st, David Tweedie, Abbington; 2d, John Archibald, Overshields; 3d, John Archibald, Lochgilphead.

4. Best Shearling Ewes or Gimmers.—1st, John Archibald; 2d, Allan C. Pagan, Innergeldie; 3d, John Archibald.

CHEVIOT.

5. Best Tup, above 1-shear.—1st, Thomas Elliot, Hindhope, Jedburgh; 2d, Herbert Brydon, Selkirk; 3d, John A. Johnstone, Archibank, Moffat.

6. Best Dinmont or Shearling Tup.—1st, Thomas Welsh, Archibald, Stow; 2d, Sir Graham Montgomery, Bart., M.P.; 3d, James Johnstone, Moffat.

BORDER LEICESTER.

7. Best 5 Ewes above 1-shear.—1st, James Brydon, Moffat; 2d, James Archibald, Lauder; 3d, Thomas Elliot, Hindhope.

8. Best 5 Shearling Ewes or Gimmers.—1st, James Archibald, Lauder; 2d, James Brydon, Kinnelhead; 3d, John M'Gregor, Dumfries.

9. Best Tup above 1-shear.—1st, George Hope, Fenton Barns, Drem; 2d, Thomas Ferguson, Kinnochtry, Coupar Angus; 3d, Adam Smith, Stevenson Mains, Haddington.

10. Best Dinmont or Shearling Tup.—1st, James Clarke, Cockburnspath; 2d, the Earl of Southesk, K.T.; 3d, Thomas Simson, Lauder.

11 Best 5 Ewes above 1-shear.—1st, George Laing, Coldstream; 2d, George Hope, Fenton Barns; 3d, Thomas Ferguson.

12. Best 5 Shearling Ewes or Gimmers.—1st, John Lees, Haddington; 2d, Charles Lyall, Old Montrose; 3d, James Clark, Oldhamstocks.

LONG-WOOLLED OTHER THAN BORDER LEICESTER.

13. Best Tup of any age.—1st, Thomas Wilkin, Dumfries (Lincoln); 2d, W. Norman, Aspatria (Lincoln); 3d, W. Norman (Lincoln).

14. Best 5 Ewes of any age, or Gimmers,—1, Thomas Wilkin, Dumfries (Lincoln); 2d, William Norman (Lincoln); 3d, W. Norman (Lincoln).

SOUTHDOWN.

15. Best Tup of any age.—1st, Robert Scot Skirving, Camptoun, Drem; 2d, ditto; 3d, John Gordon, Aberdeen.

16. Best 5 Ewes of any age, or Gimmers.—1st, Robert Scot Skirving; 2d, ditto.

SHROPSHIRE.

17. Best Tup of any age.—1st, the Earl of Strathmore; 2d, Andrew Crawford, Perth; 3d, the Earl of Strathmore.

18. Best 5 Ewes of any age, or Gimmers.—1st, 2d, and 3d, the Earl of Strathmore.

SHORT-WOOLLED OTHER THAN SOUTHDOWN AND SHROPSHIRE.

19. Best Tup of any age.—1st and 2d, John P. M'Pherson, Forres (Oxford Down), shearling tups.

CLASS IV.—SWINE.

1. Best Boar, large breed.—1st, R. E. Duckering & Son, Northorpe; 2d, ditto; 3d, George Mangles, Ripon.

2. Best Boar, small breed.—1st, R. E. Duckering & Son, Northorpe; 2d, Charles A. Murray, Stanley; 3d, George Mangles.

3. Best Boar, Berkshire breed.—1st, R. E. Duckering & Son, Northorpe; 2d, Robert Lyall, Brechin; 3d, Sir David Baird, Bart.

4. Best Sow, large breed.—1st, R. E. Duckering & Son; 2d, ditto; 3d, George Mangles.

5. Best Sow, small breed.—1st, R. E. Duckering & Son; 2d, Alex. Stewart, Bridge of Earn; 3d, John L. Gow, Raith.

6. Best Sow, Berkshire breed.—1st, Sir David Baird, Bart.; 2d, Alexander Stewart; 3d, Lord Kinnaird, K.T.

7. Best Pen of 3 Pigs, not above 8 months old, large breed.—1st, R. E. Duckering & Son; 2d, George Mangles; 3d, ditto.

8. Best Pen of 3 Pigs, not above 8 months old, small breed.—1st, R. E. Duckering & Son; 2d, John L. Gow, Raith; 3d, Robert Philip, Bridge of Allan.

9. Best Pen of 3 Pigs, not above 8 months old, Berkshire breed.—1st, William Harris, Aberfeldy; 2d, Sir David Baird, Bart.

LABOURERS' COTTAGES.

We offer the accompanying illustrations of a block of three cottages (figs. 227, 228, 229), as an example of an arrangement affording extended accommodation, at once convenient and economical, — remembering that while the farmer seeks to have as many labourers as possible near his homestead, the landlord is desirous of providing them with homes at as cheap a rate as possible.

This latter object is best attained by combining several dwellings under one roof, since by such means much external walling, and a very appreciable amount of roofing are saved.

In the example before us the main object has been to place all the front doorways facing the street, and at the same time to secure porches for each at little cost with a pleasing appearance. This is well effected by the arched openings shown in the elevation, which give a distinctive character to the buildings. They are also manifestly convenient when the cottages are placed as lodges at the entrance road to the homestead.

Another point to be observed is, that whereas the two outside cottages have three bed-rooms each, the centre dwelling has only two bed-rooms, thus affording accommodation for a small family, while the end cottages serve for larger ones.

The cubical space provided within the cottages is as follows:—The two outside cottages contain, in the living-rooms 1100 feet each, in the sculleries 704 feet, in the pantries 256 feet, in the fuel stores 256 each, in the porches 128 feet, in the stairs and landings 341 feet, in the parents' bed-rooms 720 feet, in the second bed-rooms 701 feet, and in the third bed-rooms 492 feet cube each.

The centre or two-bed-roomed cottage contains, in the living-room 1012 feet, in the scullery 596 feet, in the pantry 224 feet, in the fuel store 208 feet, in the porch 112 feet, in the stairs and landing 308 feet, in the first bed-room 967, and in the second bed-room 780 feet cube. These figures together make a total of 13,603 feet cube for the entire block.

The cottages, without the outbuildings, have on an average cost the sum of £125 each, or £375 the block. They are from the designs of Mr. Bailey Denton, jun., of the firm of Messrs. Bailey Denton, Son & North, by whom they have been erected in different parts of England, among which we may cite the Livermere Park Estate in Suffolk, and the Henlow Grange Estate in Bedfordshire.

We may add here that the whole series, we believe, of Mr. Denton's farm cottage designs are to be seen at Henlow, where an estate formerly in very dilapidated plight has been most admirably equipped under the public-spirited direction of the Rev. H. Addington.

Home Correspondence.

Are we again to have Cesspools?—Your German correspondent is mistaken. I continue my irrigation. On the sewaged Italian Rye-grass (14 acres) I have kept 200 sheep and lambs from April, seven horses for seven weeks, and yet a nice little haystack. I only regret that I have not a town sewer to supply my suction-pipe, for I cannot get manure enough in the ordinary way without investing a large additional capital in live stock, which I cannot afford, having to limit my general tenant or farm capital to £16 per acre. It ought to be £25 per acre, and then I should make a larger percentage of profit. My live-stock capital is usually £6 per acre. Could I afford it I would make it £12 or more per acre, and then I should consume all my straw (treading none under-foot), and keep all my cattle and pigs on sparred floors. I have not near manure enough, for it is quite clear that, in the case of root crops especially (as I have proved by comparative trials), we could double our acreable produce by means of extra manure and deeper cultivation, without increasing the fixed charges of rent, tithes, rates, taxes, &c. Besides, when we have provided, by very deep cultivation and a greatly increased quantity of manure, a surplus supply of food for our Mangel crop, the corn crops following will be ample, and very different from what we find them at present. Our German friend will fail to bring back Englishmen to the old cesspool system, and if he will but inspect the sewage farms at Hornchurch and Barking, he will no longer doubt the propriety of dissolving ordure in water and thus cheaply conveying it to the soil. My nasal midnight remembrances of the (good?) old cesspool times cause me to wonder at your correspondent's letter. Besides, manure is useless without water. The manurial power of Britain is about that of two sheep per acre, and this is mixed with a rainfall of 26 inches, or 2600 tons of water per acre per annum. Mr. Hope not only uses all the town sewage, but uses it again and again during dry weather in the shape of filtered water. While by steam-power we can raise 1000 tons of sewage 300 feet high for 13*s.* to 14*s.*, it will never pay to use horse-power and manual labour in the conveyance of town sewage. *J. J. Mechi, August 1.*

Record of Improvements and Cultivation of Estates in Ireland.—Some months ago you were good enough to inquire for me, what forms were used on carefully managed estates in England for recording the cultivation and improvements made yearly on each farm and each field. One of your correspondents referred me to the Duke of Cleveland's estate, and, through the kindness of the agent, an excellent form was sent me. Another correspondent referred me to Mr. Jemmett, Murrill Hill Farm, Binfield, Berks, the author of a very useful farmers' pocket-book. Mr. Jemmett has furnished me with what he calls an estate record, on the same principle as that used on the Duke of Cleveland's estate, but of more convenient size for use, and I think even better arranged. It is the size of a large pocket-book. Each farm occupies four pages, the two first pages, open together, are for cultivation, with enough columns for six years; and a first column, in which the number of each field on the map, or a description of the field, is entered. The other two pages are, one for improvements of any sort done on the farm, the other for bought manures brought on the farm, and for hay, straw, roots, &c., sold off. Everything is thus quite distinct and clear. Once a year, when the farm is visited by the landlord or his representative—as it is certain, since the Land Act, must be done with great care if the estate is not to be subjected to every sort of exaggerated and even fraudulent claim for improvements and unexhausted tillages and manures, in the event of the tenant failing, or even voluntarily leaving his farm—entries of the facts will be made on the spot, and should be communicated to the tenant. If the entries are made by a man of character and credit, they will, after a few years, practically become like evidence of the facts than any mere recollection, or pretended recollection, can be. Without such a record, the landowner will be really at the mercy of whatever charges a tenant, with the help of a lively imagination and heated feelings, will swear to or get sworn to. Any one, who has seen some of the enormously exaggerated claims made already in land cases that have come before the courts, will know the importance of having clear proof of the facts. The subject is of the greatest importance in reference to the future "management of estates in Ireland;" only the strictest and most business-like care will enable very heavy charges to be avoided, for which no value, or a very inadequate value is left. It is this great importance of Mr. Jemmett's Estate Record to so many, that makes me anxious to inform others of it. *An Irish Landowner.*

Cabbage as a Snatch Crop.—At p. 981 you advise Cabbage as a snatch crop, but it seems to me you overlook one very important point, that Cabbage will not stand a hard winter. If you plant out Cabbages in November, the chances are that you lose three out of four; and if you only put them in in spring, they will not be ready until the end of July, and then what sort of Turnip crop will you get afterwards? The best snatch crop, it seems to me, is Rye, or Rye and winter Vetches mixed. If the stubbles which are intended for roots are ploughed up immediately, and sown with Rye and winter Vetches, they will have a capital crop of green food on them by May 1, or the end of May, according to climate, and that can either be eaten off with sheep, or cut and carried to the cattle, and the land immediately ploughed up again for Turnips. One-half of the division intended for roots might easily be so treated, but not the whole; but the use of such a snatch crop is to give food for the stock in May and June, when usually food is very scarce. I generally grow a few patches of Mustard sown in April and May, which come in during May and June; and, after they are eaten off, the land is ploughed up again, and sown with yellow or white Turnips, according to the season. *G. A. H.*

Drained and Undrained.—The effects of non-drainage is, this wet season, very striking. The unequal ripening of the cereals is perceptible from the railway train. The furrows green, the ridges yellow, when the crops ripen evenly and the heads of corn are on a level and of equal size, there is at once evidence of proper drainage, natural or artificial, and also of a proper quantity of seed, for where seed is too thickly sown the plants remind one of a mixture of grenadiers and little riflemen. This is also a season for weeds, the absence of the hand and horse hoe inflicts this year a severe pecuniary punishment. There will be some too warm

cornstacks as well as haystacks.' Strange that one sees so few of Garrett's farmers' 38s. rick ventilators: I feel independent of hot stacks with this—a farmer's invention. In a wet season like this, the difference in the time of ripening between drained and undrained land is considerable and important. Some 29 years ago, when I first began to drain this land, a field of Oats on the drained land was in stack before the undrained was harvested, although the undrained was much the earlier sown. *J. J. Mechi, July 27.*

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

MONTHLY COUNCIL: *Wednesday, August* 2.—Present: Sir Watkin W. Wynn, Bart., M.P., President, in the chair; Viscount Bridport, Lord Kesteven, Lord Vernon, the Hon. H. G. Liddell, M.P., Mr. Barnett, Mr. Cantrell, Colonel Challoner, Mr. Edmonds, Mr. Brandreth Gibbs, Mr. Holland, Mr. Hornsby, Mr. Hoskyns, M.P.; Colonel Kingscote, M.P.; Mr. Leeds, Mr. Milward, Mr. Ransome, Mr. Shuttleworth, Mr. Stone, Mr. Torr, Mr. Jabez Turner, Mr. Wakefield, Mr. Welby, M.P.; Mr. Wells, M.P.; Mr. Whitehead, Colonel Wilson, Professor Simonds, and Dr. Voelcker.

The following new members were elected:—

Anderson, William, Lesney House, Erith, Kent.
Barton, Tom, The Crescent, Carlisle.
Beach, John, Standeford Cottage, Wolverhampton.
Blandell, Arthur, Chediston Hall, Halesworth.
Booth, Thomas, Tamborne Park, Lichfield.
Bowen, James, Troedyraur, Newcastle Emlyn.
De Pass, Daniel, 9, Delamere Street, Westbourne Square, W.
Easton, James, Hothe Court, Bleau, Canterbury.
Farwell, Frederick G., Wolverhampton.
Faulconbridge, W. F., Bestwood Park, Bulwell, Nottingham.
Gough, Ralph D., Willenhall, Staffordshire.
Gouldburn, John, Broomhall, Nantwich.
Gurteen, Daniel, Haverhill, Suffolk.
Ingram, George, Chetwynd Park, Newport, Salop.
Knight, Richard, Hobbington Grange, Sittingbourne.
Lea, Henry, 316, Bristol Road, Birmingham.
Lewisham, Viscount, Patshull, Wolverhampton.
Low, George, Burghtown, Athy, Kildare.
Morgan, Richard, Newtown, Montgomeryshire.
Parson, Edgcombe, Coates, Cirencester.
Phipps, Pukering, Collingtree Grange, Northampton.
Polding, J. Bede, Burnley, Lancashire.
Price, William, New House, Carleon.
Reynolds, Osborne, Owen's College, Manchester.
Richardson, John, The Oaks, Dalston, Carlisle.
Roberts, Oscar Wilson, Fisherwick Park, Lichfield.
Sedgwick, Alfred D., Watford, Herts.
Thomas, J. Howell, Starling Park, Carmarthen.
Ward, William, Penybort Hall, Oswestry.
Whitworth, James R., Weston Underwood, Newport Pagnell.

FINANCE.—Viscount Bridport presented the report, from which it appeared that the Secretary's receipts during the past month had been examined by the committee, and by Messrs. Quilter, Ball & Co., the Society's accountants, and were found correct. The balance in the hands of the bankers on July 31 was £9441 7s. 7d., the sum of £2000 remaining on deposit. Cheques to the amount of £9977 5s. 9d. were ordered to he drawn. The committee recommend that the Secretary be authorised to transfer the £2000 on deposit to the current account. The committee have to report that, chiefly owing to the great expense attending the trials of steam cultivating machinery and traction engines at Wolverhampton, the expenditure will exceed the receipts, although the attendance was as numerous as was expected, especially when the unfavourable state of the weather on some days is considered. This report having been adopted, a conversation arose in reference to the question of the expense incurred by the Society in connection with the country meetings. Colonel Wilson and Mr. Torr expressed their opinion that some reduction in the expenditure could be made, while Mr. Ransome maintained that the money spent was carefully and judiciously disbursed, and that retrenchment could only be effected at the cost of efficiency—a result which he hoped the Council would not sanction. Finally, Lord Vernon gave notice that at the November meeting of the Council he would draw attention to the financial results of the shows held at Oxford and Wolverhampton, and move the appointment of a committee to consider the expenditure at the annual shows, and the possibility of securing equal results at less cost.

IMPLEMENTS.—Colonel Challoner (chairman) reported that the implement prize sheet for the Cardiff meeting had been revised by the committee, the proposed prize for self-moving engines having been struck out, and that the committee recommended the amended prize-sheet for adoption by the Council.—This report was adopted after some additional amendments had been made to the proposed prize-sheet.

GENERAL, WOLVERHAMPTON.—Lord Kesteven reported that the accounts due in connection with this meeting had been duly certified and recommended for payment, with certain exceptions. It was also reported that an error had been made by the judges in Class 92 (Shropshire rams above one year old), the numbers given in by them not agreeing with those to which they had affixed the cards; but as the error was merely clerical, they recommended that the cheque for the prize-money be drawn in favour of Mr. T. Mansell, who was awarded the 1st prize in that class.—This report was adopted.

GENERAL, CARDIFF.—Lord Kesteven reported the recommendation of the committee that the Cardiff meeting shall commence on Monday, July 15, and continue until the following Friday inclusive, and that the trials commence on Monday, July 8. The committee also recommended that Mr. Corbett, the agent of the Marquis of Bute, be invited to act as steward of forage at the Cardiff meeting, and, in the event of his being unable to act, to recommend some other competent person.—This report was adopted.

VETERINARY.—Mr. B. T. Brandreth Gibbs presented the following report:—An *ad interim* report from Professor Simonds was laid before the committee on the experiments he has made at the Royal Veterinary College in reference to feeding cattle on a patent cake. So far as the experiments had proceeded, up to July 31, no symptoms of injurious action had appeared. The same result had been obtained on feeding pigs up to the same date. Professor Simonds will forward a further report on the completion of the investigation. It was also reported that the Secretary had laid before the committee the correspondence between himself and the Veterinary Department of the Privy Council, together with a *précis* of the various acts and orders in Council relating to the importation of foreign animals. As this had been drawn up for the use of the Royal Society, the committee recommended that it and the correspondence relating thereto be published in the forthcoming number of the Journal.—This report was adopted.

SHOWYARD CONTRACTS.—Mr. Torr reported that the Committee had examined and certified certain accounts connected with showyard works, which they recommended should be paid, with the exception of one, which they recommended should be deferred for inquiry until November.—This report was adopted.

The death was reported of Sir Thomas Dyke Acland, Bart., a trustee of the Society.

Mr. Holland having moved the renewal of the education grant for 1872, it was seconded by Lord Vernon, and carried unanimously, after a few words from Mr. Wells, M.P., who stated that unless the number of candidates increased he could not continue to support the grant year after year. On this point Mr. Holland observed that the number of candidates could be increased if the standard of examination were lowered; but the committee were of opinion that it would be better to raise the level of the candidates, if possible, than to lower the standard of the examinations.

The Secretary was authorised to sign and seal the agreement with the authorities at Cardiff.

A letter was read from Mr. B. T. Brandreth Gibbs in acknowledgment of his election as a Vice-President.

An application for the loan of the Society's ploughdynamometer was granted on the usual conditions.

It was announced that a silver cup, value £100, will be offered by Sir W. W. Wynn, President, for the best managed farm in South Wales and Monmouthshire which shall conform to the following conditions:—1. That it is not less than 100 acres in extent; 2. That not less than one-fourth of the land (not sheepwalk) is under tillage; 3. That it is held (*a*) by a tenant-farmer paying a *bonâ fide* rent for not less than three-fourths of the land in his occupation, or (*b*) by a landowner occupying his own farm, the total extent of whose property in agricultural land exclusive of sheepwalk does not exceed 200 acres, and whose sole business is farming. The Council then adjourned over the autumn recess until Wednesday, November 1, the usual holiday having been first granted to the Secretary and clerks.

BATH AND WEST OF ENGLAND ASSOCIATION.

AT the Council meeting, July 25, a letter was read from his Grace the Duke of Marlborough, accepting the office of President, but regretting his unavoidable absence on the present occasion.

The finance committee brought up their statement of accounts, from which it appeared that although the Guildford Show was not so successful in a financial point of view as several of its immediate predecessors, yet after the payment of all expenses a balance of £27 10s. remained in favour of the Society.

The committee of stewards and officers for the ensuing year were appointed. Captain J. Tanner Davy, editor of the "Devon Herd Book," succeeds Mr. J. S. Turner as one of the Stewards of Stock; Mr. R. Neville, of Butleigh Court, is appointed a Steward of Arrangements and of Yard Implements, as also a member of the Implement Regulations Committee. Mr. T. Duckham, of Baysham Court, is added to the list of Field Implement Stewards; Mr. Troyte, of Huntsham Court (grandson of the late lamented Sir T. D. Acland, Bart.), is added to the Arts and Implements Regulations Committees; the Right Hon. the Earl of Cork and Mr. Meade King to the Railway Arrangements Committee; and Mr. Moore-Stevens to the Judges Election Committee. Captain Best, R.N., succeeds to the office of Steward of Arts, vacated by Mr. J. C. Ramsden, who, however, retains office as a member of the Finance Committee.

The stewards of stock having had their attention drawn to certain alleged irregularities committed at the Guildford meeting, reported to the Council that they acquitted Messrs. Duckering & Son of any intentional irregularity, and saw no reason to reverse or disturb the awards of the judges.

A memorial from the Right Hon. the Earl of Portsmouth and seven other breeders of pigs in favour of pigs of the small black breed being kept distinct from white ones in the Society's prize list, was referred to the Stock Prize Sheet Committee.

A letter from Mr. A. Benjafield of The Poplars, Stalbridge, recommending the offer of prizes for cheese, was ordered to be referred to the Dorchester local committee.

As a preparatory step to the meeting of the several committees the Council resolved that the amount offered in prizes for stock at Dorchester be limited to £1500, as against £1400 last year; poultry, £200, as against £180; and horticulture, £130. The musical arrangements were left to the discretion of Mr. Jonathan Gray.

Eleven new members were elected.

Notices of Books.

The Book of the Farm: *including the Labours of the Farmer, Farm Steward, Ploughman, Shepherd, Hedger, Farm Labourer, Field-worker, and Cattleman.* By Henry Stephens, F.R.S.E., &c., &c. Third Edition. W. Blackwood & Sons. [First Notice.]

This is the first of a series of somewhat exhaustive works on agriculture, which were published 20 years ago or more, to re-appear in the new and remodelled state in which their common subject now stands after a quarter of a century's growth. Mr. Stephens' work more than any of its compeers justified the special title which he had adopted. It gave a detailed account of the labours of every one employed upon the farm, from the farmer himself to the humblest of his workmen.

These characteristic labours remain very much what they were, and there is necessarily much in 1871 which offers the same material for the work of description and discussion as it presented 20 or 30 years ago. The "Book," therefore, though rewritten altogether and recast, is a new edition, not an altogether new book. There are, however, some subjects which have been re-modelled and recent—the farming of arable land since Mr. Stephens began to write. Steam cultivation and artificial manuring, and horse-driven harvesting machines has made the work of the ploughman and field-worker very different from what it was. The use of liquid manure from town drainage is likely to be another source of agricultural growth and progress, which will produce a great change over considerable districts in the next quarter of a century. Some of these subjects are fully discussed in the new volume by the author of the "Book of the Farm;" but we think that the reader will greatly be disappointed that his attention is not more fully directed to them. The book, however, perhaps is unavoidable. It is not Mr. Stephens' plan to "discuss" so much as simply to describe. He relates with carefulness and precision all that is included within the labour of the farm, and the agricultural student will find in his pages the whole detail of farm work, with not more of explanation and justification than just suffices for his intelligent guidance.

On one or two points we think that this plan has been prosecuted with greater severity than was advisable. One would like to hear more of the advantages of steam-culture and of the possibilities of fertility due to sewage irrigation, and of the practice of the most liberal farmers in respect of manuring, than these pages give; nevertheless they are full of most useful and trustworthy matter, and of the style in which they are illustrated we give specimens on the opposite page, the publisher having kindly lent us two of his blocks (alternative (fig. 230) of the former and (fig. 231) the present mode of reaping corn.

Farm Memoranda.

DELARRAN LODGE, NEAR GALLOWAY.—The agricultural prospects of this district are at the present moment encouraging, and should the weather has favourable during the ensuing month, a good harvest may be fairly anticipated. In consequence, however, of the severe spring, both cereal and green crops are not so forward as usual, and the fields will not be cleared of the grain crops until ten days or a fortnight later than last year.

The yield of Oats will probably be fully up to the average, and although early-sown Turnips suffered severely from the ravages of the fly, yet those which were put in later have entirely escaped, and are now looking vigorous, and only require some warm weather in order to yield a good return to the grower. As compared with last year the Rye-grass hay is very deficient, both as regards weight per acre and quality. Last autumn large quantities of hay were exported to England, and high as was the price during last year in London and the southern counties of England, it was probably to a considerable degree kept down by the importations from Scotland. But unless the hay crop is much better in other districts of this country than it is here, there will be no hay to export during the

approaching winter at remunerative prices. *R. C. C. G., July* 31.

KENT (*East*).—My opinion of the crops in this district is easily given, for I believe on the whole things were never better, and should the present fine weather continue there is a prospect of an abundant crop. Wheat is very good, and at present stands well; it will not be fit to cut before the middle of August. Barley is as good as can be on all well farmed land, and most of it will be fit to cut before the Wheat. Oats are not generally as good as Wheat and Barley. Beans are promising, and Peas of all sorts exceedingly good. Potatos look well at present, but I hear of some disease amoog the early sorts. The hay crop is heavy, and is now being secured under favourable circumstances; but our Sainfoin was generally injured by the rain. Mangel, Swedes, and Turnips, plant well and look promising. All feed is plentiful; cattle and sheep are doing well. *W. M.*

NORTH BEDFORDSHIRE: *July* 28.—When any attempt is made to form an opinion as to the probable produce of the corn crops (Wheat more especially), two things quite distinct must be taken into consideration, viz., the appearance of the crops and the character of the season, and the latter is, at this distance from harvest, a far safer criterion than the former. There must be a dry and hot season for a good yield of Wheat. This is an infallible rule. In this neighbourhood, last year, comparatively light crops of Wheat produced in some cases from 5 to 6 qr. per acre. The previous year heavy crops produced in some instances not more than from 3 to 4 qr. The spring and summer of 1869 were very wet until about midsummer, brilliant weather then setin; and thought his saved the quality of the Wheat, the yield was bad. This year the spring and summer have been wet and cold to the present time, with the one redeeming feature of a dry May, and about 10 days of June. It will be a matter of some interest to note what effect the dry May has upon the Wheat crop this year, as with this exception the season would lead us to expect a very poor produce in proportion to bulk and appearance.

A small portion of the Wheat is thin upon the ground, otherwise the crop is good, but somewhat broken down by the continuance of wet and windy weather.

Barley promises well, and will probably be the best crop of the season, being less affected by wet and cold weather than Wheat.

Beans and Peas are a bulky and rather rough crop, but will be good with the exception of the spring Beans, which are much blighted.

Green crops of all kinds, as well as grass and hay, are very abundant. The Mangels do not promise to be very large.

Much now depends upon the weather; the barometer is still low, and the continued sunshine we are so much in need of seems as far off as ever. *Henry A. Bottle, Patenhall.*

TIPTREE HALL, NEAR KELVEDON, ESSEX.—Wheat very good on drained and well farmed lands, but thin of plant on undrained and weedy farms. Barley, generally a very excellent crop; a good deal laid where too thickly sown on high farmed land. Young Clover a full and vigorous plant, quite a contrast with last year's. Oats, much improved lately, and corny, but not much straw. Beans, a more than average crop, and promising abundantly. Peas, much above average—very heavy crop. Winter Tares very good. Trifolium, a good crop. Red Clover, patchy; some good pieces where there was a full plant, promises a good second growth. Pasture, much better than was expected a month ago; a fair crop, very good in places. Much Trifolium, Clover, and grass hay has been damaged by frequent heavy rains. The getting has been costly, anxious, and tedious. Half mine (45 acres) was well gotten, and the rest not much injured, but we had frequently to uncock and re-cock it. Potatos and all garden vegetables a very full crop, of good quality. No disease in this immediate neighbourhood at present, but I have heard some complaints from a few miles distant. Field Cabbage, Mangel, Kohl Rahi, and Turnips very promising. On the whole, I consider that there will be more food for man and beast this year than last, taking into account meat, milk, butter, cheese, and vegetables. The heavy rains have in this neighbourhood done much more good than harm on well-farmed arable lands. Harvest will probably commence here about August 15, or three weeks later than last year—perhaps earlier, should we have hot and dry weather. *J. J. Mechi.*

Obituary.

WE have to record the death of one of the oldest and most respected gentlemen connected with the agricultural interest of the county of Cornwall. Mr. HENRY TRETHEWY, of Grampound, has long been one of the pioneers of agriculture in this county—almost foremost in introducing approved implements, the best breeds of cattle and sheep, or in effecting improvements in the land. His superior skill and judgment in all matters connected with the land and with agriculture were universally acknowledged; and perhaps more than any other man of his time was he called in to arbitrate upon such questions. Mr. Trethewy has been more especially known in the county as the steward of the Trewithen property, having first become connected therewith in the year 1810. This property is a very extensive one, consisting of much fertile land, as well as a great deal of waste land, mining property, and clay works, extending over the central and western districts of the county, more especially in Probus, Helston, the Lizard, Penzance, St. Erth, and Roseland districts, with extensive properties in the parish of St. Stephen, including clay works and the harbour of Pentewan. Mr. H. T. Hawkins, the present owner of the property, and his father, the late Mr. John Heywood Hawkins, continued to repose the same confidence in Mr. Trethewy as had been shown by the late Sir C. Hawkins.

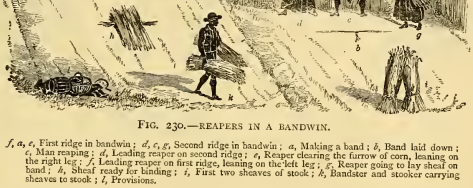

FIG. 230.—REAPERS IN A BANDWIN.

f, a, e, First ridge in bandwin; *d, c, g,* Second ridge in bandwin; *a,* Making a band; *b,* Band laid down; *c,* Man reaping: *d,* Leading reaper on second ridge; *e,* Reaper clearing the furrow of corn, leaning on the right leg; *f,* Leading reaper on first ridge, leaning on the left leg; *g,* Reaper going to lay sheaf on band; *h,* Sheaf ready for binding; *i,* First two sheaves of stook; *k,* Bandster and stooker carrying sheaves to stook; *l,* Provisions.

As a proof of the esteem in which Mr. Trethewy was held, we may mention that a few years ago his friends presented him, in the Council Chamber at Truro, with a handsome portrait of himself, which had been executed by Mr. J. P. Knight, R.A., accompanied with a service of plate, consisting of six massive silver salvers, and a tea and coffee service, also of solid silver, the whole weighing 350 oz.; the subscriptions, which were contributed by persons of every class, amounted to £400. At the ceremony of the presentation in September, 1865, the chairman, Mr. P. P. Smith, bore testimony to the fact that "of all the eminent agriculturists in Cornwall, and there were many of them, he (Mr. Trethewy) had by universal consent been considered to be the greatest living benefactor to the interests of agriculture in his native county; and his reputation was not confined to the county of Cornwall, for it extended to every portion of the kingdom in which agriculture was cultivated as a science."

Mr. Trethewy may be looked upon as almost the father or originator of the Royal Cornwall Agricultural Society, and he has always been one of its most active supporters; and up to a very recent date he was to be seen at the annual exhibitions riding about the grounds as the steward of the show field, and conducting that office with the greatest tact and discretion. His death took place at his residence at Grampound on Tuesday of last week, at the advanced age of 85 years.

Two of Mr. Trethewy's sons have attained high positions as managers of landed property, owing largely, no doubt, to the experience their father had been able to impart to them. The eldest son, Mr. Henry Trethewy, has had for many years past the management of some of the most important properties in the county, belonging to the Countess Cowper, the Earl Cowper, and other gentlemen; while the youngest son, Mr. Alfred Trethewy, is now managing a large and important property in North Wales.

Abridged from the "West Briton."

a, a, Standing corn; *b,* Reaper at work; *c,* Sheaf of corn as delivered by the reaper being taken up by a field-worker; *d,* Band for receiving the cut sheaf; *e,* Bandster making a stook.

The Week's Work.

AUGUST 5.—Clear away areaas of work before corn harvest commences.

Hedges.—Finish the summer cutting. The ground under the hedge should be kept clean by hoeing with the small hedge spade, pulling out every weed with the hand. The prize farm at Sherlowe, Shropshire, this year, doubtless owes its success in some measure to the remarkable neatness and cleanness of its hedges, obtained in this way. This is the time for clearing out and paring all watercourses, field ponds, and ditches.

Repairing and Making New Roads should be done before the corn harvest commences.

Carting stones and bricks for building purposes, and draining-tiles for draining after harvest, may supply work to the teams, and thus lessen the pressure upon them after harvest. At this season such carting does comparatively no harm to farm roads and the land; whereas in the winter time it cuts up both, the teams at the same time hauling barely half the loads they now do.

Cottages and Farm Buildings should be put in repair. Tillage implements require painting, reaping-machines and horse-rakes to be put in order, thatch provided, and the stackyard got ready for the stacks. The steam-engine, threshing, dressing and weighing machines, require overhauling, so as to have them in proper working order.

Live Stock soiled at the homestead, or in hovels and yards in the field, require to be carefully attended to, so that all may have pure air, clean water, proper temperature, and an equal share of suitable foods. When doors and windows are left open, or openings purposely made to effect ventilation, the excessive heat of the sun gives rise to chilling currents, very injurious to live stock—more especially the teams when they return from work in a state of profuse perspiration. All through currents and down draughts should be obviated.

Weaned Lambs should be put upon the best pasture—the ewes upon the worst, and let the distance between them be as far as possible. Ewes that are good nurses, and in full milk, may require milking for a short time, but bad milkers run dry without experiencing harm.

Scab, Lice and Ticks in Sheep obviously indicate a

filthy state of the skin and wool which ought not to exist, consequently cleanliness is the proper rule for getting rid of such parasites.

The Fly, as the temperature increases, becomes more and more annoying to sheep. They should be examined every day, especially those that are kept in inclosures in a woodland country. When fly-struck, a mercury stone rubbed into the place will destroy maggots before much harm is done.

Corn Harvest is generally in progress in early August in our southern counties, though this year later than usual.

Chalk, Marl, and Lime Composts, when required for immediate application after harvest, should now be got in readiness. In the olden time, when naked fallowing was common, they were frequently applied to the land prior to the seed-furrow. They may also be carted on to hay and Pea stubbles, and also burnt-up pastures. When the clay from pits contains no lime, chalk, shell, or gravelly marl, or lime from the kiln may be mixed with it in a compost heap, and afterwards be applied to the land should clay and lime both be required.

Winter Peas and Beans harvesting, prosecute as the weather and state of the crops permit. Carry as soon as ready, and never allow the stacking to fall behind. Thatch immediately.

Winter Rye comes in early for the reaping-machine and stackyard. The crop grows more freely on poor sandy and porous soils than any of the other cereals, and the farmers of the Continent study their interest in this respect better than we do; although it grows longer in the straw than Wheat, it is more wiry, and stands better up to the weather and the reaping-machine. The sheaves also stand well in the stook, and the straw makes the best of thatch and litter.

Notices to Correspondents.

DITCH WATER: *Young Hand.* Your liquid manure will probably disappoint you. You can get a good liquid manure cart of Mr. Isaac, implement maker, Cheltenham.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, July 31.

The supply of English Beasts is very short, but of foreign unusually large. Trade is hardly so good for all kinds, yet there is not much reduction in price of choicest English; it is difficult to effect a clearance of foreign. There are a few more Sheep than last week; there is, however, a fair demand, and prices are not much lower. Choice Lambs are as dear as lately, but middling ones are lower. Calves are lower. Our foreign supply consists of 2700 Beasts, 12,350 Sheep, 490 Calves, and 40 Pigs; from Scotland there are 13 Beasts; from Ireland, 120; from Norfolk and Suffolk, 180; and 800 from the Midland and Home Counties.

			Pigs	.. 3	4—4 8

THURSDAY, Aug. 3.

Although the number of Beasts is much smaller than on Thursday last, the demand has so much decreased that the prices of that day cannot at all be realised. The average quality of the supply is very middling, and only a few reach our top quotation. The number of Sheep is about the same as last week; trade is very much worse, and a clearance cannot be effected. Trade is not brisk for Lambs, but prices are not much altered. Calves are lower. Our foreign supply consists of 370 Beasts, 6700 Sheep, 656 Calves, and 15 Pigs.

MARK LANE.

MONDAY, July 31.

The very short supply of English Wheat at this morning's market was sold at an advance of 1*s.* per qr. upon the prices of this day se'nnight. The attendance was good, and for Russian and American there was a good demand at the same improvement. Barley was rather more inquired for. Beans, and Peas were unchanged in value. The Oat trade was firm, at last week's rates. In the value of Flour there was no alteration.

WEDNESDAY, Aug. 2.

Influenced by the more favourable weather, the grain trade to-day here ruled quiet, and difficulty was experienced in realising Monday's currencies. The supplies of English Wheat were short, but the arrivals from abroad were on a liberal scale. In all qualities sales were effected quietly, at about previous prices. Barley, Beans, and Peas were in limited request on former terms. The show of Oats on the stands was good. The demand was inactive, and in some instances favoured buyers. Flour was dull, and prices had a downward tendency.

SEED MARKET.

During the past week we have had an improvement in the weather, which may now be regarded as favourable to the maturity of the growing seeds. The stock of red and white Clover remaining on hand is small; values have consequently advanced some 2*s.* to 3*s.* per cwt. Of new Trefoil seed a few samples have been shown in our market, but the quality was indifferent; fine old seed is 3*s.* to 4*s.* per cwt. dearer. Trifolium is in abundant supply, with great variations in quality: the lateness of the harvest delays the English demand, prices have in consequence given way 4*s.* to 5*s.* per cwt. The new Rape which has come to hand is very fine; it realises fully 4*s.* per qr. less than the old was sold at. Canary must be quoted 5*s.* to 4*s.* per qr. higher. In other articles there is no alteration.

JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

HOPS.

BOROUGH MARKET, Aug. 2.

Messrs. Pattenden & Smith report the market in a less active state, although prices rule the same. It is thought the favourable change in the weather may improve the plantations to a slight extent if it should continue.

LETTINGHAM'S LIQUID COMPOUND, for the DESTRUCTION of INSECTS of all kinds, and MILDEW INFESTING PLANTS, has been proved to be the most effectual application for destroying Aphis of all kinds, Thrip, Mealy Bug, American Blight, Green and Brown Fly, Red Spider, Wasps, Ants, &c., hitherto offered to the Public. It will be found invaluable for Vines, Pines, and Fruit Trees of all kinds, as in most cases one dressing will keep off the ravages of Insects for a whole season.
The Liquid Compound will not injure the most tender foliage of Stove or Greenhouse Plants; and, if mixed occasionally with the water ordinarily used for syringing, will, if applied before the appearance of insects, prove a certain preventive. Broccoli and other Greens may be thoroughly cleansed from insects and filth of all kinds by sponging, or using the Liquid Compound by means of the "Horticultural Vaporiser."
We select two voluntary Testimonials from a great number we have recently received:—

"Elvastoo Nurseries, Borrowash, June 28, 1871.
"DEAR SIR,—We beg to bear testimony to the efficacy of your Liquid Compound, which we have used in our Nursery, both out-of-doors and under glass, with perfect success. We consider it the best preparation we have tried. It thoroughly clears the plant without injuring the foliage.—We remain, dear Sir, yours faithfully,
"MR H. C. FRETTINGHAM." "WILLIAM BARRON & SON."

"Upton Nurseries, Chester, July 11, 1871.
"DEAR SIR,—We have very carefully tested your Liquid Compound for destroying insect life. We have tried it upon most of the pests which prey upon vegetable life, and find it very effective in cleansing all kinds of plants from scale, mealy bug, aphides, thrip, red spider—in fact all kinds of insect life seem to succumb to its power most effectually and rapidly, and that without injuring the tenderest foliage, as far as we can observe. We consider the Compound most valuable to all growers of plants.
"FRANCIS & ARTHUR DICKSON & SONS."

Voluntary Testimonials have also been received from the following:—R. G. Rackstone, Esq., The Ash Hall.
Mr. G. Westland, Gr. to Earl Dudley, Witley Court.
Mr. Wm. Jackson, Gr. to Lord Scarsdale, Kedleston Hall.
Mr. H. Gadd, Gr. to Lord Middleton, Wollaton Hall.
Mr. Speed, Gr. to the Duke of Devonshire, Chatsworth.
Mr. Wm. Parker, Gr. to the Misses Strutt, Derwent Bank, Derby.
Mr. F. Harrison, Gr. to F. Wright, Esq., Osmaston Manor, Derby.
Mr. W. S. Milford, Gr. to T. W. Evans, Esq., M.P., Allestree Hall.
Mr. F. Ayres, C.M.R.H.S., Consulting Landscape Gardener, Nottingham.
Mr. W. Thompson, Gr. to Sir Seymour Blane, Bart.
Thos. Crump, Esq., Quarndon, near Derby.
Fitzherbert Wright, Esq., The Hayes, Swanwick.
Mr. James Tegg, Gr. to the Duke of Newcastle, Clumber Gardens.
Messrs. G. & W. Yates, Market Place, Manchester.
Mr. H. Ellis, The Gardens, Alfreton Park.
Messrs. Cole & Son, Manchester.
PRICE LIST.—One gallon bottles, 5s. 6d.; half-gallon bottles, 3s.; pints, 1s. each, bottles included. In Casks—10 or 12 gallons, 4s. 6d. per gallon; 30 gallons and upwards, 4s. per gallon, cash remittance. Carriage paid on all orders to the amount of 20s. and upwards.
May be obtained of the principal Seedsmen and Nurserymen throughout the country.

THE CELEBRATED COLLECTION OF ORCHIDS,
FORMED BY
S. RUCKER, ESQ., OF WANDSWORTH.

MESSRS. JAMES VEITCH & SONS

BEG TO ANNOUNCE THAT THEY HAVE PURCHASED THE ABOVE

MAGNIFICENT COLLECTION OF ORCHIDS

In its entirety, Mr. Rucker having decided on relinquishing their Culture.

This Collection is, without doubt, the richest as regards variety and rarity which has ever been formed; Mr. Rucker having during the last thirty years purchased, regardless of expense, both in England and on the Continent, every fine and distinct kind he could meet with.

The Plants are in the finest possible health, and the SECOND PORTION will be offered for SALE at Mr. STEVENS' AUCTION ROOMS, Covent Garden, on AUGUST 22d and 23d, details of which will appear in Mr. Stevens' Advertisements. The dates of future Sales will be duly announced hereafter.

ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, S.W.

The Gardeners' Chronicle

SATURDAY, AUGUST 12, 1871.

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Aug. 16—{ Royal Horticultural (Fruit and Floral Committees), at S. Kensington .. 11 A.M. / Ditto (General Meeting) .. .. 3 P.M.

WE are indebted once more to the courtesy of our correspondents for the means of presenting a general review of the FRUIT CROP for the present season. Our reports embrace so wide an area, and are contributed by so many observers, that the general average may be assumed to be fairly correct, although it must not be overlooked that local circumstances and local conditions very materially affect the result in certain districts. It is impossible to state accurately the exposure, nature of the soil, and general climatal conditions of each separate garden, our records would be even more valuable. One thing is clearly elicited by a study of our report, and that is, that the gardener is not responsible for climate, and that he is, as a rule, quite exonerated from the too sweeping charges brought against him in the matter of out-door fruit culture. In some cases gardens, — real gardeners we mean — announce their intention to give up the culture of Peaches and Nectarines on walls, so manifold are the chances against them. In other cases we are told that in spite of constant attention, Peaches and Nectarines on east walls have scarcely a healthy leaf, while on the south or west walls not a leaf is curled.

The May frosts (12° below freezing point on May 17 is mentioned in more than one place), indeed blighted our hopes, and with that *sequela* constituted the main reason for the general deficiency. The drought of last season, in the opinion of some of our correspondents, also had a deteriorating influence, as well as the abundant crops of last year. For our own part we are not disposed to attribute any great effect to the former cause.

Summarising the general results given in our Tables, we may state that fruit crops are not only scanty, but are from three to four weeks later than ordinary, but that, with the exception of Scotland, the returns are, on the whole, more favourable than we could have expected after the very trying season we have experienced. In the returns from Scotland the crops are most often described as moderate, though in instances total failures are reported. Correspondents state that trees looked healthy and promising, till the fruit succumbed to late spring frosts.

In the northern counties of England the crops are reported under the average, with the exception of Nuts and Apricots, which are abundant. All crops are two or three weeks later than usual.

The remaining returns, which read much alike, may be summarised as follows:—

Apricots seem to have been most abundant everywhere. The fruit is reported for the most part as having been small and late.

Apples are a very partial crop, being reported as plentiful in some places, and thin in others (generally orchards), while in some places they are a total failure. Fruit small, and trees suffering from curl, aphis, &c.

Pears are also a variable crop, being generally very fair on walls, but thin on standards. Under the average.

Plums appear to be a thin crop, the best being against walls; the trees are very much blighted.

Strawberries, where not cut off by late frosts, were an abundant crop, but much damaged by excessive wet, and deficient in flavour. The best reports of this crop come from Kent.

Dessert Cherries were scarce, but Morellos are most abundant nearly everywhere.

Peaches and Nectarines are, for the most part, described as plentiful. The trees seem to have been much injured in spring, through the cold weather, but they are now recovering. In some gardens the trees on east walls are much blistered, whilst those on west walls are clean and healthy.

Small fruits have been generally abundant, but red and black Currants appear to have suffered fearfully from blight, many bushes being reported as killed outright.

Filberts and Cob nuts have produced an extraordinary crop. Walnuts are scarce.

Incidentally we learn that the growth of shrubs, &c., has been rapid during the summer, as might have been expected in cases where they did not start into growth till after the rigours of May. Less satisfactory is it to hear of the outbreak of the Potato disease, which, we fear, threatens speedily to become general.

—— We have received the following communication relating to a proposed TRIAL OF HOTWATER BOILERS, from Messrs. WEEKS & Co.:—

"It is not a little amusing for old practitioners to note the exploded theories recently advanced, ideas which have been experimentalised upon years ago and abandoned. But we have no desire to provoke a paper war; such combats rarely terminate satisfactorily. 'Less talk and more work' is far more likely to develope sound practical information than a host of mere opinions committed to paper, and for this reason we urge that the once talked of public trial of hotwater boilers be forthwith put in operation. The subject is ripe for test, and should be taken in hand. For our own part we shall be pleased to join in the contest with our tubular boiler, also to render any assistance that lies in our power to work out the competition, and in the absence of any more convenient and suitable site being found available, we willingly offer the free use of our spacious foundry premises at Chelsea for the occasion.

"But perhaps there are those who, knowing the varied experiments made at our late show establishment (now Mr. BUTL'S), by comparing the working capabilities of many descriptions of boilers, may submit that we, being in possession of certain ascertained results, must first make them public; but these experiments were costly and carried out at our own expense, and therefore we feel justified in not publishing them. Another and not less important reason is, that any results we might publish would naturally be received with some doubt lest prejudices in favour of our own invention should have crept in; therefore we say it will be better for all to start afresh.

"Respecting the uniform capacity of boilers, we presume that the size of each would be determined by its water contents, upon the same principle as that applied to any ordinary vessel, quite irrespective of its shape or form. Allowing such to be the case, we suggest the following:—

"1. Each competitor shall be allowed to construct a vessel of any shape or form he pleases, limited in size to a given contents, or, in other words, a stated quantity of water shall be allowed to each competitor for distribution in, around, or about the fire as best he pleases, in a vessel or heating agent of any form—the same to be designated a boiler.

"2. Each boiler to be worked for a given period, say, for example, 12 days and 12 nights—being an average of four days and four nights consecutively to each of the three subjoined systems.

"*System A.*—Each boiler to be fixed in a stokehole of its required depth, or the apparatus to be elevated to such an equivalent, so as to establish the system most commonly adopted in heating by hot water.

"*System B.*—Each boiler to be placed above its work, that is to say, to have no stokehole, merely an ashpit, so that the flow-pipe shall at starting descend to the apparatus, say for a distance of 3 feet 6 inches to 4 feet, the position of the apparatus to remain unchanged.

"*System C.*—The apparatus to be so adjusted, and the boiler attached, as to convert the pipe usually the return into the flow-pipe, and the flow into the return-

pipe, or, in a word, to reverse the system standing first, and marked A, in order to prove whether any, and what, advancement has been made during the 20 years this system has been more or less in operation.

"Further and more detailed regulations will of course govern the trial, such as a sealed specification by each competitor, describing mode of connection, the classification of boiler, description of fuel, test of temperature of water, test of rapidity of circulation, arrangement for defraying expenses, &c., all of which require consideration and determination by practical men.

"Should, however, these suggestions share the fate of others which have preceded them, we beg simply to add that, *for power*, we are prepared to challenge any boiler not made in imitation of our tubular, to produce equal results with the same amount of fuel and labour; and for *durability*, we are prepared to guarantee, by contract, every Duplex Upright Tubular Boiler made and fixed by us, for 15 years. A public test, based upon the foregoing conditions, would, we venture to state, be productive of much practical good, and go far towards setting at rest this long-discussed boiler controversy."

—— London botanists will be interested in the Flora of Hyde Park and Kensington Gardens, which the Hon. J. L. Warren publishes in this month's "Journal of Botany." About 190 species are included in the list, which occupies over seven pages, and gives full details of localities. One or two of the plants—such as Trifolium glomeratum—are far from common, and likely enough to attract London botanists. We hope that none of them may be extirpated by collectors.

—— Dr. Asa Gray publishes, in the "American Naturalist," a figure and description of a new species of Erythronium, which he names E. propullans. The most singular peculiarity of the plant is found in the way in which the bulb propagates. An offshoot springs from the ascending slender stem, or subterranean sheathed portion of the scape (which is commonly 5 or 6 inches long), remote from the parent bulb, usually about midway between it and the bases, or apparent insertion of the pairs of leaves; this lateral offshoot grows downward, sometimes lengthening as in E. americanum, sometimes remaining short, and its apex dilates into the new bulb. The flower is bright pink, and much smaller than that of any other known species, being but little an inch long. It was discovered at Faribault, Minnesota.

—— The Maximum Temperatures of the Air during the week ending August 5 ranged from 80°.5 at Blackheath to 64° at Greenock, with a mean for all English stations of 75°.5, and for all Scottish of 68°.9. In Scotland only two stations recorded values above 70°, while all the English stations were in excess of 74°, with the exception of Newcastle. The Minimum Temperatures were, as a rule, higher in Scotland than in England, the mean for the former being 47° and for the latter 46°.3. They ranged from 52°.2 at Liverpool to 44° at Perth and Edinburgh. The highest mean temperature was 60°.3 at Blackheath, and the lowest 55°.4 at Edinburgh and Glasgow. The mean for England was 58°.1, and for Scotland 56°.6. Rain fell lightly over England, there being only one station (Newcastle-on-Tyne) where none fell, but in Scotland the amounts recorded were larger. The greatest fall in England was 0.41 inch, at Birmingham, and in Scotland 1.55 inch at Greenock. The mean fall for England was 0.16 inch, and for Scotland 0.68 inch.

—— A few days since we saw in the nursery of Mr. Noble, at Sunningdale, a well-marked illustration of the Influence of Scion upon Stock in Inducing Variegation, different from any that we remember to have seen recorded. The subject was the Golden-variegated Weeping Mountain Ash, worked on the common Mountain Ash (Pyrus Aucuparia). The trees had been grafted two years, and were worked standard high, the heads being rather spare than full. In four separate cases the stock had thrown out variegated shoots—one from the very base close to the ground, and the others in a similar way up, about 3 or 4 feet from the base. The variegation, which was whiter than that of the graft, perhaps owing to the shade, the trees standing in a nursery quarter, seemed to be first developed along the midrib of the leaflets, some leaves being only affected in this way, while others had the colour also developed along the course of the main veins. These are cases quite analogous to those of Mr. Laing's Abutilons and the Broadalbane Ash, which have occurred within the knowledge of living witnesses, and sufficiently so to that of the Chelsea Jasmine of which it is said in which, originally, it was only a shield of bark which united with the stock. We shall be glad if Mr. Noble would report further on the behaviour of these Mountain Ash trees, at a later date, before the leaves fall.

—— The generally received opinion among those best qualified to judge is that Nitrogen cannot be or is not absorbed by plants directly from the atmosphere, in spite of the large proportion of it that exist in atmospheric air. There seems, indeed, to be an almost unanimous consensus of opinion that *free* nitrogen is not absorbed by plants from the air. But this suggests the inquiry whether there is any really *free* nitrogen in the air? Leaving this on one side, we may call attention to the fact that the "generally received opinion" above alluded to, as happens generally in such cases, has some few opponents. Among them was Priestley, whom Saussure contradicted, and more lately the French chemist Ville arrived at the opinion that plants do obtain their nitrogen from the atmosphere, a conclusion absolutely opposed by Boussingault, as well as by our own experimenters, Lawes and Gilbert. Lately Mr. Peach, well known as an ardent horticulturist, has advanced the same opinion, and has even gone further by depreciating the value of ammoniacal manures, or rather by attributing any value they may possess to other substances than the nitrogen. Mr. Peach calls attention to the circumstance that starch, sugar, gum, and other substances abundantly developed in the plant contain no nitrogen, which is true, but then it is equally true that not a single living active cell in the plant is destitute of nitrogen. It is conceivable that the proteineaceous matters in the case of a very fat man might exist in a relatively very small proportion as compared with the hydrocarbons. But that circumstance would surely not lessen the value of the protein compounds. Mr. Peach's theory that plants are capable of absorbing atmospheric nitrogen has, however, lately received support from Mr. Geo. Davis, an analytical chemist, who, with the co-operation of Mr. Newlyn, of the Royal Nurseries, Slough, has instituted some experiments relating to this subject. The details of these experiments are contained in a recent number of the *English Mechanic*, from which we extract the subjoined particulars. We demur, however, to the largest bell-glass I could obtain, glass tubes arranged so that they could be watered without removing the bell, and an aspirator arranged so that a current of air could be sent through the apparatus, and above this a tube which was passed into the bell was passed through dilute sulphuric acid.

"Two other Beans were placed in well washed and dried silver sand, and carefully uncovered in the house, beside the two under the bell-glass.

"It will thus be seen that both sets of Beans were exposed to the same temperature, one set being exposed to an unnitrogenised atmosphere, while the air under the bell-glass was kept as free from ammonia as possible.

"The Beans being unable to obtain any nutriment from the sand alone, they were fed with organic and inorganic food, and under the bell-glass being fed by the pre-arranged glass tubes, to prevent access of ammonia contaminated air.

"The only difference in the feeding of the two sets of Beans was in the administration of ammoniacal food to those which were freely exposed to the air.

"The foods were made thus:—(A) Mineral food—calcium sulphate, 20 grains; magnesium sulphate, 10 grains; potassium chloride, 2 grains; distilled water, 1 pint. (B) mineral food—potassium carbonate, 50 grains; sodium phosphate, 20 grains; potassium chloride and sulphate, of each, 20 grains; water, 10 ounces. (C) Ammoniacal food—ammonium carbonate, 40 grains; ammonium phosphate, ½ drachm; water, 10 ounces. (D) Organic food. This was prepared by boiling sugar, 4 ounces (large pure crystals), with 16 ounces of water, and 1 ounce of sulphuric acid for two hours, replacing the water as it boiled away, allowing to cool, neutralising the greater part of the free acid with chalk, and finishing with sodium carbonate (washing soda).

"The plants under bell-glass were fed with A, B, and D, at the rate of 1 drachm of each per day; they were diluted with water before being applied, and a current of air previously passed through dilute sulphuric acid drawn through the apparatus.

"Soon after the apparatus was in good working order, one of the plants died; the other continued healthy, and bore fruit.

"Those exposed to the air were fed with A, B, C, D, and fared much worse than those from which ammonia was withheld. One died shortly after the experiment began, whilst the other was attacked with green-fly; it had no blossom, and consequently bore no fruit. The above experiments it would seem that plants were capable of existing without nitrogen, if it cannot be absorbed direct from the atmosphere; but although the air supplied to the bell-glass was thoroughly freed from ammonia, it may have been robbed of its ammonia, but I feel certain that much albumenoid nitrogen must have passed in and been assimilated; still I cannot think that all the nitrogen came from that source. Some I think must have been absorbed from the atmosphere which immediately entered into the economy of the plant."

—— In the number of the "Journal of Botany" for the present month, the Rev. J. E. Leefe has an article on Hybridity in Willows. It is well-known that many intermediate forms exist in this intricate genus, and that many of them have been assumed to be of hybrid origin. Mr. Leefe, however, draws attention to the circumstance that Willows do not readily spring from seed, and as his observations are invested with special importance, we reproduce a portion of his remarks:—

"Wishing to ascertain the opinions of competent persons, I have consulted some of my friends, who have bestowed much attention upon this tribe. The Rev. L. Darwall, who has long cultivated Willows, observes, 'Amongst seedlings I have never found any but S. caprea and S. aquatica (including, perhaps, S. cinerea, and S. oleifolia), though I have both sexes of many other species.' With this the opinion of my friend, Mr. James Ward, who has specially studied the Willows for a long series of years, substantially coincides. Prof. Balfour tells me that they have tried, without success, to raise Willows from seed in the Edinburgh Botanic Garden. To come now to my own experience: excepting S. caprea, I do not ever remember to have met with a Willow where it looked like a seedling, and this was in the shrubbery at Audley End, Essex, where the plant might have been inserted as a cutting by some one of the gardeners. I have myself cultivated the Willows somewhat extensively since the year 1838. First in the nursery garden at Audley End for about five years; then in the rectory gardens at Bishop-wearmouth, in the county of Durham, for say about four years, and for a year more in a garden in the neighbourhood of the town of Sunderland; lastly, for fully 21 years at Cresswell. For the last 21 years the plants, some of them now trees, have been growing under my own eyes, great care having been taken to keep them properly labelled, which is no easy matter. In all that time I have never seen a single seedling, though my collection comprises fully 100 forms. It is, I admit, barely possible that seedlings may have timid ways, and been destroyed in keeping down weeds, but if so, I cannot account for their not occurring in undisturbed parts of the garden and grounds, amongst shrubs and trees where seedling Sycamores are frequent, and plants of the Leycesteria formosa have several times sprung up. A few years ago I collected and sowed some seed in pots in my greenhouse, and kept them carefully watered and looked after, but the seed did not vegetate. In the spring of 1870 I made a more complete attempt, both to produce hybrids and raise Willows from seed. On the 11th of last August I sowed in three boxes filled with good compost, seeds of the following kinds:—S. Forbyana, Sm., Anderssoniana, Sm., Andersoniana, Borrer; S. Doniana, Borrer; S. Smithiana, E. Bot., S. Smithiana growing in the middle of a large bush of a monandrous Willow, allied to S. Lambertiana, Sm. I also carefully tied a branch of a female catkin of S. alaphlebia, Scop., to a branch of a female of S. pomeranica, W., dusting the stigmas at the same time with the pollen. In a similar manner I endeavoured to fertilise the female of S. stipularis, Sm., with the pollen of the male of S. hippophaa, Borrer; also the female of S. Pontederana, Sch., with the catkins of a beautiful Willow gathered near Rothbury in Northumberland, which I take to be the male of that species. Several of the female catkins of diphandrous forms of S. repens, L., including, probably, S. ambigua, Ehrh., sent to me by a friend from Horncastle in Lincolnshire. On all those branches, the catkins of which I endeavoured to fertilise artificially, seed was produced in abundance. The boxes were carefully watered all through the summer, and in winter were placed in a cold frame. I have examined them constantly up to the present time, and at first sowing I intended to name or otherwise mark up in them would prove to be Willows, but in this hope I have been disappointed, and now fear that the experiment has again been a failure. Last year the seed of the Willows was apparently vegetating more than usual, and became rather an annoyance in the beds and walks, but I have not seen a seedling anywhere. Although, then, I dare not say that Willows are never produced from seed, I think it is clear that this happens less frequently than is commonly supposed. My garden is about a mile and a half from the sea, and rather exposed to the north and north-west; but the soil is good (old grass land), and most of the Willows grow freely in it. I have lost far more kinds from crowding than from climate.

"Having thus failed myself, I would invite the remarks and co-operation of others who, in more favourable and southern situations, may have more successful than I have been in raising Willows from seed."

—— There is a French proverb to the effect that "As many days as the white Lily flowers before St. John's Day, so many days before the 1st of August will harvest commence." The "Revue Horticole" states that about Paris the Lilium candidum commenced to blossom on June 16, and that therefore harvest ought to have begun about July 1st; but about London, the white Lily was in bloom about June 26.

—— Mr. T. Fowell Buxton, of Stanstead Abbott, Ware, has recently stated in the *Field* that the Althæa hirsuta, one of our rarer British plants, hitherto only known to grow in this country at Cobham, in Kent, has been found in a disused brickfield at Ware, very far from any house or cottage, and where it cannot possibly be an escaped garden flower.

—— The Edinburgh Meeting of the British Association seems on the whole to have passed off well in spite of the absence of Darwin, and of any very striking paper communicated to the sections. The most remarkable feature of the Presidential address was the learned President's hypothesis of the origin of existing vegetation from the Moss-grown fragments of another world, as already mentioned in our former issue (see p. 1009). Professor Balfour's address was much more to the purpose, at least from a naturalist's point of view, and from this address we shall in our next issue make certain extracts, and further allude to some of the papers read in section D, one of which, that of Professor Dyer, is given in another column.

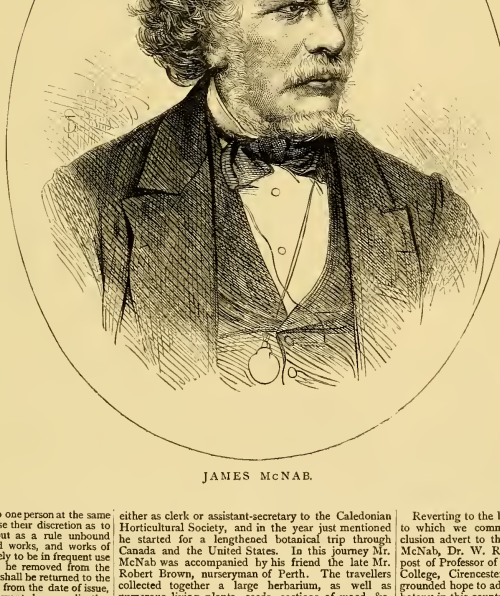
—— We have just received specimens of a small Fucoid weed, which is causing considerable annoyance amongst Ferns. It occurs both on the upper and under side of the fronds, and at first looks like thin spots of white paint which has dried rapidly, so as to leave little pits on the surface. When examined with a common lens, the appearance is very puzzling, as it looks so very much like one of those thin, pale calcareous Algæ (Melobesiæ) which are so common upon some of our sea-weeds. A closer examination shows, however, that it belongs to the same group of Fungi as the yellow, at first gelatinous, then dusty pest belonging to the genus Æthalium, which is the

abomination of all Pine-growers; another species of the same group, belonging to the genus Reticularia, sometimes destroying in a single night a whole frame of Melons or Cucumbers. We have never before seen so small a species causing real annoyance. One curious matter is that we have never before met with the species, which undoubtedly is closely allied to Physarum album, but is distinguished by its much more luxuriant growth, and the abundance of the flocci. It may be possible to get rid of it, when in its gelatinous stage, by dusting with quick-lime. It is, however, a question whether this may not prove injurious to the tender fronds. *M. J. B.*

—— The following circular has been issued by the Trustees of the LINDLEY LIBRARY, which was purchased, it may be remembered, with funds forming part of the surplus from the International Horticultural Exhibition of 1866, and to which considerable additions have been made from the munificence of donors, including, amongst others, Her Majesty the QUEEN:—

"The Lindley Library, which by agreement is deposited in the rooms of the Royal Horticultural Society at South Kensington, is open for the use of the public, under the following regulations:—1. The library is open for consultation on all week days from 10 A.M. to 4 P.M.; except on the meeting and exhibition days of the Royal Horticultural Society. — 2. The trustees reserve the right of closing the library for purposes of re-arrangement, cleansing, &c., when such may be required.—3. The fellows and officers of the Royal Horticultural Society shall have access to the library at all times, when it is open, on application to the assistant-secretary, Royal Horticultural Society.—4. Gardeners and others, not Fellows or officers of the Society, must make application to one or other of the trustees, or to the assistant-secretary of the Royal Horticultural Society, for permission to use the library, and shall sign their names and addresses in a book provided for that purpose.—5. Persons requiring the loan of books to be taken from the library must make written application to the trustees addressed to the librarian for the time being, at the offices of the Royal Horticultural Society, South Kensington, who are prepared to accord this privilege on the following conditions, viz.:—(*a.*) That the borrower be personally known to one or more of the trustees or officers of the Society, or at least shall produce satisfactory references. (*b.*) That the borrower sign a receipt for the volumes, before removing them from the premises, in a book provided for that purpose; undertake to restore the books in good condition, and generally to comply with the regulations laid down by the trustees. (*c.*) That not more than three volumes be lent to one person at the same time.—6. The trustees will exercise their discretion as to what books shall be lent out, but as a rule unbound periodicals, expensively illustrated works, and works of common reference, such as are likely to be in frequent use within the library itself, must not be removed from the premises.—7. All books borrowed shall be returned to the library within one calendar month from the date of issue, but an extension of time may be granted on application to the trustees.—8. The assistant-secretary or acting librarian is empowered to demand of the borrowers such books as are detained beyond the prescribed time, and to take such steps as may be necessary to secure the prompt return of the same.—9. The loss of any book, or any injury sustained, shall be made good by the person who has lost or injured the same.—10. The trustees reserve the right of repealing or altering these regulations from time to time as may be required.—By order of the trustees, JAMES RICHARD, Acting Librarian."

We may add, that the books are now arranged, according to their respective sizes, as far as possible, in alphabetical order, and that a complete catalogue has been prepared. It is greatly to be desired that the many imperfect sets of periodicals, &c., should be made complete up to the present time, and that they should be henceforth regularly incorporated as they are issued. Fort his purpose, however, the funds at the disposal of the trustees are quite inadequate.



JAMES McNAB.

JAMES McNAB.

GREAT botanists and great gardeners would seem to have some special faculty of transmitting to their posterity the qualities which render themselves distinguished. Two Linnés, three De Jussieus, three De Candolles, two Hookers, two Agardhs, two Morrens, exemplify this among the botanists, while amongst the gardeners the cases are even more frequent, and among them may be cited the subject of our present notice.

In 1810, as we learn, the father of the present James McNab was appointed, at the instance of Sir Joseph Banks, to fill the office of curator of the Botanic Garden, Edinburgh, and not only so, but in the same year he made provision for his successor in the person of his son, to whom he subsequently imparted the rudiments of horticultural and botanical lore. For five years previous to 1834, the younger McNab acted either as clerk or assistant-secretary to the Caledonian Horticultural Society, and in the year just mentioned he started for a lengthened botanical trip through Canada and the United States. In this journey Mr. McNab was accompanied by his friend the late Mr. Robert Brown, nurseryman of Perth. The travellers collected together a large herbarium, as well as numerous living plants, seeds, sections of wood, &c. The records of the more interesting plants obtained in this journey, are to be found in a series of papers published in the "Edinburgh Philosophical Journal" for 1835, and in the earlier numbers of the Transactions of the Edinburgh Botanical Society.

Shortly after his return from America, in 1835, Mr. McNab was appointed curator of the Caledonian Horticultural Society's Garden at Inverleith, which garden was almost entirely remodelled under his superintendence, while a large horticultural hall and extensive winter garden, as well as other plant-houses were erected, with funds collected for the purpose, mainly through the personal efforts of the curator. In what light these services were viewed by the members of the Society is shown by the fact that on his retirement Mr. McNab was made an honorary member of the Society, and presented with a handsome piece of plate. On the death, in 1849, of Mr. William McNab, who had held the office of curator to the Royal Botanic Garden, Edinburgh, for no shorter period than 39 years, it was felt that no more appropriate successor to the father could be found than the son. At that time the garden consisted of 14 acres, but subsequent additions have been made, including the garden of the Caledonian Horticultural Society, which thus once more comes under Mr. McNab's management. A Palm-house and Museum of Economic and Structural Botany, admirably adapted for the purposes of that eminently successful teacher, Professor Balfour, have also been erected.

The taste and judgment which have been exercised in these alterations, can be readily perceived at a glance, and we are sure that the numerous visitors who have probably wended their way to the garden during the present session of the British Association, will bear us out that, all things considered, no more tasteful or better arranged public garden is to be found in the kingdom, and no more complete establishment for the teaching of botany than that over which Professor Balfour so worthily presides. But Mr. McNab's claims on the esteem of his compeers do not rest solely on what he has done, but also on the help and inducements he has given others by his pen.

We have already referred to his papers descriptive of his American researches, but more numerous and more widely known are his communications in various journals on subjects connected with landscape gardening, the transplantation, culture and management of ornamental trees, the decoration and utilisation of waste places, railway embankments, town squares, and the like. Mr. McNab is a great advocate for the "stem-pruning" of certain Conifers such as the Deodar; and when the pruner is as judicious and intelligent as Mr. McNab, we have nothing to say against the practice, which, however, is one that assuredly should not be left to injudicious or careless hands, and one, indeed, that is only to be advised under certain circumstances. We have said enough to show that the Edinburgh Botanic Garden is fortunate in its curator, while the horticultural fraternity may well be proud of such a representative.

Great taste and skill have been shown by Mr. McNab in blending the old garden of the Caledonian Horticultural Society with the Royal Botanic Garden, as well as in working in, with a view both to effect and useful scientific grouping, the fine collection of Conifers which these gardens were possessed.

Reverting to the law of inheritance, with an allusion to which we commenced this notice, let us in conclusion advert to the circumstance that the son of Mr. McNab, Dr. W. R. McNab, occupies at present the post of Professor of Botany at the Royal Agricultural College, Cirencester, and is looked to with well-grounded hope to advance the progress of physiological botany in this country.

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—VI.

Subgenus 2. LILIUM PROPER.—Bulbs squamose; stigma a thick head to the style, with three blunt lobes—(*Continued*).

Group 3: ISOLIRION (Erect-flowered Lilies).—Perianth broadly bell-shaped, quite erect, its divisions oblong-lanceolate, broadest about the middle, spreading in the upper half, or third, when fully expanded. Stamens diverging on all sides from the axis of the flower.

Key to the Species.

Leaves usually in regular whorls.
Perianth 2—3 inches deep, the divisions with a very distinct claw, an inch long. } 12. PHILADELPHICUM.

Perianth 14–16 lines deep, the divisions without a distinct claw. Leaves never arranged in regular whorls. } 13. MEDEOLOIDES.

Perianth red-yellow, 2–4 inches deep, the divisions distinctly unguiculate. Style much exceeding the ovary. } 14. CATESBÆI.

Stem glabrous. Claw very narrow. Axils of leaves not bulbiferous. } 15. BULBIFERUM.

Stem cottony. Claw broader, ¼–¾ inch long. Axils of leaves often bulbiferous.

Perianth red-yellow, 1–2 inches deep, the divisions not unguiculate. Style much shorter than the ovary.

Leaves linear glabrous, ½–2 lines broad. } 16. PULCHELLUM.

Leaves lanceolate pubescent, 4–6 lines broad. } 17. CONCOLOR.

Perianth white, not more than half an inch deep. } 18. LANCIFOLIUM.

12. *L. philadelphicum*, Linn. Sp. Plant., p. 435; Ait. Hort. Kew. i., p. 431; Bot. Mag. t. 519; Redouté, Lil. t. 209; Lodd. Bot. Cab. t. 976; Bot. Reg. t. 594; Kunth, Enum. iv., p. 263; Spae, Mon. p. 25; *L. andinum*, Nuttall, Gen. i., p. 221; *L. umbellatum*, Pursh, Flor. Amer. i. 229; Schultes, Syst. Veg. vii., p. 411.—Bulb ovoid, an inch thick (according to Drummond cited by the Indians) the very fleshy scales half an inch long. Stem 1—3 feet high, rigid, comparatively slender, quite glabrous, the lowest third naked. Leaves typically in 4—5 regularly whorls of 6 to eight each, 2 to 4 inches apart, spreading, narrowly oblanceolate, 2 to 4 inches long, three-eighths to half an inch broad about the middle, narrowed gradually to a narrow base and an acute point, thin in texture though the average of the genus, indistinctly 3—5 nerved beneath, quite glabrous, not bulbiferous in the axils, the whorls often more or less, sometimes completely, broken up. Flowers 1–6 in wild specimens, when halfway down, narrowed suddenly to—12 lines above the base into a narrow claw with involute borders, which is glabrous down its face. Filaments 1½—2 inches long; anthers 5—6 lines long; pollen red; ovary about an inch long; style 15—18 lines.

Common in open copses through Canada and the Northern United States, stretching westward to the Rocky Mountains, and southward along the Alleghanies to North Carolina; and of course quite hardy in English gardens. It was sent by Bartram, in 1754, to Philip Miller, who figured it at t. 165 of his "Illustrations." The *L. umbellatum* of Pursh, and *andinum* of Nuttall, are the simply luxuriant conditions of the plant, such as is figured in the "Botanical Register." It stretches north-westward to the Red River and Saskatchewan territory, and occurs sparingly on the west side of the Rocky Mountains; but all the western specimens I have seen, though even when single-flowered retaining the whorl of bracts, have all the leaves indiscriminately scattered along the stem, as in *bulbiferum*, and the leaves also are narrower (linear not oblanceolate) and firmer in texture than in the whorled typical Canadian and New England form. *Geographically*, *philadelphicum* quite represents *bulbiferum* in the New World, and when the whorls of the leaves are thus broken up they come very near to one another, though distinct enough in the extreme states. But *philadelphicum* has always a more distinct claw than any variety of *bulbiferum*, and wants the cottony pubescence that occurs upon the stem and outside of the perianth of all the forms of the latter.

13. *L. medeoloides*, A. Gray, Mem. Amer. Acad. vol. vi. p. 415; Miquel, Ann. Mus. Lugd. Bat. iii. 156.—Stem 1–2 feet high, slender, terete, flexuose, glabrous. Leaves in the four specimens I have seen either confined to a single whorl of six in the middle of the stem, of four leaves (the latter number probably abnormal, the product of two whorls congested into one), or a few scattered, principally between this and the flowers, oblanceolate, similar to those of *L. Martagon* in shape and texture, 4—6 inches long, 9—15 lines broad two-thirds of the way up, acute, narrowed gradually to a narrow base, faintly 3—5 nerved beneath, quite glabrous. Flowers 1—3, in the latter case umbellate, the slender pedicels 1–1½ inch long, naked, or bracteolate. Perianth 14—16 lines deep, much more open than in the last, but the divisions falcate only near the tip, oblanceolate, not narrowed into a distinct claw, ¾ inch broad at the middle, reddish-yellow, with a few purple spots, not papillose on the face or pubescent down the groove. Filaments 9—10 lines long. Anthers 3—4 lines. Ovary clavate 3—4 lines deep. Style 4—5 lines.

An exceedingly distinct species, discovered near Hakodadi in Japan, in the United States' North Pacific Exploring Expedition, under Captains Ringgold and Rogers, in 1853-6, and since gathered by Oldham in Herschel Island, one of the members of the Korean group. It has never been figured, and has not been introduced into cultivation. The general habit and foliage is most like that of *L. Martagon*, but in the shape of the flower and its divisions, it resembles *L. concolor* and *pulchellum*.

14. *L. Catesbæi*, Walt. Fl. Carol. p. 123; Pot. Mag. t. 259; Lodd. Bot. Cab. t. 897; Sweet, Brit. Flow. Gard., series 2, t. 185; Kunth, Enum. iv., p. 263; Spae, Mon. p. 25; *L. spectabile*, Salisb. Stirp. Rar. t. 5, not Link; *L. carolinianum*, Catesby, Carol. ii. t. 58; Lam. Encyc. iii., p. 535.—Bulb roundish, "larger than a Walnut." Stem 1—2 feet high, slender, erect, straight, quite glabrous, naked at the flowering time in the lower third. Leaves never whorled, 20—30, ascending, moderately firm in texture, sessile, without bublets in the axils, not distinctly nerved beneath, the lower ones lanceolate, 2—3 inches long, ¼–¾ inch broad, narrowed gradually to an acute point, the upper ones growing gradually smaller and narrower, and ceasing 1—2 inches below the flower. Flower always solitary in the specimens I have seen. Perianth, 2–2½ inches deep, the divisions very much branded in different specimens from 4—12 lines, their margin much undulated, narrowed upwards into a long point, and suddenly downwards a full inch from the base into a very narrow claw with reflexed edges, bright orange-red copiously spotted with purple, the face not papillose, the claw glabrous down the face. Filaments 2½—3 inches long; anthers 3—4 lines; pollen reddish; ovary 9–12 lines long; style 1–2 inches.

Confined to the United States, but much more southern in its range than *philadelphicum* and *canadense*, reaching down into Florida and northward to Kentucky, and, according to Kunth, to Pennsylvania. It is well marked from its nearest allies, *philadelphicum* and *bulbiferum*, by the very peculiar shape which the long very slender claw and lengthened out point give to its perianth-segments. It was introduced into Europe in 1787, but is quite rare in collections and not perfectly hardy. It must not be confused with *L. spectabile* of Link, which is a subspecies of *bulbiferum*.

15. *L. bulbiferum*, Linn. Sp. Plant. p. 433.

Of this there are at least four forms which appear sufficiently diverse and constant in their characters to claim to be ranked as species, were it not for the union by these, such a number of varieties of lesser moment that it is extremely difficult to give a satisfactory account of the plants that range here. I know far too little of these subordinate varieties, of which there are perhaps not less than twenty in circulation in our gardens and large collections, to the present time. The botanic-specific Latin names, to be able to explain how they differ from one another, and should like to hear evidence on this subject from any of your readers who has watched them carefully in their various stages of growth whilst living. I will therefore confine my remarks now to the four subspecies that are known clearly as wild plants, and mention the names only of what I presume to be mere subordinate varieties without tangible characters appreciable from a botanical point of view.

Subspecies 1, *bulbiferum proper* = *L. bulbiferum*, Lecq. Fl. Auvergne, t. 226, Bot. Mag., t. 561; Kunth, Enum. iv., pp. 264 and 671; Fisch. et Meyer, Index Seminum, 1839, p. 54; Spae, Mon. p. 16.—Bulb ovoid, the outer scales an inch deep. Stem 1–3 feet high, rigid, erect, conspicuously sulcate, clothed, especially in the upper part, with irregularly scattered cottony pubescence. Leaves irregularly scattered, 50—60 to a stem at the flowering time, linear, erecto-patent, the lower ones 2–3 inches long, ¼–½ inch broad at the middle in the wild plant, thin in texture when dried, the upper surface bright green, the lower paler, prominently 5–7 nerved, nearly or quite glabrous, all sessile, the upper ones bearing clustered or solitary stalked or sessile chestnut-brown bublets in their axils. Flowers usually one only in the wild plant, but up to 12–18 in cultivation, properly racemose, but the raceme sometimes congested into an umbel, the arcuate ascending very cottony pedicles 1–2 inches long, the lower ones the longest, gradually less to the middle. Perianth 2—2½ inches deep, permanently erect, a more decided red than in *croceum*, slightly cottony on the outside, the outer divisions 8—9 lines, and the inner about an inch and a half at the middle of the claw, narrowed into a comparatively broad claw in the lower quarter, more or less spotted with black on the face, and papillose in its lower half, the basal groove with decidedly hairy borders. Filaments 1½—2 inches long; anthers 3—4 lines; pollen red; ovary 7–8 lines long; style 14—15 lines, so that the stigma falls very little short of the top of the segments in the expanded flower. Capsule turbinate, 9–12 lines long, nearly as broad, the valves bilobulate at the apex; seed deltoid, with a very narrow wing.

A native of various provinces of Austria, which was widely spread in cultivation in the days of Lobel, Parkinson, Clusius, and Dodonæus, before the Japanese crowded the American species out. It was also probably enumerated in Gerarde's list of the plants cultivated by him in 1596. Whether this subspecies has a wider geographical range than this, I cannot say positively at present. All the specimens called *bulbiferum* from France, Italy, or Switzerland, which I have seen, belong to *croceum*. *L. bulbiferum* is also rare in cultivation from Spain, but most likely that is *croceum* also, and there is a Scandinavian form, which I have not seen. *L. latifolium*, Link, Enum. i. 321, and *L. bulbiferum* β *umbellatum*, Bot. Mag. t. 1018, appear to be this subspecies after a period of cultivation in rich soil, and the latter is figured as a state similar to above with congested pseudo-umbellate inflorescence.

Subspecies 2, *croceum* = *L. croceum*, Chaix, in Vill. Delph. i. 322; Kunth, Enum. iv., p. 265 and 675; Fisch. et Mey. Index Sem. vi. 56; Spae, Mon. p. 17; Fenzl, Fl. Transsilv. 186; *bulbiferum* var. *croceum*, Fl. Dan. t. 1227, and of various other authors of floras of Western Europe. —Differs from the last subspecies by, 1, its upper leaves being always without bublets in their axils; 2, the perianth being more orange in colour, never a full scarlet or crimson, the divisions more decidedly and more spathulately narrowed three-quarters of the way down, and the claw more distinct; 3, the capsule said to be more acutely angled, and, 4, the seeds said to have a broader wing. Stem, leaves, general shape of the perianth, ovary, style, and stamens just as in *bulbiferum proper*. Flowers often solitary in wild specimens, but up to 12—18 in cultivation.

A native of France, Switzerland, and the North of Italy certainly, and perhaps also of Spain, as just noted; and like the last, of very old date under cultivation. I take this to be the parent of *L. gubsenens*, of Bernh. in Horn. Hort. Hafn. ii. 962, Kunth, Enum. iv. 264. At any rate a plant grown under this name at Kew was nothing more than long-cultivated *croceum*, but I dare say the name may be applied to forms of the last also.

Subspecies 3, *dauricum* = *L. dauricum*, Gawl. Bot. Mag. sub t. 1210; Kunth, Enum. iv. 264; Spae, Mon. p. 18; *L. pennsylvanicum*, Gawl. Bot. Mag. t. 872; *L. spectabile*, Link, Enum. i. 321; Reich. Icon. Exot. i., p. 21, t. 30; Fisch. et Meyer, Ind. Sem. vi. 56; Kunth, Enum. iv. 676; *L. Buschianum*, Lodd. Bot. Cab. t. 1628.—Stem more slender than in *bulbiferum proper*, hardly if at all cottony. Leaves more distant, longer, narrower, 5—6 inches long by 2—3 lines broad, with minute bublets in their axils. Flowers mostly solitary in wild specimens, running up to 8—9 under cultivation, the divisions a little longer than those of *bulbiferum proper*, but not broader, narrowed at the base in the same early and similar in colour; and the capsule also bluntly lobed.

Ranges through Siberia, from the Altai to Kamschatka and Amurland, where the bulb is eaten by the natives. It was originally figured in the "Botanical Magazine," under the name of *pennsylvanicum*, under the supposition that it came from America; but the mistake was rectified in the volume for 1809, and the plant re-named *dauricum*, after the region of Siberia, in which it is most abundant. This name, *dauricum*, has priority over *spectabile*, which only dates from 1821.

Subspecies 4, *Thunbergianum* = *L. Thunbergianum*, Schult. Syst. Veg. vii. 415; Lindl. Bot. Reg. 1839, t. 38; Miquel, Ann. Mus. Lugd. Bat. iii. 156; Kunth, Enum. iv. 263; Spae, Mon. p. 22; *L. bulbiferum*, Thunb. Linn. Trans. ii. 333; *L. aurantiacum*, Paxt. Mag. v., p. 12, with a plate.—Stem 1—2 headed. Leaves broader than in the other forms, lanceolate, sometimes an inch wide, rarely bublet-bearing in their axils. Perianth divisions spreading nearly from the base when fully expanded, 3—3½ inches long, the outer 12—15 lines, the inner 15—18 lines broad, the expanded flower 2 inches across, pale scarlet-red and scarcely if at all spotted.

A native of Japan, introduced to this country about 30 years ago. The above description applies to the extreme Japanese form, as figured by the three authors quoted, but the wild Japanese *bulbiferum* Lily, as represented in our herbaria, is considerably nearer the European form of the species, and is more especially broader nor the flower larger or more spreading, and can consequently scarcely be distinguished from *bulbiferum proper*, except by the absence of bublets in the axils of the leaves.

Of other named forms known in cultivation, *L. hamaticum*, Lemaire, Ill. Hort. t. 503, differs from Lindley's plant only in the colour of its flower, which is a very deep claret-red; *L. venustum*, Kunth, Enum. iv. 265, figured in Van Houtte's "Flore des Serres," t. 657; and *L. sanguineum*, Lindl. Bot. Reg. xxii. t. 50, are forms with a broader claw and a more campanulate flower, substantially the same as the wild Japanese bulbiferum just mentioned. *L. fulgens*, Morren, Spae, Mon. p. 29, as figured by Lemaire in "Illustration Horticole," t. 422, comes midway between these last and Lindley's plant. Of other names in gardens, *staminosum* (monstrosity with petaloid filaments), *maculatum*, *vitellinum*, *citrinum*, *atromaculatum*, *atrosanguineum*, and many others, range here.

16. *L. pulchellum*, Hort. Berol. 1834; Fisch. et Meyer, Index Sem. Hort. Petrop. 1839, p. 56; Kunth, Enum. iv., p. 266 and 676; Spae, Mon. p. 22; Regel, Gartenfl. 1860, p. 81, t. 281, fig. 2; Regel, 1862, p. 331, cum icone.—Bulb ovoid, about the size of a Hazel-nut, the scales few, fleshy, ovate, snow-white. Stems slender, 6—12 inches high, slightly sulcate, quite glabrous. Leaves 20—30 at the flowering time, scarcely irregularly, without bublets, erecto-patent, linear, firm in texture, glabrous on both sides, distinctly 3-nerved beneath, the edge obscurely toothed, the largest ⅓—2 inches long, ⅓—2 lines broad in the middle. Flowers always solitary in wild specimens, seen up to half a dozen under cultivation. Perianth erect, 12–14 lines deep, bright scarlet, with a few faint spots of black, the divisions opening widely when fully expanded, and half an inch broad at the middle, not distinctly spathulate at the base, slightly arachnoid on the outside, usually slightly papillose on the face in the lower half, the borders of the grove smooth. Filaments not more than 5–6 lines long; anthers 3—4 lines; pollen saffron-coloured. Ovary 3—4 lines long; style considerably shorter. Capsule oboviod, oblong, an inch long; seeds brownish, with a narrow border.

Confined to the eastern half of Siberia (Davuria and Amurland), whence it was introduced into cultivation in 1834 by Bunge, and more recently by Maximowicz. A beautiful and very distinct little species, much the smallest of the group, except *lancifolium*, resembling in size and general habit *tenuifolium* and *callosum* amongst the *Eulirions*, but in the position and shape of the flower, and in the shortness of its filaments and style, approaching no other species but *concolor*. It is not the same, as conjectured by Kunth and Spae, as *Buschianum*, which is a variety of *bulbiferum*.

17. *L. concolor*, Salisb. Parad. t. 47; Bot. Mag. t. 1165; Ait. Hort. Kew, edit. 2, vol. ii., p. 241; Kunth, Enum. iv., p. 259 and 673; Fisch. et Meyer, Index Semin. 1839, p. 55; *L. sinicum*, Lindl. in Fol. Hort. Flow. Garden, vol. ii., Misc. p. 115, t. 193; Lemaire, Ill. Hort. t. 100; Van Houtte, Flore des Serres, t. 1206.—Bulb ovoid, about an inch deep. Stem 2—3 feet high, erect, subterete, obscurely pubescent. Leaves 20 to 30 at the flowering

time, scattered irregularly, without any bulblets in their axils, spreading, lanceolate, the lower ones 3—4 inches long, half an inch broad at the middle, narrowed to both ends, obscurely toothed at the edge, faintly downy below. Flowers up to 5—6 under cultivation, corymbose, mostly solitary in wild specimens, the erecto-patent peduncles 1½—2 inches long. Perianth 1½—2 inches deep, a bright uniform scarlet, or at most only very indistinctly spotted on the face, spreading widely when expanded, the outer 5—6 lines, the inner 6—8 lines broad, at the middle, scarcely spathulate at the base, not at all papillose on the face, the groove slightly pubescent. Filaments 12—15 lines long, anthers 3—4 lines; pollen red; ovary 8—9 lines long; style about half the ovary; capsule obovoid-oblong, about an inch long; seeds very narrowly winged.

Var. 1, *coridion* = *Lilium coridion*, Siebold et De Vriese Tuinhow Flora, vol. ii., p. 341, with a figure; Miquel Ann. Mus. Lug. Bat., vol. iii., p. 156.—Flower only seen solitary, 18—21 lines deep, bright yellow, scattered over principally on the lower half of the face with distinct reddish-brown spots, the divisions 5—6 lines, the outer 4—5 lines broad.

Var. 2, *parthenion* = *Lilium parthenion*, Siebold et De Vriese, Tuinhow Flora, vol. ii., p. 341, with a figure; Miquel, Ann. Mus. Lug. Bat., vol. iii., p. 156.—Flower only seen solitary, 12—14 lines deep, bright red-yellow, faintly spotted on the face, the divisions 4—5 lines broad at the middle; filaments 9—10 lines long.

The typical form was introduced from China in 1806 by the Hon. C. Greville, and was figured and described at the time by Salisbury. *L. sinicum*, which was placed in circulation from Fortune's specimens in 1850, does not seem to be distinct from concolor as a variety. *L. coridion* and *parthenion* are Japanese Lilies of Siebold's, which I know only from the somewhat incomplete figures in the Tuinbow Flora, but judging from these they quite agree with the type except in coloration and size of the flower. None of the collectors seem to have gathered them wild in Japan, so that very likely they are only products of the horticultural skill of the natives. They are both included in M. Leichtlin's list, and I shall be very glad to learn what is his view respecting them. The species is so distinct that it runs no risk of being confused with any other. "Scentless," as Salisbury said, "but very ornamental," and it is one that I should be very glad to see much more widely spread than it is at present. Will not some one try it for a bedding effect, by way of a change for the perpetual iteration of Tulips?

18. *L. lancifolium*, Thunb. Linn. Trans. ii. 333; Kunth, Enum. iv., p. 266; *L. bulbiferum*, Thunb. Fl. Jap., p. 134, not of Linnæus.—Stem more than a foot high, stout, erect, pubescent. Leaves scattered irregularly, moderately close, ascending, the lower ones linear, 3—4 inches long, half an inch broad three-quarters of the way down, narrowed gradually to a long point, the upper ones much shorter under an inch long), lanceolate, with bulblets in the axils. Flowers two in the single specimen known, erect, the very short peduncles bracteated at the base by two much shortened ovate leaves. Perianth white, half an inch deep, narrowly campanulate.

A native of Japan, known only from the single dried specimen preserved in Thunberg's herbarium at Upsala, a drawing of which Professor Areschoug has been kind enough to send me. The general habit of the plant is completely that of *L. tigrinum*, but the flower seems very different from that of any other species. Till re-discovered, it must rank amongst the "species dubiæ," but, so far as I can judge from the drawing, this is its position. Of course it is a great mistake to confuse it with *L. speciosum*. *J. G. Baker.*

REPORT ON THE CONDITION OF THE FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS, AUGUST, 1871.]

COUNTY.	APRICOTS.	APPLES.	PEARS.	PLUMS.	STRAWBERRIES.	CHERRIES.	PEACHES AND NECTARINES.	FIGS.	SMALL FRUITS.	NUTS.	NAME AND ADDRESS.
SCOTLAND.											
ABERDEENSHIRE	Poor	Poor	Poor	Poor, except Victoria	Abundant	Poor, except Morello	....	....	Raspberries abundant; others poor	....	George Donaldson, Keith Hall
AYRSHIRE	Very few	A few on late transplanted trees: on others none	A few on walls; none on standards	Very few on walls; standards total failure	An average of first-rate fruits from second bloom	Almost a total failure	Very few out-of-doors; excellent crop indoors	Very fine indoors	Raspberry buds injured by frost, but now showing well; others variable	....	R. G. Rae, The Gardens, Eglinton Castle, Irvine
BANFFSHIRE..	Nothalfacrop, through late spring frosts	Average crop	Good crop	Poor crop	Abundant	Average	Very good	Few	Very abundant and fine	Failure	George Milne, Cullen House Gardens
BERWICKSHIRE	Very heavy crop, but late	Medium crop	Medium crop	Heavy crop, but very late	Early sorts medium; late sorts good	A failure; bloom destroyed by frost in May	None out-of-doors; medium indoors	None grown out-of-doors	Abundant, and of fine quality	Very scarce	Peter Loney, Marchmont House, Dunse
DUMFRIESSHIRE	A few	....	Next to none	....	Moderate	....	Fair crop, where covered in spring	....	Very scarce	....	D. Thomson, Drumlanrig Gardens
HADDINGTON	Average	Small crop	Large crop	Moderate	Large crop	Moderate	....	....	Abundant	....	Alex. Shearer, Yester Gardens
KIRKCUDBRIGHTSHIRE	Failure	Failure	A fair crop on walls	Very few	Very good crop	Failure	Very few	....	Abundant, except Black Currants	Very few	James Johnston, Terregles
LANARKSHIRE	Few in the district	Almost a total failure	Very few; less than for years	Short crop; in many places failure	A good crop of late sorts	Middling	Good in some districts, fair in others	....	Less than we have had for years	....	James Anderson, Meadow Bank
PERTHSHIRE	Heavy crop here	Very thin crop generally	Thin generally; good on our walls	Thin generally; moderate here	Good, but much destroyed with rains	Very moderate crop	Moderate crop	Good under glass	Good	Thin	Henry Rintoul, Dupplin Castle Gardens
ROXBURGHSHIRE	First-rate on both south and west walls.	A complete failure	Good in many cases	Second-rate crop	Good	Very few of Morellos; scarcely any of others	....	....	Fair crops	Very few	H. Knight, Floors Castle Gardens
STIRLINGSHIRE.....	Scarcely one-fourth the usual crop on outside walls	Total failure: said to be general throughout the Carse	None on standards: very few on walls	None on standards; very few on walls	Not so good an average as in former years	Very few	About an eighth of the average on outside walls	....	Not more than a good half of the usual crops	....	M. Fitzgerald, Dunmore Gardens
WIGTONSHIRE	Thin crop where grown	About half a crop	Moderate crop	Nearly a failure	Average crop	Half a crop	Thin crop where grown	Average	Abundant	....	A. Fowler, Castle Kennedy
NORTHERN COUNTIES.											
NORTHUMBERLAND....	Good crop; trees very healthy	Almost a complete failure	Where protected when in bloom, a good crop; otherwise thin and small	On walls an average crop, but much infested with insects	Very great crop, thanks to a plentiful supply of water	An average crop on all but Morellos	None outdoors	Not grown outside; plentiful in houses	Gooseberries and Raspberries plentiful; Currants not so good; much injured by insects	Not many	Robert Bowie, Chillingham Castle Gardens
	Below the average; fruit suffered on trees that were spur-pruned	On most of the trees none, and on the rest very few	Will not average more than six on a tree in this locality	Very few on walls; on standards an average crop; trees much blighted	Both early and late kinds abundant; fruit large	Dessert kinds almost a failure; Morellos below the average	Where protected a fair average crop; trees healthy	None grown out-of-doors	Very abundant, and Black Currants were very large	Scarce in the woods; no Filberts are grown	Anthony Hedley, Wallington Gardens
CUMBERLAND.	Under average	Under average generally	Under average here	Under average	An average crop in some places	Under average	Under average	Very few grown	Under average; very good here	But few grown	J. Williamson, The Castle Gardens, Whitehaven
YORKSHIRE ..	An abundant crop everywhere	A light crop in most places	In general rather below an average	A light crop in general	In general a very light crop	Much below an average crop everywhere	A good crop in many places, but not general	Good; late in ripening, but promise to be fine	Good in many places, but not general	Most abundant crop everywhere	Michael Saul, Stourton, near Knaresbrough
	Very abundant; trees making good growth	Scarcely any on walls, none in orchards	A fair crop	Good on walls, none in orchards	An average crop on two-year-old plants	An average crop	Very good crops, and trees healthy	....	Red Currants and Raspberries abundant; others below the average	Filberts plentiful; Walnuts scarcely any	Wm. Denning, Grimston Park, Tadcaster
	Abundant; required much thinning	In some orchards none, others very few	....	Very few	Plenty, but flavourless	Early kinds, poor crop; Morellos, fair	Fair crop; trees making good wood	Average crop	Abundant; never saw Black Currants so fine	Filberts and Cobs a poor crop; Walnuts very few	Jos. E. Nicholson, Mount St. John, Thirsk
	Under average; suffered when in bloom from frost	Under average; trees unhealthy, through excessive rain and low temperature	In some localities an average; trees healthier than Apples	A variable crop; trees healthy, and free from aphis	A good crop, but half was destroyed through continued rain	Under the average, and bad in flavour	Under the average in some localities; leaves much blistered	An average crop; trees healthy	Plentiful, and fine in size	Average crop of Filberts and Walnuts	R. C. Kingston, Brantingham Thorpe, Brough
	Plentiful, but late	Poor; blossom injured by east winds	Poor: injured by east winds	Middling crop	Heavy crop	Good crop	None outdoors	....	Middling crops	....	J. Simpson, Wortley Hall
LANCASHIRE..	Below the average	Much below the average	Very few, especially of the tender sorts	Below the average	Plentiful	Below the average	Very scarce	....	Gooseberries and Currants plentiful	....	Edward Greep, Bank Hall, Warrington
	....	Medium	Very poor	Very poor	Good	Morellos good, others very poor	None grown outside	None outside	All crops good	Good	J. R. Petch, Manley Hall, Manchester
	Very good	Few	Few	Good	Few	Good	Excellent	....	All good	....	James Freeman, Knowsley, Prescot

CONDITION OF THE FRUIT CROPS—(*Continued*).

COUNTY.	APRICOTS.	APPLES.	PEARS.	PLUMS.	STRAWBERRIES.	CHERRIES.	PEACHES AND NECTARINES.	FIGS.	SMALL FRUITS.	NUTS.	NAME AND ADDRESS.
NORTHERN COUNTIES.											
CHESHIRE	Very heavy crops; the trees look very healthy	On the whole, scarcely an average	Not plentiful, generally; a good crop on walls	Large quantities on walls; Damsons fine; trees healthy	Promise well; but the continued wet spoilt a great deal	A good crop, generally	Below the average on walls; very good in orchard-house	....	All kinds of small fruits very plentiful	The best crop I have seen for many years	William Whitaker, Crewe Hall, Crewe
	Good crop	Small crop	Small crop	Small crop	Very short crop	Good crop; Morellos only	Very scarce	....	Average crop	Good average crop	W. Muir, Oulton Park
SHROPSHIRE..	Average crop, but late	Good, in many places	Partial; good crop in places	Damsons partial; Plums generally partial	Abundant here; very poor in places	Good	None in this neighbourhood	....	Abundant, but very much blighted	Pretty good	Daniel Judd, Hawkstone
	Good crop, generally	Not good; have had a check in swelling	The same as Apples	No Damsons; Plums on the walls small	Good crop, generally	Good crop, generally	Good crop, but late and small	Good crops	Good crops	Walnuts fair; Filberts good crop	Charles Galloway, Halston Hall
	Abundant, but late and small	Thin in gardens; in the orchards poor	On the walls good; the standards poor	Good, generally: Damsons thin	Indifferent: rotted before they were ripe	It is rare to see a good crop	Abundant, but late, though against flued walls	Good, but fear they will drop off	Good, but dirty	Abundant	John Pearson, Kinlet, Bewdley
MIDLAND COUNTIES.											
STAFFORDSHIRE	Abundant	Average crop; some orchards heavily laden, others bare	Abundant on walls and espaliers, partial on standards	Wall trees heavily laden, standards very thin	A very light crop; some places none	Very abundant on wall trees, partial on standards	A full crop	None grown out-of-doors, plentiful in-doors	Abundant	Very abundant; Walnuts scarce	Edward Bennett, Enville Hall Gardens
	Very abundant	Light crops	Good	Abundant	Heavy crops	Plentiful	Inside only; cold houses fine crops	....	Generally good	....	Z. Stevens, Trentham Gardens
	Very good	Much below average	Not an average; fruit small	Fair crop, some places very good	Good crop, but did not ripen well	Morellos good, not so sweet sorts	Fair crop, but small at present	....	Very plentiful	Very great crops of nuts; Walnuts scarce	Edwin Simpson, Wrottesley, near Wolverhampton
NOTTINGHAMSHIRE	Extra crop	In old orchards very thin; on young trees a fair sprinkling	A fair crop on some standards; others none	A fair crop; west aspect badly blighted; east aspect extra clean	Light crop; Keen's Seedling and Marguerite the best	Thin: clean trees	Thin in many places; with me a good crop	A light crop here; in some places better	Scarce in some places; with me about half a crop	Plentiful	John Miller, Worksop Manor Gardens
	Heavy crop; old trees nearly killed by frost	Average crop; late varieties very good	A heavy crop set; one half lost through a small grub	A very fair crop; trees are dirty from fly	Very good on young plants, but old ones barren	Morellos very poor; early varieties were good	Not an average crop; trees in splendid health	....	Of Gooseberries not an average; of all others first-rate	Nearly as many Filberts and Cobs as leaves	James Hamilton, Berry Hill, Mansfield
	Average crop	Very poor crop	Very scarce	Poor crop; Damsons-Average	A failure; Keen's Seedling the worst	Very few	A small crop; but wood-making	A small crop, but will not ripen	Average; bushes have been blighted all the season	Heavy crop; Walnuts scarce	Wm. Cruickshanks, Kingston, Derby
LEICESTERSHIRE	A very large crop; require much thinning	Good here: but very few in the district	Of most sorts a fair crop, some very large	About half a crop	A very poor crop, some sorts a complete failure	Poor crop; except of Morellos, which are plentiful	A good crop; trees a good deal blighted	Very thin; not half a crop	A large crop of Currants; others variable	Walnuts very scarce; Filberts a heavy crop	Montgomery Henderson, Cole Orton Hall
	Abundant; fruit large, but will be late	Very thin crop in both orchard and kitchen garden	Variable	Moderate crops; trees much blighted	Fair crops of some kinds, others blank	Moderate crop of May Duke; abundant show of Morellos	Blighted and greatly injured by severe winter; crop thin	In favourable situations showing well	Gooseberries thin, much injured by caterpillars; Raspberries very abundant	Fair promise	William Ingram, Belvoir Castle Gardens, Grantham
	Plentiful	Very scarce	Scarce; medium on walls	Scarce	Scarce	Very scarce	A few	Not many	Plentiful	Walnuts few; others scarce	W. Burns, Whatton House, Loughboro'
NORTHAMPTONSHIRE	A first-class crop	On small bushes full; standards thin	Fair on west walls; standards thin	Half crop	Full crop	Very thin	Full crop	Half crop	Full crop, but discoloured through wet	Full crop	R. Gilbert, Burghley
RUTLAND-SHIRE	A splendid crop; later than last year	Moderate crop	Very scarce	Thin crop; trees very much blighted	A grand crop; President and Lucas the best	Morello fine; dessert kinds indifferent	On young trees a fine crop, and trees healthy	Moderate	Abundant; bushes very much blighted	An immense crop	J. Smith, Exton Park Gardens, Oakham
OXFORDSHIRE	Very great crop and fine, some few blighted	Very few; much damaged by blight early in the season	Under average; trees badly blighted, but making second growth and flowering	Fair crop; very fine on walls; standards much blighted	Good, and fruit very fine	Early sorts under average; an abundant crop of Morellos	Good; the trees outdoors now clean; in houses very good and fine	Plenty of fruit, which I fear will be of no use	Abundant; Red Currants badly blighted; Gooseberries very fine	Great crop	W. Lee, Blenheim Gardens, Woodstock
	Heavy crop; trees clean and healthy	Very thin crop indeed	Full average	Very heavy crop	Abundant	Below average, and fruit inferior	Good average	A very heavy crop, but late	Black Currants excellent, others very thin; Gooseberries average	Trees literally covered with nuts; Walnuts plentiful	Isaac Watson, Nuneham Park Gardens
WARWICKSHIRE	Very good	Thin generally	Thin generally	Thin generally	Very fine, but soon over	Very good, but thin	Very good	Promising well	Very fine where clean	Enormous, except of Walnuts	Wm. Miller, Combe Abbey Gardens
EASTERN COUNTIES.											
LINCOLNSHIRE	Very heavy crop, and in fine health	Not half a crop	Average crop, and fruit clean	Good crop on walls; standards late	Good crop of fine fruit	Heavy crop on walls	Very heavy crop; the trees healthy	Average	Currants and Raspberries, Cobs, average; Gooseberries, light	Filberts and Cobs, averages; Walnuts, light crop	George B. Tillyard, Brocklesby Park
	Abundant where protected	Nearly a failure	Nearly a failure	On walls, fair; standards a failure	An extra crop of most sorts	Under average	A very poor crop	A poor crop	Gooseberries, half a crop; Currants, a fair one	Walnuts, a failure; Filberts, a good crop	David Lumsden, Bloxholm Hall, Sleaford
NORFOLK.....	A fair average	An average crop	Under the average	An average crop	Plentiful and large	Abundant	Above the average	....	Plentiful, except Gooseberries	A fair crop	William Carmichael, Sandringham
	A good crop set, but almost all dropped off while stoning	Very few; almost a failure	About one-third of a crop; fruit small and late	Good on walls; trees very few on standards	Good crop; fruit fine, but deficient in flavour	Very bad crop; Morello good and fine	Only half a crop; the fruit very late and small	Quite a failure in many places	Currants abundant; Gooseberries and Raspberries, good	Most abundant, except Walnuts, but very late	William Smythe, The Gardens, Elmham Hall
ESSEX.....	Abundant	Very scarce	Not half a crop, and very backward	Moderate; sadly infested with insects	Fair crop, but of poor flavour	Good crop	Medium	Good crop	Abundant	Moderate crop	William Earley, Valentines
	A very good crop	A very short crop; trees very much blighted	Quarter of a crop, and small	A fair crop; trees very much blighted	A very fair crop	Morellos a very good crop	A fair crop; trees much hurt in spring, now recovering	Rather thin on walls	Currants nearly all destroyed with blight, many bushes being dead	Most abundant crop	Geo. Young, Audley End Gardens, Saffron Walden
	Very good crop	About half a crop	Very good; best on walls	Very bad	Very good	Very fine; Morellos the best	About half a crop	Very good	Plenty of all sorts	About half a crop	P. Stoddart, Wivenhoe Park, Colchester
SUFFOLK	Abundant; fruit larger than usual	Partial; some trees without fruit	Crop rather thin; fruit a good size	A light crop; Golden Drop and Jefferson plentiful	Plentiful and fine	Scarce, and black fly very troublesome	About half a crop; trees suffered from severe winter and spring	Plentiful	A middling crop; Currants much blighted	Walnuts thin; Filberts abundant	Thomas Blair, Shrubland Park, Needham Market
	Very heavy crop; trees healthy	Mostly a failure; much injured by hail	One-third crop; many failures	Good crop generally; much attacked by black fly	Very partial, except on those that escaped the effects of frost	Partial; a fine crop here	Mostly a failure; trees terribly cut to pieces by the frost	Heavy crop	Partial: white Currants much blighted	On Filberts and nuts an extraordinary crop	D. T. Fish, Hardwicke House
	Thin; trees suffered from the low temperature in June	Very thin; leaves curled, and damaged by hail	Thin on walls; fair crop on pyramids	Very thin; fly most troublesome	Heavy crop on young plantations	Medium crop; trees look well	Thin crop; trees suffered from the late frosts	Showed a very heavy crop, but half have fallen	Abundant; Currants badly infested with green fly	Good crop	Jas. Sheppard, Woolverstone Park

SUFFOLK	Abundant and fine; some of the fruit inclined to crack.	A few on the hardier culinary sorts; many trees without a fruit	Half a crop on walls, none on standards	Half a crop on walls; on standards hardly any	Abundant, and of excellent quality	Morellos only grown out-of-doors, and they are plentiful	About half a crop, and fruits do not look promising	Showing plenty of fruit, but will be late	Moderate crop; inferior in quality, and trees much blighted	No Walnuts; Filberts and Cobs plentiful and fine	P. Grieve, Culford, Bury St. Edmund's
SOUTHERN COUNTIES.											
BEDFORDSHIRE.....	Average; fruit large and fine	Scarce; trees much blighted	Average crop	Scarce; trees much affected with green fly	Plentiful, but did not ripen well	Partial crop	Plentiful; trees have suffered from a lack of warmth	Good crop; only wants sun to ripen them	Currants plentiful, but much blighted; Raspberries almost a failure	Abundant, out very late	A. McKay, Woburn Abbey
HERTFORDSHIRE	An average crop, but dropping off	Not half a crop; trees blighted	Fair here, not many in district	Scarcely any; trees fearfully blighted	Very good crop of later sorts	Fair on walls; standards scarce	Fair crop: difficult to keep fly off	Abundant in some places	Plentiful; Red Currants fearfully blighted	Excellent crop in some places	John Cadger, Luton Hoo Gardens
	Very thin, and unusually late	Very poor crop	Very much below the average	Below the average	Heavy crop; fruit large	Good, Morellos excellent	Good, on old trees, foliage healthy	....	Very plentiful; Currants much blighted	Walnuts scarce; Filberts plentiful	D. Cunningham, Moor Park Gardens
	Abundant; fruit small	Very thin; trees much injured by grub	A partial crop	An average crop	Abundant; fruit fine, but poor in flavour	Average crop, Morellos rather thin	Plentiful, but late	An average crop	Gooseberries thin; Raspberries and Currants abundant	Filberts and Walnuts plentiful	Richard Ruffett, Panshanger Gardens
	Very abundant	Partial crop	Very abundant	Fair crop	Very abundant	Medium crop	Very abundant	....	Plentiful but blighted	Very abundant	William Paul, Waltham Cross, N.
BUCKINGHAMSHIRE	A large crop; trees much mildewed, and fruit falling off	Very few; trees look bad	Half a crop	On walls but few; on standards a good crop	A good crop	Half a crop	Very indifferent, trees very much blighted	A fine crop	Currants nearly leafless; Gooseberries and Raspberries a good crop	Abundant	Thos. Bailey, Shardiloes Gardens, Amersham
	A very good crop	In most places a failure	Thin crop in most places	In some places abundant	Heavy crop, of superioquality	Thin crop, and very inferior	Fair crop, but very late	All fell off before half grown	Very good, in some places	Very plentiful	Philip Frost, Dropmore, Maidenhead
MIDDLESEX ..	Plentiful	A fair crop, but small	Fine on standards; scarce on walls	Scarcely any, and black with blight	Below the average	A very poor crop	Much blighted, good in places	....	Gooseberries plentiful; Currants much blighted	An immense crop	Richd. D. Blackmore, Gower House, Teddington
	Very abundant	A moderate crop	Very moderate	Moderate	Plentiful, but much spoiled through wet	Plentiful	Plentiful, but late	....	Plentiful, but much blighted	Very abundant	A. F. Barron, Royal Horticultural Society, Chiswick
	Very good	Thin	Thin	Good	Very heavy	Very poor	Good	Moderate	Under average	Good	Thos. Baines, Southgate
	A good crop	Fair average	A average crop	....	Very good, and large	Very good	Fine crop	Very few	A good average	....	Robt. Henderson, Fulham Palace
BERKSHIRE ..	Generally a heavy crop; fruit small	A light crop, with a few exceptions	A good average, and promises to be fine in quality	Plentiful, but inferior in quality; trees suffered from blight	Generally a light crop	A thin crop, with the exception of Morello	A good crop where the trees are clean	....	Generally a light crop; Currants injured in places by fly	Filberts plentiful, but a light crop of Walnuts	H. Rose, Royal Gardens, Windsor
	Average crop	Very partial; Northern Greenings plentiful	Very few; blossom destroyed by frost on April 8	Underaverage; trees a good deal blighted	Under average	May Dukes a full crop; of other sorts not half	A fair average crop on most trees	Fruit turning yellow, and dropping off	An average; Currants much blighted	Light crop of Walnuts; no others grown	Charles Ross, Welford Park, Newbury
SURREY.....	A partial crop: trees sadly mildewed	Partial, young trees sadly blighted	Partial on walls; on standards good	Very light; under glass excellent	A good crop of excellent quality	Under the average, except Morello	Excellent crops	Good	Middling; trees much blighted	Very plentiful	James Drewett, The Denbies, Dorking
	A fair average, but late	Under the average	Under the average	Above the average	Heavy crop, and very fine	Under the average; much damaged by rain	A full average; trees much infested with aphis	Average; under glass very good	Plentiful and good	Very thin in places	William Kemp, Albury Park Gardens, Guildford
	Above the average, but late	Failure	Failure	An average; trees affected with blight	Below the average	Average crop; Morellos excellent	Average crop	Average crop	Gooseberries a good crop; Currants a failure	Extraordinary crop	James Woodward, Garbrand Hall Gardens, Ewell
	Good	Not good	Not good	Below average	Abundant	Plentiful; quality not good	Average	....	Gooseberries plentiful; Currants poor	Very abundant	C. Green, Hillfield, Reigate
KENT	Very abundant and fine	The lightest crop for many years; trees and fruit much blighted	Very short crop indeed; far below even a moderate average	About an average crop	Abundant and fine on high ground; much injured by spring frosts	Very good crop indeed, on both pyramids and walls	About a fair average crop	Very few; nearly all the trees killed down	Very good; but very much infested with aphis, &c.	Very abundant; above the average	John Cox, Redleaf, Penshurst
	Full crop	Scarcely any	A few on walls	Very heavy crop, especially on walls	Very heavy crop for miles round	Morellos full crop; only half of others	Full crops of both	Very heavy crop	Full crop; Currants blighted and useless	Filberts heavy; Walnuts not half a crop	W. P. Roberts, Holwood Park, Beckenham
	An average crop	Much blighted	Much blighted	Much blighted	A very good crop	Under the average	Variable; some much blighted	Good	Abundant; Currants much blighted	An enormous crop	Thomas Woodford, Eastwell Park, Ashford
	Very good	Some orchards very good; others entirely destroyed by aphis	Good	Very heavy crop	Very heavy crop	Very slight crop	Moderate; trees much injured by aphis	....	Very small crop; trees much injured by aphis	Very good indeed	J. C., Bidling
	Average; rather small	Under average; abundant here	Not half a crop, small	Very few on standards; fair crop on walls	Strawberries abundant, and very good	Very fair, especially of Morellos	Average crop, but small and late	Scarce and small	Gooseberries and Raspberries abundant; Currants scarce	Abundant everywhere	G. C., Lillesden, Hawkhurst
SUSSEX	Average, but small	Much blighted	Under average	Much blighted	Abundant	Under average	Good	Average	Currants and Gooseberries blighted; Raspberries good	Over average	Thomas Jack, Battle Abbey
	A most abundant crop; fruit rather small	Moderate crop, fruit small	Fair on walls, but thin on standards	Very good in places	Abundant, and fruit fine	Average crop	Good average crop	Good, but late	Good crops	Plentiful	John Wilson, Arundel Castle
	Good crop throughout the district; trees very clean and healthy	No crop; the trees in bad state through black fly	A very light crop; trees clean and healthy	A light crop; fruit set well, but was overtaken by fly	Large crop; fruit fine, especially Sir C. Napier	Early kinds an average crop; of white and late sorts none	Very light crop; leaves blistered, and attacked by black fly	Very good on walls and standards	Large crop and fine; trees clean, except Red Currants	Good crop; much blue fly on the trees	S. Ford, Leonardslee, Horsham
HAMPSHIRE ..	Abundant and very fine; trees were protected	Good here, but thin generally in this district	Very good on walls; standards poor	Average crops	Enormous crops, very large and good	Abundant and fine, especially Morellos	Good average crops; trees protected	Good	Heavy crops, but Red Currants have suffered much from blight	Extraordinary crops, and promise to be fine	William Wildsmith, Heckfield Gardens, Winchfield
WILTSHIRE ..	Abundant	Under average	Not an average	All destroyed by spring frosts	Moderate; poor in flavour	Morellos plentiful, others scarce	Very few; trees suffered from spring frost	....	Very abundant, but suffered much from aphis	Plentiful	A. Johnson, Savernake Forest
	Plentiful, but indifferent in quality	Not half a crop	Not an average crop	Good	Plentiful	Good on walls	Good where trees received a little protection	Very good crop	Abundant	Very plentiful	William Scammell, Bowood, Calne
DORSETSHIRE	....	Very bad	Bad	Bad	Splendid	Some trees very good	Good for the year	....	Splendid crop	....	W. F. Radclyffe, Okeford Fitzpaine
	Irregular; orchard-house, fair crop	Table and cider fruit very short crop	Below average and very irregular	Very bad; trees severely blighted	Generally deficient; with us abundant and good	Below average	Outdoor crops bad; in orchard-houses abundant	Very few grown here	Abundant, except Red Currants	Walnuts below average; hedge nuts abundant	Henry Munro, Cleveland Gardens, Lyme Regis

WESTERN COUNTIES.											
WORCESTERSHIRE	Great crop and fine	Not more than one-tenth of a crop	Standards very light; good on walls	Same as Pears	A light crop through excessive drought of last year	Moderate crop; trees much injured by blight	A good crop; trees clean, fruit fine, but late	Light crop	Good, but much injured by blight in many gardens	Good crop of Filberts; of Walnuts none	William Cox, Madresfield Court, Great Malvern
	Full average	Very light; suffered from blight	A very light crop	For the most part a failure	A full average; much destroyed by wet	Half a crop	Very light	Moderate	Gooseberries and Raspberries excellent; others moderate	Filberts abundant; Walnuts very thin	George Westland, Witley Court
	Very good	Fair crop	Fair crop	Abundant crop	Very fine	Not so good as last year	Very good	....	Good crop	Trees loaded	David Mackie, Hagley Hall Gardens
	Good crop, but trees nearly leafless	In many orchards not an Apple, and others plenty	Very light; trees weak from heavy crops of last year	Moderate crop, but I fear very partial	Very light; plants appeared to have suffered from the last summer	A fair crop	Light crop; fruit very small	....	Currants abundant; Gooseberries very light	Abundant crop	John Wyke, Kyre House, Tenbury
HEREFORDSHIRE	Very good; never more abundant	None; in orchards very few	Fair crop	On east wall not a full crop, on west walls very good	Poor; many blind	Good	Abundant, but the foliage is not sufficient to mature the crop	Trees killed nearly to the ground	Good; much blighted	Filberts remarkable crop, Walnuts thin	Samuel Wells, Holme Lacy
	Heavy crop, excellent	Half a crop; blossom destroyed by blight	Half a crop; blossom destroyed by late frosts	Good crop	Good crop	Good	Heavy crop on early varieties, late varieties thin	....	Gooseberries half a crop; destroyed by frost; others abundant	Heavy crop	A. Bye, Hampton Court Gardens, Leominster
	Abundant; required much thinning	Scarce; trees badly blighted	Thin on walls, standards a failure	Much blighted; a thin crop	Moderate crop; injured by rain	A good crop, but injured by wet	Abundant, but late; trees remarkably healthy	....	Gooseberries thin; Currants much injured by blight	Filberts abundant, Walnuts scarce	William Coleman, Essinoe Castle, Ledbury
GLOUCESTERSHIRE	Heavy crop; small-sized, and at least a fortnight late	Not a fourth of a crop; trees have suffered from aphis, but recovering	A failure; moderate crops on early varieties	On standard and wall about half a crop, of full size, but late	Abundant and large, but deficient in flavour	On standards none, wall-trained trees less than a fourth	So abundant that nearly half had to be removed	Scarce, except some of the free-fruiting varieties	Abundant, but half the crop was destroyed by honey-dew	Very productive	Alexander Cramb, Tortworth Court, Falfield
SOMERSET ..	Good crop, but small	Much below the average, and small	A partial crop; bloom cut off by late frosts	Fair crop, but small	Good crop, but deficient in flavour	Morellos plentiful, choicer sorts below the average	Good under glass, a fair crop on walls	On old trees good	Abundant; saved the red Currants by syringing early with soft-soap water	....	William Dodds, the Gardens, Ashton Court
	Plentiful, but very small, and not yet ripe	Not good in gardens, and scarce in orchards	Not very plentiful	Under an average crop	A good crop	Morellos, a good crop; other sorts, small	Very small, and late; good in orchard-houses	Scarcely any, on account of the severe frost	Gooseberries good; Currants much injured by blight	A fair crop	William Hallett, Cossington, Bridgwater
	A fair crop	Scarce	Below the average	Plentiful	Good crops, suffered from wet	Morellos fine; other sorts thin	Very good	Medium	Very plentiful	Filberts plentiful; Walnuts a failure	Thomas Bray, Nynehead Court, Wellington
DEVONSHIRE .	Abundant	Under average; a poor crop of cider Apples	Average; fruit now swelling fast	Under average in most cases; Green Gages good	Fine crops of full-sized fruit	Above the average; fruit large and good	Full crops; trees much blighted, and fruit small	Good crops on standards	Large crops of all kinds	Heavy crops of Walnuts and Filberts	Robert Begbie, Bicton Gardens
	A very abundant crop	Very thin; suffered from late frosts	Generally poor; some few sorts plentiful	Under average	Keens' Seedling fair; others a failure	A fair average crop	Abundant crop	An average crop	Abundant and good of all kinds	Filberts and Cob nuts a good crop	Alexander Ayson, Oxton House Gardens
	Good crop	About an average	Light crop	A partial crop	Very heavy crop	Much below average	Very abundant	Very few	Average	Good crop	George Erskine, Lupton
CORNWALL ..	Very few grown in this county out-of-doors	A poor crop; the tree severely blighted at setting time	Considerably under the average; good crops of Chaumontel	Average crop; some of the better kinds required thinning	Abundant crop	Very good	On healthy trees abundant, but will be late in ripening	Abundant crop of brown Turkey in favourable spots	Plentiful; the Currants more usually affected by Fungi and Blister	Average crop	George & Henry Mills, Enys, Penryn
	....	Half crop	Plentiful	Half crop	Good and plentiful	Scarce	Plentiful	Plentiful	Abundant	Very plentiful	Richard Lynch, Port Eliot
WALES.											
MONTGOMERYSHIRE	Abundant; required much thinning; trees protected by netting	Heavy crop in gardens, but partial in orchards	Plentiful on walls, partial on orchard trees	Most abundant, and fine in appearance	Very good and fine, especially the true Elton	Very good	Most abundant, but will be unusually late	Under average; not extensively grown here	Gooseberries remarkably fine, also Currants in variety	Not many grown here; under an average	George Brown, Powis Castle Gardens, Welshpool
ANGLESEY	....	Below an average	Light crop	Very few	Good crop, but injured by rain	Moderate crop, fruit fine	....	....	Abundant and good	....	J. Ellam, Bodorgan
DENBIGHSHIRE	An excellent crop	A very fair crop	A partial crop	On walls about half a crop	Good, and large	Very good	Peaches half a crop, Nectarines very few	Good under glass	Gooseberries very fair, Currants good, but blighted	Filberts and nuts an extraordinary crop; Walnuts half a crop	Geo. Browne, Chirk Castle, Chirk
	Trees literally loaded, required much thinning	Very fair, except where overcropped last year	A fair sprinkling; Quinces middling	Excellent crops; Damsons very heavy	Average crop, except of Keens'Seedling	Good; Morellos very good	Plentiful	Good crop	Abundance, except Black Currants; Mulberries good	Walnuts very fair; Cobs and Filberts loaded	Peter Middleton, Wynnstay Gardens, Rhuabon
CARMARTHENSHIRE	Very few grown	Half a crop	Good on walls, none on standards	Good on walls, none on standards	Heavy crop, especially of the late ones	Morellos heavy crop	Very heavy crops	Very few	Heavy crops; Gooseberries and Currants much blighted	Light crop	James Ticehurst, Dynevor Castle, Llandilo
PEMBROKE	....	Very thin, on half the trees none	But few, many affected with spot	Abundant on walls	Moderate crop on the late sorts	Plentiful and good	Abundant where protected with a 14-inch coping	None, trees much injured by the spring frosts	Gooseberries, Currants, and Raspberries moderate	Abundant	W. Hutchison, Castle Malgwyn, Llandyssil, S. Wales
IRELAND.											
ARMAGH	....	Very scarce	Very scarce	Very scarce	A fair crop	....	....	A few	Fair crop	Three-quarters of a crop	David McClelland, Churchill
CORK	A fair crop	A good average	Heavy crop	Good	Very superior crop	Very bad	Average	Good	Very fine crop	Better than last season	J. Fraser, Gardens, Bessborough
DOWN	....	Very good	Very fair	Almost none	Very fine	Good	Almost none	....	Very fine	Fair average	John Fisher, Stormont Castle, Dundonald
DUBLIN.....	Good, and promise well	Middling	Average	Abundant and good	Under average	Fair	Good	Abundant	Plentiful	Average	D. Pressly, Knockmaroon Lodge
KERRY	None grown in this district out-of-doors	Good crops on pyramids and fruit trees	Very thin; on the west walls they are the best	Abundant here, only partial in exposed situations	Heavy crops on some sorts, the first and best blooms did not set	Heavy crop on walls, standard and orchard trees very thin	Fine crop here, in other gardens not so good, trees unhealthy	Good crops but very backward; wet and cold for the past month	Abundant crop, fine fruit	Filberts not good; wood nuts plentiful in some places	George Breese, Killarney House Gardens
MEATH	A fair average crop, but small	Plentiful on dwarf trees; on old trees none	A fine crop on trees protected from frost in spring	None on standards; very thin on walls, owing to spring frosts	A heavy crop, but one-half were lost through wet weather	A very poor crop	Plentiful, but they are very small	Very scarce	A very thin crop, deficient in flavour	Walnuts thin; Filberts and Cobs plentiful	Robert Moulton, Somerville, Navan
WATERFORD ..	Above average	Half crop of Keswick Codlin, &c., others almost a failure	Good crop on walls, new for standards and pyramids	Fair crop on walls, none on standards	Fair crop of Black Prince, other kinds very bad	A few on walls, none on standards	A fine abundant crop, but very late	A good crop, but dropping before ripe	Abundance of all kinds; Raspberries without flavour	All kinds plentiful	J. A.. Curraghmore, Portlaw
GUERNSEY AND JERSEY.	Moderate	Average	Rather below average	Not a good crop	Moderate crop	Not good	Below average	Average	....	....	Thos. C. Brehaut, Richmond House, Guernsey

REMARKS ON THE FRUIT CROPS OF 1871.

[In addition to the foregoing tabular reports, the following statements are extracted from our correspondents' returns.]

We never had a better crop of Apricots. We protected them simply with herring-net, two and three ply, and kept them out from the trees about a foot or 9 inches by means of forked sticks. Our south and west walls of Pears were protected in the same manner, and many of the trees are laden, and, in fact, all the blossom that opened kindly set well by this means. I am confident had we protected our Cherries with the same covering we should have had crops of fruit, for the trees were covered with blossom. Our great loss, the Apple crop, is serious. We have not one Apple for every bushel we had last year. The cold, dry, easterly winds in May were the most harsh I ever felt; and scarce a day had we during the whole flowering period that could be called, in common phraseology, a nice day. Old trees on the sites of two old gardens in different parts of the park, that seldom or never failed before, are fruitless; they are that old, valuable, jelly-making variety, Keswick Codlin, and their loss is deplored in the still-room in consequence. *H. Knight, Floors Castle Gardens, Kelso.*

—— With the exception of Apples, the fruit crops here are good this year, which I attribute in some measure to the soil and situation. I believe this is the driest locality in Yorkshire, and the subsoil is of a sandy, porous nature. The fruit trees in general only make moderate growths, which in ordinary seasons get well ripened. Peaches and Nectarines are a heavy crop; they set very thick, and I have had to thin them several times. In general, Peaches are not an abundant crop in this neighbourhood. Trees that bore heavy crops last year have in many places light crops this; and trees that had light crops last year, have average ones this. Apricots are in general a good crop; fully an average one. All trees that were not overladen last year have abundant crops this season; indeed, they are much better than could reasonably be expected after the heavy crops of last year. Pears are here a good crop, both on the wall trees and on the standards. A few of the trees have light crops, but the greater number have very good crops. The fruit is clean and healthy, and promises to be fine. Plums, as was to be expected after the extraordinarily heavy crop of last year, are in general light here—Victoria, Kirk's, Jefferson, Mitchelson, and some others which were not overladen last year, have good crops. Cherries are not a heavy crop. Strawberries have in general been a light crop in this part of the country. In the neighbourhood of Knaresborough, where large quantities are grown for Harrogate, Leeds, and other markets, the crop has been the lightest they have had for some years. In general the old plants have had very little fruit; what fruit there was has been borne by the two-year-old plants. The drought of last year told on the old plants, and the rains came too late for the plants to perfect their growth and form crowns here. Sir Harry, Sir Joseph Paxton, President, British Queen, Carolina Superb, Empress Eugenie, and some others, have been abundant and fine; but Keens' Seedling was a complete failure. Had it only been the old plants I should not be surprised, as they did not make any growth last year until it was too late to form perfect crowns; but a large breadth of two-year-old plants, which stood the drought and looked well last summer, were quite as great a failure as the old plants. I cannot account for it, as the runners came from a most prolific stock. The two-year-old Eltons have good crops, but the older plants have very little fruit —I grow a good deal of this for late use. I like Eleanor, but it does not bear freely on our dry soil. On the heavy clay soils around Knaresborough, it bears enormously, and being a fine, showy fruit and late, is very valuable. Fruit of all kind is very late in ripening this year, owing to the dull cold weather. *M. Saul, Stourton, Yorkshire.*

—— Apples generally in this district are not an average crop, except in sheltered situations. Our garden walls being high, and the trees young, we have a fine crop. The hardier sorts of Pears are a fair crop, but such tender varieties as Marie Louise are a complete failure. We never use any protection here except the wall coping, which projects 3 inches, and we have generally an abundant crop of Peaches. The great point seems to be to keep the trees free from insects, for which two parts of sulphur and one of snuff dusted over the trees in a dry state will be found an effectual remedy. *W. Carmichael, Sandringham.*

—— Pyramidal Peach and Nectarine trees, planted in an unheated orchard-house, bear a very light crop this season, and during the early part of which the trees were very much blighted; while in a house of similar dimensions, where the trees are trained cordon

FIG. 233.—UTRICULARIA MONTANA.

fashion, at a distance of 18 inches from the glass, and which has the advantage of hot-water pipes, by which frost was merely excluded, fruit is in great abundance, and promises to be fine. Bush and pyramidal-trained Gooseberry trees in the open quarters have not a tithe of a crop: while similar sorts trained to a north wall are bearing a most abundant crop, and the fruit is clean and very fine. *P. G., Culford.*

—— The Potato crop is very fine with me this season; I have not yet seen a diseased tuber, which I am much surprised at from the great quantity of rain we have had in this neighbourhood. *George B. Tillyard, Brocklesby Park.*

—— We have had 2.79 inches of rain in June and 3.73 inches in July. The Potato disease is spreading fast in this district, other vegetable crops are all looking well; Peas are most abundant. We had 9° of frost on the 7th and 11th on April 8. Peaches, Nectarines, and Pears were then in full bloom, the two former have set a fair crop, but we have scarcely any Pears on most of the sorts. We have most on the Beurré Rance, but the trees of that sort look more unhealthy than any of the others. *Charles Ross, Welford Park, Newbury.*

—— This season has been the worst I ever knew for blight of all kinds, especially green and black fly. At one time I quite despaired of saving the Peach and Nectarine crop owing to this pest, but by continued applications of tobacco-water, and copious washings with clear water, I have now a good prospect of being paid for my labour with good crops of fruit. I am sorry to report that the Potato murrain is spreading in this district, which is the more to be regretted as the crops are more than usually fine. Other vegetables have been, and are very fine. *W. Wildsmith, Gr. to Lord Eversley, Heckfield Place, Hants.*

—— We have had scarcely two days following each other without rain these last two months, consequently the prospects have greatly changed since May, when appearances led us to expect a dry summer, and which in some instances led to a preparation for it. Cornwall and rain, however, are so proverbially connected that you will not be surprised. Most of the county is naturally so well drained that a "six-hours'" shower would be acceptable twice a week all through the summer. The early Potatos were good, but a terrible change has come over the late ones: in some cases the haulm has literally vanished, and report says the tubers are very badly affected everywhere. Garden vegetables are in good supply, Peas without mildew, and Carrots without worm. The "bedding out" stuff is not so good as in some seasons. The soil was cold all through May; June began with cold rains, and since then the soil has been so saturated that no warmth seemed to get at the roots of the plants; they have, therefore, made but little growth. Gardeners and farmers alike are now hoping for a few weeks of fine weather in August. *Henry Mills.*

—— Cider fruits generally are much below the average, and the leaves much curled and blighted. Plum trees suffered severely from attacks of aphides, which have been very prevalent. Bush fruit has generally suffered a similar fate, many of the Currant bushes being quite destitute of foliage. Outdoor Peach and Nectarine trees have suffered from cold and wet, whilst those grown under glass are healthy, with abundance of fruit, thus again pointing to the necessity in our variable climate of covering Peach walls with glass. The Potato disease is unusually prevalent in this neighbourhood, early and late varieties alike suffering from its virulence. Parasitic Fungi—*i.e.*, moulds, brands, and cluster-cups—are unusually abundant this season, vegetation suffering from their attacks, especially Roses, &c., from Coleosporium, Lecythea, and Aregma macrantum; whilst Peas and the like are suffering from mould, &c.; and, lastly, the destructive and most dreaded Peronospora infestans on the Potato. *Henry Munro, Clevelands, Lyme Regis, Dorset.*

UTRICULARIA MONTANA.

It is about a year ago since I first became acquainted with living specimens of this curious, and at the same time highly beautiful Lentibulariaceous plant (fig. 233). When first received it was in a dried state, having been but recently imported from New Grenada; but from what locality or altitude, unfortunately, I cannot ascertain. It came to us from Stevens' Rooms with the following description:—

"Utricularia, very fine new species, never before imported into this country alive, resembles a terrestrial Orchid. From a bundle of transparent tubers the flower-stems rise to a foot in height, and bear three to five flowers of an inch in diameter. Flowers and bracts of a pure white [? pale primrose]. Having been sent in their native mould they are in excellent condition."

Professor Oliver, of the Royal Herbarium, Kew, who has specially studied this curious family, has kindly referred this plant to Utricularia montana, or

U. alpina, as it is sometimes called, and from these specific names I infer that it comes from some considerable elevation above the sea level.

When I first obtained the tubers we placed them in a shallow propagating pan "in their native mould," using a little sand and peat for filling in amongst the transparent tubers, which latter were somewhat shrivelled. After a good watering they were placed in a moderately warm and airy Cattleya-house, and in less than six weeks the delicate green foliage commenced to push through, and the roots also began to ramify in all directions through the light compost. Knowing that Utricularias were aquatic plants, we obtained a larger-sized pan, and filled it with water, into which was placed the base of the pan before alluded to. This kept the roots in a state of constant moisture, and the plants grew vigorously. They were removed to the Indian-house—or a mean temperature of about 65°—for the winter, where they still continued growing, and have just now finished blooming, having borne about a dozen spikes of their lovely flowers. It is a very pretty little plant, and worthy of careful treatment on the part of those who possess it. Ten lots of this were sold at one of Stevens' sales in June, 1870, so that we shall probably hear of its blooming elsewhere during the present year.

I have to thank C. Stead, Esq., The Knoll, Baildon, Leeds, for a flower of this charming novelty, the plant here alluded to having recently flowered in his rich collection of exotics—for the first time, we believe, in this country. *W. B.* [The plant occurs in the West Indies and in Peru and New Grenada. It has flowered recently at Kew. EDS.]

Home Correspondence.

Hellebore Powder.—Kindly allow me to confirm the letter of "G. A. H." in the *Gardeners' Chronicle* of the 29th ult. I have used Hellebore powder for some years to destroy the Gooseberry caterpillar, and I have always found it an effectual remedy. I prefer the white Hellebore powder, and to have it fresh ground if possible. The method I have generally adopted is this: As soon as the caterpillars appear, and have commenced their havoc, I get an old flour dredger or a tin pepper-box, and fill with the powder. If the leaves of the bushes are not damp enough in the evening or morning, then I sprinkle the bushes affected with the syringe, in order that the powder may adhere. With the dusting box in one hand and the shoot of the bush affected in the other, you can get at the upper and under sides of the leaves effectually. I think the use of the pepper-box preferable to throwing it out of the hand; there is then no waste of the Hellebore. The powder should be kept perfectly dry; if the least damp, it gets clammy. Sometimes there are two or three broods of the caterpillars during the season, and the eye of the diligent gardener must be constantly on the alert to detect these destructive marauders. If the berries are ready for use, or are required for bottling, &c., they should be washed or wiped clean of any powder adhering to them, as it imparts a disagreeable taste to the skin of the berry. Of course, also, Hellebore is a strong poison, so that on this account the berries should be thoroughly cleansed before using. *Thomas Campbell, Chorlton Road, Manchester.*

New Pears.—At the risk of being tedious, may I ask a "wee" corner to enable me to say to "Pari Passu" that he is right in supposing that I mean Early Benrré d'Aremberg. It is a pity that this name should have been adopted; the fruit has no resemblance to any of the B. d'Arembergs, but it has to B. d'Hardenpont d'Automne. A great deal of confusion exists about the Pears, or are required for bottling, &c., they should be washed or wiped clean of any powder adhering to them, as it imparts a disagreeable taste to the skin of the berry. Of course, also, Hellebore is a strong poison, so that on this account the berries should be thoroughly cleansed before using. *Thomas Campbell, Chorlton Road, Manchester.*

New Pears.—At the risk of being tedious, may I ask a "wee" corner to enable me to say to "Pari Passu" that he is right in supposing that I mean Early Benrré d'Aremberg. It is a pity that this name should have been adopted; the fruit has no resemblance to any of the B. d'Arembergs, but it has to B. d'Hardenpont d'Automne. A great deal of confusion exists about the Pears, or are reported to be, identical, or, more correctly, B. d'Hardenpont d'Hiver. The Abbé Hardenpont, of Mons, was the raiser, and it was named, very justly, after him. The reason it was called B. d'Aremberg was just this: that Noisette, of Paris, having visited the Duc d'Aremberg's gardens, procured scions of the sort with this name, and on arriving at Paris named it B. d'Aremberg. Glou Morceau is Walloon for a delicious mouthful, or something like it, and as the Pear merits the appellation we have adopted it in England; so here we have Beurré d'Hardenpont d'Hiver in Belgium, B. d'Aremberg in France, and Glou Morceau in England—three names for the same Pear. There is nevertheless another Beurré d'Aremberg of the Belgians, with many synonyms. This is the true B. d'A., and is perhaps best known as Orpheline d'Enghien; the fruit of the two sorts resemble each other a good deal, trees not at all. There is again our other friend, a claimant of the house of Aremberg, but he has no right to the title, only he comes into the Hardenpont family as a first cousin of B. d'H. d'Automne; in fact, the two may be, or are, nearly the same, though there seems a difference in the trees. *Pomona d'agrement* is a Russian Pear never, since it came into this country, was anything else. If Democritus had been a modern nurseryman he would have found his head crammed enough if he had tried to keep our new railroad pace. The old gentleman lived in times when he could at least keep up at a steady pace with his compeers. As to the Autumn Bergamot, I attach the following:—

"Bergamot, Autumn (English Bergamot, York Bergamot, Bergamot Commune, Bergamot Recour, Bergamot Lisse, Bergamot de la Hilière, Bergamot Rouwa, Grosse Ambrette, Bergamot Melon, Vermilion Supreme): 2 size, 1 qual., October to December. Roundish, slightly flattened; skin yellowish green, spotted and striped with red, with patches of dark fawn colour; eye small, open, often wanting, and slightly sunk; stalk, short, thin, and slightly bent, set in a wide round hollow; flesh white, melting, and juicy; juice abundant, acidulated, sweet, and perfumed. This fine old Pear is said to have come originally from Asia, and has obtained its name from a town called Bergamo or Pergame. It is supposed to have been brought into this country by the Romans, and has been cultivated in England about 300 years."

By which "Pari Passu" will see that it is not even European, but American, and may get a hint as to the origin of the word Bergamot. I must now crave a little space to reply to "Bon Chrétien," p. 175. I have read of Mahomet's Bridge, a single hair, to get to Paradise on. The Christian road is equally narrow and straight. I would modestly recommend "Bon Chrétien" to leave out the "Bon" and put in "Mauvais,"—but as he likes; he may be leal at heart and a good fellow, and as such I will accept him—of course I have no notion of his *status*, and cannot know, excepting from his own mouth, that all he advances is equally honest. I've got nothing to hide in myself open by name and invitation to be corrected, and am glad when any of your correspondents try to put me right. Error is not a desirable friend, and we ought to be thankful to all who try to improve us; even when they do not hit the mark, there is generally something to be gained from the effort, because it provokes and rectified. Such, for instance, as correcting a typographical one, as in the spelling of Napoléon Savinieu, which should be Savinien, the surname of Nicolas Savinien, *curé* of Liernu. The Pear, not the *curé*, I have fully described at p. 974. I am afraid that I may not judge enough of what a good Pear is. "Bon Chrétien's" taste may be more refined and more exacting than mine; hence we differ in these matters. I do not exactly like his sweeping denunciation of American Pears. I know many that can vie with any yet produced in Britain. I need not give a list, as no doubt most of your readers are acquainted with them. As to the correctness of fruit tree nursery collections in England, "B. C." and I are not at one in that matter. "B. C." says he is amused on looking over my list of 120 sorts, and at the end of his letter he further alludes to it as one that I have not got a long experience. Well, after 50 years of close application, I do feel I require a great deal more than I am ever likely to get; and although it may be presumptuous in me to attempt to correct "B. C.," I am nevertheless constrained to say that I think he is wrong about King Edward's or Jackman's Melting. I have never heard that it was claimed by any other country. Downing disowns it as an American, and Leroy won't take it in as a Continental sort; so I suppose his big majesty must remain with us. As to Uvedale's I have stated all I know about it at p. 974. For Tillington and its history I refer your learned correspondent to vol. iv. of the Horticultural Society's Transactions, p. 521. In conclusion, I may say that any useful information I can give will be always cheerfully at the command of any of your correspondents. Nevertheless, I do think gentlemen critics should make themselves a little better acquainted with the subject in hand before coming down so heavily upon a poor fellow. *J. Scott, Merriott.*

Cypripediums.—I am a great lover of these plants, and am always glad to obtain any information I can respecting them, but I am afraid opinion of those who volunteer to give information concerning them should understand the subject upon which they speak or write. What can we think of a writer upon Orchids in one of the magazines for this month, who, when describing *C. niveum*, tells us that it "bears a very close analogy, in the character of its foliage, to *C. Dayanum*" and *C. concolor*. Do Cypripediums have pseudobulbs? If so, where am I to look for them?—perhaps some Orchidologist will kindly answer. *Juvenis.*

Table Decorations.—It requires some courage or brass to break a lance with your correspondent "W. T." on table decorations, but as I praised, in no stinted terms, his arrangement at the Palace last year as applicable to a large public dinner, but at the same time questioned its applicability for private use, I will now volunteer a few words of opinion at the same time to give my notions on the subject. We are a people of extremes; we see it in fashions. When crinolines reached us from Paris, our fair country-women soon eclipsed, in the amplitude of their folds, the Parisian ladies; when trains came in, English ladies had theirs far longer and wider than the French. French gentlemen had their hair closely cut—our swells look as if they had just come out of Millbank or Holloway, so completely cropped are they. And so in this matter of table decoration. The Russian dinner was a wall of flowers, fruit, and plants in pots, and a few flowers amidst the dessert, and now forsooth we must set people down in a flower garden or a shrubbery, until at last it seems as if the invitation should run:—"Mr. and Mrs. ——— request the pleasure of ——'s company, to see their table decorated; dinner provided at seven o'clock." I think this is altogether wrong. At a public dinner, provided for a large number of people, you do not care much about seeing your *vis-à-vis*, and therefore your having a Gooseberry bush between him and you does not much matter. In a private dinner party, I consider, the first thing is the comfort and enjoyment of your guests; the second, that of your own household. There is always enough to do, and more than enough, on such occasions; and if this is to be supplemented by a decoration that will require some two or three hours' work from three or four people, it will be the feather to break the camel's back; and it is for this reason, and because it takes up so much of the gardener's time, that in our best circles now the thing has been shorn of its monstrous overgrowth. By all means let us have flowers, nay, plants, if desired, but let nothing be higher than a foot and a half, which I think is now considered about the correct thing; and let the other decorations of the table be such that it may not seem as if the host and hostess had invited their guests to see their floral resources and not to have their company. Has the style which "W. T." recommends, and which, as I have said, answers admirably for a large and very wide table, been adopted at the West End. Can he tell us where we can see it? In saying this, I am not, I hope, guilty of snobbishness, but I do maintain, that in all matters of taste and refinement, we shall find that the true standard is to be found amongst our aristocracy. Compare, for example, the style of dress at Kensington, or the Regent's Park shows, with that at the Crystal Palace; in the one you have the result of refinement, the other that of unlimited command of cash without it. I have said nothing about the expense, because, as a rule, I think that little matter, but this when they give a grand dinner now and then; but when, as I believe is the correct thing, frequent *réuniones* of ten or twelve take place, it becomes an intolerable bore to have these extensive and expensive decorations. Will Mr. Standish tell us something of his knowledge and experience in this matter? I believe he has much to say in this way as most people, and perhaps he would enlighten us as to what is most in vogue amongst his clients. I am sorry to differ from my excellent friend "W. T.," for his taste is of that order that if one does differ you may question whether you are right, still I believe I am, and shall be glad to see others take up this matter. *D., Deal.*

Grape Growing at Kingston Hall.—In reply to Mr. Westland's remarks on the heating of the Vine borders here (see p. 1008), I beg leave to state that your two correspondents have given the true version of it as it now stands. How Mr. Westland can labour under such an hallucination, I am at a loss to conceive. The pipes are in exactly the same position as he left them, namely, three under the border, but under the front path, or nearly a yard inside the houses, where neither roots nor border are to be found. Moreover, I am quite sure Mr. Westland could never have heated the pipes to any extent, as the so-called bottom-heat pipes were wrong, both practically and theoretically. They had one good property, and it was that no one could use them to excess. If Mr. Westland had spoken out on the subject when going through the vineries on his last visit, I could easily have pointed out the weak points in his arrangement of hot-water pipes, which I am thankful to say are the weakest now in our vineries. Further, I very much question if the present system of heating is as good as the one before the alteration took place. One thing is quite certain, that Mr. Westland's predecessor, the late much respected Mr. Mackie, managed to produce bunches of Grapes (and for years) with the old plan than either Mr. Westland or myself have yet got by the new. *Wm. Cruickshank, The Gardens, Kingston, Derby, Aug 9.*

The Potato Disease.—I thank "J. S." for his timely suggestion. I have not tried the pulling-remedy suggested by him, but I have had reason to the less radical measure of cutting away the haulm at the ground line, when the malady was unfortunately but too plainly apparent. I have information, however, that this plan has already been tested in this neighbourhood in previous seasons with but questionable success. I also hear that a large breadth of Potatos has been so treated this season, the soil being subsequently ploughed up over the rows, the results of which I hope to be able to report hereafter. It is quite certain that, notwithstanding every kind of preventive considered possible may have been tried, we should not lightly treat any that may yet be made, as the injury which this dire pest causes to our country's wealth cannot be easily estimated, especially in a season of such hope in regard to the Potato as the present. *William Earley.*

Flavour in Fruit.—I agree with your reviewer of the Rev. J. Fountaine's pamplet (p. 977) in doubting that it is "the radiation at night that enhances the flavour of the fruit" in the system of cultivation spoken of, and believe with him that it is "the exposure to the cool dews at night that is beneficial. The influences of heat and moist cold appear to be as powerful in hastening and perfecting the ripening process of fruit, as they are in promoting decay in vegetable substances. It is well known that when the latter—wood, for instance—is made alternately dry and moist, it decays much more rapidly than when kept continuously in either state; and it is quite in accordance with this, that outdoor fruit of all kinds ripens more rapidly after a day's rain than if the weather continued always dry and warm, a fact

which I have repeatedly observed. Grapes that are grown by me with the same ventilation night and day surpass in flavour all those managed on the orthodox but unnatural system of syringing, "and shutting up with an hour's sunshine on the glass;" and I have heard of the same being the case with another person. *A. Boyle, Wittland, Carmarthenshire.*

Notes on Gladioli.—I was much interested by the report of your correspondent "F. W." on Mr. Kelway's flowers. We all know how magnificent they are when exhibited as he alone seems to know how to do them; but I want to correct one error. It was not the war that prevented any Gladioli being sent over from France last year; long before it broke out it was known none would be sent, for this reason: M. Souchet is really the only grower in France, and he is in too weak a state of health to leave home, even for one night, and no one else could compete. One is delighted to hear that Mr. Kelway will not send out any but first-rate seedlings, for as yet that term can hardly be applied to any of his flowers that I have seen. *Glavieul.*

China Winter Radish.—Last autumn I sent a Radish to your office, which was described as the China Winter Radish. I think it is the best Winter Radish grown, for it will keep good all the winter. It is in size and shape like an Early Horn Carrot, of fine flavour, and very crisp. In colour it varies from a beautiful pink to a dark red. I saw the seed in August and September. *W. H. Fort, Kingsbridge, Devon.*

Drosera.—One often hears complaints of the difficulty of making that pretty little native plant, Drosera rotundifolia, grow. At Mr. Morse's nursery at Epsom they succeed perfectly. They place a small quantity of peat at the bottom of the pan, and then arrange their plants in Sphagnum, placed above the peat. The pan is then stood in a saucer of water. Nothing can be simpler, and few objects possess more interest. *John E. Daniel, The Terrace, Epsom.*

Potatos.—My "taters" are but little affected by disease. It is very bad in the parish. I planted January 7, with no manure at planting. I manured high for preceding crops. The frosts did not hurt my Potatos in the ground, but frosted a bushel and a half in the houses, though they were thickly covered with straw. Unless air is thoroughly excluded, Potatos will be frosted in severe winters. *W. F. Radclyffe.*

Varieties of Pelargoniums.—I have heard a wish expressed that the scarlet Pelargoniums were not so numerous as they are. Would it not be possible for growers to fix upon a certain number, and in the main stick to this? Say, three dozen of the Zonals of every shade of colour, half-a-dozen of the Bronzes, and half-a-dozen of the Tricolors, both gold and silver, making it a determined object to obtain and retain the best; and, as those become beaten, to take in the better kinds till they are beaten too. No sort need be cast away entirely; one plant may be kept for a year or two. Let me give an illustration of what I mean. Lord Palmerston is of the same colour as the Duchess of Sutherland, and the Duchess is decidedly the better of the two. Now, the Duchess might be grown in pots, and one plant of his lordship. Again, Dr. Lindley beats all his predecessors, and it is only reasonable to suppose the doctor will be beaten in his turn. Well, good as he is, let the best flower win. It is only fair it should do so. I have only tried to point to a principle. No doubt we shall have a flood of seedlings now; and, as far as my own feelings go, I should be sorry to see a seed lost that offered a chance of improvement. But what I think necessary is, that the best, and the best only, should be picked out of the thousands that will be raised. It will soon be no easy matter to stand, even in a respectable position, among the raisers of seedling Pelargoniums. Chance may give the palm to a very unexpected competitor. *R. F.* [This is in reality the main object of the Chiswick trials, which we hope will be carried out in future with spirit. But it must always be borne in mind that particular sorts are better in some places than in others, so that it is not practicable to arrive at a positive decision on their merits. EDS.]

Acer Pseudo-Platanus rubro-purpureum.—Allow me to introduce to your notice a new variety of Sycamore, Acer Pseudo-Platanus var. rubro-purpureum, found growing in a hedgerow of one of my nurseries. It differs from the original purple variety by robustedness and vigour of its growth, and also in the rich red-purple tint of the foliage. Budded on the common Acer Pseudo-Platanus, it throws shoots 6 to 7 feet long in a season, and from the rich colour of its leaves is a truly beautiful tree, fit to rank with the best of its companions for varying the tints in ornamental plantations. *C. B. Saunders, Jersey.* [The sample sent had the under side of the leaf reddish-purple, decidedly brighter in tint than the ordinary Purple Sycamore, and hence if it shows the ordinary character of the leaf, we shall gain here a handsome ornamental tree. EDS.]

Water Weeds.—The inclosed are two specimens of water weeds [Myriophyllum and Chara], which abound to an enormous extent in the lake here, forming a mass almost entirely throughout the lake. Will some of your correspondents, who have experience of water weeds, give me information as to the best means of keeping them down, or destroying them? At present they are being mown off, the water being previously lowered to enable the men to wade through and mow with the scythe, but it is laborious work, the lake being extensive, and the weed very thick. *W. E.*

Bluegown Cucumber and Veitch's Giant Cauliflower.—Seeing in the *Gardeners' Chronicle* very flattering accounts of the Bluegown Cucumber, I purchased a packet of seed from one of the most respectable houses in the country, thinking that if it was not much better than many pulled-up kinds, it could not be much worse. Well, I planted in March two plants of Bluegown along with Telegraph. What has been the result? From the plants of Telegraph I have cut plenty of good Cucumbers, considering the season; but from Bluegown, after four months' care and attention, I have managed to cut two fruits, and such Cucumbers I never saw grown in a frame before. In fact, some of the ridge varieties are far in advance of Bluegown. It is the coarsest, most ill-formed, and bad-flavoured Cucumber I ever met with. Several gardeners in this neighbourhood purchased a packet of it from different firms, and they one and all condemn it. There is another new vegetable I wish to say a few words about, viz., "Veitch's Giant Cauliflower." I got a packet of this at the same time as the above, and put in a pinch of seed in March into a frame with a little bottom-heat. I planted out about five dozen plants, of which one-half, or nearly so, have proved worthless; perhaps it may be owing to having been sown in heat; but the other half produced such Cauliflowers as I never saw before. I cut one today 2 feet 3 inches in circumference, as firm as a rock, and as white and appetizing could possibly be as a way of a vegetable. It is a splendid thing for an exhibition table, and the flavour is pronounced by *connoisseurs* to be everything desirable. *J. C. N., Mount St. John.* [Both have been shown good. EDS.]

Lily of the Valley.—Having noticed that some Lilies of the Valley were exhibited at Kensington a short time back, and that hints were thrown out that it would be a late variety, permit me to inform you it is nothing new to have those beautiful flowers late in the season. It can be done any time by exposing the roots and letting them get well dried before planting. I saw an instance this spring of a clump that was potted in the autumn of 1860, which refused to vegetate in 1870, and was placed under in this year it came finely in flower last June, the leaves being nearly round, and of a much deeper green than is usual. I am of opinion that the plants which flowered late this season, if let alone, will come at their usual time another year. *Ebor.* [We have other evidence tending in this direction. EDS.]

Roses.—It may be of advantage to persons not conversant with Roses to know the names of the best Roses that have come out since 1859. I shall mention those only that have good attributes. Some beautiful Roses I must omit, for the want of good attributes. *H. P. Roses:* Sénateur Vaisse, Madame Boll, Madame C. Crapelet, Victor Verdier, Duc de Cazes, Prince Camille de Rohan, Charles Lefebvre, Francis Lacharme, Madame Charles Wood, Madame Charles Verdier, Madame Boutin, Madame Julie Daran, Madame Clémence Joigneaux, Maurice Bernardin, Baronne Prévost, Lady Marechal Vaillant, Jean Hopper, Baron Adolphe de Rothschild, Princess Mary of Cambridge, Lord Clyde, John Keynes, Gloire de Ducher, Lord Macaulay, Léopold Premier, Madame Emile Boyau, Lady Suffield, Madame Victor Verdier, Dr. Andry, Pierre Notting, Marguérite de St. Amand, Madame Alfred de Rougemont, Comte Raimbaud, Abel Grand, Madame Fillion, Alfred Colomb, Antoine Ducher, Prince de Portia, Black Prince, Felix Genero, Elie Morel, Souvenir de Dr. Jamin, Monsieur Noman, Madame la Baronne de Rothschild, Duke of Edinburgh, Madame Jacquier, Eliza Boelle, Madame Wibaird, Perfection de Lyon, Comtesse d'Oxford, Edward Morren, Marquise de Castellane, and Baron Chaurand. The last is a distinct and beautiful Rose; the six Roses preceding it are first-rate. I do not yet know the full attributes of the last eight Roses, as I have not seen them bloom once. *Bourbon Perpetuals:* Baron Gonella, Marguerite Bonnet, and Baronne de Maynard. *Tea Noisette:* Rêve d'Or. *Tea Roses:* Adrienne Christophle, Maréchal Niel, Madame Margottin, and Madame Trifle. You cannot burn your fingers by selecting from the above Roses on the Manetti stock. I have been buying bad growers. Many are marked "vig.," which are not so. "Mod." in a nurseryman's garden means "dwf." in yours, which is a synonym for "death." Maréchal Niel does well here on its own roots, on the Briar and on the Manetti; my three best plants are on Manetti. *W. E. Radclyffe.*

New Annuals: Godetia Whitneyi and Phlox Heynholdii.—The first-named of these newly-introduced annual flowers having been figured, and very highly spoken of in more than one horticultural periodical during the past spring, I was consequently induced to use it rather freely, and I confess was beginning to entertain doubts as to its realising the good opinion I had been led to form of its merits, as it did not begin to flower until the first week of July. But I am now glad to be able to say that it has fully realised all my expectations. It is without doubt one of the most showy and attractive annuals that has ever been introduced, but to do it full justice it ought to be grown *en masse* in a bed of considerable dimensions, or to form a line in a ribbon border of considerable length. It is then in appearance really magnificent, resembling, at a distance, a line of the finest dwarf Rhododendrons in full flower, or of some fine variety of Hibiscus. It grows from a foot to 15 inches high, and is exceedingly floriferous, each bloom being quite 3 inches in diameter, colour rose-pink, with a crimson spot in the centre of each of the four petals; this spot, however, is more clearly defined in some plants than in others, and on this account care ought to be taken in selecting seeds from the best coloured plants. Should this plant prove to be continuous in blooming, as it has at present the appearance of being, it will certainly prove very useful, even as a bedding plant. I sowed the seeds about the middle of March in pans in a gentle heat, pricked out into pans or boxes when large enough, and finally planted out about the middle of May. Phlox Heynholdii is also an annual of recent introduction, which I think only requires to be better known to insure its being more extensively used. It belongs to the Drummondii section, but is more dwarf in growth, seldom exceeding 6 or 8 inches in height, and producing an abundance of rich flame coloured flowers. It has also the property (not always possessed by the finest annuals) of producing itself quite true—that is, without any variation either in the colour of the flower or in the habit of the plant, and continues to flower until late in the season. *P. Grieve, Culford, August 1.*

Foreign Correspondence.

THE ISLAND OF SAN DOMINGO.—The following notes on the botanical features, economic vegetable products, and agricultural capacities of this island, are gathered from a report drawn up by Dr. Pauly, the botanist attached to the San Domingo Commission.

Apart from the general facts of the geographical position of San Domingo within the tropics, its insular character and exposure to the regular trade winds of the North Atlantic Ocean, necessarily involving a warm and moist climate, productive soil, and favourable commercial facilities, the principal distinguishing feature of this island is presented in the large extent of its elevated mountain ranges. This plainly marked physical feature, which everywhere meets the eye, serves not only to give a pleasing variety to the landscape, but also to supply the conditions of a much wider range of agricultural production than would be possible otherwise. The highest mountain ranges, attaining elevations of from 5000 to 8000 feet above the sea, are clothed to their summits with a dense growth of native forests, and their crests and slopes are seen frequently enveloped by clouds or fog, creating a moist, cool atmosphere. Hence, botanically and agriculturally, the country is naturally divided into distinct districts, viz.:—

1. An irregular coast line, frequently presenting abrupt rock-bound shores, or extending in the form of gradually elevated plains to the interior mountain ridges.

2. Wide, open valleys and interior basin plains, bounded on either hand by elevated mountains.

3. The mountain slopes and ridges, rising to elevations of from 3000 to 5000 feet above the sea.

1. The coast line, or maritime belt, includes some of the least productive and most forbidding portions of the island. It embraces, along the northern and southern coasts, arid, sandy, and rocky tracts, which, being shut out from the influence of moist winds, present desert features in the growth of Cactuses, dwarfed thorny trees, with scant foliage, and an intricate maze of shrubbery next to impassable for man or beast. The moist, sandy lagoons, forming at the mouth of rivers, are occupied by dense Mangrove thickets, and in more favourable locations stretches of smooth, sandy beaches are separated with groves of Cocoa-nut, and other graceful Palms. Again, at other points, as in Samana Bay, the wooded slopes drop down abruptly to the water's edge.

In the vicinity of San Domingo city the broad ocean swell dashes against perpendicular, rocky walls, which are fantastically worked out and fissured by the waves, at only a few points presenting narrow patches of sandy beach. It is on these less productive, and even desert tracts, that some of the most valuable native vegetable products are to be found, including especially the durable Liguum-vitæ, the commercial logwood, and Fustic. In similar districts we meet with valuable leaf-fibre plants, including the Paboulla, Maguey, Bromelia, &c., all of which are in common use in the manufacture of cordage, and the dressed fibre derived from these different plants will eventually form a very important article of export.

The more undulated plains stretching inland to the interior mountain ranges exhibit certain varieties of soil, in connection with the chemical composition of the underlying rock, or superficial deposits, being either sandy, gravelly, or argillaceous, and thus adapted to the different varieties of tropical food plants. Here also the vast number of tropical fruit trees can be cultivated to an unlimited extent; and with more attention given to improved varieties, the fruit product

may be made to form a remunerative branch of commercial industry. In other districts, appropriately termed "savannas," stock raising is carried on to advantage, and several shrubs adapted for browsing still further extend the stock-supporting capacities of a large scope of country.

2. The large alluvial valleys and basin plains of the interior are especially adapted to the growth of Sugar-cane, which here grows with a luxuriance unknown in less favoured localities. The scope of country adapted to this staple can be much extended by a proper system of irrigation, by which the higher fertile grounds adjoining the river bottoms may be supplied with that degree of moisture necessary to perfect this class of cultivated plants. Cotton and Tobacco will also here find at different points a congenial soil for the production of their peculiar staples. These extensive valleys, as yet unexhausted by cultivation, will naturally concentrate the great bulk of the agricultural population, where large estates and populous cities, made accessible by railways to the commercial seaports, will in due course of civilised development present a marked contrast to their present sparsely-peopled wastes.

3. The mountain slopes, now in great measure clothed with luxuriant native forests, will constitute the first and most direct source of wealth to an enterprising and industrious population. Owing to the difficulties of transportation over the rude country roads, only passable for pack animals, much of the valuable timber growth, including Mahogany, and a great variety of cabinet woods and ship timber, is still growing in its native forests, while that adjoining the coast has been shipped to supply the commercial demands. When once made accessible by suitable waggon roads or railways, all this source of wealth will be laid open to enterprise; and in the process of clearing, the finest timbered lands will be made available for the growth of coffee and other analogous agricultural products.

One peculiarity of tropical forests consists in the number of different species in the same locality; thus, no large bodies of a single species of tree are met with as in northern forests, but a great profusion of different forms promiscuously scattered. These include, in the West Indies, over 200 different species. This fact, however, is less conspicuous at the higher elevations, where Pine groves and analogous northern forms make their appearance. At an elevation of from 5000 to 6000 feet above the sea, we meet with the atmospheric conditions favourable to the growth of Cinchona, yielding the medicinal quinine. The result of numerous experiments having now fully established the conditions necessary to the successful culture of the Cinchona, the colonial Government of Jamaica, in the Blue Mountains, has recently established a Cinchona plantation in the Blue Mountain range in that island. Having had an opportunity to visit this location during the explorations in connection with the San Domingo Commission, and to ascertain the views of the intelligent botanist in charge (Mr. R. Hill, Superintendent), the conclusion is safely reached that a larger scope of country in the mountainous districts of San Domingo is adapted to this important class of cultivated plants than any other insular locations in the Western Hemisphere. In this same connection may be noticed the great advantage which these elevated districts afford for healthful sanitary retreats, where those enervated by long exposure to tropical heats can find relief in a cool atmosphere, only a short distance from their ordinary lowland residences, but also in the capacity for raising the ordinary northern fruits and vegetables, so much prized by those who have been always accustomed to them.

The facility with which all tropical plants and trees can be transferred from one region to another within the tropics is evidenced by the great number of East India species now naturalised throughout the West Indies, including by far the majority of ordinary tropical fruits and vegetables, as well as common weeds. Thus, from other remote sources may reasonably be expected hereafter large additions to the agricultural wealth of San Domingo, on whose inviting soil may be introduced the Eastern dyes, spices, vegetable oils, gums, and drugs of commerce. The following may be summed up as comprising the prominent features which characterise San Domingo as a desirable agricultural region.

1. An insular position, exposed to the equalising influences of the surrounding sea, insuring abundant moisture for the growth of all tropical products, and affording the largest commercial facilities for export to adjoining northern countries.

2. A natural division of closely-adjoining districts, including arid tracts on the coast, adapted to the growth of valuable fibres, woods, dyes, &c.; a region of plains and large interior valleys, varying in soil and exposure from comparatively barren to exuberantly fertile, adapted to a variety of agricultural products.

3. A large extent of mountain slopes densely wooded, including some of the most valuable timber products, which, in addition to their native forests, afford the most desirable locations for the cultivation of Coffee and other tropical staples; a still more elevated district, suited to the cultivation of Cinchona, as well as the usual varieties of northern fruits and vegetables, and affording sanitary retreats to those living in the adjoining low lands, exposed to continuous tropical heats. And

4. An extensive field for the introduction of new varieties of plants and useful tropical products of other lands, on soils unexhausted by culture, and capable of supporting a vast population.

Societies.

CRYSTAL PALACE: *August* 5.—The supplementary Rose Show held here on Saturday last proved very successful indeed. The Roses, it is true, were not quite so numerous, but they were immeasurably superior to those shown on the last occasion, both in size and brilliancy of colour, and great was the surprise in store for those who thought the date was too late to attain much success. The latter class of reasoners seem to have forgotten the fact, that where a few classes only are made, and the prizes offered are liberal, plenty of Roses there surely will be, even though the season be a bad one. This may also be said to apply with equal force to most other subjects for which there is a call at our flower shows, and there is no one who better understands this part of the business than the Crystal Palace Company's General Manager, Mr. Wilkinson, whose schedules are always models of liberality and conciseness of detail. There was another prominent feature besides the Roses in the show of Saturday last, that would be well to reproduce at future exhibitions, and this was the plan adopted on this occasion for relieving the flatness and monotony of the tables, of massing alternately large and small groups of fine foliage and flowering plants at regular intervals down the centre of the stages, and between the latter where they are divided into sections. This was admirably done, and the effect was most pleasing to eyes fatigued with looking on nothing but bright colours and the everlasting green baize. We must not forget to mention that to this unique arrangement an additional charm was lent by Messrs. Downie, Laird & Laing, who contributed at each end of the central transept such splendid groups of Phloxes in pots as have never before been seen in this country. They were truly the admiration of everybody, and attracted as great a crowd of worshippers as ever the Rose did. Phloxes, it is said, are coming in great deal, for nowhere else does the queen of flowers draw half the crowds that she does here.

The first of the nurserymen's classes for Roses was for 60 distinct varieties, one truss of each, and for the four prizes offered there were six competitors, whose productions came to the mark in capital style. Here again we have to record the fact that Messrs. Paul & Son (who seem to be well nigh invincible in the champion classes) were again placed first with a good 48, as they always do they have shown anywhere this season. Next to these came Mr. Cant, of Colchester, and then the veteran Mr. Keynes, of Salisbury; the other competitors being Mr. Frantzius, Dereham; Mr. J. Harrison, Hardwicke; and Mr. J. Durbin, Englishcoombe, Bath. It is not our intention on this occasion to say which varieties were the best shown in each collection, suffice it to say that after mentioning the names of the successful men, we will give a list of those Roses which proved themselves stout and true, by appearing most often in good form. In the second class, then, for 48 varieties, three trusses of each, Messrs. Paul & Son were again 1st, Mr. Keynes coming in a good 2d.

The amateurs came out even stronger than their professional brethren, and their flowers in every way did them great credit. The best 48 single trusses were exhibited by Mr. T. Dyson, jun., Mr. T. T. Paget, Esq., Leicestershire; the next best coming from Mr. C. J. Perry, West Bromwich. The same exhibitors also competed in class 6 for 36 varieties, the same order of merit being observed in the list. Mr. J. Mc. J. Moore, Mr. T. D. Lloyd, Esq., Warwick; and Mr. May, Stileter, near Braintree, had the best 12. In the nurserymen's class for 12 Teascented, or Noisette Roses, single trusses, the 1st prize was carried off by Mr. Cant, and in the amateurs' class for amateurs by Mr. Stoddart, Wivenhoe Park, Colchester. Of yellow Roses about two dozen boxes were shown, the best coming from Messrs. Paul & Son and Mr. Keynes.

Looking over the various stands of miscellaneous plants we selected the following specimens of which were shown well in most of the collections:—Charles Lefebvre, wonderfully rich in colour all through; Lucila, rose, large and bright; Madame Vidot, purple, a pretty rose, and nicely shown; Marie Baumann, always good; Dr. Andry, Emilie Hausburg, very fine; Maréchal Vaillant, fine in shape, and exquisite in colour; Duc de Rohan, Sénateur Vaisse, Alfred Colomb, grand in shape, and a beautiful colour; Baronne Hausmann, Baroness Rothschild, La France, better in every respect than we had seen it before this season; and Madame Damaizin. Strange to say, there were not half a dozen first-rate blooms of Maréchal Niel at either this or the last show.

Amongst miscellaneous productions were the splendid Phloxes above named (and of which we shall have more to say), and a large collection of Golden and Bronze Pelargoniums from Messrs. Downie, Laird & Laing; a nice group of Scarlet and other Pelargoniums from Mr. J. Mann; collections of Begonias from Messrs. Paul & Son, and Mr. Cranston; a dozen nicely grown Fuchsias from Mr. Bristow, gr. to R. P. Harding, Esq., Dulwich; half a dozen fine Grosse Mignonne Peaches from Mr. W. Donovan, gr. to R. Hibbert, Esq., Upper Norwood; a dozen very nice cut spikes of Gladioli, from the Rev. H. H. Dombrain; a capital collection of Picotees and Carnations from Mr. Hooper, Bath; and a stand of new Verbenas from Mr. C. J. Perry, to each of which Mr. Edward Emms, Weaver, large, pink, crimson eye, a First-class Certificate was awarded. The same distinction was also awarded to Messrs. Downie, Laird & Laing, for Bronze Zonal Pelargonium, Maréchal MacMahon; and to Mr. Maurice Young, Milford, for Juniperus chinensis aurea.

At these shows the competition for prizes for plant decorations is now made a prominent feature, and that it is a feature that attracts one is evidenced by the fact that an immense amount of interest is created therein, especially amongst the fair sex, who, for the most part, indulge in unsparing criticism, and more so on Saturday last than on any previous occasion. We take it for granted that the object of the promoters of such displays—of course, putting monetary considerations on one side—is to encourage taste in that particular feature which they bring before the public, but if the examples which commanded the first prizes on this occasion are to be relied on as good ones for the purpose, we can only assert that in our opinion the results will fall far short of the mark. For instance, who would ever dream of loading their tables with such an *embarras de richesse* as was exhibited on that which was awarded the 1st prize amongst professional decorators? It should be an indispensable condition that whatever form of decoration be adopted, ample space should be provided for the usual elaborate dinner service. In this instance the space was limited to about 6 inches around the edge of the table, and beyond that a wine glass could hardly be inserted without disturbing the floral arrangements. What with pot plants and vases used to insert the cut flowers in, the table may fairly be said to have groaned beneath its weight of superfluous ornament. In our judgment, of all the groups exhibited on this occasion, the most effective and serviceable for ordinary use and ordinary means, though not the most novel, was that shown by Miss A. Hassard, St. Ronan's Church Road, Norwood, in the amateurs' class, and to which an equal 2d prize was awarded. It consisted simply of three gracefully filled epergnes, placed at equal distances down the centre of the table, with a small, neatly-grown Maidenhair Fern on either side of the centre one. This arrangement is simple and inexpensive, and could be reproduced in a comparatively short space of time, and that without exhausting the resources of small gardens to supply the cut flowers. The 1st prize was given to an arrangement in which there was some novelty, as well as some bad faults. The novelty consisted in the exclusive employment of cut flowers of hardy perennials, which Mr. Ware, of Tottenham, kindly supplied for the experiment, in place of the usual stereotyped assortment. This was very agreeable change, though the selection of the flowers was by no means so good as it might have been. Down the centre of this table (8 feet long) were three plants, with their pots sunken to a level with the table, a arrangement against which we have not a word to say, on the contrary, when the plants are of a suitable nature, and correspond in size with the surroundings, there is nothing more graceful, but where employed on a large scale the effect, without doubt, is very striking. The plants in this particular case were not well suited for the purpose, and this, coupled with the comparatively poor selection of flowers, and the by no means elegant nature of the whole, should, we think, have prevented this example from being held up as a guide.

BRITISH ASSOCIATION, EDINBURGH: Section D.—Prof. Dyer, B.A., B.Sc., read a paper "On the so-called 'Mimicry' in Plants." He said:—In all large natural families of plants there is a more or less distinctly observable general habit or *facies*, recognisable by the practised botanist, but not always as easily to be expressed in words. The existence of such a general habit in Leguminous and Composite plants is familiar to every one. What have been hitherto spoken of as mimetic plants are simply cases where a plant belonging to one family puts on the habit characteristic of another. This is entirely different from mimicry among animals, inasmuch as the resembling plants are hardly ever found with those they resemble, but more usually in widely different countries. Australia speciosa, from Western South America, a Composite, has a scandent Leguminous habit, closely agreeing with that of Lathyrus maritimus of the European shores. In the same manner different genera of Fumariaceæ (species found in distant parts of the world) indistinguishable in a barren state. The term Mimicry seems objectionable in these cases, and I consequently have not adopted it. As to the cause I propose Pseudomorphism as a substitute. As to the cause of the plants I can only suggest that the influence of similar external circumstances moulds plants into the similar form most advantageous to them. An illustration is afforded by the closely resembling habit which is often found in widely different orders of deciduous trees as modifications of stipules. I do not, however, think that the moulding influence need always be the same. I believe that different external conditions may produce the same result in this respect they may be called analogous. Several identical plants are found on the sea-shore, and also on mountains. The reason is, I believe that they are equally able to tolerate the effect of cold, and also of mountain climate; the tolerance of either unfavourable condition gives them the advantage over less elastically constituted plants, and the two are therefore analogous in their effects.

Notices of Books.

Handbook of British Fungi. By M. C. Cooke, M.A. London: Macmillan & Co. 1871. 8vo, pp. 982, tab. 7, fig. 408.

Mr. Cooke's work on microscopic Fungi, as well as his plain and easy account of British Fungi, have been so generally appreciated, that the present valuable treatise would commend itself to general notice without any review. We have already called attention to the portion which was published in the early part of the present year, but it would seem scarcely to be justice if we passed over without some especial indication, now that it is so happily completed, the results of a long series of very ardent labours. Mr. Berkeley's outlines comprised merely a list of those Fungi which required close microscopic investigation, and the student had to wade through the volumes of the "Annals of Natural History," the Linnean Transactions, &c., for an acquaintance with the specific characters of a great

portion, many species belonging to our flora not being comprised in any Continental manual; but Mr. Cooke has gone carefully through the whole range of British mycology so far as its members were ascertained up to the time of consigning his manuscript to the printer,—a labour which can be best appreciated by those who have been the most diligent students of a very difficult branch of botany. The volume comprises characters of 369 genera, added to numerous subgenera, while the species, of which specific phrases are given, are above 2800. Mr. Cooke's studies, it should be observed, have by no means been confined to British authorities, but all the best Continental works have been thoroughly analysed wherever information could be found bearing on the subject, while such species as have been most scrupulously studied with the help, where possible, of authentic specimens. Large as the number of species is, which are enumerated, doubtless much remains to be done in a very wide field. Mr. Broome still continues his labour, and Mr. W. G. Smith takes every opportunity of illustrating the order species; and should the work reach a second edition, which is very much to be desired, we shall be able to boast of a more complete mycology than almost any Continental country, except Sweden, which is unusually rich in species. Should the demand, however, not be sufficient to justify the undertaking of a second edition, Mr. Cooke proposes, from time to time, to give a supplemental volume, so as to keep the British student completely *au courant*. We conclude this short notice by cordially recommending the Manual to all our botanical friends, whether fungologists or not, as it is highly desirable that works like the present should meet with such success as may ensure further exertions.

August 3.—Comparatively cloudless throughout. Very fine.
— 4.—Rain fell about 5 A.M., and again heavily between 3 and 4 P.M. Overcast till 10 A.M. Variable afterwards.
— 5.—Cloudy between noon and 7 P.M. Nearly cloudless at other times. Generally fine.
— 6.—Generally cloudy till noon. Cloudless and very fine afterwards.
— 7.—Very foggy in the early morning. Small amounts of clouds prevalent during the day. Cloudless at night. Fine.
— 8.—Light clouds. A brilliantly fine day. Meteors at night.
— 9.—Generally cloudless. Extremely fine throughout.

JAMES GLAISHER.

Miscellaneous.

WOOD-PIGEONS.—Gamekeepers and naturalists are agreed that the wood-pigeon is, after all, the worst of the farmer's foes. It has hitherto enjoyed a sort of indirect protection, inasmuch as its natural enemies—the kite and hawk—have been well-nigh exterminated, and the gun-tax effectually discourages the efforts to destroy it which were once made by the ordinary rustic. As the season is now commencing when the bird begins to be injurious, it may be as well to offer some inducements for its pursuit. Of course, every one knows that the wood-pigeon is good eating; indeed, a "quist with a red herring in it" is regarded by west country folk as the greatest of table delicacies. But every one does not know what Mr. Walters has learned in China, namely, that its flesh composes the mind of him who partakes of it, and enables him to do with little sleep. Moreover, "its foot and leg bones have the very delightful quality of exciting affection between husband and wife. If on the fifth day of the fifth month the husband takes one of these bones and the wife takes one, each putting the bone in a basin of water, one from the left and the other from the right side, the two bones will come together and float together, thus indicating a long and happy union to the parties trying the experiment." *Land and Water.*

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

THOSE indispensable winter-flowering plants, *Chrysanthemums*, should not by any means be stopped or pinched back after this date; in fact, as I suggested some weeks since, late stopping is not at all commendable, if fine blooms are a desideratum. Manure water, properly prepared, should be given freely now to such plants as have pretty well filled their pots with roots. It should always be borne in mind in connection with this plant that to permit any to suffer from the want of water will assuredly be the cause of their losing many of their leaves, which, in an ornamental point of view so much enhance the beauty of the plants when they are in flower. No small amount of attention should be given to them in regard to earwigs and other pests, which if not destroyed eat away the young growing hearts of the shoots, and so destroy the embryo blooms. *Pyrimulas*, *Cinerarias*, and *Herbaceous Calceolarias* should now, as thirfty young stuff, be kept well in hand. The earliest batch of the former will soon be showing the first signs of forming flower-spikes, and may therefore be treated in a more liberal sunshine, *Cinerarias* must be potted on successionally as frequently as the young roots feel the sides of such pots as they may be in. In no time cannot be lost in regard to them, as the moment they become in the least pot-bound their further progress is endangered, by the fact that flower-spikes may be thrown up, the necessary conditions having been assured. Where, however, a few are required in bloom very early, this will be the best course to pursue, as a result of no very distant date. Be particular, as I have before suggested, not to leave any kind of greenhouse plants out-of-doors too long, in case we have either too much rain or a continuous moist, cold period. Where the more delicate kinds of *Erica* or *New Holland plants* are kept in cold frames, as an additional protection, let the lights be taken off bodily as frequently as possible. Under any circumstances give air freely by night, as at all other times, even if the only means to do so be the usual tilting of the lights sideways. *Bouvardias*, and especially the very beautiful winter-blooming variety *B. longiflola*, should now be turned out-of-doors in all instances where the plants were not planted out into open borders earlier, which is a good and convenient method. Some greenhouse plants, such as *Acacias*, *Clianthus*, *Brugmansias*, and, indeed, *Fuchsias*, where these are growing in the open borders, must now be periodically syringed to ward off red spider, which invariably attack them at this season of the year or during the next month or two. Be careful not to pinch back such plants as *Pimeleas* after this date, as to do so is to endanger the display of bloom next season. Those who keep the scarlet-herried *Solanums* in pots, and who have not planted them out, as was suggested in these columns at the proper time, should occasionally water them with liquid manure, as well to increase the growth of the plants as the size of such berries as are already "set," and swelling in some stage or other. As the season is on the wane, and the growth of most plants completed, it will now be advisable, should no very hot, scorching weather ensue, to permit the sun's rays to act rather freely on most hard-wooded subjects, and especially such as the beautiful *Ixculias*, *Pteronia elegans*, *Boronias*, *Acheanthera*, why not *L. biloba*, with its charming blue flowers, more generally grown?), *Darwinias*, &c., which bloom so freely and so much better when the young wood is properly ripened. Sow another batch of *Schizanthus*, they make such very showy stuff for general decoration in spring.

FORCING HOUSES.

Permit no further delay in the matter of getting forward successional *Pines* into their fruiting pots where this is not already done. Those next in order of forwardness and intended for fruiting next year, should also now be finally potted for the season. Choose for them in the main 24-sized pots, and put them into the best possible material at command that is of an open, porous nature. Attend well to the tan-beds at the same time, and prepare them by forking the old tan well up and by adding more new material where it is necessary, to plunge the pots. Except in the case of very late *Vineries*, these departments will not require much more than the regular attention of air-giving, &c. Particularly see that plenty of fresh air is allowed. Not only will this conduce to the good of the existing crops, but tend very greatly, by aiding the wood to ripen better, to the benefit that of the ensuing year. During cold nights a little fire should be started in connection with all houses, the crop in which is not fairly finished off; and where either mildew or red spider are discernible, or are anticipated, it would be as well to fresh paint the pipes with flowers of sulphur. Where the lights have been taken off *Peach* or *Nectarine houses*, it will do the trees much good, should any hot, dry weather ensue, to give them a thorough good washing with a garden-engine. This will tend to cleanse and to freshen them in a manner that even superficial showers cannot equal. Finally, for this season I would suggest that all repairs, glazing, painting, &c., be at once entered on in regard to such structures as are at liberty for that purpose. These things must be attended to, upon the principle of "making hay whilst the sun shines," if we intend doing all the good possible in relation thereto.

HARDY FRUIT GARDEN.

As the weather has been so dull, gloomy, and sunless, it will be advisable now to remove the denser leaves which shade too greatly any fruit upon *Peach*, *Nectarine*, or *Apricot trees*. This will add them in their ripening process, and tend to increase their flavour. I fear in a very general way the young wood of the current season's formation upon Peach and Nectarine trees will not be over well developed. It is more than ever necessary, therefore, to thin out the young shoots well, that those only are chosen to remain which are the best in their growth, and which may be afforded every chance to ripen without being in anywise overshadowed through the too dense crowding of branches. Nail each young shoot against the wall in such a manner as to ensure these necessary conditions. It is a plan well worthy to follow, especially after such a summer as we have so far experienced, to cut in two diagonally across the middle all large gross leaves. This, as some of our physiologists inform us, tends to change the bud at the base of very strong leaves from being a gross wood-bud into a bloom-bud, or, to say the least, less wood and more likely to form fruit-buds. Remove without any further delay the old fruiting canes from *Raspberry* plantations, and so increase the means of circulating more light and air, to insure the young canes being more favourably ripened.

HARDY FLOWER GARDEN.

The past cool, moist period has in nowise tended to keep that most showy of all summer and autumn introductions—the Golden Feverfew (*Pyrethrum*) — from attempts at blooming. It is desirable, therefore, to pinch back all the points which exhibit this tendency at the earliest moment when discernible. Make sowings now of *Myosotis* (the M. dissitiflora, so highly prized by us, should not be omitted from any garden), *Silenes*, *Saponarias*, *Nemophilas*, and all such-like plants intended for early spring decorative purposes. Still continue to peg-out, weed, "prick over," and keep tidy all flower-beds, and so afford as much display as the system will admit of.

KITCHEN GARDEN.

The winter crop of *Spinach* should be sown between the 10th and 15th of the current month. As, however, this is a crop the importance of which cannot well be over-estimated, I advise that two or more sowings be made, say, the first upon the 10th and a second one about the 15th of the month. It is always best to sow the crop in drills across any chosen quarter, as the plants can be thinned out more evenly, and the soil can be stirred amongst them with far less inconvenience than when sown broadcast. Make now a sowing of *Parsley* upon a sunny aspect; and with a view of keeping on the right side of the *chef de cuisine*, when mid-winter arrives, let a good piece of the same be now transplanted on to a south border in such a manner that one or more cold frames can be placed over it when the weather becomes at all sharp. Cut off plants which are just commencing to bloom of *Sweet Basil*, and dry it quickly for future winter use. Make yet another sowing of *Cabbage Plants*. Sow also *Lettuce* in quantity for the winter's supply. The old *Brown Cos* cannot be surpassed for this purpose, when the stock is select and true. Sow also *Onion* seeds to stand through the winter, for early spring transplanting. I should not omit to add a reminder that *Dutch Coleseed* should also be sown for future pickling purposes. It is needless to add more in the matter of routine; the subject of hoeing, manure, watering, &c., having been suggestively touched upon in the later Calendars. *W. E.*

Notices to Correspondents.

BOOKS: *Rusticus*. Hooker's "Student's Manual" (Macmillan & Co.). *Jas.* The nearest to your description is Hooker and Baker's "Synopsis Filicum."—*J. W.* No recent supplement has been published to Loudon's

"Encyclopædia of Plants." The latest catalogue of garden plants is the second edition of Paxton's "Botanical Dictionary."

CONE PROLONGED INTO BRANCH. *G., Bath.* This is common in the Larch, but we never saw it before in Abies Tsuga.

DISEASED PEARS: *D. D.* Your Pear and Cherry leaves are attacked by the larvæ of a species of saw-fly. The mode you have adopted of dusting with quick-lime is the surest way of getting rid of a very unpleasant plague. *M. T. B.*

FRUIT *v.* BLUEBOTTLE FLIES: *C. J.*, who suffered last year from a plague of bluebottle flies, which committed great havoc amongst his Peaches and Nectarines, and could not be lured away by the usual devices of sugared water or treacle, would be glad to hear of a more efficient remedy. Can any one help him? Perhaps the hand-glass trap, baited with over-ripe fruits, might be effective. We can speak favourably of the French fly-trap figured at p. 461, 1870.

FUNGI: *W. P., Shrewsbury.* Hydnum zonatum is correctly named, but the plant referred by you to Clavaria aurea is a common form of C. stricta; and the Lactarius cannot be L. plumbeus, for it differs in many respects, and is not acrid. Its mild taste and watery, insipid milk, prove it to be a mere dark variety of L. serifluus. *W. G. S.*

FUNGUS ON ROSE: *P. H.* It is impossible to say whether the Aregma may or may not come on your Roses next year. These parasitic Fungi depend so much on peculiar climatic conditions, that your Roses may be quite safe next year. The species is, however, very common, so that you cannot guard against it. Were you to destroy all the infected leaves, it may visit you from the next garden. *M. J. B.*

GRAPES: *T. T. T.* Your Grapes have apparently been scorched. This results from the temperature of the house being rapidly changed from damp cold to excessive heat, a not uncommon case during the past spring.

NAMES OF FRUIT: *H. Mobbs. Grapes:* To have named them with certainty you should have sent leaves of each, and some notes as to how they were grown. No. 1 cannot be discovered. It resembles Black Prince. No. 2, White Tokay; No. 3, Royal Muscadine.—*S. T.* Both are good. Rivers' Early Orange bears a high character.

NAMES OF FUNGI: *T. J. N.* The specimen does not belong to the genus Cantharellus, but is an unusually developed specimen of Agaricus amethystinus, which is a variety of A. laccatus. *M. J. B.*

NAMES OF PLANTS: *J. D.*, 1, Allium vineale, the Crow Garlic; 2, Senecio Jacobæa, common Ragwort; 3, Pimpinella magna, Greater Burnet-Saxifrage.—*J. H.*, Abutilon Sonneratianum, a common Mallow-wort at the Cape; no doubt a variety of Gladiolus blandus. of which a great number of differently-coloured forms are known; 3, Allium carinatum.—*Rusticus.* The Tall St. John's Wort, Hypericum elatum; not admitted as a native of England, but well naturalized in many localities, usually having escaped out of gardens. —*W. R.* Blechnum cognatum.—*Constant Subscriber.* 1 and 2, Lastrea Filixmas cristata; 3, Lastrea elongata, apparently; but the tips of large fronds are very unsatisfactory specimens.—*C. J.* 1, Adiantum hispidulum; 2, Adiantum amabile, probably, but very poor; 3, Cyrtomium caryotideum; 4, Doodia media; narrower than usual, young of Platylomia cordatum.—*E. G.* We cannot undertake to name plants from their leaves only.—*S. T.* We cannot name such shrivelled scraps. —*Manchant.* Senecio Jacobæa.

TRUFFLES: *A. B. Billy Gibbs.* There is nothing unusual in the size of your Truffles, as they have been known to weigh between 3 and 4 lb. each, and to measure a foot round. Truffles have several times been exhibited at South Kensington, but if you could let us have fuller new about their mode of growth, *habitat*, or how found, we would print it. You might also send a dish to the next meeting of the Fruit Committee, as you have them so fine.

VINE DISEASE: *James Bahnsen.* Your Vine leaves are not attacked by the Phylloxera. The spots are merely the common hypertrophy of the cellular tissue of the lower surface of the leaves, which is quite harmless. They have, however, been much injured by thrips, of which several specimens were inclosed in the envelope. *M. J. B.*

ERRATUM.—Rev. W. F. Radclyffe desires us to state that he omitted to mention, at p. 1007, Rivers' Pineapple variety being, with Rivers' Victoria, the best of all Nectarines, in his experience.

COMMUNICATIONS RECEIVED.—A. B. T. Lang & Son, Ballarat.—Breyhuys.—W. Taylor.—G. H.—W. H. G.—Dr. Juan.—H. M.—E. F. W.—D. T. F.—W. B.—J. F.—A. F.—A. McN.—W. E. and J. R. (too late).—M. C. C. (too late for this week).

DIED.—At the Nurseries, Hemel Hempstead, on August 5, Mr. WM. BROWNLEES, aged 85, highly respected and deeply regretted.

Markets.

COVENT GARDEN.—Aug. 11.

The supply of bush fruit has not been so large this week, and Currants and Gooseberries are nearly over. Hothouse Grapes and Pines still continue steady at former prices. Peaches and Nectarines are a trifle cheaper. The general tone of the market is very steady. The Potato trade is very heavy, and prices are lower by 2*s.* to 3*s.* per cwt.

FRUIT.

	s. d.	*s. d.*		*s. d.*	*s. d.*
Apples, per ½ sieve	1 0	3 0	Oranges, per 100	8 0	to 12 0
Grapes, per lb.	2 6	6 0	Peaches, per doz.	8 0	—20 0
Lemons, per 100	8 0	12 0	Pine-apples, per lb.	2 6	— 5 0
Nectarines, per doz.	4 0	—10 0	Strawberries, p. lb.	0 6	— 1 6

VEGETABLES.

Potatos (good samples), New Round, 6*s.*; Kidneys, 5*s.* to 7*s.* per cwt.

WANT PLACES.—Letters Post Paid,

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Further particulars given on application to Messrs. E. G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENER (Head).—Age 30, married; 12 years in first-class places; can be highly recommended.—J. M., Mr. Wm. King's, High Street, Bromley, Kent.

GARDENER (Head).—Age 30, married; thoroughly practical; has lived in first-class establishments. Terms £65 per annum, and House. T. Z., 20, New Street, Spring Gardens, S.W.

GARDENER (Head).—Age 36, married, no family; thoroughly practical in all branches of the profession. Capable of taking Charge of Horses if required. Excellent reference from present employer.—A. B., Post Office, Ramsbury, Wilts.

GARDENER (Head).—Age 47, married; thoroughly understands both the Early and Late Forcing of Vines, Peaches, Melons, and Cucumbers in Pits or Stove and Greenhouses. Has also the Management of Flower and Kitchen Gardens. Unexceptionable references.—W. S., 2, Nurseryman, Epsom.

GARDENER (Head), to any Lady or Gentleman requiring the services of a Man thoroughly practical in all the various branches of his profession. Good character. Good references to character and ability.—A. B., Post Office, Redbridge, near Southampton.

GARDENER (Head), to any Lady or Gentleman requiring the services of a thorough practical Gardener.—Has had great experience in the Cultivation of Stove and Greenhouse Plants, well understands Forcing all kinds of Fruits, Flowers, and Vegetables Kitchen and Flower Gardening, also Dinner-table Decorations, &c.—Can be highly recommended for years' character. — W. G., 24, North Street, Edgware Road, London, W.

GARDENER (Head).—Has a thorough practical knowledge of the profession, including the Culture of Pines Grapes, Peaches, and Greenhouse and Stove Plants; has been employed in various departments of the Gardens of Sion House, Isleworth, Castle, and Chiswick. First-class Establishment preferred unexceptionable testimonials as to personal character and professional skill.—E. W., 3, Cambridge Terrace, Cambridge Road, Kilburn, N.W.

GARDENER.—Practically acquainted with all the branches of Gardening, and the Growing of all kinds of Hothouse and Greenhouse Plants, Melons, Cucumbers, and Orchids. Good character.—W. G., Post Office, Chudleigh, Devon.

GARDENER.—Age 35, single; scientific and practical, has a good knowledge of the Culture and Propagation of Stove and Greenhouse Plants; also of designing Flower Beds and the Seed Trade. Can speak and Correspond in English, French, and German. A situation Abroad or as Collector preferred.—G. E., Kew Post Office.

GARDENER (Under).—Age 18; three years' experience in Forcing Houses. Good character.—A. V., 34, Lower William Street, St. John's Wood, N.W.

GARDENER (Under).—Age 22; four years' experience in a Nobleman's Garden. Can be highly recommended.—G. H., Ashburnham Park Cottages, King's Road, Chelsea, S.W.

GARDENER (Under) in a Nobleman's or Gentleman's Family.—A steady, intelligent young Man, who has had some years' experience.—H., Mr. Atkinson, Nurseryman, Waterton, near Brigg, Lincolnshire.

GARDENER (Under), wishes to improve.—Age 24, respectable; has been in a Gentleman's Garden for character from last employer.—Full particulars to W. S., Mr. Starnes, Grocer, Sipson, near Slough, Middlesex.

GARDENER (Second, or Improver), in the Houses, or Single, by preference.—Age 22; first-class reference.—H., Mr. Child's, Elcheiton Nursery, Rye Lane, Peckham, S.E.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 28, single; has been trained from his situation.—C. M., 13, Munden Street, Hammersmith, W.

FOREMAN.—Has had the best of practice for upwards of seven years in all departments of Gardening; lived last at one of the largest and best kept Noblemen's seats in the kingdom. First-class testimonials for the above period.—J. B., 22, Peploe Street, Bishop's Road, Paddington.

FOREMAN (or Second), in a Gentleman's Establishment.—Age 22, single; understands Forcing, Stove and Greenhouse, and Kitchen Gardening. Good character.—W. M., Post Office, Blue Pits, near Manchester.

PROPAGATOR, or PROPAGATOR and FOREMAN.—Long practical experience in Soft and Hard-wooding, Grafting, and Plant Growing.—Apply, for terms, &c., to L. C., 24, Tower Street, Pimlico, S.W.

PROPAGATOR and PLANT GROWER, either in a Nursery or in a Gentleman's Garden.—A young Man; has a very good practical knowledge of all the routine of the business required, especially Orchids, and Show Plants of all kinds.—HORTUS, 11, Barbara Street, Barnsbury, London, N.

IMPROVER.—Wants a better knowledge of Gardening. No objection to small place or Premium.—A., 8, Brown Street, Bryanstone Square, W.

IMPROVER, in a Gentleman's Garden.—Age 21. A Protestant. Can have recommended. Please state terms.—E. R., Warningstown, Lurgan, County Down, Ireland.

IMPROVER, where he will have an opportunity of improving himself.—Age 21; good character from present employer,—State wages to C. D., 23, Brighton Terrace, Brixton Road, S.W.

To Nurserymen.

IMPROVER.—Age 17, active and intelligent; has had three years' practice in the Houses.—C. G., The Gardens, Chelderton House, Salisbury.

WANTED, by TWO YOUNG MEN, a SITUATION in a NURSERY or Gentleman's GARDEN.—Five years' good character. Age 20 and 21.—T. B., 8, Mount Pleasant Cottages, London, N.W.

FARM BAILIFF.—Has had great experience in the Breeding and Rearing of Stock, and the Management of large Farms. First-class References.—A. H., J. Carter and Co., 237 and 238, High Holborn London, W.C.

FARM BAILIFF, at Michaelmas next. — Age 44, married; thoroughly understands the Management of Light Heavy, and Mixed Soils, also Breeding, Rearing, and Feeding all kinds of Stock, Land and Timber Measuring, Building, Draining, &c., and is a good Accountant. Twenty years' practical experience in the most approved system of Norfolk Farming. Wife can Manage a Dairy and Poultry if required Excellent character.—A. B. C., 279, Caledonian Road, Islington, London, N.

SALE THIS DAY, AT HALF-PAST TWELVE O'CLOCK.

Bulbs from Holland.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, August 12, at half-past 12 o'clock precisely, 700 Lots of First-class HYACINTHS, TULIPS, CROCUSES, NARCISSUS, and SNOWDROPS, from several well-known Bulb Farms in Holland. Lotted to suit the Trade.
On view the morning of Sale, and Catalogues had.

Imported Orchids.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, August 15, at half-past 12 o'Clock precisely, nearly 200 imported plants of PHALÆNOPSIS GRANDIFLORA, many of them superb plants, with leaves 3 to 4 inches broad, and a foot to 18 inches long, also of CATTLEYA DOWIANA, VANDA TERES, in good condition, and the extremely rare and handsome ANSELLIA PLANTI; also the finest ever imported variety of EPIDENDRUM BICORNUTUM, and other imported ORCHIDS.
On view the morning of Sale, and Catalogues had.

Orchids.

OF the CELEBRATED COLLECTION of ORCHIDS formed by S. RUCKER, Esq., at WANDSWORTH.

MR. J. C. STEVENS has received instructions from Messrs. Veitch & Sons, who have purchased the entire COLLECTION, to offer for SALE by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, WEDNESDAY, August 22 and 23, at half-past 12 o'Clock precisely each day, the second portion of the above magnificent lot of Plants, amongst which will be found—

Cymbidium eburneum, true, best variety	Phalænopsis amabilis, and Schilleriana
Odontoglossum Alexandræ, fine varieties	Dendrobium biforme
Odontoglossum polychelum mujus	leucolabium, crassinum, narrow leaf variety, extra fine
Colax juncea, very fine	Sacculabium pulchellum Holfordi
Lycaste Skinneri alba, true	Vanda Denniesiana
Maxillaria picta, of sorts	Dendrobium Paxtonianum
Sophronites grandiflora, fine	" Falconeri
" coccinea	" superbum
Pleione lagenaria, and maculata, good masses	Cattleya exoniensis
Aërides Fieldii, fine plant	" Bowiana
" Fieldingii, magnificent specimen	" Warneri
Dendrobium Wardi	" labiata
" Cambridgeanum, finest plant in the country	" crispa
Epidendrum myrianthum, fine plant	Lælia anceps Dawsoni
	" superbiens
	Epidendrum nemorale, rare
	" Cnyrtochium Veitchii, and other sorts, &c.

All the Plants are in fine condition, and many are in bud, or blooming.
On view the mornings of Sale, and Catalogues had.

Sale of the late Mr. Barnes' Herd.

AT WOLLATON, NEAR NOTTINGHAM, IRELAND.

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on WEDNESDAY, August 23, at 1 o'Clock, at Wollaton, near Nottingham, Ireland, the valuable and very celebrated HERD of SHORTHORNS bred by the late Thos. Barnes, Esq., whose well-known skill and judgment brought the stock to great perfection. It was founded nearly 30 years ago with two Cows of the Booth tribe, viz., Duchess 3rd and Duchess 4th. To these have been added Bright Eyes, descended, through Mr. Lawson's Herd, from Mr. Mason's stock; and Sweetbrier, of Mr. R. Booth's famous Isabella tribe. Both these Cows were hired from Mr. John and Mr. R. Booth's Herds at Killerby and Warlaby. The Herd, consequently, is entirely of Booth descent, and of the richest blood, but in very select, and the animals will be found of very great merit and exceedingly level.
Catalogues, with Pedigrees, may be had of Mr. W. BARNES, Westland, Kells, Ireland; or of JOHN THORNTON, 15, Langham Place, Regent Street, London, W.

Westland, near Kells, County Meath, Ireland.

MR. JOHN THORNTON will SELL by UNRESERVED AUCTION, on WEDNESDAY, August 23 (immediately after the Sale of the late Mr. Barnes' Herd), the whole of the HERD of PURE-BRED SHORTHORNS, bred by and the property of R. W. Reynell, Esq., of Killyon, Killucan, County Westmeath. It numbers about Thirty Head, bred from two tribes—the Fairy (descended from Stock Duke of Oxford 1st, bred by Mr. Brown, at Chilton, in 1839 (whence the Oxford tribe came), and the Isabella (descended from Isabella 2nd, bred by the late Mr. Thompson, of Burley. The Bulls used have been of the best blood at Westland, Duke of Lancaster, Royal Prince, Royal Prince 2nd, and Sir William (16,738) being the latest sires.
Catalogues, &c., may be had of Mr. REYNELL, Killyon, Killucan; or of JOHN THORNTON, 15, Langham Place, London, W.

Castle Grove, Letterkenny, Ireland.

MR. JOHN THORNTON will SELL by UNRESERVED AUCTION, on FRIDAY, August 25, at Castle Grove, Letterkenny, Ireland, the WHOLE HERD of VALUABLE PURE-BRED SHORTHORNS, the property of J. G. Grove, Esq. It numbers about 50 head of Bulls, Cows, and Heifers, among of which will be found specimens of the Fairy tribe, bred by the late Mr. Richard Booth. The others comprise several old Duchess tribe, bred by the late Mr. Barnes, and Mr. Willans' Theockmorton, Bart., will take place at Buckland, near Faringdon, on FRIDAY, August 25 next, when 80 full-mouthed Ewes and 50 Theaves will be offered, as well as portion of the Ram Lots will be let for the season; amongst them will be found the splendid Prize Rams at the Royal Windsor Meeting.
Catalogues, with particulars, may be had on application to Mr. GOLDING, Buckland, near Faringdon, Berks; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Buckland, near Faringdon.

IMPORTANT SALE of SOUTHDOWNS.

MR. STRAFFORD has received instructions to announce that the ANNUAL SALE by AUCTION of PURE-BRED SOUTHDOWN SHEEP, the property of Sir William Throckmorton, Bart., will take place at Buckland, near Faringdon, on FRIDAY, August 25 next, when 80 full-mouthed Ewes and 50 Theaves will be offered, as well as portion of the Ram Lots will be let for the season; amongst them will be found the splendid Prize Rams at the Royal Windsor Meeting.
Catalogues, with particulars, may be had on application to Mr. GOLDING, Buckland, near Faringdon, Berks; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Brailes House, Shipston-on-Stour.

SALE of PURE-BRED SHORTHORNS.

MR. STRAFFORD begs to announce that he has received instructions from Henry J. Sheldon, Esq., of Brailes House, Warwickshire, to SELL by AUCTION, the WHOLE of his PURE-BRED SHORTHORNS for THURSDAY, September 21, which will comprise about 45 Bulls, Cows, and Heifers, chiefly of Kirklevington and Fawsley blood. The Sire now in service is the 14th Duke of Oxford (16,737), and Helmet (16,736) has justly announced prize of Shorthorns.
Catalogues, with Pedigrees and other particulars, will shortly be issued, and announced in future advertisements.

Ellington, near Kimbolton, Hunts.

VERY VALUABLE SALE of SHORTHORNS.

MR. STRAFFORD begs to announce for SALE by AUCTION, without reserve, on THURSDAY, September 28 next, the valuable and choice HERD of PURE-BRED SHORTHORNS, bred by and the property of Mr. Ladds, of Ellington, which numbers about 100 Head of Cows, Heifers, and Bulls; prominent amongst them will be found several fine specimens from Red Duchess and Princess, bred by Mr. Christ; Jacintha, by Mr. Beasley; Farewell and Verbena, by Mr. Booth, as well as other old and favourite tribes of the Marquis of Exeter, Mr. Robinson, and other eminent breeders. First-class Bulls have been used for many years from Farmley Hall, Cobham Park, Revesby Abbey, and latterly, Cambridge Barrington 1st (14,223) bred by the Duke of Devonshire, Wellesley (15,421), from Lord Penrhyn's, and 2d Earl of Barrington, bred by Mr. Sheldon from the same family, and Sir Arthur (16,735), the property of Mr. Ladds.
Catalogues, with Pedigrees, will be issued in due time, and further particulars announced in future advertisements.
London: 13, Euston Square, August 8, 1871.

The Agricultural Gazette.

SATURDAY, AUGUST 12, 1871.

HOW is the farmer of 300 acres of land to participate in the advantages of steam cultivation? The large number of farms of such a size, and less, renders this one of the most momentous questions of the day. No one now denies the complete success of the application of steam to the cultivation of extensive farms, but when we consider the case of small occupations, the amount of capital required to purchase the most effective and economic apparatus is quite disproportioned to the farmer's means. The *direct* system of working cultivating implements by means of engines on both headlands, is undoubtedly the cheapest method per acre, when there is sufficient work to be done. This is, however, precisely the difficulty which meets the occupier of 300 acres, or less. He is, therefore, driven to relinquish the advantages of steam cultivation, or to one of the following alternatives — he may hire, or he must purchase. Mr. BULSTRODE, near Maidenhead, has recently discussed this difficult question in a letter to a contemporary, in which the subject is handled with clearness and strong

sense. "If," says Mr. Bulstrode, the small farmer "is willing to risk the chances of hiring, he will probably see at once that the powerful double-engine tackle will satisfy his requirements, but if he realises and appreciates the danger, the difficulty and the costliness of this course, and the great importance of having a set of machinery constantly at his command, he will also see that this grand apparatus is totally unsuited to his *purse*."

We cannot consider the question of *Hiring versus Purchasing* to be so summarily settled; and, in fact, the only real annoyance in the former method consists in having to wait the conveniences of the contractor. Thus there is constant risk of losing the great advantage of having the land worked at the right season, a risk which is magnified by the simultaneous requirements of every farm in the neighbourhood. This is the great difficulty to be met by those who are interested in steam cultivating companies, although it is one which may in a great measure be overcome by a sufficient "rolling stock," and by the encouragement of an accommodating spirit among those who employ the apparatus. "First come first served," is a fair maxim, but, on the other hand, a company would be wise to remember that a customer, who has suffered from delay at one period of the year, should be promptly attended to on a future occasion.

The farmer of some 300 acres of land, who has resolved to purchase rather than to hire, will have to consider which is the most suitable apparatus for his purpose. He will probably conclude that the double-engine system, involving an outlay of something like £1500, is beyond his reach, and he will turn his attention to some one of the single-engine systems now before the public. The *engine* being in such cases always a most considerable part of the purchase, he will soon find that one of the principal questions is, whether he should invest in a complete set of tackle, including an engine specially fitted up with self-propelling gear, "and carrying with it many cumbersome appendages" necessary for the *direct* system of steam-cultivation; or, whether he should adopt the roundabout system with a common 10-horse power farm engine.

"This," says Mr. Bulstrode, "brings the question within very narrow limits: the decision lies between the roundabout system with separate winding and (say) a 10-horse power engine, and the direct system with 8, 10, and 12-horse power engine, double drum, and disc anchor.

"I fully allow the advantages of the direct system, in its economy of power and labour, and therefore of time and money, under favourable circumstances; but we must not forget that it has also many disadvantages. The water-cart must follow the engine to all parts of the headland, however distant or difficult to reach, and (say) a engine must of necessity be self-propelling, and also carry with it many cumbersome appendages, even when employed at other ordinary work, such as threshing, &c.; nor is its disadvantage in first cost likely to be forgotten by the 300-acre tenant. Contrast this system with the roundabout system, in which the common farm-engine is available at all times for threshing, chaff-cutting, root-cutting, grinding, &c., without any extra weight or complex appendages, in which the water has only to be carted to some conveniently-selected spot, or may sometimes be pumped from an adjoining ditch or tank to which the rope can be laid to suit any irregularities of surface or boundary, and in which the first cost is at all events no small point in its favour.

"There is in this, as in most matters of dispute, much to be said on both sides; but the two systems are quite distinct. We cannot have any golden mean, but must either choose one or other, or reject both; and therefore can come but to this conclusion, that the results of the great trials of 1871 have fully confirmed the opinion that although for very large farms the double-engine direct system is unrivalled, it is also true that for the ordinary English farmer, holding some 300 acres, the roundabout system is the simplest, the most economical and the best."

We have pleasure in giving, prominence to Mr. Bulstrode's very practical remarks, and although we consider the time has not arrived for dogmatic teaching as to the best method of applying steam to the cultivation of land, we are sure that the above opinions are applicable to a very considerable number of cases.

—— The Mark Lane markets were closed on Monday. On Wednesday there was a small show of English Wheat, transactions in all descriptions were restricted, and prices easier in some instances. — Trade at the Metropolitan Cattle Market on Monday was not so good as in the previous week, but prices were not much reduced; on Thursday there was an active demand, at fully Monday's quotations.

—— The autumn session of the Royal Agricultural College will commence on Monday. We are glad to hear of the continued prosperity of this institution, the importance of which can scarcely be over-rated, if its governors continue to act up to the sound principle of Science with Practice. It is no small proof of the energy and liberality of the College Council that they have advertised in the *Times*, and other leading newspapers, six scholarships, each of the annual value of £40, open to competition to all students having a first-class certificate in the Oxford or Cambridge middle-class examinations. Such prizes, offered by an institution but recently emerged from pecuniary and other difficulties attendant on its establishment, plainly indicate the intention of the authorities there, to give back to the public those advantages which public support have conferred upon them. Let the Public support the Agricultural College, and we plainly see that the College will not forget its duties as a centre of educational light, and a nursing mother of industry and worth.

—— We have received from "F. P." a further communication on the subject of the Romford Sewage, in which exception is taken to the "brandy-and-water" simile employed by Mr. Hope at p. 988 :—

"It must be obvious that there is no similarity of position between the consumer of brandy and the consumer of water, in that one has the power of mixing water to any degree or of taking the spirit in its raw state, the other is quite unable to 'eliminate' from the sewage the water which he may consider to be superfluous, excepting through the lands and the crops. The man who takes sufficient brandy, with either very little water, or with no water at all, will become intoxicated; but he who greatly dilutes the same quantity of spirit will suffer no inconvenience, because of the prolongation of the time in which he consumes the liquor."

"F. P." questions also whether the price of brandy would be what it is if it were diluted by 30 or 40 times its own bulk of water, so that a man need drink 40 gall. of liquid to secure the benefit due to 1 gall. of spirit. But the discussion has, it appears to us, been already excessively prolonged.

—— The following important letter upon the Water Supply of London, signed "Lechlade," and therefore probably from a resident in the locality of which he treats, appeared in the *Times* of the 4th inst. :—

"Water supply to our towns is a subject which, before long, will force itself upon the attention of the people of England; and the question which it involves will be best solved by dividing the country into water districts, and distributing to each the share which fairly belongs to it, without trenching upon the property of its neighbours. Scotland alone can supply Europe with water. The four square miles of hills facing the Atlantic are ample for the wants of our manufacturing districts. The valley of the Thames can be shown to possess an abundance of water to meet the requirements of its occupants, as extensive as is the supply for London; and it is extraordinary that its inhabitants should submit to a monopoly which limits the amount and raises the price of an article which ought to be brought without fear of failure to their doors. If the subject is viewed in detail, all difficulties will vanish; the question lies in a nutshell. I confine my remarks to the upper portion of the Thames above Oxford, which derives from the character of its soil the heaviest clay we know of, it appears as if intended by Nature as a reservoir for the supply of its lower and more populous districts. The watershed of the Thames above Oxford is 873 square miles, and the average annual rainfall may be taken at 28 inches, allowing for losses, natural and artificial, leaving available 9 inches. Its area to the west is 74 square miles, to the north is 678, to the south is 123; the watershed of 900 square miles, at 9 inches of rainfall, will supply 30 gallons per head to 2,250,000 persons. The other 300 square miles are more than sufficient for that purpose; the remaining 260 square miles nearly so. The flow of water through Lechlade Bridge is from 900,000,000 to 1,000,000,000 in 24 hours, more than twice the amount required for the consumption of London; to this must be added what is drawn by steam pumps from fuller's earth, an amount perfectly incalculable; and from at Thames Head it yields 500,000 gallons every 24 hours. In the driest summer known it was impossible to pump the well dry or to reduce the water in it to a less depth than 9 feet. The early tributaries of the Thames are the Coln, Ginny, and the Churn—were directed to a reservoir of 400 acres, 9 feet deep, it would supply 1,000,000 persons, at 30 gallons per head, for one month. Additional storage is a mere matter of figures. The overflow of such a reservoir is always be utilised to meet the increasing demands of the population. Probably a number of small reservoirs would be best adapted to the public convenience. The question of cost has been solved by a very agricultural friend in the neighbourhood of Farringdon, who, for the improvement of his estate, constructed a reservoir containing 8,000,000 gallons at a charge of £8000—that is, £1000 for the storage of 1,000,000 gallons—a heavy outlay to insure a constant supply, which could be flushed down the river by opening the locks of a reservoir, to be refilled by the influx of the next flood. There is no expense of pumping required, no machinery; the natural law of gravitation will send the water down stream; but, unfortunately, it is stopped in its flow to London by the monopoly of the water companies; a constant supply, which could be delivered at an insignificant expense, and to our urban districts, is taxed for the benefit of shareholders. Neither ought we to lose sight of the fact that storage of water in agricultural districts is preferable to that in large towns, as it is free from smoke, the unwholesome exhalations which taint their atmosphere.

"It is curious to observe the change which has occurred in our rivers with the improvements in agriculture. Under the effect of steam ploughing water will sink through the heavy clay lands into 4-feet drains in seven minutes; formerly it was retained as in a sponge, gradually forced its way into a ditch, or yielded to the slower process of evaporation. It now rushes to the river, and is lost in floods which ought to be economised for the benefit of London. But however advantageous the process may be to agriculture, it is disastrous to the river. The floods carry with them large quantities of mud, to be arrested by the weeds which flourish in the absence of navigation; in time those weeds die and sink, causing a silting of its bed, which checks and diverts the course of the stream. That is of small interest to all but riparian proprietors, but in a sanitary point of view it is all-important to the population of our towns.

"Nature's best purifier is the shingle at the bottom of a river, witness clear mountain streams; the accumulation of mud prevents the contact of water with the gravel, the bed constantly rises, the hard subsoil upon which its waters ought to flow becomes a coating of deleterious matter affecting its quality as a pure and wholesome beverage. No water is better than the Thames when filtered of its impurities, none better adapted to domestic uses when it regains its natural colour; but the neglect of the stream destroys its quantity and detracts from its quality.

"The remedy is so obvious, and so cheap, that it is marvellous the inhabitants of London should remain contented with nothing more than an occasional murmur. It can only be accounted for by the fact that public opinion is slow to act against powerful and long-standing abuses.

"The case resolves into this—the formation of reservoirs in the upper districts of the Thames Valley, at a cost of £1000 for every 1,000,000 gallons—that is the fixed charge; water-rates to cover the supply, and a few steamers to prevent the accumulation of mud. Probably, after the original outlay for storage, £2000 per annum would cover every expense, and insure to the inhabitants of London an incalculable supply of pure water at an infinitesimal price.

—— The managers of the Lodge Farm, Barking, love to have their work scrutinised. In another portion of the *Agricultural Gazette* will be found a report by an eye-witness of the present state of this farm, a report which must assist the public in coming to a conclusion as to the varied uses to which sewage may be applied. A number of gentlemen, chiefly from Essex, have been round the sewaged farm, have looked over the hedge, and seen the benefit to a neighbour who has taken advantage of the fertilising flood; and arrived at the conclusion that where there was no sewage—where, from unskilled manipulation, it had ceased, there was losing fertility—both in crops and in grass. Having established the great fact that sewage is beneficially applied to our ordinary crops, the managers of the Barking farm are endeavouring to unravel questions of detail—as to whether, for instance, narrow or broad beds are the best; that is, whether beds 6 yards wide or beds 12 yards wide. The result of the above examination was so favourable to wide beds, that even Mr. Mechi was convinced—much modified his opinions—and the company pronounced in favour of a considerable distance between "carriers," and beds 50 yards wide. No statement of the commercial prosperity of the farm is made, but this is, from a national point of view at least, of secondary importance. If whilst improving our rivers, and rendering our population healthy, getting rid of disease, in fact, we can also increase our food supply, the work should go on. And if there is not sufficient profit in sewage farming to encourage private risk of capital in it, the work should be done at the public expense.

—— The Wigton Farmers' Club submit the papers which are read before them to a rough-and-ready criticism, which, whatever may be its effect on those who may be labouring for future meetings, has at any rate the effect of giving some amusement to readers. At the last meeting which we have seen reported, Mr. Wanger read a paper, advocating, among other things, practical as well as theoretical education. He thought that young men should be taught to do, as well as to know when a thing was done. It was an easy thing to take a farm and put it into good condition, if a man had plenty of money in his pocket, but this was quite a different thing from making it pay. He thought every farmer ought to learn to plough, sow, and reap well, but some mental calculation was required also, in order that a system of farming might not be followed which did not pay. After referring to the early efforts in the establishment of an agricultural college for the North of England, he turned from the question of education to that of taxation. He thought it as much the duty of farmers to look after their pockets and interests in that line as many others spoken of. Thereupon ensued a discussion:—Mr. Wright thought the paper was very difficult to understand.—Mr. Hetherington agreed with what was said about having to serve an apprenticeship to farming.—Mr. Wright said it was not necessary to be able to plough or work; they could get men to do that. What a farmer wanted was a good head-piece.—Mr. McMechan would suggest to the Chairman and the meeting whether farmers were not the "best abused" set of men going. Almost every lecturer and speaker had a fling at them, and they were spoken of as if they were half a century behind any other set of professions, whereas he believed the opposite was the case.—Mr. Ross said, when a lecturer treated upon so many subjects, it was difficult to carry them all in one's head, so as to reply to them. Farmers had certainly to direct their attention to all kinds of things, vegetables, animals. They had to acquire experience, so that if they looked at a plant or field which was not doing well they would know what was wanted; a man of letters would not know this. He thought the

paper was very good, but it embraced too many subjects.

—The CHAIRMAN much approved of that part of the paper which spoke of an agricultural college. If such a thing were established he should send a son, and he thought they ought to take some action on that question.—Mr. WRIGHT, after some further discussion, said he should propose that the Club offer £5 for the best plan of destroying the wireworm.—Mr. ROSS said he could tell him for 5*d*. It could be kept down by frequent ploughing.—Mr. NORMAN doubted this. Farmers called almost everything which destroyed the roots of plants wireworms, whereas there were about 60 different kinds of worms of this destructive sort, many of which might be killed by the soil being frequently disturbed and turned over. He thought the best plan was to roll the land very hard with a Cambridge roller.—The next meeting will take place on October 17.

—— The following particulars are taken from the columns of the *Sydney Herald*, as an illustration of the loss incurred in that colony by PLEURO-PNEUMONIA. The extent of loss due to this disease may be seen by comparing the numbers of cattle in the following years: —1862, 2,620,383; 1863, 2,032,522; 1864, 1,294,119. So that in two years in which this fatal disease was prevalent the deaths, and sales to escape death, brought down the stock to less than one-half. In the following year the numbers rallied to 1,961,805, but have since fallen again, and now stand at 1,795,874: being little more than three-fifths of the stock of nine years ago.

—— It is worth while placing on record a recent decision in a court of equity as to the right to STREET SOIL and WASTE in TOWNS, when it is not reserved, seeing that the subject has some bearing on a scavenging question in which suburban agriculture is interested. The case is thus reported in the *Times*:—

"BECKETT, BART., *v.* BOROUGH OF LEEDS.

"The question in this case was whether the lords of the manor of Leeds are entitled to the soil of the streets within the township or the owners of the adjacent houses. The case was heard some days ago. Sir RICHARD BAGGALLAY, Q.C., and Mr. NORTH appeared for the plaintiffs; Mr. BAGSHAWE and Mr. GRAHAM HASTINGS for the defendant. The MASTER of the ROLLS said that, as a general rule, the owner of a house in a street was entitled to the soil *usque ad medium filum*, unless the contrary were shown. There was no evidence of any reservation to the lords of the manor in the various grants of sites for houses, and in the absence of any evidence to the contrary he should hold that the soil of the streets was vested in the owners of the adjacent houses."

—— In the neighbourhood of Maritzburgh, South Africa, we learn that the farmers have suffered and are still suffering great losses by the increased virulence of the LUNG SICKNESS among the cattle, and to add to the severity of the infliction, another fatal disease known to the Dutch as *melt-richte*, has made its appearance, and in several instances caused great loss. This last disease proves rapidly fatal; the beast appears dull, and refuses to eat; if watched closely his urine will be found bloody, and death generally ensues within 12 hours after the first symptoms have made their appearance. An examination of the carcase will show that the fat of the heart and kidneys has disappeared, and that death has been caused by violent inflammation of the intestines. In cases where a beast recovers, large patches of the hair fall off, and the poor brute presents a deplorable appearance. The Dutch attribute the disease to extreme heat.

—— It may be well to place on record the sensible opinion of a member of the Council of the Royal Agricultural Society of England. At the Perth show, last week, replying to a toast in honour of that Society, Mr. JACOB WILSON is reported to have said, regarding the WOLVERHAMPTON MEETING :—

"Although they had 16,000 or 20,000 in their show at one time, they lost money by it; but he did not think that national associations, like the Royal Agricultural or the Highland Society of Scotland, should mind a little loss; they should rather consider the progress and improvement of the agriculture of their respective countries. He had no patience with economy in these annual showyard arrangements, and he asked, when you have from £20,000 to £40,000 invested in funds, what are you doing for the agriculture of your generation by investing that money? They were living in a time when agricultural progress was advancing with more rapid strides than had been known in times past, and he thought they could not spend their money better than by encouraging the improvement in mechanics as applied to agriculture at the present day. He instanced the case of steam cultivation, and strongly urged that its merits should be thoroughly tested regardless of cost, and instanced the example of the Royal Agricultural Society, which did not spare money in this matter. He was himself in favour of FOWLER's machine, but he was not prejudiced; if he could see a better system, he would adopt it. As regards steam cultivation he was glad to find that they had men of intelligence determined to keep up with the progress of the day, and that a society had been started for steam cultivating the whole of Scotland. Hints had been thrown out that this society was for the purpose of pushing forward a certain engine, but this he hoped was not the case. He had been a steam cultivator for many years, and there was a steam cultivating company which only the other year had got from 20,000 to 30,000 acres to cultivate. Their prices were moderate; they could earn a fair percentage for their money; and, what was far more important, it was a source of profit and accommodation to the tenant-farmers of their district."

—— The following recommendation of ENGLISH PLOUGHS for more general use IN INDIA, reaches us from the Punjaub. The writer says :—

"To show the effects of deep ploughing, I would mention that last September I sowed a piece of land with Carrot (country) using only half the amount of seed the zemindars used to. The land had only been ploughed once with STATKARTT'S plough, and side by side with the land I farmed was another field of Carrots, sown on the same day as mine, but ploughed eight times with an ordinary native plough. My Carrots were ready for consumption a full month before the zemindar's; his were 2 inches across at the head by 6 inches long, mine averaged 8 to 10 inches, and many were 12 and even 14 inches across and a foot long. A European who rents lands in these parts has literally no reason to use manure if he will employ an English plough, as at 10 inches deep he turns up maiden soil: you have only to change your land every year."

—— The extract given in another page from Dr. SPENCER COBBOLD'S LECTURE will be read with curiosity, disgust, or horror, according to the varying feelings of different people. The whole lecture will be found in the Journal of the Society of Arts for July 21. It is impossible to doubt that the risk exists to which Dr. COBBOLD directs attention. It is, however, we think, remarkable that amid all the instances of parasitism in connection with sewage irrigation which he has quoted from the Punjaub and other distant points, no mention should have been made of the fact that sewage irrigation has existed in this country for many generations of men without any consequence which he anticipates. The Rivers Pollution Commission, when inquiring into the relation of the sewage meadows near Edinburgh to the health of that city, elicited from Dr. LITTLEJOHN, the medical officer of health at Edinburgh, that there was no such thing as a prevalence of tapeworm there, nor any other disease traceable to the neighbourhood of the Craigentinny meadows; that there was an active medical school, which would certainly have detected and carefully traced any such diseases, had they existed; that the Craigentinny meadows had been an institution for 150 years, and that during all that time Edinburgh had been fed on beef fattened after being fed on sewaged grass. This is called a "new danger" by the *Food Journal*. On the contrary, whatever may be the amount of the danger, it is at least 150 years old, and nothing has yet come of it.

OUR LIVE STOCK.

CATTLE.

LAST week we published the general result of the Farnley Hall sale, which was, on the whole, successful. We append a complete list of the prices and purchasers :—

Name of Animal.	When Calved.	Price.	Purchaser.
		Gs.	
Cows and Heifers.			
Blue Belle	1861	42	Mr. G. Westworth.
La Belle	1862	43	Mr. Hargreaves.
Isabella	1863	36	Mr. Westworth.
Lady Valentine ..	1865	85	Mr. Wentworth.
Lady Maggie	1865	52	Mr. Metcalf.
Duchess	1865	30	Mr. Thomson.
Lady Beatrice ..	1866	65	Mr. W. Thomson.
Revival	1866	41	Major Greenwood.
La Brilliante ..	1867	34	Mr. Stanton(Canada).
Lady Beaujolais ..	1867	60	Capt. R. E. Oliver.
Flitch of Bacon ..	1868	40	Mr. Wilcock.
Her Ladyship	1865	29	Mr. R. England.
Thorndale's Balm ..	1869	50	Captain Oliver.
Vervain	1869	41	Mr. G. Wentworth.
Lady Bacon	1869	46	Mr. Stanton(Canada).
First Duchess ..	1869	65	Mr. G. Wentworth.
Lady Lavinia	1869	47	Mr. G. Wentworth.
Second Duchess ..	1869	31	Mr. Stanton(Canada).
First Lady	1869	36	Mr. Clarke.
Second Lady	Feb., 1870	41	Mr. Stanton.
Third Lady	Feb., 1870	36	Mr. G. Hatfield.
Fourth Lady	Feb., 1870	25	Mr. Wentworth.
Fifth Lady	Aug., 1870	20	Mr. Wentworth.
Lady of Lorne ..	June, 1870	40	Mr. T. Barber.
Lady Belle	June, 1870	36	Mr. Hargreaves.
Third Duchess ..	Aug., 1870	32	Mr. Wentworth.
Sixth Lady	Nov., 1870	42	Mr. Wentworth.
Seventh Lady ..	Jan., 1871	22	Mr. Ellis.
Bulls.			
LORD DARLINGTON ..	1867	46	Mr. Bates (butcher).
SEVENTH LORD	Jan., 1870	..	Not offered.
EIGHTH LORD	Feb., 1870	23	Mr. Wentworth.
NINTH LORD	March, 1870	150	Mr. Bates (Australia)
TENTH LORD	April, 1870	42	Major Greenwood.
ELEVENTH LORD ..	Jan., 1871	35	Mr. Ripley.
THIRD DUKE	Jan., 1871	26	Mr. J. Smith.
FOURTH DUKE	Mar., 1871	25	Mr. Wentworth.

Summary :—

28 cows and heifers at	£46 4 9 =	£1294 13 0
7 bulls at	34 18 0 =	384 6 0
35 head at	£47 19 5 =	£1678 19 0

—— On Thursday, the 3d inst., Mr. Thornton disposed of a selection of pure-bred Shorthorns, bred and owned by the Rev. J. D. Jefferson, of Thicket Priory, near York. The cattle were in low condition, and the sale was successful. Business proceedings commenced with the offer of *Julia*, a very good 8-year-old cow, by 7TH DUKE OF YORK, and of the "J" tribe, which was sold to Mr. Angerstein for 65 gs. *Jessica* and *Jessy*, both by DUKE OF WATERLOO (21,616), and daughters of *Julia*, were both bought by Sir W. C. Trevelyan for 33 and 34 gs. respectively. *Duchess of Waterloo*, by EARL OF JERSEY (23,838), and of the Bates "Waterloo" tribe, was bought by Mr. T. Wilson for 100 gs.; and *Viscountess Jersey*, by DUKE OF WATERLOO, above mentioned, and another member of the "I" tribe, was purchased at 77 gs. by Mr. W. Angerstein. In the bull sale, EARL OF THE VALLEY was sold, for 35 gs., to Mr. Danby; and COUNT JERSEY, by DUKE OF WATERLOO (21,616), was secured by Mr. Craig, for Australia, at 57 gs. The general result of the sale was as follows :—

25 cows and heifers at	£35 5 2 =	£881 9 6
11 bulls at	26 5 11½ =	289 5 6
—	—	—
36 head at	£32 10 5 =	£1170 15 0

—— The subject of internal parasites must always be important to flockmasters and graziers so long as liver fluke, "gidd," "measles," and other well-known forms of disease resulting from these mysterious creatures exist. It was with some misgivings, therefore, that the friends of sewage irrigation heard that Dr. Cobbold, the great authority in this country on entozoa, should have expressed a fear lest the application of human excreta on land should be followed by the dissemination of germs of disease in the form of "eggs" of tapeworms and other low forms of life. It is with some relief that we find at least one well-substantiated reassuring case communicated to the Romford sewage meeting, by Mr. Hope. Mr. Hope fed an ox for 22 months on sewage produce—grass, Mangel Wurzel, Cabbage-leaves, and very often the rakings of grass, and the ox was slaughtered, quite recently "in the presence of Dr. Cobbold and other scientific men, and after it had been minutely dissected and examined, the united talent of these gentlemen entirely failed to detect any trace of disease whatever, and Mr. Hope was glad to say Dr. Cobbold was entirely converted to sewage irrigation." We cannot forbear congratulating the promoters of sewage irrigation upon the easy method they have discovered of "converting" scientific men.

HORSES.

THE entries for the Birmingham horse show closed on Saturday last; we give the following satisfactory result :—

	1870.	1871.
Hunters	99	110
Hacks, Roadsters, and Cobs	63	62
Harness Horses	21	21
Ponies	63	69
Tandems and pairs	15	14
Agricultural Stallions	8	8
Other Agricultural Horses, &c.	23	None.
	282	283

It will be seen from the above that the number of horses is fully up to the mark, notwithstanding the striking out of two or three classes of agricultural horses, there being a considerable increase in the classes for hunters.

POULTRY.

How to Move a Sitting Hen.—I have moved over 20 of my sitting hens this season; four of them I brought three-fourths of a mile in baskets, at the same time, and not one of them but what took kindly to the nest prepared for them. First of all, I never attempt to make a change except in the night, when all is quiet —generally between 8 and 9 o'clock. After preparing the nest and placing the eggs in it, I go for my hen, being careful to leave all gates and doors open after me, that my passage to the nest may be uninterrupted. On reaching my hen, I place my right hand under her breast and my left on her back, to steady her, and raise her gently from where she is sitting; and as I generally have a coat on at that time, I place her head under it, that she may see nothing to startle her, for I find that once she becomes aroused and begins the struggle, the game is all up for that time. On reaching the nest, I place her on the eggs, withdraw my hands from back and breast, and spread her legs so that they come on the outside of the eggs. When they feel the eggs under them, they almost always settle themselves with a satisfied cluck, and I have no further trouble with them. Should they show any little uneasiness, I would place something either in front of or over the nest, and let it be so all the next day, when they will have settled quietly to their work, and at night the things can be removed. Should the hen in being moved become restless and frightened, and on being placed on the nest show evidences that she had concluded to sit standing up, I would return her immediately to her old sitting place, and wait until the next night before repeating the experiment. I find that once a hen becomes aroused, it is no use to try and make her sit by fastening her on the nest. You will not only break her from sitting entirely, but will be very apt to lose some of the eggs by her tramping around; and it may prove a costly experiment. I find that patience and gentleness are great requisites while among my feathered friends, and especially with sitting hens. *American Paper.*

RAM SALES.

MESSRS. LYTHALL & CLARKE held an important Shropshire sheep sale on Thursday, the 27th ult., when 122 rams and above 400 ewes were offered. The ram sale commenced with Mr. Lythall's (Radford Hall) shearlings, which realised an average of £8 11s. each, while prices varied from 5½ to 11 gs., one sheep letting for 8 gs. These sheep were principally by "Standard Bearer," winner of the 1st prize at Oxford, and by "Southport," bred by Mr. H. Smith. Mr. Yates' 16 sheep averaged £11 4s., and prices ranged from 5½ to 13 gs. Mr. Nock, of Sutton Maddock, sold 14 sheep as follows:—A 2-shear prize sheep by "Mr. Crane's ram" was bought by Mr. Gaven for £22 1s.; a 2-shear, by Mr. Pryce Bowen's 3d prize Manchester sheep, was sold for £22 1s., to Earl Ducie; a 2-shear for 15 gs., to Mr. Stokes; a 2-shear for 18 gs., to Mr. Gaven; a shearling by "Patentee" by "Conservative," for 11 gs., to Mr. R. Milward; a shearling by Mr. Byrd's "Lord Paramount," 16 gs., Mr. Milward; and the remainder for from 6 to 10 gs. Lord Willoughby de Broke's rams made from 6 to 11 gs., a head; Mrs. Beach, The Hattons, sold a shearling for £21 to Mr. J. Evans; a shearling for £43 July 20, Mr. W. Lane's, Broadfield, 54 sheep at £18 2s. 6d.; July 21, Mr. R. Garne's, Aldsworth, 54 sheep at £19 1s. 1d.; July 25, Mr. Jas. Walker's, Northleach, 38 sheep at £17 13s. 2d.

On the 28th ult. Mr. Villar sold Mr. E. Handy's rams at Sierford, when 50 sheep made an average of £12, which contrasts favourably with the average of £10 8s. 8d. of last season. At Middle Aston sale, held at Hopcrafts Holt, on Tuesday, the 1st inst., 58 shearlings and 9 old sheep brought an average of £10 11s., and the highest price, 33 gs., was given by Mr. Lane, of Broadfield. At Coates, Cirencester, on Friday, the 4th inst., Mr. Howell's 41 rams were sold by Messrs. Moore & Hill for an average of £9 12s. 7d. Last year's average was £10 11s. for 27 sheep.

Hampshire Sheep.—At Down Farm, near Little Durnford, Salisbury, Mr. Charles Waters' rams were disposed of at satisfactory prices. Ram lambs brought 16½ gs., 13½, 12½, 12, 10, 9, 8, and down to 3 gs. each. Mr. John Waters officiated as auctioneer, and the sale took place on the 1st inst.

The Bulbridge ram lambs, bred by Mr. Rawlence, were sold or let by Messrs. Ewer & Winstanley on Wednesday, 2d inst. 16 ram lambs let at an average of £22 per head, and 81 lambs were sold at an average ling rams brought from 11 to 17 gs., while others were sold at 5 to 10 gs. each. Twenty-two ram lambs averaged £8 or. 8½d., and ranged as high as £13 2s. 6d. Fifty ewe lambs were disposed of at from 41s. to 53s. 6d. per head.

Longwools.—Mr. T. Allen's sale of long-woolled rams was held on Friday, at Marksh all, near Norwich. The ram lambs offered made from £3 to £3 12s. each, the shearlings from £5 to £14 5s., and the 2-shear sheep from £5 5s. to £6 each. The averages were—ram lambs, £3 5s. 5d. each; shearlings, £7 15s. 9d. each; and 2-shears, £5 12s. 6d. each.

SKIM CHEESE MANUFACTURE.

[The following is an extract from a paper on Butter Factories in the States. vol. vii., English Agricultural Society's Journal.]

We have referred to the manufacture of "skim cheese" as a part of the butter-factory system. We have said that the cream is dipped from the milk while it is sweet, and that the latter then goes into the milk-vats for making "skim cheese."

It should be remarked that at the butter factories the quantity of milk to be manipulated is usually much smaller than at the cheese factories. In making a

to Mr. Nock; a shearling for £32 to Captain Oliver; and a shearling for £23 2s. to Mr. Gaven. Twelve shearlings in all, at an average of £17 14s. each. Mr. S. C. Pilgrim, Hinckley, sold a sheep for 10 gs. to Mr. Gaven. Mr. H. J. Sheldon sold the sheep at from 6½ to 8½ gs. each. The Marquis of Exeter sold a few at £4 to £5 each. Mr. John Stubbs disposed of one ram to Mr. Yates for 43 gs., and other breeders, among whom we may mention Mr. Z. Walker, Mr. Lort, Mr. Cotteridge, and Mr. William Picken, sold their sheep at from 5 to as much as 8 gs. a-head.

In the ewe sale Mr. Yates, of Grindle, Shiffnal, sold yearlings at from 50s. to 55s. per head; Mr. Pilgrim sold a pen of theaves, by Mrs. Beach's "Cardinal," for 6 gs. a-head; Mr. Nock sold at from 63s. to 66s. a-head; Mrs. Beach at from 90s. to 147s. each; Mr. W. Lort at from 58s. to 70s.; Mr. G. Lythall at from 55s. to 74s.; Lord Willoughby de Broke at from 92s. 6d. to 100s.; Mr. J. H. Lees at from 53s. to 56s.; Mr. James Dugdale, Wroxhall Abbey, at from 44s. to 58s.; Mr. Thomas Walker at from 74s. to 75s.; Mr. Tollfree at from 54s. to 58s.; Mr. Isaac Downing at from 47s. to 49s.; Mr. Z. Walker at from 49s. to 56s.; and Mr. Wilday at 50s. per head.

On the Cotswold Hills some excellent averages have been obtained for rams. Messrs. Acock & Hawks, in selling the shearlings of three well known flocks last month, obtained the following results:—of £10 6s. per head. Six lots of 2-teeth rams were let at £13 16s. 6d. per head, and seven 2-teeth rams were sold, one of which made 17 gs. and the other 15½ gs. The total sum realised was £1600. The sale was considered satisfactory.

Oxford Downs.—The Upper Winchendon sale, in which 58 shearlings, bred by and the property of Mr. Treadwell, were disposed of, came off on Wednesday, August 2. 58 shearlings made an average of £14 6s. 9d., and the highest price, 33 gs., was given by Mr. John Bryant, of Southleigh, Oxon. The sale was very successful, and realised about double that of last year.

Mr. Charles Howard's sale took place at Biddenham, Bedford, on Thursday, when Mr. H. Strafford submitted to auction about 50 shearling rams and a pen of older sheep. Mr. Stilgoe took the first shearling put up, at 30 gs., and Mr. Treadwell the first 2-shear at 26 gs. Every sheep was sold, the average being £13. Amongst the other buyers were Mr. Ensor, from Essex; Mr. Waters, of Royston; Mr. Hicken, of Warwickshire; Mr. Ryland, Mr. Druce, and a number of other Oxford Down flockmasters. There was a large attendance, upwards of 200 agriculturists being on the ground; and Mr. Arkwright, the master of the Oakley, presided at the luncheon.

Southdowns.—Mr. J. Bushby's sale took place at Angmering on Tuesday, the 1st inst. Several shearfancy product it is found advisable that the delivery of milk be kept within moderate bounds, say from 300 to 400 cows. The factory milk-vats are all essentially alike in form and size. They hold from 500 to 600 gallons.

There is a great variety of heating apparatus, boilers, steamers, tanks for hot water, and what is termed "self-heaters," that is, with fire-box attached to, and immediately below, the milk-vat. This kind of heater is very popular at the butter factories, as it consumes but little fuel, is easily managed, and does as good work as the best.

The ordinary heater is constructed separately from the vat, and consists of wrought-iron pipes, screwed together in such a manner as to form a fire-chamber, and present a large amount of heated surface (figs. 234 and 239).

Where a boiler and engine are used, power is afforded for driving the churns, and in this respect this system must prove most convenient. Still, as the expense is considerably more than for the self-heater, both in the first cost and for fuel, many prefer the latter. We give figures of two kinds of heaters that are very largely in use (figs. 234, 236).

The factory vat (fig. 235) is constructed on the same principle as that for farm dairies (fig. 236). The fire-box underneath (fig. 235) runs from end to end. It is simply a copper cylinder with a jacket 2 inches or more

from cylinder on lower side, so that water surrounds the cylinder or fire-box. This vat requires but very little fuel. I have one of the farm vats upon my farm, and my farmer, in summer, has done all the work in making cheese from my dairy of 30 cows, using only "2 pan of chips," say to to 12 quarts. The pipe at A hanging over the vat is a movable syphon for drawing off whey. It is represented with one end inserted in the tin strainer, which is also movable, or so as to be detached ; B is the smoke pipe.

The engraving fig. 236 represents the tin or inner vat raised, and the sides of the outer vat broken out to show the heater, and the supports of the inner vat.

The outer vat is lined with galvanised sheet-iron ; B is the inner tin vat ; C the copper vat heater, extending the entire length of the vat, and surrounded by water in a semi-cylindrical jacket open at the top, which water also fills the space between the vats ; D is the tank or reservoir for hot water, separate from that between the vats, and E the copper heater for tank or reservoir ; F smoke-pipe for both vat and tank heaters. The numbers indicate the following parts :—1, faucet connecting water-space between the vats with tank ; 2, water-gate in outside vat ; 3, water-gate in tank ; 4, tube through which the whey is drawn from the strainer inside the inner vat. The strainer and whey faucet are not shown in the engraving.

The above milk-vat is for farm dairies. There is another door or fire-box at the back, similar to that at E, where fire is made to heat the water under the vat (B), when in place.

In making skim cheese the milk is set at 82°, and sufficient rennet added to coagulate it in from 40 to 60 minutes. It is then cut in cheeks with a gang of steel knives, the blades set ¼ inch apart.

It is now left at rest for a short time for the curd to subside, when it is further divided, the gang of blades being set at an angle of 45° with the bottom of the vat. It is now gently lifted with the hands, and the process of breaking or subdivision completed Then a slow heat is begun to be applied to the mass ; the curd, meanwhile, being stirred to keep it from packing, until a temperature of 96° is reached. This is the highest heat to which the curds are subjected.

When the curds have acquired a sufficiently firm consistency, the whey is drawn, and the curds thrown upon a sink to drain and cool, after which they may be run through a curd mill and salted, and then put to press.

The manufacture of skimmed cheese is very similar the American process of manufacturing whole-milk cheese, except that a lower heat is employed in "scalding," and less salt is used ; the proportion of salt being at the rate of 2½ to 2¾ lb. for 1000 lb. of milk.

The cheeses are made thin like the single Gloucester, about 4 inches thick, and pressed in hoops 14 to 15 inches in diameter. The style of cheese, however, varies at different factories, some making a small-sized fancy shape, 8 to 10 inches in diameter, and about the same height. [Direct reference to some of the illustrations is not made in the text ; but the descriptions attached to them renders that almost superfluous.]

(To be Continued.)

VISIT TO THE SEWAGE FARM AT BARKING.

BY invitation of the managers of the Lodge Farm at Barking, a large portion of which is irrigated, as is well known, by metropolitan sewage, a number of country gentlemen and well-known agriculturists recently paid a visit to it for the purpose of observing the application of the sewage, and of witnessing for themselves its effects upon the crops. The company was composed of the following gentlemen, viz., Mr. J. Oxley Parker, Mr. Edgar Disney, Major Bringhurst, the Hon. A. Petre, Mr. Julian Goldsmid, M.P. for

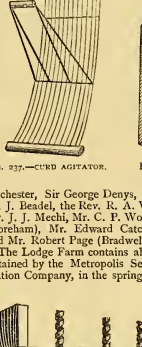

FIG. 237.—CURD AGITATOR.

Rochester, Sir George Denys, Mr. E. L. Denys, Mr. W. J. Beadel, the Rev. R. A. Westhorpe (Willingale), Mr. J. J. Mechi, Mr. C. P. Wood, Mr. James Pertwee (Boreham), Mr. Edward Catchpoole (Feering Bury), and Mr. Robert Page (Bradwell).

The Lodge Farm contains about 218 acres, and was obtained by the Metropolis Sewage and Essex Reclamation Company, in the spring of 1866. At first one quarter of its area was laid out for sewage cultivation. This portion has been enlarged from time to time since, and there are now 162 acres under sewage, about 62 of these acres having been brought under this system of cultivation during the past year. The Lodge Farm differs from most farms of the kind in that not only root and green crops, but grain crops also are produced upon it in considerable quantities. At present, the land to which sewage is applied is growing the undermentioned crops :—Wheat, 24 acres ; Onions, 24 acres ; Oats, 10 acres ; Mangel, 22 acres ; Sugar-Beet, 4 acres ; Parsnips, 7 acres ; Carrots, 2 acres ; Rye-grass, 7 acres ; Potatos, 16 acres ; Cabbage, 25 acres ; Beans, 5 acres ; Strawberries, 5 acres ; fallow, from 15 to 20 acres. The farm was thoroughly examined—scrutinised, perhaps, would be a better word—in every part, and the impression produced upon all the visitors was, as they openly professed, extremely favourable.

The crops, all round, bore the examination to which they were subjected—an examination which lasted nearly four hours—remarkably well, for they were found to be in nearly all cases good, and in some cases remarkable, alike in point of size and colour. Prior to speaking of any part of them in detail, we will dispose of two little matters that arose, and that were discussed with some interest, during the inspection. The company were shown a piece of land occupied by a gentleman adjoining the sewage farm. Naturally, it is of a very hot and stony character, and, under ordinary circumstances, could probably not produce, as one of the visitors put it, food enough for a goose per acre. This year the managers of the Lodge Farm prevailed upon Mr. Coppin to irrigate it with sewage, and he has done so upon the catch-water system, that being, said Mr. Morgan, the only sytem which could be applied to the field on account of its pecular formation. As a consequence, it is now growing Rye-grass very fairly. But what struck most observers was that, here and there, there were large patches almost entirely bare. This was explained by the fact that the sewage had been applied by a labourer not skilled in the art, and it had been unevenly distributed. Where the sewage had touched, there the grass was strong and green ; where it had not touched, it was weak and yellow. This seemed to be regarded as a pretty conclusive proof of the efficiency of sewage when applied, at all events, to this particular sort of soil. So much for the first preliminary point. The next point to which we refer is the question of small *versus* large beds on sewage farms. On this matter Mr. Morgan, the present manager, would seem to differ somewhat from his predecessor. Mr. Petre, in his report upon the farm for the season of 1869, says : "My present experience inclines me to use wide beds for grass, corn, and such crops as grow thick on the ground, and narrow beds for Cabbage, Mangel, and such as require space between the plants." Mr. Morgan would have large beds for all kinds of crops. His argument is that a large bed absorbs the good parts of the sewage best, since it is a longer time in passing over. This argument was put to a very practical test. Beds of both sorts were examined one after the other. Some were only 16 yards wide, while others—notably a bed of Mangel—were as much as 50 yards. If the visitors had been polled, they would have polled almost unanimously in favour of large beds. On these the crops were very even—as good at the remotest point from the sewage carrier as close to it. Mr. Mechi, who has hitherto, it seems, been in favour of small beds, confessed at a luncheon which ensued, that his opinions upon the point were considerably modified. Having disposed of these matters, we turn our attention to the appearance of particular portions of the crops, and first, we will speak of the grain crops, for those are supposed to be most difficult to produce on a sewage farm. First we viewed a crop of Talavera Wheat, growing after Mangel, the Mangel having had the sewage and the Wheat none in itself. Its condition was thought very fair for the season, and the produce was estimated at from 6 to 7 qr. per acre. Next, we saw a larger crop of ordinary Wheat, after grass, on a very gravelly soil, which has had three dressings of sewage this year, or about 1300 tons per acre. It looked very well, and it was estimated that it would produce from 4½ to 5 qr. per acre Last year it yielded from 5¼ to 6 qr., with 3 loads of straw to the acre. One portion of the plot we are now speaking of has grown five crops of Wheat in

succession; in other words, it has grown Wheat since the sewage operations began, and this portion was thought to be doing best. The Oats, of which there were 10 acres, also looked well. Of Onions there were magnificent crops. Last year, when Onions on ordinary farms were scorched up, there was a considerable yield there, and they sold, on the ground, for £50 per acre. This year, owing to the great plentitude of this production, they are not expected to sell for more than £30 per acre in the market. Some of the Onions last year were 17 inches round. The Rye-grass, as usual under sewage, had a splendid appearance. To this crop 12,000 tons of sewage per acre has been applied this year, and four crops, amounting to 30 tons per acre, have already been cut. Two more, equal in quantity, are expected. The Potatos were fair, but touched, as they are almost everywhere, with the prevailing disease. The Mangels, both yellow globe and long red, were much praised. Mr. Mechi expressed the opinion that one field of yellow globe passed through would produce as much as 50 tons to the acre. The Turnips were equally good, and there was hardly a crop on the whole farm to which exception was taken.

After the inspection, the company were entertained to an excellent luncheon in one of the farm buildings. One or two toasts were proposed, and the farm and its management were spoken of in the most complimentary terms. Many present also wrote. We ascertained that the migration of the larvæ, or the six-hooked embryos, which escaped from the eggs, produced symptoms in the animal on the 15th, 16th, and 17th days after the administration of the eggs. You will remember also that we fed the animal with the joints of a particular parasitic tapeworm, known as Tænia mediocanellata. The calf having recovered, we caused it to be slaughtered at the expiration of 14 weeks, and the result of our examination of the flesh after death was such as to give us very characteristic specimens of measled meat. In this jar on the table I have portions of muscles of the calf, and also portions of measled beef from a subsequent experiment. In either case the larvæ are well displayed. Here is a small egg of a tapeworm, say 1-80oth of an inch in diameter, containing the six-hooked larval parasite. When the egg has been introduced into the alimentary system of the ox, the gastric juice dissolves all the coat or shell, and the hitherto contained embryo makes its escape. Theembryo then bores its way through the walls of the canal, and passes into the blood-vessels; and thence, by the medium of the circulation, towards the muscles. Having by further boring gained access to the muscular tissue, it comes to a state of rest. During the resting stage it parts with the six hooks (which are no longer wanted for the purpose of tearing and boring), and undergoes a series of changes of too complicated a character for me to detail to you, but which are, nevertheless, represented in the diagram. By these changes it is converted into a Cysticercus, that is to say, into a larger larval condition, characterised by the presence of a head, with or without hooks, according to the species; in this case without any hooks, but with four suckers, as in the adult animal, a neck, and a large bladder-like tail. Now, when it has arrived in the muscles—precisely as obtains in the case of the Trichina—it waits to be eaten. If it is not eaten it will die. It is a point, therefore, of some importance to determine how long it will live in this situation before finally perishing. In the case of the Trichina, the larval life is longer than that of the parasites I am now describing. In the second experiment, which I performed in conjunction with Professor Simonds, the heifer was not slaughtered until the expiration of more than a year, thus affording the very kind of information I was anxious to obtain. We had thus given the Cysticerci time to live as long as they could, and I found all the little eyes, with one exception, had undergone a process of degeneration. Thus, therefore, a natural process of cure by means of calcareous degeneration was demonstrated to have taken place. This is practically very interesting, because even if you had an animal whose flesh happened to be crowded with these measles, and even there would be, you perceive, after a short time, a perfect destruction of the parasitic inhabitants of the bearer. The meat could be eaten with impunity, nor would there be any injury to the flesh, rendering it in any other sense unfit for human food.

The practical question before us is this—How do the measles obtain admission to the human territory under ordinary as well as under unusual circumstances. When the flesh of any animal is eaten by us, if the flesh be not properly cooked, Cysticerci will become transferred to our alimentary system, and they will undergo changes quite as remarkable as those which obtain in the trichinous larvæ, as already explained. Thus, if we swallow a portion of this calf, each one of the little cysts would be liable to undergo changes which would result in the formation of a creature from 10 to 15 feet in length. As soon as the larva is transferred to the vital organs of man, the cyst in which it is enclosed is readily digested, and the little Cysticercus makes its escape, after the fashion of the six-hooked embryo when the egg was previously swallowed by the intermediary bearer. Curiously enough, the gastric juice dissolves away all the bladder-like tail portion of the animal, but the head and neck retain sufficient vitality to enable the animal to fasten itself on the wall of the alimentary canal; and, immediately thereafter, by a process of budding, little joints begin to form below; so the process goes on, week after week, until 11, 12, or 13 weeks, and at the end of that time you have a completely developed Tænia from each larvæ.

Now, how do we know that is the case? The evidence on this point is perfectly distinct and conclusive. [Then follows the history of a conclusive experiment in proof of the assertion.]

All these experiments, made on animals and man, have led to the inevitable conclusion that certain larval parasites, when swallowed, will bring about the development of well-known adult forms of Tænia. There is no escape from this. But some say, we are not satisfied that such things do really take place in the ordinary course of Nature? Has any one ever seen such a thing as a beef measle in any animal killed for food? How can you adduce proof that these changes take place naturally? To all of these, and many other kindred questions, I am in a position to give entirely satisfactory and affirmative answers. You must understand that, for the detection of parasites of this kind, people must be educated properly. A meat inspector must be a far more skilled representative in many respects, but if he never saw these things, of what use is it to ask him to look for that which he does not recognise even when he sees it?

But, touching the question as to whether the Cysticercus bovis has ever been seen in a state of nature, I happen to have in my hands the most satisfactory evidence. This *brochure* is the Bombay medical officer's report for the last quarter of 1870. It forms a most satisfactory contribution to our knowledge of the facts as they occur in Nature. Dr. Hewlett, the writer, has not only made himself acquainted with this parasite, but has given the most distinct representation of the creature, quite as good, if not better, than any which Leuckart, myself, and others have published as the result of our experimental researches. Dr. Hewlett says:—"During the quarter, the carcases of 13 full-grown cows and one bullock had been destroyed by my orders on account of the fact of these animals having been found to be infected with what is popularly called tapeworm or measle." Let me tell you that these records from India give us the first indication of a true knowledge of this subject abroad; and this knowledge of what may be found in the flesh of cattle has been derived entirely from the investigations of Professor Leuckart and myself in this connection. We had experimented in this way, and had published the result of our experiments, and told people to open their eyes and they would find these things in Nature; and, though they have not been found in our own country, as yet, in this state, they have observed the indications we pointed out, and our predictions have been verified to the very letter. This shows that science does really originate sometimes the most interesting practical discoveries. Dr. Hewlett also gives another figure of a small portion of the meat in which is seen a specimen (this might have been taken from our experimental calf), showing the parasite of its natural size. I will not detain you by reading any lengthened extracts from his valuable report; but in his advice as to burning, Dr. Hewlett has gone further than I should now be prepared to go, and he has quoted a statement of mine, made some ten years ago, which I could now repeat only in a qualified sense. After considering the number of these and other parasites existing in cattle, he says, he "thoroughly endorses Dr. Cobbold's *dictum*, that all entozoa which are not preserved for scientific investigation and experiments should be thoroughly destroyed by fire, and under no circumstances should they be thrown away as harmless refuse." Herein lies an important practical matter. Under ordinary circumstances, tens and hundreds of thousands, nay, millions of eggs of tapeworms are daily distributed in our sewers. I suspect that at least 4000 of the inhabitants of this metropolis have the honour, if you may so call it, of playing the part of host to these singular creatures, and every day one or two of the individual segments of each living tapeworm will pass to the outer world, causing 40,000 eggs to escape along with each of them. These go down the sewers, and if that sewage be collected and utilised over our fields, it follows that these hundreds of thousands of eggs will also distributed. The thing is clear to demonstration. And what happens? The eggs, furnished with a covering which it has been stated will resist any amount of atmospheric changes, are swallowed by the cattle feeding on the grass.

When an ox swallows an egg, or a hundred eggs, each egg is liable to become transformed into a Cysticercus. At the present time it is certain that only a comparatively small number of cattle obtain the eggs in this way. It must inevitably follow, however, that if you distribute artificially these ova, without stint or limit, the cattle will have much greater opportunities so to speak, of getting the eggs, and therefore, of having the larvæ developed in their interior. In like manner we shall, in our turn, have greater opportunities of eating these Cysticerci in the meat; and therefore, if we do not take the very simple precaution of having our meat sufficiently cooked, more of us will play the part of host to these creatures than is now the case.

But some person will come and say "I like meat underdone; it loses all its goodness if it is over-cooked." There is abundant truth in that remark, for the meat is injured by excessive cooking. Another says, "I have eaten underdone meat ever since I was a child, and never suffered any ill consequences; therefore your statements cannot be true." The reply is this—You fortunately live in a country where the distribution of sewage, in a fresh state, has not been carried on to any great extent, and where, moreover, the general habits of the people are more cleanly than obtains amongst the uncivilised occupants of other lands. Hereafter you may not be in such a proud position as regards freedom from parasites; and that will depend upon the steps taken to ensure the destruction of the parasites, in some one or other of the stages of development through which all of them must inevitably pass. Chemical changes in the sewage itself may cause the destruction of many parasites; but, not being a chemist, I have no original researches on this head to lay before you. As to the evidence of the prevalence of these things in a state of nature, nothing can be stronger.

Home Correspondence.

Labourers' Cottages.—Your correspondent, Mr. Strickland, has expressed a wish that I should point out some of the differences between the plans lately represented in your pages and that of Messrs. Richardson & Ross, and I have much pleasure in doing so. In the first place, it will be observed that the two ground-plans are dissimilar; since in the amended design the pantry is rectangular, and a commodious fuel space is provided, which does not appear in the Leeds design. Then the staircase in each case is different, as in one case it starts from the middle of the house, and in the other from behind the front door, and is open from the top to the bottom, thereby affording ventilation to the dwelling. Upon the bedroom floors the arrangements in the rooms is somewhat different, and the existence of an open landing gives a slight advantage to the amended plan. More height has also been given to the bedrooms, which were previously found to be too low. But perhaps the most important alteration is a structural one, the placing in bringing the chimney-stack out in the centre of the span of the main roof, instead of through the flat gutter, which has been alluded to by Mr. Strickland, and which will be found to be shorter in the amended than in the Leeds plan. Thus, a serious objection to the Leeds design is overcome, and to a great extent avoided. It is hoped that this explanation will not be for an instant regarded as an attempt to detract in any way from the merits of Messrs. Richardson & Ross's very excellent plan, but rather as an act of courtesy towards inquirers like Mr. Strickland; and if Mr. Strickland, or indeed any other subject, would like to see the working drawings of the amended plan, and compare them with their prototype, which was fully illustrated in the "Farm Homesteads of England," p. 112, I need not say that we shall be glad to show them to him, and give him any other information on the subject. I hope Mr. Strickland will forward you for publication the design for cottages of which he thinks so highly, and which he says can be carried out so much cheaper than those that are now in question. *A. Bailey Denton (Jun.), 22, Whitehall Place, London.*

Tiptree, August 9.—Glorious harvest weather! Commenced cutting on the 7th, crops promising, and not being too thickly sown are but partially laid, some very little so, although tall and thick. There is a great advantage this year in drained over undrained lands, not only in earlier harvesting but in quantity and quality of crop. Draining would have paid this year, in many cases, a profit of 30 or 40 per cent. on its cost. It is a conjoint and important question for landowner and tenant. The former cannot expect his tenants to find necessary capital, and surely it can be only considered as an honourable and profitable action to allow them to do so, where it is inconvenient for the landowner, however wealthy in land, to find the ready cash. Our harvest wages are as follows:—Each man takes 10 acres to cut, stook, at 1*s.* per acre; when we lend them the reaping machine (Samuelson's side-delivery), they are charged 3*s.* per acre, and they find the driver. We find them in small-beer and ale, at a cost of at least 2*s.* 6*d.* per acre. The letting consists of Wheat, 49 acres; Barley, 6 acres; Oats, 6 acres; strong winter Beans, 9 acres; total, 70 acres. The spring Beans are generally cut by women. The Wheat crop will average, I think, quite 5½ qr. per acre. When we harvest the Pea haulm of green Peas picked for market, we remove the haulm to a grass field, and at

once cart off the weeds after scarifying, and sow over Turnips. This saves a week's time at an important period. This is also a good way to do with the regular Pea crop. *J. F. Mechi.*

Local Taxation.—At p. 089 Mr. Magniac says, "Mr. Harvey had referred to local taxation, but he had heard men who were competent to reason that question out say that it depended on the rent, and that it was as broad as it was long." I take this to mean that the landlords pay all the local taxes indirectly through the tenant. That reasoning will not hold good, be Mr. Magniac's competent men who they may, for I am quite certain that a very heavy percentage of local taxes are paid by the tenant, not as a part of rent, but absolutely paid from what ought to be part of a tenant's living. When tenants take farms they look to the poor and road rate as well as other local taxes, and they take them into calculation as they stand at the time of taking a farm as a part and parcel of the rent, but they do not take into account sums that have never appeared as local taxes, yet do afterwards appear, and they are made to pay them. We will take a clear case in point. We have now the school matters before us. The present tenants when they took their lands did not bargain to buy land and build schools, yet there is a law passed that will compel them to do so, the payments for which are to be drawn from the tenant upon the above-bleeding principle (borrowing money) in a way that they cannot be recovered from the landlord, and are, in fact, a rise of rent inflicted by law. A parish of 1100 acres near here is about borrowing £500 for that purpose, because it shall come out of the tenants' pockets, yet lands in that parish are now let very dearly; then the payment of this £500 off in 20 years, with the interest, must be a rise of rent that the tenants never bargained for yet is forced upon them. That same slow-bleeding principle was brought to bear upon the tenants when our workhouses were built, and our roads throughout the country have been made with tenants' money by the arbitrary enforcement of the General Highway Act of 1835. Our large landlords knew the value of good roads by way of an improvement to their estates, so they let their lands, and then got lackeys who drove or rode over the roads in the various districts to goad the ratepayers, and thus force them to improve the roads. In that way the roads throughout the country have been made with tenants' money, and the landlords have picked up the golden egg by a general rise of rent, the result from improved roads. I am writing all this from my own knowledge, therefore I know what I am writing about. The "reasoning" of Mr. Magniac's "competent men" is rotten at the core. If not, why is it that landlords do not get a law passed to make them pay all the local taxes themselves direct from their own pockets, and thus make it clear to the world that they do pay all the local taxes, instead of belying their own consciences by trying to make the world believe that they do, when they know full well that they have forced upon the tenants a large percentage of them. Mr. C. S. Read, M.P., says that "local taxation was not a question between landlord and tenant." It may not be the great question as to whether all the wealth of the nation should relieve its poor, make its roads, punish crime, &c.; but it is a question that wants deeply looking into, for if the law heretofore had made the landlords pay the local taxes direct from their pocket, they would have looked to wealth long ago, instead of being lax about tenants' payments. They preteud to represent tenants in Parliament, yet they fix loads upon tenants that they ought to fix upon themselves; and, "competent men," by the aid of an underhand craft, they would make the world believe that these loads are borne by themselves, whereas they have been greatly borne by the tenant. *William Smith, Woolston, Bletchley Station, Bucks, July* 31.

Thin-skinned Land.—What is the real meaning of this? I am so frequently told, "I have no depth of soil, mine is thin-skinned land," that I naturally ask whether there is hard rock immediately under this thin skin of 5 inches of ploughed land, and then I find that there is under it, probably, 150 feet deep of good honest land, but that it has only been skinned, the body remaining untouched. Now there is nothing, really, more easy and simple than deepening this thin staple to any reasonable required extent. Keep the top soil where it is, but break up the hitherto undisturbed subsoil, so that air and water can have free access into and through it, and so that the top soil and manure may rest upon broken ground and gradually mix with it. This has been my practice for the last 28 years, and, as a natural consequence, I get these large crops, which are the surprise of many who once knew the poverty of the soil. I effect this object by following in the track of the first plough with another plough, unless the breast, drawn by four or six horses, the first plough turning the top-soil on to the broken under-soil. The effects are prompt and obvious; rain-water sinks rapidly through the top-soil into the broken under-soil, and thus facilitates its passage to the drains. The top soil is thus left dry, and fit to receive the full benefit of warmth and changes of temperature, the subsoil partaking also in degree of the like advantages. As a rule, the subsoil having remained unbroken for ages, is panned down so tight, as to become almost impervious, and certainly, in a great degree, debarred from atmospheric influences. All this becomes gradually changed by subsoiling or under-ploughing, called trench-ploughing. See what takes place on our heath. The upper soil has often been taken away, the exposed subsoil, for a time, remains barren, but, after a certain period, it becomes improved by the action of air and water, and is again well coated with vegetation, and is again robbed, or stripped, as I have frequently witnessed during 30 years. Elements of fertility exist in our subsoil abundantly, but are in an unavailable or passive condition, and they require the agent cooking by atmospheric exposure and influence. How well the late Rev. Samuel Smith, of Lois Weedon, understood this. He not only exposed the subsoil to atmospheric action, by ploughing his top soil together, and leaving the intermediate space of raw subsoil uncovered, but greatly hastened the cooking process by intermixing with the bared subsoil plenty of manure, so that it became very quickly good feeding ground for the roots of plants. The adjoining root crops (Swedes) soon found this out, and occupied the hitherto barren soil with their fibres. The evidences of the benefits of deep cultivation are plainly shown wherever a ditch has been filled up, or where the drains have been deeply placed. There the crops show a visible advantage for much more than 20 years. Some fancy that it is because the land is there better drained, but that reason is the deep loosening and disturbance of the soil. Deep and good cultivation and manuring remain visible for nearly a century or more. Walking with a friend on his fields, I asked what was the cause of one portion of the crop looking so much better than the rest. "Oh!" he said, "that was once a cottage garden—a long while ago. I have known the field 50 years, and it must have been some time before that." I have a proof of this on my own farm. In 1846 I exchanged 2 acres of land with a neighbour. These 2 acres (in common with the rest of my land) had been drained and deeply subsoiled about forty years previously. Twenty-five years have since elapsed, and during the whole of that period the crops on these 2 acres have shown a marked superiority over the rest of my neighbour's field. As a basis and permanent improvement, I look upon deep cultivation as equal in importance to drainage. Nay, I look upon it, where drainage, give the key to profit. It is very much to the credit and profit of Mr. Smith, of Woolston, that he concentrates the power of his engine on a single subsoil tine passing deeply into the furrows between the ridges. The disturbance of the subsoil can never be too deep, provided the surface soil is allowed to remain uppermost, or gradually intermixed with the subsoil. Every impediment to the fibres of plants is a loss to the farmer, causing delay in development; we all know that the compression of heavy land by carting or treading renders it comparatively barren—witness a cart track. The elements of fertility are there, but are not available. The roots of plants descend many feet in a friable subsoil, naturally or artificially drained. The old story conveys a sound agricultural moral. The old man, on his death bed, told his sons that somewhere in his field he had buried some property. The earth was deeply and carefully searched; the money was not found, but a treasure arose in the greatly increased produce, resulting from deep and perfect cultivation. Most of the great old Docks, Thistles, and other weeds, that I see as I pass by rail standing high above the laid corn crops, have a safe and lasting anchorage in the undisturbed subsoil. My agricultural friends, like myself, are, I know, fond of profit. Let me assure them that one of the most ready ways to get it is by deeper cultivation. Every farmer covets deep, friable soil; as it is so scarce, let us make some; we can do so profitably if we choose to use the means. *J. F. Mechi, July* 31.

Societies.

ROYAL AGRICULTURAL OF IRELAND.

The exhibition held in Dublin last week may be pronounced eminently successful. The attendance was much greater than what was expected, the both visitors, exhibitors, and those who managed the show, seemed satisfied with themselves and with each other. The presence of Royalty, favoured by fine weather, attracted thousands of spectators to the showyard on Tuesday and Wednesday, and excursion trains brought the country folk for Thursday and Friday's show in numbers truly astonishing.

As mentioned last week, the horse show seemed to be the chief attraction. The number of entries were within one of 600, and the excitement promised in the jumping of the hunters was irresistible, and consequently the tickets for the 5s. and 1os. enclosure were bought up with avidity, and before noon on Wednesday not a ticket could be had for payment.

CATTLE.

Shorthorns.—In point of number of entries this department was not so successful as might have been desired, and we missed many old exhibitors from this side the Channel. There were, however, many very excellent animals shown, some being veterans of showyards. The position given to Mr. Challoner's celebrated SOVEREIGN was disappointing to many, and there were those who regretted that this splendid bull had not been allowed to rest satisfied with the honours already accorded to him. Considerable doubt as to the propriety of the decision was expressed, but an impartial examination of both animals will prove satisfactory. SOVEREIGN, possessing true Booth blood, is by ROYAL SOVEREIGN (22,802) dam *Village Rose* by BLOOD ROYAL, going back through g.g.g.dam to PILGRIM (4701). He is a bull of immense substance, with an apparently grand constitution, capable of taking any amount of forcing. He is now five years old and fairly active. His showyard career may, however, be now said to be at an end, as his aldermanic fare seems to have produced an increase of girth in the position where even bulls cannot appear gross and look well. SOVEREIGN is not such an even bull as the 1st prize animal. He is, too, a little flat-ribbed, and not sufficiently full "through the heart;" he is, however, a very excellent animal, and his being placed 2d to Mr. Cooke's ST. RINGAN (27,417) does not detract from his great merit. ST. RINGAN was bred by the Hon. G. Lascelles, Moon Hill, Leeds. He was got by GOOD FELLOW (19,191), out of MOONE (19,911); he is only nine months younger than SOVEREIGN, and now, at four and a-half years old, he is as even all over as a yearling. He is a beautiful roan, with a touch like moleskin—a splendid breast, without coarseness, grand fore rib, and his hips fine, but a little plainness at the tail, may well be passed over. He wins for this year the cup presented by the proprietors of the *Farmers' Gazette*, the "Purdon Challenge Cup." Mr. Smith, of Croom, shows another son of *Village Rose*, THE EARL (27,623), by RAVENSPUR. He is two years younger than SOVEREIGN, and is a very beautiful bull. He possesses in a compact frame on short legs very great evenness and quality. He is a bull fit for any company.

In the class for 2-year-olds there were some first-class animals. Mr. W. Moutray, of Aughnacloy, takes it up with WOODHOUSE BLISS, a roan bull of great merit. It is just possible, however, that this animal has seen his best days. He now has great substance, but his hollow back, large belly, and drooping at the tail, which are evidently growing upon him, may prevent his coming creditably forward at future shows. LORD WODEHOUSE is by DUKE OF MARLBOROUGH (23,768), out of a daughter of one of the first high-priced bulls that were imported to the county Wexford, GREY GAUNTLET (19,908), bred by Mr. TOTT, and bought in partnership by Messrs. Meadows, Bolton, and Armstrong, at one of the spring shows of the Royal Dublin Society some years ago. GREY GAUNTLET was a very good animal, and did good service in his Irish home. Second to LORD WODEHOUSE comes PRINCE MASON, bred by and the property of Mr. Meadows, of Wexford. PRINCE MASON is a half-brother of the deceased celebrated BOLIVAR, and if he only had the "coat" of BOLIVAR he might to-day occupy a position very much higher than what he does. He is a very attractive animal, white with a little roan about the head. As he trotted with old Quinn into the ring, there were those who would have put him first, notwithstanding. But all hair turned the scale, and the judge's hands were obliged to set aside what might have been the verdict of their eyes—the old story, quality before appearance. A near relative of LORD WODEHOUSE, shown by Mr. Gumbleton, county Cork, is highly commended. Of the yearlings, Mr. Maxwell, of Belfast, with his HALF SOVEREIGN, takes 1st place. This animal is full of Booth blood; he is by SOVEREIGN, the bull already noted as 2d in the aged section; he is out of *Rose of Castille* by BRITISH FLAG, and contains the blood of BLOOD ROYAL and CROWN PRINCE. He is a bull of considerable merit, of good substance and good quality, even, and evidently possessed of a good constitution. The 2d prize is awarded to a nice even yearling of Mr. Challoner's, of almost purely Booth extraction. Mr. L. H. Bland, of Abbeyleix, showed a red bull of the "Gwynne" blood, and deservedly secured the 3d place. The celebrated herd of Lord Viscount Monck. A class for calves finished the male sections, and there were many at the show who thought this class might well be excluded. There must always be considerable difficulty in adjudicating the merits of calves; a calf alters wonderfully between the ages of four and twelve months. There really cannot be much practical utility in bringing together such an assembly of young calves as was shown in Dublin last week. The 1st and 2d prizes were awarded to Mr. Downing, of Fermoy, for two nice calves of Booth blood.

There were only 32 female Shorthorns entered for competition. Amongst these, Mr. Smith's yearling heifers, *Repose* and *Truelove 5th*, carried off the Purdon Challenge Cup, as well as 1st and 2d prizes in their class. The aged cows were few. The 1st prize animal, with Booth and Bates blood, is a good even 7-year-old. Her head detracts from her general merit; it is coarse. Lord Fitzwilliam's highly-bred *Adelina* is patchy, and very much inferior to the 1st prize cow.

There were only two 3-year-old heifers shown, and these were not of much merit.

Mr. Moutray took 1st prize with a very good 2-year-old, bred by Mr. Meadows. This animal is well made up for show. Her points are almost perfect, if we except a little plainness of head. The 2d prize

pattern, shown by Mr. P. J. Kearney, is a very good Booth heifer. The yearlings were good, but not numerous. Heifer calves of 1871 were shown, but the remarks as to bull calves will apply here.

From the foregoing it will appear that Booth blood enters largely into the prize animals. It does not follow that it takes a place higher than Bates; the fact is, there is very little of Bates blood in the animals shown. And in Ireland, it would appear, that animals of Booth extraction have raken a more extended hold than any other. The great breeders of the county Meath rely almost entirely upon Booth.

The classes for Herefords, Devons, Polled Angus, West Highlands, and Ayrshire were very badly filled, some of these sections not having an entry. The animals shown were scarcely above mediocrity, and the competition was confined to a few amateurs. These breeds do not make progress in Ireland, the chief reason being that the Irish farmers find that the Shorthorn crosses are better adapted to the dairy farming of the country; and also the young stock of this cross are better suited, through early maturity and fattening, to the requirements of grazing at home and for export. A native breed, the Kerry, is exhibited in large numbers, and for the mountainous regions there cannot be a breed better suited; they are hardy animals, good milkers on short keep, and fairly profitable as graziers. They cross well with the Shorthorns, and in the grassy dells and valleys of their native mountainous country they yield a large quantity of rich milk. Mr. Brady, of Raheny, whose name in connection with Kerries is famous, takes the 1st prize with his Rory of the Hills. Captain Bailey, of the county Dublin, and the Knight of Kerry, are the other chief prize-takers in this class.

SHEEP.

Leicesters.—A very good show of sheep was brought forward, the two classes, English and Border Leicesters, being well filled with animals of very good quality. The Cork Challenge Cup, value £50, was awarded to a Border Leicester tup of Mr. Robertson, Athy. The bringing English Leicesters and Border Leicesters into competition for this prize is not quite consistent with the Society's keeping the breeds separate for the other prizes. In discriminating the merits of animals of different variety a great deal depends upon the views of the judges and their tastes as to variety; and as the points of these two are widely different, it would seem proper that the prize should be limited to competition in one of the classes. The Border Leicester tup of Mr. Robertson is a very excellent animal; good size and quality, well in the body, and full of vigour; but he has the fault of the breed—a want of wool on the belly, and bareness of head.

The English Leicesters of Mr. Scymour Mowbray, of Mountrath, who took 1st prize in sheariings, are good representatives of the class of sheep that have been taking prizes at the English shows lately. They seem to have a large amount of luge blood. Mr. Geo. Turner, of Uppingham, showed a good many rams, and took a 2d prize with his shearling. Mr. Turner's sheep are now pretty well known as prize-takers. Mr. Marris, of Ukeby, took 3d prize; his sheep are a trifle larger than Mowbray's and Turner's. Mr. Owen, of Blessington, co. Wicklow, who at one time seemed invincible in sheep-showing, was not placed.

There was a very large show of Border Leicesters, and the prizes were divided between Mr. Tbos. Robertson, of Athy, and Mr. Bland, of Abbeyleix. The ewe classes were not well filled, and the sheep shown here did not possess any distinctive merit. There was a very good variety shown—the native Roscommon sheep; they are large in frame, well covered with good wool, of early maturity, and evidently a paying breed. The Royal Agricultural Society has shown much wisdom in encouraging the improvement of this breed. They resemble the Lincolns in many respects; the chief points of difference are the smaller head of the Roscommon sheep and the wool not being of the lustrous quality of the Lincoln. This breed furnishes the splendid wethers shown by thousands at the Ballinlow Strokestown, and other great sheep fairs of the west of Ireland.

The *Lincolns* were a poor show, and since the days when Mr. Page so energetically worked for their introduction into Ireland they do not seem to have made much advance. It is said they have been fairly and well tried in Ireland, and that they are not likely to make further progress. The probability is that English and Border Leicesters with Shropshire Downs are likely to make their way more readily.

"*Shropshire* and other Downs" was the heading under which were classed in this case two varieties now very dissimilar, and into this class might be brought animals whose respective and distinctive qualities entitle them fully to separate classes. H.R.H. the Prince of Wales showed a very excellent Southdown ram, and if the judges had been men of Southdown proclivities, the probability of this ship taking a prize would have been very great. Mr. Charles William Hamilton, of Hamwood, Clonee, took the 1st prize with a very beautiful sheep, of first-rate wool, and general good quality. With a good neck, loins, rib, and breast, well-filled twist, he seemed a sheep fit to be seen in any company. Mr. Hamilton was one of the first to introduce Shropshires into Ireland; he has worked long and industriously for their propagation there. Mr. Naper, of Loughcrew, and Mr. L. H. Bland, of Abbeyleix, took 2d and 3d prizes respectively with very neat animals. The show of Shropshire rams was, on the whole, very good. A great uniformity in the quality of the animals was observable.

In Down ewes H.R.H. the Prince of Wales took 1st prize with a pen of splendid Southdowns, this being the only pen of that variety shown.

SWINE.

The exhibition of pigs was not as large as has been seen at former shows held in Dublin, but the quality of the animals was generally good. Amongst Berkshires Lord Clermont and Lieut.-Colonel Chichester were the largest exhibitors. There is a striking difference in the appearance of the Berkshires of these two breeders, whilst Colonel Chichester's pigs are large framed, on long bony legs, Lord Clermont's are short-legged, fine boned, thick bodied, wide backed, and well covered with hair. Lord Clermont's boar, "Prime Minister," is a very useful animal; he is full of flesh, on neat, short legs; he is, too, of good size. Mr. J. Molloy, of Mountjoy Street, Dublin, took 1st prize in aged sows with a very good Berkshire; her chief defect is want of size. The sow of Mr. Cooper, of Limerick, which took 1st prize in the young sow class is a very heavy fleshed pig, on short legs.

As a class the white breeds are inferior to the Berkshires, and we found large small varieties competing against one another in a curious sort of way. Here the individual tastes of judges might not be approved of by all; some favour the large breed of pigs, whilst others are strong in the conviction that nothing can compare with the small breed. It would be more satisfactory to have classes for each variety.

HORSES.

As already mentioned, this department of the show seemed to be the great feature; there were 599 entries, divided as follows:—

Thorough-bred sires	25
Hunters, roadsters, cobs, ponies, and young horses of these sorts	502
Brood mares	33
Agricultural horses	40
	599

The jumping prizes were competed for on Wednesday, Thursday, and Friday, and on each day the numbers of people on the stands and around the ring evidenced the popularity of this *fête*. It was computed that not less than 15,000 people were spectators of the jumping on Wednesday; this, coupled with the fact that an almost fabulous sum was received for stand tickets, does not sustain the idea that jumping horses at exhibitions will ever be altogether excluded. The arrangements for the trial of hunters were certainly arranged on a faultless system. Within an arena of considerable size were placed hurdles, bank, wall, and hedge and water jumps, which, whilst sufficient to test the powers of the various competitors, were so constructed as to prevent the possibility of accident to man or horse.

The riding of the horses may be pronounced generally bad, the few brilliant exceptions being thus brought more prominently forward. Mr. Flynn, of Talska, county Roscommon, who is well known as a judicious rider, and Mr. Bernard Sweeny, of Castlerea, were adjudged by *vox populi* as having acquitted themselves most creditably last week. Whether it is that animal magnetism is transmitted from the rider to horse, it was perfectly clear that the nervous, hasty 'gent' in the style generally bungled at the jumps, and if the horse got over at all, it did so in such a discreditable manner, as to merit the jeering which accompanied the unseemly performance. On Wednesday, the prizes for jumping the wall were awarded, 1st, to Mr. Flynn's "Harry Lorrequer," 2d, to Mr. Keating's "Playboy." The performance of these two animals was really excellent. A substantial wall, nearly 5 feet high, is not a trifle to contend with. The ease and precision with which these two horses cleared the obstacle were creditable alike to the horses and riders. The jumping of "Jack Sprat," by the gelding of Mr. George Low, of Athy, although done in a clumsy manner, was safe.

For the bank and water prize, Mr. Bernard Sweeny, with a well-named horse, "Safety," took 1st place. A good many other horses competed, many getting through their work in a creditable manner.

Thursday's trials were most exciting; a large number of horses were entered for the jumping prizes. The jumps were made more difficult, and altogether the spectacle, from its greater danger, seemed to be more attractive. The wall was raised to above 5 feet, and promised to prove a regular rasper, which it did in reality to some of the horses' noses and legs. Mr. Wm. Sneyd, with his grey mare "Maria," took 1st prize; Mr. Low, with "Jack Spring," 2d.

It is supposed that a large number of horses changed owners. Amongst the sales we may note the following:—Mr. Kenny, Knockmullin, Colloney, sold his chestnut gelding, "Charmer," by Coningsby, dam by Woodpecker, to Mr. Chaine, for a long figure; Mr. John Trimble, of Drumconrath, county Meath, sold his bay gelding "Flash," by Lightning, to Mr. James Daly, at 120 gs.; Mr. R. Flynn sold "Emerald Wreath," at 300 gs., to Mr. Darby, who also bought "Maria," by Harkaway, who, as will be seen, gained the 1st prize for jumping on Thursday. He also purchased a perfect hunter, up to 14 stones, from Mr. E. Flynn, of Rathmines, at 200 gs.; and also bay mare "Puss," from the Hon. E. Preston, at 220 gs.

The following is the list of Awards:—

CATTLE.

Shorthorns.

Purdon Challenge Cup, value 60 gs., for the two best Shorthorn Heifers calved in 1870.—1st and ad, E. J. Smith, Islamore.

1. Best Bull, calved on or after January 1, 1866, and previous to January 1, 1869.—1st and 2nd, Purdon Challenge Cup, J. Cooke, New Ross; ad, R. Chaloner, Moynalty.

2. Best Bull calved in 1869.—1st, W. Moutray, Aughnacloy; 2d, J. Meadows, Wexford.

3. Best Bull calved in 1870.—1st, P. Maxwell, Belfast; ad, R. Chaloner, Moynalty.

4. Best Bull calved in 1871.—1st and 2d, J. Downing, Fermoy.

5. Best Cow, in calf or in milk, calved previous to January 1, 1868.—1st, W. Moutray, Aughnacloy; 2d, Earl Fitzwilliam, Carnew.

6. Best Heifer, in calf or in milk, calved in 1868.—1st, Wm. Moutray, Aughnacloy; 2d, Samuel Talbot, Durrow.

7. Best Heifer, in calf or milk, calved in 1869.—1st, Wm. Moutray, Aughnacloy; 2d, P. J. Kearney, Clonmellon.

8. Best Heifer, calved in 1870.—1st and 2d, E. J. Smith, Croom.

9. Best Heifer Calf, calved in 1871.—1st and 2d, H. Lyons, Croom, Limerick.

Herefords.

10. Best Bull, calved on or after January 1, 1866.—1st, S. Gilliland, Londonderry; 2d, P. J. Kearney, Clonmellon.

11. Best Cow, in calf or in milk, calved previous to January 1, 1868.—1st, P. J. Kearney, Clonmellon; 2d, S. Gilliland.

12. Best Hereford Heifer, in calf or in milk, calved in 1868.—1st, S. Gilliland, Londonderry.

13. Best Hereford Heifer, calved in 1869.—1st, P. K. Kearney.

Devons.

14. Best Devon Bull, calved on or after January 1, 1866.—1st, John Peake, Monaghan.

15. Best Devon Cow, in calf or in milk, calved previous to January 1, 1868.—1st, John Peake.

16. Best Devon Heifer, in calf or in milk, calved in 1868.—J. Peake.

17. Best Devon Heifer, calved in 1869 or 1870.—J. Peake, Monaghan.

Polled Angus.

18. Best polled Angus or Galloway Bull, calved on or after January 1, 1866.—1st, W. Owen, Blessington; ad, A. Tiernan, jun., Slane.

19. Best polled Angus or Galloway Cow, in calf or in milk, calved previous to January, 1868.—No award.

20. Best polled Angus or Galloway Heifer, in calf or in milk, calved in 1868.—1st, A. Tiernan, jun., Slane.

21. Best polled Angus or Galloway Heifer, calved in 1869 or 1870.—W. Owen.

West Highland.

22. Best West Highland Bull, calved on or after January 1, 1866—T. Butler, Priestown.

23. Best West Highland Cow, in calf or in milk, calved previous to January 1, 1868.—T. Butler.

Ayrshire.

26. Best Ayrshire Bull, calved on or after January 1, 1866—1st, Lord Clermont, Newry; 2d, Wood Patton, Monaghan.

27. Best Ayrshire Cow, in calf or in milk, calved previous to January 1, 1868.—1st, D. Patton, Monaghan; 2d, G. A. Stephens, Dublin.

28. Best Ayrshire Heifer, in calf or in milk, calved in 1868.—1st, D. Potton, Monaghan; ad, G. A. Stephens, Dublin.

29. Best Ayrshire Heifer, calved in 1869 or 1870.—D. Patton.

Kerry.

30. Best Kerry Bull, calved on or after January 1, 1866.—1st, R. Brady, Raheny.

31. Best Kerry Cow, in calf or in milk, calved previous to January 1, 1868.—1st, B. Marley, Mullingar.

32. Best Kerry Heifer, in calf or in milk, calved 1868.—Highly Commended: Capt. D. Bayley, Dublin.

33. Best Kerry Heifer, calved in 1869 or 1870.—1st, W. R. Stephens, Dublin.

Channel Island.

34. Best Channel Island Bull, calved since January 1, 1866.—1st, G. Dawson, Dublin; 2d, D. H. Plunket, Johnston.

35. Best Channel Island Cow or Heifer, in calf or in milk.—1st, D. H. Plunket, Johnston; 2d, J. Smith, Carlow.

Brittany.

36. Best Brittany Bull, not exceeding three years old.—No entry.

37. Best Brittany Cow or Heifer in calf or in milk.—J. P. Redmond, Dublin.

38. (Open for competition to tenant-farmers whose Poor-law valuation is over £100 per annum.)—Best Cow for dairy purposes.—1st and 2d, J. Peake, Little Meath.

39. (Open for competition to tenant-farmers whose Poor-law valuation is under £100 per annum.)—Best Cow in calf or in milk.—1st, P. Quinn, Frenstown; 2d, D. Patton, Monaghan.

40. Best Heifer calved in 1868.—1st, D. Patton; 2d, P. Quinn.

41. Best Heifer calved in 1869 or 1870.—1st and 2d, P. Quinn.

SHEEP.

The Cork Challenge Cup, value 50 sovs., for the best Shearling Ram in classes 42, 46, 50, and 54.—Mr. T. Robertson, Athy (Border Leicester).

Leicesters.

42. Best Shearling Ram.—1st, Seymour Mowbray, Mountrath; 2d, G. Turner, jun., Uppingham; 3d, T. Marris, Ukeby.

43. Best Ram of any other age.—1st, G. Turner, jun., Uppingham; 2d, T. Marris; 3d, G. Turner, jun.

44. Best pen of 5 Shearling Ewes.—1st, S. Mowbray, Mountrath; 2d, Sir A. Walsh, Bart., Stradbally.

45. Best pen of 5 Lambs.—Sir A. Walsh, Bart.

Border Leicesters.

46. Best Shearling Ram.—1st, no award; 2d, G. Laing, Coldstream, 3d, L. H. Bland, Q.C., Abbeyleix.

47. Best Ram of any age.—1st and 2d, L. H. Bland, Q.C.

48. Best Pen of 5 Shearling Ewes.—1st, A. H. S. Barry, M.P., Tipperary; 2d, L. H. Bland, Q.C.; 3d, R. G. Cosby, Stradbally Hall, Queen's Co.

49. Best Pen of 5 Ewe Lambs.—1st, A. H. S. Barry, M.P.

Roscommon Sheep.

50. Best Shearling Ram.—1st and 2d, J. B. Smyth, Limerick; 3d, W. Cotton, Castlerea.

51. Best Ram of any other age.—1st and 2d, T. Robertson, Strokestown; 3d, W. Cotton, Castlerea.

52. Best Pen of 5 Shearling Ewes.—1st, J. B. Smyth, Limerick; 2d, R. Coffey; 3d, W. Cotton, Castlerea.

53. Best pen of 5 Ewe Lambs.—1st, R. Coffey, Killucan.

54. Best Shearling Ram.—1st, W. F. Marshall, Branston; 2d, C. Going, Nenagh; 3d, W. F. Marshall.

55. Best Ram of any other age.—1st, 2d, and 3d, C. Going.

Shropshire and other Downs.

58. Best Shearling Ram.—1st, C. W. Hamilton, Clonee; 2d, L. H. Bland; 3d, C. W. Hamilton.

59. Best Ram of any other age.—1st, C. W. Hamilton; 2d, T. Marris, Ukeby; 3d, C. W. Hamilton.

60. Best pen of 5 Shearling Ewes.—1st, H.R.H. the Prince of Wales; 2d, J. Peake, Monaghan.
61. Best pen of 5 Ewe Lambs.—1st, Sir A. Walsh, Bart, Stradbally.
62. (Open for competition to tenant-farmers whose Poor-law valuation is over £50 and under £100 per annum).—Best pen of 5 Ewes which have reared lambs in 1871.—1st, W. Esker, Timahoe; 2d, P. Quinn, Priestown.
63. Best pen of 5 Hogget Ewes.—1st, P. Marnane, Tipperary; 2d, J. W. Esker, Timahoe.
64. (Open for competition to tenant-farmers whose Poor-law valuation is under £50).—Best pen of 5 Ewes, having reared lambs in 1871.—1st, M. Marnane, West Tipperary; 2d, J. Sweeny, Priestown.

SWINE.

COLOURED BREED.

65. Best Boar under 18 months old.—1st, Lord Clermont, Newry; 2d, C. H. Pennell, Wexford.
66. Best Boar over 18 and under 36 months old.—T. Butler, Priestown.
67. Best Breeding Sow under 18 months old.—1st, J. C. Cooper, Limerick; 2d, Lord Clermont.
68. Best Breeding Sow over 18 months old.—1st, J. Molloy, Dublin; 2d, Lord Clermont.
69. Best Berkshire Sow and litter of not less than six Pigs.—R. G. Cosby, Queen's County.
70. Best pen of three Breeding Pigs of the same litter, above four and not exceeding eight months old.—1st, W. L. Joyat, Dublin; 2d, J. Molloy, Dublin.

WHITE BREED.

71. Best Boar under 18 months old.—1st, J. L. Naper, Oldcastle; 2d, J. C. Cooper, Limerick.
72. Best Breeding Sow under 18 months old.—1st, J. Molloy, Dublin; 2d, R. W. Boyle, Milltown.
74. Best Breeding Sow over 18 months old.—1st, S. W. Perry, Ballymore; 2d, J. L. Naper, Oldcastle.
77. (Open for competition to tenant-farmers whose Poor-law valuation is over £50 and under £100 per annum) — Best Breeding Sow over 8 and under 18 months old.—1st and 2d, M. Marnane, Tipperary.
(Open for competition to tenant-farmers whose Poor-law valuation is under £50 per annum.)—Best Breeding Sow.—1st, M. Marnane, Tipperary.

HORSES.

THOROUGH-BRED STALLIONS.

160. Thorough-bred Sire in the stud book, which, in the opinion of the Judges, is best calculated to improve and perpetuate the breed of sound and stout thorough-bred horses, weight-carrying hunters, and horses for general stud purposes.—1st, His Excellency the Lord Lieutenant; 2d, H. Fower, Mallow.
164. Thorough-bred Sires, calculated to get carriage, troop horses, or roadsters.—1st, G. Mansergh, Tipperary; 2d, D. Dickson, county Down.

FOR YOUNG HORSES SUITABLE FOR HUNTERS.

165. Best 4-year-old Colt, able to carry 13 stones 7 lb. and upwards.—1st, R. Galwey, Nenagh; 2d, Lee Brothers, Swords; 3d, T. O'Reilly, Dublin.
166. The best 4-year-old Filly, able to carry 13 stones 7 lb. and upwards.—1st, Rev. F. Briscoe, county Meath; 2d, P. Quinlan, Clonard; 3d, J. Morrin, Johnstown.
167. Best 4-year-old Colt, able to carry from 11 stones to 13 stones 7 lb.—1st, Major-Gen. W. Irwin, Glendalough; 3d, B. Sweeny, Cahir.
168. Four-year-old Fillies, able to carry from 11 stones to 13 stones 7 lb.—1st, M. Seery, Delvin; 2d, J. Trimble, county Meath.
169. Three-year-old Colts—1st, J. Connolly, Garradice; 2d, Mrs. Davis, Courtown; 3d, A. H. Pollok, Ballinalee.
170. Three-year-old Fillies.—1st, J. Tisdale, Kells; 2d, E. Morrison, Esq., Mountrath; 3d, J. J. Jones, Dublin.
171. Two-year-old Colts and Fillies.—1st, Lord Clanmorris, Creg Clare; 2d, T. Scott, Ballina, 3d, A. Pollok, Ballinasloe; 4th, R. Redmond, Dublin.
172. One-year-old Colts and Fillies.—1st, Lieut.-Col. J. Lloyd, Monaghan; 2d, C. W. Wise, Esq., Cahir; 3d, Dr. Sheil, Ballyshannon; 4th, J. Kendall, Jr., Irvinestown.
173. Ladies' Mares and Geldings.—1st, E. Kingley, Dublin; 2d, P. Georges, Clontarf.

WEIGHT-CARRYING COBS AND ROADSTERS.

174. Cobs or roadsters not exceeding 15 hands; calculated to carry 15 stones and upwards.—1st, C. W. Wise, Cahir; 2d, T. Beggs; 3d, R. F. Stack, Omagh.
175. Cobs or Roadsters, from 14 to 15 hands, calculated to carry from 13 to 15 stones.—1st, D. Rogerson, Roundtown; 2d, Hon. E. Preston, Balbriggan; 3d, J. Costello, Dublin.

(Local Committee's Prizes.)

HUNTERS.

182. Best Weight-carrier not less than 5 years old, equal to 11 stones and upwards.—1st, R. Walsh, Saggard; 2d, Lieut.-Colonel J. Lloyd, Monaghan; 4th, D. Cummins, Carrick-on-Suir.
176. Cobs or Roadsters under 15 hands; calculated to carry over 13 stones.—1st, J. Rutledge, Tuam; 2d, J. Fraser, Esq., Dublin; 3d, Col. L. White, Clonsilla.
177. Ponies from 12 to 14 hands.—1st, Wm. D'Arcy, Bray; 2d, G. O. Springfield, Esq.; 3d, Cust, Tipperary.
178. Ponies under 12 hands.—1st, Capt. W. R. Brereton, Killcullen; 2d, J. Fewings, jun., Chotard; 3d and Silver Medal for the best pony exhibited: R. Purdon, Delvin.

BROOD MARES.

179. Thorough-bred Mares, in foal, or having had foals in 1870 or 1871.—1st, J. L. Ellison, Castlerea; 2d, E. J. Smith, Croom; 3d, C. L. Ellison, Castlerea.
180. Mares calculated to produce weight-carrying Hunters, in foal, or having produced foals in 1870 or 1871.—1st, P. Fitzpatrick, Naas; 2d, J. Morrin, Johnstown; 3d, J. S. Winter, Agher; 4th, L. Cornwall, Navan.

(Open to Competition to Tenant-Farmers whose Poor-law Valuation is under £100.)

181. Best Brood Mare.—1st and 2d, P. Quinn, Priestown.
182. Best agricultural Brood Mare, in foal, or having produced a foal in 1870 or 1871.—1st, S. Rad Kerr, Rathmoyle; ad, Messrs. Mooney, Crumlia; 3d, J. Denais, Finglas.
183. Best Gelding for agricultural purposes, over two and not exceeding four years old.—1st, J. Rooney, Clonsilla; 2d, R. Patterson, Dundalk.
184. Best Filly for agricultural purposes, not exceeding five years old.—1st, L. Joynt, Raheny; 2d, Messrs. Mooney, Crumlia.

AGRICULTURAL STALLIONS.

185. Agricultural Stallions of the Clydesdale or Suffolk breed.—1st, P. O'Malley, Santry; 2d, S. R. Kerr, Rathmoyle; 3d, T. Butler.
186. Best Agricultural Stallion of any other breed.—3d, L. M'Court, Dublin. No merit for others.

JUDGES.—Horses: B. Persse, R. Watson, H. Thurwell, Captain Bernard, Hon. W. F. Arbuthnott, F. Barlow, H. A. Corbett, H. Briscoe, A. Darley, N. M. Archdall. Shorthorns: Mr. Crisp, Mr. Unthank. Herefords and Devons: H. Heywood. Polled Angus: George Gibbons, A. Berthwick. Kerries: George Hewson. Roscommon sheep: Samuel Garnet, Major D'Arcy. Lincolns: W. C. Grave, A. Borthwick, W. Clay. Leicesters: L. Bonnard, J. Harris, T. Potter. Shropshire: Thomas Horley, T. Coxon. Swine: H. M'Clintock, A. Warburton. Special prizes: Mr. Wade, Mr. Boyce.

YORKSHIRE AGRICULTURAL.

THE fine weather with which this meeting opened on Wednesday last continued during the two following days, and on Friday one of the most successful meetings which this great Society has had was brought to a close. In connection therewith the following statistics of entries, prizes, and receipts will prove of interest :—

Comparative Amount of Prizes offered by the Society during the last three Years.

	1869.	1870.	1871.
Cattle	£287	£371	£365
Sheep and pigs	344	352	325
Horses	793	791	825
Wool	10	10	10
	£1434	£1524	£1525

Entries during the last five Years.

	1867	1868	1869	1870	1871
Cattle	228	253	217	246	220
Sheep and pigs	363	330	443	362	407
Horses	10	13	8	9	9
Implements	1038	1260	1406	1364	1393
Foxhounds	82	60	83	59	90
	1736	2000	2233	2288	2241

Receipts for Admission of the Public at the present Show.

Wednesday, 12. 6d. each	=	2,530	=	£63 5 0
Thursday, 12. 12. each ..	=	20,250	=	1012 10 0
Friday, at 1s. each ..	=	10,108	=	505 8 0
				£1832 18 0

Preliminary to our observations on the several classes of stock exhibited, we may remark as a special characteristic of this show, that the term "country meeting" applies to it merely as regards the locality in which its shows are held : the large amount of prize money awarded in the classes of horses, Shorthorns, Leicesters, and pigs, makes the competition really a national one. Moreover, it is in this county that these animals are a staple product, and consequently local animals which have not been on the grand tour of the Royal and other shows, often come out and run away with the laurels. Indeed, until the horse or Shorthorn wearing Royal honours passes "final" examination at the Yorkshire, he is not secure in his position. And, on this occasion, it will be found that several important judgments have been made contrary to previous decisions.

Taking the live stock in the order of the catalogue, we come first to

SHORTHORNS.

This class at the Yorkshire is always a meeting of notabilities, with some new faces dangerous to look upon. On this occasion Sir George Wombwell, Mr. Singleton, and Mr. Knowles come out with animals that step over the Wolverhampton winners. Of these, however, we will speak when we come at them. The number of animals shown at this meeting was larger than usual. The aged bulls are seldom numerous. In the yearling bulls there was a share of superior animals. Mr. Stamper's GRINDELWALD took the first prize, being the Marquis of Exeter's 2d prize at Wolverhampton, TELEMACHUS, Lady Figot's CHARLES LE BEAU, Mr. Willis' WINDSOR FITZ-WINDSOR, and other good animals—the first bull of great size and symmetry, but has not quite the quality of the others. TELEMACHUS is a compact clever Shorthorn, has fine fore-quarters and loins, and capital handling. He might be an inch or two longer. The next bull belongs to Mr. Knowles, Wetherby. He was bred by Mr. Cliffany, and was unknown to the Royal showyard. The 2-year-old bulls were a splendid class. Out of 16 animals, 9 had run over the Wolverhampton course. The winners came here in their places exactly as at the Royal—LORD IRWIN, WINDSOR FITZ-WINDSOR, and BYTHIS, being 1st, 2d, and 3d here, and 1st, 2d, and 3d at Wolverhampton. Mr. Linton appears satisfied with the admirable manner in which LORD IRWIN has gone on since last year; he must have capital stamina to go from place to place and improve in his looks, as he does. Mr. Outhwaite's 2d prize bull is a thick good specimen of the Booth family. When two tenant-farmers can produce two animals like these—victors over all comers, both at the national and the country meeting—is a proud thing for Yorkshire, and shows that success is as attainable in this walk by the tenant as the owner. Anyhow, it is clear that in Shorthorns you have Yorkshire to conquer after you have won at the Royal. BYTHIS, the 3d prize, has fallen from his high estate. The 1-year-old bulls were a small class of seven, but the winner was an unknown animal again; and the 2d and 3d both commended at the Royal. Sir George Wombwell's NEWBRO' 3D, the 1st prize, is a beautiful calf, much younger than the 2d and 3d animals. The bull calves were 11—a fair entry in number, in quality very good. Messrs. Dudding's BRITISH FLAG was 1st here, as at the Royal; and, similarly Mr. Linton's LEEMAN was 2d at both places, and Major Stapylton obtained 3d with a nice calf allied to Gunter blood.

In cows of any age, the 3d Royal prize cow, *Windsor Butterfly*, takes 1st here in a class not quite as good as the Royal. This cow, however, should have been higher placed at Wolverhampton. Of her we then wrote as follows :—"The 2d prize is a strong cow, with gaudy hind quarters; she is certainly wrong placed. The 3d cow, Mr. How's *Windsor Butterfly*, is to our mind a better animal." Results justify this. She is here 1st prize, and Mr. Outhwaite's Brigg prize cow, *Wevandiers*, wins 2d cleverly. The 3d prize, Mr. Stamper's cow, is of the old style, and not at all to our mind. She is deep, but not cylindrical, and is flat on her fore-ribs and crop. The 3-year-old heifers were only nine, but of rare merit. The decisions in favour of Mr. Foljambe's *Concert*, 1st; Mr. Tenant's, *Daisy* 2d, and Mr. How's *Vesper Queen* 3d, left out the Royal 1st prize, Lady Figot's *Dame Swift*. At Wolverhampton *Vesper Queen* was 2d and *Concert* 3d, here *Concert* is 1st and *Dame Swift* out altogether. The Dame is pulled out of shape by being in calf, but still is worth more than neglect. Her quality is not equalled by *Vesper Queen* and *Daisy*; *Concert* is a magnificent heifer, of wonderful size and touch, but she has not the tip-top touch. In this class many men have many minds, but still *Dame Swift* for a place say we. That she was not entitled to a commendation is absurd. Two-year-old heifers were a grand class of 9, in this class at the Royal, Mr. Outhwaite's *Lady Brough* stood 1st; she has gone abroad, and Mr. Foljambe's *Fleur-de-Lis*, which took the 2d to her, is 2d at York. The 3d prize, Mr. Howe's *Verona*, cuts out Colonel Towneley's *Baron Oxford's Duchess*, the 3d prize at Wolverhampton. *Verona* is a plump good heifer, full of flesh, and good handling. *Oxford's Duchess* is a loose, long heifer; but the 1st prize is an animal that has never been shown before. Again a Yorkshire farmer bowls out the leading men in the Shorthorn game; Mr. Singleton has sold some Waterloos for long figures, but in his *Queen of Trumps* with his name on the rump in a canter, is a combination of Waterloo and Grand Duke blood. For quality, touch, and hair, it is impossible to get beyond her. She is pure white, of fine bone, sweet looks, and true cylindrical make.

The Champion Cup, value 50 sovs., for the best female Shorthorn, LORD IRWIN'S heifer, no difficulty in winning. No other animal approached him—*longo intervallo*. Mr. Singleton's heifer, and Mr. Foljambe's 3-year-old heifer, were the only animals, if we except Sir G. Wombwell's young bull, worthy to compete with him.

The capital dairy cow, *Primrose*, belonging to Mr. Briggs, Selby, beat Mr. Statter's Royal prize cow, *Beauty*. *Duchess of Lancaster*, Colonel Towneley's Shorthorn, the winner in the dairy class at Wakefield in 1870, was worthy of distiction in this class.

HORSES.

The entry of horses must be considered a large one. Of the 407 horses entered, 203 are hunters. The 1st prize stallion for hunters, "Stampedo" is a well-bred animal. His hocks, however, are far from satisfactory. Indeed, the vet is put to the rack and the decisions one of those "accidents" that will happen in the best regulated showyards. At the Royal show, where the hunter decisions were most satisfactory, he could not chalk a commendation. The 2d prize horse here, "Sincerity," is a good strong well made, and very likely a hunter. He took 1st at Wolverhampton, where he beat "Blinkhoolie," "Laughing Stock," "Tim Whiffler," &c. "Suffolk," the 3d prize at Wolverhampton, was not noticed here, the 3d prize going to "Theobald," a son of "Stockwell." The second class horses were as usual in Yorkshire, such as we cannot find elsewhere. In roadsters "Lord Derby," the 1st prize, is a stylish chestnut, clever, but slightly short of bone. "Atlas," the 2d prize, is a short-legged animal of rare quality and action. Mr. Hart, Dunnington, showed the rare old weaver "All-fours." There were two or three lumbering animals in this class.

The agricultural stallions were a dozen, and contained no extraordinary animals. The 1st prize is a capital thick horse, and the 2d prize, "Le Bon," was the 3d winner at Wolverhampton; he is only three years old, and has capital legs and short back, but his back rib is not quite the thing. Dray horse stallions were a small class, of no particular merit. In hunter brood mares with a foal, Mr. Darrell's "Songstress" was 1st, and Mr. Robinson's old celebrity, "Go-a-head," the 2d, in a good class. Hunting mares were numerous and excellent, as were roadsters. The winners of the agricultural brood mares were beyond criticism—three better animals we never saw together than Mr. Bromley's "Damsel," Mr. Banks' "Trip," and Mr. Statter's "Highland Lassie." The young agricultural geldings and fillies were a fine show. Upwards of 20 4-year-olds came to the post; they were the best lot we ever saw together. Mr. E. Crowe, of Downham Market, took 1st, with "Smart;" Mr. Brierly, Manchester, 2d and 3d, with "Warwick" and "Sensation." In the Royal and other showyards "Sensation" has always been our *beau ideal* of a farm animal, yet here she is placed 3d.

Passing over several useful classes of young coach-horses, we come to roadsters, hackneys, and ponies. In the hackneys, to carry 15 stones, Mr. Bailiffe's "Flora" is a clever animal, and won the only strong class of 12. The 2d prize, Mr. Clarkson's "Flora,"

is a sweet goer. The 12-stone hackneys brought out Mr. Lovell's neat "Woodbine" and 14 others, including a good 2d, the property of Mr. Bowman, Ripon. Of the 22 ponies, 12½ hands, 12 were capital fellows. Mr. Stephenson's "Harlequin," a roan, the 1st prize, can carry any weight. The 2d, a stylish chestnut, from Kirton Lindsey, is by an Arabian. Some commendations were due in this class. In the children's ponies the prize, "Tommy," is a miniature horse, perfect in form and pace.

The 2-year-old hunters were 14. Mr. Myas' 1st prize, "Coastguard," and Mr. Mason's 2d prize, are promising geldings. Of the 25 3-year-old hunters brought out Mr. Armstrong's "Banker," Mr. Hepworth's "Portland," and Sir G. Cholmley's "King." "Banker" was the Wolverhampton horse, and rolls as he moves; still he is a grand horse. "Portland" was 1st 2-year-old at Wakefield, and commended at Driffield. He is stylish, and will go on improving. The "King," the winner at Driffield, is not quite hunting-like, and his action is only moderate. The hunting fillies, 3-year-old, were very few, but the 4-year-old hunters made a grand parade of 32. At Wolverhampton there were only 16 in this class. Mr. Nessfield's "Geoff" won, and cleverly. He is the best goer in the field, and A 1 as a horse, according to our measure. The 2d, Mr. Brunton's "Joe Bennett," is a magnificent animal, and he stands next to "Nobility," whom, though he did not get a place here, we have marked as the finest galloper in the class. He was 2d at Brigg. The 3d horse, Mr. Hornby's "Spellahoe," does not stand well, but goes, and was good enough to take a 1st at Driffield. "Dandy," Sir G. Cholmley's 3-year-old winner last year, did not this year come to the mark; and "Tancredi," a winner at Brigg, is a showy horse, with fine flat legs, and moves well.

The Bramham Moor Cup, of 50 gs., £20 second, £10 third, for 5-year-old and upwards geldings, went to Mr. Bayley's "Banner Bearer (Mr. Booth's Wolverhampton winner), Mr. Barkworth taking 2d with "Pelham," a rather common-necked horse, but a mover; Mr. Jewetson's "Lyreton" coming 3d. "Pelham" was a Driffield's prize-taker, and could also "go." There were 28 in this class.

For the York and Ainsty Cup, value 50 gs., 35 animals contended, and the contest was between Mr. Bayley's "Borderer" (Mr. Booth's Oxford prize horse last year) and Mr. Welfitt's "Loiterer," so celebrated now in showing history. "Loiterer" won the cup at Wakefield in 1870, and was beat at Wolverhampton by the Earl of Coventry's "Bird on the Wing." "Loiterer" is nine years old, and now beats "Borderer," and Mr. Hornby's lively "Lioness," 3d; also "Marmalade," "Lothair," "Gamester," and "Sam Weller," the Driffield cup horse for light weights. "Loiterer's" head and neck are not put on properly, and he has no behaviour in hand; still he has rare legs and substance. He could not get through dirt at Wolverhampton, where he did better, and beats "Borderer." His luck is in Yorkshire. He is a great enigma of the year certainly. "Borderer" did not seem drawn out fine enough, to our eye, on this occasion.

In the class of hunters (tenant-farmers), for £60, £30, and £10 prizes, 54 entries were made, and nearly all appeared. Horses entered in other classes were allowed here, and Mr. Brunton and Mr. Hornby, the winners of the 2d and 3d in the 4-year-old hunters, were selected for 1st and 2d prizes—Mr. Letts' 1st prize 4-year-old, "Nelly," taking 3d prize, and Mr. G. Ringrove's 5-year-old, "Willerby," the 4th prize. To criticise this exhibition in detail is impossible; it is sufficient to say, that in this and the two previous classes upwards of 100 of the best hunters in the kingdom were brought into the ring. This one feature made the York show something to see and to remember.

SHEEP.

The show of sheep comprised 113 entries, of which 55 were Leicesters. The improved Leicester is a specialty of Yorkshire, and the defeat of the Yorkshire sheep at Wolverhampton has put the "edge on" the breeders: and we had here 11 competitors with 33 entries, in the shearling ram class, against five exhibitors at Wolverhampton. We never saw so uniformly good a lot. Every sheep was a specimen of a family, and noticeable as representing a distinguished flock. The well known names of Horton, Kendall, Simpson, Tindall, Riley, Jordan, Hutchinson, and Wrangham completed a strong team for Yorkshire. Against these were pitted Mr. Cresswell, of Ravenstone, and Mr. Turner, of Uppingham. Mr. Borton took 1st and 2d in the class, and Mr. Turner's Royal prize sheep did not attain a commendation. As no other sheep did, we presume the merit was generally so great that it was unwise to make any distinction amongst the unsuccessful. Capital animals were shown in this class by Mr. Hutchinson and Mr. Jordan. Mr. Jordan's 2d prize Bridlington sheep was very good. Mr. Turner's Royal prize sheep, though defeated, was not disgraced; he is the style of sheep many admire. Mr. Riley's 2d prize Easingwold and Driffield sheep are useful animals. Mr. Hutchinson's Thirsk prize sheep beat Mr. Borton there and Mr. Riley at Easingwold, and was greatly fancied here by a numerous party. Mr. Simpson's Bridlington shearling was a fine upstanding sheep.

The aged rams were also a good class of 16. Here, again, Mr. Borton took double honours, beating Messrs. Turner, Cresswell, Hutchinson, and Riley. After the judgment in favour of Mr. Borton in the previous class, this award was a necessity; the 1st and 2d are, however, grand sheep. So are Mr. Turner's and Mr. Hutchinson's, after their kind, for they are distinct types. Mr. Turner's sheep have true Leicester form, Mr. Borton's excel in quality and style, and Mr. Hutchinson's have substance and wealth. Mr. Riley's 2d prize Easingwold and Driffield sheep, and Mr. Hutchinson's Easingwold 1st, are very good animals, but they succumbed to Mr. Borton's Bridlington and Driffield prize sheep.

The *Leicester Shearling Gimmers* were a small class of fine pens. Competitors: Hutchinson, Riley, Tindall, Knowles, and Borton. Again Mr. Borton's star was in the ascendant, and he took 1st place, and Mr. Hutchinson's Royal 1st prize was placed 3d, and a pen of Mr. Tindall's, Malton, 2d. Here, again, Wolverhampton ruling was turned over, and something more. After the ram awards, it was, however, consistent, as far as Mr. Borton's pen was concerned; but few would have placed Mr. Tindall before Mr. Hutchinson. Mr. T.'s gimmers may be types of pure Leicesters, *i.e.*, pure, but they are coarse; but they are also pure in the sense of being equally free from every approachment that usually attaches to the modern Leicester. They go back to what Leicesters were 40 years ago, and are deficient in bone, wool, and lean mutton. They have *petite* heads and *petite* frames, and to make them prize specimens of the Leicester is certainly moving crablike—backwards. Mr. Borton's gimmers are finely drawn as they need be; a shade more would bring them into the category of the ornamental rather than the useful.

In the *Lincoln Classes*, 19 shearling and 10 aged rams appeared. Mr. Cartwright showed three grand shearlings, and he scored 1st prize with his Wolverhampton 2d prize; Mr. Wright coming 2d, with a sheep that took 2d prize at Brigg, but was not shown at the Royal. Mr. Dudding obtained 3d prize, with a sheep that was 2d at the same place at Wolverhampton; while Mr. Marshall's 1st at Wolverhampton sheep was here unnoticed, even by a commendation. So much for the uncertainties of the show ring! A 1st prize Royal winner unworthy of notice altogether is an anomaly.

In the aged rams, Mr. Wright took 1st, and Messrs. Dudding 2d. At the Royal (in Mr. Wright's absence), Mr. Dudding took 1st, with this sheep; Mr. Wright won also at Brigg a few days ago.

The *Lincoln Gimmers*, strange to say, were a stronger class than the Leicesters—there being nine pens. Mr. Clarke's gimmers belonging to Mr. Pears, were 3d at the Royal, with a Wolverhampton 2d sheep Gunnell, who did not show here; and by Mr. Cartwright, who was 2d there, and in no place here—another contrary judgment! Moreover, the 2d pen here, Mr. Clarke's, beat the present 1st prize pen at Brigg.

That *Shropshire Downs* are little known in Yorkshire, and competition was small, and merit not excessive. In shearling rams Lords Wenlock and Chesham took 1st and 2d prizes respectively, with sheep that were unnoticed at Wolverhampton. In aged rams the same noblemen took 1st prize; and Mr. Gimmers Lord Chesham took the 1st prize, and Lord Wenlock the 2d in a class of three competitors. In the mountain sheep the competition was not worthy of notice.

PIGS.

The pig competition at the Yorkshire is always close and exciting, even if not numerous. On this occasion, however, every class was well represented. The total entries were 107. Mr. Peter Eden, of Salford, and Messrs. Duckering, of Kirton Lindsey, are the giants of these days in the pig breeding and showing department. In boars of the large breed, we have, on this occasion, Mr. P. Eden 1st, and Messrs. Duckering 2d; in sows of large breed, Messrs. Duckering come 1st, and Mr. Peter Eden 2d. Finer animals than all these cannot be found, and it is not surprising that they vary in position at different meetings.

In boars of small breed and sows of any breed, Mr. Eden carried away the 1st honours, while in sows of small breed and sows of black breed, Messrs. Duckering took 1sts, and 2d for sows of any breed, leaving only the 2d prize for small white sows and 2d for black sows to Mr. Jas. Rose-Royds; the prizes for black boars to the West Riding Asylum and Mr. C. R. N. Beswicke-Royds, and 1st and 2d for boars not qualified for other classes to Mr. Ambler, Halifax, and Mr. John Umpleby, Leeds.

While the large boar of Mr. Eden is possibly unequalled, his boar of the small breed, and Messrs. Duckering's sow of the small breed, are, in our eyes, the gems of the yard. In section 8, for pigs not exceeding 12 months, there was good competition in all the seven classes. Young animals it would be superfluous to criticise in detail, as mother's milk and management are the great agents in getting up piglings. The systematic methods of Messrs. Eden and Duckering, under which every artificial aid is brought to bear in protecting and feeding the infant animals, and by which they are enabled to raise large litters without losing a tail, much less, as is usual on the farm, half the litter by accident or hunger—gives them great advantage. Thus out of 14 awards they take seven in section 8. In young boars of large breed Mr. Rudsdale, Yarm, took 1st and 2d, and also 1st for young sows of large breed. In the other young classes Mr. Beswicke-Royds got 2d for small white sows; Mr. Hutchinson, York, 2d for small black sows, for a very neat one; Mr. Walton, Halifax, 1st in the same class, and Mr. Knowles 2d for a capital young black boar. Of the other prizes two 1sts and two 2ds went to Mr. P. Eden, and two 1sts and one 2d to Messrs. Duckering. In the fine class of three store pigs under nine months old, Messrs. Duckering had two strings to their bow, and they secured the 1st prize over their great rival, Mr. P. Eden, who had only one entry, and achieved the 2d place. On the whole the pig contests were very interesting.

The classes were not laden with rubbish; as in sheep the exhibits generally were from well-known stocks, and the competition was very close, as is always the case in a select field.

The *Wool* prizes went to the districts of Wetherby and Thirsk, Mr. Matthew Tomlinson, Cowthorpe, taking 1st, and Mr. Barrowby, Thirsk, 2d and 3d. Mr. Barrowby is an old winner. They were fine specimens of fleece, we think. This show explains why the best hog wool has been sold at 28s. per stone at Wetherby and Ripon during the present season.

The following is the list of awards in the several classes:—

CATTLE.

SHORTHORNS.

1. Bulls any age above three years old—1st, T. Stamper, Oswaldkirk; 2d, Marquis of Exeter, Stamford; 3d, J. Knowles, Wetherby.

2. Bulls above two and not exceeding three years old.—1st, W. Linton, Sheriff Hutton; 2d, J. Outhwaite, Catterick; 3d, Lady Pigot, Branches Park.

3. Bulls above one and not exceeding two years old.—1st, Sir G. O. Wombwell, Bart.; 2d, Lieut.-Col. J. Reeve, Grantham; 3d, G. Mann, Doncaster.

4. Bull calves, above five and not exceeding twelve months old.—1st, Messrs. Dudding, Wragby; 2d, W. Linton, York; 3d, Major Stapylton, Darlington.

5. Cows of any age above three years old, in calf or milk.—1st, J. How, Huntington; 2d, John Outhwaite, Catterick; 3d, R. Emerson, jun., Darlington.

6. Heifers, not exceeding three years old, in calf or in milk.—1st, F. J. S. Foljambe, M.P., Worksop; 2d, R. Teasant, Leeds; 3d, J. How, Bromefield.

7. Heifers not exceeding two years old.—1st, J. R. Siogleton, Great Givendale; 2d, F. J. S. Foljambe, M.P.; 3d, J. How.

8. Heifer calves, above five and not exceeding twelve months old.—1st, R. Stratton, Swindon; 2d, Lady Pigot; 3d, W. R. Bromet.

Silver Cup to the best Shorthorn in any of the foregoing classes.—W. Linton, Sheriff Hutton.

DAIRY CATTLE.

9. Cow for dairy purposes.—1st, W. Briggs, Selby; 2d, T. Statter, jun., Stand Hall.

10. Alderney, Jersey, or Guernsey, Cow or Heifer, in calf or milk.—1st and 2d, C. Marsden, Doncaster.

SHEEP.

LEICESTER.

11. Shearling Rams.—1st, 2d, and 3d, J. Borton, Malton.

12. Rams of any other age.—1st and 2d, J. Borton; 3d, E. Riley, Beverley.

13. Pens of 5 Shearling Gimmers.—1st, J. Borton; 2d, T. H. Hutchinson, Catterick; 3d, J. & E. Tindall, Killington, York.

LINCOLN.

14. Shearling Rams.—1st, T. Cartwright, Dunstan Pillar, Lincoln; 2d, R. Wright, Nocton, Lincoln; 3d, Messrs. Dudding, Wragby.

15. Rams of any other age.—1st, R. Wright, Nocton; 2d, Messrs. Dudding.

16. Pens of 5 Shearling Gimmers.—1st, J. Pears, Mere, Lincoln; 2d, C. Clarke, Sleaford.

SHROPSHIRE DOWN.

17. Shearling Rams.—1st, Lord Wenlock, Escrick Park, York; 2d and 3d, Lord Chesham, Latimer, Bucks.

18. Rams of any other age.—1st, Lord Wenlock; 2d, Lord Chesham.

19. Pens of 5 Shearling Gimmers.—1st, Lord Chesham; 2d, Lord Wenlock.

Silver Goblet for the best Ram exhibited in Classes 17 and 18; Lord Wenlock.

MOUNTAIN.

20. Rams of any age, of the Lonk breed.—B. Dobson, Ilkley.

21. Rams of any other Mountain breed.—W. Rudsdale, Yarm.

PIGS.

TWELVE MONTHS OLD AND UPWARDS.

22. Boars, large breed.—1st, P. Eden, Salford; 2d, R. E. Duckering & Son, Northorpe.

23. Sows, large breed, in pig or milk.—1st, R. E. Duckering & Son; 2d, P. Eden.

24. Boars, small breed.—1st, P. Eden; 2d, C. R. N. Beswicke-Royds, Roydsdale.

25. Sows, small breed, in pig or milk.—1st, R. E. Duckering & Son; 2d, C. R. N. Beswicke-Royds.

26. Boars, black or Berkshire breed.—1st, West Riding Asylum, Wakefield; 2d, H. Crossley, Halifax.

27. Sows, black or Berkshire breed, in pig or milk.—1st, R. E. Duckering & Son; 2d, C. R. N. Beswicke-Royds.

28. Boars of any breed, not qualified to compete in Classes 22, 24, and 26.—1st, F. Ambler, Halifax; 2d, J. Umpleby, Leeds.

29. Sows of any breed, in pig or milk, not qualified to compete in Classes 23, 25, and 27.—1st, P. Eden; 2d, R. E. Duckering & Son.

NOT EXCEEDING TWELVE MONTHS OLD.

30. Boars of large breed.—1st and 2d, W. Rudsdale, Yarm.

31. Sows of large breed.—1st, Wm. Rudsdale, Yarm; 2d, R. E. Duckering & Son.

32. Boars of small breed.—1st and 2d, P. Eden.

33. Sows of small breed.—1st, P. Eden; 2d, C. R. N. Beswicke-Royds.

34. Boars, black or Berkshire breed.—1st, R. E. Duckering & Son; 2d, J. Knowles, Wetherby.

35. Sows, black or Berkshire breed.—1st, F. Walton, Halifax; 2d, G. Hutchinson, York.

36. Pen of 3 Store Pigs from any breed, from 4 to 9 months old.—1st, R. E. Duckering & Son; 2d, P. Eden.

HORSES.

FOR BREEDING.

37. Stallions, thorough-bred, for getting weight-carrying

Hunters.—1st, A. Beaumont, Huddersfield; 2d, J. Casson, Burgh-by-Sands, Carlisle; 3d, H. S. Constable, Hull.

38. Stallions for getting Coach Horses.—1st, H. Laverack, Brough; 2d, J. Ward, York.

39. Stallions for getting Roadsters.—1st, J. Leake, Drewton; 2d, J. Crompton, Burton Agnes.

40. Stallions for getting Agricultural Horses.—1st, J. Forshaw, Leeds; 2d, C. Sharpley, Louth; 3d, S. Barker, Doncaster.

41. Stallions for getting Dray Horses.—1st, R. Marshall, Hull; 2d, W. Storey, Sneath.

42. Brood Mares for Breeding Hunters, with Foals sucking.—1st, R. Spraggon, Rufforton; 2d, T. H. Miller, Stockton; 3d, H. S. Constable, Hull.

43. Mares for breeding Hunters, without a Foal, but stinted to a thorough-bred horse.—1st, J. S. Dayrell, West Ayton; 2d, J. T. Robinson, Ghirla.

44. Brood Mares for breeding Coach Horses, with foals sucking.—1st, J. Reader, York; 2d, W. L. Robinson, Thormanby; 3d, R. Robinson, Bedale.

45. Brood Mares for breeding Roadsters, with foals sucking.—1st, R. Williamson, Ripon; 2d, Mrs. A. Cook, Pocklington.

46. Brood Mares for breeding Agricultural Horses, with foals sucking.—1st, W. Bramley, Amcotts; 2d, W. Banks, Howden; 3d, T. Statter, jun., Whitfield.

For Agricultural Purposes.

47. Two-year-old Agricultural Geldings or Fillies.—1st, G. Robson, Easingwold; 2d, W. Walker, Scarborough.

48. Three-year-old Agricultural Geldings or Fillies.—1st, Ann Hedden, Thirsk; 2d, T. Statter, jun., Whitfield.

49. Four-year-old and upwards Agricultural Geldings or Fillies.—1st, E. Crowe, Downham Market; 2d and 3d, C. W. Brierley, Manchester.

Coach Horses.

50. Two-year-old Geldings or Fillies.—1st, G. F. Wormald, Kirby Moorside; 2d, H. Pettinger, Easingwold; 3d, John Stephenson, Hull.

51. Three-year-old Geldings or Fillies.—1st and 2d, T. Darrell, West Ayton, York; 3d, J. Johnson, Driffield.

Roadsters, Hackneys, and Ponies.

52. Hackney or Roadster, any age or sex, equal to carry 15 stones, W. Lovell, Ripon; 2d, R. M. Bowman, Ripon.

54. Ponies, any age or sex, not less than 12½ and not exceeding 14½ hands high.—1st, W. Stephenson, Hull; 2d, W. Little, Kirton Lindsey; 3d, E. Dixon, York.

55. Ponies, any age or sex, not exceeding 12½ hands high, suitable for children, to be ridden in the ring by boys under 15 years of age.—1st, T. Howdle, Hull; 2d, J. Roecliffe, York; 3d, W. Routledge, York.

Hunters.

56. Two-year-old Geldings or Fillies.—1st, W. Myas, Hull; 2d, J. Marwood, Ripon; 3d, Sir Cu. Cholmley, Bart.

57. Three-year-old Geldings.—1st, W. Armstrong, Kendal; 2d, J. B. Barkworth, Brough; 3d, Sir G. Cholmley, Bart.

58. Three-year-old Fillies.—1st, J. B. Darnton Catterick; 2d, Wm. Green, York.

59. Four-year-old Geldings.—1st, R. Nessfield, Scarborough; 2d, R. Branton, Middlesborough; 3d, B. Horsley, Gauton.

60. Four-year-old Fillies.—1st, J. Lett, York; 2d, C. Rose, Malton; 3d, R. Inge, Pocklington.

61. Geldings or Mares, five years old and upwards, and qualified to carry at least 15 stones, with hounds, the Bramham Moor Hunt Cup.—1st, T. H. D. Bayly, Ollerton; 2d, J. B. Barkworth, Raywell, Brough; 3d, H. Jewison, York.

62. Geldings or Mares, five years old and upwards, and qualified to carry not less than 12 stones with hounds, the York and Ainsty Hunt Cup.—1st, T. H. D. Bayly, Ollerton; 2d, S. J. Welfitt, Louth; 3d, E. Hornby, Ganton.

63. Hunting Geldings or Mares, any age from three years old off to five years old off, *bond fide* the property of tenant-farmers in the county of York, who are not licensed horse dealers.—1st and 2d, R. Branton, Marton; 3d, J. Lett, York; 4th, G. Ringrose, Ganton.

Judges.—Cattle: H. Aylmer, Stoke Ferry; J. Douglas, Drem; M. Savidge, Chipping Norton.—Long-woolled Sheep: S. Jefferson, Winchcomb; W. Bowman, Lincoln; J. Turner, Ilcley.—Short-woolled Sheep, and Pigs: S. Bruce, Eynsham; T. Atherton, Liverpool; J. Stephenson, Woburn.—Horses (Hunters and Roadsters): J. N. Maine, Melrose, N. B.; T. Burnham, Bedford; E. Paddison, Lincoln. Coaching and Agricultural: J. Farrell, Durham; S. Robson, Louth; W. W. Hawdon, Durham.

Farm Memoranda.

SPALDING.—In this neighbourhood we noticed Peas being carted, Oats being cut, and in two cases Wheat being mown, on Tuesday, the 8th inst. The present hot weather will speedily make harvest general. ED.

ISLE OF ELY. — We have had a long continuance of cheerless, rainy weather, and it is hard to realise the fact that August is here, for we cannot conceive that summer is rapidly passing away, and with scarcely any real summer weather. Rain and cold have prevailed for many weeks, and have occasioned considerable anxiety as to their effect upon the harvest. Already the fields are whitening to the sickle, and the present week will scarcely close without some early Oats being cut. But it must be the end of another week, if not later, ere the Wheats will be ready for the sickle. The Wheat crops are not generally satisfactory. Upon the gravelly soils, where the bulk is not too great, there is a brightness and kindness in their appearance, which we think indicates both an average yield and quality, but on some of the black and deeper soiled lands, where the crop is heavy especially, there are signs of blight and mildew to a fearful extent, and there must in many instances be a deficient yield, and an inferior quality. Weather and warmth, similar to what has been experienced during the last three days, will do much to preserve the crops from further ruin. A return to showery weather may be disastrous. Oats and Barley are heavy crops, and appear likely to produce largely. Beans are bulky, but infested with fly, but to what extent they may be injured it is difficult at present to determine. Potatos were largely planted in the spring, but the continued rains have encouraged disease. We fear the crop must be seriously injured. There is no trade for them at present, buyers being afraid to speculate. Grass keeping is plentiful, and the prospect of the root crops highly encouraging. Sheep and cattle both fat and lean, sell at extravagant prices, much to the chagrin of the consumers. The corn trade is ruled by the barometer; as the one rises the other falls. *Your Fen Reporter, Aug. 2.*

Miscellaneous.

BUTTER FROM MILK.—With the view of learning the amount of butter to be obtained from a given quantity of milk, I have recently tried the following experiment at my creamery, in Onondago County, N.Y., where I receive milk from 300 cows. The milk delivered at the factory on Saturday evening, July 30, and Sunday morning, July 31, amounting to 5729 lb., as soon as received was run into deep cooler pails, and these were set into the tank of spring water. The temperature of this water is maintained uniform, at about 53°, by the introduction of an inch stream of water from the spring. In this vat the pails remained for about 30 hours, when they were removed, in order that by a free exposure to the atmosphere the milk might be soured. It might have produced a better result if the pails had been allowed to remain immersed in the water until the milk became loppered; but we feared that so long an exposure of the milk and cream to such a degree of cold would cause a bitterness of flavour to the cream and the butter made therefrom. When about 48 hours old, the milk having soured and thickened, the cream was removed and kept until the next day. On Wednesday churning was done, in large dash churns, operated by steam-power. From this 5729 lb. of milk there was produced 232 lb. of butter. This shows an average of 24.69 lb. of milk as being required for a pound of butter. The closest estimate in the opinion generally held, that two-and-a-half times as much milk is used in making a pound of butter as in producing a pound of cheese. At the season of the year above named a yield of 1 lb. of cured cheese from 10 lb. of milk is very satisfactory. This would have produced 573 lb. of cheese from the milk used in this experiment, which gave me 232 lb. of butter. Cheese at that time was worth 14 cents a pound. Butter, to pay as well as cheese at this price, would need to sell at fully 35 cents a pound, allowing that the material used in making and packing butter cost one-half cent per pound more than those required for cheese. From this loppered milk, which in my case went to the pigs, there is sometimes made a kind of cheese, used mainly by the German Jews. The curd is heated to a high temperature, is not salted, but is placed in paper bags holding about half a pound, and subjected to moderate and long-continued pressure. When removed from this pressure the cheese is cone-shaped, two sides being flattened; salt is rubbed upon the outside, and the curing is made in a cool damp place, as is the case with Limburg cheese. There is considerable profit in this kind of cheese, and if there was a large demand, the prejudice of the Jews will allow them to eat only that which Jewish hands have made. *American Paper.*

The Week's Work.

AUGUST 12.—*Autumn Turnip Sowing.*—As the work of corn harvest advances, the land may be ploughed close up to the stooks, and, as the stooks are ready for the stackyard, the narrow strips on which they stood are next ploughed, and the sowing of the autumn crop proceeds. In front may be seen the reaping-machine, with the stooks rising up close to each other, but as wide between the rows as can be, for the greater breadth of tillage. No sooner are the stooks up than the whole force of tillage implements now in use is brought to bear. The greater part is now grown with artificial manure, from 3 cwt. to 5 cwt. of superphosphate, or Turnip manure being drilled in along with about 4 lb. of Turnip seed per acre, and as the land is generally clean, the work, although heavy and expeditious is simple. But to this there are here and there exceptions, where the old practice of gathering and burning weeds, and the carting out of farmyard manure, gives variety to the practice. In dry weather the liquid-manure drill should invariably be used with a plentiful supply of water, and if the seed is got in with a sufficiency of sap it braids rapidly, and soon gets out of reach of the fly from the temperature of the land in our southern counties. Much of the success of growing autumn Turnips depends upon this high temperature of the land, and the getting in the seed with plenty of sap.

The expedients possible in a wet harvest appear from the following note by Mr. Hallett, of Brighton, written 11 years ago:—

"On the three days, August 30, 31, and September 1, expecting the wet weather to continue, I had 30 acres of Wheat reaped and placed under cover in barns, hovels, cattle and implement sheds, &c., — in fact, in everything that had a roof to it,—setting each sheaf upright on the ground, thus exposing the whole of it to the action of the air. Each acre of sheaves occupied an area of 400 superficial feet: roughly speaking, I reached before the close of the year. commence threshing it to-morrow." Had the wet weather continued, the whole might have been removed in a few days, and stacked either out-of-doors or under the same roofs, making room in the former case for 30 acres, and in the latter case for at least 20 acres more. To show that in the extreme case of the weather not permitting the Wheat to be cut dry it might still be saved, I may mention that two waggon-loads of sheaves standing in the field throughout the wet week ending August 25 were carried on that day in the pouring rain and placed under cover. They were then soaked throughout, and are now, September 10, fit to thresh. I had one field of 10 acres dried in the straw on three kilns in a malt-house, each of which was 25 feet square, and contained upwards of an acre of sheaves."

Wheat Harvest progresses. Happily the force of reaping-machines now in the field enables farmers to cut down their crops in time. Where the crop has ripened uniformly, there has been, and will be, no difficulty in determining when to start the reaping-machine, but where ripe and green ears are growing together it will be otherwise. The old rule says, "split the difference."

Notices to Correspondents.

RYE: *L. A. N.* Rye-corn contains in its natural state as to dryness about 11 per cent. of gluten, 51 per cent. of starch, 9 per cent. of sugar and gum, 10 per cent. of husk, 13 per cent. of water. Wheat will contain 16 to 20 per cent. of gluten, 46 to 50 per cent. of starch, 12 per cent. of husk, and 12 to 14 per cent. of water.

STEPHENS' BOOK OF THE FARM: *Erratum.* We find it unfortunately necessary to reprint the following sentences from a notice of this work on p. 1024, in order that their meaning may be understood:—"The soil, therefore, though rewritten, remodelled, and recast, is a new edition, not an altogether new book. There are, however, some subjects which have been remodelled and recast in the light of farming of to-day, since Mr. Stephens began to write. Steam cultivation and artificial manuring, and horse-drawn harvesting machines, have made the work of the ploughman and field-worker very different from what it was. The use of liquid manure from town drainage is likely to be another source of agricultural growth and progress, which will produce a great change over considerable districts in the next quarter of a century. Some of these subjects are fully discussed in the new volume by the author of the 'Book of the Farm;' but we think that the reader will generally be disappointed that his attention is not more fully directed to them. In this, however, perhaps he is unreasonable. It is not Mr. Stephens' plan to 'discuss' so much as study to explain."

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Aug. 7.

The supply of English Beasts is larger, but smaller of foreign, the total number being only a few more than on last Monday. Choice qualities are not plentiful, and consequently not much lower; inferior are a slow trade. There are a few more foreign Sheep, and English about the same as last week. Trade on the whole is not quite so good; however, a fair clearance is effected, and prices are not much reduced. Lambs are unsaleable, at late rates. Calf trade very dull. Our foreign supply consists of 2400 Beasts, 14,200 Sheep, 445 Calves, and 75 Pigs; from Scotland there are 10 Beasts; from Norfolk and Suffolk, 170; and 1339 from the Midland and Home Counties.

			Pigs	3 4—4 8	

Beasts, 3919; Sheep and Lambs, 24,900; Calves, 483; Pigs, 165.

THURSDAY, Aug. 10.

The number of both English and foreign Beasts is smaller than on Thursday last; the demand is active, and a clearance is effected at fully Monday's quotations. The total number of Sheep is smaller; some choicest qualities made rather higher prices; trade closes dull. Good English Lambs are also rather more plentiful and cheaper. There is a slight improvement also in the Calf trade. Our foreign supply consists of 235 Beasts, 5700 Sheep, 300 Calves, and 5 Pigs.

MARK LANE.

WEDNESDAY, Aug. 9.

The Corn Exchange to-day opened and closed quietly. The show of English Wheat was small, but from abroad the arrivals were good. Transactions in all descriptions were restricted, and prices in some instances were easier. Barley was in limited request, on former terms. Malt was dull, but prices were unchanged. There were large supplies of Oats on offer. Trade was inactive, and prices favoured buyers. Beans and Peas were quiet, and prices were with difficulty sustained. Flour experienced a slow sale, at drooping prices.

LIVERPOOL, Aug. 8.—The market was thinly attended. White Wheat brings the full prices of Friday last, but red must be called 1*d.* lower, with a small business. Flour dull, and 6*d.* lower. Beans dull, and in favour of purchasers. Oats and Oatmeal quiet, at late rates. Indian Corn in moderate request, at former prices; mixed, 30*s.* 9*d.* to 31*s.*

SEED MARKET.

The Mark Lane markets were closed on Monday last, in accordance with the provisions of the Banks' Holidays Act. Our seed trade continues in pretty much the position described in our last. Trefoil seed is creeping up in price. For Trifolium there is as yet very little home demand; values must be quoted 2*s.* to 3*s.* per cwt. lower. Samples of new Peas, and also of new winter Oats and Rye, are now coming to hand. Fine Rape seed is, in certain districts, rather scarce; it now meets with a somewhat improved demand. Offers and samples of new French Italian have reached us, but currencies are not yet fixed. Hemp seed is dull. Canary very firm. Other articles are without alteration.

JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

HOPS.

BOROUGH MARKET, Aug. 9.

Messrs. Pattenden & Smith report the market firm and healthy, with a very limited supply of good Hops on offer. Prices unchanged. The latest telegrams from the Continent, as well as from America, are of a very unfavourable character as regards the prospects of the new crop, and prices are daily advancing on the other side in consequence.

COALS.—Aug. 9.

THE BOILER PROBLEM SOLVED.

April 14, 1871. **MANLEY HALL,** MANCHESTER.

GENTLEMEN,—In reply to your letter, I have pleasure in stating that the works executed by your Firm, extending over the last nine years, have proved in all respects satisfactory. During the late severe winter the Boilers have acted efficiently and to my entire satisfaction.

I am, Gentlemen, yours faithfully, SAM MENDEL.

ZOOLOGICAL SOCIETY'S GARDENS,

April 12, 1871. REGENT'S PARK, LONDON, N.W.

GENTLEMEN,—I have much pleasure in adding my testimony in favour of Weeks's Patent Duplex Boiler. It does its work well and satisfactorily, being both economical in fuel and labour, and, in my opinion, cannot be surpassed in heating power, the late severe season having fully tested its capabilities. I may add that the amount of 4-inch piping heated by this one boiler is about 4600 feet.

WM. PASFIELD, Clerk of Works.

GOODWOOD, CHICHESTER, SUSSEX.

April 4, 1871.

GENTLEMEN,—My opinion of your Upright Tubular Boiler remains unaltered, as I have never seen anything to equal it during my experience in gardening. Our new works have given the greatest satisfaction.

I remain, Gentlemen, faithfully yours, GEO. CAMERON,
Gardener to His Grace the Duke of Richmond.

CASTLE GARDENS, CARDIFF.

April 6, 1871.

GENTLEMEN,—I have much pleasure in stating that the Upright Tubular Boiler and Heating Apparatus supplied by you here has in every respect perfectly answered my expectations.

Respectfully yours,
EDWARD N. COX, Gardener to the Marquis of Bute.

KITCHEN GARDENS, BURGHLEY.

May 9, 1871.

The Upright Tubular Boilers set here two years back continue to meet my entire approval. One Boiler is doing the work which usually took *ten*. I have worked these Boilers *sixteen years* in many parts of England, always finding them there when wanted. I may add, if honours and medals were given to Hot-Water Apparatus manufacturers, John Weeks's breast would be covered with distinction. R. GILBERT,

Head Gardener to the Most Noble the Marquis Exeter, of Burghley.

THE GARDENS, WILTON HOUSE.

April 12, 1871.

GENTLEMEN,—It is now ten years since your Upright Tubular Boiler was fixed here, and if gives me great pleasure to be able to say that during that time it has not cost a farthing in alterations or repairs. We have 2000 feet of piping attached to it, which heats 15 early forcing-houses and plant stoves. I find no difficulty in burning any kind of fuel in it, having used nothing but small cinders for some weeks past, with an occasional lump of coke when the weather is severe. During my experience I have proved nearly every kind of boiler, and can with confidence assert that yours is the most powerful and economical, and requires less attention, than any I have tried.

I am, Gentlemen, yours respectfully, THOMAS CHALLIS,
Gardener to the Earl of Pembroke.

THE GARDENS, SEVERN STOKE.

April 10, 1871.

GENTLEMEN,—In reply to your note, I am glad to say that the whole apparatus is in perfect working order, and gives every satisfaction. I have, during the last 10 years, worked a variety of boilers, but for power and economy I have not found one to equal your Upright Tubular; and to surpass it, I am convinced, is an utter impossibility. Therefore, I have much pleasure in adding my testimony to its very superior merit.

I am, truly yours, H. ROWBREE,
Gardener to the Right Hon. the Earl of Coventry.

THE GRANGE, ALRESFORD, HANTS.

April 14, 1871.

GENTLEMEN,—I find your Upright Duplex Tubular Boiler more economical in the consumption of fuel than the old Saddle, and does not require so much labour in stoking. During this last severe winter we were able to bank our fires up at half-past ten, and find the temperature all right in the morning.

I remain, Gentlemen, your obedient servant, ROBERT BAKER,
Gardener to Lord Ashburton.

RUXLEY LODGE.

April 8, 1871.

GENTLEMEN,—The Upright Tubular Boiler which you fixed here, gives entire satisfaction. From my own experience in working your boilers, I have no hesitation in saying that I believe them to be the best boilers in use.

I am, Gentlemen, yours, &c., J. HOWIE,
Gardener to the Right Hon. Lady Foley.

ASHTON COURT, BRISTOL.

April 11, 1871.

GENTLEMEN,—I am happy to state that the Horticultural Buildings erected by you here, during the past nine years, continue to give Sir Greville Smyth and myself every satisfaction. As for the Heating Apparatus, nothing could be more satisfactory, the two boilers at the Court Gardens, fixed in 1862, not having cost one shilling for repairs, and, so far as one can judge, are as sound as when originally fixed. I may further observe that during 40 years' experience as head gardener almost every description of boiler has fallen under my supervision, and without the least hesitation I impartially state that none have equalled Weeks's Upright Tubular. I prefer them with a safety expansion pipe, filled with rainwater, kept clean, and in constant operation. By attention to these rules, I believe they will last for 20 years.

I am, Gentlemen, yours obediently, WILLIAM DODDS,
Gardener to Sir Greville Smyth, Bart.

LEYBOURNE GRANGE, WEST MALLING.

April 6, 1871.

GENTLEMEN,—It gives me much pleasure to inform you of the great satisfaction I have received from your New Tubular Duplex Boiler that you sent me last season. Of all boilers at present in use for heating horticultural structures there is nothing to equal the above for heating power. A boiler of such great power as the Duplex I should think offers great advantages to the successful heating of large public buildings of every description, where a certain amount of heat is often wanted within a very limited space of time. Your Duplex is the key to success.—I remain, Gentlemen, yours truly,

WILLIAM BOWMAN, Gardener to Sir Joseph Hawley, Bart.

THE GARDENS, DRAYTON MANOR.

April 8, 1871.

DEAR SIRS,—Your Upright Tubular Boiler has successfully and economically worked our Forcing department (2540 feet of piping) for upwards of seventeen years, without a single mishap of any kind, and when examined with the view of testing its soundness, about four years ago, it was found thoroughly sound, and to all appearance equal to the like term of years again. During the late severe winter I found no difficulty in maintaining the desired temperatures, and that by banking up the fires at 10.30, as in ordinary seasons. OWEN THOMAS,
Gardener to the Right Hon. Sir Robert Peel, Bart., G.C.B., M.P.

THE GARDENS, BEDDINGTON HOUSE.

GENTLEMEN,—You are at liberty to make use of my name in any way you think proper respecting your Upright Tubular Boiler, as it has given the greatest satisfaction here. I remain, Gentlemen, your obedient servant, THOMAS PENFOLD,
Gardener to the Rev. A. H. Bridges.

STANSTED PARK, EMSWORTH, HANTS.

April 15, 1871.

GENTLEMEN,—I have much pleasure, now that we may consider the winter past, to let you know that your Upright Tubular Boilers have done their work to my entire satisfaction; and if it were necessary for me to make a change, it would only be to substitute the Duplex Compensating for the old Upright Tubular, for I believe the Patent Duplex Compensating Arrangements have made the Upright Tubular Boiler as near to perfection as it is possible to be.

I remain, Gentlemen, yours respectfully, GEORGE THOMPSON,
Gardener to Mrs. Dixon, Stansted Park, Emsworth, Hants.

THE GARDENS, HOOLEY HALL.

April 8, 1871.

SIRS,—Having had your New Duplex Patent Boiler in constant work for the last six months, I have much pleasure in bearing testimony to its great superiority over any other boiler that I am acquainted with. I have found it to be most powerful, quick in its action, very moderate in fuel, and so constructed that it requires very little attention.

I am, Sirs, yours truly, JOHN JACQUES,
Gardener to J. C. P. Cunliffe, Esq.

WIDMORE LODGE, BROMLEY, KENT.

April 18, 1871.

GENTLEMEN,—It is rather out of my line of things to recommend *anything*, but in reference to your inquiry about the Upright Tubular form of Boiler, I may say I am quite satisfied with it. Giving all other inventors and manufacturers of hot-water boilers due praise for trying to meet the growing wants of horticulturists, yet, to Mr. Weeks alone, we, as *gardeners*, have to date the first steps in alleviating the midnight ordeal of young gardeners. The Upright Tubular Boiler has stood the test for years, and even now, as far as my experience goes, there is no other form of boiler equally powerful and so easily stoked.

I remain, Gentlemen, yours respectfully, PETER M'PHAIL,
Gardener to C. Telford, Esq.

THE MOUNT, BISHOPSTOKE, HANTS.

April 24, 1871.

GENTLEMEN,—I have much pleasure in reporting upon the working of your new Duplex Upright Tubular Boiler, and feel that I cannot do better than give a correct statement of its operations. Previous to the removal of the old boilers, our average consumption of fuel was, during winter, about 10 tons per month, and with the new boiler it averages from 5¾ to 5¾ tons, thus saving a little more than 4 tons per month. The quantity of piping heated is about 2300 feet. I may also add that we have a much stronger command of heat in every house and pit than we ever had with the two old boilers, which were of a large size. The whole apparatus now acts most satisfactorily, and further, I, having had upwards of 40 years' experience with almost every description of boiler, pronounce most impartially for the new Upright Tubular.

I am, Gentlemen, your obedient servant, THOS. LOWE.

THE GARDENS HANBURY HALL.

April 10, 1871.

DEAR SIRS,—I am much pleased to to be able to say that the Duplex Boilers you fixed here some time ago do their work well, and need as little care and attention as it is possible for boilers, doing the work they are doing, to need. We have never worked, but for trial, more than one, and that has needed nothing more than to be cleaned once a year. We have power enough to work double, or even treble, the houses we have here at present. I am, Sirs, yours truly. WILLIAM BISHOP.

NORMANHURST COURT, BATTLE.

April 14, 1871.

MESSRS. WEEKS & CO.: GENTLEMEN,—We have one of your No. 5 Upright Tubular Boilers here, heating about 3400 feet 4-in. piping, with little trouble and great satisfaction. I am, Gentlemen, your humble servant, GEO. SMITH.

IWERNE HOUSE, BLANDFORD.

April 11, 1871.

GENTLEMEN,—After twelve months' trial of your Patent Duplex Boilers, I feel perfectly satisfied with them in every way, and believe them capable of doing any amount of work you may require of them; they are very simple, and easy to manage, and a great improvement on your other boilers where only one boiler is required.

I remain, yours most obediently, E. JAMES,
Gardener to Thos. Bowyer Bower, Esq.

HALL PLACE, LEIGH, KENT.

April 14, 1871.

DEAR SIRS,—I give you the liberty of using my name in any way you please that will add weight to your testimonials. Nothing can answer better than your Duplex Upright Tubular Boilers, and I am very pleased with their operations; they act admirably. I could expatiate at some length upon the merits of your old pattern boilers, having worked them for a number of years, but have no doubt that the Duplex arrangement is a valuable improvement. I am, dear Sirs, yours truly,

JAMES KETTLE, Gardener to Samuel Morley, Esq., M.P.

The Gardeners' Chronicle

SATURDAY, AUGUST 19, 1871.

MEETING FOR THE ENSUING WEEK.
THURSDAY, August 24 { Royal Horticultural of Ireland (Autumn Exhibition).

NO persons know better than gardeners how complex and puzzling are the EFFECTS of FROST on VEGETATION. Gardeners see and experience to their cost the most varied effects arising from apparently similar causes. It is in reference to this point that we have pointed out from time to time that the data afforded us by the meteorologist are not sufficient for the purposes of the practical cultivator. A thermometer freely exposed to nocturnal radiation is one thing, a living plant of complex organisation, and placed under similar circumstances, is another. The so-called laws influencing the one are not indeed inoperative in the case of the other, but they are so much modified by other circumstances which the meteorologist, *pur et simple*, can hardly be expected to unravel, that they have only a limited application to the facts of vegetable life. To thoroughly comprehend the injuries inflicted by low temperatures on plants, we require first of all to know what is the nature of the injury, and then how those injurious effects are modified in certain cases and from what causes. It used formerly to be supposed that the mischief was

done by the freezing of the juices of the plant and the tearing asunder of the tissues consequent on the expansion of the watery contents of the tissues as they froze. Recent more exact observations of PRILLIEUX and MER have, however, shown that there is very rarely any rupture of tissue; that ice is comparatively seldom formed in the cells, but rather between them; and that, when any rupture does occur, it takes place in these intercellular spaces, while the cells themselves are intact. Moreover, in most cases the young tissues are destroyed from the operation of the cold, without the formation of any ice at all in the tissues of the plant. To what, then, are we to attribute the injuries we meet with?

The answer which M. MER gives to this question is—drought; that is to say, loss of water and consequent drying of the tissues. The cold contracts the cells, the contraction, which is manifest even to the naked eye, squeezes the liquid contents through the cell-walls into the intercellular passages, there perchance (though rarely) to freeze. Now, then, for the modifying circumstances. In the first line we must put nocturnal radiation. If this go on freely, as it will do if protection be not afforded artificially or naturally, we know to our cost what the consequences will be upon tender stuff: the plant loses its heat, loses its water, shrivels, dies. The duration of the cold must also be taken into consideration. If it last but a short time, comparatively little effect will be produced, and on the resumption of more favourable conditions the plant may recover itself. Another important circumstance, modifying injuriously the action of low temperatures on plants, is the presence of a thin layer of water or dew on the surface of the leaves. When this happens cold acts much more injuriously than when the leaves are dry on the surface. Thus may be explained the greater injuries received by plants in valleys and wet places as contrasted with those on the hill-sides. This also may serve, in part, to explain the greater severity of the action of the frost near the ground than at some few feet above it, in cases where the branches are not protected in some way or another. The air near the soil in valleys is laden with moist vapour which condenses in the form of dew on the plants, and loses much of its heat in the process. Plants in such a situation, then, are covered during the night with drops of water; they are environed by a cold stagnant atmosphere, and they are at the same time exposed for a longer period to night's cooling by radiation than their fellows on the hill tops. Still another and most potent factor in the injuries experienced by plants in consequence of low temperatures, is the exposure to the sun. We have had this spring but too many examples of the effect of a hot sun following on a cold night. Actual frost is not necessary to produce these results. It has been found by experiment that plants placed in a cool atmosphere some degrees above freezing, and then exposed to bright sunlight, perished as if frost-bitten. Clearly, ice in the tissues could not here have been the cause of the injury. Equally obvious is it that such exposure to heat must favour that rapid desiccation on which the ill effects of low temperatures are shown to depend. In connection with this point we may allude to a circumstance mentioned by M. MER, and to which, no doubt, many of our readers could furnish a parallel. In May, 1869, after a hot day, a nursery quarter, stocked with Oaks and Chestnuts, was injured in the course of the night by frost, except on the north-east and south-east aspects. As the nursery was sheltered on all sides by a wood, the exemption of the two portions in question could only be accounted for by the circumstance that the portions in question were not exposed to the sun till after the middle of the morning, so that the water squeezed out by the cold had time to be reabsorbed before the sun's power was felt, and in consequence no desiccation took place. Other causes, which co-operate with, and modify the effects of cold on plants, are the nature of the soil in which they grow, and the consequent variations in humidity, rapidity of heating, slowness of cooling, and the like.

These are some of the circumstances which render the data as furnished us by the meteorologist less directly serviceable than might at first be supposed would be the case.

A CURE for the POTATO DISEASE seems hopeless. Our correspondent "A. D." wishes to relegate the matter once more to scientific authorities. There can be no objection to this, but we fear the results will be one more discomfiture to science. Such maladies seem to elude the grasp of the nicest investigations. The nature of the disease is patent enough, but its cause is still shrouded in mystery or hidden in a maze of speculation. For years science has puzzled over it and practice has striven to explain and vanquish it, and the result is that we seem as helpless and ignorant as ever. No one can certainly say whence it comes, nor whither it goes. Does it fall down a crushing blight from Heaven, or is the Potato shocked, wounded, or bruised by the discharge of an electric battery from the lower regions of the earth. It seems to us as if the tops were hit first, but no sooner does the well-known mark appear on leaf and stem than the seed of the disease seems sown in the tubers as well; and, singularly enough, the result on each is more like a bruise than aught else, as if some force had violently hit or crushed a portion of it, and left the virus of the bruise to spread death and decomposition through the whole of the plant and its produce.

Doubtless if the British Association, the Royal Society, or the Royal Horticultural and Agricultural Societies, or any of the scientific committees and men of science throughout the world, were to set to work to discover the cause and cure of the Potato disease, it would be an object well worthy of their best energies, and if success rewarded their efforts it would be the means of immensely raising the character and the estimate formed of the value of science to the everyday affairs of life. And while it might be worth the while of any and all such institutions to re-investigate the matter, we are of opinion that such cultivators as "A. D.," Mr. FENN, and others would render higher service to Potato culture by directing their energies to the organisation and multiplication of good-keeping early varieties. What are most needed are hardy sorts, that will endure the cold of spring, tuber and grow rapidly, and keep well after they are lifted and stored. It is seldom that the potato disease appears till July; and it surely might be possible to select and raise races of Potatos that could be harvested before the end of that month, and that would keep good for seven or eight months afterwards.

Thus might the main Potato crops be lifted out of danger before the disease appeared. Probably by the adoption of this course the disease might die out, and we might again recur to later sorts if necessary. But if early varieties could be kept almost as well as later sorts, there would be no advantage, but the reverse, in growing the latter.

It would be an immense gain to the country could the Potato grounds be cleared in July or early in August, since the whole of it could be stocked with winter greens, Turnips, Cabbages, Leeks, spring Onions, Broccoli, Lettuces, Endive, Spinach, &c. Two perfect crops would be grown instead of one, or at least a sort of one and a half, which is about all that the most expert croppers can get off the late Potato grounds.

But, of course, the greatest gain would be the salvation of the Potato crop. None but the poor know what the partial and entire loss of this crop is—what pinching hunger, what suffering and want to women and children, it brings into tens of thousands of households. To such, an early crop would bring double food—the Potato safe, and sauce grown in plenty on the same grounds to eat with it. Let the early varieties be instantly harvested, and kept in narrow pits in the earth. Lest the disease should be in the air, pit them; that is, cover with earth, basketful by basketful, as they are taken up. Experience seems to prove that, if not diseased when harvested, they do not contract it afterwards; but upon this point, as also concerning the best keeping early varieties, we invite the opinions of practical correspondents. The matter is one of the greatest moment, the object being to remove a most important article of food out of the way of this most virulent disease, by having it safely stored before it arrives. Such a mode of prevention would be better than cure; and, besides, the cure really seems hopeless, while this appears quite possible.

—— UNDER the name of *ÆCHMEA* MARIÆ REGINA, has appeared at our flower shows during the present summer one of the most beautiful Bromeliaceous plants ever introduced to our gardens. It was first exhibited at the Regent's Park early in July, by its introducer, Mr. WENDLAND, Inspector of the Royal Gardens, Hanover, and received a First-class Certificate, and it was again exhibited a few days later at the Royal Horticultural Society's show at South Kensington, where it also received a First-class Certificate, and, in addition, a silver Medal for its superior excellence and extreme beauty. We are informed that the flowering specimen may still be seen in full beauty at the establishment of Mr. B. S. WILLIAMS, at Holloway, who has arranged with Mr. WENDLAND to receive the entire stock. This handsome plant is of somewhat robust habit. The leaves are 18 inches in length, arranged so as to form a beautiful vase-like plant. The flower-spike rises from the centre, and attains a height of about 2 feet; half the length is clothed with large boat-shaped bracts, some 4 inches long, of an intensely rich rose-pink; the flowers, which are tipped with blue and change to salmon-colour with age, are arranged compactly upon the upper portion of the spike, and materially add to the beauty of this extremely grand plant. The bracts are very persistent, retaining their rich colour in full perfection for several months. This superb plant, when known, cannot but become a universal favourite, and no doubt Mr. WILLIAMS will soon be able to distribute this treasure to the lovers of rich and rare plants, in whose gardens it is sure to find a welcome.

—— We are informed that a meeting of the FLORAL and FRUIT COMMITTEES of the Royal Horticultural Society will be held on Tuesday next at CHISWICK, for the purpose of judging the florists' flowers grown in that establishment for trial, and to inspect the recent alterations in the garden. The Council has, we also learn, invited the exhibitors at the Society's shows to visit the garden on the same day.

—— It is often a matter of surprise, and we may say disgust, to see the wretched ACCOMMODATION provided for the GARDENER and other retainers in some of the establishments of this country. We see a comfortable, often splendid, mansion for the proprietor, while his gardener is lodged in places not so good as the stables, while the "young men" are often lodged in bothies, worse by far than some pigstyes. There has been a manifest improvement in this matter of late years, and it may be some consolation to those who are still miserably housed to know that in certain Government establishments matters are better. The last paragraph of the annual report of the Calcutta Botanic Garden says: "The Curator of the garden is still condemned to live in the house, which has been officially reported unfit for human habitation."

—— A fresh supply of the APPLE-LIKE BODIES on RHODODENDRON FERRUGINEUM has been received from Mr. FERGUSON, and also from Sir W. C. TREVELYAN, who, on ourselves, can find no trace of insect larvæ. It is quite certain that they are not galls, but whether aphides have anything to do with these productions we have no evidence to show. From both quarters we have them now both on the leaves and terminal buds, and in every case we find the surface covered with moulds, which either consists of short asci containing sporidia, or delicate short threads, with oblong conidia. We have, therefore, no hesitation in adhering to our first opinion, that they belong to the same category as the Peach blister. We have had no opportunity of examining perfectly fresh specimens; such like moulds do not bear carriage well, besides being liable to alteration from being confined for one or two days in a closed box. Every one of Mr. FERGUSON'S specimens was examined, and the result was as indicated above. *M. J. B.*

—— From the annual report of the Royal Society of Arts and Sciences of Mauritius for 1870, we learn that the fishermen of that island occasionally suffer severely from the wounds inflicted by a fish locally known as the Laffe, the Synanchia verrucosa of naturalists. It appears that at the base of the dorsal fin is a reservoir of whitish liquid, which is expelled with force when the fish is irritated by contact or pressure, and which, entering the wound caused by the fin, gives rise to excruciating pain, which is relieved by the application of the pounded (leaves?) of a Composite plant, Microrhynchus sarmentosus.

—— Acting on the principle that we derive consolation in our own troubles from the misfortunes of other people, we may call attention to the remarkable letter of M. NAUDIN in another column, and in which he refers to the extreme FLUCTUATIONS in TEMPERATURE at Collioure, in the Eastern Pyrenees. We may infer from this that our own climate is not so much worse than that of other people, and that, as we have often pointed out, the thermometer *per se* is not a fair index of the effect of low temperature on plants. We may incidentally mention that M. NAUDIN has established an experimental garden at Collioure, and those who have it in their power to send seeds for experiment as to acclimatation, or economic uses, cannot do better than send some to this accomplished botanist and conscientious observer.

—— At the request of Mr. BARR the following varieties of ONION were TRIED at SIBBERTOFT, which is 600 feet above the level of the sea, as winter sown, transplanted, and spring sown. The soil is the stiff clay of the upper lias:—

1. *Late White Italian Tripoli Onion.*—It wintered badly, but enough plants were left both to transplant and stand. The transplanted individuals produced some very large Onions, of which specimens were taken to South

Kensington on Wednesday last; those which were not removed stood well, producing some good bulbs, but not so fine as the transplanted ones.

2. *Early White Italian Tripoli.*—Wintered badly, but afterwards stood well. The transplanted individuals bulbed well, were decidedly much earlier, but did not produce such large bulbs as No. 1.

3. *Red Italian Tripoli.*—Wintered badly, but afterwards stood well, and when transplanted produced good fair-sized bulbs.

4. *Giant Globe Modeira.*—Wintered well, and produced good bulbs, whether standing or transplanted.

5. *Red Sallon.*—Wintered admirably, and stood well, producing, whether transplanted or otherwise, good bulbs.

6. *Modeira Santa Anna.*—Wintered well, and produced good bulbs, whether transplanted or otherwise.

7. *Giant Rocco.*—Wintered well, and produced good sound bulbs, but did not succeed when transplanted.

Though the bulbs were in general good, they would doubtless have been much larger had not the plants been attacked at a critical moment by Peronospora destructor, a mould belonging to the same genus with the Potato mould. The result of spring sowing has not been satisfactory, the weather having been unpropitious. Nos. 1 and 2 did not stand the early frosts well, but the latter is decidedly earlier in every case than No. 1, a circumstance about which some doubt was expressed last year at South Kensington. *M. J. B.*

—— Referring, in the House of Commons on Thursday, the 10th inst., to the New Postal Tariff, Mr. Monsell explained, in reply to Mr. Graves, that the delay in bringing the new postal tariff into effect was owing to the magnitude of the alterations required. The large additional work thrown on the Post Office by the proposed changes had rendered necessary an alteration within the Post Office itself, which was being made by the Office of Works with great diligence, but it could not be completed till the second week of September. No less than a thousand officers of the Post Office would have their duties altered by the introduction of the new system, and the apertures of the various letter-boxes in the Post Offices would have to be enlarged. October 5 had been fixed for the commencement of the new system, but it was not without misgivings that so early a date had been named. Of course we shall wait with becoming patience, and the more readily as the Postmaster-General has shown himself by no means averse to make certain necessary changes. The restrictions as to the sample post have frequently been productive of some injustice, and much inconvenience and annoyance to ourselves in the conduct of this journal.

—— The Maximum Temperatures of the Air in England during the week ending August 12, ranged from 86°.7 at Leicester, to 80° at Newcastle-on-Tyne, with a mean for all stations of 84°.9. The Minimum Temperatures in the same country ranged from 54° at Newcastle-on-Tyne to 47° at Hull, with a mean for all of 51°.3. The highest mean temperature was 68°.3 at Blackheath, and the lowest 64°.3 at Hull. The mean for the whole country was 66°.4. At one station only in England rain fell during the week, viz., Birmingham, and the amount recorded there was but 0.01 inch, being in striking contrast to the previous wet period. In Scotland the maximum temperatures ranged from 80° at Leith and Perth to 71°.5 at Greenock, with a mean for all of 76°.6. The minimum temperatures ranged from 57° at Greenock to 49° at Edinburgh, the mean for all stations being 52°.3. The highest mean temperature in Scotland was 65°.6 at Perth, and the lowest 62°.2 at Greenock. Rain fell at Aberdeen and Greenock only, the amount recorded at those places being 0.10 inch and 0.12 inch respectively. (See Mr. Glaisher's Tables, p. 1075.)

—— A fact worthy of notice, relating to the Fertilisation of Flowers, is recorded in the current number of the "Botanical Magazine." A very pretty new Abutilon, raised by Mr. Darwin, from Brazilian seeds, is figured in the periodical in question, under the name of Abutilon Darwinii; and it is stated that, during the early part of the flowering season, it is absolutely sterile with its own pollen, but fertile with the pollen of any other individual of the same species, while later in the season it is capable of self-fertilisation.

—— The history of a species of Vicia, published by Mr. Watson in the "Natural History of the Azores," under the name of Vicia Dennisiana, is both interesting and remarkable. "Chance only appears to have saved it from becoming an extinct species almost immediately after it became known at all." It was found by Mr. T. C. Hunt on the mountains at the east end of the island of San Miguel, growing on damp, earthy precipices; but in one spot only, from which it has since disappeared through a landslip. Mr. Hunt unsuccessfully sought for the plant elsewhere in the same neighbourhood, and no other collector has found it in any of the isles. Mr. Watson preserves the plant in his garden, where it flowers occasionally; but severity of weather and late frosts have once or twice proved nearly fatal to the small stock in hand. As far as we know, therefore, the species, but for human intervention, would have become extinct.

—— With reference to the Culture of Cotton in India, the Acting Superintendent of the Botanic Garden, Calcutta, thus writes in his annual report for 1870-71:—

"It is plain that the results are discouraging, and very different from the expectations formed, and the hopes held out last year. It must be understood that no difficulties were met with in growing fine plants of Cotton. The point where the experiments failed was in the securing the crop. Just as the plants were coming into fine bearing, a rain would come, split all the ripening bolls, and throw the plants anew into vigorous vegetative growth. By the time these were again covered with young bolls, another fall of rain would occur. This is the more disheartering, because during last season the hot weather was more free from showers than is usually the case at Calcutta. The inference would appear to be that the climate of Calcutta is too moist for these perennial Cottons, and that the only chance of securing a crop is with the more rapidly-maturing annual Indian varieties. Perhaps a climate and elevation somewhere about Chota Nagpore remain to be discovered, intermediate between the dry tableland of Berar and the moist delta, which may prove a locality where these high-class exotic Cottons can be cultivated at an economic profit. The experience of this year, moreover, has been very unfavourable to the beautiful hybrid seedling Cottons of Major Trevor Clark. These hybrids do not appear to maintain their characters under cultivation. I suggested formerly that this might be due to their being cross-fertilised in our mixed beds; but Mr. Scott is of opinion, from his observation of these hybrids, that with this degree of care in their culture can they be preserved as distinct varieties."

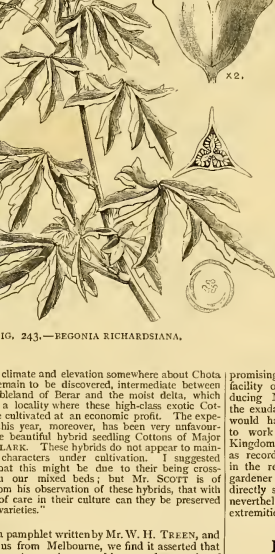

Fig. 243.—Begonia richardsiana.

—— In a pamphlet written by Mr. W. H. Treen, and forwarded us from Melbourne, we find it asserted that the Majetin Apple is not subject to the attacks of the American Blight, on which account it is recommended as a stock for grafting. It is not pretended that the stock confers on the scion any power of resisting the attack of this pest, but simply that the "roots of Apple trees grafted on the Majetin stock will always be entirely free from blight; in fact, all below the graft will be clean." The fact was first noticed in George Lindley's "Guide to the Orchard," but so far as we know, Messrs. Lang & Co., nurserymen, of Melbourne and Ballarat, were the first to turn the fact to good account. These gentlemen appear to have been experimenting on the subject for some years, and in the pamphlet before us they give the following list of Apples nearly blight-proof:—Cardinal, Constantinople, Cornish Gilliflower, Devonshire Quarrenden, Duchess of Oldenburg, Grand Duke Constantine, Gravenstein, Hawley, Irish Peach, London Pippin, Maiden's Blush, Northern Spy, Triomphe de Luxemburg. Other lists are given of Apples only slightly affected, and of others severely infested by the aphis. The result of all these trials is that the Winter Majetin, and perhaps the Northern Spy, are reported on as blight-proof. Assuming the facts as recorded in Mr. Treen's pamphlet to be correct, we should be glad to have the experience of our own cultivators upon a point of so much moment. Mr. Treen, it further appears, anxious to ascertain to what causes this exemption of the Majetin Apple was due, submitted a specimen and one of the Crab to the Government analyst at Melbourne for analysis. The result of the analysis, as given by Mr. Johnson, "show that the Majetin Apple tree, which is free from blight, is a much larger consumer of lime, and it is most probably to the presence of this substance that such immunity from blight is due. The Crab, on the contrary, seems to have absorbed a much greater quantity of clayey matters, which have not been able to protect from the attack of these insects." The ash of the Majetin, according to the analysis given, contains over 50 per cent. of lime, while the Crab contains but quite 23 per cent. These results strike us with some astonishment. Of course we do not in the least degree impute bad faith to any one, but before we can place implicit credence in them we should like to see the experiments very carefully repeated with Apples of various kinds grown on different soils. If from these analyses, such as those just alluded to, and carried out on a scale large enough to preclude or compensate accidental errors, similar results are obtained, the boon to fruit growers will be enormous—greater even, we will venture to say, than the discovery of a blight-proof Apple. We earnestly commend the subject to the notice of fruit cultivators, and of those chemists interested in horticultural pursuits.

—— A remark in the Report of the Botanic Garden, Calcutta, for 1870—71, which is now before us, adds confirmation to the oft expressed opinion, that, in order to be really profitable, a plant, no matter what its valuable properties, must be cultivated. Fibre must be procured by the ton to be remunerative. A wild Nettle may appear to be abundant in the Sikkim jungles, yet it is found practically a serious matter to get in 60 lb. of dry fibre. Any wild plant can only be economically valuable if it can be grown at small cost as a dense crop. Excellence in fibre, moreover, we are told, is not the most necessary condition that a fibrous plant has to satisfy in order to recommend it as likely to be economically valuable. The principal merit of Jute as a valuable fibre is that it can be easily prepared. The Nettle fibres generally will not endure lengthened maceration in water to get rid of the cellular tissue. Some 14 species of the Nettle family have been selected for experiment, all of which are common in lower Sikkim. Of these Villebrunnea appendiculata, a small tree, which may be grown as Osiers are here, seems at present the most promising, from the excellent and easy facility of its preparation. Among these fibre-producing Nettles is mentioned Laportea crenulata, the exudations from which are so virulent that it would hardly be possible to induce any labourers to work with it. Dr. Hadley, in his "Vegetable Kingdom," cites the virulent effects of this plant as recorded by Leschenault de la Tour, and in the report before us we are told that the head gardener at Rungbee protected himself from being directly stung while stripping the fibre, but was seized nevertheless with a violent swelling of the limbs and extremities, which lasted 24 hours with great severity.

New Garden Plants.

Begonia Richardsiana, *sp. n.*

Tuberous, glabrous; stem dwarf, erect, fleshy, with slender branches; leaves obliquely ovate acuminate, bipartite, 5-lobed, the lobes unequal, dentate, one of them elongated, the lateral lobes shorter, teeth few, triangular, the acute sinus projected upwards, discoloured, and setose; stipules carinate oblong-acute setoso-ciliate-dentate; cymes axillary few flowered, bracts broadly ovate caducous; male flowers with two roundate-reniform white sepals; petals none; female fl. 5-lobed, the lobes obovate, unequal, the inner ones smaller, capsule 3-winged, the wings equal, terminating in an obtuse angle above. Hab. Natal.

An elegant little greenhouse plant (fig. 243), with the tuberous fleshy stems and general habit of B. Dregei, but differing altogether in its deeply-cleft leaves, in which respect it would appear to approach closely the B. suffruticosa of Meissner, but from which, according to the description, it differs in several points—notably in the absence of petals. Moreover, the singular puckering of the acute sinus formed by the few coarse

teeth of the leaves, and the transparent bristles developed from these points, are not alluded to in the very careful description of the vegetative organs given in De Candolle's "Prodromus" (xv. 385). The plant is dwarf and densely branched. The stem is fleshy, not at all zigzag as described in subfruticosa, stout below, slender above, of a deep wine-red colour, as are its numerous slender ramifications. The leaves have red petioles, upwards of an inch in length, and a limb 2 inches long, and nearly 1½ inch broad, divided in the line of the petiole into two portions, of which one is again separated into two lobes, the inner of which is much elongated, and the other is cut into three unequal shorter lobes; each lobe has a distinct costa, prominent below, and a less distinct vein parallel with the margin. The persistent stipules are whitish, oblong, keeled towards the point, terminating in a short bristle. The flowers grow in small cymes from the leaf axils near the ends of the branchlets, and are white, the males with two broad or roundish reniform sepals, and no petals, the females with five unequal obovate divisions, and a three-winged ovary,—both forms being developed from the axils of broad, ovate, concave, almost cordiform bracts.

The elegantly branched habit of this pretty shrub, and its close dwarf habit will render it an acquisition among the smaller decorative plants for the greenhouse. It is a native of Natal, whence it was received by James Richards, Esq., of the Royal Horticultural Society, after whom it is named. We believe the stock is in the hands of the Messrs. Veitch & Sons. *T. M.*

BRITISH ASSOCIATION.

THE meeting of the British Association for 1871, in the capital of Scotland, is an event long to be remembered by those who had the good fortune to be present thereat. This cannot be accounted for by reason of any demonstrative welcome, in which previous meetings have been eclipsed, because it is many years since so little of the outward and visible signs of display have been exhibited. Bell-ringing and "banting" are not Scottish institutions, and those functions have reverted to Exeter and Norwich, as gay with flags, and merry with the clangour of bells, found a wonderful contrast in the conspicuous absence of all such accessories in Edinburgh. Neither can it have been from the surpassing interest of the subjects discussed in the sections, for "old members" who have presented themselves annually for many years past, declared the sections to have been "slow." Nor was any particular excitement derived from the President's address, which by infusion of its enthusiasm might have carried its influence through a whole week. Admirable as it might have been in some respects, it failed to produce any excitement, and the only feature remembered by many was the novel expedient of tracing the introduction of vegetation to this earth of ours through the medium of "moss-grown fragments from the ruins of another world." Yet the British Association sitting in "Auld Reekie" has been a memorable event. After so long and dreary a prelude of rain and cloud, fine weather came just when it was wanted for the success of the meeting, and, perhaps more than anything else, contributed to the good humour of everybody, and contributed largely to the satisfaction of visitors. The fine old city itself, and its manifold associations, contributed their share also to the common result, and despite all drawbacks, and the absence of some artificial stimulus, the general results have left their mark behind.

The biologist, leaving the presidential address as dealing chiefly with subjects beyond his sphere, found much compensation in the address of the President of the Biological section. Professor Allan Thomson, after rehearsing the history of the section, its titles and divisions in the past and in the present, passed on to a consideration of the question of liberality to research, and the influence which the British Association had exerted beneficially thereon. Out of £34,500 contributed by the Association to the promotion of scientific research, about £2800 had been devoted to biological purposes. It may be remarked in passing that the absorption of so large an annual grant for one purpose as that hitherto required for the New observatory, is likely to be obviated in future, and there is a hope that no cause of complaint will hereafter be given to those who have thought, and not altogether without reason, that one branch of science had been favoured. Adverting to the wide range of biological science, and the enormous extent of knowledge and research in its various departments, he indicated the danger of confined views on the part of those whose attention is too exclusively directed to the details of one department, or a subdivision of it.

"It is incumbent," he said, "on all those who are desirous of promoting the advance of biological knowledge, to combat the confined views which are apt to be engendered by the too great restriction of study to one department. However much subdivision of labour may often be necessary in the origin, investigation, and elaboration of new facts in our science (and the necessity for such subdivision will necessarily increase as knowledge extends), there must be secured at first, by a wider study of the general principles and some of the details of collateral branches of knowledge, that power of justly comparing and correlating facts which will mature the judgment and exclude partial views. To refer only to one bright example, I may say that it can scarcely be doubted that it is the unequalled variety and extent of knowledge, combined with the faculty of bringing the most varied facts together in new combination, which has enabled Dr. Darwin (whatever may be thought otherwise of his system) to give the greatest impulse which has been felt in our own times to the progress of biological views and thought; and it is most satisfactory to observe the effect which this influence is already producing on the scientific bodies of this country in which the habits of mind perceptible in recent times to the too restricted study of special departments of natural history. I need scarcely remind you that for the proper investigation and judgment of questions in physiology, a full knowledge of anatomy in general, and much of comparative anatomy, of histology and embryology, of organic chemistry and of physics, is indispensable as a preliminary to all successful physiological observation and experiment. The anatomist, again, who would profess to describe rationally and correctly the structure of the human body, must have acquired a knowledge of the principles of morphology and physiology, as also of the comparative anatomy, development, and the must have mastered the intricacies of histological research. The comparative anatomist must be an accomplished embryologist in the whole range of the animal kingdom, or in any single division of it which he professes to cultivate. The zoologist and the botanist must equally found their descriptions and systematic distinctions on morphological, histological, and embryological data. And thus the whole of these departments of biological science are so interwoven and united that the scientific investigation of no one can now be regarded as altogether separate from that of the others. It has been the work of the last 40 years to bring that intimate connection of the biological sciences more and more fully into prominent view, and to infuse its spirit into all scientific investigation."

After more specially alluding to histology and embryology, and the immense progress made in the former since the improvement of the microscope, the professor passed on to the evolution of species, with the following remarks :—

"On the subjects of zoological and botanical classification and anthropology, it would be out of place for me now to make any observations at length. I will only remark, in regard to the first, that the recent progress of research has witnessed a very great modification in the aspect which the affinities of the bodies belonging to these two great kingdoms of Nature bear to each other, and the principles on which in each groups of allied organisms are united together in classification; for, in the first place, the older view has been abandoned that the complication of structure rises in a continually increasing and continuous gradation from one kingdom to the other, and extends in succession from one group to another in either of the kingdoms separately. Evolution into a gradually increasing complexity of structure and function no doubt exists in both, so that types of the highest complexity are lodged in each, accompanied by typical resemblance of the plan of formation of a most interesting nature; but it has become more and more apparent in the progress of morphological research that the different groups in either extend not in touch one another at certain points of greatest resemblance, rather than one continuous line, or even a number of lines, which partially pass each other. Certain simpler bodies of the two kingdoms may thus exhibit the greatest resemblance to each other, until at last the differences between them wholly disappear, and we reach a point of contact at which the properties become almost indistinguishable, as in the remarkable case which Haeckel instances. A fully agree, however, with the view stated by Professor Wyville Thomson in his introductory lecture, that it is not necessary on this account to recognise with Haeckel a third intermediate kingdom, the Volum. Each kingdom presents, in its sphere, a radiating expansion into groups for itself, so that the relations of the two kingdoms might be represented by the divergence of lines spreading in two different directions from a common point. Recent observations on the chorda dorsalis of some Ascidians (or supposed notochord) tend to revive the discussion at one time prevalent, but long in abeyance, as to the possibility of tracing a homology between the Vertebrata and the Invertebrata; and if any should this correspondence be confirmed and extended, it may be expected to modify greatly our present views of zoological affinities and classification, and be an additional proof of the importance of minute and embryological research in such determinations. The recognition of homological resemblance of animals, to which in this country the researches of Owen and Huxley have contributed largely, form one of the most interesting subjects of contemplation in the study of comparative anatomy and zoology in our time; but I must refrain from touching on so seductive and difficult a subject."

The teaching of natural science in schools, and spiritualism, formed the remaining topics of the address, which was received with loud demonstrations of satisfaction.

The botanical papers in the Department of Zoology and Botany were, as a whole, unimportant. Professor Dyer, an abstract of whose paper on the so-called mimicry of plants has been previously given, called attention to plants belonging to different natural orders, and found in widely separated countries, in which the habit and foliage were strikingly alike. He attributed the cause to the action of similar chemical agents; but the chief object of the paper professed to be a protest against using the term "mimicry" in such cases, and the application of that of "pseudomorphs" to such divergences from the normal form in the order or family to which they belong.

Dr. Murie afterwards made a communication on the development of Fungi within the thorax of living Insects. The subject was the remarkable fact that organised vegetable structures being not unfrequently found growing in animals and man, both externally and internally. For the most part these affected the skin, giving rise to several cutaneous diseases. They also flourished in the alimentary canal; and, among others, one peculiar form (Sarcina) had been described by the late Professor Goodsir from the human stomach. In nearly though not all instances where vegetable organisms flourished within the living body, it was in organs where a certain amount of air had free access. It was more difficult, though, to account for the cases where vegetable parasites arose in, so to speak, closed cavities. The instances which he (Dr. Murie) brought forward as coming under his own observation were three in number—viz., a Fungus-like growth in the abdomino-pleural membrane of a kittiwake gull, a great white-crested cockatoo, and a rough-legged buzzard. After a general description of the specimens in question, the author referred to them as in some ways bearing upon those doctrines whereby living organisms were supposed to originate out of the tissues themselves.

The organisms, as figured on the diagrams exhibited, consisted of a pale greenish patch, made up of delicate threads interlaced with elliptical spore-like bodies, somewhat like the Sporotrichum. How the spores, if such they were, were attached was not shown. Dr. Perceval Wright thought that the organism was a Protococcus, and Mr. M. C. Cooke, being appealed to by the President, declared the drawing itself insufficient to determine whether the substance was algoid or fungoid, although evidently it was some low form of vegetable life. Dr. Bastian, believing it to be of very secondary importance what the organisms were, proceeded amongst Bacteria, and other infinitely minute bodies, to develope spontaneous generation.

Dr. Calvert read two papers on an allied subject, "On the Action of Heat on Germ Life," and "On Protoplasmic Life." A number of experiments were described which had been made by the author for the purpose of determining the effect of heat on living organisms. He took a solution of white of egg, and also of gelatine, and of sugar and milk of microscopic life. These solutions were put into little tubes and submitted to temperatures of 100°, 200°, 300°, 400°, and 500° Fahr. It was found that at 100° the living organisms were not at all affected; at 200° they were not affected; at 300° they were still alive—three or four vibrios in each field; and it was only at that that life disappeared. The same solutions were then put on some single slips of glass, dried, some in the air and some at a temperature of 212°, and introduced into tubes. As before, it was only at 400° that life disappeared. By another experiment it appeared that in a fluid where life had been destroyed by heating to 400°, no life was subsequently developed, whereas in one which had been heated to some of the lower temperatures, such development took place. It, said Dr. Calvert, there was such a thing as spontaneous generation, he could not understand why that should not have been life reproduced in his tubes which had been heated to 400°, whilst a little life was reproduced in one heated to 300°, and more in one heated to 200°. It appeared to him that medical men would do well to consider the temperature at which life was destroyed. Admitting that the contagious disease was due to the introduction into the system of a germ of some kind, either vegetable or animal, so far as his experiments went, a temperature of 400° was necessary to destroy such germs on clothing to which they might have become attached.

Mr. John Sadler read a paper on the species of Grimmia (including Schistidium) as represented in the neighbourhood of Edinburgh.

Mr. A. G. More exhibited living plants of Spiranthes gemmipara, from Ireland, where he stated it to be rather plentiful on the one station where it is found. Professor Babington remarked on the interest of this plant, and the probability that only three botanists, himself, Mr. More, and another, had seen this plant in a living and growing condition. Dr. Balfour promised to take charge of the plants with a view to their cultivation, if possible, in the Botanic Garden.

Mr. More made some observations upon Eriophorum alpinum, which was said to be an Irish and Scotch plant; he had traced the Irish record to be a false one, and the Scotch one was so doubtful that he did not hesitate to express the opinion that it was not a British plant at all. Professor Balfour narrated the circumstances connected with the collection of the single Scotch specimen in his herbarium, when he was a young man, of its being confounded with other plants for some years, and ultimately rescued from oblivion. It seemed to be the opinion of botanists present that it is hardly safe to consider it a British plant at all, without further confirmation.

A few other botanical papers were read in the section, but none of them of special interest—J. Birkbeck Nevins "On the Changes which occur in Plants during the Ripening of Seeds;" Professor W. T. Dyer, "On the Climate Anomalies of the Genus Cinchona;" J. Neil Stewart, "Observations on the Intimate Structure of Spiral Ducts in Plants and their Relationship to the Flower;" Prof. Balfour, "On the Cultivation of Ipecacuanha in the Edinburgh Botanic Garden for transmission to India." They had two varieties of the plant in the Botanical Garden, one of which had been cultivated there for 40 years, and the other had just been procured from South America. It was hoped from the union of these two varieties to get a perfect seed, as hitherto they had

not been able to get the perfect seed of the plant, and its propagation was accordingly but slow. Mr. McNab had discovered that by cutting the root numerous new shoots could be obtained, and the plant so propagated much more easily and plentifully. A brief discussion followed, in which Professor Christison, Dr. Cleghorn, and others joined, during which it was suggested that as so many difficulties beset the cultivation and introduction of this plant, that it might have been much better first to have carefully experimented with native Indian plants, such as Tylophora asthmatica and some others, both in India and in this country, as it was by no means certain that a good substitute for Ipecacuanha could not be found in a native plant, without the trouble and risk of naturalising a foreign one.

Dr. Robert Brown also read two short papers, one on "The Flora of Greenland," and the other on "The Geographical Distribution of the Flora of North-West America." Professor Dickson made "some Suggestions on Fruit Classification," and Neil Stewart communicated a paper entitled "An Inquiry into the Function of Colour in Plants; or into its Relationship to the Manner of their Illumination during different Stages of their Development."

Hence it will be seen that the papers on botanical subjects were few, and scarcely of the value or interest that might have been expected during one week's meetings of the British Association. After the last paper was read, members congratulated each other and dispersed, some to their homes, some to the mountains and lakes, and after the great gathering on Thursday all was over. Edinburgh, so meagre of "bunting" as the Association commenced, was gay enough as it dispersed. Wednesday, in honour of Scott, manifested where the heart of Scotland lies hidden. Nearly all Edinburgh was abroad, and the old city was in holiday attire. The modern Athens paid its homage to the mighty dead. The members of the British Association may now anticipate for twelve months the meeting at Brighton on August 14, 1872, under the presidency of Dr. Carpenter, F.R.S., &c.

THE AMATEUR GARDENER.

Propagation of Bedding Plants.—It seems premature to begin to talk of next season's supply of plants for open air culture, almost before the present stock has attained its expected display of flowers, but the experienced amateur knows that it is not so, and that if a strong supply of cuttings is to be had for 1872, they must be taken off and rooted during the present month. Materfamilias, more used to the children's nursery than to that of the garden, is very suspicious of our movements at this time of the year, and expresses discontent at our "poking about" among the bedded exotics, and extending here and there sundry shoots not always destitute of bloom, which we convey to the potting shed. But in this respect the gardener must be resolute of purpose, and rather risk disturbing a little the perfect symmetry of the parterres, than allow the autumn to come upon him without any preparation being made for another year.

We are writing now of those gardeners whose pleasure consists in a large degree in all horticultural manipulations being performed by themselves. We have no sympathy with the large class of well-to-do people who adorn their residences as ladies do their persons, with things ready-made to their hands, and whose wishes are all realised by the effect produced by the outlay of a few pounds at a neighbouring nursery. The feeling of a man whose garden is filled with plants all "struck" by his own hand, or under his eye, is entirely different from that of the wealthy possessor of a brilliant display, for the production of which he has done nothing but pay the money. We question whether the pleasure of the cultivation is not greater than that produced by the crowning success of the flowering season, and this will account for the apparently reckless way in which we decimate our beds in August so as to have under our care a nursery of young stock for next year.

We know it is possible for a gardener to defer propagating till September, or even till the frost comes and robs the garden of its beauty, but then he must have at his command a supply of artificial heat, with appropriate glass houses, by which cuttings may be effectually rooted even during the winter. We write for those whose means or whose wishes do not rise so high as this, but who aim solely at keeping during the cold months what will make their garden gay in the warm ones. The gardeners we contemplate would not entrust the work to a nurseryman, even if they could afford the necessary pecuniary outlay, so they begin now to provide for the future. Very much is gained in filling a bed with exotic plants, if they have attained a good shrubby growth, and are well knotted with terminals ready to break into flower. We all know how long the bedding Geraniums, for instance, and Verbenas, bought by the dozen at a nursery, are before they do much in the flowering way and fill up the vacant spaces in the bed; and this inconvenience is avoided by the amateur striking his cuttings early, and subjecting each of them, when potted, to a process of training for producing an early effect when put out in the spring.

When it is known that most soft-wooded plants, as Geraniums or Pelargoniums, will strike readily if dibbled in the open ground in August, it will be seen that very little trouble is necessary to secure a stock for the future. Last month we visited a relative near the Crystal Palace, who has a large garden, and who kindly furnished us with a collection of cuttings of Zonal Pelargoniums, some of them of the newest kinds. These we planted the next day in an open border, after mixing the soil with a liberal supply of sand. We gave the whole a good watering, and left them to the weather till a month had passed, when, being rooted, they were all safely potted off and housed for future use. Another method, equally successful, but which requires more watching, is to put each cutting at once into the small pot which it is to occupy till the spring comes round. If looked after, and supplied moderately with water, these cuttings will do well, and when once rooted they are safe, and need very little care, except to keep them from damp and frost during the winter.

Many hard-wooded plants, as Roses, require a gentle hotbed for the quick production of roots, or, at the least, a frame or a hand-glass over them. Nothing is more easily propagated than the bedding Calceolarias, for they quickly produce roots, and will survive the hardest frosts if struck under a hand-light and afforded the protection of a mat in sharp weather. As the Calceolaria grows very rapidly when once rooted, we delay the striking operation as long as possible, indeed until the plants ont-of-doors are no longer ornamental. We then strip off the side shoots, trim them up, and dibble in shallow boxes, which are placed under a north wall, bedded up to the edge in the soil of the garden. All that is needed afterwards is the protection mentioned above.

We do not approve of the plan of asking for cuttings of plants except on the principle of reciprocity. When we have given 5*s.* for a new variety, it is not pleasant to be asked for a "bit" of it, unless we can make the same demand on him who begs the favour. This equitable principle being understood, the eyes of the amateur should be kept open as he visits his friends' gardens, and the process of barter may be liberally carried on. But a lover of flowers should be generous in expenditure, according to his means, and not grudge rewarding the clever florist for his skill in raising new varieties of plants. We have no fellow-feeling with those who think that flowers are the last things on which money should be bestowed, and attempt to keep up a stock for amusement or display by boring all their friends and acquaintances for slips or cuttings. This system is as bad as that of never buying an umbrella, but relying on others to defend us from the rain. *H. B.*

FIG. 244.—CROTON (CODIÆUM) HOOKERI (HORT.)

CROTON HOOKERI.

WE are indebted to Messrs. Veitch & Sons for the accompanying illustration (fig. 244) of this beautiful ornamental plant; as also for the following description, which we take from their catalogue: — "Another of the beautiful South Sea Island Crotons, brought home by the late Mr. J. G. Veitch. It forms a handsome compact-growing shrub, with broadly ovate lanceolate leaves, abruptly tapering or rounded at the base. The upper surface of the foliage is of a beautiful dark shining green, broken at the base with a broad blotch of golden-yellow, and with irregular projections of the same colour running from the midrib towards the margin, the midrib being golden-yellow, as are also the young stems and leaf-stalks." It appears to be the var. flavum, described at p. 943 of our volume for 1868.

BAMBOOS.

THERE is no more graceful object in the vegetable kingdom than a fine clump of Bamboos—a good large clump, consisting of from 50 to 100 stems, growing as closely as possible together, and their extremities arching over and pendent, like the drooping foliage of a Weeping Willow, only more openly and far more symmetrically, recalling to mind a plume of lax feathers upon an exceedingly gigantic scale.

Perhaps the very finest of all this group of arborescent grasses is the Bambusa gigantea of the Indo-Chinese countries, which there attains the height of 100 feet, in low, swampy localities, each of the lower joints ranging from 20 inches to 24 inches in length, and as much as 36 inches in circumference. Under

very favourable conditions this superb Bamboo has been known to grow as much as 18 inches in 24 hours; but, rapid as such growth undoubtedly is, it does not equal that of some of the species found in Lower Bengal, as will be noticed in the sequel. At Rangoon the Bambusa gigantea does not attain to more than 70 feet to 80 feet in height, and somewhat over 2 feet in circumference at the base. Introduced into Lower Bengal it further degenerates, so as not to exceed 65 feet or thereabout in height, though the stems still retain sufficient bulk to distinguish them readily from the various species of Bamboo which are there indigenous. As usual, the joints increase in length as the plant grows. Thus Bengal-raised specimens of B. gigantea, averaging 65 feet in height, have a length of joint at the base of about 10 inches, the second joint of 11 inches, the third of 13 inches, the fourth of 14 inches, and the fifth of 15 inches, and so on till an upper joint, in about one-third of the height, will measure about 20 inches long, and still higher about 24 inches; increasing yet more towards the top. The circumference of a joint at the base of the stem will be about 20 inches, the next joint 19 inches, the third and fourth 18 inches, and the fifth 17 inches.

The "tulda bâns" of the natives (B. tulda) is one of the highest-growing Bamboos indigenous to Lower Bengal, and it far exceeds the great Burmese species in rapidity of growth. This Bamboo rises to its full height of about 70 feet in a month or thereabouts, its stems being about a foot in circumference at base. The "bâlcoo bâns" (B. balcooa) equals the "tulda" in height when growing in favourable localities, though not in rapidity of growth. This latter species also abounds in Burma, where it attains a finer development than in Lower Bengal. Under ordinary circumstances, n the latter country, the "bâlcoo bâns" averages from 50 feet to 60 feet in height, with a girth of from 12 inches at the base to 10 inches at the fifth and sixth joint, and with a length of joint at the base of 9 inches to 9 inches, and, of course, more in the upper part. This Bamboo is much prized for its extreme toughness and solidity, and it is consequently preferred to most other kinds for building purposes.

The small Chinese Bamboo, B. sinensis, thrives in Lower Bengal, and is there occasionally used for hedges, having been so employed in Upper Egypt to good hedge, and in the climate of the south of England this species is almost hardy. Left to itself, it grows much as the other species do, and its comparatively diminutive size suits it to adorn gardens and pleasure grounds wherever it grows freely.

No one who has resided even for a brief period in any tropical country can have failed to observe the very numerous purposes to which these most useful plants are habitually applied. To enumerate all or nearly all of them would occupy more space than is here available. I will, therefore, mainly content myself with citing a brief extract from a paper "On the Uses of the Bamboo," which was read before the Botanical Society of Edinburgh, and contributed by Dr. Alexander Hunter, of Madras :—

"The leaves when young and tender are eaten by various animals. The grain is given, in the form of a decoction, as a remedy for fever in cattle (though I should doubt with any effect). The young tender shoots, solid or hollow plant are used for making arrows, while those of the male or solid plant are largely exported to Europe for the making of the tips of fishing rods. The pointed lateral shoots are used when young as pins. The stems are employed for props, palings, roofing, flooring, doors, and blinds. Some houses are built entirely of Bamboo. Paper and cloth are manufactured from it. The tender shoots are used for pickles, and form one of the ingredients of the celebrated Chinese preserve, called "chow-chow." Baskets and boxes of various kinds are made of Bamboo. The lacquered boxes and cups of Burma are deservedly beautiful. Among the uses of the plant were noticed the following : Poles for palanquins, for carrying water, and for pushing boats, floating rafts, swinging poles at feasts, light bullock carts, ladders and fire escapes. Hollow poles for punkas, spear shafts, garden chairs, plant stands, distilling tubes, hookahs, and bows and arrows. The joints are employed for water pails and bottles; also for holding letters, for musical instruments, and for blow-pipes.

The joints are sometimes used, instead of earthen vessels, for cooking purposes. The natives of the interior of Arakan thus cook their rice in two-jointed Bamboos, for want of earthen *handies*. The rice is put inside with a small quantity of water, and then placed over a slow fire. By the time the wood-fuel is consumed the Bamboo is heated, and the rice is cooked. By the same kind of process, a sort of sweetmeat is made of sweet rice in Rangoon, and is commonly there sold in the bazaar.

About twenty years ago the "bâlcoo bâns" was turned to a novel use by the Burmese. It was just after the last war, when the inhabitants of Dalla and other villages near Rangoon were troubled with night attacks from marauders and desperadoes of all kinds. In the absence of any of the usual weapons of defence, the poor people converted the stumps of this Bamboo to account. By taking three joints, then cutting one to make a mouth, thoroughly scooping out the centre joint, and boring a touch-hole in the third, and then loading it with powder and shot, they managed to keep off the intruders. These imitation guns would often stand out five or six shots when well wrapped up with strong Jute fibre or any other strong description of rope. In the absence of this protective covering, the Bamboo cannon would commonly burst at the second discharge.

Wherever Bamboos abound, as in Lower Bengal, where available timber is expensive, they are very extensively used for building purposes, and always for scaffolding and for ladders. In the interior of the Tenasserim provinces the Kârens are famous for building a dwelling house in two hours that will last for three years after undergoing such repairs in the third year. This I have personally witnessed. I was accompanying a friend, who was the Assistant Commissioner of Upper Martaban, for a four days' walk through the forest, in the course of which we had to cross the winding Yun-za-lin river several times upon Bamboo rafts. Houses of the kind to be described had been erected at suitable intervals, at which we successively slept and took our mid-day meal; but one afternoon, just as we had arrived at the bank of the river, a violent storm was evidently coming on, and there was no proper shelter from it to which we could resort. But our train of Kâren coolies who were carrying our packages immediately set to work, dividing themselves into three parties, one of which proceeded to fell Bamboos, another to lop off their side shoots and bring the trimmed stems to the place selected, while the third party undertook the building of the habitation. The framework, with a skeleton penthouse roof, was soon put together, some 14 feet long by about 10 feet broad, the fastenings being effected (if I remember rightly) with the tough, pliable stems of some creeping plant. Then a number of trimmed Bamboos were thrice half split longitudinally, and so opened out, and these served for the walls and flooring, the hard and smooth outer surface being of course placed upwards to form the floor, and outwards to form the walls. The flooring was elevated about five feet from the ground. The rapidity with which the whole proceeding was accomplished was startling, and when as many Bamboos were cut and trimmed as were required, the first and second parties set to work, obtaining a quantity of pinnate fronds, like those of a Cocoa-nut or Betel-nut Palm, or of the Nipa fruticans, and the midribs of these were half split, and then one half inserted in the party wall, with a Bamboo as an admirable and water-tight thatch. Before the thatching was half-finished, however, the thunderstorm came on, and we were glad to take shelter from the streaming rain beneath what part of the thatch had been put together. But the Kârens still worked on, and the habitation was completed, a short bit of Bamboo left and when as many Bamboos were cut and trimmed as were required, the first and second parties set to work, obtaining a quantity of pinnate fronds, like those of a Cocoa-nut or Betel-nut Palm, or of the Nipa fruticans, and the midribs of these were half split, and then one half inserted in the party wall, with a Bamboo as an admirable and water-tight thatch. Before the thatching was half-finished, however, the thunderstorm came on, and we were glad to take shelter from the streaming rain beneath what part of the thatch had been put together. But the Kârens still worked on, and the habitation was completed, a short bit of Bamboo left and were constructed by which to ascend and enter, the whole being completed within two hours from the time when all the materials of which the house was composed were alive and flourishing in the jungle.

Then the Kârens set to work to construct a roomy shed for their whole party, and also a Bamboo raft, by which we were to cross the stream on the following morning. By the time that these were finished the rain began to hold up, and away went our native servitors to collect a variety of plants, including different Fungi, of which they made a supper, thus obtaining food when our provisions like experiences would starve; but they did not overmuch like my prying into their culinary operations, suspecting, possibly, that I wished to take a toll of them. A beautiful evening ensued, and far from being fatigued by their labours, our Kâren friends kept up their favourite game until darkness compelled them to desist from it. This game was a sort of battledore and shuttlecock, only that the sole of the foot served for the former, and the very large seed of the Entada Pursætha, a Leguminous plant with a slender creeping stem, and bearing a small pinkish white blossom that is followed by large racemes of pod, often 4 feet in length, with seeds of a magnitude to correspond ; and these are the seeds which are tossed by the soles of the Kârens from one to another.

Bamboos make capital trellis-work for creepers in gardens ; so long at least as they last, for in the rainy season, more especially in Lower Bengal, they become thoroughly rotten the third year, and are not good for much after the second rainy season. This is the great objection to them as building material—they decay so soon in a hot moist climate. Another objection to them is, that for building purposes, for ladders, for hackeries (native carts), &c., they admit of no improvement in construction, as in the case with the wood of exogenous trees, and thus the inventive faculty is not called into play, and people must needs go on as did their ancestors before them for countless generations, so far at least as the utilisation of the Bamboo is concerned—*stat pro ratione voluntas*. Those of my readers who are daily accustomed to witness the multifarious uses to which the Bamboo is habitually applied, it really seems difficult to imagine how people can ever get on without it ; and the same might be said of the Cocoa-nut Palm in Ceylon. I have seen friends in the Kârens of whom I have been writing, when preparing to cross a steep chain of hills where water is not readily to be obtained, cut and trim a few small Bamboos, bore through the septa of their joints with a red-hot iron, and then fill them with water to carry on their journey.

It is very rarely that the ordinary Bamboos flower and seed in the climate of Lower Bengal, and only in exceptionally hot and dry seasons, as was that of 1858, the year of the suppression of the great mutiny in India. The seed was then produced in large quantities, so as to lie two or three inches deep on the ground under the plants in many instances ; and after flowering and seeding the common Bamboos invariably die. One species, however, the B. baccifera, produces seed annually, though only upon a few small and short stems, which do not perish after seeding. The death of so many ancient Bamboos in and about Calcutta in the hot season of 1858, after seeding, considerably altered the familiar aspect of certain localities. By the poorest class of natives the seeds of the Bamboo were then ground and variously prepared as food. Z., *in The Field*.

THE NATURAL HISTORY OF A FLOWERING PLANT.

[The following is an abstract report of Professor Thiselton Dyer's fourth lecture on "The Natural History of a Flowering Plant," in the Royal College of Science, Stephen's Green.]

The plant is a community, the different parts of which labour for the common interest in varying but always subservient ways. The leaves, as we have seen, produce elaborated food ; they build it up from matters in part absorbed by themselves—in fact, supplied by the roots, and derived from the outside mineral world. The sun's light and heat give them the force they need to pull these in pieces, and re-combine them into more complex combinations, containing less oxygen than the materials therefore, to combine with more when burnt. Plant structures are our great stores of force, whether as food or as fuel ; the force did its work at the time of growth in detaching the oxygen; it is therefore again set free when oxygen re-combines with their component elements. The human race must inevitably be ultimately restrained in its extension by the diminution of existing supplies of fuel, the consumption of timber and coal certainly going on at a quicker rate than any kind of renewal. Animals could not exist without plants—the materials they create upon could support no animal's life ; as Professor Huxley has remarked, a solution of smelling salts supplies almost all a plant needs for food, but an animal might swallow hogsheads of it and still starve. The products elaborated by the green parts of plants are nutritious to animals—i. e. they are parasites. Still, what they borrow is not wholly without acknowledgment ; the roots collect what the leaves, when expanded, will work upon, and the flowers produce seeds which perpetuate the race. Nevertheless, the plant community could go on, and does, indefinitely in many cases by its roots indefinitely, without producing seeds ; so that flowers are really consumers of the plant resources of which all the other organs are more or less productive. It follows, therefore, that inflorescence is always an exhaustive process ; indeed, in many cases, so much so that the whole life is one great preparation for the production of flowers, which crown its existence with a true euthanasia. The development of the mass of flowers is in such cases rapid, and the consumption of the plant's store of food correspondingly so. In the Sago Palm the soft, pithy centre of the trunk is full of starch (sago when purified). Till the outside of the trunk hardens it is protected by long and stout spines from the wild hogs which would otherwise destroy it. "When the flower and fruit are allowed to perfect themselves, which is in two years from the first appearance of the inflorescence, the starch is found dried up, the leaves have fallen, and the plant perishes." The so-called American Aloe (which is properly an Agave, and not an Aloe at all), has a similar fate, which may, however, be very much deferred if it be grown slowly at a low temperature. The stem of the plant consumed in flowering is frequently take the form of insoluble starch ; to turn this into sugar, which is soluble and available, an excess of carbon is got rid of, in combination with oxygen which is absorbed. It is, in fact, burnt off, though very slowly, and the effect is to raise the temperature of the surrounding atmosphere, especially where, as in Arums, the flowers are crowded together. The individual peculiarities of flowers are probably all the result of modifications of their particular organisation, so as best to do their work with regard to external conditions ; the different ways in which they lend themselves to the visits of insects especially illustrates this. Probably the colours of flowers have their true use in guiding insects to the bribe of sugary nectar which plants offer them. It is well known that a flower is only the equivalent, although modified, of a leaf shoot ; leaf-buds and flower-buds indeed, under some circumstances, are interchangeable. Leaf-shoots, when first expanded, are often brightly coloured, becoming green when commencing their proper work ; flowers, it may be said, therefore, preserve the temporary coloration of the young leaves, because they never do true leaf-work. It may happen that the

flowers are attractive to the eye, not from colour of the floral envelopes proper, but from that of adjacent or floral leaves. This is pre-eminently the case with many of the Euphorbia family; in the Poinsettia, for example, the true flowers are quite inconspicuous, while in some species of Dalechampia they become green instead of pink when the fruit is formed, as if for the purpose of concealing it. The perfect flower consists of four circles of organs, the two outer being protective, the two inner producing pollen and ovules respectively. The fertilisation of the ovules by the pollen is essential for their development into seeds; directly this takes place the flower withers; but, if prevented, the freshness may be prolonged very considerably. All the organs of the flower are merely leaves specialised in their development for particular work; this is proved by instances in which all the organs have one or other changed places; and cases where they are entirely converted into leaves are not rare. Usually flowers are circularly symmetrical, but there are many deviations from this; these sometimes become symmetrical by the irregular portions being either suppressed or else regularly developed all round.

ON THE PLANTING AND KEEPING OF CEMETERIES.

THE Corporation of Salford has a cemetery extending over many acres of land, situated at the end of Stafford Street, on the Eccles New Road, about three miles from the Manchester Exchange; and it is but justice to say that this has been laid out and planted with trees and shrubs at considerable expense. The same Corporation has also a park for the people, called Peel Park, and this is kept partly as a flower garden, and partly as a green park for recreation. The keeping of this park is entrusted to a good practical gardener, and the planting of the flower-beds and the excellent condition of the walks are highly creditable to him; and he sees that the lawns or principal grass plots are kept neatly mowed and swept. Now, this is just what I and many others want to see done at the cemetery, viz., that it be as neatly kept as the garden part of Peel Park; and this is by no means an unreasonable standard of excellence, for if Peel Park were part of the private grounds of one of our merchant princes, its lawn grass would be more frequently mowed and swept than it can be now with the limited number of hands employed. As a place of burial this cemetery is as yet only in its infancy, and that is just the reason why its arrangements are not perfect at the outset, as it were, be made to harmonise with the spirit of the age.

The closing of churchyards has thrown the business of sepulture into cemeteries everywhere, and thus the subject has become invested with an interest which it never had before, for the early part of the history of establishments were almost unknown. It is fortunate that this cemetery belongs to a public body, and that graves are bought and sold in the same business-like manner that a Manchester manufacturer would dispose of a bale of goods. There are, therefore, no vested rights to be protected, and no private interests to suffer, by ventilating the subject. That this cemetery and its keeping concerns me will be gathered from the sequel of this letter, but the careless way in which this and several other places of sepulture which I could name are kept, concerns many others as well as myself, and, therefore, with your kind permission, I will state a few plain facts, in the hope of bringing about a better state of things. This, I hope, will have more force than speaking at random, which might easily be mistaken for ill-will.

About two years ago I had to buy a grave in this cemetery, and, after laying a loved and dear one in her last resting-place there, I had intended to set up a headstone to mark the spot where loving hands had laid the mother of the family. Our oldest son, however, forestalled me in this, and got a headstone erected of stone and iron stone border to round the grave, with his mother's name, age, &c., duly engraved on the headstone. It only remained, therefore, for me to have the grave planted, and this I undertook to do with my own hands. In Buchanan's "Land of Lorne," we read that the mariners inhabiting that stormy coast prepare their gravestones during their lifetime, and the reader will readily perceive that I am going to tell him, how I have planted what may be my own grave. My memory supplied me with a long list of low-growing plants, suitable for such a purpose; a halfpenny card would have ordered them from the nurseries where I knew they were to be found, and a post-office order would have settled the small bill for all the plants wanted to cover a space of less than two square yards, so that there could be no excuse for me to have the grave improperly planted. Now had I used turf, it would have required cutting frequently, which cemetery keepers would never have done, so I decided that the double-flowered fragrant herb Chamomile, with its elegant feathery foliage of the liveliest green, should be the carpet or canopy over the grave. As the red berries of the Cotoneasters have such a lively look in winter, I planted near the headstone a Cotoneaster Simmonsii about 2 feet high, which has bloomed and is now blooming freely, so that we may look for it to bear berries in due time, but its flowers are inconspicuous, and therefore some other plant with flowers fair and sweet had to be added, so I planted one Rose on its own roots, and one with a stem about 1½ foot high, and they have both bloomed freely. After all, there comes a time when Roses fade and their foliage falls to the ground—for Roses are far from being perpetual, although paraded as such in the catalogues—so there still had to be planted two real evergreen shrubs, to maintain a little liveliness in the dead of winter, and for this purpose I planted two Savins—one green and the other variegated; these would eventually cover the grave with their embrace, for they spread horizontally, like winged plants, brooding over what is beneath. Rich manure in plenty of manure was given freely for planting, and the soil, or rather subsoil, was removed from the surface of the grave. The Chamomile completely covers the area allotted to it, and is not surpassed in beauty by any plant that I could have employed, although it has not flowered, and does not like to let it flower, because its leaf has such a fine effect.

Here, then, I have given the actual facts of the plants and the planting, as a guide to others similarly situated, for there is no end to the blunders made in this way—thus, a Rose-bed here a few square feet that in a few years would occupy a space 8 or 9 feet in diameter; annuals that, in the barren sand, yield only a harvest of disappointment; bedding plants in flower, plunged in the pots, in the same poor medium that starved the tender-rooted Rose plants as the latter can only be for a very short time. What I complain of, however, is, not the blunders of well-meaning people planting unsuitable plants at untimely seasons, but the miserable way in which this Salford cemetery is kept; for long after midsummer I had to cut the grass on my wife's grave with that grew between the gravel, and I found that the keepers had then only just begun to mow the grass for the first time in another part of the cemetery. Once a month during the growing season all the grass in the cemetery should be mowed and swept. The heavy charges made for graves, we say it openly, will not justify this keeping, for keeping should not be measured by this standard, as if profit alone were the object the Corporation has in view. Public opinion should be enlisted in favour of a proper and decent keeping, and respect for the dead should have its due weight with those who have authority.

We read in the first history of the field with the trees, and the cave of Macpelah before Mamre, that Abraham bought for a burial-place of Ephron the Hittite; and from the account given, the field of Ephron was indeed a cemetery of a very high character. Later on, we read of the *cortège* taking the magnificently embalmed body of Jacob out of Egypt, when his princely son Joseph carried his father's bones to the same family vault, with a train of chariots and horsemen and a great company, such as had never been gathered together on such an occasion before, for we read that at the floor of their threshing-ground the Jordan they actually spent seven days in vehement lamentation; leaving us an example of veneration for the dead such as, perhaps, never has been equalled.

Then we read in Homer's immortal verse of "the honoured Hion in her hero years," where Achilles slept the mighty Hector's shade." The shrines of illustrious characters everywhere attest the same veneration for departed worth, and the authors of fiction have often seized on these materials and worked them up with good effect. Thus Sir Walter Scott hitches Old Mortality into the tale on one who frequented the graves of the martyrs to the Solemn League and Covenant. In our day, one author would deprive us of the dignity of our origin, and another would deprive us of the dignity of our end. Du Chaillu, describing his first gorilla, has given us a faithful picture of the hairy beast "sitting on his hind legs, just like what a toad would be if reared up to look out for danger. Where would be our restraint on the score of morality if we were descended from such apes as these? It must be a degrading superstition that would rob a man of the image of God, to make him a creature of mere instinct, with a four-footed beast. There was a Latin inscription, beginning *Hic Simia*, &c., on a stone in the grounds at Sion House, where a favourite monkey had been buried. To this there was a counterpart, for be it known that Hugh Percy, Duke of Northumberland, was a successful breeder of monkeys. Whilst I lived at Sion one of them died, and T. Mott begged the body to have it stuffed, but when he had skinned the brute, and cut off the head and the feet, the appearance of the trunk was so like that of some child murdered and mangled, that he got the stolen to make away with it; he in his haste flung it over the garden wall into the Brent, but when the tide was out, the carcass was seen in the mud, a great uproar was made, and barbarous cruelty was laid to the charge of some person or persons unknown, though poor "Jocko" had had a comfortable life, and died a natural death. The tide at length took the better half of him off to sea, and it is doubtful whether his friend with the Latin, &c., equalled him as regards the numbers that came to his funeral, and mourned the monkey mistaking him for mankind. It appears from the "Life of Lord Brougham," written by himself, that when a young man he had lost the Christian faith (if he ever had any), and entertained, like many others, great doubts about there being any future state of existence. In order to settle this important point, he drew up an agreement with one of his companions, written in blood (according to popular superstition), that whichever of them should die first should appear to the other. Not a word about common sense in the matter, which tells every one that a dead body is utterly incapable of fulfilling any engagement entered into during life; but when 60 years had gone by, Brougham's youthful companion had grown an old man, and resided in India, yet on the day of his death (Dec. 19) he appeared to Lord Brougham, and sat on a chair. By a piece of special pleading, Brougham, after relating these facts, tries to account for the vision, which happened on the very day of his friend's death, by thinking that he (Brougham) had been dreaming during the time he was in a warm bath. The whole affair had an impious character about it, and the terrible termination of the last act nearly shook the life out of the "learned lord." The truth of the narrative is not likely to be called in question; moreover, we have it from the first hand that his friend "impersonated the premises," and Brougham, with all his failings, was never reckoned guilty of deliberate falsehood; but he is gone to his account, and what he has left upon record cannot now be arraigned, save only at the "last assize."

It is easy enough to make light of what is called a ghost story, but St. Paul rests everything upon Christ being risen from the dead, and it is upon this cardinal point that honour and respect are claimed for the places of sepulture of our departed friends. The escutcheon is always charged with the word *Resurgam*. In shunning the belief in ghosts, Lord Brougham, in early life, like many others, had gone sadly too far on the other side, so that the sublime vision of St. John in the Apocalypse, where the saint relates, "I saw the dead small and great stand before God," would to such an one have been only a gigantic ghost story. There is no way of dissociating the death of friends, and their funeral obsequies and places of interment, with the immortality of their souls, or, in other words, with the rising again to a life where poverty here will be no bar to greatness. Why should we be robbed of this hope? The poet Cowper lost his mother at an early age, and with his highly sensitive feelings he has left us the unreparable loss; but mark the childlike simplicity with which he speaks of the world to come, and of his unbounded trust in God, when he said—

"There is a golden harp for me:"

as if he had said—Child of Song that he was—"Surely God, who has bestowed on me the gift of song, will for His glory perfect me in power to sing His praise."

In conclusion, let me state that the poorest persons may plant flowers upon the graves of their friends, and thus manifest their respect for the link that united them with a former generation. We see, however, in the public cemeteries, what was never seen in the parish churchyard, viz., three small churches, where the burial services are conducted. Thus even in death we are still divided, and cannot show a bold front to the scoffer. So that when we have mourned the dead we may even drop a tear for the living. *Alex. Forsyth, Salford.*

REMARKS ON THE FRUIT CROPS OF 1871.

(Continued from p. 1030.)

THE present season, so far, has been of unusual severity, and its effects upon the fruit crops most capricious; for while a few on high and fully exposed positions are rejoicing in the abundance of their crops, by far the greatest portion are all but a failure, as regards Apples, Pears, Plums, and Currants that bloomed profusely and suffered irremediable damage from insect pests, the leaves being shrivelled up, and in many instances entirely gone, the low ground temperature and persistent cold, cutting winds, with nightly frosts, entirely mastering growth. I am afraid that the late growth the trees are now making will not become sufficiently mature to bring a crop next year, unless the autumn proves unusually fine. The Potato disease is making rapid progress; one-third of the early kinds are now gone. Carrots have suffered greatly on all kinds of soil from the wireworm. Vegetables of all kinds are plentiful, and of extra quality. *G. Westland, Witley Court.*

—— Peaches and Nectarines are a good crop where the trees were plentifully supplied with water last summer, and the insects vigilantly destroyed last autumn and this spring. The black aphis was very prevalent last autumn; and where it was left unmolested, under the impression that the season was too far advanced for it to do harm, the trees shed their leaves prematurely, and at the time of opening in the spring the bloom was small and weak, and ill calculated to withstand the cold weather. Apples have suffered much more on dwarf trees than they have on large orchard ones, the latter being much more under the influence of wind and rain,—conditions that are not so favourable to the development of insect life. Here is another instance in support of the views I have always maintained, that fruit trees that make comparatively little wood through a judicious system of root-pruning, produce bloom stronger and better able to resist spring frosts than those not so treated. In February, 1870, we had occasion to move a number of large Gooseberry trees; these made little wood last summer, and have this year borne heavy crops; others not so treated, but under exactly similar conditions as

to exposure, had their bloom completely destroyed by the frost. *T. Baines, Southgate House, N.*

—— The fruit crops in general are very fair considering the past severe winter, the cold and inclement spring, and the extremely wet summer. The small fruits have been fairly harvested for preserving, &c., although much later than usual, and fruit over-ripe was rendered useless by the rain; some varieties of Cherries were rotted before they could mature. Vegetables are doing well, but a little over-vigorous, Onions especially. Peas have overgrown their usual height by 2 feet, but have fruited well. Beans have done well; French Beans having been very late, and some sorts set their fruit badly; Globe Artichokes lost all their early fruiting crowns by the severe frost, in fact we thought we had lost them, but they have thrown up shoots wonderfully, and are now fruiting well; early Cauliflowers were very tardy, but now spring planted plants have done well; out of 1500 Brocoli plants of ten different sorts, only 15 escaped the general havoc of the frost—nearly all of them were layered in autumn; Tomatos will be very late. Bedding plants are inclined to be vigorous; Coleus, Amaranthus, and such-like have had a miserable existence. Subtropical plants have made a slow and sturdy growth; Ficus elastica has stretched out a foot; Draczenas have stood better than last year; Cannas, Ricinus, Solanums, &c., have grown well. The sunless weather has had a material effect on the colour of indoor fruits, which have done well this season. The rainfall for the first seven months of 1871 was as follows:—January, 2.14 inches, rained on 13 days; February, 2.80, rained on 16 days; March, 2.06, rained on 14 days; April, 2.44, rained on 17 days; May, 2.29, rained on 10 days; June, 3.21, rained on 14 days; July, 4.77, rained on 27 days; total rainfall up to the present, 19.71 inches, raining on 111 days, giving an average rain every alternate day. On June 23 it rained 1.45 inch, being more than the quantity which fell on June and July last year. This year has been as extremely wet as last year was extremely dry. *P. Middleton, Wynnstay Gardens, Rhuabon.*

—— Notwithstanding a very cold spring we had every prospect of a very heavy crop of Apples and Pears up to May 10. That night there was 9° of frost, which destroyed all blossoms then open. Even now the trees present an unhealthy appearance, the leaves being spotted and curled up. The wind continued from the north and north-east for many weeks, which had a scorching effect upon fruit trees not protected by a wall. Many varieties of the Thorn still retain their blackened foliage. Previous to the above frost the Plums were set and partly covered with leaves. The aspect being south-west, they were screened from the north-east wind. Peaches will be three weeks later than usual; indeed everything is late, as we have had no summer weather. *W. Hutchison, Castle Malgwyn, Pembroke, South Wales.*

Home Correspondence.

Orchid Cultivation.—In your edition of July 15, p. 906, I see Mr. Anderson's reply to mine at p. 874. With the spirit in which it was written I can have no sympathy, and I feel satisfied Mr. Anderson and his friends will regret that it was written; as it has been, I must reply. Mr. Anderson says, "Your readers may ask me how I know 'G. H.'s' establishment, and what object I have, even supposing I knew it, of exposing his hand." I believe the rules of newspaper controversy are, that, if a writer chooses only to put his initials without address, it is considered to be a name of incognito, and no one has the right to penetrate the mystery. The advantages of such a custom are many, and not the least of these is, that it prevents writers whose argument has given out, from falling back upon personalities to screen lieu. Now it may be said that this makes an unequal contest. In the present case it does not, for Mr. Anderson was perfectly aware two years since who "G. H." was; he then visited "the establishment," as he says, and my name was given him by Mr. Brooke, but as he could not see his information, he tries now to make out that he has found it out himself. If he has lost sight of the real question, either to convey or to gain information upon the cultivation of Orchids, he had better retire from the controversy. With regard to the catalogue he named, your readers must judge for themselves if he has quoted fairly: and, as to the matter, I neither contributed to it, nor do I consider that I am able to draw up such a catalogue. I have not even used it, but, as I hear from Mr. Brooke that he has been encouraged by those who have—I believe yourselves among the rest—I have advised him to seek assistance in making it more complete and valuable to gardeners. Mr. Anderson may rest satisfied that such assistance will be acknowledged, and if there are any subjects found within the range of my capabilities, that he will find "G. H." at the end of such contributions. I think I have now said enough upon this personal matter, and I will proceed to again take part in the discussion upon Odontoglossum cultivation, to which I am already greatly indebted for information. I have read with great interest Mr. Gosse's letter, and the extract from Dr. Lindley's pamphlet, and Mr. James McPherson's letter. I am sorry that the latter does not give us the locality as well as the elevation at which Captain Auchterlonie's Tables of temperatures and rainfall were taken. When I last wrote I said that Mr. Isaac F. Holton's "Twenty Months in the Andes" had just come to hand. I take this opportunity of again thanking M. Jean van Volxem for the information he has thus placed in my hands. In the appendix I find the Table of temperatures he mentions, which I will send you, and you must use your discretion about publishing it. I also find another Table, which I should like you to give your readers, as a companion to Dr. Lindley's. I consider it an exceedingly valuable one. He calls it a Tableshowing altitudes, climates, and productions. Mr. Holton does not seem from this book to have been at all aware of the value of Orchids, and he only mentions them incidentally, but he seems to have investigated the effects of the climate upon vegetation very thoroughly, and I find great difficulty in selecting extracts to send you; so for the present I will say that he confirms in all respects the extracts I have given from Messrs. Purdie, Bates, and Orton, in the clearest way, and goes on to what may perhaps be more interesting, as supplementing the account M. Jean van Volxem gave, in your impression of April 1, at p. 419, of the station where his splendid Odontoglossums are growing. The altitude he gives for the falls of Tequendama, and the town of Fusagasuga, are so nearly the same as Mr. Holton's, that it becomes unimportant; but as Mr. Holton is so very particular in his description of these places, which are the result of personal observation, I think M. Jean Volxem will consider that my sending them to you is not in the slightest degree because I doubt what he has told us; on the contrary, I find Mr. Holton to bear out exactly what M. van Volxem wrote: and I take it that in giving me the name of Mr. Holton's book, M. Jean Volxem was, that I should refer to this, which he thought was a trusty source of information. The description of the falls of Tequendama is rather long, but full of interest:—

> "The point where these observations are best made, is a sort of table-rock just at the brink of the water. Beautiful rainbows hangings it, covered with bushes, Ferns, and Orchid plants, making almost a grotto for the observer. The mist of Tequendama has started some philosophical speculations in my mind. The people say the mist often spreads in a dense fog over the surrounding country. This fog begins in the morning, at from 9 to 11. Is there more fog here than at Bogota? A day fog would diminish the mean temperature of a place; a night fog would increase it. The temperature of the falling water to be lower than elsewhere at the same level. I found it by the water of a mine, about 54°, but I would like to see it confirmed. Now, although Bogota is 850 feet higher, its temperature is given as higher. This indicates a confirmation of my suspicions. In passing four times in sight of the Fall Mountains, I have always seen the mist either hovering among them, or pouring from them to overspread the square and the adjoining country. Now, we must remember, that this country has no fogs like ours, but bears clouds and mountain mists in tropical profusion. This small body of water contrives to manufacture a condensed-fold more mist than Bogota, at a lower altitude. The mist is begun mechanically; of this there can be no doubt. Is it not propagated meteorologically? Has not one particle of mist the power of generating another in a favourable atmosphere? Here is a grave question—the quantity of mist generated directly by the falls seems very small; that proceeding from them varies at different hours of the day, and often streams off for miles. Tequendama is one of the most humid localities of plants I have ever seen. The woods are damp, while most land at this altitude is dry; on four of the five days I have spent here, I have literally loaded myself with water. In the Table Bogota 850 feet higher than temperature at 59°, Bogota 56°.] From Cibaté I rose till I had a fine view of the plain, of which we must now take a long farewell. Nothing but the cold makes it a gilad one to leave the hacienda. I saw the Indians of various plants nipped with frost, a rare occurrence indeed, but one that may happen any month in the year, not only under the mists of Tequendama, but all over the plain." The plain of Bogota, Fusagasuga, and Tequendama are all more than Tequendama, and a little higher than La Mesa, which is one of the highest spots in which Oranges grow.

> "I had no thermometer with me, but I have a strong suspicion that the temperature is put too high by Caldas, 59°. Mosquera's estimation is higher. I think it must be near 70°. Never was there a more beautiful climate than that of Fusagasuga. Twice have I celebrated New Year's day here by bathing in a stream of delightful temperature, swimming, and of snow at home. It is just at the upper limits, or rather above the convenient culture of Cane, Plantain, and Oranges; and for these I would submit to a slight increase of heat."

Thus it was at about 500 feet higher than at this spot where Mr. Holton thinks the mean temperature should be put at 70°, or from 2½° to 5° lower than the two native authorities he quotes, that M. Jean van Volxem found O. Alexandræ growing. As your correspondent "Ex-Cantab" says (at p. 907) that I have not answered his question at p. 380, I will again give a quotation from mine at p. 450, which must have escaped his notice, and it will enable your readers to see how far I was out in my ideas of cultivation. But first, one of the native authorities, Mosquera, puts the mean temperature at 75°; now turn to Dr. Lindley's list, where such a mean is said to give 80° for a maximum and 55° for a minimum; what can this mean, but that the minimum is very rare? On a previous occasion I gave a quotation from Dr. Hooker, to show that moisture enables plants to attain to much higher elevations than they otherwise could; and I now should be able to add many quotations from Mr. Holton's book, showing how little variation in temperature there is experienced throughout the whole country. I should advise your correspondent, "X.," to give night ventilation, and in summer to syringe frequently not only the house but the plants, and to keep the temperature down in hot weather. I begin to think that it is more important to keep the temperature low in summer than in winter. However, this is what I wrote at p. 450:—

> "I do not see why Odontoglossums having a temperature of 80° in the day all through the winter, and do not know that I have advised it. I gave a mean for the year with a daily range of 10°; my house will go up to 90° with the hot weather, and no doubt go as low as 50° in the cold weather; but as I cannot prevent their growing—that is, not only making up bulbs, but also commencing fresh growths,—I cannot think that I should be wise to reduce the heat below 60° in the day as a rule, and running it up to 70°, if there was any chance of giving air."

At the risk of making my letter too long, I cannot resist giving another quotation from Professor Dyer at p. 771 of your journal:—

> "There is an inherent disposition common to all plants to hibernate during the winter; hibernation is forced upon them by the deficiency in one or more conditions necessary to their growth—namely, warmth; and the absence of another condition—moisture—in hot, tropical countries, produces the same enforced rest in vegetation, only at the opposite end of the year. Wherever the winter is sufficiently mild, vegetation is not arrested; the trees retain their leaves all the year, and many of them keep growing continuously. All plants, however, even in warm countries, cannot do this. The great effort of flower-producing needs a special season of preparation and rest."

I think that Professor Dyer is right, and that he has placed before us the true test of successful Odontoglossum cultivation, which system prepares them the best for this effort of flower production. I congratulate Mr. Culley on the size of his flowers. *G. H.* [We may find an opportunity shortly to publish the Table and plan kindly furnished us by our correspondent. EDS.]

To Trap Bluebottle Flies.—In answer to your correspondent, "C. J.," as to some method of stopping the attacks of bluebottle flies on fruit, I can say that for many years I have known a hand-glass trap answer the purpose excellently. The plan used, which is very likely the same to which you allude, is to set one of the largest-sized hand-glasses, which are square below and conical above, on four bricks, so as to raise it from the ground; another hand-glass is placed on this—usually one of the same shape, but, if at hand, of a smaller size, and the junction between the glasses is carefully secured with Moss, so as to prevent the escape of any insects; of course the small hole in the top of the lower glass is left open, that in the upper one closed. A little decayed fruit thrown under the glasses attracts the insects, which, flying upwards, are captured in countless numbers, and much more successfully than by another method in common use, which I have seen tried. *E. A. O.*

—— I conjecture that your correspondent "C. J.," like myself, is plagued with cats, who kill all the birds. There is no other effectual way of keeping the multiplication of insects within proper bounds beside the creatures for whose food the Creator has destined them. I recommend him to stick up a notice such as I once saw in a large house: "No cats allowed." *J. S.*

Fairy Rings.—Two facts as to these:—1. The dark-coloured grass that forms the ring seems owing to the fertilising nature of the fungus. 2. Where in a new field Bees have beneath not having been touched for a month, the ring-grass outgrew the surrounding pasture more than double in height and luxuriance. 2. In another field fed off by cows, the ring-grass was eaten by them closely down, showing that they relished it. Both fields had many rings. *Hobbyist.*

Orchard-houses.—To those who, like myself, cannot conveniently go in person to see the famed houses of Mr. Pearson, nothing could be more agreeable than a description of them by so competent an observer as your correspondent "F." (p. 1010). venture, however, to make a few observations on a sentence which occurs in "F.'s" letter. It is a well-known axiom among Peach growers, that the hearer the glass the finer-flavoured the fruit;" and in accordance with this axiom, "F." prefers Peaches from trellises, 9 to 18 inches from the glass, to those grown in pots at a distance of 3 or 6 feet. Now that sunlight is the prime agent in giving flavour to Peaches is indisputable; though, whether this effect is due chiefly to the luminous, or to the heat-giving, or to the chemical portion of the rays, I will not attempt to decide. I have also noticed, as mentioned by "F.," that Peaches grown on the lower portions of bush trees, and therefore more shaded, are inferior in quality. But in gardening, as in most other things, we have often only a choice of evils, and in the trellissed houses which I have seen (though I admit my experience is limited) the plants have suffered severely from red spider, notwithstanding the peculiar advantages which the trellis gives for syringing the underside of the leaves. A few days ago I purchased in Covent Garden the best specimen I could find of a Peach from an ordinary

Peach-house. It had just arrived, was quite ripe, and for the variety (Noblesse) was well coloured. But upon comparing it with my orchard-house fruit I found it poor indeed. Possibly the tree may have been over-watered, but it is equally likely that the foliage was injured by red spider. I find in the orchard-house that shoots which stretch themselves near the glass are thus affected, notwithstanding a daily syringing, damping the floors frequently, and abundant ventilation. The experience of orchard-house cultivators seems to be leading them away from the time-honoured axiom we are now considering, for in my frequent visits to Sawbridgeworth I have seen the original small and low house gradually giving way before the larger and loftier form, and have tasted from these newer houses quite as good fruit as could be produced in the old. In my own houses, which are of the original build, I often suffer from too much sun, and am obliged to whiten the glass to prevent the Peaches ripening prematurely, and either becoming mealy or falling off while still acid. As to Strawberries, which all authors tell us must be grown close to the glass, all I can say is, that I am satisfied with fruit grown at a reasonable distance. *G. S.*

Tricolor-leaved Turnip.—I enclose a leaf of a Turnip (Red Tankard), which, besides the white and green variegation, is prettily bordered with pink. I do not know whether the latter circumstance is peculiar, white and green leaves are not uncommon. The pink tinge evidently arises from the colour of the root. I have ventured to send this specimen, as variegated plants are interesting, and the cause of such variegations still more so. *W. R.* [We have not previously noticed to so great an extent the pink variegation which occurs in this specimen. EDS.]

On Growing Pinks, &c.—If every nurseryman in the kingdom were asked how he would increase his stock of Pinks next Bianthly, nine out of ten would believe, say by pipings. Carnations and Picotees are more safely grown from layers, but many of these are propagated very successfully by pipings. Indeed I remember once seeing a frame full of pipings of Picotees put in by a lady, and a better take could not be for every piping grew. The frame was on the cold ground, the soil inside was rather sandy ; a more thriving lot of plants than these became I would not wish to have. If I had a number of pipings of Pinks, say a hand-glassful, I would put up a bed 2 feet square and 2 feet high of rather short fresh manure, pressed somewhat closely together. Upon this I would put 6 inches of sifted sandy soil at once, fix my hand-glass to mark the space for the pipings, put them in not over long, give them a good watering with the rose, fix the glass firmly on, shade when needful, and I should have every hope of perfect success. The warmth from the dung would give the needful impulse to the cutting, causing it to strike without risk of burning, and as soon as the true signs of growth appeared I would give a little air. Pipings for speed, layers for certainty. *R. T.*

The Effects of Dew.—In reading so orthodox an article as that at p. 1006 upon the treatment of Peach trees by the late Mr. Radclyffe, I cannot help feeling grieved at meeting with an heretical notion which has accidentally crept into it. Mr. Radclyffe cautions his readers against the evil effects of dew, as the means by which the frost is enabled to bite ; the fact being, that the dew, or hoar-frost, disarms the frost of half its power. Dew, or hoar-frost, is deposited upon trees in consequence of their loss of heat by radiation, when their leaves, or branches, become colder than the surrounding air ; but when the vapour dissolved in the air is so deposited, a large amount of latent heat is given out upon the change from vapour into water, and again upon the change from the liquid to the solid state. In frosty weather by all means let the trees be kept dry ; in other words, warmer than the surrounding air, when no dew will be deposited. But, in a calorific point of view, I should say that the deposit of dew, or even of hoar-frost, would certainly mitigate the severity of the cold. *An Amateur.* [See p. 1063. EDS.]

Jackmanı's Clematises.—Jackmanii and Rubella have large rounded flowers, broad in the petals, and very handsome, as well as quite distinct. They form excellent companions. Prince of Wales and Rubroviolacea have narrower petals, smaller flowers, and are so much alike, as well as not sufficiently distinct from Rubella and Jackmanii, the latter especially. These four I have now grown for three years past, with the same result. One cannot praise Jackmani too highly ; it is the grandest hardy climber we have. I know of nothing that can equal it. On the front of my residence at Ealing, which has an east aspect due south, there is a plant of it that must have fully 500 expanded flowers at the present moment, of a fine bluish-purple tint. For six weeks past it has been loaded with flowers. It is cut down to the ground every winter, plenty of manure forked in about the roots, and during the summer it has an abundance of water, and an occasional supply of liquid manure. It must be grown generously. It is so much admired, that I confidently anticipate quite a local eruption of this rich blue-purple on our villa residences a few years hence, as every one who sees it declares that he must possess it. It is one of the best hardy plants of the past ten years. *Richard Dean* [Rubella is equally deserving of praise, and for distinctness magnifica is not to be despised. The great merit of this strain of hybrids is their wonderful fertility of flowers. The plants are literally and continuously masses of blossom ; and such blossoms too ! EDS.]

Treating on the Potato Disease.—A few mornings ago I received some letters by the early post, one of them was from a locality in which there were "40 acres of Potatos, 29 of which are stricken with the disease. They are being taken up and clamped. Those which are now left in the field, but some will doubtless escape observation, and if stored along with the sound ones, will they impart the murrain to the whole lump ?" I gave, as an inevitable consequence, the "little leaven" of Scripture for analogy, and at the same time I advised the bays of barns, cattle feeding or other sheds now most at liberty, to become the dry, twilighted receptacles for affected crops. I recommended that the tubers, as they are taken from the ground, should be spread out thinly in the above mentioned places, and turned and inspected once a week ; and those that show the least sign of decay should be boiled at once, with about a handful of salt per bushel, for the pigs, and the water well strained away from them when cooked. But should there be more of them than the pigs could consume, then I advise that the surplus be rammed well down into bog-holes, for use as wanted ; and so, if humanity becomes directly baulked of the food, it will at any rate reach us some time or other through the instrumentality of bacon or pork. Still, precautionary, in case the largest and most matured tubers should be required for human consumption, they may be assorted at the digging and housed in a dry, airy place, and the diseased ones singled from them as they occur, as stated above ; but of course they must be constantly kept in the dark, for if allowed to become "greened" they would be unwholesome for domestic purposes. In a month or so, to both ends of the tuberous maze he considered safe, through the practice of inspection, and unless "clamping" be absolutely necessary I would prefer to store them in lofts, or in a cool dry twilighted place, to be under observation and free from frost. I would not allow them to be heaped together more than 3 feet deep, encouraging ventilation by rubbed off and weaken them. Thus managed, capital seed may be expected from them next spring. My correspondent had 11 acres of his 40, which were late planted, free from disease ; and these, through the favourable change of atmosphere which has occurred, I trust may be saved to him from both ends, second, first, of it. As "evil" afflicted with Potato on the brain, comes from the site of the first propoundings of Elizabeth Lazenby's sauce. He writes how "this plaguey disease is bothering of him altogether," and requests to learn of me if I "know what it is." What matter is it whether it is the leaf, in the old tuber, or in the root ? Is it the result of atmospheric action ? Is it the result of electricity ? and, if so, what affinity has the Potato to electricity ? I want to know the actual cause of the disease, how it operates, and why it operates, and why the Potato should be the special victim. Well, certainly, to one who wishes to lead a quiet, practical, horticultural life. My convictions, from years of "strike-home" observation, have led me to conclude, that the Potato disease must be caused by electricity, in connection with what is commonly called "white rain," *viz.*, those insinuating showers which accompany effete lightning and thunder, with hot sultry intervening sunbeams, and moist muggy nights. The leaves always become first affected in the above state of atmospheric muddle, and the haulm browned in patches, and more frequently fully destroyed by three or four days' continuance of such weather. But when we get an honest, open-faced sky, with sun and drying intervening winds, it shrivels up the affected leaves to powder, and frequently then the stems will remain green minus the leaves, on account of the Potato being saved, having been allowed sufficient time to insinuate itself along a damp bed of enduring moisture to become generate into living forms. Zoospores, the Rev. M. J. Berkeley, at p. 944, tells us are unable to move without wet, which, by-the-bye, our best living authority in mycology has, according to my thinking, thus scientifically "scotched this snake," exactly in accordance with my long practical pre-conceived notion of it ; and I dare say it is well known how, under my dead and gone *incog.*, I have been with him in combating these zoospores, by growing my Potatos high and dry in ridges, and by plying the soil with lime rubbish and quick-lime at the time of planting—by allowing sufficient room between the rows for the sun and air to penetrate, and otherwise to keep the surface of the earth in as dry and friable a state as possible. The appearance and present state of my crops will back Mr. Berkeley up in what he says at p. 944. I have frequently had to do combat in print in defence of the ridge-and-trench system, though I do not presume to say that I can prevent the disease by adopting it ; still, even now as I write, why should Providence favour me more than my neighbours, if there was nothing in it ? They are complaining sadly of "the rot." Not one single affected tuber have I dug up to this present time, and, with the exception of one delicate, soft, hairy-foliaged new seedling, the leaves of above 60 varieties of my own I have under observation on the 2nd are comparatively green and promising ; and yet this garden, both for soil and surroundings, is most favour able for the "taking" of the disease. Yes, depend upon it, dryness is the only panacea for the murrain, and the ridge-and-trench system the antidote, as I tried to explain it in Nos. 6 and 13 ; and I trust in a few weeks' time it will enable me to appear at South Kensington as usual, to illustrate its excellent results. So, lance at rest, allow me to further parley with our querist. Most usually the foliage of Potatos becomes stricken with the spot at a certain matured stage, viz., at about the time of the "setting" of the skin, and then it must be that the energies of the leaves are being taxed to their utmost possibly to a degree to exhaust them, and so make them more susceptible to attack when batteries of electric fluid, with moisture, acting upon so delicate texture as the leaf of a Potato, and the generation of fungoid mould in its most destructive form, combine (all the more easily at that particular stage), to the annihilation of leaf, stem, and tuber. As a case in point, I have now got between 1000 and 2000 seedling Potatos of my last year's crops, growing under glass in an orchard-house, most fortunately, where a drop of atmospheric rain has not been able to fall upon them ; and they are, every individual plant without an exception, free from the fell spot, whilst some of the very same batch of seedlings which I pricked out in the open air for want of room under the glass, are stricken. This seems to show, as another conclusive proof, if one is wanted, that the mould-laden rain is at the bottom of the mischief ; for the mere atmosphere would, in its action, be the same inside as outside of the house, as I keep every available opening unclosed—and they are many—in order to "draw up" the young hopefuls. Besides, they are artificially watered as required. In fact I have never found either rain or wet affect Potatos in the haulm unless tempest is prevalent : witness 1860. The uniform cold rains, unaccompanied by an electric atmosphere, of white rains, I find not affect them. Never were better Potatos grown, or freer from disease, than in that cold, wet, untoward season. When a diseased dried up "old tuber" is planted as seed it will tell its own tale by unhealthy growth altogether, and probably succumb, whether the disease becomes prevalent or not. I will not say that frost is origin either in root or tuber, so far as I have ever been able to discover. So for my part I give the result above as the actual features of "How it comes? What brings it?" and what sort of "atmospheric action" prevails for the production of the Potato disease. The Potato is not a "special victim" to electricity. A man, an animal, a tree, "what know I," have affinity to electricity in peculiar states of their existence. A duo of human bipeds shall be walking or standing together, and how often do we read that one will act as a lightning conductor, and the other strike, whilst the other is left ? And to common observation do not these attacks occur when Nature is "most put to it," when nervousness, over-exhaustion, or being in contact with such ? The "stoning" of the fruit, and at the full swelling-tide of the vegetables—are not these their most typical seasons ? Have we not seen them various causes ? We must ask these things of science, and some day perhaps we shall get our answer. Let "us other" keep our pens and wits sharpened, and our shoulders well up to the wheel, in connection with it ; for most assuredly, in our day, practice cannot get on without science. *W. Robt. Fenn, Rectory, Woodstock, August 2.* [Yes, but you deal too much in mere assumptions in the matter of electricity. EDS.]

Campanula Barrelieri.—I wish to commend this species as a plant for window gardens. It deserves a double First-class Certificate of Merit. Outside of my window there stand two to-inch pots, each containing a plant of this lovely Campanula. It hangs down over the sides of the pot to a depth of 4 or 5 inches, and the plants are now, literally speaking, of a delicate greyish mauve, the flowers nearly 1 inch in diameter. It is perfectly hardy. If this species were bedded out, and used as a dwarf edging plant, it would create quite a sensation. *R. D.*

Grape Growing at Kingston Hall. — To say that the true version has been given, and that the border chambers are open to the arches underneath, is a mistake, as no alteration whatever has been made in respect to the chamber underneath the border, except the doing away with the ventilators in the interior wall of the house, against which the flues or pipes are now placed ; hence the reason of the arch being turned slightly underneath to admit of ventilators to the chamber, which extends something like 15 feet under the border, sloping with the declination, and which has no connection whatever with the arches of the interior, for had this been the case, the chamber would been open to receive the full force of heat from the pipes as originally used, it is very evident what would have been the result on the Vine roots. I do not accept either censure or praise as to its merits or demerits,—to the originators alone are these due. Mr. Cruickshank draws upon his imagination as to the superiority of the original method of having the whole of the pipes underneath, a method that no practical person would for a moment uphold, and I may, moreover, add, that I found the present heating arrangements to answer admirably, and never lost a single container during my one in charge. I think it would have been more graceful in Mr. Cruickshank to have pointed out any defect

which might be attributable to me, than to insinuate that I should speak out on a subject I had not entertained or heard mooted before. I simply write for the vindication of truth, and I have not a doubt that in this respect my assertions will be verified by those who may take the trouble to examine for themselves, and explore the vaults underneath, as well as the interior chamber under the Vine border, which is in every respect as I have represented it to be. *Geo. Westland.*

—— I do not for a moment contest the point with Mr. Westland. My examination was not thorough enough to pronounce on the matter positively, as will be seen on turning to my notes. I wish now it had been more so; but my time was limited, and I was not aware but that alterations had been made. I followed local information, and also, I admit, your special correspondent, in the statement that the borders were not heated with pipes underneath them. If the fact is as Mr. Westland states, then, possibly, the high condition of these fine bunches of Grapes owes more to bottom-heat than would appear from my brief notice. With this modification, my account is still trustworthy. Of course, my sole object was to record facts, and I have to thank Mr. Westland for correcting me in such a gentlemanly spirit. *F.*

Gold and Bronze Pelargonium Beauty of Preston.—Of several Gold and Bronze (bicolor) Pelargoniums I am growing this season, the one most to be commended is Beauty of Preston. It is one sent out a short time ago by Mr. Thomas Sampson, Preston Road Nurseries, Yeovil, and to the best of my knowledge the Floral Committee of the Royal Horticultural Society awarded it a Certificate when seen growing at Chiswick. Compact in growth, yet free, short-jointed, and making a low spreading growth, it is well adapted for bedding; the leaves are quite golden in colour, with a regular orange-chocolate zone. Compared with those of the other two, the flowers are quite green, while they are more rank in growth. *R. D.*

Utricularia montana (see p. 1039, fig. 233.)—I saw this curious plant when abroad some years ago, and had the pleasure of receiving living specimens from the Botanic Garden, Trinidad, in 1858. It is very plentiful on the mountains in Trinidad, growing on the trunks of trees, living and dead, among Moss, Lycopods, and trailing Ferns, in very shady situations, where the atmosphere is charged with moisture to such an extent that the clothes of the traveller become saturated in a very short time, and a peculiar chill is felt. The plant is seen to the best advantage on the moss-covered trunks of trees. It increases as rapidly as the Strawberry, and in the same manner, so that it will soon be plentiful. *Ebor, Blackpool.*

Bluegown Cucumber. — Your correspondent "J. C. N." (p. 1041) is at sea about the merits of this Cucumber. I planted two plants of this sort in a small three-light dung frame some time in the early part of May, and up to this time I have cut more than 40 yards of Cucumber of fine quality. If your correspondent would but call at the Newton Nurseries, near Bedale, which I presume is not far distant from Mount St. John, he would see a plant growing there which was a cutting about a month since, showing some splendid fruit. If your correspondent is not well up in growing good Cucumbers in a short time, he might get a few hints there, as they are grown largely for sale. *Cucumis.*

—— "J. C. N." could not have had the true Bluegown Cucumber. I planted in April two plants raised from a packet of seed sent by Mr. Turner; the produce has been most satisfactory—plenty of Cucumbers, averaging from 9 to 14 inches in length, of good appearance, and excellent flavour. They are growing on a hotbed, with the Telegraph in the same frame, which also is one of the best Cucumbers grown. *W. Fowle, Dogmersfield Gardens, near Winchfield, Hants.* [We have letters testifying to the excellent merits of this Cucumber. Eds.]

Trial of Hot-water Boilers.—I think the Messrs. Weeks & Co. are deserving of hearty thanks for their suggestions upon this matter. Whether the place and mode of trial are the best that could be suggested, may safely be left to the collective wisdom of the boiler-makers and your readers. I may, however, add that I think the established boiler-makers have had but scant justice in recent controversies, and I am very glad to see one of the first and largest amongst them give a challenge to all comers to a trial of power, efficiency, and durability. My rule—and I have found it a very safe one—is never to part with an old servant —or boiler—in favour of a new, as long as the old one will do its work well. No one can doubt that tubular boilers have done good work, and many contend that they are the most economical of all forms, but these are the very points that ought to be settled by a fair test. I still think that this is a matter that the Royal Horticultural Society ought to take in hand, in the kind of the Messrs. Weeks to offer the use of their place and their assistance, but other makers might object to go there. The competition should be on neutral ground, and be superintended by a body free from interest in any particular boiler. The time allowed might easily be contracted. A twelve day and night trial would prove a very formidable matter; I see little difficulty in bringing it within much narrower compass. Were the boilers placed side by side, as near as might be, and some general principles of testing and trial agreed upon by the exhibitors, and thoroughly understood by the jury, the results might soon be collected and assessed at their proper value. Neither do I consider any system but that designated A by the Messrs. Weeks & Co. worth the labour of trial. Those who believe in sending the water down below the level of the boiler, as suggested in system B, and those inclined to drive the whole of the water by caloric alone, and thus dispense with the aid of gravity, and in fact fight against it, as in system C, would be free to test their theories against system A; but for each boiler-maker to test the three plans seems to me like a waste of time and a reflection upon our knowledge. A man may assert that trees would grow best planted head downwards, but that is no reason that we should seriously try the experiment. By all means let those try it that believe in it, and so let each maker put up one boiler alike in capacity and work provided for it, and let that one which does most work in the shortest time, with the least expenditure and without endangering its durability, win the highest honours. I do hope that our boiler-makers, old and new, will enter heartily into this trial of merit, so that we may have some better authority than every man's estimate of his own boiler to guide us in the difficult matter of selecting the best. I met with a most intelligent gardener the other day, who assured me that a boiler that has recently been much lauded for its economy and efficiency is the most extravagant form that was ever made. It burnt so much fuel last winter, that it is in serious contemplation to replace it with a tubular before another comes. All such incidents show the need of a thorough trial, and it is to the interest of the makers as well as the purchasers that the best one should win, for one form is just about as easily made and as profitable to the makers as another, and we are only concerned with the efficiency and economy of boilers. *D. T. Fish, Aug.* 12.

—— I was not a little delighted to read in the last *Gardeners' Chronicle* of a proposed trial of boilers. I should certainly be most glad to take up my position in the competition. As the heating apparatus is the very heart and life of every horticultural establishment, perhaps nothing is more important to its welfare than a good boiler; and therefore I think the Council of the Royal Horticultural Society ought to take this trial in hand, so that it may be thoroughly and effectually carried out in mid-winter, in one of the arcades adjoining the conservatory. The place is admirably adapted for the purpose, and it would cause little or no loss or inconvenience, nor run to much expense, as there is an abundance of piping, and it can easily be fixed in whatever way may be deemed advisable. Moreover, as Messrs. Weeks have a boiler already in its place, I should imagine they would willingly agree to have the trial carried out there. I cannot see that their first condition as regards water above level is in the least degree to do with the case in point requiring elucidation, that of heating a greenhouse say 100 feet long and 20 feet wide, some distance away from it. The question is, what apparatus can throw the most heat into it, in a given time, and in a uniform state, say for 48 hours—longer, with the least expense of fuel, labour, and attention, and which boiler is most likely to continue to do this for the greatest number of years without incurring doubt as to safety and expense. In the event of the Council not feeling disposed to offer to carry out the above trial, I should be glad to have my pet little boiler tested, side by side, anywhere, with any other, a committee of six thoroughly practical men deciding upon the rules to be laid down—the winner to be proclaimed the best boiler, without fee or favour. *H. Cannell, F.R.H.S., Woolwich.*

Cypripedium niveum.—In reference to your paragraph on p. 1040, perhaps you can also inform "Juvenis" and myself who the celebrated "Mr. Downing" is (mentioned in the same monthly magazine as a "raiser of *species* and hybrids of Cypripedium"). That cannot be a misprint for the name of my respected friend Mr. Downie. Query: Should it be the "Downey Cove" or "Artful Dodger"? Gentlemen, can you also tell me where I can purchase seeds of that new Heartsease, said to have been lately exhibited at Regent's Park. I believe it is called the Chim-pausy. *O. O. Green, Ireland.* [Can you inform us which you pride yourself most on, your slang or your puns? Eds.]

A Heavy Thunderstorm.—We had a thunderstorm here yesterday, which will be long remembered. For several days previous the thermometer had ranged high—82° to 85°, wind variable, and on Sunday last we had thunder, but only some 0.12 inch of rain. Yesterday the thunder was first heard about 4 P.M., to the east, and for a time, but was not long in being close upon us, and after some heavy peals the rain came down heavily. Shortly after 5 the storm abated, going off in a northerly direction, but soon returned; and all round, from 5.30 to 8 o'clock, we had a continuous storm, some of the peals of thunder being exceedingly loud, with much lightning and torrents of rain; indeed, in the four hours the storm lasted our rain guage gave 4.24 inches —the largest quantity ever known to have fallen in this neighbourhood in such a short time. Of course much damage is done, the roads and walks in many places being washed out to their foundations, as where, from local causes, a rush of water took place, the drains were found quite insufficient; part of the low flower garden was under water for some time; the pond overflowed its banks, and the kept grounds in the valley below were flooded at the lower end, and some wire fencing laid flat with the ground, and further down the park a house was flooded to the depth of 3 feet on the ground floor, the furniture floating about. Still lower down, at Melbury Village, in two instances, aged women were rescued with difficulty, and taken to other houses for the night—the flood passing in and out at their cottage windows. Several narrow escapes are reported, and we shall doubtless hear of many losses sustained, and by those who can ill afford to bear them. At present I have only heard of two Oak trees having been injured by the lightning. *T. C. Elliott, Melbury House Gardens, Dorchester, August* 15.

Dinner-Table Decorations.—According to my experience of dinner-table decorations, what "D., Deal," says is correct. What we have had to do in this way for the aristocracy never exceeds 18 inches, more often under a foot; but the newest thing now is to decorate on the table-cloth, without any stands at all. My opinion has always been, that the stands and decorations exhibited at all the flower shows were an absurdity, and got up by people who had never seen a dinner on the tables of the "upper ten thousand." *F. Standish, Royal Nurseries, Ascot.*

Gooseberry Caterpillars.—To do away with the danger of being poisoned with the dust of Hellebore powder on Gooseberry trees, when the time arrives for digging between the trees carefully remove the soil from beneath them into the trench. I have always this done with a hoe. By this means the grubs that are afterwards hatched into flies that lay the eggs on the bushes are destroyed in the bottom of the trench. We were eaten up with caterpillars some years since; but, by following out the above directions, the trees are now entirely free. *W. F.*

Roses from the North.—Being present at the Supplementary Rose Show at the Crystal Palace on Saturday last, I was struck with the remarkable beauty of the Roses; and, considering the extraordinary season, I think it was a great success, both in respect of quality and quantity. What I thought the most interesting feature was the display by Mr. J. Harrison, of Darlington. Grown so far North, and forwarded a distance of about 240 miles to compete with our southern growers, the flowers stood forth in a manner, not muddy or "dust," but scattered about in sprays with a plentiful background of Moss; which, though it took off the brilliancy of colour, yet threw out boldly the massive healthy foliage and buds with which almost every bloom was surrounded. I marvelled to learn such fine natural trusses obtained neither prize nor commendation. I always understood that foliage and buds were a great acquisition, and always taken into consideration by the judges. I presume that taste in the arrangement, so as to show a mass of bloom, is of more consequence than merit. I shall be glad to learn, through the medium of your valuable paper, whether any other visitors noticed the absence of these northern trusses, and also to learn whether it is necessary to arrange them in the boxes, as shown by our southern growers? If so, I for one would advise our northern friends to adopt the same plan. *J. H. A.*

Use of Nitrogen in Vegetation.—I would not again have ventured to trespass on your space with respect to the nitrogen question had you not mentioned my name in connection with it in your leading article on the 12th inst., when recording an interesting experiment conducted by Mr. George Davis and Mr. Newlyn. When questioning the accuracy of Liebig's broad assertion, that plants are incapable of assimulating nitrogen direct from the atmosphere, I did so because I had nowhere read the record of any very satisfactory or convincing experiment to prove they could not, and I was in hopes, by publicly calling attention to the matter, as I ventured to do at the Ratcliffe Observatory, Oxford, I might induce experimental chemists to turn their attention that way. I am still of opinion that even if free nitrogen cannot be obtained by the plants direct from the atmosphere in which they live, that still the value of ammonia, and other nitrogenous compounds as manures, does not consist merely or principally in supplying the plant with the requisite nitrogen. The percentage of nitrogen in all growing plants is so small, and the percentage in the air so great, that it seems contrary to the general economy of Nature and the usual order of Providence to surround plants with what is of vital importance to their existence, and yet deny them the power of obtaining what they require direct. It would be like putting an aquatic plant in water, yet denying it the power of obtaining hydrogen from it. The most important nitrogenous manure is ammonia, and we do not yet know what part ammonia may fulfil as a physical and chemical agent in the sap, enabling the plant to elaborate from the sap (the life blood of the plant) those various solid constituents that help to build up and form the plant; and undoubtedly ammonia is a great solvent of the various forms of carbonaceous matter to be found in all soils, especially those of a peaty

nature, several of which are of themselves insoluble in water. Because plants are enabled to absorb carbon from the carbonic acid of the air, it has been assumed that they can obtain all the carbon they require from this source; but as the weight of the carbon in most plants is nearly 50 per cent., and in the air there is only about two parts in 10,000 of carbonic acid, this is assuming too much. May not ammonia, therefore, play the same part in the economy of plant life, as the gastric juice, pancreatic fluid, and other similar chemical compounds do in the human system, which enable us to assimilate and digest the food which we take? Moreover, both in plant life and animal life all nitrogenous compounds are more easily decomposed and digested, or assimilated, than those which do not contain N, and it is only while the power of vital force is in operation that the nitrogenous compounds of the human body are capable of existing without decomposition. Chemical analysis (both quantitative and qualitative) is only up to a certain point reliable: for instance, gum, starch, and sugar, are each by quantitative analysis the same, the formula for all these being $C^{12}.H^{10}.O^{10}$, and yet no chemist would distinguish one from another. In seeds, as of Wheat, for instance, a particular chemical substance called diastase is capable of converting starch into sugar. This is what takes place in sprouting Barley for malting purposes; diastase is capable of changing the insoluble starch into soluble sugar. May not nitrogenous compounds play some important part of this sort in the sap of plants, changing insoluble to soluble, and assisting in the endosmosis and exosmosis from cell to cell in vegetable substances? I know all this is matter of mere conjecture, but there are many elements of truth in it than there is in the Darwinian theory, that man is merely a development by natural selection from an ascidian, when in the whole course of historical and geological records there is no proof of any one species having changed into another, and though there have been many different types in the same species, as is the case in dogs and horses, pigeons, &c., yet in every case these different types have been fixed by human agency, not by natural selection only. This, however, is a digression. I cannot resist quoting an extract from Professor Johnston's "Agricultural Chemistry," p. 800:

"If pure oil, which contains no nitrogen at all, will produce an enriching manure by mere mixture with the soil, or will increase greatly the effect of bones, we must obviously seek for some other principle upon which to account for the effect of rape-cakes, &c., in addition to the proportion of nitrogen they contain. It is true that impure or refuse whale oil, when used for composts, may contain some nitrogen, but when pure oil is used, such can scarcely be the case to any great extent.

"While, then, we put so much faith in theory as to believe that substances which contain much nitrogen are very likely to prove valuable manures, we must not allow ourselves to be so carried away by the application of the principle as to believe either that the relative effects of manures upon our crops may be always estimated by the proportion of nitrogen they contain, or that a substance may not increase largely the produce of our fields in which no nitrogen is present at all. Indeed the effects of saline substances alone are sufficient to satisfy us how untrue to Nature this latter opinion would be."

C. P. Peach. Our correspondent seems to have overlooked the experiment of Boussingault. Eds.

Foreign Correspondence.

COULLIOURE, PYRENEES ORIENTALES.—The year 1871 will be noted in meteorological records for its irregularities and its excesses, and even as far south as this we have not been free from them. The severe winter temperature which have done you in the north so much harm in the spring and early summer.

The month of May was quite a summer month with us; its mean temperature was 16°.68 Cent. = 62°.02 Fahr. On June 3, however, we experienced a strong gale from the north, which lasted for three days, and was both very cold and very dry. In the night of June 3—4, the thermometer went down as low as 6°.4 = 43°.52 Fahr., an unparalleled thing at such a time in this locality. If it had been simply cold as a result of radiation, no harm would have been done to the plants subjected to its influence, but being cold by convection and the accompanying wind violent and of long duration, the mischief done in gardens was great. I had a fine collection of Cucurbitaceæ, most of which were sent to me from the Imperial Horticultural Society of St. Petersburg, with a request that I should examine them carefully and report on them. Up to June 3 these plants were in good condition, and I flattered myself I should obtain some valuable results; but the great and sudden lowering of temperature, in consequence of the north wind, killed them nearly all, and that suddenly. I call attention to this because many horticulturists and meteorologists seem to overlook the fact that the cold of convection is more injurious to vegetation than the same degree of cold produced by radiation in a still atmosphere.

Six weeks later we were witnesses of facts not less remarkable and unusual, but of exactly an opposite nature—an excessive degree of heat—excessive even here. Like the cold in the early part of June it occurred suddenly. On July 5 the thermometer indicated 35°.7 Cent. = 96°.26 F.; on the 16th, 34°.4 = 93°.92 F.; on the 17th, 37° = 98°.60 F.; on the 18th, 38°.2 Cent. = 100°.76 F.; and on the 19th, 39°.4 Cent. = 102°.92 F.

These readings were taken from a mercurial thermometer hung in the shade in a current of air, and swaying to and fro in the wind, but the fixed thermometers in a north aspect protected registered on July 19, 47° Cent. = 116°.4 F. This day was most trying for human beings as for plants. The leaves of the Vines were rusted as if scorched by a furnace. Many of the stocks were killed, and at least a third of the Grapes destroyed by desiccation. The Figs altered their appearance, and their leaves were strewn on the ground as in November. The Olive crop, which up to that time was very promising, is much injured by this sudden Sahara-like temperature. Herbaceous plants left unwatered were roasted like a slice of bread on a gridiron.

In spite of these meteorological excesses, I have some interesting plants doing well. Among them the Solanum quitoense, which has edible fruits, and of which I received seeds from Mr. Daniel Hanbury; also a very curious grass from Guatemala, probably an undescribed species, but in any case one very remarkable for the vigour of its growth. If I succeed in making it flower and perfect seed here, it will probably prove a forage plant of first-rate importance. I received it from M. Durieu, of Bordeaux, who supposes it allied to Coix, and to the Job's tears. Coix—intermediate between the two. I have been less successful with the Voandzeia subterranea of Madagascar, which flowers with me in the open ground, but perishes immediately after, except in the case of one plant, which I have succeeded in keeping alive by watering it three or four times a day, from which I infer that it is a semi-aquatic plant. If any correspondent of the *Gardeners' Chronicle* can give me any information as to the conditions under which the Voandzeia grows in its native country, I shall be much indebted to him. *Charles Naudin.*

Societies.

ROYAL HORTICULTURAL: *August* 16.—W. Marshall, Esq., in the chair. At the general meeting, which was of very short duration, the chairman of the Fruit Committee laid the names of Fellows, proposed by that body, stated that it had that day, and for the first time, had one of its First-class Certificates returned, under the following circumstances. At a meeting, held on August 17 last year, the Committee was shown to Mr. Pearson, of the Chilwell Nurseries, near Nottingham, for a seedling White Grape of great promise, named Chilwell White. Later on in the year Mr. Pearson suspected, from some peculiarities in or two berries, that the Grape would not keep, nevertheless he propagated the variety to a considerable extent. This year, however, the fault has developed to such a degree that he cannot conscientiously send it out, and has therefore decided to destroy the whole of the stock on his hands, and to return the award made to him. It appears that the variety in question has a large receptacle, which is generally considered to indicate good keeping qualities; but in this instance its tendency to separate is so great, that Mr. Pearson (to his honour be it said), instead of causing much disappointment, has determined to destroy the whole.

The Rev. M. J. Berkeley then proceeded to comment upon some of the objects of interest brought before the Floral Committee, first stating, with reference to a flower of Anthurium Scherzerianum, from the gardens of Mr. W. G. Saunders, that it had a most delicious scent, and that nothing could be more beautiful than the contrast between its rich green foliage, white spathe, and delicate pink spadix. He had also received from the same gentleman a Gesneraceous plant, which he believed to be Drymonia bicolor, and of which there is a figure in the "Botanical Register" (vol. xvii., plate 4). Mr. Saunders exhibited also a fine specimen of *Lycaste Skinneri*, the species there is a figure in "Paxton's Flower Garden," and the description states that the plant is downy, whereas in this case it is glabrous. Alluding then to specimens of Trifoli, exhibited by Messrs. Carter & Co., to show its value as a new food for cattle, Mr. Berkeley observed that it was figured and described in the "Botanical Magazine" so far back as 1823 (vol. xlix., tab. 2283). He also called to the Trifolium *resupinatum* (now Mahomed lotus cærulea), and it was known in Switzerland many years before—Caspar Bauhin, in his "Pinax," mentioning the use of this plant made by the Swiss for preserving cheese. Trifolium *Alexandrinum*, but more especially the flower head, possesses a powerful scent of Fenugreek, an odour grateful to many, but to others extremely disagreeable. Previous to the Abyssinian war, Abyssinia was grown as a food crop for the sake of its scent, and was frequently laid in wardrobes to drive away moths. In Mr. Berkeley's opinion it would prove beneficial to fattening beasts, but not to cows, on account of the peculiar flavour which it might impart to the milk. Reference was then made to a trial of Onions, which will be found more fully described at p. 1064, the speaker remarking that a small Fungus, near to Peronospora destructor, nearly destroyed his crop, through killing the foliage.

Floral Committee.—Dr. Denny in the chair. From Mr. Croucher, gr. to J. T. Peacock, Esq., Sudbrook House, Richmond Park, a fine collection of Agaves, to two of which, named Simsii and imbricata, First-class Certificates were awarded. Mr. Green, gr. to W. W. Saunders, Esq., sent a cut specimen of Anthurium ornatum, a new species from Santa Martha, having bright green cordate leaves, a white spathe and delicate pink spadix; a decided acquisition, which also commanded the highest honours that could be conferred. Mr. Saunders also exhibited a very fine new Dracæna, named D. fragrans, received from South Africa, and flowering examples of Encomis clavata, and Griffinia intermedia. Mr. B. S. Williams sent two nicely flowered specimens of Erica Turebullii, the merit of which consists in its free growing habit, as compared with others of the high-coloured sorts; and from Mr. Mackintosh, Hammersmith, came cut flowers of an inferior pink Epiphyllum. Mr. Wilson, gr. to W. Marshall, Esq., Enfield, sent a flowering plant of Lælia elegans var. Turneri alba, remarkable for the distinct form of its richly-coloured lip —a plant which ought to have been certificated; the Rev. Lord Hawke, Willingham, Gainsborough, had a stand of fine seedling Pelargoniums; and Mr. Hollyhocks, a stand from Mr. Wills came a nicely grown specimen of the Ivy-leaved Pelargonium, Duke of Edinburgh.

The show of Gladioli, the principal feature of the meeting, was an unusually good one, the spikes being generally very fine, and exceedingly bright in colour. The first class was an open one for 24 cut spikes, the prizes being offered by the President, His Grace the Duke of Buccleuch. Messrs. Kelway & Son, Langport, were 1st with a splendid stand, consisting of the best of the older kinds, and several splendid new seedlings, the following of which were afterwards selected for First-class Certificates:—Araximenes, vermilion-scarlet, crimson-feathered, petals very broad and stiff; Yellow King, the gem of the exhibition, pale yellow, flamed with crimson, petals very broad and flat, forming a large, broad and compact spike; Astrea, bright scarlet, feathered with crimson, the spike fine but narrow; Lady Bridport, a shaded pink, feathered with crimson, and very fine petals; Lord Bridport, rosy pink, deep crimson feathered, in fine spike; Arabella, white, feathered and flamed with crimson; and Phidias, claret-crimson shaded with white, a very attractive flower. Mr. Douglas, gr. to E. Whitbourne, Esq., was a very close 2d, with good spikes of Meyerianus, Princess Mary of Cambridge, Empress Eugénie, Princess of Wales, and several promising seedlings. Mr. G. Wheeler, Warminster, was 3d, and the Rev. H. H. Dombrain 4th, an extra prize. In the amateurs' class for 12 Mr. Douglas came in 1st very easily with a stand of flowers equal to any in the show. This also included some remarkably fine seedlings, raised by Mr. Douglas, as Prince of Whitbourne, Bessie, beautifully flamed with rich crimson, forming a close, neat spike; Mrs. Francis Whitbourne, flowers larger and of a more pure white than the former, feathered purplish crimson, petals broad, and a handsome spike; William Earle, a fine light yellow, flamed with a reddish pink; and one of M. Souchet's new sorts, named Talisman, clear deep rose, with broad stiff petals, and a fine spike. These also were awarded First-class Certificates. Mr. W. Marsh, gr. to J. Marshall, Esq., Belmont Park, Taunton, was 2d, with nice spikes of Lord Granville, Sir William Hooker, Pegase, Le Poussin, Sir J. Paxton, &c.; the Rev. H. H. Dombrain was 3d, and Mr. Douglas an amateur exhibitor came in 2d in the class for 6. Mr. Douglas again being 1st with Orphée, Madame Desportes, and four fine unnamed seedlings; 3d honours were divided between Mr. Wheeler and Mr. W. Rowland, Wellfield Road, Croydon. Messrs. Kelway & Son also sent a grand collection of 72 spikes, amongst which Lacépede, Horace Vernet, Plutarch, Norma, Madame Desportes, Meyerbeer, Sophocles, &c. Messrs. Le Mayne, Lemoine, Calvat, and Heraclitus, were especially fine. An extra prize was awarded. Messrs. Carter & Co. also exhibited a large collection of seedlings and named varieties, and Mr. W. Holyoake, Hammersmith, sent a fine vase was taken by Mr. W. Chater, Saffron Walden, who had excellent specimens of Bullion, Queen of the Yellows, Marion, Fair Ellen, Majestie, Fascination, &c. Mr. Slater was also 1st in the class for Phloxes. Messrs. Paul & Son being 2d; and Mr. G. Wheeler 3d. In the first named collection, Fred. Chater, Splendidus, Prince Albert, Leviathan, Joy, Eclipse, Invincible, and Enchantress were fine. For 12 cut spikes of Pompones, distinct, Messrs. Downie, Laird & Laing were 1st, and Messrs. Paul & Son 2d; and Mr. G. Wheeler 3d. In the first named collection, Fred. Chater, Splendidus, Prince Albert, Leviathan, Joy, Eclipse, Invincible, and Enchantress were fine. For 12 cut spikes of Pompones, distinct, Messrs. Downie, Laird & Laing were 1st, and Messrs. Paul & Son 2d. Some very nice flowers were shown, but they flagged soon, and did not look nearly so fresh and attractive when put up in vases. Prizes were offered for a single dish of Apricots, and these were awarded 1st to Mr. G. Craddock, gr. to Lord Willoughby de Broke, Compton Verney, Warwick, and 2d to Mr. Smith, gr. to the Gainsborough, Keele Park, Rutland, both competing with Moor Park. Messrs. J. & C. Lee, Hammersmith, exhibited a very large collection of cut branches of hardy ornamental trees and shrubs, including a splendid specimen of the variegated forms of the most noticeable were Acer campestre variegatum, Castanea vesca albo-marginata, Cornus sanguinea elegantissima, Fraxinus aucubæfolia, Ilex argentea, Quercus purpurea, Fagus purpurea major, and Platanus elegantissimus. Other kinds, remarkable for the distinctness or boldness of their foliage, were Alnus cordata, bearing small cone-like fruit; Betula Kenwigiei, Ghedtsoka Engeli pendula, Ulmus Wredei, Morus hispanica, new; Pyrus Aucuparia sibirica nana, bearing pretty scarlet fruit; Robinia hispida, Fraxinus Juglandifolia, Robinia pendula, Betula laciniata pendula, &c.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. On this occasion Special Certificates were awarded to Mr. Tillery, Weldale, Ware, for a basket of Pitmaston Peaches, along with which also came examples of a seedling Nectarine, raised at Welbeck, from Violette Hâtive, which becomes of a peculiar black colour when ripe; and a fine dish of St. Ambroise Apricot; to Mr. Thomas, gr. to T. Chamberlayne, Esq., Cranbury Park, Winchester, for two fine and well-ripened Queen Pines; and to Mr. J. Douglas, gr. to E. Whitbourne, Esq., for capital examples of Royal George and Bellegarde Peaches, and Washington Plums. Dishes of Apricots were shown by Mr. W. Gardiner, gr. to W. E. P. Shirley, Esq., Lower Eatington, Stratford-on-Avon, and Mr. Rutland, gr. to the Duke of Richmond, Goodwood, which, like most other Apricots this season, were much wanting in flavour. Mr. T. Thornton, Heatherside Nursery, Esgshot, sent fine specimens of the Hunt's Seedling Cucumber, a neat smooth variety, which, if a good one for winter use, the Committee thought would be accept-

able, and to that end they requested that it should be sent again in January next. Mr. Meaks, gr. to R. Fowler, Esq., Petersham, again sent specimens of Ingram's Scarlet Gem Melon, grown in a cold frame, and very poor in flavour. Mr. W. P. Roberts, gr. to Lady Derby, Holwood, Kent, sent three bunches of Grapes, cut from Vines over 100 years old, which a few years ago were in a very bad state, but are now recovering well, as the two both of black and berry fully testified. Mr. Pearson, Chilwell, exhibited a nicely finished bunch of his new Grape, Ferdinand de Lesseps, highly flavoured; two white seedlings, from Duchess of Buccleuch, totally distinct in character; two large black varieties from Black Morocco, distinct in character, good setters, producing large berries, and showing no signs of cracking; and a seedling variety from Mrs. Pince's Black Muscat, which produces a close very compact bunch, and fine berries. Some of these were considered very promising, but unfortunately all were unripe, so that a correct opinion of their merits could not be formed. Mr. Earley also sent a small berried seedling Black Grape, not quite up to the mark in flavour. Mr. Maurice Young, Milford, near Godalming, sent a Cucumber plant from 4 to 5 feet long, the stem of which was broadly fasciated, which seems to produce fertility, as the plant bore a fruit, all about the same age. Mr. Gardiner sent branches of Apple trees, to show the heavy crop they are bearing; and Mr. Foote, gr. to Sir A. H. Elton, Bart., Clevedon Court, Somerset, sent some fine Morello Cherries.

ROYAL BOTANIC: *August* 10.—The 32d anniversary meeting of this Society was held at the gardens, Regent's Park; his Grace the Duke of Buccleuch in the chair. Business the Prince of Teck was re-elected President, and Mr. W. M. Coulthurst, Treasurer; Dr. Brewer, M.P., and Mr. W. F. Low, were elected new members of Council. The Secretary, Mr. W. Sowerby, read the annual reports of the Council and auditors, from which it appeared that notwithstanding the very unfavourable weather during the season, the total receipts had exceeded the total of last year. This increase was in consequence of a large sum received on account of subscriptions. The total receipts from all sources, including the special subscription for the new conservatory building, was £8373 18s. 6d., and the expenditure, including liabilities, to 31st of July. The expenditure included above £2000, the cost of building a new wing to the conservatory, building stores and potting sheds, laying on water, and other permanent works completed during the year. A large number (585) of new Fellows had joined the Society during the year, and the ordinary subscriptions had been £3823 1s., a sum which has only been reached this during the 32 years of the Society's existence. The facts, however, of most interest to the public were found in the reports related to the valuable facilities gratuitously afforded to students for the study of plants in connection with medicine, the arts, and manufactures. 231 free orders of admission had been granted, and 22,512 cut specimens distributed, against 182 and 10,712 respectively in 1870; and the officers of the Society are constantly attending to artists, merchants, manufacturers, and others valuable information in answer to queries connected with their various pursuits, and illustrating the same by reference to the living plants furnishing the raw materials. The number of distinct species of plants in the educational collection is more than 5000, while above 500 are of medicinal or other economic value. A covered way, 200 feet long, from the public road to the conservatory, is in course of being built, and is expected to be finished by the end of November next, thus affording access to the conservatory in all weathers, and making it a true winter garden. Thanks were voted to the President, Vice-Presidents, and Council, the members of committees and officers, and the proceedings terminated with a vote of thanks to the Chairman.

GLASGOW ROYAL BOTANIC: *August* 10 to 13.—This was the first of a contemplated series of flower shows to be held in the Botanic Garden at Glasgow. The directors of the gardens, assisted by the curator, Mr. Fullen, have prepared a special exhibition ground, laid out in agreeable undulations, the principal groundwork being covered with green turf, and intersected by spacious walks for promenading. This arrangement permitted the grouping of the plants in picturesque style, and very much enhanced the effect. Every one entering the spacious marquee thrown over this exhibition space must have felt that something of the kind was what every flower show committee should aim for both for the comfort of the visitors and for the right and proper grouping of the plants. The day was brilliant.

The most prominent features of the show were arranged in the manner above alluded to, and consisted chiefly of three miscellaneous collections of plants, which occupied the terraced divisions in the centre; the interior margins being filled with the lesser groups representing the subsidiary classes, all very tastefully grouped. The 1st prize was awarded to Provost Russel, Falkirk, whose gardener (Mr. Sorley) put up an admirable lot of plants in a most artistic manner. His plants of the Australian Dracænas, especially *D. australis*, and the elegant-looking Australian Dracænas, towered quite up to the canvas, and formed excellent contrasting material with the beautiful cut-leaved Cupania filicifolia, a grand plant for ornamental purposes, and the New Zealand Coprosma Baueriana variegata, which, along with the equally hardy variegated Aralia of Siebold, and even the golden-topped Yews, show their adaptability for general purposes. Conforming these was one of the rarest of rare Orchids, Laelia elegans Turneri, than which nothing in colour or substance could be finer. This, and the Lady's Slipper Orchid, Cypripedium superbiens, associate well with Ferns, among which there is no better species for hot-house culture than Adiantum farleyense, which was well shown in this collection, as were Yucca quadricolor and Cordyline indivisa. Messrs. J. & R. Thyne, who were placed 2d, had a group which showed good cultivation. Prominent were the tall tree forms of Areca sapida, a noble Palm, Cyathea princeps, and Phœnicophorium sechellarum. There were some excellent Crotons and Dracænas in this collection, one or two Pitcher Plants, some well-grown Todeas and Filmy Ferns, and one or two half specimens of Heaths, particularly of Erica Austiniana and Marnockiana, both sorts raised from seed by the indefatigable gardener at Bothwell Castle, Mr. Turnbull. Mr. Coats, of Fergusile, gr. to Mr. Dickson, had a lot confined in less space, but which contained some excellent examples of horticultural skill. His Aerides nobile and Saccolabium Blumei majus, were two of the finest flowering plants in the show. The Heaths in this collection were also good, particularly Massoni, which is difficult to cultivate, but was here produced in fine style.

The smaller groups of miscellaneous plants were deficient in quality. Amongst them, however, were twelve Pelargoniums, very fine flower, and very remarkable for their foliage, which were magnificently grown.

The Roses from Messrs. Dickson & Sons, Newtonards, were grand, showing how the mild climate is adapted to the growth of these beautiful flowers. Dahlias were good, considering the season, the best coming from Ireland.

Fruit was really a very good exhibition. The collections from Mr. Johnston, gr. to the Earl of Strathmore, and from Mr. Methven, gr. to Colonel Campbell, of Blythswood, were excellent. The former had very beautiful bunches of Buckland Sweetwater Grape, Muscat of Alexandria, and Golden Prince—all ripened up in fine order, which was highly commended. Pansies were good, but not numerous. Vegetables did not form a large exhibition, but were a fair representation of what is in season at this time.

Among other miscellaneous awards, a Special Certificate was given to Mr. G. White, Ladyburn Nursery, for a dark self seedling Pansy; while Mr. W. H. Hilton, Liverpool, received a Certificate for his new patent Grapery border cutter, for horticultural purposes; and Mr. A. M'Lachlan, Greenock, received a First-class Certificate for his new patent verge cutter.

The directors dined with the judges in the afternoon in the gardens. Upon the whole, the first exhibition in connection with the Royal Botanic Society may be pronounced a success—a success due in a great degree to the unwearied energy of Mr. Bullen, the curator.

Notices of Books.

The Horticulturist; *or, the Culture and Management of the Kitchen, Fruit, and Forcing Garden.* By C. H. Curtis. Edited and revised by William Robinson. Warne & Co., 8vo, pp. 707.

This is an admirable book on practical gardening, and the publishers have done well in reissuing it and in entrusting its editorship to Mr. Robinson. We may congratulate the editor on the success of his task, and on the valuable assistance he has obtained and duly acknowledged from Mr. D. Fish, Mr. Taylor, and other practitioners. If now, after this general commendation, we proceed to point out sundry minor defects or points in which the work has not quite been brought up to the present time, it must be understood that we by no means intend to disparage the value of the work as a book. Thus, at p. 461, and find a brief, and, we must say, insufficient account of the new Vine disease. There is no clue given as to the date when the disease in question was first observed; so that, as far as appears from anything in the present volume, the disease might have been new in London's time. There is not a word indicative of the fact that the insect was first described scientifically in our columns by Prof. Westwood months before the French commission began their investigations. There is nothing to show that "M. J. B." had also, unless we mistake not, discovered the identity of the insect with the mischief on the leaf before MM. Planchon and Lichtenstein began their observations. In fact, nothing is said as to the insects attacking the leaves at all; and lastly, we fear that the statement that the pest "is said to exist in one or two vineries," by no means conveys any adequate notion of how widely spread the disease really is. In so saying we do not wish to raise an unnecessary alarm; we merely state that it is much more prevalent than the passage we have quoted would lead the reader to infer, basing our own statement on the number of specimens forwarded to us from various parts of England in the last year or 18 months. Speaking generally, however, the editor has kept well abreast with the progress in practical horticulture that has been made since the book was first written, though here and there it is very doubtful in the mind of the reader whether it is author or editor who is speaking, while in most cases the state of things is rendered apparent by the anachronism evident. Such slips on the part of the editor are, so far as we have seen, comparatively few, and do not impair the value of the work.

We need only mention the issue of a seventh edition of *Thomson on the Vine* (Blackwoods). Such a fact speaks for itself. Of all classes of books, those devoted to practical gardening seem to be the most successful. Edition after edition is published with a rapidity that only a successful novel can rival, and keeping pace with these unceasing re-issues is the launching of new candidates for popular applause.

—— There is no necessity to commend to the notice of the aspiring young gardener or bailiff a knowledge of mensuration, a subject they will find of use to them nearly every day of their lives; but we may be doing them a service by calling attention to a brief and unpretending but clear treatise on the subject lately published, by Messrs. Longmans, under the title of *Explanatory Mensuration*, by the Rev. Alfred Hiley.

Florists' Flowers.

THERE is much reason to fear that, by the accident of non-use, many good plants are falling away into the cold shade of neglect,—plants that deserve to be much more kindly regarded. One of these is the PHLOX DRUMMONDII. Why this is so is not difficult of demonstration. It is not from any fault of the plants themselves, but simply because fashions change in matters of gardening as they do in many other things; and to be in harmony with the prevailing fashion is thought by many to be the *ne plus ultra* of human existence. Thus when glaring red Pelargoniums came to be the prevailing feature in flower gardening, there was a general outcry at a floral scarcity, and what the Phlox Drummondii had to give way to the new style, quite apart, however, from any relative value of the two, but simply because Pelargoniums were the correct thing. Strange, that to be fashionably correct should very often imply much moral and social confusion and contradiction. But it is so.

My next-door neighbour has a bed of Pelargoniums, and I a line of Phlox Drummondii along a narrow, sunny border. He vows he will next season discard the former, and go in for Phlox Drummondii. The neighbours, having floral tastes, pass from a Pelargonium with a mere glance, but pause before my line of Phlox Drummondii, and wonder what they are. And well enough they might; for the sake of their pretty pleasant flowers be it stated, they are not grown so extensively as they deserve to be. I met with a capital bed of several varieties of this charming annual Phlox in an old-fashioned flower garden a few days since, and the various colours mingled together ranged from white with a slightly coloured centre to a rich sha led blood-crimson; and it struck me it was a happy thought that suggested to the gardener the planting among the Phloxes of some of the yellow Antirrhinum Drummondii, which being of a somewhat spreading growth, did not get above the Phloxes, and supplied a colour in which they were most deficient.

Since the lilac-purple Phlox Drummondii was introduced from Texas, nearly 40 years ago, a number of garden varieties have been raised from it, of all shades of colour, and any one of these, even though the seed may be selected and saved with the greatest care, will be certain to show considerable variation in the seedlings. Some of the varieties are noted for their extreme richness of colour, others for their soft and delicate tints, and all for their profusion of bloom, as well as for the long time they continue in flower.

Some years ago nurserymen used to grow a batch of the finest and most distinct varieties of Phlox Drummondii, the plants raised from cuttings. The pretty striped form, Radowitzii, can still be found in catalogues, and it not only makes a charming bedding plant, but is also very valuable for pot culture, and if kept during the winter, and allowed to get a little pot-bound, will flower very freely in the spring. A few years ago a fine and distinct striped variety was introduced by Messrs. E. G. Henderson & Son. Of varieties of self colour, we may recommend Cardinal, deep bright crimson, with a slight dark centre; General Grant, shaded purplish crimson, dark centre; and Rose d'Amour, pale pinkish rose, with shaded crimson centre. Each of these have produced types somewhat distinct in character, some of darker and some of lighter shades, some of the same tints with differences in the density and quantity of the central shading; and in the case of the rose-coloured variety several have a distinct white ring round the eye. Even more marked are the differences in the form and substance of the flowers, some have large, flat, stout, and finely rounded flowers; others small, pointed, thin, and star-shaped. Some of the forms of Cardinal are of a shining black-crimson hue. Other good varieties are Alba, Empress Eugénie, crimson and white; Heyrholdii, striped; Marmorata, marbled; Oculata alba, white and crimson; and Victoria Regina, purple.

A packet of mixed seed gives a good variation for placing in a bed indiscriminately. The seed should be sown in a pan or box in a mild heat, and pricked off into other pans or boxes, about 2 inches apart, as soon as the plants are large enough, and then hardened off in a cold frame, or any sheltered place in the open air, where some covering can be placed over them during cold nights, till the weather is sufficiently warm to admit of planting out in beds or borders. A good rich, light soil, of some depth, is the one that suits this Phlox best; the leading shoot should be pinched back to induce lateral growth; and the strongest shoots so made should be treated in the same way. A dense bushy growth results, and then is secured a mass of shoots, the main of which put forth laterals also. This keeps the bed dwarf, and at the same time well filled; and a bed thus formed, as well as one formed of Ver-

benas, in which the different colours are blended together similarly, will be among the pleasantest in the flower garden, especially if edged with some suitable foliaged plant. *R. D.*

August 10.—Hazy and foggy in morning. Generally cloudless throughout. Many meteors at night.
" 11.—A little cloud present at times. Very fine meteors at night.
" 12.—Generally cloudless. A brilliantly fine day. Lightning at night.
" 13.—A little light cloud occasionally. Very fine. Frequent lightning at night.
" 14.—Generally cloudless till after 9 P.M.; cloudy between 10 P.M. and midnight. Fine day.
" 15.—Cloudless throughout. A very fine day. Lightning at night.
" 16.—Cloudless, with the exception of the period comprised between 4 and 9 P.M., when clouds were prevalent. A fine day. Hazy.

JAMES GLAISHER.

Miscellaneous.

THE BRITISH ASS.

(Sung by a Cub at the Red Lions' Feed, Edinburgh, August 7, 1871.)

Air: "THE BRITISH GRENADIERS."

Some men go in for Shooting,
And some go in for Shams,
Some roar like hungry Lions,
And others bleat like Lambs;
But there's a Beast that at this Feast
Demands a special glass,
So let us bray, that long we may
Admire the British Ass!

With a tow, row, row, &c., &c.

On England's fragrant Clover
This Beast delights to browse,
But sometimes he's a rover
To Scotland's broomy knowes;
For there he finds above all kinds
The Plant that doth surpass,
The Thistle rude—the sweetest food
That feeds the British Ass!

We've read in ancient story
How a great Assyrian swell
Came down from all his glory
With horned beasts to dwell.

If you would know how it happened so,
That a King should feed on grass,
In Section D, Department B,
He had joined the British Ass!

On Grecian senses charming
Fell the music of the spheres,
But voices more alarming
Salute our longer ears.
A swell profound doth now propound
How life did come to pass,
From world to world the seeds were hurled,
Whence sprung the British Ass!

In our wandering through Creation
We meet these burning stones,
That bring for propagation
The germs of fish and bones.
And is it not a thrilling thought
That a huge misguided mass
Will come some day to sweep away
Our dear old British Ass!

The child who knows his father
Has aye been reckoned wise,
But some of us would rather
Be saved that sweet surprise,
If it be true that when we view
A comely lad or lass,
We find the trace of the monkey's face
In the gaze of the British Ass! *Nature.*

WHAT A SPIDER DID.—A gentleman once boasted to a friend that he could investigate in an engineer of more wonderful skill than Robert Stephenson. In fulfilment of the boast, he brought out a glass tumbler containing a little scarlet coloured spider, whose beauty, with the exception of a sprig of Laurustinus, had induced a young lady to pluck the sprig from the bush where it was growing. When brought into the house, it was placed on the mantelpiece, and secured by placing a glass over it. In a very short time this wonderful little engineer contrived to accomplish a Herculean task or raising the sprig of Laurustinus, a weight several hundred times greater than himself, to the upper part of the glass, and attaching it there so firmly that it remained suspended for many years where it was hung by the spider.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

WHAT an inestimable aid to the plant grower, as well as to the ingatherer of the fruits of our hardier soil and climate, is the gloriously fine weather which is experienced before I write! Unanimously first and foremost by the gracious Giver of all good. We rarely estimate at its proper value the really beneficial influences of a clear run of unbroken sunshine, and are apt to accept with a somewhat popular enthusiasm some of its most striking features, only as being worthy of consideration or remark. If our *Camellias* swell their bloom buds freely upon the season's young growth, we are not slow to attribute it to a fine autumnal period. Now, were it possible to under-estimate these facts, I would fain say, that fine bright sunny weather at this period is of even greater importance to the grower of soft-wooded plants, and such other kinds, of whatever dimension, as make their growth later in the season than the above. Whether we take late growing *Ericas*, *Pimeleas*, &c., or simply the commoner and even more succulent *Chrysanthemum*, this view is fully borne out. I have recently suggested in these pages that Chrysanthemums should not be pinched back any later than is absolutely necessary to guarantee fair bushy specimen plants, and that it is not a judicious procedure to stop them at all after July, if the production of fine blooms is the object in view. The fact that these and other similar habited plants make their growth too late, sufficient time is not allowed for that free development which a given quantity of light affords. Under these circumstances I may also suggest that every specimen plant should be partially turned round, so that all sides may gain a like benefit from those beneficial influences. Besides benefiting the plants this also proves beneficial to the roots, more particularly if they are placed out-of-doors in fully exposed positions. Here during very hot days the roots upon the sunny sides of fully exposed pots certainly cannot be as happy as they should be. Doubtless roots are formed, destroyed, and formed again at ruinous expenditure of strength on the part of the plant, but if these are turned round occasionally time and opportunity will be afforded them to collect food and re-establish themselves without suffering much harm. The cheerful looking *Begonia weltoniensis*, *B. digrueliana*, *B. Saundersii*, &c., will now in many instances be showing flower freely, and if it is not desirable to have them in bloom at their best a month hence (even though the two latter are perpetual flowerers, the first blossoms are always the best), it will be advisable to pinch off all flowers, stop the shoots when necessary, and induce further growth for a period. Oftentimes their having become pot-bound is the cause of their showing for flower, therefore another potting may be deemed advisable. Those *Cape Pelargoniums* which were cut back a few weeks ago, if they have commenced growing again, should be turned out of the old pots; have the old soil carefully removed from their roots, and be repotted in as small pots as the roots can be forced into without unnatural crowding. The little soil necessary should be composed of the best fibrous yellow loam possible, with a goodly quantity of silver sand and decayed leaf-mould. Be careful not to over-water them until the roots have fairly made a fresh start, but it would be advisable to lightly damp the young shoots over occasionally. Another sowing of *Mignonett* should now be made in pots, for winter flowering. Use good loam, and press it firmly into the pots upon a good, though not too abundant amount of crocking, upon which the seed should be sown. Continue to pinch back *Veronicas*, *Salvias*, and such subjects as *Correas*, *Cuphæas*, *Geniatas*, &c., which grow irregularly on misplaced shoots, or are not bushy enough. In stoves proper, the *Climbing Plants* will now need more than usual attention to keep them orderly, and free from ripening and decayed leaves. The purple-fruited Passiflora edulis, carrying a crop, will be much benefited by a good root-watering of wholesome liquid manure. So also will *Oranges*, *Citrons*, or *Limes*, which are now starting with a good crop of young fruit, be materially benefited by periodical applications of a like stimulant. Syringing over-head cannot be too frequently resorted to in the evenings of sunny days, in connection with all such plants.

FORCING HOUSES.

Maintain a good mean temperature in all *Pineries* while the fine sunny weather lasts, and so make up by every means possible for the dull weather of the past portion of the year. To this end 80° may be assumed as a mean under any circumstances, with a rise of about 10° more by external influences of temperature only. Be very careful not to over-water at the root those *Pines* which have lately been shifted on; as a rule, little water is needed for the first week or two following the potting. It is far more desirable to maintain them in a state of progressive growth by superficial applications with the syringe, and by maintaining a densely humid atmosphere. Give air with all possible freedom between the hours of 8 in the morning and half-past 3 or 4 P.M., according to the aspect of the structure. When the house is closed for the day give copious waterings to the side walls, walks, and all internal cool surfaces, syringing the *Pines* freely over-head at the same time during favourable weather. Be careful not to moisten unnecessarily those *Pines* intended for winter fruiting which are now in flower and "setting." Very moisture-master freely to all such as have finished blooming, and so afford the plants individually all the aid possible at the time when they are best able to turn it to good account, as it is needless to ply them with stimulants when the fruit are finally swelling off. Also remove rubber grills and feeders early from plants of such a size, for one and the same reason. Give air with great freedom to *late Grapes*, which now in a majority of instances will be beginning to change colour, by which means a better-developed skin will be formed, and the berries will be the better able to withstand the penetrating and injurious influences of long and damp winter months. *Fig trees* from which late crops are looked for should now have a copious root watering, and if in greatly confined or poor borders, manure-water will prove beneficial.

HARDY FRUIT GARDEN.

Young trees of any kind of wall fruits planted during the past winter will, if this weather continues, and they are planted in proper condition, require root watering. It should be needless to add how very beneficial occasional syringings will be to them during such weather as this. It is not necessary, however, be it understood, to induce them to continue a too exuberant growth by this aid. If the growth already made is maintained in sound health, free from flagging, so that the young wood becomes well developed, to stand through the winter and to prepare for another season's advance, the only end that should be aimed at will be attained. To encourage a too robust growth to the last is in every way opposed to the preparation of well ripened wood. The young shoots upon *Pears* and *Apples* of the current season's formation should now be cut back to within about three leaves of their base, except where extension is requisite, when the stronger and best-placed growths should be disposed of for purposes. These should only be "headed back" a few inches. Persist in stopping any gross breast-wood that may show symptoms of pushing upon any trees not bearing crops, as there is a tendency following such a season for trees under these favourable conditions for growth to do so somewhat freely, and often at the expense of those points or shoots which may more legitimately claim support. Continue to tack those shoots of outdoor *Vines* to the walls where an extended area has to be occupied, pinching or cutting back all laterals requiring removal.

HARDY FLOWER GARDEN.

Cutting making must now be earnestly entered on in connection with "bedding plants," selecting those most forced first, and so on to the necessary extent. *Calceolarias* should remain another month yet before any attempt is made to increase the stock of them; as to strike them too early has a very injurious tendency hereafter. *Rhododendrons*, Ghent and American *Azalees*, and the lovely *Kalmias*, which bear seed-vessels tending to decrease the vigour of the plants, should have the latter picked off. The parterre and summer flower beds generally, must be frequently picked over by all who desire to blend neatness and display into a har-

monious while, in keeping with the requirements of elevated taste.

KITCHEN GARDEN.

Should the dry hot weather continue it will be necessary to water all seed-beds, comprising such things as *Lettuce, Spinach, Endive, Carrots, Onions*, &c., down to afford successional winter and early spring supply. If we wait for rain it is but just to expect that a gap will occur in our supply at a critical time, and when no afterthought can be available for one aid. Immediately a good shower comes proceed with transplanting permanently those seedling plants of vegetables of a character to which the above are sufficiently large so to do. Especially will this be necessary in regard to the kinds of salading referred to, as those now transplanted are likely to come in useful to lift for placing in frames or pits of a like approach of winter. Water *Vegetable Marrows* and *ridge Cucumbers* copiously during hot dry weather. *Celery* will also need very frequent attention in this respect, as it is now—when the lengthened colder nights arrive, and with them the heavy condensed dews, bathing vegetation all around with their refreshing moisture—that Celery begins to grow apace. At such a period all the aid we can afford is accepted, and applied with a zest to increase the vigour of the plants. *Scorzonera* seems to have a great tendency to run to seed this season, therefore the flower-spikes should be cut out at once just above the originally formed strong leaves of each plant. *W. E.*

Notices to Correspondents.

CAMELLIAS : *Young Journeyman.* It is not a good plan to place Camellias out in the full sun after they have set their buds. Often they are considerably advanced to be stood out-of-doors, a situation shaded at least from the mid-day sun should be selected for them. Azaleas require less shade.

CLEMATIS : *Z. Watson.* A good shaped flower, but apparently of a colour now plentifully supplied amongst Mr. Jackman's and Mr. Cripps' hybrids. Its merit would entirely depend on profuseness or otherwise of its flowers.

FOREIGN SEEDS : *B.* asks if anything can be put amongst seeds sent from foreign countries to prevent them being riddled by insects, as they often are. Camphor might be tried. The harbour for insects afforded by close packing is fully avoided, and the seeds hung up in canvas bags, in a well ventilated cabin.

GALLS ON ELM : *Cor.* The large galls on your Elm are those of Schizoneura lanuginosa, Hartig.

NAMES OF PLANTS : *Hooker & Co.* Catalpa syringæfolia.—*Old Subscriber, alias Globe, alias Gospel.* Polygonum aviculare.—*James, alias Globe, alias Gospel.* Ononis arvensis.—*Gospie, alias Globe.* Fedium vulgare.—*Enquirer.* Hypericum elatum, the tall St. John's Wort.—*W. Taylor.* Eutoca viscida, native of California.—*Prestbury.* 1, Spiræa aruncus ; 2, Clematis integrifolia ; 3, Spiræa callosa (otherwise, S. Fortunei) ; 4, Funkia ovata, also known as Hemerocallis cordifera.—*Edwards.* Verbascum Thapsus.

ODONTOGLOSSUMS : *P. O.* triumphans Marshallianum is a very fine and distinct variety, grown by Mr. Marshall of Enfield. The flower spike was indeterminable. We do not know Oncidium macranthum Lambertyanum. Can any of our Orchid friends say in what respects it differs from O. macranthum hastiferum ?

PARSONS' MICONOPETTE : *D.* writes, Can any uninterested correspondent furnish him with an opinion as to this plant ?

PEACHES : *C. B.* The samples reached us in bad condition, but they were amply sufficient to confirm our correspondent's statement.

PELARGONIUMS : *Amateur.* Your tricolor sport, equal to Mrs. Pollock, but much more vigorous in growth, is certainly worth saving and testing, if your description is accurate.

PROLIFICATION IN ROSES : *Corr.* Not uncommon. In your case small flowers are produced at and from the part where the seed vessel usually spring.

ROSES FOR RAILWAY STATIONS : *Alex. Boyle.* Your suggestion is excellent, for why should our railway station houses, so often tasteful and picturesque in architecture, be the only homes which shun the aid of gardens, but with some charming exceptions, have them not. In the strong loam which you mention, and with the protecting pales, most of our best Roses would flourish ; but you probably require a succession of rapid growth and economy, and I would therefore recommend the Ayrshire or Sempervirens Roses, such as Ruga, Dundee Rambler, Rampant, Adelaide d'Orléans, and Félicité perpetuelle. Gloire de Dijon would not be omitted, but you would witch the passenger world with a surprise of beauty, let me suggest an intermixture of Clematis Jackmani, the contrast of its large purple flowers with the yellow Roses being most effective. *S. R. H.*

SALAD HERBS, &c. : *W. C. Randolph.* The following list will perhaps suit you :—Celery, Lettuce, Endive, Dandelion (the improved variety), Celeriac, Beet Root, Succory, Onion, Corn Salad, vulgo Cress, Mustard and Cress, Rape, Rampion, and Radishes ; amongst the kinds to be used most freely. Then there are the more piquant kinds : Borage, Burnet, Tarragon, Chervil, Horse Radish, Mint, Purslane, Scurvy-grass—and, if you will, Wood Sorrel, garden Rockets, and Nasturtium flowers. Your other question, as to the best method of furnishing a good salad for the greater portion of the year, we cannot answer in this column, without knowing what convenience you have, in the shape of glass, &c. See pp. 125, 267 of our volume for 1868.

STOVE PLANTS : *W. Jackson.* Cycas revoluta is given as a stove plant in Paxton and Don, which is sufficient to satisfy you in showing it as such ; Chamærops excelsa is similarly catalogued. The others are certainly greenhouse plants.

VINES : *A. B. Watland.* The affection under which your Vines are suffering is akin to shanking ; caused partly through overcropping and alternate changes of dryness and excessive wet in the border.

CATALOGUES RECEIVED.—B. S. Williams' Descriptive Catalogue of Bulbs, Roses, Fruit Trees, &c.

COMMUNICATIONS RECEIVED : C. P. P.—H. W.—F. C. D. —D. S. G.—W. B. L. (with thanks).—J. G. B.—J. H.—J. W. —G. N.—H. M.—J. R. H.—D.—R. B. (anticipated).—T. C. B. —J. F.—J. P.—G. H.—J. D.—H. R. P.—J. H. (thanks).

Markets.

COVENT GARDEN.—Aug. 18.

We have again to report a falling off in the supply of home-grown fruit, but the importations have been heavy, and are now meeting with a very steady demand. Strawberries are over. The Potato trade is quieter, and prices have slightly improved. The principal flowers in the market now are, Liliums, Pelargoniums, Asters, Calceolarias, Balsams, Mignonette, Dahlias, &c.

SALES BY AUCTION.

SALE THIS DAY, AT HALF-PAST TWELVE O'CLOCK.

Bulbs from Holland.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, August 19, at half-past 12 o'clock precisely, 500 Lots of First-class HYACINTHS, Well Ripened BULBS, COLCHICUMS, and SNOWDROPS, from several well-known Bulb Farms in Holland. Lotted to suit the Trade.

To view the morning of Sale, and Catalogues had.

Highly Important Sale
OF the CELEBRATED COLLECTION of ORCHIDS formed by S. RUCKER, Esq., at WANDSWORTH.

MR. J. C. STEVENS has received instructions from Messrs. Veitch & Sons, who have purchased the entire COLLECTION, to offer for SALE by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY and WEDNESDAY, August 22 and 23, at half-past 12 o'Clock precisely each day, the second portion of the above magnificent lot of Plants, amongst which will be found—

Cymbidium eburneum, true, best variety	Phalænopsis amabilis, and Schilleriana
Odontoglossum Alexandræ, fine varieties	Dendrochilum filiforme
Odontoglossum pulchellum mupius	Saccolabium guttatum, narrow leaf variety, extra fine
Cœlogyne cristata	Saccolabium retusum, Blumei
Lycaste Skinneri alba, true	Vanda Denniesoniana
Masdevallia Harryana	Dendrobium Wardianum
Sophronites grandiflora, fine variety	" Falconeri
Pleione lagenaria, and maculata, good masses	" bigibbum
Aërides Lobbii, fine plant	Cattleya exoniensis
" Fieldingii, magnificent variety, from Borneo	" Dowiana
Dendrobium Wardi	" Warneri
" nobilium, finest plant in the country	" labiata
Epidendrum myrianthum, fine plant	" Mossiæ
	Lælia anceps Dawsoni
	" purpurata
	Epidendrum nemorale, rare
	Cypripedium Veitchii, and other sorts, &c.

All the Plants are in fine condition, and many are in bud, or blooming.

On view the mornings of Sale, and Catalogues had.

Very Important Sales of First-class Herds
OF PURE-BRED SHORTHORN CATTLE.

MR. JOHN THORNTON will SELL by UNRESERVED AUCTION, on WEDNESDAY, August 23, at WESTLAND, CO. MEATH, IRELAND, the very FIRST-CLASS HERD of SHORTHORNS, bred by the late Thomas Barnes, Esq., whose adherence to the Warlaby and Killerby Herd for the last thirty years has given him the title of the "Booth of Ireland."

Immediately after the Sale, the small SELECT HERD belonging to R. W. Reynell, Esq., of Killynon, Kilmessan, Ireland, will be SOLD at WESTLAND, from which blood it has been bred during a period of nearly a quarter of a century.

On FRIDAY, August 25, will be SOLD, at CASTLE GROVE, LETTERKENNY, IRELAND, the ENTIRE HERD of FIRST-CLASS SHORTHORNS, bred by Lord Londesborough, and purchased from Mr. R. Booth's Fame tribe, and crossed with Warlaby blood; no less than fifty-seven First-class Bulls having been used at Castle Grove during Mr. Grove's long and eminently successful career as a breeder.

Catalogues, with Pedigrees, may be had of JOHN THORNTON, 15, Langham Place, London, W.

Sale of the late Mr. Barnes' Herd.
AT WESTLAND, COUNTY MEATH, IRELAND.

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on WEDNESDAY, August 23, at 2 o'Clock at Westland, near Kells, Ireland, the old-established and very celebrated HERD of SHORTHORNS, bred by the late Thomas Barnes, Esq., whose well-known judgment has brought the Stock to very great perfection. It was founded nearly 30 years ago with two Cows of the Mantalina tribe, purchased from Mr. R. Booth, of Warlaby. To these were added Bright Eyes, descended, through Mr. Lawson's Herd, from Mr. Bates's celebrated 2nd Sweetbriar; Mr. Booth's Duchesses; Isabella tribe. Bulls were, from the first, hired from Mr. John and Mr. R. Booth, and from Mr. Kilburn of Yorkshire; and, consequently, is not only very deeply in-bred to the best of Booth blood, but Mr. Barnes's selection of Bulls will be found to have produced a most exceedingly uniform
Catalogues, with Pedigrees, may be had of Mr. W. BARNES, Westland, Kells, Ireland; or of JOHN THORNTON, 15, Langham Place, Regent Street, London, W.

Westland, near Kells, County Meath, Ireland.
MR. JOHN THORNTON will SELL by UNRESERVED AUCTION, on WEDNESDAY, August 23 (immediately after the Sale of the late Mr. Barnes' Herd), the small, select HERD of PURE-BRED SHORTHORNS, the property of R. W. Reynell, Esq., of Killynon, Kilkenny, County Westmeath. It numbers about Thirty Head in all, from two tribes—the Fairy Queen and Duchess Stock bought by Mr. Holmes of Mr. Brown, at Chilton, in 1859 (whence the Oxford tribe came), and the Duchess Stock purchased by the late Mr. Barnes from Mr. Whitaker of Burley. The Bulls used have been of the best blood at Westland, Duke of Oxford (15,604), Royal Windsor (15,866), Lord Londesborough (20,738) being the latest sires.
Catalogues, with Pedigrees, may be had of Mr. REYNELL, Killynon, Kilkenan; or of JOHN THORNTON, 15, Langham Place, London, W.

Castle Grove, Letterkenny, Ireland.
MR. JOHN THORNTON will SELL by UNRESERVED AUCTION, on FRIDAY, August 25, at Castle Grove, Letterkenny, Ireland, the ENTIRE and VALUABLE HERD of PURE-BRED SHORTHORNS, the property of Castle Grove, Esq. It numbers about 50 head of Bulls, Cows, and Heifers, and is one of the few celebrated Booth Duchess tribe, bred by the late Mr. Richard Booth. The others comprise several old Shorthorn families, and are of great repute as breeder of Shorthorns (since the death of Mr. Barnes, perhaps now the oldest breeder in Ireland). The Bull animals for Sale are the best that have been used, are the best proofs of the high standing and excellence of the stock.
Catalogues, with Pedigrees, may be had of JOHN GROVE, Castle Grove, Letterkenny; or of JOHN THORNTON, 15, Langham Place, London, W.

Milcote, near Stratford-on-Avon.
HIGHLY IMPORTANT SALE of the MILCOTE DOWN SHEEP.

MR. HUTCHINGS has been honoured with instructions from the Executors of the late J. C. Adkins, Esq., to SELL by AUCTION, on Milcote, on THURSDAY and WEDNESDAY, September 13, at 2 o'Clock prompt (Luncheon at 12), the whole of the valuable FLOCK of PURE-BRED DOWN SHEEP, comprising 218 superb breeding Ewes and Theaves, 360 very superior Ewe and Wether Lambs, and a few extraordinary Shearling Rams, and 12 extraordinary Ram Lambs.
The great merit of this Flock demands a few words as to its formation. With Oxfordshire Downs as a foundation, the late Mr. Adkins, by judicious selection, has combined with them the best Wiltshire and Hampshire Down blood, and with much judgment and careful selection succeeded in producing a distinct type of Down sheep. While the Oxford symmetry is preserved, with the hardy constitutions, the Milcote Downs are remarkable for their heavy weight of fleet and fine quality of wool, early development and maturity. The rams will be brought forward in a natural and unforced condition. The Ewes, Theaves, Lambs, and Shearling Rams are strong to this Sale; and can assure Flockmasters that an entire Flock of such high character could not be purchased elsewhere for the money.
Catalogues will be circulated in due course, and may be had of the Auctioneer, 28, Bridge Street, Stratford-on-Avon.
Trains to Milcote Station, Great Western.—From Paddington, Oxford, Banbury, Leamington, Warwick, and Birmingham, 8.40 and 11.30 a.m.; from Paddington, Oxford, Moreton, Evesham, and Worcester, 8.25, 11.0, and 1.15.

Holker Hall, Lancashire.
IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has the honour to announce for SALE by AUCTION, without reserve, on WEDNESDAY, September 6, the whole choice Selection from the renowned Holker Herd, belonging to His Grace the Duke of Devonshire, which will consist of about 40 BULLS, COWS, and HEIFERS.
Amongst them will be found some Oxfords, Wild Eyes, Blanche, Cleopatra, Asia, and other famed Kirklevington tribes. The young Bulls are of the most approved character, the Grand Duke 3rd (24,064), Baron Oxford 4th (25,580), of the same line of blood, is now in active service. And the Cows and Heifers will attract attention of purchasers of first-class Shorthorns.
Catalogues, &c., may be had on application to Mr. STRAFFORD, 13, Euston Square, London, N.W.; or of Mr. DREWRY, Head House, Grange-in-Lonsdale, Lancashire.

Beaumont Grange, Lancaster.
IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions to announce for SALE by AUCTION, without reserve, at Beaumont Grange, on Wednesday, September 6, the whole choice selection of the renowned Holker Herd (the property of the Duke of Devonshire), which will consist of about 40 BULLS, COWS, and HEIFERS.
Amongst them will be found some Oxfords, Wild Eyes, Blanche, Cleopatra, Asia, and other famed Kirklevington tribes. The young Bulls are of the most approved character, the Grand Duke 3rd (24,064), Baron Oxford 4th (25,580), of the same line of blood, is now in active service. And the Cows and Heifers will attract attention of purchasers of first-class Shorthorns.
Catalogues, &c., may be had on application to Mr. STRAFFORD, 13, Euston Square, London, N.W.; or of Mr. DREWRY, Head House, Grange-in-Lonsdale, Lancashire.

Killhow, near Wigton, Cumberland.
IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to intimate that he is instructed to announce for SALE by AUCTION, without reserve, on FRIDAY, September 8 next, at Killhow, about FIFTY HEAD of very superior SHORTHORNS, belonging to J. P. Fawcett, Esq., that have been selected and bred with the greatest care from some of the most fashionable and pure strains of blood, to which have been used Bulls of the first class, 13th Duke of Oxford (25,902), from the famed Holker Herd, is now in service, and the young Stock are chiefly by him.
Catalogues, with Pedigrees, may be had on application to Mr. FERNEYHOUGH, near Wigton, Cumberland; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

The Agricultural Gazette.

SATURDAY, AUGUST 19, 1871.

IN several of the northern departments of France cattle disease prevails, according to the latest reports, and also in Lower Austria, Gallicia, and Transylvania. Poland has not suffered any fresh outbreak since the middle of June, when it was officially reported to be free from the disease.

We learn from a report in the *Chamber of Agriculture Journal* that the attempts to cure cattle plague are still continued in France, under the sanction of the Academy of Sciences. The system which is being carried into effect includes the administration of phenic acid (carbolic acid) and some additional process, which the inventor, M. DECLAT, has not yet made public. Whatever the merits of the curative system may be, our experience in this country justifies the statement that the general results must be disastrous. So long as diseased animals are kept alive for the purposes of experiment, the risk of communication of the infection is imminent, and no precautions will avail to prevent the spread of the disease. It is difficult to secure the complete isolation of sick animals on a single farm; but when the attempt is made on an extended scale in several districts, or counties, failure may be confidently predicted.

Veterinary authorities in Germany are quite as enthusiastic in their love of research as those of France; but having been taught by experience, they no longer incur useless risk in futile endeavours to cure a malady, which, whether curable or not, is so fearfully infectious, that its progress can only be stayed by the rapid destruction of every animal, or substance in which the germs of disease reside.

With the present regulation relating to the importation of French animals and materials which have been in contact with them, we do not run much risk of the direct conveyance of the disease to our shores, but of indirect communication of infection there must always be danger when the plague is only a few hours distant from us. Pleuro-pneumonia exists in many parts of this country and also in Holland, but not to the extent which might be apprehended from the vague reports which have been current; indeed, it appears from the official returns that pleuro-pneumonia has considerably decreased in the Netherlands during the last four years.

That we are, nevertheless, exposed to the danger of importing cattle affected with pleuro-pneumonia from Holland is a fact, which has been demonstrated recently by the landing of diseased cattle in London, but no instance of an outbreak of lung disease, arising from the movement of Dutch cattle inland, has yet come under our notice; while the instances are numerous of communication of disease by means of homebred stock which have been purchased at fairs and markets, and driven to healthy localities. If the evidence, which has been obtained by inquiry and observation during the last six months, is worth anything, it tends to show that there is less risk incurred in purchasing Dutch cattle at the landing-place, than in buying home-bred stock at many of the large markets.

All that has been stated respecting the miserable condition of the Dutch cattle which are landed, at the outports particularly, is true; but the conclusion which is often drawn, of their being dangerous on that account, is entirely fallacious. No amount of hardship and privation will produce the lung disease, or the contagious maladies to which stock are liable; and even in reference to susceptibility to infection, there is nothing in the history of pleuro-pneumonia to suggest the idea, that poor and badly treated animals are more liable to take the disease than pedigree stock in the *acme* of fine condition. Foot-and-mouth disease has extended considerably in a southerly direction, and has reached Portugal, a country which is usually free from this disease. Cargoes of cattle from Portugal, affected with the malady, have been recently

landed in this country. The disease has also increased in this country, and, from the inquiry which we have made in different parts, it would appear that the local authorities are disinclined in many places to take any active steps in reference to this disease; the expenses attending a regular system of inspection are considerable, and the benefits gained not by any means commensurate with the cost. There seems indeed to be a very general impression that the malady spreads, independently of direct contact with virus, and certainly there are circumstances which support this view. Numerous outbreaks have occurred in situations where infection, in the usual sense of the word, could not have had any influence.

Scab among sheep is unfortunately very rife; and, as the disease is curable with little trouble, its continuance must be ascribed to carelessness; it never exists on a farm where the ordinary precautions are adopted.

An Order of Council dated August 5 provides a means of meeting the difficulty by giving power to local authorities to make regulations for the treatment of sheep affected with scab. It remains to be seen how far the power will be exercised; but in answer to the complaints which will probably be made as to interference with liberty of action, it may be suggested that a farmer who insists upon keeping scabby sheep on his farm inflicts injury upon the flocks of his neighbours, who have a right to adopt strong measures in their own defence. The following are the terms of the Order referred to:—

"1. This Order shall take effect from and immediately after August 9, 1871; and words in this Order have the same meaning as in the Act of 1869.

"2. The authority of the Privy Council, if satisfied on inquiry, with respect to any regulation made under this Order, that the same is of too restrictive a character, or otherwise objectionable, may direct the revocation thereof, and thereupon, as from the time specified in that behalf by the Privy Council, the same shall cease to operate."

In the less productive parts of the country, where WOODS, SHAWS, COVERTS, and COPPICES occupy a large area, a considerable revenue is yielded when the management of this kind of property is understood; as, for example, in those south-eastern counties, famous for the growth of hop-poles, hurdles, and hoops. Unfortunately, except in particular localities, and on a comparatively few estates—the neglect of woodland property—so valuable in the aggregate—is lamentable. With the exception of a few districts where the growth of underwood has been stimulated, and where land of excellent quality has been appropriated to them, it is not often that one sees a wood that was well-planted in the first instance, or that is kept properly thinned.

It generally happens that the smaller coppices are let with the farms, and the larger woods are reserved. In either case, the planting of underwoods is a costly and permanent improvement which, under ordinary circumstances, a tenant cannot be expected to undertake; and when rabbits and hares, as well as winged game, are reserved, the improvements that might be effected are rendered impracticable both to owners and occupiers; for, unless ground game is destroyed, it is useless to plant any kind of wood or underwood, except perhaps Scotch or Spruce Fir, which they do not readily devour.

Presuming then that the teeth are to be drawn, or the mouths sealed, of the rodents whose mission it is to gnaw the bark and young shoots of trees when better food cannot be found in winter, we proceed to recommend the growing of underwood and to describe the soils and spots most suitable for the different kinds of wood; afterwards we propose to say something about the preparation of the land, and the costs and value of the crop.

In the ancient Weald, or wood, of Sussex, there is a district still called "the Forest," where every kind of underwood, from Chestnut to Birch, is grown on different soils and sites; and there is, perhaps, no locality which offers a better field for practical observation on various points connected with our subject than this extensive tract, which the Romans found and named a wood, and which from natural adaptability still remains so richly wooded, that when overlooked from surrounding hills the woods of Sussex appear to the eye to be almost unbroken. The hill district and the deep clay flat which surrounds it like a belt, form two divisions, in the latter of which the Oaks grow, in a bottomless clay, free as Willows, and Ash is the prevailing underwood; in the former the clay is mixed with sand in very fine particles, and the softer particles of soil are brought down the steeps of the hills by winter rains, so that a deposit of alluvial loam collects in the hollows. When these are wet, they are planted with Willow and Alder; when they are sound, as they usually are, Ash is planted. On the best land above Chestnut and Hazel are planted, and Birch, which is one of the least valuable of underwoods, though superior to Oak and Beech, occupies the poorest soils.

Birch affects even the sharpest sands, and is the natural growth of poor soils. We have seen it springing up on the former site of a wood where no wood was sown except by the hand of Nature, and rapidly take possession of the ground without culture, as soon as the timber was removed. And when a soft silky earth, filled with the roots of Fern and other plants, had been removed from the surface of a sandhill, for gardening purposes, Birch had immediately occupied the denuded surface, growing in almost pure sand.

Hornbeam, which is to the poor clays what Birch is to the sands, and which covers a good deal of ground in some neighbourhoods, is a sure sign of neglected arboriculture, inasmuch as better wood may be grown on the same sites by properly cultivating the ground instead of leaving Nature to herself, unassisted by Art.

The Hazel requires a soil in which there is sand mixed with something better, forming what is called a tender or hazel-loam. On good soils and in sheltered spots, where the climate is mild, its growth is exceedingly rapid. The Hazel-nut is a native of Britain, but it ripens best in the southern counties, and grows fastest in the warm hollows and valleys south of the Surrey downs—a pleasant district, where folds of hazel-hurdles are set, and most of the farms are fragrant with sheep and early Turnips by September 1. We have known an acre of Hazel-nut produce 50½ dozen hurdles, at seven years' growth. The price paid by farmers to the itinerant hurdle-makers for making these useful wattles is 2s. 6d. per dozen when the rods are not so large as to require cleaving. On such soils Hazel should not be allowed to stand more than seven years before cutting it.

The Chestnut makes the most valuable underwood for hop-poles, on suitable soils, but it will not succeed either on poor soils or where the climate is severe. At exposed elevations it is liable to injury by cold winds in spring, and in low damp spots its young shoots suffer from early frosts. On any light land, of fair quality, it may succeed; and we have known it outstrip several other varieties of wood on a poor sandy stone rubble, where the Birch was the native wood. It will be understood, however, that Chestnut is not the wood for weak soils, and it is worthy of notice that on the site alluded to, the native Birch, planted on trenched land, amongst Hazel, Chestnut, and other sorts, overtopped them all. On good sound land, consisting of mixed soil, drained by a chalk subsoil, Chestnut for hop-poles at 11 years' growth has been sold at more than £60 an acre, the buyers cutting it at their own cost. The value of the land to rent was about 35s. per acre.

The Ash, though by no means the only underwood growing in the clay district we referred to, is the most valuable and almost the only sort which is selected for clays when the land is prepared for the express purpose of planting. It grows, however, on a great variety of soils, and, mixed with Hazel, forms the *rowse*, or wide hedges, planted for shelter, which frequently divide the fields in exposed situations on the chalk downs, where the rock is covered by drift.

Oak makes indifferent underwood, and Beech the worst of any. There are no other sorts of wood that merit particular notice.

We now come to the preparation of the land and costs. As a partial improvement, the vacant places in woods should be filled up with plants, raised in nursery beds, of varieties suited to the soil, and planted where the stubs that were thin or declining have been put to their proper use behind the winter's fire. Strong plants should be set in comfortable beds, made by digging holes 18 inches square and a spit deep. The cost of labour is 1s. 6d. per 100 holes in soils of common texture. The Marquis CAMDEN'S beautiful woods at Frant, in the Forest-district which we referred to, have been treated in this manner with great success; and on the soft rubble and mixed sand and clay which compose the soil and subsoil, the Chestnut grows apparently as rapidly as it would if the land had been trenched.

In general, trenching is recommended for Chestnut plantations at a cost of £8 per acre; and though not practised in the case of the famous Ash-groves in the Weald, some persons go so far as to recommend trenching even on the clays, apparently under the impression that the more you do for the plantation the better it must be in the end. Our own method of preparation, which we recommend to proprietors or tenant-farmers, is to clear the land in the ordinary way with the plough, and to use the subsoil-plough if there is a pan underneath. We recommend planting all kinds of wood at distances of 3 feet—4840 plants per acre—planting the kinds that are observed to be best suited to the soil, and keeping the varieties separate, so as to have only one kind in the piece. Autumn-planting is best, and early in November is the proper time. In the case of wet land the surface drainage, which alone is necessary or practicable, by means of watercourses, "grips," and ditches, should be completed before planting commences. The plants should be three years old. The market price of well-rooted plants is from 20s. to 40s. per 1000, according to the sort and the locality, Chestnut being the most costly. They can all be more economically raised at home; foreign Chestnuts being set on seed-beds from which the surface-soil has been removed for the purpose of covering the fruit.

Weeds must be kept down until underwoods are old enough to smother them. Ash of nine or ten years' growth makes a good pole for various purposes. The Chestnut plantations in Sussex and Surrey which are grown for hoops for the London market, are cut down three years after they are planted, after which eight years' growth is the proper age for hoop-making, both for the Chestnut and other sorts. The price of well-established "planted underwoods," without timber, at the above age, is usually from £25 to £30 per acre.

These large figures and quick returns may, perhaps, induce some of our readers to plant, or to improve those unprofitable timbered woods where the good timber has been already removed, that which remains is not thriving, and the underwood, perhaps, is only worth £5 or £6 per acre at 14 or 15 years old! We saw recently 500 acres of woods and copses on one estate, where the planted underwood was worth £20 an acre as it stood, and the timbered underwood, at the same age, on similar soil, was only worth 20s. an acre; and the growth of the timber had made up only a small portion of the difference.

The prices paid for cutting underwood are—6s. per load of hoops, 1s. 6d. per dozen hurdles, 3s. per 100 for cutting out "spray" faggots and stacking them, 4s. for house faggots, 2s. 6d. per 100 hop-poles.

THE possibilities for the AGRICULTURAL LABOURER, and the actual facts of his condition, are two very different things. And whose fault is that? The whole subject has lately been exceedingly well discussed in the columns of the *Chelmsford Chronicle*, from which we extract the substance of several letters in another page. One of these, written by Mr. OFFIN, who occupies probably more land as a tenant-farmer than any other Englishman, will be read with much interest. We believe that, in the long run, that condition which arises out of a given set of circumstances, where there is no artificial interference with the natural tendencies, is the best of which that set of circumstances is susceptible. Let exceptional energy, industry, and wealth bear its natural fruit without hindrance—let farms increase in size by the failure of some and the success of others—let the labourer do the best he can for himself without any tie actual or implied to farm or parents—let every motive which freedom can offer be active everywhere for the increase of profit, whether to landowner

working man, or tenant—let the profitable results of industry, whoever may be the recipients, be cordially welcomed as the natural premium by which industry is promoted, and we believe that the best results will come out of which the circumstances admit. But what are "the circumstances," or rather what is the leading circumstance, on which the whole depends? Unquestionably the whole condition depends infinitely more on character than on any other thing—the character including intelligence as well as morals, including industry and honesty, sobriety and resolution, as well as dexterity and skill. Education, therefore, is what is wanted—that sort of education especially which both inspirits and equips a man for the right discharge of whatever duties belong to the station in which he is born.

We add nothing further at present to the letters on this subject in another page; they give, we believe, nearly all that can be said, whether in commendation or in blame, of the several classes represented—in whom we at present witness the wealth and poverty, the recklessness and industry, the selfishness and self-denial, the merit and demerit on which partial critics successively comment.

—— A small supply of English Wheat at Mark Lane on Monday (including a few samples of new) met with a fair inquiry at previous prices; red declined 1s. to 2s. on the prices of that day fortnight. Trade was quiet on Wednesday, at previous rates.——The hot weather caused a slow trade at the Metropolitan Cattle Market on Monday, but prime qualities were not much affected in price. Choice Lambs were scarce and dear. On Thursday trade was again dull, at declining prices. ——The excitement in the Wool Market continues.

—— The Northumberland Agricultural Society's Meeting at Alnwick last week was most successful. The progress of this society has been exceedingly satisfactory, as is indicated by the large increase in exhibits. There were 84 entries in the Shorthorn classes, and among the bulls Mr. W. Linton's Earl Irwin took the first prize in a commendable and commended class. The show of cows was excellent, the 1st prize being awarded to Sir John Swinburne for an animal which was also successful in obtaining Sir Walter C. Trevelyan's silver cup, valued at £20. Calves of both sexes also formed a good feature of the exhibition. The display of sheep was one of the best ever witnessed in the district, the prize-takersbeing the Rev. R. W. Bosanquet, Rock; Mr. G. Hope, Fenton Barns; Mr. Thomas Forster, jun., Ellingham; Mr. Thomas Elliot, Hindhope; Mr. Robert Shortreed, Attonburn; Mr. John Robson, Byrness; and Mr. T. H. Hutchinson, Manor House, Catterick. We are glad to learn that the shearing question was "the subject of considerable remark," and that the "opinions of the secretary and committee of the Northumberland Society are such that steps will probably be taken before long to prevent, if possible, the practice of clipping animals into shape." For the rest, there was a good show of horses, comprising 383 entries, well on to 100 more than had ever been entered before. Implements also formed an interesting and useful feature of what appears to have been a most excellent meeting.

—— The annual Midland Counties Show of Horses was opened on Tuesday at Bingley Hall, Birmingham. The weather was very fine, the show an excellent one, and the attendance large. The entries this year, as previously stated, were 283 against 282 last year. There was a great increase in the hunter classes. Thoroughbred stallions for getting hunters occupied the premier position. The class was a small one, there being only seven entries, and the 1st prize went to Messrs. C. and J. Moffatt, of Kirklinton Park, Carlisle, the owners of Laughing Stock. The winner of the 2d prize, Gem of the Peak, is the property of Mr. W. H. Logan, of Tamworth. Mr. W. E. Everett, Pinstall House, Bromsgrove, took 3d prize for Paul Jones, the winner of the Hunter Cup and the St. Leger. In the class of hunters exceeding 15¼ hands high, and equal to 15 stones, the 1st prize fell to Mr. J. Harvey, and D. Bayly, of Ollerton, Notts, for a chestnut horse; Mr. T. Perceval, Wansford, took 2d prize; and 3d fell to Mr. T. Bowman, of Eaglebaston. In the class of hunters exceeding 15¼ hands high, without condition as to weight, and five years old and upwards, there were no fewer than 23 entries. Mr. S. J. Welfitt, of Tathwell Hall, South Lincolnshire, took the 1st prize; the 2d went to Mr. A. Newman, of Winchcombe, Cheltenham; and the 3d to Percival, of Wansford, was awarded the 3d prize. For hunters not exceeding 15¾ hands high, there were only two prizes offered. Mrs. C. F. Dilke, Coleshill, took the 1st prize with a horse which has been a competitor and taken prizes in previous years at this show, and the 2d fell to Mr. E. S. K. Wolferstan, Stafford Hall, Tamworth, for a grey gelding. In the class for 4-year-old hunters, Major Barlow, of Hasketon, Suffolk, took the 1st prize with a horse which was 2d in the same class at Wolverhampton; the Major also took the 2d prize with the 1st prize horse at Islington last June; the 3d prize went to Mr. C. Cooke, of Taddington, Winchcomb. The prize-winners in the class of 3-year-old colts and fillies for hunting purposes were Major F. Barlow, Mr. E. Phillimore, Prestbury Park Farm, Cheltenham; and Major Barlow. In the class of 2-year-old colts for hunting purposes, the 1st prize fell to a gelding belonging to Mr. J. Goodliff, Conington Lane, Stilton; the 2d to a gelding, the property of Mr. J. M. T. Musgrave, Beverley; and the 3d to Mr. J. Watson, Hartlebury, Worcestershire. In the class of agricultural stallions, the prizes were awarded to the horses belonging to Mr. H. Tomlinson, Blickford, Ongeley; Mr. John Manning, Orlingbury, Wellingborough; and Mr. T. Middleton, Lyddington, Uppingham. The entries in the various classes of roadsters, hacks, and ponies were numerous. For weight-carrying hacks, not exceeding 14¼ hands, the 1st prize was taken by Mr. H. Frisby, 13, James Street, Buckingham Gate, London; and the 2d by Mr. G. W. Shillingford, Eynsham, near Oxford. Mr. Frisby also took 1st for the best harness horse not exceeding 15 hands, the 1st in the class for horses exceeding 14, but not above 15, hands, and the prize for the best pair of horses in harness. Mr. H. J. Wilde, Bridgnorth, took the 1st prize for horses in saddle not exceeding 14 hands high; Mr. H. Gameson, of Birmingham, the 1st prize in the class of ponies in harness not exceeding 13 hands; Mr. F. A. Grew, Birmingham, the 1st in ponies not exceeding 12 hands; Mr. J. Goodliff, Stilton, the 1st in ponies not exceeding 12 hands high, to carry children; Mrs. C. F. Dilke, of Maxstoke Castle, the 1st in pairs of ponies in harness; and the 1st in ponies in tandem under 14 hands, went to Mr. C. Myring, Walsall.

OUR LIVE STOCK.

CATTLE.

The following prices were realised at the sale of Lord Faversham's Shorthorns, on Thursday, the 10th inst., at Duncombe Park.

Name of Animal.	When Calved.	Price.	Purchaser.
Cows and Heifers.		Gs.	
Sympathy	1865	33	Mr. Hodgson, Highthorne.
Pearl..	1866	26	Mr. R. H. Bower.
Royal Celia..	1868	33	Mr. Cattley.
Peppermint	1868	40	Hon. E. Lascelles.
Magdala	1868	31	Mr. Coverdale.
Leoline	1868	33	Hon. E. Lascelles.
Syren..	1868	32	Mr. T. Stamper.
Princess of Ryedale ..	1869	37	Mr. W. Scoby.
Polygeneva	1869	56	Mr. Hodgson.
Victoria 3d	1869	39	Mr. Cattley.
Lily of Ryedale	June, 1870	21	Mr. Newton.
Lozenge	Mar., 1871	51	Mr. Cattley.
Cornucopiæ	1867	58	Mr. Newton.
Rose of Ryedale 2d ..	June, 1870	20	Mr. Radcliffe.
Bulls.			
Manchester (26,798) ..	1866	45	Mr. Cattley, Stearsby.
Capri	1867	30	Mr. Newton, Overton.
Hospitality	1867	35	Rev. Mr. Dauby, Stamford.
Pyladis	1868	33	Mr. T. Brookes, Thirsk.
Colonist *..	1869	53	Major Stapylton.
Coriolanus	1868	37	Mr. Burt, Grantham.
Chancellor	1869	31	Mr. W. Taylor, Malton.
Corinthian	1869	33	Mr. J. Newton.
Colonist 2d	Feb., 1870	55	Sir H. Johnstone.
Fine Star	June, 1870	31	Mr. W. Harvey.
Sedan	Sept., 1870	30	Mr. Priestman.
Cicero	Jan., 1871	24	Mr. Elliot.
Colonist	Feb., 1871	17	Hon. E. Lascelles.
Victorious..	Feb., 1871	17	Rev. W. Prest.

—— Next week will witness three important Shorthorn sales in Ireland, conducted by Mr. John Thornton. On Wednesday the 23d inst., the late Mr. Barnes' herd, comprising 43 head, and Mr. Gaynell's herd, comprising 24 head of cattle, will be disposed of. On Friday, 25th inst., the Castle Grove herd, so well known in connection with Mr. J. G. Grove, and consisting of 45 head, will be sold. Slightly reviewing these catalogues in the above order, we find a reservation on the part of Mr. W. Barnes of a bull and seven cows, to be the nucleus of a future herd. The catalogue opens with *Medera* by Dr. M'Hale (15,887), a direct descendant of *Medora* by Ambo, the first of the five tribes into which the entire catalogue may be divided. The names of Nimrod (13,388), Selim (6454), Rex (10,000), and Hamlet (8126), leading back to the celebrated Ambo family, and later of Duke of York (23,804) and King Richard (26,523) attests the care with which this family has been bred. This excellent strain was introduced by the purchase of Mr. R. Booth's *Swaithtier*, of his favourite "Hamlet" tribe, and consists at present of 13 females and three bulls. *Gift 5th* (lot No. 2) is the first of four descendants of *Gift* by Hamlet (8126) and also of the renowned Frederick (7023). *Spiranza* by British Flag (19,351), *Brilliant* (lot 4) by Ravenspur (10,628), and *Bright Eyes* (lot 5) by Ravenspur (20,628), three daughters of *The Nun* by Dr. McHale, are descendants through Mr. Lawrence's herd, from Mason stock, and are the origin of a large section of the Westland herd, comprising in all nine individuals. *Grand Duchess* by Mr. S. E. Bolden's Grand Duke 3d (16,182), dam *Sylph* by Hopewell (10,332), and of the famous *Mantalini* by Marcus (2262) tribe, was the ancestress of no fewer than ten animals, comprising *Grand Duchess 3d* by Royal Sovereign (22,802) and *Bracelet* by Royal Duke (25,014). Lastly, there are five descendants of *Red Rose* by Roseberry (5011), one of the first bulls used in the herd, and purchased from Mr. R. Booth.

Mr. Reynell's herd, which has been carefully reared at Killynon, Co. Westmeath, during the last 25 years, consists almost entirely of two tribes. It was first started with the cow *Fairy Queen*, purchased on the recommendation of the late Mr. Holmes, who had bought the cow by Mr. Mason's *Matchem* at the time of the Chilton sale from Mr. Brown, the breeder of the *Matchem* cow, which was sold to Mr. Bates and became the ancestress of the celebrated Oxford tribe. The "Pauline" family, bought of the late Mr. Barnes, was purchased by him from Mr. Whitaker, of Burley, Yorkshire, whose herd was noted for its great dairy properties. The bulls since used have been bred by Mr. Barnes, at Westland, and are chiefly of the celebrated "Mantalini" family. Several of the animals are by those noted sires Duke of Leinster (17,724) and Royal Prince (27,384), both hired to go to England, and used by eminent breeders. The young calves are chiefly by Lord Spencer (26,738), who will be sold with the Westland herd.

The Castle Grove herd consists of eight families, all of which are of Booth origin. The sires have been selected from Killerby and Warlaby, and have been used in the following order:—Prince Arthur (13,497), King Alfred (16,334), King Arthur (13,110), War Eagle (15,483), Sir Roger (16,991), Elfin King (17,796), Sir James (16,980), British Crown (21,329), The Sutler (23,061), Great Hope (24,082), and England's Glory (23,889). The catalogue opens with *Coquette* by Cornet (11,298), and from *Norma* by Druid (10,140), a direct descendant of Mr. Booth's celebrated cow *Fame* by Rasper (1857). This excellent strain of blood is represented by 11 females and three bulls. Mr. John Colling's *Rachel* by Frederick (1060) was the foundress of what is known as the "Ruth" tribe, represented at Castle Grove by eight individuals, and Mr. Mason's *Lady Sarah* by Satellite, dam *Portia* by Cavo, is the common ancestress of nine heifers. The remainder are good cattle, having in several cases five or six crosses of first-class Booth bulls.

—— At the Winterfold sale on the 20th ult., Mr. Strafford disposed of 50 head of Shorthorns, the property of Messrs. John Harward and Isaac Downing, for the very good average of £54 15s. 9d. Thirty-nine cows made £61 15s. 9d. each, and 11 bulls made £59 19s. 5d. each, the total realised being £2,159. We have only space to record the highest prices obtained. After the first two lots had been disposed of, *Kirklevington 16th*, by Duke of Wetherby (17,753), dam *Kirklevington 12th* by 4th Duke of Oxford, and therefore an extraordinarily well-bred cow, appeared in the ring, and was bought by Mr. Thornton, for the Earl of Bective, at the high price of 355 gs. *Tacita*, by Duke of Rutland, was sold to Mr. F. Leney, for 60 gs. *Cherry Blanche 2d* by Charleston (21,400), and of the "Blanche" tribe, to Lord Chesham for 85 gs.; *Kirklevington 17th*, by Duke of Wetherby, to Mr. R. P. Davis for 175 gs.; *Lady Mary 3d*, to Mr. J. K. Foster for 83 gs.; *Kirklevington 22d* by 5th Lord Wild Eyes (26,762), dam *Kirklevington 16th* by Duke of Wetherby (17,753), was secured by Mr. Thornton for the Earl of Bective, for the very high price of 300 gs. *Countess Blanche* by 3d Duke of Claro, was sold to Captain Webb at 71 gs.; *Lady Worcester 8th* to Colonel Kingscote at 80 gs.; and *Kirklevington 24th* by 5th Duke of Wharfdale (26,033), to Mr. W. Ashburner at 100 gs. In the bull sale, the only prize worthy of special notice, from the extraordinary figures above given, was 70 gs. for the Earl of Chatham by 3d Duke of Claro (23,729), given by the Rev. C. W. Holbeach.

—— Mr. F. Leney's *Grand Duchess of Geneva*, a daughter of *7th Duchess of Geneva*, purchased at Windsor for 700 gs., produced on the 6th inst. a very good white cow calf, got by Grand Duke of Kent (26,289).

SHEEP.

The Right Hon. Lord Chesham has sold the whole of his draft Shropshire ewes to Richard Milward, Esq., Thurgerton Priory, Notts, and his lordship has selected a ram lamb from the flock of Mr. Thos. Nock, of Sutton Maddock, at 35 gs., being one of the pen of five which obtained 2d prize at the Royal Agricultural Society, at Wolverhampton.

RAM SALES.

At Adcott Hall, on Wednesday the 9th inst., a large number of breeders assembled to witness the sale of Messrs. Masfen's rams. The first ram was a 2-shear, Major, winner of the "Royal" 1st prize, 1871, by Conservative, bred by Mrs. Wadlow, which was also the sire of many of the best lots. He was purchased for Mrs. Beach, at 50 gs.; the 2d, also a 2-shear, and winner of the 2d prize at Oxford, being let to Mr. C. Byrd, at 40 gs. Mr. Kemp Bourne gave 32 gs. for a 3-shear, which had been let

in previous years to Mr. Coxon and Mr. Firmstone, at 40 and 45 gs. Then followed the shearlings headed by the Wolverhampton 2nd prize ram, True Type, by the Marquis, which was hired by Messrs. Masfen and Keeling at 71 gs. ; Mr. C. Byrd taking the next at 40 gs., at which figure a shearling was hired for the Earl of Bradford ; and Mr. May secured a good shearling for the season at 31 gs. Other shearlings made 37 (to Mr. Bostock), 25, and 20 down to 5½ gs., the average for the 43 being close on £20.

The ewes did not make as much as was anticipated ; four pens going to Lord Chesham at 67s. 6d. to 92s. 6d. each, two to Mr. German, at 90s. and 92s. 6d., and others to Messrs. Felton, Roberts, Juckes, Price, &c., at from 80s. down to 60s. The average was about 72s. 6d.

—— Mr. W. G. Preece's 36th great annual sale, at Shrewsbury, commenced on Thursday week, when a very large number of rams from some of the most noted flocks in the kingdom were submitted. The attendance was scarcely so large as usual ; but the rams offered, it was admitted, were, as a whole, of the very highest character, and at times the biddings were very spirited. The first lot brought to the hammer was a 3-shear ram by Young Patentee, the Prime, which was sold for 10 gs. A 2-shear, by Lord Warden, was let for 14 gs. ; and a shearling, by Conservative, for 5 gs. Thirty-five rams, the property of the executors of the late Mr. Crane, of Shrewsbury, and Mr. Edward Crane, of Forton, were next submitted. A grand shearling ram by Crosswood Hero, dam by Duke of Newcastle, was let for 41 gs. ; and another by Crosswood Hero, dam by Plymouth 2nd prize, for 44 gs. The whole made an excellent average. The Rev. W. Peter sold two shearlings for 53 and 6 gs. respectively. Mr. Thornton, of Pitchford, disposed of a 3-shear ram, by Volunteer, for 18 gs., and a 2-shear for 17 gs. Mr. T. Horton, of Harnage Grange, sold 13 rams at a fair average, the highest figure being 16 gs. Mr. Harding Pirate, by Corsair, a "Royal" 1st prize The Hon. E. Kenyon obtained 16 gs. for a good 2-shear by Packington 2d ; but sold four other rams at lower figures. Mr. Joseph Crane, of Calcott, realised an average of over 12 gs. for five rams. Mr. Fenn, of Stonebrook House, Ludlow, and Mr. Hardlass, of Bromfield House, offered 14 rams, all of which were sold ; and a 2-shear ram, their property, was let for 20 gs. A 2-shear ram, by Fatback Patentee, was let for 50 gs., and a shearling, by the same sire, for 17 gs. Another shearling was sold for 27 gs. Fifteen of Mr. Chesham's rams were disposed of ; the competition being very keen for a shearling by Duke of Manchester, which realised 36 gs. The next highest price was 21 gs. for a shearling, by Kenyon's ram (No. 3). Mr. E. Bostock, of The Hongh, Stafford, sold five rams ; a shearling, by Horton's Duke of Lorne, making 20 gs. Mr. Andrews, of Nobold, let one ram for 10 gs.

Nearly 1000 ewes were sold the second day (Friday), and would average close upon £4 each, these being sent by the following breeders :—Messrs. Crane, Evans, Horton, Fowler, Fenn and Harding, Williams, Edwards, Bostock, Price, Mitton, Payne, Lee, Everall, Pickering, Freece, Holder, Nevett, Bridgeman, Jones, Wood, Morris, Bather, and Captain Lovett. In several instances as high figures were paid for ewes from an ordinary farmer's flock as for the drafts from the most noted ram breeders, but a few show pens realised as high as 10 gs. per head.

—— At the Oxford ram sales in Mr. Smith's Close, near Worcester College, on Wednesday week, nearly 800 rams and other sheep from the most celebrated breeders in the country changed hands. The auctioneers were Messrs. Jonas Paxton and G. Castle, J. & W. Scroggs, Franklin & Gale, and Mr. J. A. Mumford. There was a large attendance of farmers and breeders from this and neighbouring counties, and the rams, which were of excellent quality, and for the most part of extraordinary size, fetched very high prices. Many of those submitted to public competition were from flocks which had won prizes at the Royal Agricultural Society's and other exhibitions. The sheep were generally admired, and the competition throughout was spirited. Mr. Blake's (Botley) 45 Oxfordshire Down ram lambs realised £6 16s., the highest price being 11½ gs.—Mr. Joseph Roberts, of Curbridge, sold 40 Oxfordshire Down shearlings, for an average of £16 9s., and this, we understand, is the highest average for this class of sheep that was ever obtained. The highest-priced sheep was sold to Mr. Treadwell, of Winchendon, for 42 gs. The next highest was sold to Mr. Wallis, of Shifford, for 41 gs. Mr. Longlands purchased one at 33 gs., and two were sold to Mr. Baldwin (Stratford-on-Avon) and Mr. J. Bryan (Southleigh) for 28 gs. each.—Mr. G. Wallis' shearlings realised an average of £13 11s. 6d. ; the highest figure was 21 gs., the buyer being Mr. Hobbs, of Maiseyhampton, and one was sold to the Duke of Marlborough for 13½ gs.—Mr. C. Gillett's 16 Cotswold rams fetched an average of £7 12s. 3d. The highest figure reached was 13 gs., the purchaser being Mr. C. Duffield, of Marcham. Mr. G. Drake, of Bignell, purchased one at 11 gs., and Mr. Brooks, Lyford, one at 10 gs.—Mr. W. H. Hunt's 12 Oxfordshire Down shearling rams were disposed of at an average of £12 14s. 6d. The best sheep in the flock was sold to Mr. Richard Eagle, Northmoor, for 18 gs., and one to Mr. Prickett, of the same place, for 13½ gs.—Mr. C. Gillett, of Cote House, sold some Oxfordshire Down shearling rams at an average of £10. The highest figure was 15½ gs., the buyer being Mr. Badcock, of Abingdon. Some of Mr. Gillett's sheep have won prizes at the Royal and other shows.—Mr. J. Parker, of Ifley, sold his Oxfordshire Down ram lambs at an average of £6 5s. 9d. One was sold to Sir Henry Dashwood for 13 gs., and one to Mr. Allin, Littlemore, for 10 gs. Mr. Parker took a 1st prize for sheep at the Royal Agricultural Society's Show at Oxford in 1870.—Messrs. W. and F. Franklin, of Ascott, sold 39 at an average of £6 8s. 10d. The highest figure was £15 10s., the purchaser being Joseph Gale, of Caddesdon. Mr. Franklin, of Cumnor, purchased one for £11 10s.—Mr. W. H. Gillett, of Southleigh, sold his Cotswold ram lambs at an average of £5 2s. 6d. Mr. Bolton, of Finstock, purchased the best sheep for 8½ gs. —Messrs. Franklin & Gale submitted for public competition about 50 Oxfordshire Down ram lambs, the property of Mr. H. Gale, of Caddesdon, and they averaged £6 3s. 3d. each, the highest price being 16 gs., and the lowest 3½ gs. Mr. J. T. Gale, of South Minster, Essex, purchased the highest priced sheep.—Messrs. Franklin & Gale also sold 200 ewes and lambs, and 100 ewe lambs, the property of Mr. W. Parsons, of Elsfield, being the whole of his breeding flock of Oxfordshire Downs. This capital flock is descended from some of the best Oxfordshire Down blood, and was disposed of in consequence of the owner relinquishing breeding. The ewes and lambs made from 50s. to 73s., and the ewes and the lambs from 38s. to 70s.—Messrs. J. & W. Scroggs offered 35 prime Oxfordshire Down ram lambs and 8 shearlings, belonging to the executors of the late Mr. F. Pratt. They possessed good skins, were of first-class colour, and combined blood from the celebrated flocks of Mr. C. Gillett, Mr. Wallis, and Mr. Treadwell. They realised an average of 8½ gs.—Mr. J. A. Mumford submitted for competition about 20 Oxfordshire Down ram lambs, from the noted prize-taking flock of Mr. J. K. Shrimpton, of Easington. The average of this lot was £4 4s., the best lamb fetching 6 gs., and being purchased by Mr. Hancock, of Boarstall. The other purchasers were Mr. Hopcraft (Brackley), Mr. Byford (Suffolk), Mr. Dover (Aston Sandford), Mr. White (Pollicott), Mr. Lindars (Tetsworth), Mr. Louch, Mr. Sheppard, and Mr. Clark.

—— On Tuesday Messrs. Ewer & Winstanley, of Salisbury, put up to sale by auction, at Salisbury, upwards of 200 rams and ewes of the noted Hampshire Down breeds, the property of Mr. Dibben, of Bishopstone. There were six lots of rams to be let until September 1, and for one of them the extraordinary price of 70 gs. was given by Mr. Budd, of Hatchwarren, Hants. The other five went at the following figures :—Lot 1, 8½ gs. ; lot 2, 7½ gs. ; Mr. R. Coles ; 4, 9½ gs., Mr. Barton ; 5, 8 gs., Mr. Olding ; 6, 8 gs., Mr. Jones. Lambs sold as follows :—Lot 7, 11½ gs., Mr. Blake, Chitterne ; 8, 12 gs. ditto ; 9, 14 gs., Mr. Coles ; 10, 6½ gs., Mr. Brown, Stockton ; 11, 6½ gs., Mr. Jones ; 12, 7½ gs., Mr. Stevens ; 13, 6½ gs., Mr. Barton ; 14, 11½ gs., Mr. E. Pinckney ; 15, 23 gs., Mr. J. Fleetwood ; 16, 17 gs., Mr. Olding ; 18, 11 gs., Mr. Pern ; 19, 10½ gs., Mr. Pinckney ; 20, 24 gs., Mr. W. Taunton.

—— The sale of Mr. Coxon's flock on Monday of last week, which was entrusted to Mr. Preece, of Shrewsbury, opened with Conductor, a "Royal" prize sheep, which was let for the season for 101 gs. to Mr. German, after a keen competition from Mr. E. Crane. No. 2, winner of 1st prize at Oxford, used last year by Mr. German, went to Mr. Barnwell at 24 gs. ; and other aged sheep made from 10 to 16 gs. The first shearling ram by Mansell's Manston 3d, gone to Mr. Hamilton, Dunbyne, at 41 gs. ; and another by Commander, to Earl Howe at 31 gs. Others sold at 24, 20, 19, 16, down to 6 gs. ; the average being £47 4s. The ewes ranged from 135s. to 60s., several pens making 100s. or upwards. The buyers included several gentlemen who are establishing a flock of Leicesters. The results of the above sale tend further to prove that ram breeders must pay high figures to secure the best sires, if they are to maintain their positions ; as new men are fast treading on their heels from the opportunities afforded for the obtaining the best blood in the ewes offered at the various public sales.

—— Mr. Cole's annual sale and letting of ram lambs and rams, by Messrs. Harding & Sons, of Frome, took place in a field adjoining the Boreham Road, Warminster. The sale commenced by letting ten ram lambs, some for a month, others for the season. Lot 1 was let for a month, at 9 gs. ; lot 2, for the same time, at 5 gs. ; one other lot at 5 gs., one being let under, viz., 4½ gs. The ram lambs for sale then followed. Lot 13 made 15 gs. ; lot 15, 8 gs. ; others made 7½, 6½, 6, to 5 gs., no animal being sold under that sum.

—— At the Cirencester August sheep and cattle fair, Messrs. Moore & Hill sold 16 Cotswold shearling rams, the property of Mr. Edward Fowler, of Aston Farm, at an average of £15 7s. 1½d. ; 11 rams, the property of Mr. Charles Barton, of Coln St. Dennis, at an average of £13 13s. ; and 14 rams, the property of Mr. Thomas Clarke, of Frampton Mansell, at an average of £12 16s.—Mr. James Villar sold 6 Cotswold rams for Mr. T. Bevir Browne, of Salperton Park, at an average price of £10 17s. ; 10 rams for Mr. W. Smith, of Bibury, at an average of £10 4s. 9d. ; 26 rams for Mr. Henry Cole, of Ashbrook, at an average of £14 15s. 7½d. ; 4 rams for Mr. W. Peachey, of Cubberley, at an average of £8 10s. 6d. ; and 3 for Mr. R. Peachey, of Chedworth, at an average of £7 17s. 9d.—Messrs. Acock & Hanks sold 13 Cotswold rams for Mr. J. H. Pedley, of Bibury, at an average of £11 16s. 2d. ; 12 rams, the property of the executors of Mr. Thomas Gillett, of Kilkenny, at an average of £17 6s. 6d. ; and 30 rams, bred by Mr. Barton, of Fyfield, at an average of £14 12s. 7d. Mr. Barton's average last year was £10 14s. 8d., for 50 sheep.—Mr. Villar also sold 22 Oxfordshire Down rams for Mr. C. Hobbs, of Maiseyhampton, at an average of £12 7s. 6d.

A WALK IN WESTMORELAND.

The year 1870 proved a most disastrous one as regarded the hay and green crops in the south of England ; while in the North a succession of showers in May and June made the meadows more than usually full of grass, and the hay was housed in the middle of July in excellent condition ; in fact, the yield was larger than were the demands of the district, and the slender crops of the South were supplemented, at a reasonable price, from the North. Green crops, too, were unusually luxuriant, and more hay was sold in consequence. A fortnight's tour in the Lake districts of Lancashire, Cumberland, and Westmoreland, in the middle of July, has induced me to make a few practical remarks on the agricultural and horticultural capabilities. Seeing much over which to rejoice and much to admire, I yet saw a good deal to deplore.

First, then, in season, I was glad to see the excellent crops of hay grass. The meadows are very full, and the recent and almost daily showers have greatly thickened the crops at the bottom growth. Owing to the difficulty which has been experienced in working and housing, consequent on the showery season, a portion of the hay must have deteriorated in quality. Sufficient, however, remains to render the crop considerably above an average. Some farmers, in their eagerness to get the grass under cover, took advantage of every gleam of sunshine to shake out the hay. In those cases considerable harm has followed, whilst those who left it standing in cock till a fine day came—and the wet and fine have been pretty alternate—housed it without material hurt. From the nature of the season, the fog or after-grass must necessarily be a heavy crop ; meadows, from which the hay had been removed a fortnight previous, presented a most luxuriant growth.

In many portions of the country, however, acres and acres of good meadow land are to be seen quite overgrown with the Ox-eye Daisy, and many fields present the appearance of having been visited by a heavy snow storm. The plague of locusts with which Egypt was visited in the days of Pharoah was not more destructive than is this pest to the grass lands, and unless some united effort is made by farmers—and that speedily—it will entirely usurp the place of grass in the whole country. Every practical farmer is well aware that cattle will not eat the Ox-eye Daisy in its green state, and only in the extremity of want will they eat them when mixed with the hay. Such is the pertinacity of the seed, that it will grow after passing through cattle. An easy method of clearing the pest is to pasture the land, where it prevails, by sheep for three successive years. The sheep eagerly seek and nip the young flowers, and thus prevent them seeding ; and if the farmer will take the precaution to cut off the few flowers which, in autumn, may escape the sheep, three years will see his land relieved from the incubus which now seriously threatens to destroy its fertility. This seems to me a duty which every agriculturist owes to himself, his landlord, and his neighbour. Another point we must briefly touch upon. As a nation, we are liable to especially produce to supply our wants. Yet, in the districts referred to, I have seen hundreds of acres of land, in the hands of landed proprietors, which did not produce one-tenth what they might be made to produce. From year to year, I was informed, the land has been left unlimed, and the scanty produce sold by auction, until, at the present time, the grass crops are scarce worth the cost of labour to make them into hay. I should think a Bill to compel landowners, in the interests of the nation, to properly fulfil their duties to their fellow men, might meet with more favour than have many Bills of the present session. The green crops which are grown in the districts under observation are—Turnips, Mangel Wurzel, Carrots, Potatos, and a few Cabbages ; more of the latter might be grown to profit. In all these the crops are very heavy and healthy. Potatos are especially productive, and free from disease), mostly very clean, and evincing great care. That these counties will have a sufficiency of autumn and winter fodder seems now almost beyond the possibility of doubt. Of the fruit crops I cannot speak so favourably. A severe night's frost in the middle of May completely destroyed the blossom of very many orchards, and the trees now present a leaf-blackened appearance, as though blighted by lightning. Gooseberry trees suffered from the same cause, and the caterpillar has also been very abundant. The latter pest is the easy remedy that I wonder at its yearly infliction. A bunch of Grote (or, as it is called in

some districts, Whin,) tied in the middle of the tree, is an unfailing preventive. Wheat and Barley, of which there is a great breadth sown, particularly in Furness, evinces evidence of more than an average yield, and a fortnight of warm sunny weather would make them ready for the reaping-machine. Splendid in ear and long in stem—many of the fields showing a height of 6 and 5 feet respectively—the Wheat and Barley fields present a sight well calculated to gladden the eye of the agriculturist. Of the corn crop I cannot speak so favourably. Looking from a distance, no fault can be discerned, but a close examination shows a woeful number of black or "smut" ears; in fact, I never saw it more prevalent, and the quality of the grain will be much affected by it in the threshing and grinding. To prevent this, change of seed is frequently tried, but, in most cases, in vain. The surest method is to throw on to the seed a spadeful of quick-lime, work it up with a hay-rake till the seed is white, and then pass it through a pailful of old urine, or, as it is commonly called, "old chamber ley," and then dry. Another pest of the corn fields I was sorry to see most luxuriant, viz., "Wild Kail." Many acres of grain presented the appearance of the "Field of the Cloth of Gold." It is firmly believed by many farmers with whom I conversed whilst on my tour, that it is impossible to eradicate this weed, which only springs into existence after the land has been ploughed. I know of many fields, which had been free previously, been disturbed within the memory of man, on being gone over with the plough, produce a heavy crop. My remedy is to well and carefully harrow the land in the autumn, and thus eliminate all the "wicks;" then green crop for three successive years, taking care to hand-weed should any stragglers make their appearance. I do not say that this will in all cases totally eradicate the "kail," but if proper precaution be taken it will be many years before it will again cause the farmer any inconvenience. In conclusion, I congratulate the farmers of the North on the promising prospects. A fortnight of warm, sunny weather will give them crops of all and every description, such as has not been experienced for many previous years. *Y. R.* [Our North Lancashire correspondent, writing on the 9th inst., says that "The hay harvest is now completed, and, owing to the almost total failure which has overspilled since Saturday last, a great quantity of hay, previously uncut, has been housed in good condition, thus rendering the well-secured crop above an average. A succession of hot days, combined with brilliant sunshine, is also fast changing the colour of the grain, and some farmers have commenced Oat cutting. The fine weather has come in the nick of time, and will, no doubt, materially alter the aspect of affairs for the better; and the grain crops of the district, which a week ago were viewed with despondency, now promise a bright future. The same remarks will apply to green crops. Another week of similar weather to that of the present will place us in the midst of harvest."]

STEAM ROAD ROLLING.

[We extract the following from the columns of the *Athenæum*, where it appears as a Review of the "Report on the Economy of Road Maintenance and Horse Draught through Steam Road Rolling," by Frederick A. Paget, C.E. (Spon.)]

THE state of the roads of a country is at once an index and a cause of the general civilisation of the period. No individual element of human progress is of more, it would be hard to name one of equal, importance. A visit to Portugal, to Greece, or to Southern Italy, is calculated to impress this fact very forcibly on the mind. Good roads bring freedom of intercourse, equality of prices, and encouragement for industry, and are the veins of that circulation, in the absence of which the body politic festers in sloth and brigandage.

The mighty European revolution, in the midst of which we find ourselves, is due, at all events as to its actual state, to the wonderful impetus given to national and international communication by the application of steam power to transit by land and by sea. Long before George Stephenson had astounded a committee of the House of Commons by proposing to travel at the rate of 16 miles per hour, we had attained that respectable speed by some of our best-appointed coaches. On the highway, as well as on the ironway, speed is to a great extent dependent on the smoothness of the surface of the road. Less than a century ago England was not better off in respect of internal communication than the less civilised parts of Europe are at this day. Even on the great mail routes different time-tables were adoped for summer and for winter. The scarlet-coated guard of the royal mail often laid down his blunderbuss to seize hold of the warm some heavy, plodding waggoner to draw his vehicle aside out of his rut, and let the king's service pass. The man who effected this change—need we say that his name was Macadam?—enjoyed a green old age in the memory of some of us who do not yet consider ourselves old men.

The ideas carried out by this great reformer of our highways were simple, and were true. The earth has ultimately to bear the weight of all moving traffic. To do so, it only requires to be kept dry, and with an unabraded surface. Therefore the old idea of forming a road like a continuous arch, and throwing a stress on wedge-shaped stones driven in at the sides, is a mistake. Let the road be fairly levelled, sloped to either side, properly drained, and then covered with an artificial breccia, or stratum of broken stones, not larger than 5 or 6 oz. in weight, which will consolidate into a homogeneous mass, and at once keep the earth below from being cut into by the felloes of the wheels and from being soaked by the rain.

So far all is plain. Then comes the question, How is the broken stone to be consolidated? Here our road-surveyors stopped, arrested by the fear, which was a misjudged one, of expense. They left this consolidation to be effected casually, by the natural traffic passing over the road. In so doing they committed, and daily commit, two great economical sins. They consolidate their road in at once the least effective and the most expensive manner. They never make a homogeneous road. Ruts are formed in places, before the greater part of the surface has become smooth. Water percolates during the whole process. Repairs are needed irregularly, locally, and in the most inconvenient and expensive manner; and while the cost of the work actually done by the road-surveyor—the cost of metal, labour, and repair—is thus actually doubled, as compared with that of a similar road finished and consolidated at once, the cost incurred by the owners of the vehicles, which are thus converted into very inefficient rollers, may be estimated by the fact that the draught over the new road is five times that over an old road which has become smooth.

It is, therefore, a remarkable and not a creditable fact that, while steam road-rollers have been used in France, with admirable results, since their invention by M. Louis Lemoine in 1859, and have even been seen on some of our principal metropolitan thoroughfares, completing, in a few hours, work with admirable and perfect success, the work which is yet thrown on the owners of private vehicles, we are content to abuse the parish authorities, to double our road rates, to lame our horses, and to shake and damage our carriages, and our nerves into the bargain, by the barbarous layers of broken granite which are duly spread to welcome the London season. Only so recently as the opening of the Embankment road it was remarked, as a striking proof of the incompetence of the Metropolitan Board of Works, that the steam roller had not been employed. It is therefore, with some surprise that we receive a "Report on the Economy of Road Maintenance and Horse Draught through Steam Road Rolling," which is "printed by order of the Metropolitan Board of Works."

How this report came to be not explained. In fact the little pamphlet is not, strictly speaking, a "report." It is the work of an advocate,—a fair advocate, no doubt; but does not attain the judicial impartiality proper to an inquirer's report. The author tells us that "it is proposed to prove that rolling roads is indubitably a powerful means of economy to the road maintenance." He keeps his word, and gives a large amount of valuable information bearing on the subject, both from English and foreign sources.

The residents of London are especially interested in the question, from the fact that paving is rapidly displacing Macadam. The lesser cost of maintenance on a paved road subjected to heavy traffic is such as to cover the larger original expense of paving. As it is in evidence that the durability of the Macadamised road is nearly doubled by the employment, in the first instance, of the steam-roller, every householder and shopkeeper in the great lines of traffic has a direct personal interest in the matter.

As to the ratepayers, Mr. Paget gives us some very detailed estimates, to the effect that the average sum of £280,000 per annum is expended annually on the maintenance (exclusive of cleansing and watering) of 1127 miles of Macadamised road within the City and the 38 parishes and districts of the metropolis. He tells us, indeed, that "within a radius of only 12 miles from Charing Cross there are at least forty millions of square miles of Macadamised road;" but this is, no doubt, only one of the inexplicable freaks of our "drudging goblin," the printer's devil. But the steady rate of metropolitan increase, the population doubling in rather less than 40 years, promises at least an equally steady augmentation of road area and road cost. To save £100,000 per annum at once is a consideration for the rate-payers, and it is well that they should know that this large sum is now wasted by the neglect of a simple and proper engineering process.

With regard to the actual money cost, and the far larger damage by way of depreciation, sustained by the proprietors of the 72,000 horses and 30,000 vehicles, that are now involuntarily employed in pulverising the broken granite, which they never properly consolidate, the estimate is less easy to form. If extra labour, shoeing, and damage to the horses, were taken at an average of 2*s.* 6*d.* per horse per week, which, probably, few proprietors would think too high, we come to a tax imposed on horses of £468,000 per annum. Let us suppose the extra wear and tear of carriages and harness (the total value of the capital invested in which Mr. Paget estimates at £1,150,000), to be included in this allowance. The figures would give a cost of between 5*d.* and 6*d.* per superficial yard of Macadamised road as the cost of badly compressing it by expensive vehicles; and it is by no means certain that such an estimate would be excessive.

Mr. Paget has rendered a service to civilisation by bringing together in an accessible form so much information on a subject in which every Londoner may be said to be personally interested. We hope that the 39 governing bodies of the metropolis will be compelled by those whom they govern, no longer to take this extra £140,000 a year (to say nothing of the higher estimate) out of the pockets of the rate-payers. Drivers and driven in any vehicle, from the most elegant landau to the most closely packed omnibus, as they set their teeth when they find themselves grinding over broken granite, should be made aware that it is an unnecessary evil, altogether due to the obstinate neglect of the use of the steam-roller. Of that fact we have long been convinced; and we trust that the Metropolitan Board will proceed to practise what they preach with such undeniable force.

THE SANITARY CONDITION OF SCOTCH VILLAGES.

COLONEL SIR JAMES E. ALEXANDER read a paper before the British Association at Edinburgh, "On Sanitary Measures for Scottish Villages." Among the evils pointed out as existing in these villages were the overcrowding of cottages, the system of "box-beds," in which father, mother, and children might often be found huddled together, the built-in windows quite incapable of being opened, the general want of air and ventilation, and the proximity of cow-sheds and pigsties. The writer showed how ministers, surgeons, schoolmasters, and employers might promote the welfare of the people by inculcating the laws of health and promoting a taste for pure and innocent recreation.

MR. WILKINSON, Hertfordshire, did not intend to go into the question of drink, but was persuaded that a diminution of the number of beer-houses in country villages would do more than anything else to improve the moral, physical, and religious aspects of the poor.

MR. LAMFORT, alluding to the erection of houses for the people, said his own idea was, that the working classes would not be got into good dwellings until they were educated to understand that their pockets were ultimately concerned in living in wholesome dwellings.

MR. THOMAS KNOX said it occurred to him there was a previous question to be considered with regard to houses before any real progress could be made in sanitary reform, and in lowering the death-rate either in cities or villages. The questions of water, beer-shops, &c., were not essential. The first thing they had to do was to define what was a fit and proper human habitation—how many cubic feet of air must a family of a certain size possess in order to live a healthy life. He held that traders in houses, like traders in every other thing, must be made amenable to fixed laws. Dealers in meat and bread were not allowed to expose unwholesome food for sale, and he held that any legislation must apply primarily to houses, and people should not be allowed to be huddled up simply because they were too poor to defend themselves. It might seem to be an interference with the liberty of the subject, and what was called free trade, only to be believed it was the only one in the end to realise a perfectly moral and sanitary state of society. They did not go into these things at present on the ground of extravagance, but nothing was so expensive to a community as an epidemic. They sowed the seeds of epidemics in the lanes of the poor, and spread their present monstrous condition, and yet they thought it very remarkable, and an inscrutable act on the part of Providence, when they had a scourge passing from end to end of the city, and striking down rich and poor. In point of economy and humanity, they must commence at the back in first principles, and insist that no man should bring a house into the market which was not safe and habitable for human beings.

DR. J. H. GLADSTONE, adverting to the question of water, said that there fell upon the roof of every house about enough water to supply the inmates, if they took care of it, but in scarcely any cottage was provision made for securing the rain-water. Were tanks or storage attached to each cottage, they should seldom hear complaints of drought, and they should also cultivate habits of purity and cleanliness. He advocated, with the writers of papers, than which, nothing of greater importance had been discovered within the last ten years.

MR. WILLIAMS, Wishaw, said that a short time ago he had come to Scotland to erect iron works, and he had also found it necessary to build houses for the men whom he brought from England. Many of these men would not enter the Scotch houses, and wondered how people could live in such abominable places.

REV. W. CAINE, Manchester, said he had been for two years chaplain of one of the largest gaols in the kingdom. About 800 prisoners, on an average, were under his charge at once, and, on inquiring into their antecedents, he had found that a very large amount of crime arose from deficient house accommodation.

Professor RAMSAY, Glasgow, stated that in Glasgow a ticket was placed on each common lodging-house, showing the amount of cubic feet of air it contained, and the number of inhabitants it was allowed to accommodate under the Police Act. The regulation was strictly carried out, and had done much good already to the city.

MR. A. E. MACKNIGHT, advocate, traced a great deal of the evils in the social and sanitary condition of the poor to the conduct of the landlords in the country,

who were unwilling to give land for building additional village accommodation; and he thought some compulsory measure was wanted to compel them to give the land at fair and reasonable prices.

SKIM CHEESE MANUFACTURE.

[The following is the conclusion of our extract from a paper on Butter Factories in the States, vol. vii., English Agricultural Society's Journal.]

The Oblong Shape.—Recently a new form, or style of cheese, has been introduced, which promises to be a success. The advantages claimed for it are—

1. The curd is pressed in a large cake (pressing in one curb or mould from 10 lb. to a 1000 or more) and then cut into blocks of any desired size. These blocks are then bandaged, and placed in the mould in layers, and again pressed, and the whey starts again, especially at the freshly cut sides. In this manner cheeses may be made weighing from 10 to 100 lb. each, to suit any market, and small cheeses can be made at very nearly the same expense as large ones.

2. The escape of the whey by evaporation is greatly facilitated by this form of cheese-cakes, for, as the whey percolates towards the bottom of the cakes (these cakes being turned from time to time only a quarter of a revolution), the whey, instead of turning back toward the centre of the cheese—as is the case with all round cheese—is turned at right angles thereto, and is consequently always tending towards the outside; and the whey is so far expressed and evaporated that decomposition is much less liable to take place.

3. These cakes being entirely covered with bandage, may be cured with or without greasing, and are thus rendered safe from flies.

4. They are much more easily turned and handled than round cheese.

5. They are shipped to market in boxes of thin stuff of any kind of timber. Any farmer can make them, making the boxes of such size as he chooses, and at an expense much less than for round boxes. For 10 lb. cheeses boxes are used with success containing 18 cheeses, 180 lb.; and for 30 lb. cheeses, 8 in a case, 240 lb. This item of boxes is a great advantage. The boxes are solid, and there are no covers to come off. The cleats on the outside of the boxes prevent them from being packed too closely together in carrying or in store-houses. There is a great saving in weight, as, in the old style, down weights are given in each cheese, while in this shape only one down weight is given for 18 small cheeses or 8 large ones.

6. For retail trade this form of cheese is of great advantage. The dealer can weigh the whole cheese, and cut by measure the exact weight required, and many of the cheeses are sold without cutting.

7. For family use small cakes are a great success. A 10 lb. cheese is 10 inches in length and 5 inches square, and is cut for table use as follows:—

Turn the bandage back from the end, cut a thin slice from the end of the cheese, then cut off the desired slices for the table, and replace the thin slice and bandage; set the cheese on end, and it is sealed and as safe as an uncut cheese.

8. These cheeses cure much better than round ones, as the gases, if any be generated, escape from the ends, and are not forced back and forth through the cheese as with round ones.

9. They take less room in the dry-house, and women and children can easily turn and handle them.

10. For exportation they greatly excel the round cheese. They can be packed closer, boxes cost less, and small cheese can be boxed and shipped at nearly the same expense as large ones. They have been shipped to England with great success. We give cuts which will explain more fully this invention (figs. 245 to 248).

Fig. 246 represents a sectional elevation of a cheese-vat or mould. When the curd is ready for pressing, it is placed in the mould (A) of rectangular form, and with one side (B) arranged to swing open on hinges for the removal of the cakes after they are pressed. After the curd is pressed into a broad flat cake it is vertically cut with a fine saw into two or more blocks (C C), and bandaged with muslin. These are placed one upon another in layers, say two deep, in the mould, with thin boards or other plates between them, and are again subjected to the action of the press, by which the whey is still further pressed out, especially of the freshly cut sides of the cakes. The pressing is continued as long as needed, after which the cakes are removed to the shelf or curing-room, to allow the remaining whey to escape by evaporation. This is claimed to be facilitated by the form of the cake, because, as the whey percolates towards the bottom, and in turning as is required, from time to time, the cakes are only turned a quarter of a revolution, the whey instead of being turned directly back in its course is turned at right angles, and is consequently always tending nearer to the exterior.

In this way, together with the pressing, it is claimed the whey is so far dissipated that decomposition is much less liable to take place, and, therefore, the cheese may be preserved without the greasing commonly employed.

Fig. 248 represents a perspective view of a cheese made according to this improvement. It rests upon a table with scale-board (E), and with knife (F) for cutting into different weights, according to the measurement on the scale E. Fig. 247 represents a perspective view of a cheese cut and partly used.

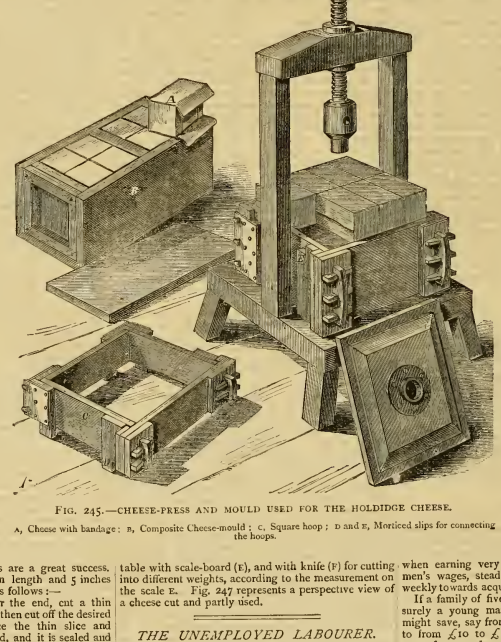

FIG. 245.—CHEESE-PRESS AND MOULD USED FOR THE HOLDIDGE CHEESE.

A, Cheese with bandage: B, Composite Cheese-mould: C, Square hoop; D and E, Morticed slips for connecting the hoops.

THE UNEMPLOYED LABOURER.

[A correspondence has lately appeared in successive numbers of the *Cheltenham Chronicle* on this subject. We take the following extracts.]

1. MECHANICS are much better educated than agricultural labourers, and consequently are more independent, because knowledge is power and teaches them to know their value. The labourer, working by himself, or, at most, with two or three mates, has not the same opportunity of interchanging ideas. There is no institute for them where they can meet together to ventilate their grievances, saving that institution, the taproom of the village public, where, over a pint or two of "adulterated," the little intellect they possess becomes woefully bemuddled, and from which the most respectable of their class keep away. Born and bred to their lot, they accept it; they are inured to it; they scarcely murmur, because they dare not, because that spirit of independence which every honest man should possess is crushed out of them. Because their murmurs are not heard, it does not follow that they have no grievance to complain of; because they submit to their lot it does not follow that lot is not a hard one. The fact is, they are utterly powerless; they are under their master's thumb, who very frequently is their landlord as well as their master, and as they do not wish to be turned out into the street, they submit almost to any conditions that may be imposed on them.

And it is unquestionably this system of large landholding and off-hand farming that fosters and increases an undue feeling of utter dependence upon his employer, on the principle that the fewer the number of farmers the fewer the number of hands employed, because the demand for labour is less. This state of things is unhappily exemplified in the parish where I live. Here the land is mostly held by a very few large farmers, and the consequence is that except at the busiest times of the year—viz., haytime and harvest—there are always hands out of work, not from any fault of their own, but because little more than three-quarters of the labourers are employed that would be were none of the land let off-hand; while in the neighbouring parish, where this pernicious system does not obtain, and where the number of farmers is greater, the demand for labour is higher, and consequently it is an exceptional thing to find a man out of work.

It would be very interesting if some of your readers would furnish the public with a few statistics, such, *e. g.*, as the number of acres there are in their parishes under cultivation and the number of hands employed per acre. For instance, let us take the case of Mr. Olfin, who I am informed is the largest tenant-farmer in the county, and who farms I don't know how many off-hand farms. (I have not the pleasure of his acquaintance, though report says he is a kind-hearted, liberal man; but that is not the question. I select him only because he is a very large farmer; and I hope he will pardon me for using his name, but not in vain.) Does he employ as many labourers as would be employed were all the land he holds split up into smaller farms of not more than 400 acres each, with a tenant resident in each farmhouse? If he does not do so, then, kind and good as he may be, he is inflicting a great injury on the country, he is diminishing, or is helping to diminish, the amount of the public revenue, and is increasing or is helping to increase the local rates."—*Observer*.

2. I think it important that there should be a good discussion on the subject of the farm labourer, his condition and prospects. As my contribution to it, allow me to suggest that the labourer's wrongs are in many cases self-inflicted. True, when a farm man has a family, it is well nigh impossible for him to put by against a rainy day. But take the case of young men. Why should not they when earning very nearly, and in some cases fully men's wages, steadily resolve to save a few shillings weekly towards acquiring a more independent position?

If a family of five or six can live on 12*s.* per week, surely a young man earning 10*s.* or 12*s.* per week might save, say from 4*s.* to 5*s.*, which would amount to from £10 to £13 per year. Various suggestions may of course be made as to the best mode of using these savings, but the most desirable appears to me to use a portion in emigrating to a country where labour is much more highly paid, where the rent of land is merely nominal, where thousands of acres are waiting for the labour with which this country is superabundantly supplied. A small capital spent in emigration must, if properly managed, yield a rich harvest; and besides providing a comfortable home and income for himself, his future wife, and family, the emigrant lessens the number of workmen in this country, rendering it easier for those who remain to find remunerative employment. But how few are willing to exercise sufficient self-denial to enable them to save even 2*s.* or 3*s.* a week. Instead of this, young men in too many cases squander their earnings while single, or marry early, thereby putting it out of their power to save money at all, and then follows the state of affairs described in the letter of "A Labourer." I have no wish to assert that the farm labourer is more improvident

than many men in other classes. I know the difficulties with which he must contend are great, but not, as I think, insuperable. What is needed is more provident habits, industry, energy, and self-denial, qualities but too rare in all ranks of life.

If a farmer by taking several farms is enabled to discharge a few labourers, without diminishing the annual produce of those farms, the profits are increased by the amount of the wages of those labourers, and the wealth of the country is augmented. But if this increase of wealth is spent by the farmer and his wife on themselves, it is clear that in the end the wealth of the country remains the same as if he had not discharged the labourers. In the one case the increase of wealth, which might be saved and employed in producing more, is enjoyed by the farmer and his wife, and in the other case it is divided among the labourers. No doubt it would be better for the labouring class if the farmer would forego the hunters, &c., and employ more labourers, but in so doing he would be performing an act of charity—he would be employing a portion of his income for the benefit of the labouring classes. He might benefit them more effectually by employing his surplus in emigration. *Another Observer.*

3. Beyond a sense of Christian obligation, which unhappily is not to be in general expected, what motive has the young farm labourer of 20 for being exceptionally abstemious, frugal, honest, and industrious? Why should he take pains to understand soils, cattle diseases, and the best methods of cropping and general farming, seeing that he has no longer the remotest chance of being in a position to think and farm for himself? Why not marry before he can keep a wife, and drop his surplus at the taproom instead of the savings' bank, seeing that his becoming a pauper is only a question of time, and no character he could earn, or little capital he could put by, would ever give him a chance with the selfish landlord, who neither knows nor cares, nor means to know or care, about him? I forbear saying what such men are preparing and maturing to do for themselves.

All these and other moral coming evils and difficulties connected with bloated farm-holdings have been to some extent noticed. The following have not:—

1. When the village blacksmith, and wheelwright, and shopkeeper are gone (the two first reduced to the ranks as mere journeymen on the farm, the last superseded by the co-operation farm store), how are parish offices to be filled? how are coroners' juries and petty juries to be empanelled?

2. All not and its not useful objects suffer, needing help in or outside the parish? I have in my eye a parish of 1200 acres. There were eight small but thriving farmers, true English stock, none of them ever wanting help, but all more or less ready to give it—now and then a stingy one, but the majority could always be depended on. Now the eight are reduced to two, and both are stingy, so the springs of charity are all but dried up. *A Third Observer.*

4. I do not intend to follow "Observer" through all the ramifications of his letters, but simply to state a few facts for his information.

As a farmer holding from 5000 to 6000 acres of land, I have several farms I hold off-hand which have come into my occupation through the landlord not being able to find a resident tenant, in consequence of the deplorable state the farm had been left in. I will just mention one special case.

A farm of about "Observer's" favourite maximum size for resident holding was occupied, to my own knowledge, by five different tenants in 15 years; each of those tenants took all he could out of the land, without putting anything into it; they employed little or no labour, and at last it was thrown on the landlord's hands, with a loss of two years' rent.

I would ask "Observer" what the landlord did for his property by allowing such tenants to occupy it? and what "Observer" would have done under the circumstances had he been the landlord? There can be only one reply, viz., to let the farm to a man of skill, with plenty of capital, for a given time at a lower rent, in order that the land, which had been starved to death, should be restored to life. I ask "Observer" how this could have been accomplished without great additional cost?

"Observer" appears to consider that off-hand farming to a large extent is detrimental to the "labourer, his condition and prospects."

I demur to this. I have cited one case only, thinking it would be sufficient to show "Observer" how it is that farms are held "off-hand" to the extent they are at the present day.

I could give him many more instances of the kind.

Several of the farms I hold off-hand were pressed upon me under similar circumstances to that I have stated, but by means of capital I have been enabled to make the land yield me a fair return.

"Observer" will understand the word capital to mean "labour," which is the essence of capital. Money cannot yield a profit without labour. In my off-hand farms I keep sheep where no sheep used to be kept; I keep a herd of bullocks where no bullocks used to be seen; I keep double the number of horses and men my predecessors kept. I have everything possible consumed upon the farms instead of selling everything from them, and the average wages of the majority of my men throughout the year upon all my occupations is from 15*s.* to 16*s.* per week.

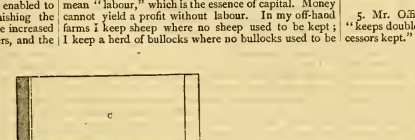

FIG. 246.—CHEESE-VAT, OR CHEESE-MOULD, FOR HOLDIDGE CHEESE.

I should not have troubled myself about "Observer's" letters but for his having brought my name before the public in his letter No. 2.

I think your correspondent's letter No. 1 would have been better appreciated had he continued throughout

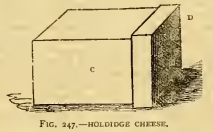

FIG. 247.—HOLDIDGE CHEESE.

to have advocated the "condition and prospects" of the labourer instead of showing his dislike to the farmers' wives of the present day, who I have no doubt perform their household duties in their day and generation quite as well (but in a different way) as their grandmothers did.

"Observer" tells us what an old man said to him a few days ago, who had been to every farmer in the (his) neighbourhood in a vain attempt to get work. Well, it may be even so, but what sort of old man was

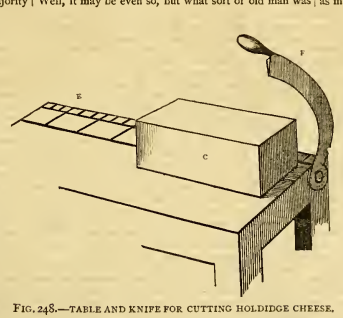

FIG. 248.—TABLE AND KNIFE FOR CUTTING HOLDIDGE CHEESE.

it? Perhaps one who had had as many masters as he had seen summers—a man never satisfied. I regret to say I have some such in my neighbourhood. Good respectable labourers being scarce throughout the country, it is not necessary for such to travel far without finding constant employment and good wages.

Your correspondent apologises for making use of my name in his letter No. 2, and states he has not the pleasure of my acquaintance. I therefore invite him publicly to come to Hutton, and I will introduce him to each of my separate holdings, where old labourers are still alive who worked for my predecessors, and from whom "Observer" might get some valuable information, so that when next your correspondent sits down to write upon the "Labourer, his condition and prospects," he may be better acquainted with the subject than he at present appears to be. *John Offin, Hutton, July 17.*

5. Mr. Offin states that in his off-hand farms he "keeps double the number of horses and men his predecessors kept." But does this prove that he keeps more than a respectable tenant and good farmer would keep? It seems to me merely to prove that his predecessors were not respectable tenants, or good farmers, and nothing more. Indeed he tells us so himself with respect to one of the off-hand farms which his landlord "pressed on him;" that "they took all they could out of the land without putting anything into it;" that "they employed little or no labour, and that at last it was thrown on the landlord's hands with a loss of two years' rent."

But had his predecessors been respectable tenants, is it not reasonable to suppose that they would have treated the land fairly? and is it not rather throwing a slur on the character of the Essex farmer to suppose the contrary?

The fact, then, that Mr. Offin employs double the number of labourers and horses his predecessors kept merely proves that he is a respectable tenant and a good farmer, and nothing more. The real question at stake is, does Mr. Offin employ as many men and as many horses on these off-hand farms as a respectable resident tenant, were there one such in each farm, would employ?

Mr. Offin puts two questions to me. First, "What the landlord did for his property by allowing such tenants (as the five predecessors Mr. Offin described) to occupy?" There can only be one answer. But, perhaps, some blame might be attached to the landlord himself in selecting a tenant. The fact, however, remains; it was bad for the land, and unfortunate for the landlord. Mr. Offin asks me, secondly, what I would have done under the circumstances had I been landlord? To this I reply, I would certainly not have let the farm in question off-hand to Mr. Offin, but would have let it at a low rate to some respectable resident tenant—to one who, even though he might not be a man of such capital as Mr. Offin, would at all events treat the land fairly.

Mr. Offin says he could "give many more instances of this kind;" but, as they would one and all only prove the same thing—viz., that Mr. Offin is a good farmer, and that his predecessors were bad ones, I need not stay to consider them.

It may then happen that on this one individual farm, or in "the many more instances of the same kind," that Mr. Offin keeps "double the number of men, &c., his predecessrs kept;" yet till he informs us what is the total amount of acreage he holds, and the total number of men he employs and horses he keeps, it is impossible to decide whether he employs as many on each of his off-hand holdings as a resident and respectable tenant would employ.

Suppose, for instance, Mr. Offin to hold 10 off-hand farms, and, if he will allow me to "cut him up" (metaphorically, of course) into 10 individualities — to place a resident Mr. Offin on each of these 10 farms, can the individual (non-resident in nine farms) Mr. Offin assert, that he now keeps as many men, &c., on these 10 farms as the 10 metaphorical (residents in 10 farms) Mr. Offins? This seems the fairest way of putting it. Would not the 10 Mr. Offins each keep a horse and gig? As it is, the revenue of the country loses the tax on nine horses and nine gigs. Would not those 10 families give more work to the village carpenter, blacksmith, &c., and would they not consume more food, and therefore do more good to the village butcher, baker, and in fact to all the local tradesmen, than the one individual Mr. Offin could or can possibly do? (I am leaving the fact of a great number of labourers being employed purposely out of the question for the nonce.) And, lastly, would not Mr. Offin's brother farmers who have sons and daughters growing up have a better opportunity of getting the former into farms and of seeing the latter married than they now possess by the 10 farms being in Mr. Offin's sole holding? *Observer.*

6. Does not one great reason of the want of efficiency in the labourer arise from the miserable deficiency of cottage accommodation? I feel sure that the limited room in the cottages of the labouring poor is the sad cause of the low state of morals so evident among them. How is it possible that the herding of the sexes while young can have any other effect? I fear their best feelings are tainted in the early period of childhood.

Is there not also another cause—that is, the almost entire absence of a good moral and mental training? True, many—perhaps most—of the children attend

some school, but are they not withdrawn from such influence long before they are at all grounded in the rudiments of even reading, writing, or the first rules of arithmetic? Moreover, can the moral taint that so many so early imbibe be eradicated by three or four years of school training?

It may well be replied, But this is the effect of taking them away from school to agricultural pursuits; and it appears to me that the Factory Acts as regards women and children might be brought partially into operation; I say, partially, because from the want of labourers at certain times of the year they must be called from the school to the field, or most serious results will follow to the producers and consumers of farm produce. To a certain extent the truth has been told as to the occupation of large farms having an unfavourable influence, but I cannot think it has much; for on inquiry it will be found that such occupiers, being as a rule better cultivators of land, employ more hands than smaller occupiers. Here let me however state that a more serious injury, arising from large occupations, is the fact that so many families of the tenant class are deprived of the opportunity of having farms, as, too, they are by its kindly influence would greatly increase the sympathy which should exist between the employer and the employed. This, however, only indirectly touches the subject in question, though it must be evident to all that an occupation, say of 400 acres, with the farmer and his family as occupiers, must exercise a more healthy influence, and be locally more beneficial, than the same occupation with perhaps only a bailiff in the house and the rest let off to a movable population, who only reside at the busy seasons of the year. I ask, can "Observer" have made himself acquainted with the condition of the labour market when he asserts that there is a surplus of efficient labourers? I think not, for I cannot agree with him. True, there are times when there are labourers out of employ, and localities where there is an excess. But I do think that this arises, not so much from a deficiency of labour as from the fact that the vast proportion of partially employed labourers are a class of men who cannot be trusted to do their work efficiently. Such men are justly marked, and do not remain in permanent employ for that cause. It is too true that in some localities the labour market is glutted, and that low wages are the result, but the young labourer has his remedy if he will avail himself of it by seeking work elsewhere.

From my experience I think that a comfortable cottage and good early moral and mental training would greatly remove from the labouring classes the results I must allow have, I cannot but think, that a healthy public opinion will soon be brought to bear on all classes, for it cannot be denied that there are bad landlords, bad tenants, and bad labourers; and I trust we are approaching a time when it will be kept in mind as an active feeling that all classes are dependent the one on the other, for what would the landlords do with their broad acres without the tenants' capital, or the tenant without the brawny arm and willing service of the labourer and the artisan? *A. B. C.*

LEGISLATION ON THE UTILISATION OF SEWAGE.

On Wednesday, the 2d inst., some members of the Essex Chamber of Agriculture paid a visit of inspection to the farm of Mr. W. V. Hope, in the parish of Hornchurch, which is irrigated with the Romford sewage, and, subsequently, held a meeting in the town of Romford, to discuss the subject of legislation affecting the utilisation of sewage.

Mr. Hope, in introducing the subject, proposed to divide it into three parts, and consider, first, why there should be any legislation at all upon it; secondly, what legislation there should be; and thirdly, what legislation there ought to be in future. Regarding the first point, he read some extracts from a book by Professor Corfield, prepared for a committee of the British Association appointed three years ago, showing that from 1604 down to quite recently defective and improper drainage had in various towns produced fevers, cholera, and plagues. This, in fact, was the state of things which existed in almost every town in this country till his friend, Mr. Chadwick, whom he was happy to see among them to-day, took them in hand many years ago, by his persistent efforts to spread out of the towns into the agricultural districts, and thus affected the whole community. Properly to manage the cleansing of a town was always a most difficult and expensive operation, but it paid in a twofold way when done. Health and strength were the labourers' working capital; but, to the disgrace of Government, at present the working classes as a rule were anything but strong and healthy, and the mortality tables told a fearful tale of fevers and kindred diseases, the product of dirt—that was, matter in the wrong place—and the shortened lives of these unfortunate creatures was not only lost to the community, but each death of the head of a family inflicted a fine upon the surviving population by throwing the family on the parish. He thought, therefore, there was very little doubt that some legislation was imperatively necessary. The introduction of water-closets had been of immense assistance in carrying away all the filth which formerly filled the open cesspools and wide ditches, but to carry away this refuse into a river, to pollute that river, and to spread disease among the neighbours, was only benefiting themselves, without doing the country at large any service at all. Then with respect to the question of infection. These open cesspools, open ditches, and polluted rivers bred diseases, but until lately it had been very much disputed how these diseases were spread. In fact, the medical camp was divided into two parties—one who supported the germ theory of disease, and the other who supported the more empirical idea that the infection was carried in the atmosphere, and yet had no material existence.

Then he came to the question what parts of town sewage contained the dangerous germs of disease, and he was afraid that on this point as yet little was known. The Rivers Pollution Commissioners considered a certain standard of nitrogen in the effluent water capable of producing disease. But nitrogen in itself was not unhealthy. On the contrary, when we wanted to nourish ourselves we ate nitrogen, and if a patient had a bad headache the doctor ordered him ammonia, therefore in ammonia there was nothing *per se* unhealthy. But it would appear that some of the other ingredients that were generally concurrent with ammonia and nitrogen in the sewage contained the pernicious germs, and, in ignorance of what the particular sources of infection really were, it had been found convenient by the Rivers Pollution Commissioners and the Thames Commissioners to take the percentage of nitrogen as the measure of pollution. The measure of pollution was also the measure of production to the agricultural chemist. All manures were sold according to their analysis, and the price was regulated by the percentage of ammonia which they contained. He would now refer to the value of town sewage. A great many chemists had devoted their attention to this subject, and Professor Corfield, in his book, gave a *resumé* of the different analyses that had been made, from which it appeared that the value of the manure created by each person annually was about 8*s.* per year. He (the speaker) took the trouble some two years ago, in a paper which he read to the Institution of Surveyors in London, to work out the value of this wasted manure in loaves of bread. He calculated that one additional quarter of Wheat or two additional quarters of Oats over and above the ordinary produce of a farm might be obtained by the application of the sewage of four persons to an acre. Striking out the scattered population of the rural districts, there was a town population in the United Kingdom of upwards of 15,000,000, whose sewage, therefore, would produce 3,750,000 qr. of Wheat, or 7,500,000 additional quarters of Oats. From particulars obtained from bakers, who differed very much in the weight they allowed in a quarter of Wheat would produce 108 quarters loaves.

A Member: A quarter of Wheat will produce 180 quarters loaves.

Mr. Hope said that was so much better for his argument. If a quarter of Wheat would produce 108 quarters loaves, it followed that by the present sanitary arrangements we wasted 405,000,000 of quartern loaves of bread every year; if a quarter of Wheat would produce, as had just been stated, 180 quartern loaves, then something like 700,000,000 loaves were wasted every year, and at the same time the waste of matter was polluting rivers that would otherwise be beautiful, poisoning fish, and spreading disease. Many said it would not pay to utilise sewage. It was this unfounded superstition which sent these millions of loaves of bread down the rivers, which necessitated our sending ships thousands of miles for food which we might produce at home, and which compelled us to ransack foreign parts in search of manures. In ten years, from 1841 to 1850, there were only 3½ millions of people in this country fed exclusively upon foreign Wheat, but in the last ten years no fewer than 8,600,000 were fed on the same quarter of Wheat would produce 180 quartern loaves, he could have fed the whole of these people with food grown in this country, if only the sewage had been properly applied. The Wheat paid for by these 8,600,000 people must have been worth at least 14½ millions sterling, and yet we were content with the improper drainage had in various towns produced fevers, cholera, and plagues. This, in fact, was the state of things which existed in almost every town in this country till his friend, Mr. Chadwick, whom he was happy to see among them to-day, took them in hand many years ago, by his persistent efforts to spread out of the towns into the agricultural districts, and thus affected the whole community. Properly to manage the cleansing of a town was always a most difficult and expensive operation, but it paid in a twofold way when done. Health and strength were the labourers' working capital; but, to the disgrace of Government, at present the working classes as a rule were anything but strong and healthy, and the mortality tables told a fearful tale of fevers and kindred diseases, the product of dirt—that was, matter in the wrong place—and the shortened lives of these unfortunate creatures was not only lost to the community, but each death of the head of a family inflicted a fine upon the surviving population by throwing the family on the parish. He thought, therefore, there was very little doubt that some legislation was imperatively necessary. The introduction of water-closets had been of immense assistance in carrying away all the filth which formerly filled the open cesspools and wide ditches, but to carry away this refuse into a river, to pollute that river, and to spread disease among the neighbours, was only benefiting themselves, without doing the country at large any service at all. Then with respect to the question of infection. These open cesspools, open ditches, and polluted rivers bred diseases, but until lately it had been very much disputed how these diseases were spread. In fact, the medical camp was divided into two parties—one who supported the germ theory of disease, and the other who supported the more empirical idea that the infection was carried in the atmosphere, and yet had no material existence.

Then he came to the question what parts of town sewage contained the dangerous germs of disease, and he was afraid that on this point as yet little was known. The Rivers Pollution Commissioners considered a certain standard of nitrogen in the effluent water capable of producing disease. But nitrogen in itself was not unhealthy. On the contrary, when we wanted to nourish ourselves we ate nitrogen, and if a patient had a bad headache the doctor ordered him ammonia, therefore in ammonia there was nothing *per se* unhealthy. But it would appear that some of the other ingredients that were generally concurrent with ammonia and nitrogen in the sewage contained the pernicious germs, and, in ignorance of what the particular sources of infection really were, it had been found convenient by the Rivers Pollution Commissioners and the Thames Commissioners to take the percentage of nitrogen as the measure of pollution. The measure of pollution was also the measure of production to the agricultural chemist. All manures were sold according to their analysis, and the price was regulated by the percentage of ammonia which they contained. He would now refer to the value of town sewage. A great many chemists had devoted their attention to this subject, and Professor Corfield, in his book, gave a *resumé* of the different analyses that had been made, from which it appeared that the value of the manure created by each person annually was about 8*s.* per year. He (the speaker) took the trouble some two years ago, in a paper which he read to the Institution of Surveyors in London, to work out the value of this wasted manure in loaves of bread. He calculated that one additional quarter of Wheat or two additional quarters of Oats over and above the ordinary produce of a farm might be obtained by the application of the sewage of four persons to an acre. Striking out the scattered population of the rural districts, there was a town population in the United Kingdom of upwards of 15,000,000, whose sewage, therefore, would produce 3,750,000 qr. of Wheat, or 7,500,000 additional quarters of Oats. From particulars obtained from bakers, who differed very much in the weight they allowed in a quarter of Wheat would produce 108 quarters loaves.

A Member: A quarter of Wheat will produce 180 quarters loaves.

Mr. Hope said that was so much better for his argument. If a quarter of Wheat would produce 108 quartern

Mr. Hope's. He quite expected to see that other towns would adopt this beneficial measure. With respect to legislation he might mention that some years ago, in order to drain a settled estate, it was necessary to make an application to the Court of Chancery. On that, he (Mr. Chadwick) submitted to Sir Robert Peel's Government that there ought to be a cheaper mode of attaining this object, and the result was successful. One serious evil of the present day was the great cost of obtaining local or private Acts of Parliament for small towns. In fact it amounted to a legislative abomination, which certainly ought to be got rid of. He sincerely hoped that the county of Essex would support Mr. Hope in this important agricultural movement.

Mr. ANGEL, engineer to the West Ham Board of Health, agreed with most that Mr. Hope had said, and was perfectly satisfied that in this movement he would come out successful, but he disagreed with some of his remarks about past legislation. The Government had published their experience, which had done good, and power had been given to purchase land at a cheap rate, which was a great concession. It was contrary to the spirit of legislation in this country to force certain views down the throats of the people, and it would be a serious thing to compel towns to buy so many acres of land or to compel farmers to take the sewage. As to making profit of sewage irrigation, that depended greatly on the geographical position of the town, but he believed in the system, and was convinced it would make its way.

Mr. PERRY WATLINGTON desired to say just one word in reference to future legislation. The sanitary law was at present most confused, and something like a simplified code would be most desirable. The Commission which sat last year made a report, and the result had been embodied in a Bill which was before the House of Commons only on the previous night, when one gentleman stated that the Commission had under its consideration no fewer than 45 sanitary Acts. Perhaps people in towns could manage, but certainly people in the country found it very difficult indeed to work 45 sanitary Acts.

Captain RUSS also insisted upon the necessity of simpler and better legislation, and called particularly for the abrogation of the seven years' purchase clause, which prevented gentlemen from taking sewage-farms.

The PRESIDENT then proposed the following resolution, of which, he said, Mr. Hope approved: "That in view of the large amount of foreign Wheat paid for every year by the population of this country, and the large amount of manure wasted in polluting rivers with town sewage, it is desirable that such pollution should now be prohibited by legislative enactment, and that the 45 sanitary Acts in existence should be repealed, and a general and comprehensive law enacted."

The resolution was carried.

The proceedings concluded with votes of thanks to Mr. Hope and the President.

Home Correspondence.

Green Food: Stackyards: Machinery: Thick Sowing, &c.—The longer I farm the more I am convinced that the turning out and roaming-at-large system will come to an end, especially as land gets scarcer and dearer. It is cheaper and better to bring the food to the animal than the animal to the food; because in the latter case he is permitted to trample upon it, excrete upon it, and lie upon it. One of the largest and most successful farmers that I know has always folded his sheep and cut the grass for them—one man, a lad, and a horse-chaff-cutter being on the field, there feeding the sheep with grass, chaff, mixed with cake, &c. Although 77, he is, and always has been, among the very best root and corn growers among my acquaintance on an area of 1500 acres. Green Tares, Clover, &c., are all passed through the chaff-cutter for my horses and cattle, the corn ground and roots pulped. One trial will prove the fact, and put money into the pockets of my agricultural friends. Our sheep and lambs are close folded, and have no more food than they clear off. Fold moved twice a day—one 75 feet iron hurdle on wheels to every five sheep. Lambs have their tiths, and are followed by the ewes to clear it all up. Our green food (Tares, Clover, or Italian Rye-grass) after passing through the chaff-cutter, is spread thinly over an asphalted floor in the cool barn to prevent heating.—We must endeavour, myriads, or each separate our stacks as to leave room for working the corn and hay elevators worked by a pony—for in one case near me the farmer who bought one of these finds it almost useless to him, because his stacks are placed close to each other in the stackyard; the pastures makes a good stackyard as far as corn is concerned. The horse-work elevators, that carry up the sheaves or hay, and drop them in the centre or any other part of the stack, save the labour of quite three men, which is very important at hay time or harvest. Machinery grows upon us year after year, therefore our landowners will have to increase the machinery sheds, charging a fair percentage on their cost.—Is not mildew often caused by too thick sowing and early laid crops? I believe that this is one of the true causes. See what takes place. The densely packed mass of plants, weak below, tumbles down flat or twisted in various directions by winds and thunderstorms, and thatches the earth; so that, while rain can pass through the thatch, the wet earth is shaded from the action of the sun and air, and becomes in the like condition to a dark and damp cellar, where, we all know, mildew and Fungi flourish. I have a dark corner in a portion of my house here, where my boots and shoes always mildew, if left long unexposed to light. When crops stand erect, as nearly all mine do this year and generally, there is free circulation of air and light, and a free evaporation of moisture from the earth. Therefore, although from the intensely green luxuriance of the corn crops, mildew is often predicted by my visitors, it never comes. Of course, the drainage of land has a good deal to do with this, and so has the absence of trees and fences; but, wherever there is a dense closing in of the moist earth, either by a dense, flaggy, vertical, or laid crops, there we have risk of mildew, especially on rich boggy lands, that force a great or rank development of Flag. Some very good farmers remove the Flag from their cereals. My Wheat crops from a bushel per acre, drilled, are all that I desire, even when the grass per acre are undistinguishable from the rest of the field. Barley, 6 pecks, Oats, 2 bush., are enough for me. *J. J. Mechi, Aug.*

Labourers' Cottages.—A plan somewhat similar to the one you publish at p. 1023, of two cottages with three bedrooms in each, and one between these with two bed-rooms, may no doubt be adopted occasionally with advantage; but I think there are some defects in the plan you give which, to some extent, may be avoided with slight alteration. It is a great fault in a cottage when the living-room has two doors opening into it, unless, at least, they be close together. Everyone knows how uncomfortable a thing more than one door is even in a large room in a gentleman's house, and all the more should this apply far more strongly to the living-room of a cottage. In the two end cottages in the plan given this defect can be perfectly well avoided by making the entrance-door at the side, either under the staircase (b), or at the end of the pantry (c), which is further from the front; and this would improve the plan in other respects, besides the improvement to the living-room. I should also prefer making the pantry open into the porch, instead of into the living-room. Some people object to the staircase being in the scullery, but I do not see much harm in it; and it certainly, in many instances, makes a plan of a cottage more simple. In the middle cottage it is, of course, difficult to avoid making a passage of the living-room; and for this reason I should in general object to building cottages in blocks of more than two. Moreover cottages, I always like to have a good garden attached to them (not an allotment at a distance), and this can hardly be done with the middle of the three. Of course all cottages do not require to have three bed-rooms; but as a rule I think it would be better and more economical to provide the two-roomed cottages requiring by building one and two of cottages on the plan No. 9 in my book; and for the rest, pairs of cottages on Richardson and Ross's plan. The cost would hardly be greater, and the accommodation would be very far superior. *C. W. Strickland, Whitby, August* 10.

Mr. Mechi and his Live Stock.—At p. 1023 Mr. Mechi says:—"On the sewaged Italian Rye-grass (14 acres) I have kept 200 sheep and lambs from April, for seven hours per day, or 2,800 sheep per week per stack" (date August 1). Will he kindly give us more particulars. 1. The number of sheep and the number of lambs, and the age of the lambs, for we reckon nothing for a lamb during the first three months? 2. What date in April did the sheep go on, and what date did they come off, and did they get nothing else except the grass all the time? 3. Were the seven horses kept wholly on grass during the seven weeks, or did they get Oats and hay or straw in addition? 4. How large is his haystack (in tons)? It is usually considered that an acre of well-grown Turnips will keep from 2000 to 2400 sheep for one day, or an acre of well-grown Rape will keep 1800 sheep for one day; and if we allow an acre of Rye-grass for the four best months of the year to be equal to an acre of well-grown Rape, then his 14 acres ought to have kept 1800 × 14 = 25,200 sheep for one day, or 2,800 ÷ 200 = 14 sheep for 120 days. Mr. Mechi seems to have kept 200 sheep and lambs (suppose we call them equal to 150 full grown sheep) for 120 days, or 150 × 120 = 18,000 sheep for one day. He also kept seven horses for seven weeks (49 days), and if we allow each horse to eat as much as 15 sheep, then seven horses would be equal to 105 sheep, and these were kept 49 days, or 105 × 49 = 5145 sheep for one day. This, added to the former, gives us 18,000 + 5145 = 23,145 sheep for one day, whereas 14 acres of well grown Rape would be kept 25,200 sheep for one day, so that he is 2055 sheep short; but then he has a nice little haystack, and this, I suppose, may be put down as the extra produce raised by the sewage. *G. A. H.*

The Harvest.—Glorious harvest weather, more than a week of bright sunshine, and a drying east wind, have converted the dark-looking and doubtful crops into a golden healthy hue, and taken most people by surprize. I suppose that, owing to the east wind coming overland, it dries everything quicker, and makes us feel the heat more than does a westerly wind coming over nearly 3000 miles of Atlantic waves. Certain it is that there have been several cases of sun-stroke last week, some of them fatal to labourers—the reaper has been spared much of the severe labour. We commenced harvest on the 7th, and have most of our corn down; all of it will be cut by the 18th, except some Beans. I need hardly say, that it is all dry enough to thresh, and much of it even to grind. I hear sorrowful accounts of the yield. Three days' threshing, not a hundred miles from here, only yielded 3 qr. per acre where the estimate was 6 qr.; and in another case, a whole day's threshing only gave 20 qr. I expect to hear of great disappointments where there has been thick sowing and early-laid crops. Nearly all my Wheat is sown with 1 bush. per acre. On one half acre we have only 2 pecks per acre. It has all along been undistinguishable from the 4 pecks, although drilled the same day, and surrounded by the bushel. We have cut it, and have the same number of sheaves as from the bushel. The stubble is also undistinguishable. It has been seen by a great number of practical farmers. As soon as threshed I will state the result. There are about 620 sheaves to the acre. The Wheat is Club-headed Rough Chaff White, drilled upon a clover-lea, once mowed for hay and then cake fed. If the disappointment as to yield of Wheat is extensive it must certainly have a considerable rise in price. Our Barley, which is stacked and thatched, is long in the ear and plump kernelled—14 to 18 of a side. We sowed 7 pecks per acre, after Wheat; our usual quantity is 6 pecks, but it was on wireworm land. Our second crop of Clover grows so rapidly, that our 200 sheep cannot consume it, so we shall have to mow some for hay a second time. Our 13 acres, which was so thin that we once thought of ploughing it up, has now a fine second crop of red Clover. I must repeat here, what I have many times proved, that wasted Clover-lea manure is not wasted at all, but often fails to produce corn, the elements of the grain having passed away with the drainings. This seems likely to be the case this year in too many instances. It is now 20 years since I first commenced using the reaping-machine, and 15 years since Fowler's steam-plough, with a double 8-share subsoiler attached, was exhibited in work on this farm. P. S. Our root crops (Mangel, Kohl Rabi, and Cabbage) promise abundantly. Beans first-rate, both winter and spring. *J. J. Mechi, August.*

Crops in Northamptonshire.—I must supplement my opinion of the crops round here, sent to you on July 24. Since then we have had a great fall of rain—no less than 1.25 inch—0.88 of which fell on Saturday and Sunday last. The Wheat is terribly knocked about; Beans are now covered with fly, and will be considerably below an average, and during the last few days the Potato blight has increased rapidly. I never saw the haulm decay faster. Hay very much damaged. *T. Berlase Tibbits, Barton Seagrave, Kettering, Aug.* 1.

Foreign Correspondence.

BERLIN.—There is sweetness even in death, and still more in any phase of life, however melancholy. Supposing the German soil were, like the English, a mixture of feudal-and-common-lawlessly-lost-and-nobody's-property, how much would have been of the German nation in the late crisis? And supposing the German nobles were not impoverished, what would have become of the country? I dare say Polonia will serve as an illustration. There is no lazzaroni in all Napoli more fond of his *dolce far niente* than an average Polonian noble of his town, fonder than cut of gambling, and of the beaker after truly German cut. In former times they drank out of a boot, a something like six blunchers made into one. You may find innumerable old and new ballads sung by labourers in the fields, and by students at their beer, about some old Landgraf gambling away with one of his villages after the other, and in one afternoon, too—being lifted on to his horse by four stout connobles, and riding off, to be seen no more! It is the gambling that is setting them, gambling being, as Tacitus told you, one of the chief and most noble occupations of the German freeman from time immemorial. Even in our times, when common sense ought to tell them that there is no longer any difference between a nobleman and a rich man, except the money, they have not yet acquired the art of earning it. If you meet with any illustrious name with the Von prefixed you may be sure it is of modern date—the Von Bismarcks and Von Moltkes are but exceptions. Even Von Thaer has been nearly ruined. And if your eye is struck by a Von over a shop-window of some butcher, you may be sure the meat, the money, and the industry, have come from the master's side, her maiden name being something like Stumps, while my lord, the father, giving his noble name to an ignoble son, has, as soon as sober, shot himself.

How about modern agriculture and the tile draining-plough, with such material as this? Who can wonder that a man like Fürst Bismarck has—with a sigh, perhaps—decided upon assisting the National Liberals, the Jews and their money, and daring unpopularity with the Junkers, just to get the country out of the mire as soon as possible, and has made it his life's task

to get rid of those little courts, who cultivated gambling—generals with an army not quite strong enough to stand, all the lot, under one Lime tree during the hot hours.

You must not, however, imagine drinking and gambling to be an intrinsic part of the national character, which only privileges could spoil and freedom improve. I have been for years about all parts of the country, and found sobriety to reign supreme. The thing is, that topers will die early, and have done so for centuries without, or with but a feeble, progeny; and so the type of mankind most addicted to drink has died off ever since alcohol came into vogue, and it may be owing to the severe ravages of the alcohol devil during the middle ages and during the Boors war that the power of N_2 H_3 O_2 has broken down from want of material, the Mohicans having vanished. Perhaps there is some solace in this for the teetotallers and for the national economists, the labourers' friends and parsons in England.

The labourer's social position is, on the whole, I dare say, a shade happier than on the Isles, chiefly because they are of a philosophical turn of mind—silent, never boisterous, even during the harvest festival, and ever pondering upon something. This something is sometimes of a most transcendant nature. One of them asked me—just imagine !—whether I had the force of mind to present to my senses the world with everything in it just the reverse of what it was at the time being. Now, you might write a book upon this settler; you would go mad upon it most likely; but the man who suggested the idea to me was a "mayer," an overseer or head labourer, the most practical artisan, and quite a Bismarck in his little sphere, if little archeres there be.

This comparative richness of mind is not so much owing to any comprehensiveness, proper only to the German brain by preconstruction; it is due rather to compulsory school training, which they have all, rich and poor, undergone—which is, by-the-bye, too, on the same plan of 1807, to which Germany owes the mobilisation of her soil. It may be termed the mobilisation of mental power in analogy, for it has given many a chance to low-born genius, created, too, many a Cobbett to be mentioned, many an artist, many a poet, from the most unlikely source, and is a necessary assistant to the military training which, drawing country people into the towns, certainly trains the agricultural districts, but adds another chance of getting up in the scale of society according to talent.

I will not enter upon the economy of the farm labourer's house and home. Money is dear, the average wages do not rise above 1*s.* a day, women receiving but 6*d.*, and children 3*d.* But they are put into a little house, two families under one roof, semi-detached; they fatten a pig or two, cherish a goat like a grandmother, have a cow in the farmer's stable, and a few sheep, perchance; grow some geese, the feathers of which, stored in gigantic beds, they put great pride in; gather some dry wood in the forests on certain days in the week, some hay on some ditch side, and have a little plot of land given to them to grow Flax and Potatos. So, with a stray bottle of thin beer from the group (there is no public-house within less than a mile of stocking, spinning their Flax, and looking to their little ones' slate, on which the queerest characters and figures appear and vanish like dissolving views, they manage to pass through existence quite smoothly, and pass that much of their time which is not taken up by field work in comparative innocence too.

They are not so well nourished, however, as the English labourers, nor can it be denied that there is something slow about their everyday life, which, I venture to say, is owing to their want of acquaintance with proper animal food—Potatos, bread, dumplings, and clear soup, cold Buckwheat with milk, being considered the only ingredients of the human body, besides Chicory and Tobacco.

As to their higher endowments, they are mostly rationalists of the purest water. They don't believe in anything they can't see, but they make up by going to church, for the sake of singing an old venerable hymn. On the whole, however, they are not as yet the race for intensity of anything, least of all of agriculture.

I am speaking of the poor provinces now, and of the back lands in the East. In consequence of the predominance of capital in the West, and of the gradual condensation of industrial powers towards the great centres, and along the railways and rivers, these back lands have been sorely depopulated. So much so, that the eastern railroads have had to be built chiefly with foreign money, and by English labourers, which no doubt about it, are in better training for such kind of work, and go at it with twice as much muscular energy at least, because of their eating meat and drinking tea.

Then, again, the Russian frontier is a great obstacle. It is like a world's end, or rather, like a dark cloud at the horizon. There are many false notions afloat in England about German alliance with Russia, but I can assure your readers that Germany has no greater enemy to her national development than that giant in the East, and that her statesmen act on compunction if ever they go hand in hand with Russian desires. It is one of the most imprudent things English statesmen could have done to make common cause with France and Austria against German unity, and to want the hands of Germany to be shackled by the French in the West. England knows well, which will be her chief enemy in less than a century hence; who then prevent a brother nation from growing strong against that same giant, who is no less her enemy too? I suppose I must not but touch upon this in an agricultural paper, still it is just on the ground of agriculture that Germany feels herself most oppressed by Russia shutting herself up. It is not fair that Germany should have to carry the blame of a willing alliance where it is not willing in the least. They are planting Oak trees now all about Germany in commemoration of the late triumph over the Erbfeind, who is more commiserated than triumphed over (for they say it ought not to have come to the destruction of Paris, under any circumstances whatever, and Bismarck ought to have prevented it). I do not believe these Kaiser trees will bear fruit before what I have said above will have become more apparent to the English.

There are other complaints still ushered by the agriculturist party in the East, and they have put them all into a programme for their representatives in Parliament to stand upon. They will remind us of the period preceding the Reform Bill in England, and with their enumeration I will drop the curtain for to-day.

1. The inequality of taxation between town and country has to cease, the country having to bear about 70 per cent. of the income-taxes, and thereby being depopulated.

2. The indirect taxation (chiefly on colonial wares and iron implements) must gradually be reduced. Tea, tobacco, coffee, &c., must be taxed, not according to weight but to quality, so that the rich may bear proportionally to their wealth, and that the necessaries of life, as also the implements of culture, may be cheaper.

3. The city octroi on agricultural products (meat, corn, cattle, &c.) must cease, because it oppresses agricultural produce and the every-day consumpt of the poor. This octroi exists in many of the large towns,—Berlin, Stettin, Königsberg, Breslau, Magdeburg, &c., and has been added to income-taxes in some of them already.

4. The military duties of the agriculturists, both in peace and in war, viz., giving shelter to the manœuvring troops, giving their fields to be trampled upon, their horses to be driven to death, and their larders to be pilfered, must be remunerated according to the laws of equity. (This smacks of the Game-laws and the law of trespass.)

5. Free trade (introduced by Baron von Stein) must not be abused, merely for the sake of the manufacturers, who, with their products have free passage, whilst the iron implements (from England), cloth, &c., have to bear a heavy duty, in consequence of which the 78 per cent. of agriculturists and agricultural labourers in Prussia become tributary to the 22 per cent. of town inhabitants, and the back lands (Prussia proper, Silesia, Pomerania, Posen) tributary to the western parts of the empire.

6. The guardianship, which is assumed by the Government, over the credit and insurance institutions of the agriculturists must cease (acting in the way of a stamp, which till now no other money transactions have to bear). And now what sort of people are these progressionists? Are they Whigs or are they Tories? *O. B.*

Societies.

LEICESTERSHIRE AGRICULTURAL.

THE third show since the amalgamation of the Sparkenhoe with the county society, was held on the 9th and 10 inst. We condense the following from a contemporary :—

Horses were a little more numerous than usual, and, as may be expected in the hunting county, many first-class weight-carriers were amongst the 177 entries. The £20 and £10 prizes, whether open to All England or limited to the Belvoir, Quorn, Mr. Tailby's, Cottesmore, Atherstone, and Pytchley Hunts," were awarded to local men. Mr. F. L. Ward, of Burton Overy; Mr. J. E. Bennet, of Husbands Bosworth; and Mr. R. D. Miles taking the three first and the "jumping" prizes; and Mr. Bennet's fortune was in the ascendant in three other classes.

The great contrast between the present gathering and the Leicester meetings of the "Sparkenhoe" Club lies in the cattle classes. Then we had Mr. Swinnerton's ox, about twice as big as anything on the ground this year, and who won the great prizes of Smithfield, Birmingham, and Liverpool; and we had the pride of the Branches Park and Bushey Grove herds. Comparing this year with the last there is a falling off of one-fifth in numbers. The five prizes for fat oxen and cows brought out five competitors, and the same number competed for the four bull prizes, two of them going to Sir W. de Capel Brooke for an 18 months son of Mr. F. Leney's DUKE OF WATERINGBURY, and for a 4-year-old son of Mr. Tanqueray's KNIGHTLEY GRAND DUKE, both sires being descended from *Charmer* by LITTLE JOHN. The winner of the latter prize is a straight level red bull with great size and substance; he "lies out with the cows," and is in just the condition that store bulls should be in. Mr. Bradburne's well known WHITE SATIN (1st at Hinckley last year) stood 2d. The bulls under one year were very moderate, only one exceeding five months old.

Mr. W. Bradburne took 1st and 2d prizes for cows in milk, 1st for cow above three and under four years old, 1st for in-calf heifer, and 2d and a commendation in the tenant-farmers' heifer class, four of which, as well as WHITE SATIN, were at the Wolverhampton Royal. They are heavy fleshed animals, but have not style enough for a very high position. Mr. Cheney sent two daughters of *Lord Waterloo 11th*, a yearling by GENERAL NAPIER, thick but not very showy, and a very nice calf by 7TH DUKE OF YORK.

To say that Lord Chesham and Mr. W. Baker sent more than a dozen pens of Shropshire sheep, is to say that it was a good class. The county members' prizes for breeding ewes require pens of 10 instead of 20 as in former years, when they were the most interesting of the sheep classes. It is true that the new Leicesters were left to their fate amongst Longwools, when in their county; only two entries were made in the breeding classes, and these neither bred nor fed in Leicestershire.

The following is a list of the prizes awarded :—

HORSES.

JUDGES.—Hunting and Hack Horses : C. Millward, Esq., H. Corbett, Esq., G. Higgins, Esq. Cart Horses : G. Bedford, Esq., G. C. Woolhouse, Esq.

1. Hunter, Gelding, or Mare, not less than five years old and under ten, open to all England.—1st, R. D. Miles, Keyham; 2d, J. Pain, Shangton.

2. Gelding or Filly (four years old) adapted for hunting purposes, bred within the limits of the Belvoir, Quorn, Mr. Tailby's, Cottesmore, Atherstone, and Pytchley Hunts.—1st, F. L. Ward, Burton Overy; 2d, J. Milner, Knoulton.

3. Gelding or Filly (three years old) adapted for hunting purposes, bred as above.—1st, J. E. Bennett, Husbands Bosworth Grange; 2d, G. Hill, Bourne.

4. Gelding or Filly (two years old) adapted for hunting purposes, bred as above.—J. E. Bennett.

5. Yearling Colt or Filly.—J. E. Bennett.

6. Mare, calculated to breed hunters.—1st, J. W. Jenkins, Husbands Bosworth; 2d, Capt. Hale, Hilston Grange.

7. Hack, not less than 14½ hands, and not exceeding 15·1 hands high.—1st, J. E. Bennett; 2d, L. Turner, Leicester.

8. Colt, not exceeding 14½ hands.—1st, J. Burnaby, Kettering; 2d, R. Milward, Southwell.

9. Pony, not exceeding 13½ hands.—1st, R. D. Miles; 2d, W. Fowler, Tippenham.

10. Gelding or Filly (two years old) best adapted to the general purposes of agriculture.—1st, J. N. Brown, Hstock; 2d, J. Perry, Claverley.

11. Gelding or Filly (one year old) best adapted to the general purposes of agriculture.—1st, and, S. Pilgrim, Bushley.

12. In-foal Mare best adapted to the general purposes of agriculture.—1st, J. A. Beale, Brockhurst; 2d, H. Burgess, Ilston Grange.

13. Stallion for agricultural purposes, *bond fide* the property of a member of this society.—1st, H. Spencer, Loughborough; 2d, J. S. Hall, Oakham.

14. Foal best adapted to the general purposes of agriculture.—1st, the Executors of Lord Berners; 2d, H. Burgess.

CATTLE.

JUDGES.—C. Howard, Esq., and T. Harris, Esq.

17. Bull, above one year and under two years old.—1st, Sir W. de Capel Brooke, Bart., Geddington Grange : 2d, R. D. Miles, Keyham.

18. Bull, of any breed, over two years of age.—1st, Sir W. de Capel Brooke, Bart ; 2d, W. Bradburne, Wolverhampton.

19. Bull calf, under one year old.—C. Bays, Kettering.

20. Cow in milk having had a live calf since January 1, 1871.—1st and 2d, W. Bradburne.

21. In-calf Heifer, above three and under four years of age, having had a live calf since January 1, 1871.—1st, Wm. Bradburne ; 2d, J. J. Sharpe.

22. In-calf Heifer, above two and under three years of age.—1st, W. Bradburne ; 2d, R. D. Miles.

23. Stirk, above one and under two years of age.—1st, J. J. Sharpe ; 2d, T. Harris, Claverley, Coddesby Hall.

24. Heifer calf, under one year old.—E. H. Cheney.

25. Longhorn Bull.—1st, J. Godfrey, Hinckley ; 2d, W. T. Cox, Barnwell.

26. Longhorn Cow, in milk, having had a live calf since December 1, 1870.—1st, W. T. Cox ; 2d, R. H. Chapman, Upton.

27. Longhorn Heifer, in calf, above two and under three years of age.—1st and 2d, W. T. Cox.

28. Alderney and Guernsey Cow, or Heifer, having had a live calf since January 1, 1871, or now in calf.—R. D. Miles.

29. Bull, of any age, which is *bond fide* the property of the exhibitor.—1st, J. A. Beal ; 2d, Joseph Mudford.

30. Cow, in milk, having had a live calf since January 1, 1871.—1st, E. Wright, Wyonby House ; 2d, J. Pain, Shangton.

31. Heifer, under three years old.—1st, J. J. Sharpe ; 2d, W. Bradburne.

32. Pair of Stirks, under two years old.—1st, R. H. Chapman ; 2d, S. Burchnall, Burton-on-Trent.

SHEEP.

JUDGES.—R. Brown, Esq., and T. Cartwright, Esq.

33. Pure-bred Leicester Shearling Ram.—G. Turner, jun., Allerton Hall.

34. Pure-bred Leicester Ram of any other age.—G. Turner, jun.

35. Long-wooled Shearling Ram.—1st, J. Lynn, Stoxton ; 2d, A. Hack, Buckminster.

36. Long-wooled Ram of any other age.—1st, J. Lynn ; 2d, A. Hack.

37. Pen (of three) under 20 months old, Pure-bred Leicester Fat Wether Sheep.—1st and 2d, the Executors of Lord Berners.

38. Pen (of three) under 20 months old, Long-wooled Fat Wether Sheep.—Sir W. de Capel Brooke, Bart.

39. Pen (of three) Long-wooled Ewes.—1st and 2d, J. Lynn.

40. Pen (of five) Long-wooled Theaves under 20 months old.—T. W. D. Harris.

41. Pen (of five) Long-woolled Ewe Lambs.—T. W. D. Harris.

42. Shropshire Shearling Ram.—1st, W. German, Atherstone ; 2d, Lord Chesham.

43. Shropshire Ram, of any other age.—Lord Chesham.

44 Pen (of three) under 20 months old, of Shropshire Fat Wether Sheep.—Lord Chesham.

45. Pen (of three) Shropshire-bred Fat Wether Sheep, under 20 months old.—Sir W. de Capel Brooke, Bart.

46. Pen (of three) Shropshire Ewes.—1st and 2d, Wm. Baker, Atherstone.

47. Pen (of five) Shropshire Theaves, under 20 months old.—Lord Chesham.

48. Pen (of five) Shropshire Ewe Lambs.—Wm. Baker.

49. Pen (of ten) Long-woolled Breeding Ewes.—1st, T. W. D. Harris ; 2d, Wm. Barnard, Narborough Wood.

50. Pen (of ten) Short-woolled Breeding Ewes.—1st, W. Baker ; 2d, S. C. Pilgrim.

PIGS.

Judges.—R. Brown, Esq., and T. Cartwright, Esq.

51. Boar of the large breed.—1st, M. Walker, Stockley Park; 2d, R. E. Duckering & Son, Northorpe.

52. Boar of the small breed.—1st, R. Duckering & Son; 2d, M. Walker.

53. Berkshire Boar Pig, not exceeding 18 months old.—1st, R. E. Duckering & Son; 2d, J. Wheeler & Son, Shipston-on-Stour.

54. Breeding Sow of the large breed.—1st, M. Walker; 2d, J. Wheeler & Sons.

55. Breeding Sow of the small breed.—1st, J. Wheeler & Sons; 2d, R. E. Duckering & Son.

56. Three Breeding Pigs of the large breed.—1st, R. E. Duckering & Son; 2d, M. Walker.

57. Three Breeding Pigs of the small breed.—1st, R. E. Duckering & Son; 2d, J. Wheeler & Sons.

EAST LOTHIAN.

Land Letting in East Lothian.—At the last meeting of this Club, Mr. R. Scot Skirving said he wished to make a statement with regard to the remarks of Mr. Smith at the previous meeting on the renewing of leases in the county. He was sorry that he had not been present, and he wished to refer to the matter now, because by reading the proceedings he could not see whether Mr. Smith's statement had been homologated and adopted by the Club, or whether it had been disputed. It appeared that somebody in England wrote something in the Journal of the English Agricultural Society at the prompting of Mr. Hope, of Fenton Barns. Mr. Hope appeared to make a very languid answer and reply, and the only thing he seemed to accuse Mr. Smith of was youth and inexperience.

The Chairman: I was reported as saying that Mr. Smith was a young and inexperienced man, but I never said any such thing.

Mr. Scot Skirving: Well, what he wished to say was that Mr. Smith seemed to have misapprehended the drift of the article, in so far as renewals of leases were concerned. Mr. Smith asserted that of late years most of the farms had been let on renewals. He (Mr. Skirving) was exceedingly happy to hear it; only he did not think that was the point at issue at all. The next four or five years might reverse that; and it was only when they took a considerable period of time that they could give a common, yes or no, to the question whether farms were generally being renewed in East Lothian. He did not say whose fault it was, or that it was the fault of any class; but simply as a matter of fact and truth, he thought the truth should be known, and the real facts should go forth. He had been at considerable pains to ascertain the real state of the case; and the result of his inquiry compelled him to come to the conclusion that Mr. Smith's statement was radically wrong, and that Mr. Hope's statement, as published in the paper referred to, was radically and justifiably right. Mr. Smith stated at last meeting that he had examined the list of farmers in the county as published in Neill's Register last year, and had drawn his information therefrom. He (Mr. Skirving) did in another way the same thing as Mr. Smith. The principle he went on was this. The leases in East-Lothian ranged from 19 to 21 years—the great majority being 19 years. He had therefore taken the list of tenants as it stood a quarter of a century ago, and compared it with the list of the present year, and partly from his own knowledge, and partly from the source, he had taken down the names of every farmer in the county (dealing as such with holders of 20 acres and upwards); and the result of the whole comparison was this—that there were 55 names standing on the register at the present day which existed as families (not merely as individuals) farming land in the county 25 years ago, and that 138 names, which appeared as well-known farmers in the county 25 years ago, had, either as individuals or families, utterly disappeared from the register. A very few more would have made the proportion of changes three to one. This change was not altogether equal over the county. They had been talking a good deal about Salton lately, and he found that the changes on that estate were fewer than on any other in the county, while on Yester they were greatest. He could only find the name of "Crease" remaining in the parish of Yester of those who had farmed there 25 years ago.

Mr. Durie: He is not a farmer now. There is no such a name.

Mr. Skirving: The name stands against the same piece of land as a voter that it did 25 years ago.

Mr. Harper: Mr. Murray's family was there at that time.

Mr. Skirving said he might be wrong as to that matter of detail, but they could examine the returns which he had prepared for themselves. They would find that, while on some estates there had been almost no change, on others the old families were nearly all swept away.

Mr. Smith (Whittingham), in replying, said he was glad Mr. Skirving had limited his observations to matters of fact. Until a short time ago, when Mr. Skirving told him, he had not been aware that he was under a delusion in what he had stated at the last meeting; and he had offered to Mr. Skirving what he now suggested to the Club—that scrutineers should be appointed to go over the list to which he (Mr. Smith) had referred, and so to test the accuracy of his statement at the previous meeting. He had no objections to take to what Mr. Skirving had advanced, further than this—that he had put it as if he (Mr. Smith) had really not dealt with what Mr. Jenkins had written. Now Mr. Jenkins did not deal with the county as it was 20 years ago, but as it appeared in 1870, and his report bore that it was founded on what he saw and heard in the county in that year, when he (Mr. Smith) had personally met with him. In that case how could Mr. Skirving correct him when he had gone on the data plainly furnished by the article itself which he had laid before the meeting when he made his statement. If the question at issue was tested over a period of 25 years, it might make a considerable difference. He could not tell what phase the matter would assume in that case; but he contended that the drift of Mr. Jenkins' article, as read by any stranger, was that in East Lothian farms were put up to competition, and that through the law of hypothec such high rents were drawn that it was impossible for tenants to renew their leases. That was the real gist of the whole article, and it was a very different thing from the question raised by Mr. Skirving. He did not wish to enter on any discussion with reference to the changes in the tenantry, as represented by Mr. Skirving; but he was prepared to maintain that the changes that had taken place in any period did not arise from high rents. If families had disappeared, it might have arisen from ordinary causes which affected all populations, more especially in busy centres of industry. He did not pretend to account for these changes, but all he meant to say was that the article of Mr. Jenkins conveyed an erroneous impression as to the state of matters as they at present existed in East Lothian. At the same time, matters of fact must be kept in view, and he did not wish for a moment to challenge Mr. Skirving's statement of these facts, neither had he any inclination to notice the various articles which his statement had called forth. There was one, however, which he would just mention. One writer stated that if a person started at one end of the county, and passed along the great post road to the other, he would not get more than three farms on the whole road that had a tenant under a renewed lease. Now he had no hesitation in saying that was not the fact.

Mr. Durie: Can you say how many there are?

Mr. Smith: No; he had not gone over the line of road with that question in view; but he could say within a few miles of that road they would find three cases of renewed leases. Had he known the subject was to be brought up there that day, he would have been prepared to go into that particular matter. Other things had been said, but of so irrelevant a character, that from the way in which Mr. Skirving had taken up the question, he did not think it necessary to go into them.

Mr. Scot Skirving wished Mr. Smith to know that he had written nothing on the subject, and knew nothing about the authorship of the articles referred to. He (Mr. Skirving) was glad the subject had been again brought up. He had wished the discussion at the previous meeting adjourned, because Mr. Smith's remarks went to show that renewal of leases was the rule in that county. Now, everybody who knew East Lothian knew that that was not the case, and he had expected that a man in Mr. Smith's position, who ought to have known better, giving out such a statement. Mr. Smith talked about finding three cases of renewal in a ride through the county by the post road; but suppose he had found six cases, did that prove renewal to be the rule in the county?

Mr. Douglas: What is the proportion of renewals according to your list, Mr. Smith?

Mr. Smith: I said about one-half.

Mr. Douglas: Do you dispute it, Mr. Durie?

Mr. Durie: I say distinctly that renewals must be the exception to the rule, according to Mr. Skirving's list, there have, during the last 25 years, been only 55 renewals against 138 changes.

Mr. Douglas: But is that a true bill?

Mr. Durie: I take it to be a fact as it is there. I don't say there is anything wrong about these removals. The land belongs to the proprietors, and they can do with it as they like, but at the same time that is no reason why a factor in the county should come here and say that the rule is reletting, and changes of tenants the exception. Why, in the parish in which I was born there are only one old family left.

Mr. Douglas: It would surely be a simple matter to prove the accuracy of Mr. Smith's data.

Mr. Smith: I have suggested scrutineers; but I think that is losing sight of the real point of the article I commented on. If you admit that it was not from over-renting that the changes took place, then I have nothing to say as to how many changes there are.

Mr. Scot Skirving: We admit nothing.

Mr. Smith: I will go back 29 years if you like, and I will say that the changes that have taken place in East Lothian have not been caused by over-letting; and to prove that I say that the men who succeeded the previous tenants in these changes have thriven, and are thriving as a body at the present day. Hence the whole force of Mr. Jenkins' article was not only a mistake, but a misrepresentation. I say that the changes that have taken place have not been from the causes stated in Mr. Jenkins' article. They have arisen from purely natural causes, and not from any wholesale clearance on the part of proprietors.

Mr. Scot Skirving: I am content to deal with the matter of fact. As to going into causes, that is a different thing, and one into which I do not care about entering at all.

Mr. Durie: But I maintain that every one of these removals has been caused by high rents. Why else should they have removed? Do you think they went out of their farms for nothing? I am telling Mr. Smith a fact, when I say that every tenant who has been removed has been removed because he could not pay the rent that the landlord wanted.

Mr. Douglas: But that does not prove overrenting. These parties were removed after they had had an opportunity of retaking their farms, and did not do so, while others did and throve in them. You cannot say if a man left his farm rather than pay a particular rent, and another man stepped into his shoes, and profited thereby that the first tenant was removed in consequence of over-renting?

Mr. Smith: That was all I meant.

Mr. Durie: Well, I maintain that they are not either thriving or prospering. In my farm three tenants have been rouped out of it because they could not pay their rent, and I am nearly being the fourth.

Farm Memoranda.

Farm of the Board of Education, Glasnevin.—An agriculturist, visiting the Irish metropolis, could not employ a portion of his time more agreeably or profitably than by visiting the farm of the Board of Education, situate at Glasnevin. At the present time this institution is in most creditable condition, and evidences the judgment, care, and industry of the manager. There are something like 200 acres, divided into three portions, each of which is farmed on systems supposed to suit the great bulk of Irish farms. There is the small farm of five acres, which, as it is now managed, is ample proof that such *pitch cultivate* need not be a bugbear to political economists of a certain class. Here we have a farm, which carries a stock of three cows, a pig or two, and provides about 1½ acre of Potatos, with a like quantity of Oats each year, and with little extraneous aid from manure or purchased food, we find a progressive improvement in the quality of the soil. It may be asked how this improvement can be possible when the bulk of the farm produce in milk and corn is sold off. Careful cultivation, and sedulous attention to the manure-heap, are the agents which have certainly improved very materially the value of this small farm. It is cultivated by a paper hanger's husbandry, and is intended to show what may be done by a farmer with the assistance of his family. The implements used are spade, fork, hoe, sickle, and handcart, or wheelbarrow. The cows, three in number, are of the cottager's class. They are well-bred, and with a small stock for exercise, they enjoy perfect health. For results, it is honestly shown that a farmer may support with comfort a family on a farm, such as the "Glasnevin small farm;" and Mr. Baldwin, who devised and elaborated the system, deserves much credit for what has been done. He has done his duty. It now remains for others to do theirs by extending throughout the country what would undoubtedly enable many to live comfortably who are at the present time engaged in a severe struggle for existence.

A farm of 25 acres is managed to exemplify what would be an improvement in the system of cultivating such farms in Ireland. Here the stock and appliances are such as are within the reach of what are called in Ireland medium-sized farmers. A four-course rotation with a piece of land in permanent grass, is the system of cultivation; a stock of 10 cows, three heifers, one horse, and some pigs are fed; the milk is either sold in the city or converted to butter, the corn of the Wheat crop is sold, as is a portion of the Oats, a small quantity of artificial manures is bought, and occasionally a little artificial food. A systematic and exact set of accounts are kept of the whole of this farm. About 150 acres are farmed on a more liberal scale. Here we find all the aids which a large farmer would call in: a team of good strong horses and modern implements are kept, skilled workmen are engaged, a stock of well-bred dairy cows, sheep of good breeding, and pigs of the white and black breeds are kept, in fact stock breeding, summer grazing, house feeding, and tillage farming are all shown here. Not the least interesting is the portion of the farm set apart for the trial of experiments; this must always have an interest for farmers. As a rule, agriculturists are not experimentalists, and those who expend time and intelligence in conducting experiments are true benefactors. English agriculture would not occupy the position it now does were it not that there were enthusiasts and self-sacrificing men who laboured hard in experimental farming. At the present time the most interesting experiment in the effects of various manures is being carried out, and it is to be hoped Mr. Baldwin will make the results generally known.

That the Albert Model Farm is calculated to work much good is certain. There are a large number of young men sent from it every year, either to farm on their own account, or to conduct the farming operations of large occupiers of land. These young men cannot have attended the lectures on scientific and practical agriculture which are delivered each session without carrying with them much that is valuable. The example of neatness, regularity, and order which are for ever observable must do a great deal, when carried throughout the country, towards remedying the

slovenly systems which have been too long observable. Amongst the chief difficulties which such institutions have to contend against is the idea—pretty general—that immediate good results ought to follow their operations. Agriculture is a slow-paced animal, and it has a wonderfully powerful enemy in those head-shaking, hands-in-the-pocket gentlemen, who are Sir Oracle when anything "new" is proposed, and who are content to jog along in the old style so long as they are saved the trouble of looking far into the future. *T. C.*

Miscellaneous.

LIME.—We have before us a curious old work on "Agriculture," that first saw the light in the days of Cromwell, in which lime is highly commended. It seems to have been among the first attempts at book-writing on agriculture in England. The writer, a Capt. Bird, aims to be practical, and though somewhat confused and complicated in style, yet, as showing the "wisdom of our ancestors," an extract may not be deemed out of place. "Liming, he writes, "is of so great use that whole countries, and many counties that were naturally as barren as any in this nation, and had formerly (within less than half an age) supplied with corn out of the Fielding corn country, and now is and long hath been ready to supply them, and doth and hath brought their land into such a posture for bearing all sorts of corn, that upon land not worth above 1*s.* or 2*s.* an acre, they will raise (well husbanded with lime) as good Wheat, Barley, and white and grey Peas, as England yields; yea, they will take a parcel of land from off a lingy heath, or common, not worth the having; nay, will not have it to husband it, and will raise some gallant corn, that naturally is so barren, worth £5 or £6 an acre. * * * If men would, after good liming, take three, four, or five crops, and then lay down to grass, it would not be the least prejudice; a little more now would produce more fruit than as much more upon the old sward. Many men have had ten crops of gallant corn after one substantial liming, some more upon very reasonable land of about 6*s.* 8*d.* an acre. Some men have had and received so much yield from their lands upon once liming, as hath paid the purchase of their lands. I myself have had great advance thereby, yet I lived 20 miles from lime, and fetched it so far by waggon to lay it upon my lands." *American Paper.*

THE TRICHINA SPIRALIS.—A case of Trichiniasis is reported from Workington, and is the subject commented on by Dr. Cobbold in a recent lecture before the Society of Arts of Workington:—

"Dr. Dickinson has at the present time under his care a family suffering from the so-called flesh-worm disease, resulting from the consumption of ham prepared from pigs reared by the family themselves. A portion of ham sent to me swarmed with recently encapsuled trichinæ. Dr. Dickinson being thus the first person who has diagnosed trichiniasis in the living subject in England, I hope he may be induced to give us further particulars." The editor of the "British Medical Journal," in commenting upon this letter, added a practical point, which I wish especially to bring to your notice. He says:—"The subject of parasitic diseases of domestic animals is one of widespread and increasing interest. It being treated in the Cantor lectures, now in course of delivery at the Society of Arts. it is immediately related to the irrigation of fields with sewage. The other evening, made after that statement on independent grounds, and on his own responsibility. If he had said the subject bears an indirect relation to such questions, he would have said no more than is absolutely true. But I shall take occasion before the close of the lectures to explain, therefore, that there is no reason to suppose that certain forms of parasitic disease may be propagated by means of sewage. In this connection some of you may be disposed to ask the question:—"Are there any sources of comfort to be gathered from the facts?" Or you may say, supposing that in future our British swine are not as free from trichinæ as they have hitherto been, can we possibly avoid the contingency of playing the part of host to those creatures? Certainly, I reply; it is simply a question of cooking your food. If these farmers have not cooked their food at all, or scarcely at all, that will at once explain how their being laid up. I should tell you that the lady and the daughter are recovering, that they are convalescent, but that the man-servant is very ill indeed." If the man-servant ate only 1 oz. of this flesh with living trichinæ in it, he will have, I reckon, at this present moment at least 42,000,000 of those guests in his muscles. You will say at once. Will he recover? Yes; if he ate no more than that: but I am afraid that he has eaten many more than that. If he has eaten 2 oz. thoroughly underdone, depend upon it he has 80,000,000, and if he has eaten 3 oz. he will have over 100,000,000 of trichinæ in his muscles. Could he survive if he had eaten over 3 oz., and thus have 100,000,000 and upwards of these inhabitants? I think he could. I have evidence on this point from a case the nature of which I hardly like to open in your view, because, perhaps, it would make you more uncomfortable than you wish to be. For myself, there is little or no discomfort on the subject, since, in the course of the last 20 years, I have escaped almost entirely from any annoyance, although millions of these creatures and their eggs have passed through my hands. However, it is something to know what you are handling, and what you are looking at, because there are many parasites which are dangerous. There are some residing in meat which you and I eat every day without any bad consequence. Though of a totally different zoological character, they are as harmless as cheese-mites.

"There is no need to be in the slightest degree nervous about flesh-food, provided it is properly cooked. I believe there will be no fatal issue in the case of any of the three individuals alluded to; but the chief practical point before us arises out of the fact that we have here, for the first time in England, the commencement of an epidemic of trichiniasis. By thus calling attention to the subject, it will be easy to take those precautions by which future epidemics of the kind may be readily avoided."

The Week's Work.

AUGUST 19.—There is nothing more difficult than the harvesting of corn when the atmosphere is highly surcharged with vapour, for, instead of drying, the standing corn and stooks absorb moisture, and thus become more wet. In such weather corn and straw both lose colour, quality, and value. Small sheaves should be made with only eight or ten to the stook if the straw is long, and only six to the stook if the straw is short; some put on two hood-sheaves, and a well hooded stook will carry off rain for a long time, but when the stook is badly set, and the hoods improperly put on, they often do more harm than good, and on that account hooded stooks have become the exception—the object now aimed at in setting a stook to fend rain being to bind the straw straight in the sheaf, to plant each pair of sheaves opposite each other, and bring the stook to a fine ridge, as in thatching a stack, so as to carry off the rain to either side.

Drying Corn artificially in Harvest, so as to fit it for stacking or threshing, is one of the many improvements of the day. Like all others in farming, the practice now in use is doubtless subject to further improvement, for, as has justly been observed, "there is no end to improving a thing;" but to look on at corn and straw being spoilt in the stook is now unpardonable, provided the expense of drying is less than the loss sustained. In this subject, the reports of Mr. Gibbs' drying machinery may be consulted.

Stacking Corn is a work requiring the highest degree of skill and art to perform it properly, the stacker being generally considered the best man in harvest. An apprenticeship is necessary to learn the art. A well-built stack is not a question of mere form and outward appearance, although too apt to be viewed in this light. Thus a good stacker will "build out the rain," a bad one will "build in the rain;" the former will "prevent a stack heating," while the latter will "set a stack on fire," and so on. These are extreme but familiar expressions in most places, embracing a broad difference. In some districts the labour of two workmen who too frequently look for the same amount of wages. Every farmer knows what a relief it is to have a man in the stackyard in whom he can place implicit confidence. Stacks, whether round or oblong, should always be built on stack-stands, and the stack-stands should be prepared so as to provide for the proper ventilation of the stacks, for an improperly ventilated stackyard will heat whilst a well ventilated one will keep cool, other things being equal. If a stack is confined and close on one side and free on the other, it will set down unequally, however perpendicularly it may appear to stand; but if it stands in a properly ventilated all round, and built uniform in density, it will settle down fairly and cool, assuming the sheaves to be equally fit for stacking in both cases.

Thatching should be done immediately the stack is up. To delay until it is seen how the stack will settle down, is at best a poor apology for bad stacking. And the same remark applies to cutting the outsides of the stack—cut the outsides as you build, and let the thatcher follow close up, the stacker taking care to have the roof of the stack properly consolidated and raked down hard in the building.

Rye-grass and Clover Seeds, when intended to follow either Wheat, Barley, or Oats as a grass or hay crop, may be sown on the stubble as soon as the labours of the harvest will permit. Clover or corn crop is harvested in August, seeding after harvest will be found preferable to seeding in spring, both for the corn crop and the seeds. Where the land is clean, as it always should be, and free from weeds, sow on the stubble, and bush or fork harrow in about the same quantity of seed as directed in spring. Where the seeds were sown in spring, and have brairded, but the plants are partially killed by the drought of summer or otherwise, blanks and thin places should be seeded with the hand, and the seed left to be washed in or covered by the first shower of rain, as the harrow cannot be used, and rolling is objectionable at this season.

Live Stock find little in the stubble now as compared with the olden time. Autumn tillage amongst the stocks, and the seeding of the land with Turnips, Rape, &c., preclude the admission of either sheep, black cattle, or pigs into corn stubbles. The old bands of gleaners are likewise excluded. But the improvements thus taking place have all for their object more food for stock, not less; and as suitable provision for live stock in August is a cardinal point in stock management, the practical solution of the question is often no easy task.

Lamb Weaning in Scotland (Cheviot and black-faced) usually takes place from the beginning to the middle of the month. Blackfaced and Cheviot ewes that have fattened cross-lambs will also be ready for drafting for the shambles.

Notices to Correspondents.

AGRICULTURAL PRINTS: *T. C.* We know of no special place where prints of Shorthorn cattle may be obtained, but have frequently observed them and purchased them in second-hand book and picture stalls in London. They are very generally diffused, and can be bought for little money.

DISEASED CHICKENS: *A Subscriber* says—I have lost a great many chickens this summer when they get to seven or eight weeks old. I have some still with the same complaint; loss of appetite, drooping wings and tails, sore swollen eyes, go quite blind, look very red all over, smell very offensive, then die. A hint would greatly oblige. [Wholesome food and frequent change of place ought to do much to remove what you complain of. Keeping chickens cooped on the same ground is a fertile source of loss.]

DRESSING GRASS LAND: *Redcliffe* asks—What quantity of gas-lime per acre would be sufficient to dress grass land with? and what quantity of soil would be required to mix with a ton of gas-lime for the same purpose? [Mr. W. Scott, of Howford, gives his experience in the latest edition of "Stephens' Book of the Farm." He makes a compost of two-thirds earth and one-third lime, letting the heap lie at least six months, turning it once or twice in that time, and giving from 10 to 12 tons on one acre.]

UTILISING PEA HAULM: *Rusticus.* Good Pea haulm will be eaten with relish by live stock, especially sheep, without any preparation. The suggestion to chaff and treat with steam or water may possibly be an improvement. We hope that the conclusive answering of the above inquiry will be undertaken by some one of our numerous practical readers.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Aug. 14.

There are a few more foreign Beasts, but not quite so many English, making the total number about the same as last week. The hot weather causes a slower trade, but choicest qualities are not much lower. The number of Sheep is rather smaller; the average quality has, however, improved. Trade is not so brisk as of late, and Thursday's quotations are barely maintained. Choice Lambs are still scarce and dear. Calf trade is unaltered. Our foreign supply consists of 2550 Beasts, 12,780 Sheep, 255 Calves, and 5 Pigs: from Scotland there are 5 Beasts; from Ireland, 200; from Yorkshire and Norfolk, 40; and 1125 from the Midland and Home Counties.

	s. d. s. d.		*s. d. s. d.*
Best Scots, Here-fords, &c.	5 8to6 0	Best Long-wools	.. to ..
Best Shorthorns..	5 4—5 8	Do. Shorn	6 0—6 4

Do. Shorn	.. —..	Lambs	7 0—8 0
	6 4—6 8	Calves	3 8—5 8
		Pigs	3 4—4 8

Beasts, 3920; Sheep and Lambs, 13,720; Calves, 269; Pigs, 70.

THURSDAY, Aug. 17.

We have a much larger supply of Beasts than on Thursday last, and the demand is very limited, consequently prices generally are lower, and a clearance cannot be effected. The number of Sheep is also larger, and trade very dull; prices 2*s.* per Sheep lower, and several lots remain unsold. Choice Lambs continue to be very scarce and dear; in some instances our top quotation has been exceeded. Calves are dearer. Our foreign supply consists of 440 Beasts, 6340 Sheep, 450 Calves, and 5 Pigs.

JOSHUA BAKER.

MARK LANE.

MONDAY, Aug 14.

There was a small supply of English Wheat at this morning's market, of which a few samples of new were shown; for white there was a fair inquiry, at previous prices; red sold slowly at a decline of 1s. to 2s. per qr. upon the prices of this day fortnight. The attendance was small, and to effect sales a similar reduction on all descriptions of red foreign had to be submitted to. Barley, Beans, and Peas were unchanged in value. Oats were in small demand, at a decline of 6d. per qr. Flour must be quoted 6d. to 1s. per barrel and sack lower.

WEDNESDAY, Aug. 16.

At Mark Lane to-day there has been a moderate supply of English Wheat, and fair receipts from abroad. The trade has been quiet, at the rates previously current. There has been a fair supply of Barley on offer. Transactions have been restricted, on former terms. Malt has been dull, at late prices. Oats, the show of which has been good, have met a moderate inquiry, at previous quotations. Beans and Peas have changed hands slowly, at about late rates. Flour has been quiet, on former terms.

ARRIVALS OF GRAIN, &C., INTO LONDON BY WATER CARRIAGE.

LIVERPOOL, Aug. 15.—The attendance was not numerous, but there was a fair consumptive demand for Wheat, at steady prices for fine descriptions, while inferior was irregular. Flour slow, but unchanged. Oats steady for fine, but others were rather easier. Oatmeal slow. Beans 3*d.* to 6*d.* lower for Egyptian. Peas unchanged. Barley, no sound here. Malt dull. Indian Corn in moderate request, at 3*d.* to 6*d.* reduction on the week.

SEED MARKET.

The agricultural seed trade continues in a quiet state. In red Clovers there is for the moment nothing passing. Trefoils are in improved request, and realise more money. White Clover seed is firm. New winter Tares have appeared this week at market, but the high prices demanded have prevented business. Of new winter Barley there is an abundant supply offering. New Rye for seed is in good demand. Trifolium is easier; of fine quality seed there is, however, very little now left. Rape and Mustard are without alteration. We have an inquiry for new blue Peas. Canary seed shows an advance of 1*s.* to 2*s.* per qr.

JOHN SHAW & SONS, Seed Merchants,
16, Water Lane, London, E.C.

HOPS.

BOROUGH MARKET, Aug. 16.

There is almost no demand for Hops in our market, and prices remain unaltered. The weather appears to be favourable to the growth of the Hop plant in most places, but some planters think heavy rain for a couple of days would assist in effecting improvement. From Uppringle's the accounts come better, but in Alost, one-eighth of a full crop is all that is expected. The last advices received from Bavaria and Bohemia are not encouraging.

COALS.—Aug. 16.

Agricultural Land Improvements.

DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY.
(Incorporated by Act of Parliament in 1849.)

DIRECTORS.

J. Chapman, Esq., F.R.S.
George Thomas Clark, Esq.
Henry William Currie, Esq.
The Right Hon. Viscount Combermere.
Edward John Hutchins, Esq.
The Rev. William Tite, M.P., C.B.
The Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works by their own agents.

Tenant Farmers may also, by agreement with their Landlords, procure the execution of such Improvements.

The outlay, with all official expenses, may be charged upon the Estate, and paid off by a Rent-charge of about 5 per cent., in 21 years, or at the option of the Landowners in a shorter term.

No investigation of title necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, and others for applying the Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof may be provided for by a loan in gross, or by a terminable yearly payment, discharging in a fixed period the principal amount with interest thereon.

Application is made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 22, Whitehall Place, S.W.

THE LANDS IMPROVEMENT COMPANY.
(Incorporated by Special Acts of Parliament.)
DRAINAGE, RECLAMATION, FARM BUILDINGS, LABOURERS' COTTAGES, TRAMWAYS, RAILWAYS, &c.
DIRECTORS.

John Clutton, Esq.
Frederick R. Cockswood, Esq.
Henry Farquhar, Esq.
John Gellibrand, Esq.
John Horatio Lloyd, Esq.
Granville R. Ryder, Esq.
Granville H. Somerset, Esq., Q.C.
Henry W. West, Esq., M.A.
Charles Wentworth Williams Wynn, Esq., M.P. (Chairman).

The Company advances money, unfettered in respect of the purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of Settled and other Estates, and to the Clergy in respect of their Glebe Lands.

Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.

UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeeming principal and interest, over 25 or 30 years.

No investigation of title is required.

For Forms and further information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S. W

Notice.

(By Appointment to the Royal Horticultural Society.)
TO HORTICULTURAL IMPLEMENT MAKERS, NURSERYMEN, FLORISTS, and OTHERS.

ADAMS and FRANCIS INSERT ADVERTISEMENTS in all the leading Country, Colonial, and Foreign Newspapers, Magazines, and Periodicals, WITHOUT EXTRA CHARGE to the Advertiser.
ADAMS and FRANCIS, Advertisement Agents, 59, Fleet Street, E.C.

CENTRAL ARGENTINE LAND COMPANY, LIMITED.
Chairman—JOHN HEGAN, Esq.
Agent in the Republic—E. HARRY WOODS, Esq., C.E., Buenos Ayres.
Superintendent—WILLIAM PERKINS, Esq., Rosario de Santa Fé.

The Directors offer, on advantageous terms to Settlers, either as Tenants or Purchasers, FLOTS, varying from 80 to 200 ACRES each, of the COMPANY'S LAND, situate on each side of the Central Argentine Railway, from the Port of Rosario, to the Chief Cordova, the entire length being 226 miles. Towns and Villages are being laid out at various points on the Line, where smaller Plots may be secured for Building purposes.

To secure the best class of Agricultural Settlers and facilitate the Emigration of Families, the Directors are prepared to treat for the Colonisation of Lands within easy reach of the Stations on the Central Argentine Railway, already adapted for immediate cultivation.

Further particulars may be obtained at the Offices of the Company:
London—St. Helen's Buildings, Bishopsgate Street, E.C.;
Buenos Ayres—87, Calle de la Reconquista;
Rosario—Office of the Central Argentine Railway;
Where the Surveys of the Land (about 1,000,000 Acres), together with the Plans of the Colonies already established, can be inspected.

GEORGE WOODBRIDGE, Secretary.

85, Palmerston Buildings, Bishopsgate Street, London, E.C.

LEGAL and GENERAL LIFE ASSURANCE SOCIETY.
10, Fleet Street, Temple Bar. (Founded 1836).

The Parliamentary Accounts required by the "Life Assurance Companies Act, 1870," may be obtained on application.

Policies of this Society are guaranteed by ample funds; receive nine-tenths of the total profits as Bonus; enjoy peculiar "Whole-World" and other distinctive privileges; and are protected by special conditions against liability to future question.

TRUSTEES:
The Right Hon. the Lord Chancellor.
The Right Hon. the Lord Cairns.
The Right Hon. Sir W. Bovill, Lord Chief Justice, C P.
The Right Hon. Sir Edward Vaughan Williams.
The Hon. Sir George Rose.
Sir Thomas Tilson.
Thomas Webb Greene, Esq., Q.C.
John Gibson, Esq., Q.C.
Robert Bayly Follett, Esq., Taxing Master in Chancery.

Settlement Policies in favour of Wife and Children are granted in terms of the "Married Women's Property Act, 1870."

E. A. NEWTON, Actuary and Manager.

Works on Botany, by Dr. Lindley.

SCHOOL BOTANY; or, THE RUDIMENTS OF BOTANICAL SCIENCE. In One Volume, 8vo, half bound, with 400 Illustrations, price 9*s.* 6*d.*

DESCRIPTIVE BOTANY; or, THE ART OF DESCRIBING PLANTS correctly, in Scientific Language, for Self-Instruction and the Use of Schools. Price 6*s.* 6*d.*

MEDICAL and ŒCONOMICAL BOTANY; or An Account of the Principal Plants employed in Medicine or Domestic Œconomy. In 1 vol. 8vo, with numerous Woodcuts, price 7*s.* 6*d.*

THE ELEMENTS of BOTANY, STRUCTURAL AND PHYSIOLOGICAL. With a Glossary of Technical Terms, and numerous Illustrations. 12*s.* cloth.

This completes the series of Elementary Botanical Works by Professor LINDLEY, of which "School Botany," and "The Vegetable Kingdom," form the other two.

The first two Parts of THE ELEMENTS OF BOTANY, comprising Structural and Physiological Botany, and a Glossary of Technical Terms, are published in one octavo volume, price 12*s.*

These three parts form a complete manual of Botany for Medical and other Students who have made themselves acquainted with the Author's "School Botany."

N.B. The Glossary may be had separately, price 5*s.*

THE VEGETABLE KINGDOM; OR, THE STRUCTURE, CLASSIFICATION, AND USES OF PLANTS. Illustrated upon the Natural System. In One Volume, 8vo, cloth, price 36*s.*, with upwards of 500 Illustrations.

EXTRACT FROM THE AUTHOR'S PREFACE.

"The Vegetable Kingdom contains, among a large quantity of plants of no known importance to man, various useful species employed in medicine, the arts, or in the many branches of domestic economy. The principal part of those which can be brought by teachers in Europe under the notice of students, are of the most great importance, deserve to be among the earliest subjects of study, are mentioned in the preceding pages, when they occurred in the natural system of the present work. The Vegetable Kingdom of the author, with the sequence of the Orders, is a few sections in advance of it. I believed that the convenience of younger students would be consulted by doing so. The author trusts that this selection will be found to have been made in a way that will render the work of reasonably extensive means of illustrating their lectures, and all Botanical Gardens, and Botanical Museums, will be found to contain all that is mentioned. A small selection was indispensable; firstly, because a greater work would be too large and too heavy for the majority of purchasers; and secondly, because experience shows us that those who have to teach Botany, in addition to their other duties, cannot concentrate their attention, in the first instance, upon a limited number of subjects."

London: BRADBURY, EVANS, AND CO., 11, Bouverie Street, E.C.

THE NEW METHOD of GROWING FRUIT and FLOWERS (by the Rev. JOHN FOUNTAINE, Southacre, Brundall, Norwich). Illustrated with Woodcuts. Richard Hoare and Conservatory, as now worked in a New House erected for the purpose at Chiswick. Third Edition, Illustrated. Free for seven stamps to the

"Journal of Horticulture" Office, 171, Fleet Street; or to the Author.

Dr. Lindley's Theory of Horticulture.

In 8vo, with 98 Woodcuts, price 12*s.* cloth.

THE THEORY AND PRACTICE OF HORTICULTURE; or, an Attempt to explain the Chief Operations of Gardening upon Physiological grounds: being the Second Edition of the Theory of Horticulture, enlarged. By JOHN LINDLEY, Ph.D., F.R.S.

"The First Edition of this valuable work was issued in 1840, since which time it has had an extensive circulation, and has been translated into the German, Dutch, and Russian languages. Being more particularly restricted to principles, however, the author at length resolved to render the work more generally interesting and useful by a further reference to practical operations. He has thus greatly extended the matter by supporting the physiological doctrines with an appeal to the daily practice of cultivators, or which ought to be; and the result is a still more interesting and popular compendium of the principles of horticulture than the former edition."—*Gardeners' Chronicle.*

"This is a Second Edition of the 'Theory of Horticulture,' with the addition of a large quantity of practical matter introduced to show how entirely scientific principles are carried out in practical operations. The volume contains about four times as much matter as the first edition. . . . Although very large additions are made to every chapter, while many passages in the first edition have been wholly struck out, it may be proper to say that the greatest changes are those which relate to vitality, climate, domestication, ventilation, propagation, pruning, resting, and soils and manures; such being the subjects in which practical men are most interested. The whole work has, indeed, assumed such a form as to make it evident that the great object of the author is to bring the practice of gardening to the test of science, but one which every well-informed person may understand and apply. The Table of Contents, besides being a very complete Index of matter, there is no difficulty in finding where any given subject is treated of."—*Gardeners' Chronicle.*

London: LONGMANS, GREEN, AND CO., Paternoster Row, E.C.

THE COTTAGER'S CALENDAR of GARDEN OPERATIONS. By the late Sir JOSEPH PAXTON, M.P.
Reprinted from the *Gardeners' Chronicle and Agricultural Gazette* with Additions.
Price 3*d.* each, or 5*s.* for 25 Copies for distribution amongst Cottage Tenantry.
Delivered anywhere in London on receipt of a Post Office order, payable to WM. RICHARDS, at the King Street Office, Covent Garden.
Published at the Office of the *Gardeners' Chronicle and Agricultural Gazette*, 41, Wellington Street, Covent Garden, London, W.C.

New and Enlarged Edition.

Thirty-six Illustrations, and Five Photolithos,
A PRACTICAL TREATISE on the CULTIVATION of the GRAPE VINE, by WILLIAM THOMSON, of Tweed Vineyard, Clydebank, Dumbartonshire, Gardener to his Grace the Duke of Montrose, K.G., at Dalkeith Park. The Seventh Edition, enlarged.
WILLIAM BLACKWOOD and SONS, Edinburgh and London.

THE CELEBRATED GRANITIC PAINT.
Manufactured Solely and Only by the Silicate Zopissa Composition and Granitic Paint Company.
For Price Lists, Testimonials, and Patterns of Colours, apply to THOMAS CHILD, Manager, 39A, King William Street, London, E.C.

THE SILICATE ZOPISSA COMPOSITION.
TO CURE DAMP in WALLS, and Preserve Stone, &c., from Decay. Manufactured Solely and Only by the Silicate Zopissa Composition and Granitic Paint Company.
For Particulars and Testimonials apply to THOMAS CHILD, Manager, 39A, King William Street, London, E.C.

OSLER'S CRYSTAL GLASS CHANDELIERS,
TABLE GLASS OF ALL KINDS,
CHANDELIERS IN BRONZE AND ORMULU,
Moderator Lamps, and Lamps for India.
London—Show Rooms, 45, OXFORD STREET, W.
Birmingham—Manufactory and Show Rooms, Broad Street.

KINAHAN'S LL WHISKY.—
This celebrated and most delicious old mellow spirit is the very CREAM of IRISH WHISKIES, of a quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the words, KINAHAN'S LL, on seal, labels, and cork.
New Wholesale Depôt, 61a, Great Titchfield Street, Oxford Street, W.

WILLIAM YOUNGER AND CO.
DINNER ALE.—Sparkling and Refreshing.
INDIA PALE ALE.—Unsurpassed as a Tonic.
EDINBURGH ALE.—Nourishing and Invigorating.
Of all Retailers, in Cask and Bottle.

Pure Aerated Waters.
ELLIS'S RUTHIN WATERS, Soda, Potass, Seltzer, Lemonade, Lithia, and for GOUT, Lithia and Potass. Corks Branded "R. ELLIS AND SON, Ruthin," and every label bears their Trade Mark.
Sold everywhere, and Wholesale of R. ELLIS AND SON, Ruthin, North Wales. London Agents: W. BEST AND SONS, Henrietta Street, Cavendish Square.

Sauce.—Lea & Perrins
THE "WORCESTERSHIRE," pronounced by connoisseurs "the only good Sauce," improves the appetite and aids digestion. It is matured for piquancy and flavour.
Ask for LEA AND PERRINS' SAUCE.
Beware of imitations, and see the names of LEA & PERRINS on the Bottles and Labels.
Agents—CROSSE AND BLACKWELL, London; and sold by all Dealers in Sauces throughout the World.

DINNEFORD'S FLUID MAGNESIA.—
The best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion; and the best mild aperient for delicate constitutions, especially adapted for Ladies, Children, and Infants.
DINNEFORD AND CO., 172, New Bond Street, London; and of all Chemists throughout the World.

BILIOUS and LIVER COMPLAINTS, Indigestion Sick Headache, Loss of Appetite, Drowsiness, Giddiness Spasms, and all Disorders of the Stomach and Bowels are quickly removed by that well-known remedy, FRAMPTON'S PILL OF HEALTH.
They unite the recommendation of a mild operation with the most successful effect; and where an aperient is required nothing can be better adapted.
Sold by all Medicine Vendors, at 1*s.* 1½*d.* and 2*s.* 9*d.* per box, or obtained through any Chemist.

COCKLE'S ANTIBILIOUS PILLS.
THE SAFEST FAMILY APERIENT,
In boxes, at 1*s.* 1½*d.*, 2*s.* 9*d.*, 4*s.* 6*d.*, and 11*s.*

COCKLE'S ANTIBILIOUS PILLS.—
These Pills consist of a careful and peculiar admixture of the best and mildest vegetable aperients, with the active principle of the resin of the Chamomile. They will be found a most efficacious remedy for derangement of the digestive organs, and for torpid action of the liver and bowels. Their action is prompt in the several varieties of bilious and liver complaints. They speedily remove the irritation and feverish state of the stomach, allay spasms, quicken the circulation, and in short produce indigestion even to digestion, promote a due and healthy secretion of bile, and relieve the constitution of all gouty matter and other impurities, which, by obstructing the circulation, frequently affect the action of the kidneys; thus, by removing the causes productive of so much discomfort, they restore the energies both of body and mind. To those who indulge in the luxuries of the table, these Pills will prove highly useful, occasioning no pain in their action, unless they meet with an unusual quantity of acrid bile, and acid matter in the stomach and bowels. To females of every age in the Pills of Chamomile they are recommended as a preservative against the fatal disorders peculiar to tropical climates. Their occasional use, if combined with the strictest attention to diet, will be found sufficient to ward off attacks of fever, the influence over the secretions, that congestive and unhealthy condition of the liver which is so often the earliest antecedent of severe febrile and constitutional disturbance. It must be understood that these Pills are not recommended as containing any new or dangerously active ingredients; on the contrary, they are characterised by a remarkable simplification, and whatever merit they may claim to be found to possess depends as much upon the selection of pure drugs, and the unusual labour and attention bestowed upon their subsequent preparation, as upon the acknowledged superiority of their combination. They are not recommended as a panacea, nor are they adapted to all complaints; but as a mild and efficacious aperient and tonic in the various forms of indigestion and ill health, perhaps, be an exaggeration to state that they have been resorted to under all systems of diet, changes of climate, or atmospheric alternations, with an extraordinary degree of success, for upwards of 70 years. This celebrated Family Aperient may be had throughout the United Kingdom, in boxes, at 1*s.* 1½*d.*, 2*s.* 9*d.*, 4*s.* 6*d.*, and 11*s.*, as well as in India, China, New Zealand, and the Australian Colonies.

COCKLE'S ANTIBILIOUS PILLS.
THE OLDEST PATENT MEDICINE,
In boxes, at 1*s.* 1½*d.*, 2*s.* 9*d.*, 4*s.* 6*d.*, and 11*s.*

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Aug. 30 } Crystal Palace Flower Show.
THURSDAY, " 31 }

THERE are certain phenomena of vegetable life which are familiar to us from daily observation, but of which, nevertheless, we know wonderfully little. This is the more to be regretted, inasmuch as there can be but little doubt that the thorough investigation of the causes and *modus operandi* of these phenomena would ultimately lead, not only to results of the highest value scientifically, but also of the greatest importance from a practical point of view. Let us take, for instance, the MOVEMENTS which occur not only in climbing plants, but in leaves and flowers, and, indeed, more or less in ALL PARTS of the PLANT. Time was when all these movements were vaguely referred to vital force, organic irritability, and such-like expedients for concealing ignorance. These and similar expressions abound even in our best horticultural text-books, and their influence is likely to be baneful, as putting a check to investigation by the assumption of a limit, which may indeed exist, but which certainly has not been reached. To give precision to our remarks, let us take the case of those movements now known to be consequent on VARIATIONS in the degree of TENSION in vegetable tissues. We will specify some of these, and endeavour, so far as our means and limits will allow, to explain them in accordance with the facts brought to light in recent experimental inquiries.

Let us take, first, one of the simplest of these cases, the separation of the divided portions of a stem when cut lengthwise. Take almost any young growing shoot, preferably one hollow in the interior—the flower-stalk of a Dandelion, for instance, and cut it down lengthwise for a short distance ; immediately the separated portions diverge one from the other, just as happens when a shoulder of mutton is carved at the dinner-table. The appearance thus presented is like that of the letter Y ; or when, as often happens, the edges roll up, we have an appearance resembling that of the zodiacal sign of Aries, ♈. Again, let the layers of bark and wood tissue be carefully dissected off from a young Vine shoot, so as to leave the pith exposed ; and it will be seen that, while the bark and wood become contracted, or in other words shorten, the pith lengthens. A similar contraction ensues, but in a transverse direction when a ring of bark is cut off from a shoot ; it contracts ; try to fit it on to the stem from which it was taken, and it will be found impossible to replace it accurately.

Other examples might be cited did space permit. It must suffice merely to allude to the movements of climbing plants, of sensitive plants, the turning of leaves and flowers to the light, and so forth.

Now, every one of the phenomena we have just alluded to would, a few years ago, have been explained as manifestations of so-called vital force, a force modified, it is true, by physical agencies, but one assumed, on the whole, to be beyond man's ken. Fortunately, now-a-days, the tendency is to get out of this groove, and to take a wider view of things. Dr. GOLDING BIRD was, so far as our knowledge goes, one of the first to show that the divergence in the case of divided stems to which we have just alluded, was due to physical causes. If, as had been previously suggested, the divergence during the vital irritability of the wound did not occur, as it does, as well in dead tissues as in live ones. Dr. BIRD, moreover, decisively proved that the divergence in question was due to varying degrees of tension, these variations being dependent in his experiments on the alternate emptying of certain cells, and the filling or turgescence of others, and *vice versâ*,—the transfer of fluids in this case from cell to cell, taking place in accordance with what is now called osmosis, or the tendency which a thin fluid has to intermix with a denser one separated from it by a membranous barrier. Dr. BIRD's experiments were published as long ago as 1837, in "Loudon's Magazine of Natural History," then edited by CHARLESWORTH, and sufficient credit has, to our thinking, not been given to him by later experimenters and writers.

It seems certain, however, that though this passage of fluids from cell to cell by osmosis is an efficient cause of the movements witnessed in certain cases, yet that there are other instances, and these the most numerous, where no such passage of fluids takes place, and yet the movements occur. For instance, a field of Wheat is laid by heavy rains, such as we have had in the present season. Under certain circumstances the straw will get up again. How is this? Clearly the turgescence of certain cells would not be likely to produce this result, but rather the reverse.

In endeavouring to explain what is the real cause of the phenomenon, we must allude briefly to what the physiologists, and specially those of Germany, HOFMEISTER, SACHS, KRAUS, and others, have lately told us as to the nature of tension in vegetable tissues. Certain of the tissues are erectile, left to themselves they have a tendency to extend in all directions ; certain other of the tissues are by comparison passive, and act as a check on the erectile tissues. Speaking generally, the spongy cellular portions, such as the pith, and the cellular portions of the bark, are erectile, *i. e.*, have a tendency to swell ; while the skin or epidermis and the fibrous stringy tissue (wood) are passive. To varying relative conditions of these parts the movements of plants may, in great measure, be attributed. For instance, the divergence which occurs when a Dandelion or other herbaceous stem is cut down, depends on the sudden disturbance of the balance heretofore existing between the more elastic central portions and the passive outer portions of the skin : the latter gain the advantage, and curvature results, owing to the adhesion of the cells to the rind ; but if, as in Dr. BIRD's experiments, the advantage of the central tissues is restored by the imbibition of fluids, the cut surfaces then lose their curvature and become parallel to each other. And so, in regard to our second illustration, the contraction that takes place when a ring of bark is removed from the subjacent cells affords another illustration of the difference in tension of the different elements of the stem.

The tension which occurs in plants is always liable to fluctuations in degree, and may either be permanent or transitory. Permanent tension is that which occurs as a result of unequal growth, while transitory tension is due to variations in the quantity of water absorbed, as in the experiments just alluded to. There is always a tendency to maintain an equilibrium, the tensive forces are, in theory, at least, equally and symmetrically distributed, but this equal distribution is continually being interfered with by variations in the vigour of growth and the amount of light, heat, and moisture to which plants are subjected.

For instance, to refer again to laid Wheat, we may suppose that the elasticity of the passive tissues on the side of the straw next to the ground is diminished, it offers less resistance ; while, on the other hand, the expansion of the erectile tissues, finding the less obstacle, and stimulated by light and heat, tends to pull the stem into an upright position again. But, it may be asked, if this is a correct interpretation, how is it that creeping plants, or plants which normally hang down from rocks, walls, &c., do not get up? Simply because, according to KRAUS, the amount of tension-force in their tissue is not sufficient to allow them to do so.

Alterations in tension, too, produce a healthy vigorous growth. KNIGHT used to unnail his Peach trees and let them blow about for a time in the wind ; HERBERT SPENCER has shown how the progress of the sap is facilitated, and the deposit and ripening of the wood augmented from the same reasons. Let us see what light these comparatively new researches on tension throw on these matters. It has been long known that if a growing shoot be shaken several times in succession, a curve will ultimately be formed in it, the centre of which curve corresponds with the place where the tension is at its maximum. The disturbance produced by the continued shaking stretches the passive tissues (epidermis) and diminishes their elasticity and consequent power of resistance to the erectile tissues within, which are, in consequence, enabled to grow the more rapidly. If this stretching of the rind be uniform on all sides of the shoot, a simple lengthening will take place ; but if, as is usually the case, the stretching be more on one side than on the other, then a curve is produced.

The degree of tension varies in different parts of the day ; in different plants, as we have already mentioned in the case of spring plants ; and in different parts of plants. Under ordinary circumstances, the tension diminishes in early morning, and is at its minimum at 2 P.M., from which time it gradually increases.

In annual plants, according to KRAUS, the maximum degree of tension is at the base of the stem, and diminishes towards the ends of the branches and of the roots. Now it will be remembered that these are precisely the points where growth is most active, and the effect of the increased tension at the base of the stem would be to force the nutritive fluids in the two directions where it is most required. In trees the young shoots act in the same way as annual plants.

In the case of plants with bulbous, tuberous, or fleshy root-stocks, if the intensity of tension were greatest at the base of the stem the sap would, it is clear, be driven away from the reservoir, bulb, tuber, &c., where it is most required for future growth. Accordingly, we find that the point of greatest intensity changes in these plants ; all the time leaves and flowers at one end, and roots at the other, are forming, the greatest squeezing force, if we may so term it, is exerted at the base of the stem—the most advantageous place, but when the necessities of the case are altered, and it is time to provide for the store-house bulb, rhizome, tuber, or what not, then (that is, towards the end of summer) the maximum squeezing power is exerted higher up the stem in such a manner as to facilitate the passage of the nutritive juices from the branches to the bulb. Another of those wonderful provisions of Nature which testify to the infinite wisdom and prescience of its Author.

The great importance of these matters, from a practical point of view, must serve as an excuse for our endeavour to lay before our readers an account of these, at present, very obscure and complex phenomena.

—— WE are glad to be able to state that a most interesting and, as we believe, useful MEETING, was held in the CHISWICK GARDEN of the ROYAL HORTICULTURAL SOCIETY on Tuesday last. The occasion was that of the examination of Bedding Pelargoniums by the Floral Committee—a good and useful work, partially resumed since the remodelling of the garden has been completed. The Council, very judiciously, took advantage of the opportunity which thus presented itself to meet the Society's working committees, and at the same time the whole of the exhibitors, who were invited to join in the inspection of the newly-

arranged garden. Nearly 100 persons were present. After the primary work of the day had been got through by the Floral Committee, and the members of the Fruit Committee and the visitors had made an inspection of the new arrangements, which seemed, so far as we could learn, to be highly approved (especially when the short time which has yet elapsed since the beginning of the new works is considered), the whole party partook of luncheon in the great conservatory, beneath the shady foliage of the Vines, and under the presidency of Mr. Wilson Saunders. This part of the programme also appeared to afford satisfaction to those engaged in working it out. A very pleasant afternoon was spent, during which sundry matters connected with the future operations of the Society, especially in the exhibition department, were brought under discussion by various speakers, Mr. Wilson Saunders, Maj.-Gen. Scott, C.B., Major Clarke, Dr. Masters, Mr. G. F. Wilson, Mr. W. Paul, Dr. Denny, Mr. J. Fraser, Mr. T. Baines, Mr. Williams, Mr. Lane, Mr. Cox, Mr. Kelaby, and others; and no doubt the various hints and suggestions which were dropped will be gathered up and turned to useful account, in the conduct of the more extended operations to which the prosperity due to the connection of the Society with the International Exhibitions seems likely to lead. At any rate, it was a good day for Horticulture when the different sections of the horticultural world thus met in friendly *réunion* in the old garden whose very existence was so seriously threatened a year or two since, but which has always been regarded by horticulturists as the real headquarters of Horticulture in this country.

—— Professor Koch, referring in a recent number of the "Wochenschrift" to our article (p. 737, 1871) on the Fertilisation of the Flowers of the Grape Vine, says that his observations lead him to believe that self-fertilisation does not take place. He states as a general fact that the stigma is incapable of receiving the pollen until it has been exposed, for a short time at least, to the influence of the air; and further, that the stamens shed their pollen simultaneously with the fall of the petals; hence the necessity of foreign fertilisation. Professor Koch has, however, fallen into error in his assumption of our view of the matter, for, although we said that self-fertilisation "clearly does occur," we also observed further on that "we found many instances in which the pollen was ripe before the stigma had attained maturity, and *vice versâ*." From this we may infer, perhaps, that there is no certainty or constancy in the order of development of these organs in the Grape Vine.

—— Mr. T. Lamson Scribner, of the Maine Agricultural College, has issued a little *brochure* upon the Weeds of Maine, affording brief popular descriptions and practical observations in regard to the habits, properties, and best methods of extermination of nearly 250 weeds found in the State. The work, though small, is of considerable interest, many details being given as to the introduction and spread of the various weeds. We find that various secondary introductions from Europe, is very troublesome, and that our Transatlantic brethren share the English belief that this species is degenerated Wheat. Several years ago, when first introduced from Europe, it was known as "Willard's Chess," and fabulous prices were offered for the seed. It was not long before the true character of the plant was found out; and people became aware that it was too poor in quality and quantity to be worth cultivating, and that they had been encouraging the growth of a troublesome weed. By sowing clean seed and clearing waste ground of this grass, it may be kept under.

—— Mr. Chapman has sent us sketches of his registered Multum in Parvo Plant and Flower Protector. It consists of a wooden box made in two parts which are held together by clips, and filled with glass top, and supported by a notched stake when used to protect flowers, such as Dahlias, at a distance from the ground. An indiarubber valve prevents the ingress of insects. For such purposes it would appear to be an efficient contrivance. Mr. Chapman also proposes to use it for ground plants instead of hand-glasses. Of course, when used in this way, it would answer in the case of plants requiring such light only as the glass top would admit, but the questions of cost and durability would intervene before its real merits could be ascertained. From being made in flat parts Mr. Chapman believes they may be much more readily stored away when not in use.

—— What is Tulp? A serious inconvenience to those whose lands are infested with it, if we may judge from a case recently tried at Graham's Town, and reported at length in a newspaper of that region. It appears that some cattle having been put out to graze upon a certain farm, "the said pasturage was unfit for the depasturing of the said cattle, it being covered with Tulp, whereby, and by reason whereof, the plaintiff lost two oxen," and naturally desired to get back the money which he had paid in advance for this objectionable pasture. From the evidence it appears that "cattle won't eat Tulp unless they are very hungry, when it is in flower;" that "there is Tulp about all farms about town;" while one witness deposes that he had "seen lots of oxen dead with Tulp," and that "many of the oxen were sick with" it, though only two died. We have made many inquiries, and have consulted many books, but have failed to ascertain the botanical name of this noxious weed. Can any Graham's Town correspondent enlighten us?

—— The Ants in Panama are not merely mining engineers; they build tubular bridges. A corresponding member of the Glasgow Natural History Society, who has lately been in that country, describes the curious covered ways constructed by these ingenious insects. In tracing one of these covered ways he found it led over a pretty wide fracture in the rocks, and was carried across in the air in the form of a tubular bridge of half an inch in diameter, which was the scene of busy traffic. There was nearly a foot of unsupported tube from one edge of the cliff to the other. Fancy the Menai Bridge being only the result of transmitted instincts after all.

—— We are used to wonders from America, but the following account of a New Jersey Apple Tree, although vouched for by good authority, is even beyond the ordinary range of Yankee achievements. This tree, on July 26, 1869, had upon it Apples nearly full grown, the blossoms of which appeared at the usual season. On the same branches was another set of Apples, less advanced, from blossoms which appeared in June; while the wood of last spring was covered with blossoms, which it was expected would produce good fruit, and a fourth show of bloom was preparing for August. The Apples are all of the same kind, and, as to quality, the only difference being in the time of ripening. The tree keeps bearing in this way from year to year.

—— The Maximum Temperatures of the Air during the week ending Aug. 19 ranged from 89°.2 at Blackheath and Leicester to 66° at Greenock, with a mean for England of 82°.1, and for Scotland of 72°. The Minimum Temperatures of the Air ranged from 55° at Leeds to 43°.2 at Glasgow. The mean for all stations was 48°.9, and for Scotland 48°.9. The highest mean temperature recorded in the past week was 67°.1 at Blackheath, and the lowest 56°.3 at Glasgow. The mean for the English stations was 63°.7, and for the Scotch stations 58°. Thus it will be seen that the temperatures in the northern country were more or less unfavourable in all respects. Rain was recorded as having fallen at all stations on one or more days during the week, the greatest falls being 1.79 inch at Birmingham, and 1.13 inch at Greenock. The mean fall for England was 0.69 inch, and for Scotland 0.62 inch.

—— Out of evil comes good. The Siege of Paris has, amongst other things, demonstrated the value of Plantain (*Plantago lanceolata*, Spinach, and above the hardiness of Niphobolus Lingua and Choisya ternata, both of which are stated in the "Revue Horticole" to have sustained the frost of last winter uninjured. In the same journal many Cacti, as well as Agave mitræformis, A. micrantha, A. Salmiana, and A. Jacobiana, are mentioned as having supported a temperature many degrees below freezing point.

—— We are enabled to supplement the information we gave recently concerning the Alexandra Park, at Hornsey, with the following details furnished by the Secretary:—

"This building is situate on the highest part of the park, commanding on all sides extensive, varied, and beautiful views of the surrounding country. The building is erected partly from the material of the late Exhibition building at Kensington, designed to make it appropriate to its new situation and purposes. The general plan consists of a nave 900 feet long and 85 feet wide, a centre transept 430 feet long and the same width as the nave, and two shorter transepts, each 320 feet long, the same width also as the nave, and intersecting at a short distance from each end of the centre transept. The nave is of intersection of the nave and transepts; the centre has erected over it a great dome, which is 170 feet in diameter, and 220 high in the interior, appropriately panelled and decorated, light being admitted near the top, and by lunette windows at the sides. At the intersections of the shorter transepts with the nave there are pendent octagon copulas supported on slender columns, lighted by windows on their sides. The ends of the nave and three transepts are terminated with large circular or rose windows, decorated with stained glass. On each side of the nave and transept are erected buildings about 50 feet wide and two stories high; these have brick external walls, with arcaded openings and windows, and form extensive galleries next the nave and transept. The ground floor, on the south-east side, will be almost entirely devoted to refreshment and dining rooms, of various sizes and classes, opening by French windows to a verandah overlooking the terrace beyond; and in the basement beneath are such extensive and complete culinary arrangements, as may insure a first-rate and hot dinner for private parties, and general convenience and perfection in the refreshment department for large numbers. Other arrangements, such as news, reading, writing, and coffee-rooms, library, museum, picture galleries, sculpture, plants, and flowers, &c., are all considered, together with many things tending to the entertainment and comfort of the public; and an organ, one of the most powerful and complete in England, will form the centre of an orchestra for musical performances on a grand scale. The building will be thoroughly lighted by gas in an ornamental and brilliant manner, for evening promenades, &c., and will always be maintained at a genial and agreeable temperature. The interior is elegantly decorated throughout in coloured ornamentation, and will be filled with objects of beauty and interest arranged in spaces so as not to interfere with the grand avenues for promenade. Externally, the end of the nave and transepts present eight grand façades flanked by supporting turrets, containing the large windows and entrances. These façades are united by the walls of the lower buildings, two storeys in height, and by the clerestory walls and roof of the nave and transepts; and the whole is terminated by the ornamental towers at the angles. The general character of the architecture of the exterior is Italian, and consists principally of brickwork in colours, with stone dressings and ornamentations. Above the roofs in the centre of the building rises a bold tumbour, pierced with windows, from which springs a great dome, terminated at the top by a simple balustraded parapet, and a standard mast 90 feet high. This dome, and the octagon copolas at the smaller intersections, are decorated with moulded ribs and panelling in bold relief. On all sides of the building are formed handsome and spacious terraces, on which, and the ornamental arches opening them, are placed large and handsome trees, giving relief and effect to the building. The terrace on the north-west side, which will be 1000 feet long and 160 feet wide, supported by Italian arcades, will cover a noble railway station, from which access will be had directly to the building at the ends of the three transepts, and to which station all the railways of London will ultimately be brought. There will also be a spacious carriage entrance at the ends of the nave, communicating by an easy drive with the public roads. Adjoining the building, and commanded by the southern slope of the hill on which it stands, is the racecourse, with a grand stand replete with all conveniences. There are also cricket and archery, &c., grounds with their appropriate buildings and accommodations. The extensive park is laid out in agreeable carriage drives, walks and avenues, interspersed with flower gardens."

—— It would seem, from a paper read before the Institution of Engineers of Scotland, by Mr. William Clapperton, that there is now a fair chance of a sufficient supply of pulp for Paper Making being obtained at a remunerative rate from wood. Shavings of deal are repeatedly boiled under high pressure in water charged with a certain proportion of caustic soda. By these means the resin, oil, and turpentine, are removed, and the wood reduced to a condition suitable for the use of the paper-maker without any admixture. By this process, paper can, it appears, be more cheaply produced than with Esparto-grass, the price of which has greatly risen of late.

OVERCROPPING IN ORCHARD HOUSES.

The prevalence of red spider in this remarkable fruit season cannot be entirely attributed to the great climatal disturbances which are its chief feature. Whatever may be the causes otherwise, it is generally agreed that weakness of the trees exposes them to greater risks from insects and blight, and there is no surer means of producing this weakness than by excessive cropping. It is easy however to theorise, but our practice does not always correspond. This is the reason that I remind cultivators of the soundness of the maxim, that they will obtain far better, and also greater crops of fruit in the average of years, by considerably diminishing what has become to be considered a proper allowance for a tree to bear. For in seasons like the present these will have to undergo severe trials, which we should bear in mind at the thinning season next year.

These remarks apply chiefly to trees in orchard-houses, and of these we know that Peaches and Nectarines form the staple. But they are applicable to Peach trees on the open wall, and the observations of that sound and practical cultivator, Mr. Radclyffe, have always been read by me with pleasure, for he seems so thoroughly to know the habits of the Peach out-of-doors, and its wants in our climate. I myself of late years have removed a whole wall of Peach trees, partly because they were overcropped, and partly because we had such an abundance in the orchard-houses, and so much finer fruit. I have again, however, laid in a few on Dubreuil's first system, which I first began with, 16 years ago, and which were the first ever so tried in England; and I remember of this journal before any have seen them, I shall be happy to afford them, for the trees are doing remarkably well, and are very healthy and strong. They are diagonal cordons, with long shoots tied to the wires—the only long pruning I care for.

One of them is the Princess of Wales. I chose it because Mr. Radclyffe had frequently written to me about it. We have it in the houses, but this is no perfect guide for outdoor culture. But in such seasons as this extra care is required to produce really fine fruit. This year many think our crop of Peaches and Nectarines small in size, and so there would be, were it not for the former over-cropping, and now the attacks of red spider will reduce still further the vitality of the later trees, so that thinning during next season must be freely done.

It is also a pity to lower our standard of fine fruit for the sake of mere number and apparent display. No doubt the temptations to exhibit an enormous crop are great, and in certain cases it is even necessary. The evil can also be remedied by renewing or completely resting the trees. Amateurs, with vigorous young trees, are anxious to prove their skill, and realise some profit, and gardeners have too much expected from

them by ignorant employers. But, after all, the fact remains, that this is contrary to Nature's teaching and to the best experience, and, practised on a large scale, would bring serious loss with it. Study the health of the tree above all, and let it undergo no sudden shock to its constitution from any cause within our power to prevent. *Th. C. Brehaut, Richmond House, Guernsey.*

BOTANY FOR BEGINNERS.—XIII.

It has often been our lot to look through local herbaria and collections made by juvenile botanists, and to note the comparative rarity with which such common plants as the Daisy and Dandelion are collected and preserved. This arises, probably, from the frequency of their occurrence. What can be got at any time is very liable not to be procured at all. Another phenomenon of quite an opposite character, and which has very often struck us, is this, that the would-be botanist has a tendency to try his hand at first starting on Daisies and Dandelions, under the impression, perhaps, that they must be easy, because they are common. It is quite necessary to dissipate this notion, and to recommend the student to begin his dissections with flowers of simpler character and larger size, such as those mentioned in the earlier articles of this series. In truth, the so-called flower of these plants is really a mass of tiny flowers. A Sunflower, a Dahlia, an Aster, a Chrysanthemum, all of which are near allies of our humbler Daisies and Dandelions, in like manner do not bear single flowers, but a large number of minute flowers—florets as they are called—grouped into heads; hence, the term composite flowers; hence also the name Compositæ applied to the whole group, a group the most extensive, in point of numbers, of

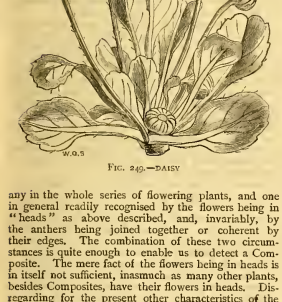

Fig. 249.—Daisy.

any in the whole series of flowering plants, and one in general readily recognised by the flowers being in "heads" as above described, and, invariably, by the anthers being joined together or coherent by their edges. The combination of these two circumstances is quite enough to enable us to detect a Composite. The mere fact of the flowers being in heads is in itself not sufficient, inasmuch as many other plants, besides Compositæ, have their flowers in heads. Disregarding for the present other characteristics of the Compositæ as a whole, let us indicate some of the structural peculiarities of the two plants before us. In the Daisy, as in the Dandelion, the true stem is excessively short. The consequence of this is that the leaves are closely packed, and spring, as it were, from the very top of the root, and lie flat on, or at no great distance from, the ground. The main distinction between the stem and the root consists in the power that the stem has of bearing leaves in some shape or another. A true root has no such power, and so when, a few lines previously, we described the leaves as springing from the top of the root, we committed a technical error. The so-called top of the root, or crown of the root as a gardener would call it, is really in this case a short subterranean stem, because the *internodes* are not developed. In the Houseleek, or in a bulb, the leaves are closely packed from the same cause,—the spaces between them are not developed. So in an ordinary flower, the sepals, petals, and stamens, are all in close approximation, because the *internodes* are not formed. Thrust forth from the axils of the leaves in the Daisy and Dandelion rise the flower-stalks, straight, undivided, usually leafless branches, bearing at the summit the head of flowers surrounded by a ring or rings of small closely-packed green leaves or bracts. This ring of bracts has very much of the appearance of a calyx, but a calyx belongs to a single flower; this ring of bracts encloses a large number of flowers, hence the necessity for the distinguishing term of *involucre*, which is applied to a ring of bracts encircling a number of flowers.

In the case of the Dandelion the involucre, as shown at E, fig. 253, consists of two or three rings of bracts, of which the outer are bent downwards, while the inner are erect. Pull off all the flowers within the involucre, or cut the flower through the centre from below

Fig. 250.—Section through Daisy flower, showing receptacle.

upwards, and the end of the flower-stalk will be seen expanded into a sugar-loaf-shaped mass in the Daisy (1, fig. 251), into a flat cushion in the Dandelion (fig. 253, F). This expanded portion is the *general receptacle*, from which all the florets spring. It bears the same relation to all the florets of the head that the *thalamus* does to each individual flower. Children have a very ready way of demonstrating the general receptacle of the

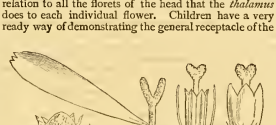

Fig. 251.—Separated florets of Daisy.

1, Receptacle and involucre; 2, Ray-floret; 3, Floret of disc; 4, Section of floret of disc, showing stamens.

Dandelion when they blow off the feathery seed-vessels to see, as they say, what o'clock it is (O, P, fig. 253).

Now we come to an important difference between the Daisy and the Dandelion. The florets of the former are of two different shapes and of two different colours—"daisies pied," as Shakspeare, and Milton after him, called them. At the circumference we have a ring of white florets, often "crimson tipped," as

Fig. 252.—Dandelion.

Burns describes, and in the centre a dense mass of yellow tubes. The white florets are those of the *ray*, the central yellow ones are the florets of the *disc*. In the case of the Dandelion (which, beautiful as it is, does not seem to have attracted the attention of the poets), the florets are all of one shape and colour, and hence there is in that plant no distinction into florets of the disc and of the ray respectively.

Picking off a ray-floret of a Daisy, the beginner will look in vain for a calyx. In truth, the calyx, distinct at a very early age, becomes fused with the ovary long before maturity, so that in the adult stage no trace of it, except in connection with the ovary, is visible. The calyx, though similarly adherent to the ovary in all Compositæ, generally presents more traces of its whereabouts than is the case in the Daisy, as will shortly be pointed out. The corolla is much more conspicuous; the "wee crimson-tipped" strap is the corolla, in fact, but a corolla of peculiar shape.

Let us describe the floret as it appears, and then attempt to explain the peculiarity. Starting from below, then, each of the florets (2, fig. 251) springs from a short tubular portion; suddenly there comes an alteration, the tubular form is exchanged for that of a flattened strap turned to one side, and at the tip of the strap are usually to be seen two or more shallow notches. These notches are all that are left to indicate five petals. In point of fact that now apparently simple strap is a compound of five petals united together, turned to one side, except at the very base, where they are in their ring-like order, and form the short tube. This is hard to see certainly, and may be hard to be believed, nevertheless the advanced pupil will have no difficulty in verifying the statement by a comparison with other Compositæ, in which the five petals are more clearly distinguishable. Even the Dandelion (fig. 252) may help to make this matter more apparent. The ray florets of the Daisy, then, are made up of five petals, absolutely free only at the extreme tips, imperfectly separate in the middle, where they form a flat strap, perfectly inseparate or connate below, where they form a tube; at the base of the strap-shaped floret thus constituted, is the ovary, of a single cavity with a single ovule in it, and surmounted by a style, apparently single, but really of two congenitally

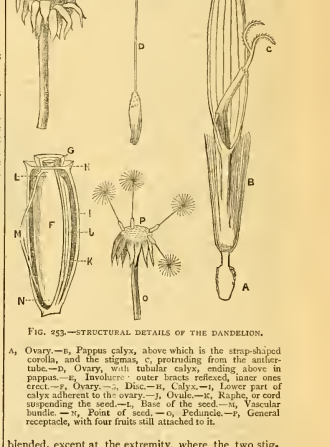

Fig. 253.—Structural details of the Dandelion.

A, Ovary.—B, Pappus calyx, above which is the strap-shaped corolla, and the stigmas, C, protruding from the anther-tube.—D, Ovary, with tubular calyx, ending above in pappus.—E, Involucre: outer bracts reflexed, inner ones erect.—F, Ovary.—G, Disc.—H, Calyx.—I, Lower part of calyx adherent to the ovary.—J, Ovule.—K, Raphe, or cord suspending the seed.—L, Base of the seed.—M, Vascular bundle.—N, Point of seed.—O, Peduncle.—P, General receptacle, with four fruits still attached to it.

blended, except at the extremity, where the two stigmatic ends reveal the constitution of the style. There are no stamens in these florets.

The florets of the disc (3, 4, fig. 251) are of a different nature. The calyx is the same as in the former case, but the corolla is here of a strictly regular tubular form, made up, as may easily be seen, of five petals, free at the tips, inseparate below. Slit up the tube with a needle or knife point, and the five stamens will be seen inseparate from the corolla below, the filaments also free, but their anthers cohering by their edges into a sheath or tube, surrounding the style, so that with a little care one may easily extract the style without disturbing the sheath formed by the stamens. This cohesion of the anthers is the characteristic mark of Compositæ.

The style is of the same conformation as in the ray-florets.

Turning now to the Dandelion (figs. 252, 253), we find all the florets are strap-shaped, and that all have both stamens and styles. Moreover, the calyx is more apparent than in the case of the Daisy, inasmuch as, instead of being wholly blended with the ovary, as in the Daisy, a portion is free and is easily recognisable, from its light, feathery-looking appearance (fig. 253, B). A feathery calyx of this description is called a *pappus*, and a very large number of Compositæ have this pappus calyx, which is only too familiar to gardeners in the form of Thistle-down or Groundsel. It generally increases in size as the seed vessel ripens,

perhaps in correspondence with the increased weight of the seed, which it serves to transport on the wings of the wind. The other points in the construction of the Dandelion have either been already mentioned, or are too similar to those of the Daisy to demand further notice in this place.

The two forms of the corolla are readily enough observable in many of our garden flowers—the Sunflower or Marigold, for instance, with their ray-florets and their florets of the disc; the Dahlia and Chrysanthemum, in which the florets of the disc have by the gardener's art been brought to resemble the florets of the ray. In Nature we have some Composites with strap-shaped florets only, as the Dandelion, Lettuce, Chicory, &c.; the plants of this group have usually a milky juice. There are other Compositæ which in the wild state have tubular florets only, like the Thistles; while a third group, including the Daisy, the wild Chrysanthemum, the Coreopsis, and a host of garden flowers, have both forms associated in the same head.

SCIENCE AND PRACTICE.

YOU deserve the thanks of all the craft horticultural for your vigorous leader on this subject, p. 901. I hope it may screw as a winnowing-fan to sweep off the huge mass of encumbering chaff that has gathered round it. Those who object to science among gardeners really don't mean what they say, or say what they don't mean; while those who refuse to concede to the ordinary run of clever horticulturists that they are scientific, are alike ignorant of the business of gardening and its practical professors. These misconceptions have arisen chiefly from those mistakes about names which are and always have been, so common. True, we are constantly queried, What's in a name? and the answer virtually is, nothing; and if we doubt this rendering, the hackneyed quotation is hurled at us with a defiant air of triumph which bears down all opposition, "A Rose by any other name would smell as sweet." Would it though? I don't believe a word of it. Only dub it Nettle, Dock, or Hemlock for a century or so, till all the sweetness, beauty, and fragrance that has reached our hearts on the back of Rosa is forgotten, and see if it would be as much prized then? Why every sharp thorn darts up defiantly from Queen Rosa's perfumed bed to protest against the loss of her charming name, and we hug it fondly to our heart of hearts as a sweet portion of the flower. Yes, there is very much, I had almost said everything, in names. The world is governed by names. Hearts and homes are lost and won by them. Men rule, deceive each other, nay more, play pranks upon themselves, through the cunning witchery of mere names.

"Give a dog a bad name and hang him" is as true of men and things as of dogs. The proverb has its better side; thus, "Give anything a good name, and idolise it." In fact, the saying about the Rose's name and the dog's character are but the obverse sides of the same medal, stamped at the mint of truth. Nothing escapes whole from the destructive power of names. Bad names are like swaddling-clothes fettering our mental limbs; good are intellectual baby-jumpers, raising us higher than we could reach without them. Even knowledge, though heaven-born, has not escaped from these subtle influences, or, rather, it has been forced to lie under the ban of names it ought else. Call common knowledge by the high name of science, and some fall down and worship it. The wildest fancies, the crudest speculations, the most baseless fabrics of impracticable dreams, have thus been deified by a name. The greater the idol or, at least, the more dense the mystery, and at times the more foggy and indistinct the muttering voices, the higher the respect, the deeper the veneration of many. There are those that respect science as the old lady did her clergyman—in the exact ratio of her inability to understand him; her veneration grew as his theology deepened, and reached a climax as she declared that nobody, she even doubted whether the Almighty, quite knew all he meant. With such, whatever is incomprehensible is esteemed as scientific, and prized accordingly.

Again, there are others who reckon science the art of classification, or description of natural laws or phenomena. For things, principles, forces, powers, realities, they give you names; and their science is a sort of nicely-arranged cabinet of the skeletons of names. Those are mostly saintly scientifics who take up science and wear its honours as they would any other accomplishment. All such, however, and many others that might be specified, speak well of science, whatever they may mean by it.

But a much larger class run a tilt against science, as a mad bull at a red rag. The very name excites them to anger and strife, more especially if the science is found among those in lowly station; they treat it as an enemy deserving of no quarter—a something to be gored, torn, rent, trampled under foot—a nuisance to be rid of at any price—a thing that no sensible man wants in his garden.

And yet this very science is the talisman of success in horticulture. Show me the amount of a man's science, and I will tell you the measure of his power. True, we hear much about thoroughly practical men—mere working gardeners, and the absurd inference is hurriedly drawn that he who has least science will do the most work. There never was a greater fallacy. The truth lies wholly on the opposite side of that proposition. We have no work apart from thought outside Bedlam, and, if we had, it would be worse than useless in our gardens. The value of every man's work is in proportion to the thought, that is to say, the science, he puts into it. And if this is true of other work, it is emphatically so in gardening, every process of which is a fresher, higher, better thought. And this law holds good of the hewer of our hands as of that of the brain; or, rather, the brain helps the hand to do even its most common operations,—and never was there such a helpmeet to the strong hand as the scheming mind. The two together constitute the finest scientific machine in the world.

Take a man from the plough-tail, and set him in a garden to dig; observe what a mess he makes of it, how irregular and uneven lies the ground. The man has strength, will—why then does he fail? He lacks the science of digging, that is, the knowledge how to dig; give him that and he does it well; and even far scientific than that. But is this not a better workman, worth more money, that is, does more and better work with science than without it? Undoubtedly, and it is so through all the operations of gardening. The more science, the better we can mow, sow, train, cultivate, plan, excuse (every working gardener will admit a no exception to the rule) is valuable in proportion to the science put into it. Why are the lawn-mowers, grass and corn reapers, so much stronger, cheaper, and more efficient workers than the scythe? Because they embody more and higher science. All machinery is the outcome of the sermon on the inexhaustible text—"Knowledge is power." Yes, and the more knowledge the more power, and with every additional increment of power there is a saving of time, a lessening of cost, and greater efficiency in the arts of planning, controlling, beautifying, producing. Strange inconsistency, that people who are glad enough to welcome science almost everywhere else should attempt to drive it forth from the Edens where it is of all places most useful. Everywhere else men have gladly sanctioned the nuptials between science and mechanical force, but when it comes to the growing work of the world has been taken off our hands. We are waited upon hand and foot by science. It fetches and carries, hews our wood, draws our water, does most of our heavy work, drives all our machinery. Everywhere it is chained by skill to the hand of labour, and who are these that would banish all this flaming sword in the girt of prejudice and the worn-out leather of obsolete ignorance, to set it up, to warn science out of our earthly Edens? It cannot be. We have tasted of this tree of life, and hunger to eat more of it. The more we eat, the more beautiful the gardens will become. For science is strength and beauty, while the want of it is weakness and worthlessness to gardens. A want of science is the loss of force; it is working in the dark instead of the light. Ignorance is a blind Sampson—strong, indeed, but only strong to ruin, mar, destroy. It is a game of chance, a medley of haphazard. As proof in point, what could be more apposite than the doings of your correspondent? Blind as a mole, because without science, he gropes along, trying to hybridise Heartsease with Calceolarias, Pansies with common Brakes, Hemlock and Geranium, Borage and Pelargonium, and then reveals his yet grosser darkness by telling you how he had succeeded! Here, however, his caution seems to have got the better of him, and, a vision of an editorial request looming in the future, to send up samples of these little wonders appearing to him, he conveniently shuts down the coal-hole. Did not this long, indeed! Was there ever a stronger proof (and thousands of a similar sort are happening daily) that ignorance is ever weakness—utter uselessness, if not worse? A very little science would have turned all this energy into useful channels; for the want of it, all was lost.

And yet we have employers deprecating science, and great societies ignoring its existence among practical men, though every step in horticulture is right or wrong as science guides, or does not guide it. Talk of dividing science and practice: the thing is impossible. Science is practice, and best practice is saturated with science—the only science worth the name rests on a practical basis. How, then, are these prejudices to be removed? Well I agree with you, that it may be wise for one thing to change the name if we can save the knowledge intact by the sacrifice of this little bone. Did not Davy long, indeed! say there ought to be a better name for chemistry? Was there ever a stronger proof (and thousands of a similar sort are happening daily) that ignorance is ever weakness—utter uselessness, if not worse? A very little science would have turned all this energy into useful channels; for the want of it, all was lost.

And yet we have employers deprecating science, and great societies ignoring its existence among practical men, though every step in horticulture is right or wrong as science guides, or does not guide it. Talk of dividing science and practice: the thing is impossible. Science is practice, and best practice is saturated with science—the only science worth the name rests on a practical basis. How, then, are these prejudices to be removed? Well I agree with you, that it may be wise for one thing to change the name if we can save the knowledge intact by the sacrifice of this little bone. Did not Davy long ago, according to Walker, may surprise me a few—"Knowledge: certainty grounded on demonstration; art attained by precepts, and built on principles; and generally any art or species of knowledge." Why, these read like the veritable qualifications of a modern gardener, and unless there be those who prefer darkness to light, weakness to strength, uselessness to efficiency, surely all else will say, the more of such qualifications among gardeners the better. But let us lay aside the name of science, and follow after knowledge; and with the name it is to be hoped the prejudice against science will cease, and that the more a man knows, and the better use he makes of his knowledge, the higher he may reasonably expect to climb in his profession, and the more ought he to be respected. Knowledge is the highest power in horticulture, and as such it is worthy of more direct recognition and encouragement than it has mostly received from our official bodies. Possibly orders of merit or fellowships sparingly and wisely awarded would work well. At present, when circumstances and tastes are favourable, a man puts his knowledge into prize fruits, plants, flowers, or vegetables, and is rewarded. Others put theirs into a landscape flower garden, a well ordered garden, a fully, richly supplied home table, a book, an essay, the press; and the societies entirely ignore all the latter class, which are by far the more numerous and equally talented and deserving. Without taking anything from our present prize-takers, might it not be possible to distribute at least some honours and rewards among these outsiders? Doubtless knowledge is its own reward, but, like the bread and butter our London friends set before their country cousins, such rewards will bear doubling a good many times. *D. T. Fish, F.R.H.S.*

DIGGINGS FROM OLD MINES.

THE EFFECTS OF THE SCION UPON THE STOCK, AND VICE VERSÂ.

A GOOD deal has been made of some recent instances of the Abutilon Thompsoni infecting with its variegation the common Abutilon striatum, and I have lately seen some curious cases of a modification of the character of black Grapes, alike in flavour, size, and colour, by being grafted on the White Syrian and White Nice; notably, that recent introduction, Mrs. Pince, had its bunches and berries both grown out of normal character, and its flavour spoilt by being so treated. Other cases, such as the Purple Laburnum, are familiar to most cultivators. Among back-to-back times the most instances cited from experiments made by Mr. Fairchild, as to his budding or inoculating of a Passion-flower, whose leaves are spotted with yellow, into one of that sort of Passion-flower whose leaves are plain, and though the buds did not take, yet after it had been budded a fortnight the yellow spots began to show themselves about 3 feet above the inoculation, and in a little time after that the yellow spots appeared on a shoot, which came out of the ground from another part of the plant. The same thing happened to the variegated variety of the common white Jasmine. Mr. Fairchild likewise grafted the evergreen Oak, or Ilex, on the common Oak. The leaves of the common Oak fell at the usual time, but those of the evergreen held its leaves and continued green as usual; thus proving that the scion had the power of attracting a sufficiency of sap through the deciduous stock at an unfavourable time.

The same gentleman exhibited many other experiments before the Royal Society, as the New England Cedar, or rather Juniper, grafted on the Virginian, and a branch left several inches below the grafting continued growing as well as the upper part above the grafting. A Cedar of Lebanon was also grafted on the Larch, and continued to grow and retain its leaves all the winter, equally good and healthy, above and below the graft.

Another point demonstrated by Mr. Fairchild was, that the scion supported the stock, the branch the root, as much so as the stock the scion, or the root the branch, and that, in a word, the sap flowed in any direction where it was needed.

To establish this fact the following experiments were made just 150 years ago, in March 1721-2:—This experiment was, that a Pear branch was inarched upon two Pear stocks, leaving the roots out of the ground, and was in a good flourishing state with a branch in blossom, that received no other nourishment but by the juices that returned down the other two branches, which, though it had been done two years, yet it continued sending suckers out of the roots, which is esteemed as a proof that the branches are as useful to support the roots as the roots the branches; and hence we infer that it is not strange that so many trees miscarry in planting, when there are no branches left to the head to maintain the circulation to the roots. This sensible observation is not yet universally acted upon, and the severe cutting-in of newly planted trees is still a fruitful source of failure.

The Rev. Dr. Hales, who differs entirely from Mr. Fairchild about the circulation of the sap, yet accepts the fact of the gilding of the inoculated buds of the Passion-flower and the Jasmine, and thus accounts for it: It is easy to conceive how some of the particles of the gilded bud in the inoculated Jasmine may be absorbed by it, and thereby communicate their gilding miasma (for from a flattering description of our variegation manual to the sap of the other branches, especially when, some months after the inoculation, the stock of the inoculated Jasmine is cut off a little above the bud, whereby the stock, which was the counteracting part of the stem, being taken away, the stem attracts more vigorously from the bud.

The fact of the grafts infecting the stocks of fruit trees with canker is explained in the same manner. Lastly, the argument is very cleverly carried against those who contend for a compound circulation of the sap in plants analogous to that found in animals by the pertinent query addressed to the stock of the deciduous Oak, why the evergreen scion does not enable it to keep green also throughout the winter? In the *Gardeners' Chronicle*, a few months

since, there was an inquiry to the effect whether the Larch might not be considered a kind of deciduous Cedar. It might be worth trying to graft the Deodar upon it, and to see whether by such means it might become evergreen. Several of these old experiments seem worth repeating and carrying further. In this matter we are hardly wiser than our fathers; doubtless had the beauty and usefulness of these varie-gations been seen or appreciated 150 years ago, instead of being stigmatised as gilded mania, we should have had our fine-fohage era a century earlier. As it is, possibly we owe some of our best so-called sports of to-day to the experimental graftings, buddings, inocu-lations, and mixing of sap by our forefathers 150 or 200 years ago. *Antiquator.*

FLAVOUR IN FRUIT.

My attention was called to an article at p. 1040 under the above heading, which, with your per-mission, requires a little explanation from me. In a short review you were kind enough to write in a pre-vious number of your paper, on my third edition of "The New Method of Growing Fruit, Flowers, &c.," you doubted whether it was the radiation at night which enhanced the flavour of the fruit, attributing it rather to the free exposure of the trees to the night air; in which view your correspondent in the above article concurred. I am glad not only to receive information, but correction also, at the hands of my brother gardeners. In the present case it must, I think, be from not having expressed my views clearly that a misunderstanding of them has arisen. I quite agree with yourselves and your correspondent that it is the amount of cold which the plant attains by free expos-ure to the night air which causes the change of circu-lation (if I may so express myself), which is so bene-ficial to the general health of the plant. The position I wished to establish, and which is indeed beyond controversy, is, that no amount of ventilation given at its sides would allow the plant to become so cold by several degrees, as being quite clear overhead, and having no intervening body be-tween it and free space perpendi-cularly. In short, the ventila-tion given by the side lights of a house, beneficial though it is to the plants in its immediate proxi-mity, will not produce the same result as free exposure to the night air (as you rightly add), "judici-ously managed."

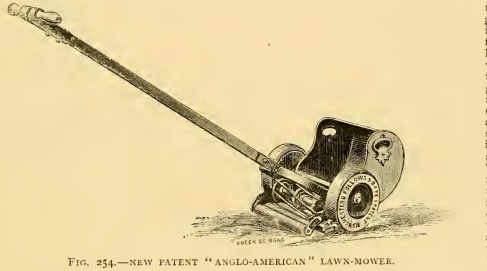

FIG. 254.—NEW PATENT "ANGLO-AMERICAN" LAWN-MOWER.

The old and well-known theory of M. Prevost, of Geneva, in which he was followed by Dr. Wells, in his celebrated treatise on dew, was taken by me to illustrate the position. He attri-butes this extra cold to a latent power in the plant to radiate its heat into free space perpendicu-larly, but not laterally, till it becomes actually colder than the atmosphere, and thus a deposit of dew takes place, where such radiation is not interfered with, while it does not take place where the free air is only admitted at the sides. It is to this extra amount of dew-producing cold, so pernicious in the spring, and so valuable in the summer, that I attribute the excellence of the flavour of fruit submitted with judgment to its influence. I am aware, and have stated in my printed, that different views are taken of the cause of this extra cold, but I purposely avoided enter-ing at large into the scientific question, the result being all that was required for my purpose. Indeed, in all matters connected with the organisation of plants, and the different influences and processes which produce their growth, ripening, and decay, great care and circumspection are required before hazarding an opinion. The results we may give fearlessly, but the causes, whether tested by induction, or even chemical analysis, are so delicately strung together as to tax to the utmost the judgment of our scientific men. *John Fountaine, Southacre Rectory, Brandon.*

"ANGLO-AMERICAN" LAWN MOWER.

A NUMBER of lawn-mowers of different sizes of this pattern were exhibited at Chiswick on Tuesday last, and gained the approbation of the several committees and of the exhibitors there present. The revolving cutter consists of six knives, placed diagonally, as usual. There are two driving wheels, and a collecting box in front of the knives, which may be removed at pleasure, in which case the grass is scattered. Behind the knives is a small wooden roller. The handle is in a direct line with the axles of the driving-wheels, a circumstance which adds greatly to the easy working of the machine; which, from what we saw of it in operation, we are disposed to think very highly of. The sketch we give with this (fig. 254) will show the nature of the machine better than words could describe it. We incline to the opinion that it is much superior to the Archimedean, but we have had no oppor-tunity of testing its merits on slopes or on uneven ground.

Home Correspondence.

Condition of the Fruit Crops in Scotland.—In looking over your report on the condition of the fruit crops in Scotland this season, I find no returns from Caithness-shire, Sutherlandshire, Ross-shire, and In-verness-shire, and, as I have travelled through these counties lately, and been in almost every gentleman's place of note in them, I send you the following notes:—Caithness: Apples, abundant; Pears, fair crop; Plums, fair crop; Strawberries, abundant; Cherries, fair crop; Raspberries, Gooseberries, and Currants, abundant. Sutherland: Apples, Apricots, and Pears, average; Plums, poor; small fruits, abun-dant; Cherries, average. Ross: Apples, Pears, and Apricots, average; Plums, moderate; Strawberries most abundant, and other small fruits, average. Inverness: Apples, half a crop; Apricots, average; Cherries, good; Plums average; Strawberries, average; small fruits, good. *John Downie, South Frederick Street, Edinburgh.*

Gloxinias and Achimenes Flowering in Autumn.—It may not be generally known among those who possess a little greenhouse, and a frame or two only, that these pretty things may be had in flower by them through August and September. With only ordinary attention given to them, I have seen fine plants—indeed, I have some now—that have been brought on by no other means, and which are cleaner, more healthy, and quite as full of flower as those which are found in hothouses. In the beginning of May place the bulbs into well drained pots—size accord-ing to the size of the bulb—which have previously been a little more than two-thirds filled with equal parts of burned earth, wood-ashes, and good loam—if the last is not available, good garden soil. In covering allow a little room for water, but do not water them immediately, say not for a week, if the soil is at all damp, and even after that, very sparingly until the leaves begin to appear. If this is not attended to the bulbs will in all probability rot. Calculate to have a hotbed made a fortnight previous, in which Cucumbers may be sown; place the pots into this frame, they will there soon push on: care must be taken against too much moisture. A little air given at the back every night, just sufficient to let the steam escape, is neces-sary. Before the Cucumbers over-run them, place the pots into another warm frame—one prepared, it may be, for Melons; before they get in the way there they may be placed in the greenhouse, where they will go on and flower, and well repay the trouble taken. Care must be taken that the bulbs are well dried off in the autumn. Afterwards put each sort into a little bag, with its name if desired, and place them into a warm cupboard, where they can remain quite dry through the winter and early spring. *H. M.*

Varieties of Pelargoniums.—In answer to your correspondent "R. F.," it would not do for nursery-men to erase too hastily old favourites among bedding Pelargoniums. There are no doubt in many lists far too many sorts, but the chief fault lies in recommend-ing new sorts as superior to the old ones without sufficient trial. Some raisers of Pelargoniums think their own seedlings superior to those of others, and they send out a new batch every year, both for the sake of profit, and to keep their names before the public, inde-pendently of their merits. There are others, again, who devote great care and attention to the subject, and who never send a seedling out till they have fully proved it, and are convinced of its superior merit. There are, of course, a great many nurserymen who are not raisers, but who merely propagate those sent out by others; they are obliged to take these seedlings on the credit of the raiser's reputation, or on the recom-mendation of those who have seen them flowering. It takes, however, at least three seasons to fully try the merits of new Pelargoniums, although where there are already so many good ones it is easy to discard some at the end of the first season. It would, however, be a great step to improvement if nurserymen had to entail their number of varieties to 70, as "R. F." suggests. I have on trial this year above 100 sorts of the flower-ing section of bedding Pelargoniums (that is to say, not including Tricolors, Bronzes, or variegated sorts). I have 54 varieties of these in separate beds, and yet out of these I shall only discard this year some eight or ten, among them Cybister, Glorious, Roi d'Italie, Vesuvius, Glow, Masterpiece, Kentish Fire, W. Under-wood, Duchess. Some of these, as Glorious and Roi d'Italie, I should have discarded before, but have heard them so highly praised by others that I have extended their trial, thinking their merits would eventually be brought out. Some persons will be surprised at my discarding Vesuvius, but I have two others much better of the same shade of colour, and the flower trusses are not sufficiently large to make it attractive. One of the great faults of the system of bedding-out, is that too many go in for mere masses of colour, and do not make their gardens interesting by having sufficient variety. If, for instance, a long border is divided out into panels, and the dif-ferent divisions of the panels are mere repetitions of one another—as soon as you have seen one part you have seen the whole; you may admire the general effect, but the details will be uninteresting. If, however, no two beds of Pelargoniums are alike, the effect of the whole is much softened, and increased interest gained by comparing one sort with another. The best beds I have this year are Violet Hill, Grand Duke, Duke of Devonshire, Bayard, Vesta, Waltham Seedling, Maid of Kent, Lady Kirkland. Duchess of Sutherland is, as your correspondent observes, in some respects better than Lord Palmerston; but again, Lady Kirkland is better than Duchess of Sutherland; but they all three have faults. Dr. Lindley has long ago been discarded by me; both Lord Derby, Clipper, and Rival are better; so is Marie Sisley. But a new one of Pearson's, Corsair, is likely to be the best of all this type. Violet Hill is my model of what a bedding Pelar-gonium ought to be—free bloom-ing, short jointed, short stiff flower-stalk, large truss, dwarf habit; but it requires high cul-tivation, and the beds may be manured thoroughly, as it never grows coarse. I am sorry to say, however, that there is a duplicate Violet Hill in the trade, a very inferior flower with a straggling habit. I have seen it in two nurserymen's collections, and sent to them as the true sort. The reason why Violet Hill is not more known and grown is, that it is difficult to get a stock of it, and nurserymen do not like it on that account. I have never thrown a plant away, and give away all I can spare. Some of the plants I am now bedding for the fourth season are still not more than 6 inches high, and it will never do any good with those who starve and maltreat their plants during winter. *C. P. Peach.*

Orchid Cultivation.—After a long silence, your correspondent, "G. H.," again comes forward in defence of his favourite theory, and, as usual, supports his views by extracts from a work upon tropical climates. Now, I think it is worthy of notice that "G. H." has brought forward no examples of his own cultivation since January (see p. 76); and further, that the spike of Odontoglossum Alexandræ there alluded is the only specimen of the cool Orchids that he has brought forward at any time this year. Now, when we consider the very prominent position occupied by "G. H." in this discussion, it does appear somewhat remarkable that there should be such an utter absence of home-grown examples, your correspondent appearing to rely almost exclusively upon the Travellers' Library. Far be it from me to undervalue the information to be derived from such a source, but I may say that if "G. H." wishes to convince the Orchid-growers of the present day that cool treatment is a mistake, he must bring forward home-grown examples of his own system—or, as he puts it, arguments require examples to the point to convince. Many examples of cool treatment have been given in these pages at different times by various writers, thus confirming the theory by their practice, and "G. H." will do well to follow their example. We can appreciate good plants, and honour the man that will show us how to grow them better than we do at present, but we do not appreciate all book and no plants. *Ex-Canada.*

Table Decorations at Flower Shows.—Few can have failed to observe how deficient in taste and judgment have been many of the displays of dinner-table decorations lately seen at the London flower shows. Much of this has been, in my opinion, attri-butable to a want of understanding between the exhi-bitors and the prize givers. It is, therefore, with much pleasure that I learn from the honorary secretary of the Metropolitan Society for the Encouragement of Florists' Flowers, that at their next exhibition, to be held at the

Crystal Palace on the 30th inst., the competitors will be given to understand that no decorations will be allowed round the margin of the tables for a distance of 15 inches from the edge, and that the tables will all be of one size, 8 feet by 4 feet. This is a move in the right direction, tending to put all exhibitors to a great extent upon an equality. We shall now see what are the views of the various decorators, both amateur and professional, upon the quantity and variety which looks best upon a table of a definite size. *W. T.*

—— At p. 1042 your correspondent mentions cursorily the professional class, and complains that there was not room left upon the tables for glasses, plates, &c., the tables being crowded to groaning. Had he read the schedule, he would not have fallen into this error. The Palace Company, in their schedule, wisely invited tables of 9 feet, to be furnished florally only. From this arrangement designs were expected which, collectively, would be suitable for a very large party and which would also be available for a very small one. From the design to which the first prize in the professional class was awarded, a table was shown florally decorated for a company of at least 100 persons, and which could be so reduced as to accommodate companies down to a couple of persons. Again, he alludes to wet stands; but here, too, the error was not made in the decorations which, professionally, were placed first. Now your correspondent should be more scrupulous how he reports upon matters which require a careful and refined taste. There were, upon this occasion, the bulk of the exhibitors contesting, including the names of Buster, Chard, &c., exhibitors whose taste has been extolled from time to time in your pages, besides very many others who, exhibition after exhibition, have distinguished themselves; and, altogether, there never was before such a display as was rendered upon this occasion. Mr. Standish, likewise, has gone far beyond reasonable bounds, when replying to the invitation of "D., Deal." There is nothing new—indeed, much very old—in the idea of decorations upon the cloth; and I can fairly and practically negative the statement of Mr. Standish that this fashion has been discommoded this season. I can affirm that very few of the rank and fashion of Belgravia will allow upon their tables anything so devoid of grace and beauty as the arrangement propounded by him. What we should all aim at is to inform, not mislead, those who are unable to attend these great rivalries, and to judge for themselves; and I will leave the readers of these pages to judge for themselves whether the remarks of Mr. Standish are likely to bring about less absurd arrangements than were to be seen in any design to which he refers. *Ransley Tanton, F.R.H.S., The Nurseries, Epsom.*

The Potato Disease.—I bend low in the presence of Mr. Fenn, and I am ready to subscribe for a gold medal in bas-relief, emblazoned with his best "taters," to be presented by the marshalled hosts of Potato-eaters throughout the three kingdoms, and to be worn by him as a badge of honour for evermore. No man is more worthy of such honour. He speaks and writes with an authority on these matters that other scribes cannot pretend to. Still, I cannot but think that I had left upon him the impression that he was taking us in and doing for us, and enjoying the fun of our discomfiture. He fills our eyes with the dust of zoospores, takes our breath away with showers of white rain, hurries us with his Potatos on to high and dry ridges; and then, when Nature is nervous, and sweetens and sets to, he finishes readers and "taters" off together, by making both the special victims of a series of shattering shocks from fully-charged electric batteries, that take one and leave another in the most inscrutable manner of which prudence is meant to teach us that the Potato disease is an inscrutable mystery, in other words, is caused by electricity. But Mr. Fenn, as is his wont, gives us practical lore with these transcendental theories. He tells us how to scotch this terrible snake, the Potato disease, by growing the Potatos on ridges, high and dry, with plenty of space between. The plan is a good one, only it will not cure the rot. Some years ago I had the same recipe from Belvoir. I brought it, and the very sorts, specially Paterson's Victoria, which had proved disease-proof there, home with me to Hardwicke. The ridges were duly made, plied well with earth, and planted quicklime, and the result was such wholesale disease that I lost the varieties so grown altogether. I agree with Mr. Fenn about the time that the disease attacks the Potato. There is a certain time of the year, and a certain stage in the growth of the Potato, which may be truly defined as the time of disease. But why skin-setting time? Mr. Fenn answers, "because then Nature is most put to it." And he proceeds to compare this skin-setting to the full swelling time of vegetables, and the stoning time of fruits. I fail to discover any analogy between the processes. On the contrary, the skin may be held to set because growth has ceased, while the stoning of fruit makes large demands on the vital energies of plants, and is followed by a second and rapid enlargement. I cannot see how, upon any comprehensible theory of over-exhaustion, the Potato should become a special victim of disease at that particular period of growth. Finally, I conclude that the electrical hypothesis is a guess at truth, and nothing more. Does not, indeed, the immunity of Mr. Fenn's seedlings under glass disprove the agency of electricity; or is it seriously contended that the passage of electric currents through glass would rob them of their disease-originating force? Or, is the electricity powerless unless associated with the white rain, which forms the tail of effete thunder and lightning, whatever the latter may be? Perhaps those seedlings, yet so green and promising, have not yet reached the skin-setting, that is the disease-hitting, stage. No one who knows Mr. Fenn's intensely practical devotion to his favourite tuber, will begrudge him this outing on the high bracing Alps of speculation. When he returns to the sound level of his most successful practice, I would respectfully call his attention to the views propounded in your leader of last week. As the raiser of many new and good Potatos, I know no one so fit to work out the great problem of providing us with strains that will ripen so early and keep so late that they may be safely harvested before the disease comes. It seems as if this were the only possible mode of saving the noble tuber from plague and pestilence and sudden death—that is, the disease. Mr. Fenn will, I am sure, forgive the freedom of these criticisms. I challenge him to pay them back with interest, full measure, pressed down and running over, and I thank him by anticipation for his hearty response. I took his advice, put my shoulder to the wheel, and this is what has come of it. And as to science, it has done nothing for us yet, in the way of cure, in this matter of the Potato disease—I wish it had; but I have more faith in Mr. Fenn to help us than in this vague Deus ex Machina than all the philosophers, and I trust he will inform us what he thinks of the early harvesting and late keeping remedy in your next. *D. T. Fish, F.R.H.S.*

Scale on Vines and Lemon Trees.—Will some of your correspondents say what is the most effectual way of getting rid of scale on Vines and Lemon trees? I have had every leaf of my Lemon tree washed above and underneath with strong solution of Gishurst Compound, carelin oil, and carbolic acid, and powdered with tobacco, while the scale leaves are now full of scale in a couple of days. The above liquids were left on the leaves. The carbolic acid destroyed the scale and leaf too. *R. B.*

The Effects of Frost on Vegetation.—The hypothesis of Messrs. Prilliieux and Mer, as set forth rather prominently in your article (p. 1064), may possibly be true; but it makes too great a demand upon our faith, until the reasons are given for assuming that the vital power of *Spirogyra* by which plants are killed by undue exposure to cold is "their loss of water, and the consequent drying of their tissues." [Rather the passage of the water out of the cells into the spaces between the cells, the latter becoming desiccated.] So far as we understand the article referred to, the theory of the desiccation of the plant seems to be the cornerstone of the hypothesis. But is there any reason to believe that a tender plant exposed to extreme cold, in an atmosphere saturated with moisture, will be desiccated, or that it will not be killed? Again, we ask, what is Mer's theory? Is not the plant, certain trees were injured by frost in the night, but that in certain other trees on the same occasion "the water which had been squeezed out by the cold was afterwards re-absorbed, and no injury took place." What proof is there that water was "squeezed out" or "re-absorbed," and that the water was not a mere deposit of dew, which disappeared before the rays of the sun? If the blood of an animal were once "squeezed out" by cold, it would be a hardy assertion to say that it could ever be re-absorbed, and restored to circulation so as to do no more injury than that which the extravasated sap, or blood of plants, could ever be re-absorbed, and restored to its proper and innumerable cells. The action of cold upon life is a very complicated and obscure subject, but there seems little reason to believe that it has anything to do with mechanical contraction. It is true that the loss of water and of heat have only a limited application to the facts of vegetable life," but they afford a very complete and reliable explanation of all the phenomena in which heat or cold is concerned. *A Meteorologist.*

Melons.—Is it the fact that to grow Vegetable Marrows in the vicinity of a Melon bed is destructive to the quality of the latter fruit, through the agency of the bees conveying the pollen of one to the other, or any other cause? Also, in seasons favourable to Melons have had little better flavour than Turnips, or at best Marrows, and, as my gardener selected the seed from first-rate sorts and different places, I can only account for the failure in the way above suggested. Am I right? and, if so, how is the matter to be remedied in future? At what distance can it be safe to grow both Melons and Marrows? *S. P.* [We should hardly expect foreign pollen to alter the character of the fruit, but rather that of the seedling plant, though it has been stated that in certain cases the fruit has been affected. Eds.]

Gladioli.—It is gratifying that your correspondent "Glaieul," in your issue of August 12, endorsed much that I said relative to the Gladiolus, but as he has made a remark of an unfair character relative to the Messrs. Kelway, and has also said something not very complimentary about M. Souchet, I am induced to trouble you with a few lines by way of rejoinder. "Glaieul's" opinions are not supported by facts when he speaks disparagingly of the Messrs. Kelway's seedlings, and, in common fairness to these eminent growers, the following statement should be published:—Refering to the report of the Floral Committee of the Royal Horticultural Society (the highest recognised authority) of August, 1868, I find that three First-class Certificates were awarded to the Messrs. Kelway for seedling Gladioli, one of which was considered so superior by the editor of the "Floral Magazine" that he figured the flower in the number for October, 1868, and thus describes it: "Julia, the flower figured in our plate, is a large, well-shaped flower, very much in the style of that fine flower, of M. Souchet's, Madame Furtade, and shows that Mr. Kelway is not only a successful grower, but that he has obtained a good strain of seedlings." At the Royal Horticultural Society, in August, 1869, the same English raisers were awarded two First-class Certificates for seedlings, "One of which," says the *Gardeners' Chronicle* "is the boldest and finest shaped flower of its race." During the present month the Messrs. Kelway have received no less than eight First-class Certificates from the Royal Horticultural Society; and the general impression at the last exhibition of the Society was, that the other seedlings were of an ordinary character, and that they would certainly compare favourably with the Continental varieties. Any one knowing the character of our English growers, is aware of the scrupulous care they exercise before pronouncing a seedling worthy to be placed in their list. Madame Furtade, and alluring descriptions of new sorts, as put forth in some of the Continental catalogues, have led to much disappointment in the growing of such sorts, and I need only appeal to both amateur and professional growers to receive confirmation of the statement. I observed that 33 varieties were staged by M. Souchet in 1869, not more than six were exhibited at the Kensington show of August 16. With regard to "Glaieul's" remark that M. Souchet could not compete last year at Kensington because he was in too weak a state of health, I can hardly understand its meaning, as he is being of an unusually sanguine character. That M. Souchet's cultivation went on pretty much as usual I have proof in the fact that the catalogues are made up with his seedlings much as usual; and surely his establishment is not so inefficient but that some one could be found to whom to entrust a few grains to England. *F. W., Croydon.*

—— Your correspondent's remarks on Gladioli (p. 1041) tend to convey the impression that no good seedlings have issued from our establishment. If he will refer to the awards of the Floral Committee of the Royal Horticultural Society, South Kensington, reported in the *Gardeners' Chronicle*, he will find that 14 First-class Certificates have been awarded on the following dates, viz., August 18, 1868; August 17, 1869; August 2 and 16, 1871; and in addition upwards of 30 more at other exhibitions, including four at the Crystal Palace. *James Kelway, The Nurseries, Langport, Somerset.*

A Fruitful Cool Peach-house.—*Apropos* of the scanty crops of Peaches and Nectarines out-of-doors this season, it may be instructive to know what can be done under glass. Outside, skeleton trees, with bare arms, or covered with stunted fruit—the deep scars left by one of the most inclement seasons ever known; inside, in many cases, one of the richest harvests of choice fruits that has been gathered in small houses. What has recently been adverted to in your columns, as seen at Kingston Hall. I saw another and a fuller one to-day at Bury St. Edmund's, in the garden of Chas. Beard, Esq. To this gentleman's love of horticulture we are indebted for his patent mode of glazing, and his glass was the first I have ever seen. Geophobus was anxious to test his theories by the touchstone of experience before offering them to the public. With this object he erected several houses, of various shapes and sizes, for different purposes in his own garden. Some were devoted to fruit, others to plant-growing. All these early houses were, I believe, made to galvanised iron. In one of these original structures, erected nine or ten years ago, and which has not cost a crown for repairs or paint since, is now to be seen one of the finest crops of stone fruit that it is possible to find anywhere. The house is not large, but it is unusual wide, 20 feet high at back, and has a front elevation of 2 feet, wholly of glass. It is 12 feet wide, and 40 long. Trees are trained on a portion of the back wall, for several of them have not reached the top, and on a trellis within 15 or 18 inches of the glass roof. Some of these trees are now in small pots, but the good portion of the upper part of the trellis is not clothed at all. Probably it is not too much to affirm that one-sixth of the entire area of the roof and wall are uncovered. Notwithstanding this curtailment of fruit-bearing space, the quantity of fruit now ripening in this modest-looking house, which could be erected of virtually indestructible materials for something like £60, is astounding. On the roof trellises 38½ dozen Peaches, 27¼ dozen Nectarines, and on one Hamburgh Vine 50 bunches of Grapes; on the back wall, &c., 45 dozen Apricots, Plums, &c., several of which have been gathered. Independent of the Grapes, over 100 dozen of stone fruit from a cool Peach-house, that is secured from all the ills of such a winter and spring as the past by the aid

of these roofs alone, speaks volumes for their efficiency. Neither are these small or indifferent fruits; on the contrary, the majority are of fair size and marvellously rich in colouring. Nectarines are glowing with scarlet, almost all round alike, and the Peaches are painted with the most exquisite tints. [We can confirm this. EDS.] Even Galande and Noblesse Peaches are suffused with softest pinky feathering, on a rich creamy ground, which evidences to the very highest lusciousness of flavour. The entire house and the trees are flooded with light, and the result is seen in the unusual vividness of colouring, and tasted in the quality of the fruit. What surprised me most, however, was to learn that this house had had no heat, none whatever during the late most severe winter and trying spring, and yet how often we hear that these metallic houses are colder than others. I have already pointed out, in your columns, that Beard's patent rafter is probably as warm, or warmer, than a wooden one of equal, or stronger scantling. The conductive power of the metal is cut short in the middle, or rather close to the outside, by the intervention of one thickness of glass and two of stout felt between the T rafter and the upper covering bar; this arrests conduction, and effectually baulks the egress of heat from, or the ingress of cold to the house. It is impossible, therefore, that the metallic rafter can facilitate the loss of heat, as the glass used is stout, 26 oz. to the foot, these houses are warm as the majority of wooden ones. Such was my opinion from the beginning, and certainly a fruit crop such as now fills this house, grown without aid from artificial warmth in such a winter and spring as the past, completely confirms it. These metallic houses are not exceptionally cold; the glass is warm as any other glass of equal thickness, and neither heat nor cold can pass directly through the metallic rafters by conduction. Certainly it is most satisfactory to find that this splendid crop was produced without any artificial heat. I ought to add that Mr. Beard, who is a keen gardener as well as a skilful mechanician, and an ardent experimental philosopher, has a theory about his success. He is a great advocate for skilful ventilation; and ought to be skilful, for he has turned his attention to mechanical contrivances for placing it under immediate and facile control. His principle is to ventilate at the lowest and the highest points—the ground line and the apex—but never, unless during fine genial summer weather, to open the two sets of ventilators together. It matters not, he thinks, than is generally supposed which ventilator is opened; but till the end of May in cool fruit-houses, never open both at the same time. Draughts are ruin to fruit trees in bloom, or the tender leaves of stone fruits in the early spring. Thus ungenial spring weather don't trouble much about air at all. Should the sun run up the temperature a good many degrees it matters little. If forced by bright weather to admit air, give but little, and beware of the wind rushing in or down upon your trees. There is probably a good deal more in this than might appear at first sight. This much is at least certain, Mr. Beard has achieved a great success, and as a faithful chronicler I could hardly do less than reveal, for the thoughtful consideration of your readers, the chief causes of that success, as they appear to him. I am authorised to add, in conclusion, that the house may be seen by any respectable persons interested in horticulture. But those who intend to visit this rich little shrine of Pomona must do it quickly, as the fruit is ripening fast, and the altar will speedily be stripped of its richest offerings. *D. T. Fish.*

Trial of Hot-water Boilers.—While thanking you for kindly inserting our letter, and apologising for troubling you again so soon, we venture to express a hope that cause will not be given us to say more upon this subject than that the proposed trial has been put into some definite form. We do not fail fully to appreciate the complimentary observations of Mr. D. T. Fish upon our former suggestions, and duly reciprocate his sentiments, that "the established boiler makers" have had scant justice in recent controversies." However, we have now two distinct things. With respect to his proposal that the period of trial named by us should be curtailed, we would respectfully remark, that in matters purely floricultural we should hesitate before differing from him, but on the other hand, by hot water, our friend must generously excuse us if we speak with less reserve. Now, without entering upon a host of explanations, which would look like lecturing others, we simply assert, and are prepared to show, that a boiler (especially those of the horizontal form) rarely exhibits its real capabilities during the first day or two of its operations, hence the period named by us should at any rate form the *minimum;* and if any alteration be made, it would be better to prolong rather than shorten the time. Again, Mr. Fish repudiates the extension of trial to system is upon the ground that the whole of the water is driven "by caloric alone," and that we "thus dispense with the aid of gravity." This one sentence clearly indicates how little our theorists understand the matter, because practically the "aid of gravity" is much more depended upon in system a than in A, but to what extent it is one of the objects of the trial to ascertain, as upon this point hinges to a great degree the vital question of a deep, a shallow stokehole, or their entire abolition. Respecting the trial being carried out with the present piping in the arcades of the Royal Horticultural Society, we see several objections to this, and it will be time enough to enter into that matter when the subject is fairly set on foot by the properly constituted authorities. Finally, we observe that if ever what is worth doing at all is worth doing well, surely this is one of those subjects to which the adage applies. In order to frame a more comprehensive set of laws than those published for the proposed Paris trial of 1869-70, it is to be hoped, after a general committee is properly constituted, and a finance committee and a committee of organisation elected, one of their first acts will be to receive evidence and suggestions from such practical manufacturers as are willing to compete, and so collect the best materials wherewith to form the basis of the rules by which the trial is to be governed. *J. Weeks & Co., King's Road, Chelsea.*

Fertilisation of Leschenaultia formosa—It was Darwin who first pointed out that self-fertilisation was injurious in the long run, and this important fact we continually see confirmed by weighty evidence, not in the vegetable kingdom alone, but also in the animal world. I happened the other day to examine rather closely certain flowers of that somewhat uncommon greenhouse plant, Leschenaultia formosa, and was agreeably surprised to find it furnished with everything needed in order to insure the most perfect fertilisation of the stigma by pollen from its own flower, or, to speak more correctly, every provision is made for the pollen to become located in the stigmatic cavity of the style, although the production of perfect seed is not at all common by this plant,—a fact rather surprising to a superficial observer, since the most perfect arrangements are made for the pollen to become not only deposited, as I said before, but retained there very effectually by the peculiar construction of the stigma itself. In order to make myself fully understood a few figures will be necessary, and it will be as well to state at the commencement of my description that the pollen is shed by the anthers before the expansion of the flower, as is the case with many plants, those belonging to the Leguminosæ more especially. When young, or in the unexpanded bud, the style is

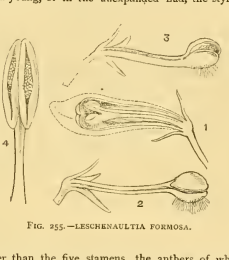

FIG. 255.—LESCHENAULTIA FORMOSA.

shorter than the five stamens, the anthers of which slightly cohere by their margins at this stage of their development, as is the case also in Composite plants. At this time the mouth or stigmatic cavity of the style is open, as at 1, fig. 255, which represents the style after it has forced its way up the tube formed by the coherent anthers, rupturing them until they only cohere by their apices. When the style has lengthened sufficiently to bring the apex, or stigma, in close contiguity with the nitrose anthers, the latter shed their pollen, and from their peculiar position around the open stigma it is nearly impossible that any can escape, seeing that the anthers form a close basket, so to speak, round the apex of the style, and the whole being closely enveloped by the, as yet, unexpanded flowers. After the pollen is shed from the anthers the flowers expand, and the style elongates still more, but the mouth of the 2-lipped stigma becomes firmly closed, as shown at 2, but in every flower I examined (35) I found pollen located in these closed, cone-like stigmas, as at 3, which grows one partly opened by force. The flowers themselves are irregular and tubular, the upper three lobes of the corolla being slightly reflexed, the two lower, which form the keel, are projected at a right line with the tube, and the style and stigma rise on these other the full expansion of the flowers. The lower portion of the stigma is bearded, as shown in the figure (2, 3), and immediately above the hairy portion it is slightly glutinous. Now, looking at the above-mentioned facts, one is led to inquire how it is that a plant like the present—the flowers of which are invariably fertilised with their own pollen—comes to be comparatively barren. I myself have never seen seed produced, but a well-known plant-grower and horticulturist informs me he has obtained seed from it, but whether naturally or by artificial fertilisation with pollen from other flowers, I am not in a position at present to state with that degree of certainty requisite in inquiries of this description. The question naturally enough arises, Has the plant degenerated and become sterile in consequence of this invariable self-fertilisation? If so, how can we account for the Leguminosæ, most of which are naturally fertilised by pollen from their own flowers, for they—like the plant at present under consideration—in many cases shed their pollen before the corolla expands? Perhaps some of your numerous and intelligent readers can inform us if they have ever gathered perfect seed from Leschenaultia formosa. *F. W. B.* [A very interesting case. EDS.]

Standards, Pyramids, and Bushes, for Orchard-house Culture.—It is now some 12 or 15 years since I commenced growing fruit trees as standards and half-standards in my orchard-houses; their head, formed on the tabular system, is described in the "Orchard House," p. 87. For some five or six years I was much charmed with this mode, but I now find that it is most difficult to keep these tabular trees, some of them 15 years old, in a proper state, even with the most severe pruning, for their heads become too thick, so that much of the fruit is hidden by the foliage from the sun, and is colourless. After all, for large trees there is nothing to compare with the pyramid. Many of my trees are now 9 to 10 feet in height, and the fruit at the bottom of the trees, resting on the pots, is as large as that S feet from the ground, and, what is valuable, it is ripe often days later. Pyramids require skilful culture, but when well done, they are unrivalled. For forcing, bushes are to be recommended, and even for orchard-house culture they do well. My bush trees twenty years old are marvels of health and fertility. *T. R., Sawbridgeworth.*

Hoar Frosts.—I am a very poor physiologist, but "facts are stubborn things." I suffer b.at little here from hoar-frost, being on the apex of Okeford; but at Rushton, in my glen, I was in the valley, close to the riverside, and there hoar-frosts made sad havoc, till I covered my Peach trees with sheets at night. I put them on early (4 P.M.), and took them off at 10 A.M., as quick transition from cold to sudden exposure to the sun's rays is most mischievous. Before I sheeted my trees I grew literally nothing, but after I had my trees, and kept off "Amateur's" friendly dews, I grew in nine years on three Peach trees (Royal George) 4560 Peaches. The valley, for eight or ten weeks off and on, was like Moscow in the Napoleonic winter. I was obliged to cover my Ashleaf Kidneys with a trough, like the roof of a house. Those exposed to the hoar-frosts were cut down and blackened; those kept dry by the troughs felt no effect of the hoar or black frosts. The rays of the sun, following the frosts, do great mischief. At p. 1004, the Editors express my experience, from the words, "if this go on freely," down to the words, "is the exposure to the sun." I call "Amateur's" attention to them. *W. F. Radclyffe.*

Hardy Plants for Table Decoration.—Several of your correspondents during the last three years have been advocating the claims of hardy plants for decorative purposes. It will be to them a pleasure to hear that one of the prizes, which were awarded at the last flower show at the Crystal Palace for table decorations generally, two of those prizes were taken with hardy flowers and Ferns; and this on an occasion when the competitors were numerous, and their flowers generally were good. Your reporter is of opinion that the hardy flowers used were "a comparatively poor selection." I made a note of what the selection was, and how they were grouped. If your reporter will favour us with some other selections, I, for one, shall be much obliged to him. The vase that took the 1st prize for a drawing-room table contained Nymphæa alba, Gypsophila muralis, a large spike of Bizia, and common male Fern. There were three pairs of vases on the dinner-table to which I allude; one pair had, below, large deep blue Delphinium and Coreopsis lanceolata, while above them were spikes of Pentstemon hartwegii, and grasses; another pair had, below, scarlet Gladiolus and double-flowered Spiræa Filipendula, the prominent flowers in the upper part being Campanula rotundifolia; the third pair consisted of Nymphæa alba and Statice latifolia below, with grasses above. Gypsophila muralis was used freely throughout to give lightness. The foliage was confined to the fronds of the male Fern. The colouring on this table was so soft and delicate, compared with the brilliancy of the scarlet Pelargoniums and yellow Calceolarias on some neighbouring tables, that many were disposed to pass it by as wanting in effect. A more patience, though doubtful at first, became admirers of the arrangement when they had looked on it long enough to forget the more gaudy displays close by. I trust the success achieved on this occasion with hardy plants will assist in bringing them into more general requisition for such purposes. *W. T.* [Our reporter's objections apply to the "weedy" look which some of the vases alluded to presented, and which might have been obviated by selecting flowers of stouter habit. Lightness is one thing, but a straggling habit is another. EDS.]

Potatos.—I have dug up all my Potatos ripe, and find more damage than I supposed when I last wrote. I have to thank Mr. Rivers for the Royal Ashleafs and Mr. Fenn for the Lapstones, Gryffe Castle Seedling, and Pebble Whites—of the Lapstone strain; deducting the bad ones they are an excellent crop. Of the Napoleons, Early Uprights, and a friend's seedling, three parts out

of four were bad. Of the Yorkshire Hero and Taylor's Yorkshire Hybrid at least one-half are bad. The Potatos are very fine this year. The crop of all, if unmolested, would have been three quarters of a sack per perch. I am, on the whole, quite satisfied. As we dig we plant Cabbages, or sow Early Stone Turnips, so that my ground will not owe me much. The Editors' advice is good. "Get early ripeners, and among them some that will keep till Ashleafs come in." Get these: Rivers' Royal Ashleaf, or Veitch's, or Myatt's Prolific—all good sorts to begin with. Plant Gryffe Castle Seedling, of the class Regents, a white round Potato, of good quality, a good cropper, an early ripener, and with short haulm. Deep-eyed Potatos, and such as have strong haulm, are not early ripeners, and suffer more than short-haulmed varieties in disastrous seasons. Gryffe Castle is not a late keeper, but Royal Ashleaf is, and it will take you to Christmas. Then the Lapstones—best of all Potatos—Pebble White, Hero, and Taylor's Hybrid—all early ripeners, late keepers, and with short or moderate haulm, will serve you till new Potatos come in. I never have a bad Potato for dinner. Do not manure Potatos at planting time, but manure highly for preceding crops: make your ground as light as you can: plant with a stick, as it causes drainage under the roots. The origin of moral evil and the Potato disease alike confound me—I never could discover a fungus or insect. I think it must arise from electrical rains: it never occurs in dry seasons. Probably the stalk is overcharged with more moisture than it and the leaves can elaborate, and the solanic juices poison the Potatos. I merely guess, and cry, "O dark, dark, dark." *W. E. Radcliffe.* That the whole course of the Potato disease is perfectly well known, but the means of cure or of prevention remain at present mysterious. Eds.]

— I think Mr. Fenn has done much during the past 20 years towards attaining that desideratum mentioned in your leading article (p. 1041), namely, the "multiplication of good keeping early varieties" of the Potato. Only those who enjoy the friendship of Mr. Fenn know how patiently and persistently he has worked in this direction. At my seed grounds at Bedfont there were lifted, a few days ago, several of Mr. Fenn's seedlings, all of which have been tested for from three years at least; and of these some 12 or 15 were selected and named, subject to a fourth and even fifth year's proof. I dare say something will be heard of these ere long. Mr. Fenn's determination first of all to secure definite results in the way of his seedlings, and then to thoroughly test and fix their desired characteristics, regardless of the time and toil expended on the work, is worthy of the highest commendation. The influx of coarse American varieties during the past few years, which, quite irrespective of their quality, have been sold at fancy prices because they were American varieties, may perhaps have diverted the attention of some from a regard to quality to that of mere quantity; but the disappointment many have already experienced will cause them to welcome anything of approved character that has been carefully tested. When the reaction sets in with a full flow, Mr. Fenn will, I hope, be found to be prepared to offer, in the place of large tubers of coarse texture and indifferent quality, something entirely opposite in character, that it will be both pleasant and profitable to cultivate. *Richard Dean, Ealing, W.*

— I procured in the spring of last year 1 lb. of Early Rose Potato, which I cut into sets, and the result was 60 lb. of Potatos. I took 1 lb. from them this spring, which I cut into 40 sets, and the result this season is 72 lb. of very fine Potatos; 3 lb. of these were diseased. I purchased this season 1 lb. each of Peerless and Climax, and the result is as follows:—Peerless, 57 sets, produced 86 lb., of which 14 lb. were diseased; Climax, 62 sets, produced 60 lb., 3 lb. being diseased. The tubers of Peerless are very large and heavy, and of the Climax a fair average size. I think the American Potatos have proved less liable to disease than many of our older sorts. I have some Regents, Early Frame, and Paterson's Victoria, which are not worth lifting, while the Early Rose has produced a fine crop from a peck of cut sets. I lifted 10 bush., and found but very few diseased. *John Harland, Gr., Writtle Park.*

— In the spring of the year I purchased 1 lb. of Bresee's Peerless Potato, and cut them into 46 sets. I planted them February 16, dug them up August 22, and the produce was 135 lb. Many of the tubers weighed 2 lb. They were planted in the ordinary kitchen garden soil, without any additional manure. *Thomas Pender, The Gardens, Sharpham, South Devon.*

Grape-growing at Kingston Hall.—As Mr. Westland only writes for the vindication of truth, I hope before he again gives a description of the heating arrangement at Kingston he will himself explore the chambers under the Vine border, and thus refresh his memory. First we had hot-water pipes under the external border, which I deny, and now we have "an arch turned slightly underneath to admit of ventilators to the chambers." These exist only in Mr. Westland's imagination, as there is neither arch nor ventilator to be found here, as represented by him. Should any one have a wish to explore the chambers under the Vine borders (and I hope some one may turn up to verify the case), I must here say that they cannot get under three of our Vine borders, unless they can get through a pigeon-hole 9 inches by 8. Still this difficulty may be overcome, as I myself, three years ago, had a man-hole cut in the front wall of the early vinery, so that I could get under the border with thermometers for my own personal observation. Into this any approved person may get, and it will illustrate the whole range, as they, I presume, are all alike. Should they find two 4-inch pipes under the external border, or an arch turned slightly with ventilators to the chambers, as represented by Mr. Westland, then, and not till then, will I acknowledge that any misstatement has been made by your two correspondents or myself. I this morning measured the chamber under the border. It is exactly 18 feet from the front wall outward. The two so-called bottom-heat pipes are under the front wall, just 4 inches from the outer edge, and I repeat that may come from them enters the chambers under the borders through a few pigeon-holes, 9 inches by 8 inches. But it was impossible for them to heat to any extent. Never having seen the original system at work I may not judge; but as Mr. Westland has not denied that beautiful crops were produced by it, my imagination still points to its having something practical about it. Now for my ungracefulness. As your first correspondent mooted this heating question in your columns on June 24 (see p. 810), and Mr. Westland's visit did not take place until July 1 and 2, I leave your readers to judge whether he could have spoken on the subject when here. I think he might have given me the first opportunity of correcting any misstatement, if one had been made by either of your correspondents, through my information, instead of adopting this unprofitable and unedifying controversy. *William Cruickshank, Kingston, Derby, August 23.* [Enough of this. Eds.]

Veitch's Autumn Giant Cauliflower.—I was surprised to read "J. C. N.'s" remarks, at p. 1041, on the above vegetable. I have at this time about 1000 plants of it in different stages, and have only had occasion to pull up about four or five "rogues" amongst them. Probably the fact of "J. C. N.'s" seed being sown so early may have something to do with the running prematurely, though I myself sowed a pinch of seed in February which turned out well. I am of opinion that when this Cauliflower becomes more known, and seed is a little more plentiful, it will be prized as the best winter Cauliflower we have. I had a small plantation last year, and, from what I saw of them, I should have no hesitation in undertaking to furnish a supply of it until the end of February, with proper successional sowings. Some of ours were taken up and put in the vegetable shed, with a little moist leaf-soil amongst the roots, the largest leaves being cut off, and they kept in good condition for a week, previous to being taken up they stood 10° of frost without injury, and the only protection they had was a few leaves broken over them. Our plants were seen in October and November last year by several good gardeners, who all pronounced them to be the finest Autumn Cauliflowers they had ever seen. If sown in the middle of April it will come in well the beginning of October anywhere in the south or south-west. *Gr., Hackwood Park, Basingstoke.*

Water Weeds.—In reply to the inquiry of "W. E." (at p. 1041), in reference to water weeds, I may state that some years ago the lakes in the Botanic Gardens at Manchester were one mass of Anacharis, Myriophyllum, Potamogeton, &c. They used to be mown down several times during the season, and laborious work it was to get through the matted mass. So rapid was the growth of the Anacharis, that it was completely the master of the lakes. Ultimately swans were introduced, and they soon proved themselves the best extirpators of these obnoxious weeds; for, in a short space of time they quite cleared the lakes of the Anacharis, &c. If "W. E." has no swans on his lake, I would advise him to try a few couples, and I think he will be pleased to find that swans are useful water scavengers, as well as noble, elegant, and graceful aquatic fowls—an ornament to any sheet of water. To have his lake concreted would be an expensive affair, so the swans are the simplest remedy. *Thomas Campbell, 11, Thurza Street, Chorlton Road, Manchester.*

Poisoning by Fungi.—A week or two ago a case was reported of a family being poisoned by unwholesome Fungi. Mr. Guppy, his wife, a woman and two children partook of the Fungi; and, according to the printed statement of T. Stokes Guppy, M.D., of Falmouth, "no symptoms of poisoning occurred till about 14 hours after [an unusually long period], when violent vomiting and purging came on, followed some hours after by delirium in the mother, and convulsions in the children." After lingering for three days, both children, aged respectively 6 and 13, died, but the mother gradually recovered. Dr. Guppy also states that three fowls were killed by some of the Fungi left being thrown out to them, and that a gentleman in the same village, about two weeks previously, threw some suspicious Fungi (probably the same species) to eight chickens, and they all died after partaking of them. Some half-dozen specimens "of the kind eaten by the Russells, picked from the same place by one of the family," were kindly forwarded to me from Mr. Guppy (through the Rev. J. E. Jones-Machen) for examination. They proved to be the well-known Champignon (Marasmius Oreades). They differed slightly from the normal type, in being very strongly scented, and having the gills connected with veins. No species of Fungus enjoys a better name than Marasmius Oreades: Mr. Berkeley says it is "the very best of all our Fungi," and that "no species may be used with less fear," yet I have long been disposed to think it occasionally dangerous. I therefore had the six Falmouth specimens cooked at once, and I ate them. I suffered no serious inconvenience at the time; but an hour or two after the usual symptoms of poisoning by Fungi came on, with burning of the throat, irresistible depression of spirits and disordered stomach; but I soon got round. I have no doubt I shall ask why I write to you; that Marasmius Oreades worked the mischief. I have several times suffered slightly from it, and once seriously, but at that time I laid the charge against an immediate ally. As the account of the latter incident has been published, and is confirmatory of the sometimes dangerous character of Marasmius Oreades, I cannot do better than repeat it here:—

"I think I was once poisoned by it (M. urens) in Bedfordshire. I well remember, on my return home late one evening, gathering a quantity of Champignons for supper; as it was dark, I imagine I gathered both species (M. Oreades and M. urens). I did not cook them myself, neither did I examine them after they were taken from the basket, but I noticed at supper time that they were unusually hot, and I thought the old woman who cooked them had put too much pepper in the stew. In about half an hour after partaking of them my head began to ache, my brain to swim, and my throat and stomach to burn, as if in contact with fire. Before the same hours, a terrible fit of purging and vomiting set in, which appeared soon to set me to rights, for after a day or so I was no worse for it."

I have since had reason to believe that I did not make a mistake and mix the poisonous species with the edible, but that the Oreades was the culprit. A large cupful of sweet oil is a good thing for urgent cases. *Worthington G. Smith.* [As the Champignon is so largely used without ill effects, we can only suppose that the drying to which it is generally subjected dissipates the poisonous properties; at any rate, the case above quoted is most important. We should recommend an emetic to be given immediately, and the doctor to be sent for without delay. Oil would merely palliate and dilute, not remove, the poison. Eds.]

The Thinning of Grapes by the Syringe.—It seems strange that any one who has ever grown Grapes should believe this to be practical. Either the healthy flowers of the Grape Vine—and by the word healthy here I mean those that would set if left alone,—can be assisted effectually by the syringe or they cannot. If they can, what security have we that a stream of water will thin the Grapes with regularity? If the water removes any, why not too many—all? And who in his senses would risk such a result for the sake of saving a little time in thinning? Could reckless folly further go than to injure the roots, building houses, making borders, buying Vines, growing them, and then committing the produce, crop or no crop, to the blind keeping or destroying of a mechanical squirt? Talk about penny wise and pound foolish, such a course as this is not even penny wise, while the risk is the most foolish of foolishness. But I contend that the syringe, unless applied with a force that would ruin all, will not remove any embryo Grapes that would have set. There are many berries show that don't set; they are defective from the first. Nature seemingly never designed them to hold on. It is her way of thinning, and in some varieties, such as the Canon Hall Muscat and others, it is rather too effective. Sweep a stream from a syringe over these, and off they come. Give the Vine a shake or a tap, and they do likewise. And I might just as logically affirm that I can, or do, thin Grapes by tapping, which, as a rule, always precedes the scissors, as that others can or do thin them with the syringe. I hope I have now drifted into an answer that will satisfy your correspondent, Mr. Foyle, and others, and that we have now heard the last for a long time to come of one of the most preposterous ideas that ever was seriously discussed—that of thinning Grapes with the syringe. Those who think good Grapes not worth the most careful and painstaking thinning had better leave off growing them. They certainly are not worth a cook upon nor to eat good Grapes. I have thinned many and eat but comparatively few, but I trust the time may never come when the glorious bunches that adorn our Vines will be turned over to be washed out anyhow by a stream of water, or given up to a mechanical operation. We have too much of the latter already; Grape thinning demands above all things intelligence and expert manipulation. When these can be put into a dashing spray of water, then may the end of the syringe or the conductors of our squirts be brought upon our bunches of Grapes in flower, or after, for the purpose of thinning them with regularity and skill, not before. *A Practical Hand.*

Jackman's Clematises.—I was not particularly struck with C. *magnifica*, as shown by Messrs. Jackman & Son at South Kensington on August 2. Perhaps the fact that it was grown in a tub was hostile to its

proper development of character. My note of it, made at the time, is as follows:—"Colour, washed-out purple, with flame of pale red along each segment; poor, and not sufficiently distinct;" a criticism both robust and emphatic. I have not grown it, but will give it a trial another season, in the hope I may be converted to a better appreciation of its merits. I was much more struck with C. Alexandræ, which bore pale blue flowers, pretty in hue, and somewhat distinct in character; as shown, a capital companion to C. Jackmanii. Mrs. Bateman was very pretty also; the flowers opened of a pale reddish-claret hue, then changed to pale mauve, which improved in colour as the flowers aged. These two will certainly be added to my collection. The first bloom of C. tunbridgensis has just expanded. The first is small, because the plant is quite young; but I have marked this variety as both free-growing and free-blooming. I don't set myself up as an authority about Clematises. I am deeply interested in them, and I venture to commend those I have tried with marked success. *Richard Dean.*

Parsons' Mignonette.—Observing "D.'s" inquiry, in your issue of last week, in reference to Parsons' Mignonette, I send by sample post specimens of that and of the common kind perpetuated by "self-sowing" during many years, by which you will see that about 57° N. lat., on a rather stiff and cold clay, there is not much gained by growing the new variety. The plants of Parsons' are stronger, doubtless, a result of more liberal treatment, but much less sweet-scented than the old variety, perhaps from the same cause. As many hundreds throughout the country, from the noble and wealthy, to whom half-crowns are of little significance, down to the humble cottager, whose time spent half-creases both limited, will have tried this old favourite under its improved (?) form, it would be interesting to know whether any peculiarity of treatment, or special condition of soil, has been found instrumental in bringing it into the condition in which it has undoubtedly been shown by the raiser during many years. *Yeltsley.* [There is no appreciable difference in the samples sent. Probably the new variety has not been sufficiently fixed before sending out. It was certainly shown good, and apparently distinct, last year. EDS.]

The Golden Hamburgh Vine.—This season I was surprised at seeing the foliage of this Vine stained with yellow blotches on the green ground; and on examining the bunches of fruit, nearly formed, numbers of the Grapes on them shaken about a month before the usual time of their ripening. Had this Vine been alone I should have expected to have found the cause in the roots; but it is in a house in which there are 15 varieties, the foliage of all the others remarkably fine, clean, and without a spot on any of them, having measured 15 inches across. This accident has an impression he has heretofore seen an observation in the *Gardeners' Chronicle* on this Vine, that it is not to be relied on for two years together. Perhaps some of your readers may have had the like experience, and would state whether, in such case, there would be any objection to treat it as a stock to bud another sort on at this season, rather than risk the disturbance of the roots of its neighbours by removing this Vine of some years' growth. *Charles Lauvence, The Querns, Cirencester.* [This variety is liable to be affected in the way described. EDS.]

Potato and Artichoke Grafting.—I give Mr. A. Dean full credit for "open confession;" for your readers will remember that, when this subject was first mooted in your columns between two and three years ago, Mr. Dean was amongst the first to try and stifle it; and so thorough was his scepticism at that time, that he even believed if he were to graft a Potato into a cricket-ball he might just as reasonably expect that the produce (if any) would be "cricket-balls;" as to expect any change would be effected between the stock and scion of the Potato; nay, he even went further, and disallowed the terms stock and scion in the above sense altogether. Not so now, however, as see p. 837, where he not only pays a compliment to (quoting his own words) "that persevering apostle of the Potato-grafting theory, Mr. R. Fenn, of Woodstock," but openly avows himself a convert to the faith. Well done, Mr. Fenn! If every true apostle can succeed in winning but one disciple from scepticism to true belief, there is cause for thankfulness, inasmuch as it would ultimately lead to the conversion of the whole community. I also hope, and firmly believe that the day is not now far distant, when I shall be able to convert Mr. Dean and other sceptics into the belief that it is possible to effect a reciprocal first between the Jerusalem Artichoke (so called) and the Potato. I have repeated my former experiments, but will reserve any comment for the present, and allow the produce to speak for itself at one of the Royal Horticultural Society's meetings in September; and in the meantime I should like to know what has become of the Chiswick experiment, also whether it has been repeated in any other quarter, and with what results? *Thos. Simpson, Broomfield.* [We shall require much convincing ere we become converts to our correspondent's views. EDS.]

Yucca filamentosa.—Few things are more attractive in the shrubbery at this season of the year than the noble looking spikes or heads of flowers of these plants. Spiræas, &c., are over, and the varied tints of the leaves are not yet ripe, nor are there any berries yet of sufficient colour to be noticeable. This plant, therefore, comes in just when something is wanted; they contrast well with the Hydrangeas, which, by-the-by, are flowering very early this year. Planted in clumps they look well almost anywhere; they are also worthy a prominent position in the herbaceous garden, or what used to be the flower garden. Even now it may be used with effect in the present style of flower gardening. It is one of those things that would serve to break the monotonous look of many gardens. Good sized plants, if planted in the centres or angles of beds, or as one of the back rows of a ribbon border, would lend to them a noble appearance when in flower, and the leaves of the plant after flowering would look better than many things, or, as is sometimes the case, nothing at all, in winter. Plants, when once established and literally treated with, will flower every year. Cutting away the dead flower stems and leaves in the autumn, and thinning out the plant so as to leave the strongest sucker which will flower the next year, and one to grow on to prepare for flowering the year after that, will ensure a yearly display; the suckers thinned out will make large, good sized to the spring of plants. *Henry Mills.* [Single-stemmed plants of the variegated Acer Negundo, introduced amongst evergreens, have a distant effect, very similar to that of flowering plants of Yucca filamentosa. EDS.]

Foreign Correspondence.

MADRAS: *July* 24.—It may, perhaps, be interesting to some of your readers to hear something about the Neilgherry Hills in a botanical aspect. It is not new ground, and few unknown plants remain undiscovered to science, yet numbers of very rare plants, which have never been introduced to England—plants well worthy of especial attention, and a place in home gardens, where they would stand out for the greater part, if not the whole, of the year, with a little additional protection during the winter months.

The thermometer at Ootacamund in June stands at about 65° F. in the middle of the day in the shade, and in the cold season there are sharpish frosts in the mornings.

These hills are now reached—that is to say, Coonoor—in 24 hours from Madras, partly by rail and partly by transit. There are steamers almost every week to England from Madras through the Suez Canal, and moved freights compared with the old Peninsular and Oriental Company's rates, thanks to competition and M. Lesseps, so that living plants can be sent home much cheaper than formerly, and without any transshipment. I sent a Ward's case a few days since, which cost £6 10s. 6d.

The ascent of these hills from the east, or Madras side, commences at a place called Kulur, 33 miles from the railway. The new ghaut is 16 miles, being just double in distance to the old one. The old one is still in use for horses and palanquins.

The new ghaut is not an easy ascent, the heaviest gradient being about 1 foot in 19. The scenery is very beautiful, the mountains right and left of the valley rising abruptly 5000 to 6000 feet. At the foot of the ghaut about Kulur the jungle is chiefly of Bamboo, and it is very certain and dangerous to be passing the night. Here I noticed several Orchids, particularly a large mass of Vanda Roxburghii, in full flower, the flowers varying in shades of colour. This variation in the colour tints of the flowers of plants, in Orchids especially, I have frequently noticed, and the cause I have never been able to find a satisfactory reason for.

My first impression was, that these variations in tints depended on the amount of light and shade the flowers happened to be subject to, or that the colouring matter of the bark of the tree upon which the plant was located entered into its circulation, or that the cellular tissue of the flowers varied in consistency or thickness in different parts, the chemical distillation, or action set up to produce the colour, was imperfectly performed. Vanda Roxburghii is described in Wight's "Icones," p. 10, vol. iii., and a very meagre description it is. One of its nearest allies, Vanda Bensonæ, described in Bot. Mag., tab. 5611, Nov. 1866, has a different habit of growth, and each in its native habitat could never be mistaken for the other. In Vanda Bensoni, as in V. Roxburghii, there is the same want of uniformity in the colour of the flowers. Leaving this subtle investigation to be solved by some of the philosophers of the city of Hulee, mentioned in "Frazer's Magazine" for June last, I will continue my description.

Cymbidium erectum, very like C. aloifolium, Vanda Wightiana, and a small Luisia, were the Orchids which I observed until I had arrived at about 2500 feet, where Saccolabium paniculatum came to the front, so to speak. From the description of S. rubrum in Wight, I mistook this plant for it, never having seen either before. For beauty, now that I have seen both in flower, I am dubious to which to accord the palm.

The white variety of paniculatum is very delicately marked on the lip with a magenta stripe. It is an exceedingly pretty flower, and the inflorescence very compact. Many of the plants have a single spike; on the other hand, rubrum—at least what appears to me to be a variety of rubrum (Warneri?)—is sometimes paniculate. In paniculatum the seed vessel is more rounded, with strongly emarginated sutures, whilst those of rubrum are angular, somewhat flat-sided. I am inclined to think that the slight difference in those two plants is caused from the different elevations at which they are found; thus paniculatum, growing at low elevations, is nearly white, increasing in depth of colour at the higher altitude of 6000 feet; Coonoor and Kartary, pale pink or rose; at 8000 feet, deep red, or "rubrum." Of course this is mere conjecture on my part, but the more I see of species approximating to each other in the same parallels of latitude, the more strongly am I impressed that climate is a powerful agent, although slow in its operations, in causing variety in species. The change, I suspect, is too gradual to be perceptible to man.

The age of some Orchids is very great. I have in Saccolabium giganteum counted as many as 60 cicatrices of the fallen leaves. Many other scars, too much obliterated to be counted accurately, were present, but taking one year for each cicatrix, which is much below the mark, the plant might be fairly computed to be above 100 years of age. It is quite cheerful as you mount up to see the wild Rose creeping over the top of the underwood, showing its large white petals—Rosa involucrata; it reminds one of the hedgerows in old England.

Coonoor is the first station on the hills, about 6000 feet above the sea. There is no plateau. The houses are built on the sides of the hills, the church on a prominent position in the centre, thus giving the scenery a very picturesque effect, being surrounded with higher mountains.

The temperature of Coonoor is about 76° in the shade in the middle of the day. The rainfall is small, being shadowed from the south-west monsoon by the higher range intervening between it and Ootacamund; the highest point in the whole range—Dodapet, above 9000 feet, being one. The vegetation shows the absence of great moisture; the trees and rocks, instead of being crowded with epiphytical and parasitical plants, are relatively bare to what they would have been at the same elevation in Burma. The Tree Fern, Alsophila, grows abundantly in the watercourses, and in some the trunk was, I should say, at least 20 feet high, but slender. Rhododendron arboreum is also thickly dispersed throughout these hills, of great size. It is a glorious plant. The number of Loranths was astonishing. In one morning I counted during my ride no fewer than 10 different species. Wight gives 11, I think; but this I should say was much under the mark. In the vicinity of Coonoor, a handsome shrub, Loranthus bandanus, described by Wight as Solanum verbascifolium. The flower is inconspicuous, but the cluster of fine red berries, contrasting with the white leaves of the plant, makes it handsome and showy, well worthy of a place in the garden at home as a decorative bedding-out plant. The same may be said of Solanum Wightii. It is found on rocks, in decayed vegetable soil, its large deep blue flowers rendering it a most noticeable plant. It is as fine a plant as any I met with in those regions. Again, Lysimachia Leschenaultii (a Primula), accordingly to Wight, is found in the higher and the higher ghaps about Ootacamund. Its flowers are red, the stamens exserted, inflorescence racemose, compact, and large, the protrusion of the stamens giving it a hairy appearance.

Sonerila speciosa I do not recollect seeing in England; here it grows in moist places on the rocks, where there is trickling water. Its flowers are deep scarlet, with orbicular leaves, reddish above, and deep purple below. For its foliage alone it is a good plant. In some of these moist, mossy spots, on stones, its companion is a beautiful gem—an Impatiens. It has a single dark green round leaf, with a scape bearing several rich rose-coloured flowers. It seems to sparkle with the moisture, and would answer for rockeries in conservatories on the edges of artificial pools of water. Mr. Mendel's magnificent ferneries at Manchester immediately occurred to me as a suitable home for this beauty.

Of Balsams there are a great variety: some of the Impatiens might be termed arboreous, from their thick stems and large size.

Aerides Lindleyanum, the finest Orchid on the hills (with the exception of Schroederi, of which only one plant has as yet ever been found), grows on rocks; it is a free flowerer, and ranges from 5000 to 8000 feet. Those growing at higher elevations have a longer stem with narrower leaves. This is too well known to require further comments from me. The following are some of the Orchids I came across:—Aerides Wightianum, Vanda n. sp. ?, rather pretty and sweetly scented; Bolbophyllum neilgherriense, Cœlogyne nervosa, C. odoratissima, Dendrobium aureum, Eria reticosa, Saccolabium Rheedi, to me a variety of S. Blumei. There are two more plants I must not forget to mention, and they are, 1st, a very handsome pink Begonia, Begonia dipetala (?), and a little Didymocarpus, with blue and yellow flowers. Most of the plants mentioned here have been sent home by me.

For new species or varieties I should say there was a good field for inquiry amongst Zingibers, Cucumis, Aroids, and Asclepiads, all interesting orders.

I was only a short time at Ootacamund, but visited the Botanical Gardens, for which purpose I went expressly. Mr. Jamieson, from Kew, is in charge,

He deserves great credit for the way in which they are kept. It is a lovely spot, formed in the ravine of one of the surrounding hills by a series of ascending plateaus. There is a glasshouse at the entrance, as ugly an object as can well be conceived or contrived; it intercepts the view and breaks up the entrance space; the sooner it is removed the better, in my opinion. I think botanical garden is a misnomer—horticultural would be more appropriate. The plants are not even named. There is no herbarium and no special collection of valuable indigenous plants for economic purposes, distribution, &c., but as a garden for floriculture and beauty, for its limited size, it equals any I have ever seen. *H. Benson, Colonel, F.L.S.*

Florists' Flowers.

A DRY spring, with a chilly east wind and sunny days predominating, followed by an early summer, as uncongenial as could be imagined, did seem, and was generally believed to be, hostile to the development of Roses. They were backward, and the early blooms thin, but, notwithstanding, some grand Roses have been shown during the past two months, and especially from the nurseries of Messrs. Paul & Son, at Cheshunt, who have been pre-eminently successful as Rose exhibitors during the present year. Perhaps, of all the high-class features belonging to the Nottingham show, there was not one of more general interest than the twelve magnificent stands of Roses with which Messrs. Paul & Son won the Rev. S. R. Hole's handsome cup. The Nottingham Rose growers, who can grow, and therefore keenly appreciate beautiful and finely developed Roses, hung about this stand, loud in exuberant praise, with hearts overflowing with admiration.

The new Roses of 1869-70 have been tried at Cheshunt this season, and while some have failed to answer the descriptions given of them, others have proved first-class acquisitions. The following were seen in bloom during the third week in July:—Auguste Neumann, bright red, with a shading of violet-crimson, very fine and full, and a good grower. Candide, clear fleshy white, and in bright weather becoming pure white; a thoroughly good Rose, that needs fine weather to bring out its delicate beauty. Climbing Victor Verdier, very fine, and having a vigorous climbing habit, and so will make a splendid pillar Rose; this originated as a sport at the Cheshunt Nurseries. Comtesse d'Oxford, bright carmine-red, very large, full, and of fine form; this is one of the Victor Verdier race, is of vigorous growth, and of an exquisite glow of colour. Edward Morren, glowing rosy-pink a grand full Rose of great substance, and of violet-crimson, very vigorous constitution. Ferdinand de Lesseps, violet-purple, with dark shading; a thoroughly first-class Rose, and giving a very acceptable hue of colour. General de Lamartinière, the centre bright crimson-rose, the circumference of the flower bright lake; very large, full, and of fair form. Lena Turner, bright pale cerise, a very pretty pale Rose, but not so good as Madame Charles Crapelet, which is in the same way. Louis Van Houtte, scarlet-crimson, finely shaded with darker crimson, a grand full Rose of a splendid hue of colour; the flowers also off well on a fine vigorous. Madame Laurent, brilliant cherry-rose, fine globular form, full, and rich hue of colour; habit vigorous. Madame Liabaud, one of the very best of the white Roses; this opens blush white, changing to pure white as the flowers become fully developed. Malle. Eugénie Verdier, a very beautiful Rose, of a bright rosy flesh hue tinted with salmon and white, large deep petals, full, and of fine substance. Marquise de Castellane, clear vivid rose, flowers very large and finely expanded; vigorous habit. Paul Neron, bright rose, flowers very large and full, and measuring when fully expanded 6¼ inches in diameter; growth vigorous: this promises to become a very popular Rose. Reine des Blanches, delicate flesh, almost white; a seedling from Victor Verdier, of large size and good form, but so very dwarf in growth as to affect its usefulness. This does not include all the new hybrid Perpetuals, as some were scarcely in bloom, while others had passed the blooming season. Size, fulness, rich or delicate colouring, and robustness of habit, appeared to characterise a great portion of the foregoing.

Of the newer Hybrid Bourbons, Malle. Favart, shining pale rose, with pale dashes distributed over the flower, fine in form, very promising, and of good habit, appeared to be a good addition to this section. Among the Noisettes, Rêve d'Or, deep yellow, to all appearance a climbing pale-coloured Madame Falcot, as the flower is of the build of this favourite Tea-scented Rose, can be highly commended. The new Teas were not in condition, but it was noticeable how fine the old rose and white Rubens had come this season, the flowers large, finely coloured, and very full.

A great number of Seedling Roses, raised from seed sown in April last, were already blooming, though so young. There were patches of seedlings raised from Duke of Edinburgh, General Jacqueminot, Charles Lefebvre, and other fine varieties. Seedlings from Duke of Edinburgh were conspicuous for their robust growth, and in many instances the wood was thickly spined, which is not a characteristic of the parent. As a matter of course the blooms were small, but sufficiently full to enable a rosarian to give some idea of their probable value. There was a very rich crimson seedling of Charles Lefebvre, of the same build of flower, but much deeper in colour, and of a very strong constitution. Another seedling from the same parent had white flowers, and seemed full of promise. A white Charles Lefebvre would be indeed an acquisition. Several seedling Roses were in course of trial, but as they will have another season's growth, it would be premature to speculate on their merits. A seedling from Duke of Edinburgh, very much deeper in colour, and so free in growth as to suggest it would make a good climber, was thought much of.

There are yet the two new varieties raised by Mr. Thomas Laxton, namely Princess Louise and Prince of Wales, which have just been distributed by Messrs. Paul & Son. The former is blush white, large, full, and of fine form, and vigorous in growth; the latter is a greatly improved Lædia in point of colour, being of a glowing pale pink hue, fine in shape, and of full substance. Earl of Eldon, a Tea-scented variety, raised from a Cloth of Gold, has a very vigorous habit, and promises well as an effective pillar Rose.

Messrs. Paul & Son have in their possession an exceedingly novel and very fine Tea-scented Rose, named Cheshunt Hybrid, some blooms of which were shown at Nottingham. It was raised from seed of Madame de Tartas, which was grown in the house of Tea Roses in the nursery; and growing by the side of this was a plant of Prince Camille de Rohan. It is thought the former must have been accidentally fertilised with the Hybrid Perpetual, as the flowers are large, deep in build, very full, and of a deep violet-rose colour; it is also highly perfumed. *R. D.*

The Apiary.

IN looking over an old book, on "Insect Transformation," published by Charles Knight in 1830, I read, in the first chapter, of the first hive that was roughly invented, by one who was evidently "an out-of-doors observer of Nature;" and although he had had, at the latter part of his career, his eyes put out to make sport, he had his revenge in a fearful manner upon his friends, as well as his secret enemies, who had assembled one day to rejoice in his humiliation. For he had given in earlier days his would-be friends such a puzzling question about bees, their honey, and the kind of hive they had occupied, that they actually left the house near and dear to him to tell them the secret, which was to be found out before the wedding breakfast he had prepared; and thus, poor fellow, he lost his wager on that day. Nevertheless, it is written, he did invent a skeleton hive. My object in bringing forward, in this book was to try and trace the truth "if all insects came from eggs, as plants do from seeds;" but the question of wasps, aphides, and raising the larvæ by "osmosis," or "feeding," has really taken up so much of your space, that I will beg only for an easier task, and attempt to elucidate the principle of the following remarks on the "best beehive," not only for observing the operations and natural history of the honey bee, but it should be the best beehive, in which the bees may be left to their fate under the greatest amount of neglect that the bee-keeper can bestow. "Bees and bee-keeping" is the subject I shall be able summing up of the writer in the *Quarterly Review*, some 30 years ago, when reviewing "Bee Books and the Beehive," with the advice to country gentlemen to read up the fourth "Georgic" of Virgil on that subject, and to keep to the old-fashioned straw hive, with the various associations of childhood, Watts' hymns, and contentment," I am almost inclined to fall back into the same tone of mind, and pray, like the country mouse, "Give me again my hollow tree" (a straw hive)—more picturesque than any of those modern patent wooden boxes, or coal scuttle bonnets, or even Woburn frames, so charming and pleasant days, and wish those reviewers still lived to cheer on, whilst correcting the errors of enthusiasm, the painter or poet, the politician or the naturalist, as writers; but to us older men, who are left, even Darwin's epitome of this book, from p. 9:—"The ancients, it would appear, had the shrewdness seldom to venture upon illustration of their philosophical romances by particular examples; this was reserved for the more reckless theory builders of our own times." We find Erbinet, for example, asserting, as it was Nature's chief object to make man, she began her "apprentissage" by forming minerals resembling the single organs of the human body, such as the brain, in the fossil (Meandrena cerebriformis, Parkinson). Darwin, again, dreaming that all things arose from a single filament, of the cradle of matter, which, by its efforts to procure nourishment, lengthened out parts of its body into arms and other members, made the oyster grow into arms and legs, and then, when it tried to rise from its native rocks, wings were produced, and it became an insect. Goethe, again, changed into a bird. The different forms of the bills of birds, whether hooked, spooned, or long, were, he says, gradually acquired by the perpetual endeavours of the creatures to supply their wants. The long-legged waterfowl (Grallatores, Vigors) in this way acquired length of legs sufficient to elevate their bodies above the water. "A proboscis," he says, "of admirable structure has thus been acquired by the bee, the moth, and the hummingbird, for the purpose of plundering the nectaries of flowers." But I must turn to the kind of hive the bee requires to lay its eggs in, to be in its natural condition; but, not to lengthen this communication unduly, I must defer speaking of this matter till another opportunity. *W. A. Munn.*

Garden Memoranda.

VICTORIA PARK.—This is one of the most beautiful of our London Parks, yet one that we hear little about. It consists of about 200 acres, and is situated in the midst of a thickly-populated district in the East End of London. I was greatly astonished on the occasion of a recent visit, for it surpassed my expectations. It is most tastefully laid out, and great credit is due to those who had the arrangement and making of such a public boon as it is. Before it was taken for this purpose, it was evidently a piece of flat ground, but by skilful management it has been converted into a beautifully undulating and well-wooded park; the banks of trees and shrubs, which appear to support beds of the gayest colours, are very luxuriant. The beautiful specimens of Hollies, Thorns, Chestnuts, &c., and, indeed, the general collection of trees, is not to be equalled in any park near London. The lakes are a prominent feature here. They are studded with pretty wooded islands, the most conspicuous trees being Purple Beech, Weeping Willows, Weeping Elms, and many others that make a really effective intermixture, and produce a most refreshing effect on the visitor as he rests on the seats around their banks and under the splendid avenue of trees which occupies one side of the park, on such a hot day as I experienced there, and one on which the shade afforded by Nature is so appreciated; as it was in the fullest sense of the word by the thousands of people that were there.

All kinds of recreation and amusements are to be found. Amongst the most important are the bathing lakes, cricket field, and two large pieces of ground set apart as public gymnasiums. There is accommodation for several thousand bathers, who have the privilege of using the water from 4 o'clock in the morning until 8. This is really a boon and refreshment to those who make use of so advantageous a gift.

Coming to the horticultural department, it must be mentioned that the flower gardening is well done; the beds are prettily formed, and the flowers in them are well arranged. I noticed two most beautiful beds having trees in the centre, and around each of which there were some 1200 bedding plants; they were tastefully arranged with Pelargoniums, Ageratums, Verbenas, Coleus, Calceolarias, and a variety of other beautiful plants. Besides the two beds already mentioned, there were numerous others, the design of form; one especially beautiful, in the shape of the Prince of Wales' feathers, which was surrounded by beds that harmonised with it in colour as well as in form, all backed with the foliage of lovely trees. In almost every part of the park flowers as well as trees form an important feature in its laying out.

Tropical gardening is also carried on, and with very good effect, the undulations, banks, and glens being so suitable for the purpose. I noticed a most beautiful piece of work of this description laid out on a rocky bank; the Echeverias, Dracænas, Yuccas, and the different kinds of Sedums, &c., were in a most thriving condition, and very artistically arranged. The winding walks are a great advantage to this park, as you do not get the whole view at once, but at each turning come on something fresh and lovely in tropical gardening.

The scenery is more varied and charming in this park than I have seen in any other; in some parts you could imagine yourself miles in the country, seeing nothing but lovely trees and flowers—it almost reminds one of the dreams of childhood, or of an imaginary peep into Fairyland—instead of being surrounded by bricks and mortar, and those not of the brightest hue imaginable. One grand evidence of benevolence must be credited to the Baroness Burdett Coutts, in the shape of a massive and handsome drinking fountain, which I believe was erected at a cost of something like £13,000. It is chiefly composed of various kinds of marble and granite; it seems to be appreciated by the public. If such magnificent donations were more common, we might be sure of having our streets as well as our parks much freer from the effects of strong drink. Around this fountain is a well arranged garden, and pieces of water between each large bed of flowers, and at each corner is a splendid planted vase, all tending to make the crystal stream more tempting. I was fortunate enough to meet with Mr. McIntyre, the new superintendent, who appears to be the right man in the right place. A fine park is of little use unless made attractive by the energy and management of its superintendent, who should be thoroughly practical, and well up in his business.

I should advise all who are lovers of gardening to lose no time in visiting this place, for it so much pleased my friends and myself that I could not refrain from giving the public a short description of it. Although living within a few miles I had never before seen it, but I trust my first visit may not be the last. *B. S. W.*

Obituary.

We greatly regret to see the announcement in the "Revue Horticole" of the death of Professor Lecoq, of Clermont, in his 70th year. M. Lecoq was well known as a geologist and naturalist, who was possessed of a very wide range of knowledge. His *magnum opus* was a work on the geographical distribution of plants, as full of facts and inferences as the treatises of Mr. Darwin. M. Lecoq has left considerable legacies to the Botanic Garden and other institutions of Clermont, and has bequeathed to the town his valuable collections in all branches of Natural History. M. Lecoq was one of the distinguished foreigners who took part in our Botanical Congress in 1866, and charmed us with the fulness of his knowledge and the fluency of his speech.

August 17.—Light clouds prevalent during the day. Overcast at night. Rain fell from 10 P.M. till midnight.
— 18.—Rain fell till 5 A.M., and again at times during the day. Overcast till night; then generally cloudless.
— 19.—Variable till night; then cloudless. A fine day.
— 20.—The clouds varied rapidly from time to time. Windy.
— 21.—Generally overcast.
— 22.—Foggy in morning. Generally cloudy till night.
— 23.—Generally cloudy throughout the day. Rain fell heavily about 2 P.M., and thinly at times in the evening.

James Glaisher.

Miscellaneous.

Mr. Rucker's Orchids.—The following are some of the prices realised at Stevens' Rooms on the four days' sale of this magnificent collection:—

Masdevallia speciosa, bought by Mr. Rucker for M. elephanticeps, £5 10s.; Cymbidium eburneum, four plants, £8 10s.; Masdevallia candida, £6 10s.; Saccolabium guttatum, Mr. Rucker's No. 3 variety, £8; Epidendrum vitellinum majus, best variety, very fine plant, in flower, £16 10s. (Lord Londesborough); Odontoglossum triumphans Marshallinum, £7; Vanda Denisoniana, fine plant, 14 leaves, £5; Cattleya labiata, autumn-flowering variety, the finest specimen in the country, £36 15s. (Lord Londesborough); Vanda Batemanii, in flower, 22 leaves, £5 10s.; Phalænopsis amabilis, fine specimen, one of the three plants originally imported by Messrs. Rollisson, £8 10s.; Phalænopsis Schilleriana, £6 10s. and £4; Cattleya devoniana, £15 (Lord Londesborough); Coixa lugeus, very rare, £8 10s.; Aerides quinquevulnerum, fine plant, in bloom, 20 leaves, £7; Agræcum sesquipedale superbum, a fine specimen, £15 15s. (Lord Londesborough); Oncidium Barkeri, £7; Cattleya Mossiæ superba, splendid specimen, £6; Dendrobium Wardianum, fine plant, rare, £15; Cypripedium lævigatum, fine plant, two strong growths, £8 10s.; Aerides Veitchii, fine specimen, £22 1s. (J. Day); Aerides Fieldingii, Gomez Ingesus, very rare, £8 10s.; Aerides quinquevulnerum, fine plant, in bloom, 20 leaves, £7; Agræcum sesquipedale superbum, a fine specimen, £15 15s. (Lord Londesborough); Oncidium Barkeri, £7; Cattleya Mossiæ superba, splendid specimen, £6; Dendrobium Wardianum, fine plant, rare, £15; Cypripedium lævigatum, fine plant, two strong growths, £8 10s.; Aerides Veitchii, fine specimen, £22 1s. (J. Day); Aerides Fieldingii, Gomez Ingesus, very rare, £8 10s.; Cattleya exoniensis, fine plant, £12 12s. (Mr. Bockett); Epidendrum verrucosum or nemorale, £11 (J. Day); Vanda insignis, true, £12 12s. (Mr. Bockett); Dendrobium Wardianum, very fine variety, in bloom, £5; Pleione maculata, £7; P. Wallichiana, £5 5s.; P. humilis, £6 6s.; Aerides affine, Loddiges' old variety, £5 10s.; A. virens, Kenrick's variety, fine specimen, £5 10s.; A. larpentæ, £5; A. Lobbii, £5 10s.; A. Fieldingii, a very fine specimen, 30 leaves, £15 (W. Bull); A. rubrum, £5; A. Schræderi, fine plant, £6 10s.; Cattleya Reichenheimii, £7 10s. (J. Day); C. exoniensis, Tautz (W. Bull); C. labiata var. Sion House, £6; C. Schilleriana, magnificent specimen, £19 10s. (J. Day); C. amethystoglossa, fine specimen, £5; C. Leopoldi, £6 10s.; C. superba Chamberlainiana, £6; Lælia superbiens Dawsoni, £6; L. anceps Barkeriana, £8 8s.; L. elegans, a magnificent specimen, £20 (Mr. Hanbury); L. elegans Turneri, £7; L. elegans Wolstenholmiæ, £5 10s.; Phalænopsis Schilleriana, £5; P. grandiflora, fine plant, £5 10s.; P. amabilis, fine plant, £7 10s.; P. grandiflora, nice plant, £7 10s.; Epidendrum vitellinum and vitellinum majus, £6 10s. and £5 10s., fine specimens, in flower; Oncidium Kegenii, of which it is said there are but four plants in Europe, a piece of the original plant, £12; Cypripedium Harrisianum, £5 10s.; C. Veitchii, £7 and £5, fine plants; C. villosum, extra fine specimen, £10 (Jackson & Son); C. Lowii, fine plant, £5 5s.; C. Lowii, very fine, £6; V. Lowii, magnificent specimen, £20 (J. Day); V. cærula, fine plant, £6 10s.; Miltonia candida major, fine plant, £13 13s.; Masdevallia coccinea, £10 10s. (W. Bull); Cattleya Mossiæ, autumn-flowering, £10 10s. and £5 15s.; O. pulchellum, fine specimen, £12 10s. (J. Day); O. Phalænopsis, splendid mass, £7; Dendrobium crassinode, £6 6s.; D. Schræderi, fine plant, true, £12 12s. (Lord Londesborough); D. Devonianum, Veitch's variety, cidium eburneum, unmatchable specimen, £73 10s. (Lord Rendlesham); C. Mastersii, fine specimen, first rate variety, showing flower, £6 10s.; Angræcum sesquipedale, fine specimen, £5 5s.; Sobralia macrantha (Wooley's variety, very rare), £5 10s.; Dendrochilum filiforme, magnificent specimen, £18 10s.; Saccolabium guttatum, fine plant, £10 10s. The principal purchasers were Lord Londesborough; Lord Rendlesham; Messrs. Bull, Cannell, Tottenham; R. Haubury, Esq., the Poles, Ware; — Bockett, Esq., Clapham; W. F. Terry, Esq., Fulham; Rev. W. Ellis, Hoddesdon; Mr. B. S. Williams, Mr. W. Bull, Messrs. Jackson & Son, &c.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

Those shown by mid-winter decorative plants, *Poinsettias*, than which for that season there is nothing more attractive, should now in all instances receive their final shift. The summer or autumn-struck cuttings need not be put into large pots; indeed, those that were struck late, and are about 6 or 8 inches in height, will furnish fine large bracts in 48-sized pots only. Small thrifty plants of *Euphorbia jacquiniæflora* may also receive another moderate shift. Both of these subjects succeed in having their leaves frequently syringed with fresh water. Conservatories and showhouses will now require a considerable amount of attention in the matter of supplying a constant succession of flowering plants, and in regulating the growth of Creepers, &c. *Genistas* of the Reine Hortense and similar sorts must now be pushed along quickly. Small shifts only are advisable, and these into a compost of two parts of coarse fibrous peat, one of fibrous loam, and a good sprinkling of leafmould. Drain the pots effectually, and pot the plants firmly. Also continue to shift on *Heliotropes*, *Salvias*, and *Zonal* and *Scented-leaved Pelargoniums*. Tie up neatly *Chorosemas*, *Hoveas*, *Stephanotis*, &c., and so expose the wood of each that it may become well-ripened in due season. Give manure-water freely to Italian Tuberoses—*Pelanthes tuberosa*—now that they are showing, and give all their delicate but delightful fragrance. Carefully remove all old flowers from *Lechenaultias*, and look sharply after mildew both on these and on *Gompholobiums*, *Boronias*, *Heaths*, &c., as it is very likely to establish itself quickly at this season, especially amidst such alternations of temperature as we have experienced during the last few days. Thin out young seedling plants of *Mignonette* to five, seven, or nine plants in each pot. It is injudicious to leave them too thickly in pots of any size. Continue to maintain a moist warm temperature, and leaves properly shaded from bright sun. Endeavour, by affording as much air as possible, in conjunction with the maintenance of a sufficiently high temperature, to insure to all *Orchids* a suitable ripening period, for without this, whether the plants possess pseudobulbs or not, there will be but little hopes of attaining success in the flowering season. I have lately referred to the fact that red spider at this season readily attacks *Fuchsias*, which are flowering freely, also *Clianthuses*, *Acacias*, *Tacsonias*, &c.; therefore apply the syringe vigorously amongst them occasionally.

FORCING-HOUSES.

During dull cold days, such as are often experienced for short periods during weather fluctuations at this season, it will be necessary to apply brisk fire-heat to all *Vineries* containing Muscats in the last stage of ripening; as it is only by a high temperature that the rich aromatic flavour peculiar to this class is fully brought out. Of course this must be varied by the admission during the early morning—very early if fine and sunny—of fresh sweet air. Though a high temperature is necessary to insure a good "finish" to late thick-skinned Grapes of the Lady Downes type, it is injudicious to push them along faster than is absolutely necessary. See that all *Pines* which have set their fruits, and have commenced swelling, are afforded a liberal supply of wholesome properly prepared liquid manure. At this stage any assistance of the above kind is of much more benefit to them than if applied subsequently, when the fruit is three parts grown. The protection of fruit in *Vineries*, &c., from the ravages of wasps, flies, &c., should be well attended to now. The former are not so numerous this season as usual, but even a few will do much injury by puncturing the berries to their irremediable injury.

HARDY FRUIT GARDEN.

Strawberry plants grown for forcing should, as soon as the pots become tolerably well-filled with roots, be supplied with alternate waterings of liquid manure. Care must be taken, however, to afford them only that which is of very moderate strength, because to incite them too greatly at this season is to risk the formation of fresh leaves, and so to impoverish the crowns. Early *Pears* should be gathered two or three days before ripening, more especially if the sun has much power, as it forces the ripening process too quickly, to the deterioration of the flavour; but if gathered a day or two sooner, and stored in a cool place, the process is more gentle and the flavour better. Even in the cases of *Peaches* and *Nectarines*, it is better to gather them by anticipation than to leave them until such time as they may be endangered by falling, or by the tender mercy of insects. *Figs* ripening out-of-doors are attacked the most here in Essex, but it is necessary that they should remain upon the trees until fully ripe; and the only hope of saving any sweetness to the flavour is a few dozens of months' drying, moving them from those which are ripe and picked on to such as are next in order of ripening, and so on.

HARDY FLOWER GARDEN.

Proceed with all despatch in the matter of propagation. Insure a good stroke of desirable varieties of *Verbenas*, following with *Heliotropes*, *Fuchsias*, *Ageratums*, *Pelargoniums*, *Tropæolums*, &c., in rapid succession. Again I recommend the gardener to leave the *Calceolarias* until later on. Remove all flowers from *Dahlias* as soon as they are past their best, as they impoverish the younger blooms coming on. Where an autumn display of *Roses* is of importance, attend to the plants in the matter of removing too exuberant shoots, and encourage those having bloom buds at their apices. In addition to the mulching lately recommended as being a great aid to them, liquid manure of great strength may be afforded when the roots are moved with the tucking-in of climbing plants to walls, and fasten such as require it to pillars, &c. Attention must now be given to the selection and purchasing of bulbs for the ensuing spring display. Make the selection at once and give your order, remembering that the old adage, "First come best served," has a great deal of truth in it. Matters of taste vary so greatly that it would perhaps be superfluous to add anything regarding the varieties, but I may state that where any are required for forcing in pots this should be stated in the order. Single *Hyacinths* of various colours are remarkably beautiful, and take them all-in-all. Of *Tulips* the old double Tournesol is the most showy and generally useful. The dwarf single white *Roman Hyacinth* is a perfect gem when grown three or five in a small pot, and forced into flower at Christmas; it is, besides, the most fragrant. Bulbs should now be planted out permanently when it can be done without unduly interfering with such plants as already exist in beds or borders. Remove, as they continue to form, the side shoots or suckers from all plants of *Violets*.

KITCHEN GARDEN.

The late showers have proved of great assistance to vegetable growers. They have aided in setting a heavy successional crop upon *Kidney Beans*, which has begun to jerk off their blooms, as well as afforded an opportunity of transplanting successional crops of *Coleworts*, *Lettuces*, *Endives*, &c., dispensing materially with the thankless work of artificial waterings. Attend to the cutting down of all old flower-stalks upon *Globe Artichoke*; it not removed they tend greatly to impoverish the base, from which young shoots should now emanate sufficiently strong to maintain the stools in a robust state throughout the trying period of winter. Tie up *Endive* and a further batch of *Lettuces* for early autumn use. Finish transplanting *Leeks*, and sow a small and last sowing of *Turnips* upon a fully exposed situation. Thoroughly thin out the leaves upon fine plants of *Parsley*, transplanted and intended to stand the winter through. By these means firmer leaves will subsequently form, and the check will tend to harden each plant to withstand frost. *W. E.*

Notices to Correspondents.

APHIDÆ ON SPINACH: *C. C.* Sprinkle sifted wood ashes heavily over the bed after a natural or artificial shower, or heavy dew; be sure to let the ashes remain on the leaves till quite dry; then cleanse your plants by watering. *Alb. M.*

CUCUMBERS: *T. F.* Your Cucumber leaves are infested by myriads of a minute species of aphis, on which several small yellow larvæ of a Syrphus are feeding. Proper close fumigation with tobacco smoke will certainly destroy them. *J. O. W.*

FUCHSIA: *W. T.* By a light-coloured Fuchsia is meant one of those with pale tube and sepals. Those with scarlet tube and white corolla form a distinct group, and must not be classed with the light-coloured sorts.

GLASS: *W. Taylor.* The patent rolled glass—by which we understand you to mean that which is not clear, but cloudy—is not in favour either with plant or fruit growers. Better shade when necessary than adopt perpetual shade, except for such plants as Ferns or perhaps Camellias.

GRAPES ON TENDRILS: *J. M.* sends us an illustration of this not very unfrequent occurrence, which confirms the opinion that the tendril of the Vine is an abortive flower-stalk.

LATE SALES: CHRYSANTHEMUMS: *An Old Subscriber.* It is injudicious to keep your late every closed "night and day," as you cannot retard your late Grapes by such means. Give air freely by day, and with moderate freedom by night. As much have, by keeping them close, no doubt induced a somewhat weakly growth, enter upon this fresh phase of air-giving by degrees, so as not to expose them all at once to the searching influences of air from without. We approve of occasional overhead syringing of Chrysanthemums, and your future intentions regarding taking them up next month. You, doubtless, grow them in this manner to save labour, otherwise it is not the best way, if great success is looked for. They must be grown in pots from the first, if the finest possible blooms are required. Choose a moist, rainy period, towards the middle of the month, to pot them up, and aid them where the check occasioned thereby by frequently sprinkling the surface and by applying manure water to the roots. *W. E.*

NAMES OF PLANTS: *T. W. Smith.* Scolopendrium vulgare means by a variety of one of our common British Ferns.—*R. F., Tooting.* Spiræa bella of Sims (the Comely Spiræa).—*H. D. P., Redditch.* Your plant, found growing in a Clover field, is the common Melilot (Melilotus officinalis). —*J. E. B.* Abelia rupestris.

PEACHES: *T. Wilson.* The beginning of August is the usual period for early outdoor Peaches, but the seasons vary from one to ten days.

POTATO DISEASE: *Correspondent.* Surely you overlooked the phrase, "the nature of the disease is patent enough." The researches of Berkeley and others have put this beyond dispute, and we certainly did not intend to convey the impression that the cause of the disease was still unknown. We were alluding to the means of prevention or cure, as the whole tenour of our article shows.

PRIMULAS: *Constant Reader.* We cannot tell without seeing them why your rare Alpine Primulas won't grow. Probably the hot, dry season has been too much for them, and the cooler nights and moister skies we now enjoy will be more propitious.

PRIZES AT EXHIBITIONS: *R. B.* We cannot undertake to give lists of all awards made at flower shows.

RUST ON GRAPES: *R. H.* The discoloration of your Grapes seems to be an exaggerated form of rust, which arises generally from sudden chill, or cold draughts of air. The specimens are, however, scarcely sufficient for forming a good opinion. *M. T. B.*

STOVE PLANTS: *E. H.* We cannot, without far more information than your letter conveys, tell why your stove plants drop their flowers without expanding, and show a spindly growth. Probably it is from want of due and sufficiently early ventilation. As, however, you are in the centre of a city, the one may be caused by want of water, the other by want of light. Is there any escape from the flues, or any other appreciable impurities? Has the watering been duly attended to, but without excess?

WATSON'S LAWN SAND: *W. M.* See our advertising columns, or apply to your nurseryman.

Markets.

COVENT GARDEN,—Aug. 25.

Light supplies and a moderate demand have prevailed during the week in connection with home-grown supplies, but importations continue heavy, in Pears and Plums especially. West India Pines are over for this season; home-grown ones in rather better quality.

Nursery Business.—Partnership or Otherwise.

WANTED IMMEDIATELY, a thoroughly practical Man, with a capital of £2,000 to £3,000, to act as MANAGING PARTNER in a thriving Nursery within an easy distance of London. The Business is established, and in a most favourable terms. Part purchase money may remain.—VERITAS, 26, Park Road, Haverstock Hill, London, N.W.

WANTED, as HEAD GARDENER, in Sussex, an active, energetic, married Man, without incumbrance, thoroughly experienced in Grape Growing, Plant and Flower Culture, Rearing of Stock, Forcing, and general Keeping of a place in good order. Long character from last place as to ability, honesty and sobriety indispensable. Wife for Dairy. A good cottage.—Letters, stating service, wages required, &c., may be addressed to M. P., Mrs. King's, Duke Street, Portland Place, W.

WANTED, a MAN to take Charge of the Propagating and Forcing Houses in a Nursery near London. Address, in own handwriting, stating references and wages required, W. HOOPER, New Windsor Nursery, London, S.W.

Cheshire.

WANTED, a GARDENER, who thoroughly understands Flower and Kitchen Gardening. No glass. Age 25 to 30. State terms and references.—Box H. H. 7, Post Office, Manchester.

WANTED, a GARDENER and BAILIFF, who understands Meadow Land and Stock, also Wall Trees and Growing Cucumbers and Melons. Wife for Dairy.—Address, stating full particulars, including last situation and length of service, A. 2, 3, Hyde Terrace, Pinner.

GROUND WORKMEN.—Mr. AYRES is in IMMEDIATE WANT of steady and experienced Men to act as GROUNDSMEN.—Address with references and terms, W. P. AYRES, Nottingham.

FOREMAN and SALESMAN REQUIRED by LUCOMBE, PINE AND CO., Exeter Nursery, Exeter. No one who is not acquainted with the Nursery Business, and thoroughly competent to act as Salesman, need apply.

WANTED, an OUTDOOR FOREMAN, who thoroughly understands Fruit Trees, Roses, &c., and to act as Salesman at outdoor Plants.—Apply by letter only, giving references required, to DOWNIE, LAIRD, AND LAING, Nurseries, Forest Hill, S.E.

WANTED, an OUTSIDE FOREMAN, who understands Budding and Grafting Fruit Trees and Roses, Propagating Greenhouse Flowers, and is capable of taking charge of general Nursery Stock. Must be a good Salesman, and have first-class references.—DOWNIE, LAIRD, AND LAING, Nurseries, Forest Hill, S.E.

WANTED, as NURSERY FOREMAN, in a country Nursery, a good general Man, well up in Fruits, Roses, and with a knowledge of the other branches generally of the Trade and Nursery. Above all, he must know how to do his work, and to take the head of those employed.—Address, stating full particulars, B. S., Post Office, Ashford, Kent.

F. AND A. SMITH have an OPENING for a young MAN as Propagator and Grower of Soft-wooded and Bedding Plants, such as Zonal Geraniums, Hydrangeas, Phloxes, Penstemons, Verbenas, Dahlias, Bouvardias, &c. To an energetic and careful Man the situation will be permanent if otherwise suitable.—The Nurseries, Dulwich, S.E.

WANTED, a PROPAGATOR of Soft-wooded Plants.—A young, active, industrious Florist, of ability and good character, will meet with every facility, and be fairly remunerated. A permanent situation to a suitable person.—F. AND A. SMITH, The Nurseries, West Dulwich, S.E.

NURSERY FIREMAN.—E. G. HENDERSON & SON, St. John's Wood, N.W., REQUIRE a competent MAN to Manage Fires. State age, if married, and reference where last employed.

NURSERY CLERK.—JAMES DICKSON & SONS REQUIRE, for their Nurseries, a thoroughly respectable and competent CLERK, accustomed to Correspond, and who has filled a similar situation in a large general Nursery. State age, and all particulars as to experience, salary expected, &c.—"Newton" Nurseries, Chester.

BARK AND SUGDEN, 12, King Street, Covent Garden, W.C., are desirous of OPENING for a respectable, intelligent young MAN, who has just completed his Apprenticeship in a good provincial House. Preference will be given to one who has spent part of his time in a Nursery, or who has been some time employed in a Gentleman's Garden. Salary progressive, commencing at 21*l.* per week.

WANTED, a SHOPMAN, having a thorough knowledge of Garden and Flower Seed Requirements. One with some experience in the Cut Flower Trade preferred.—Particulars as to age, salary expected, &c., to DRUMMOND BROTHERS, 52, George Street, Edinburgh.

To the Seed Trade.

WANTED, ONE or TWO SHOPMEN, within a month or two, by W. DICKINSON & SONS, 58, Dawson Street, Dublin. Young Men just out of their Apprenticeship preferred.—Apply, stating age, length of service, and giving reference to last employer.

Seed Trade.

THE SUBSCRIBERS are in WANT of a thoroughly efficient SHOPMAN, well up in Garden and Farm Seeds; one having some knowledge of Nursery Stock and able to take short journeys preferred. An energetic and reliable Man the situation will be permanent and comfortable.—Apply, stating experience and salary expected, to SMITH AND SIMONS, Seed Merchants and Nurserymen, Glasgow.

WANTED, as ASSISTANT SHOPMAN, a young Man, of good address, and possessing a general knowledge of the Seed Business.—EDMUND PHILIP DIXON, Yorkshire Seed Establishment, Hull.

WANT PLACES.—Letters to be Post Paid.

To Gardeners and Bailiffs (Head, Foremen, or Under).

JAMES CARTER AND CO. having many applications for the above situations, find that the usual VAGUE ADVERTISEMENTS will send NAME, ADDRESS, and COPIES of TESTIMONIALS, LET ENTRY in their REGISTER. Only those who can send unquestionable references need apply.
Any Lady or Gentleman requiring GARDENERS or BAILIFFS may rely upon J. CARTER & CO. adopting the most stringent regulations in reference to testimonials as to ability, honesty, &c.

EXPERIENCED GARDENERS (or as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen.—Address, with stamp for reply, HENDERSON & SON, Wellington Nursery, St. John's Wood, N.W.

£10 WILL BE GIVEN to any person who procures for the above Advertiser a Man that he can APPROVE, or charge of a Department in an extensive Establishment. Has lived as FOREMAN in one of the best Nurseries, and can produce the recommendations.—G. N., 7, Edern Terrace, Langsdale Street, Islington, Liverpool.

GARDENER (Head).—Age 27, married; no incumbrance.—Well skilled in all branches of the profession. Good reference.—C. M., Flora Cottage, Lion Road, Bexley, Kent.

GARDENER (Head).—Age 46, married, no incumbrance. Near town preferred. Six and a half years' good character.—J. G., Eydes Hill House, Guildford, Surrey.

GARDENER (Head).—Age 29, single; 14 years' experience in the Cultivation of Stove and Greenhouse Plants, Flower and Kitchen Gardening, &c. Two years' character.—G. H., 7, Britannia Road, Surbiton, S.W.

GARDENER (Head).—Age 34, married; thoroughly understands the Management in all its various branches. No objection to Medow Land. Good recommendation from last and previous employers.—G. Hooper, Hounslow.

GARDENER (Head), to any Lady or Gentleman requiring the services of a thorough practical Gardener.—Has had extensive experience in Early and Late Forcing, also the cultivation of Stove and Greenhouse Plants, Flowers, and Kitchen Gardening. Can be highly recommended. Nine years' character.—W. G., 54, North Street, Bishop's Road, London, W.

GARDENER (Head), where three or more Men are kept.—Age 34, no family; thoroughly practical in each branch, and has a first-class character from present and previous employers.—S. WHITE, Barr & Sugden, 12, King Street, Covent Garden, W.C.

GARDENER (UNDER).—A respectable young Man, with three years' good character.—R. K., Post Office, Hildenborough, near Tonbridge, Kent.

GARDENER (UNDER).—Age 18; three years' experience in Forcing-houses. Good character.—A. V., 31, Lower William Street, St. John's Wood, N.W.

GARDENER (SECOND, or SINGLE-HANDED), in a Gentleman's Establishment.—Two years' character from last employer.—H. A., 2, Osborn Villas, Lee Green, S.E.

GARDENER (SECOND), or where he could improve. Age 21. Has had the Management of Stock.—Good character.—Z. V. X., 5, Norwood Terrace, Gipsy Hill, Upper Norwood, S.

FOREMAN (WORKING).—Thoroughly practical, and acquainted with the Propagation and Management of Nursery Stock, both in and outdoor. Good knowledge of Plants, and their names. Well known to most of the principal London Nurserymen. Will be disengaged end of September.—J. SMITH, 64, Hill Street, Newry, Ireland.

HORTICULTURAL BUILDER and REPAIRER, in a Gentleman's Establishment or Nursery, where the services of a thoroughly useful Man are required. Advertiser is an experienced Gardener.—J. S., 8, Chambers' Terrace, Victoria Road, Stoke Newington, N.

IMPROVER, in a Gentleman's Garden or Nursery.—A respectable Youth may be a Premium. Can be highly recommended.—G. D., Hanworth Rectory, Hounslow.

BAILIFF.—An experienced married Man, who understands Farming in all its branches, both Heavy and Light; thrashing, Reaping, and Mowing Machines; also all kinds of Stock. Has had good Dairy and Poultry Woman. First-class testimonials from late employers.—R. S., Post Office, East Grinstead, Sussex.

TRAVELLER or FOREIGN CORRESPONDENT.—Well acquainted with the English, German and French Seed Trade, and speaks and writes these languages fluently. Has already travelled successfully in the Seed Trade. Unexceptionable references.—P. W. V., 28, Fenelow Road, Warwick Road, Kensington, W.

Seed Trade.

TRAVELLER or SHOPMAN.—Good knowledge of the Trade. Highest testimonials.—L. B., General Post Office, Birmingham.

Seed Trade.

SHOPMAN (UNDER).—Age 19; has been in the Wholesale and Retail Trade. Good reference. Town or country.—M. J., *Gardeners' Chronicle* Office, W.C.

For particulars apply to

Mr. C. WILSON, Warwick.

Milcote, near Stratford-on-Avon.

HIGHLY IMPORTANT SALE of the MILCOTE DOWN SHEEP.

MR. HUTCHINGS has been honoured with instructions from the Executors of the late Mr. Thomas Fox, Esq., to SELL by AUCTION, at Milcote, near Stratford-on-Avon, on WEDNESDAY, the 6th day of September, at 2 o'Clock precisely, the whole of the celebrated FLOCK of MILCOTE DOWNS, comprising 48 Shearling Breeding Ewes and Theaves, 30 very superior Ewe and Wether Lambs, 22 grand symmetrical Shearling Rams, and 24 extraordinary Ram Lambs.

The great celebrity of this Flock demands a few words as to its formation. With Oxfordshire Downs as a foundation, the late Mr. Adkins, for many years, introduced occasional rams of the Cotswold and Hampshire Down blood, and with much judgment and careful attention succeeded in producing a magnificent type of sheep. With great size, grand symmetry, good colour, and hardy constitution, the Milcote Downs are remarkable for their great weight of lean meat and of wool, and for their early development and maturity. The rams will be brought forward in a natural and unforced condition, and the purchaser may with great confidence call attention to this Sale: and can assure Flockmasters that an entire Flock of such high character has not been offered to Farmers since the Exhibition.

Catalogues will be circulated in due course, and may be had of the Auctioneers, Milcote, Stratford-on-Avon.

Trains stop at Milcote Station as under:—From Paddington, Oxford, Birmingham, Warwick, and Bicester, 9.30, 10.40, and 11.18. From Bradford, Oxford, Moreton, Evesham, and Worcester, 8.25, 11.0, and 1.15

Brailes House, Shipston-on-Stour.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to announce that he has received instructions from Henry J. Sheldon, Esq., of Brailes House, Warwickshire, to SELL by AUCTION, at BIENNIAL SALE of PURE-BRED SHORTHORNS for THURSDAY, September 21, which will consist of about 40 Bulls, Cows, and Heifers, the property of Kirckevington and Fawsley blood. The Sire now in service is the 18th Duke of Oxford (25,998), bred at Holker from this justly renowned tribe of Shorthorns.

Catalogues, with Pedigrees, may be had on application to Mr. STRAFFORD, 11, Euston Square; or of Mr. SHELDON, Brailes House, near Shipston-on-Stour.

Ellington, near Kimbolton, Hunts.

VERY IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to announce for SALE by AUCTION, without reserve, on THURSDAY, September 28 next, the extensive and valuable HERD of PURE SHORTHORNS, bred by and the property of Mr. Laddy, of Ellington, consisting about 100 Head of Bulls, Cows, and Heifers; prominent amongst them will be found several fine specimens from Red Duchess and Princess, bred by Mr. Christ; Duchess, by Mr. Beasley; Farewell and Verbena, by Mr. Booth, as well as other old and favourite tribes of the Marquis of Exeter, Mr. Robinson, and other eminent breeders. First-class Bulls have been used for many years from Farnley Hall, Cobham Park, Revesby Abbey, and latterly, Cambridge Barrington 1st (14,623), bred by the Duke of Devonshire, Wellesley (9,542), from Lord Penrhyn's, and 2d Earl of Barrington, bred by Mr. Sheldon from the same famed line of blood: the two latter are now in service.

Catalogues, with Pedigrees, will shortly be issued, and further particulars given in future advertisements.

London: 13, Euston Square, August 24, 1871.

Upper Tooting.

A CHOICE COLLECTION of STOVE and GREENHOUSE PLANTS, in first-rate condition, the property of a Gentleman leaving the neighbourhood; including Orchids, Gardenias, Allamandas, Dracænas, Sophronitis, Begonias, Ericas, Camellias, very fine Azaleas, Epacrises, Oleanders, Aloes, Fuchsias, &c.

MESSRS. HARDING AND DEAN will SELL the above by AUCTION, at the Garden of Park House, Upper Tooting, on TUESDAY, September 5, at 12 o'Clock.

Catalogues of the Auctioneers, 4, Regent Street, Cheapside, 17, High Street, Clapham, S.W.

Shropshire Sheep.

THIRD GREAT SALE in the SMITHFIELD, SHREWSBURY.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, in the Smithfield, Shrewsbury, on TUESDAY NEXT, August 29, at 11 o'Clock to the minute, 140 Pure-bred SHROPSHIRE RAMS, and SHEARLING and OLDER EWES, from the noted flocks of—

T. Lloyd, Esq., of Aston Park, Shifnal.	Mr. Tanner, Frodesley, Salop.
Mr. H. Matthews, of Montford, Salop.	Lord Willoughby de Broke.
M. L. Meire, Esq., Eyton-upon-Severn.	Mr. Wedlock.
Messrs. Morris, Gare, Welshpool.	Mr. Williams.
H. J. Sheldon, Esq., Brailes House.	Mr. Yates.
	Mr. Yates, Grindle, Shifnal.
	Mr. E. Lythall.
	Mr. S. Ashton.

The above will include several Royal Agricultural Society Show Sheep, and amongst the Lots will be found many worthy the attention of the first Ram Breeders.

For Catalogues apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

MESSRS. LYTHALL AND CLARKE have received instructions from Mr. H. Matthews of Montford, for the Sale of about TWENTY highly-descended SHEARLING RAMS, and a Few older Rams, TWENTY SHEARLINGS and older EWES, to be held in the Smithfield, Shrewsbury, on TUESDAY NEXT, August 29, at 11 o'Clock.

The MONTFORD FLOCK of SHROPSHIRES was one of the first established, having been founded by the ancestors of the present Proprietor upwards of 200 years ago, since which period it has been kept entirely by Royal Descent, and has produced valuable sources from which to obtain sires of pure breeding and uniform character, and Flockmasters have always evinced a strong desire to obtain the Montford Sheep, as they have the advantage from the purity of their blood, hardihood of constitution, great size, high quality, firm texture of fleece, and true symmetry.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

ELFORD PARK FLOCK, NEAR LICHFIELD.

MR. MAY'S IMPORTANT ANNUAL SALE of PURE-BRED SHROPSHIRE RAMS and EWES.

MESSRS. LYTHALL AND CLARKE inform the Breeders and Feeders of Blackfaced Sheep that they will SELL by AUCTION, at 2 o'Clock, on TUESDAY, September 5, at Mr. Elford Park, by kind permission of Lord Lichfield, about FORTY First-class RAMS, and ONE HUNDRED large-sized healthy EWES and SHEARLINGS.

Elford Park is one mile from the Hasebur and Croxall Stations on the Midland, and Four miles from Lichfield on the South Staffordshire Railway.

An Omnibus will meet the 11.4 A.M. down train, and 12.10 and 12.18 P.M. trains at Tamworth.

The above are a genuine lot of Shropshire Sheep—pure in blood—very large in frame, full of wool and mutton—and very suitable for improving the stamina of a Blackfaced flock, or for crossing with other breeds.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, at New House, Sutton Maddock, Shifnal, on FRIDAY, September 22, at 11 o'Clock punctually, about FORTY First-class SHROPSHIRE RAMS, consisting of SIXTY SUPERIOR SHROPSHIRE EWES, and ONE HUNDRED SHEARLING and STOCK EWES, the property of Mr. Henry Smith.

The noted Flock of Mr. Smith has attained a position second to none among the Shropshires. It has secured the highest honours at the Royal Agricultural Society's England, the Birmingham, Smithfield, Bath and West, and other important Shows, where no fewer than 130 prizes in plate, money, cups, and medals, have been awarded to it. The Rams and Ewes which compose the Flock have inherited its superior merits, and the last three Royal meetings have amply confirmed its value, by the positions obtained by Messrs. Mansell, Lewis, Evans and Ewes.

Conveyances will meet trains at Shifnal and Coalport Stations. An omnibus will also leave Shifnal at 11.30, and return after the Sale.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Holly Bank, near Burton-upon Trent.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, on WEDNESDAY, September 13, PURE-BRED SHROPSHIRE SHEEP, FORTY RAMS; the HERD of FIFTY HEAD of SHORTHORN CATTLE, several of them being of pure Bates' blood; also, PIGS, IMPLEMENTS, HAY, and CHEESE, &c., the property of Willoughby Wood, Esq., who has let his Home Farms).

The Sale will commence at 11 o'Clock punctually.

Trains stop at Burton and Walton Station, on the Midland Railway, and at Wichnor Junction, on the South Staffordshire Railway.

ORDER OF SALE.

TUESDAY, September 12, Stock of Sheep.

WEDNESDAY, September 13, Implements, Cattle, Horses, Pigs, Poultry, Cheese, &c.

Luncheon on Tuesday at 11.30; Sale at 1 o'Clock.

Luncheon on Wednesday at 10.30; Sale at 11 o'Clock.

The Rams are the produce of Prize Wool Cutters, and possess plenty of muscle. The Ewes are remarkably true in character, with good heads, and very prolific. Trains at Burton and Walton Station, on the Midland Railway, and at Wichnor Junction, on the South Staffordshire Railway.

The Dairy Stock are remarkably well bred, many having three or four crosses of pure blood.

They are of great size, rich colour, and good milkers.

The Young Stock are worthy the attention of gentlemen wishing to commence with bred stock.

The Auctioneers can confidently recommend this Sale as a first-rate opportunity to any one desirous of establishing a high-class Flock of Shropshires or Shorthorn Herd. As Mr. Wood is giving up his farm, the whole of the Stock will be sold without reserve, and it is seldom a better bred or more useful lot of Sheep and Cattle are offered.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

THE THIRTEENTH GREAT CENTRAL SALE, at BINGLEY HALL, BIRMINGHAM.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, on THURSDAY, September 14 next, at 11 o'Clock punctually, TWO HUNDRED PURE-BRED SHROPSHIRE RAMS, and SIX HUNDRED EWES, from the noted Flocks of

The Right Hon. the Earl of Bradford.	
The Right Hon. Lord Wenlock.	
The Right Hon. Lord Leigh.	
The Right Hon. Lord Willoughby de Broke.	
Mrs. Beach.	Mr. S. C. Pilgrim.
W. C. Firmstone, Esq.	H. J. Sheldon, Esq.
Mr. Glover.	Mr. Dodds.
W. Lort, Esq.	Thomas Walker, Esq.
Mr. Lythall.	C. Stubbs, Esq.
Mr. Cox.	Mr. Yates.

And Others.

The above will include Prize Rams and Ewes at the Yorkshire and other important Shows.

Auctioneers' Offices, 39, New Street, Birmingham.

Early further entries should be sent to the Auctioneers before September 1.

THE LANDS IMPROVEMENT COMPANY.

(INCORPORATED BY SPECIAL ACTS OF PARLIAMENT.)

DRAINAGE, RECLAMATION, FARM BUILDINGS, LABOURERS' COTTAGES, TRAMWAYS, RAILWAYS, &c.

DIRECTORS.

John Clutton, Esq.	Granville R. Ryder, Esq.
Frederick L. Dashwood, Esq.	Granville R. H. Somerset, Esq., Q.C.
Henry Farnfar, Esq.	Henry W. West, Esq., M.P.
Lord Carlies, M.P.	Charles Watkin Williams Wynn, Esq., M.P. (Chairman).
John Heriot Maxwell, Esq.	

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy in respect of their Glebe Lands.

Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging the cost upon the Inheritance.

UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeemable principle and interest, over 25 years.

No investigation of title is required.

For Forms and further information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S. W.

Agricultural Land Improvements.

DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY.

(Incorporated by Act of Parliament in 1849.)

DIRECTORS.

T. Chapman, Esq., F.R.S.	The Right Hon. Viscount Combermere.
George Thomas Clark, Esq.	Edward John Hutchins, Esq.
John C. Cobbold, Esq.	Sir William Tite, M.P., C.E.
Henry William Currie, Esq.	

Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon advanced to Landowners on the most favourable terms by their own agents.

Tenant Farmers may also, by agreement with their Landlords, execute improvements on the Inheritance.

The outlay, with all official expenses, may be charged upon the Estate, and repaid by a Rent-charge, not exceeding 6 per cent. in 31 years, or at the option of the Landowners in a shorter term.

No investigation of title is necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, and Landowners for underlaying Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, discharging 10s a fixed period the principal amount with interest.

Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 76, Victoria Street, S.W.

CENTRAL ARGENTINE LAND COMPANY, LIMITED.

Chairman—JOHN HEGAN, Esq.

Agent in the Republic—H. HARRY WORMS, Esq., C.E., Buenos Ayres.

Superintendent—WILLIAM PERKINS, Esq., Rosario de Santa Fé.

The Directors offer, on advantageous terms to Settlers, Farms in the Argentine Republic, from 80 to 320 acres each, being portions of the COMPANY'S LAND, situate on each side of the Central Argentine Railway, from the City of Rosario to the City of Cordova, the entire length being 246 miles. Towns and Villages are being laid out at various points on the Line, and numerous Sites may be secured for Building purposes.

To secure the best class of Agricultural Settlers and facilitate the Emigration of Families, the Directors are prepared to treat for the Erection of Cottages, Buildings, Implements, &c.

Further particulars may be obtained at the Offices of the Company: 2, Crosby Square, Bishopsgate Street Without, E.C.;

Buenos Ayres—87, Calle de la Reconquesta;

Rosario—Central Argentine Railway Station;

Where the Surveys of the Land (about 1,000,000 Acres), together with the Plans of the Railway established, can be inspected.

GEORGE WOOLCOTT, Secretary.

85, Palmerston Buildings, Bishopsgate Street, London, E.C.

The Agricultural Gazette.

SATURDAY, AUGUST 26, 1871.

IT is said that our countrymen are less careful of SMALL GAINS than people on the Continent, where, so far as Agriculture is concerned, little farmers are obliged to look closely after little things, or the little freehold would soon be mortgaged! Great gains, especially in farming, are made up of small ones aggregated together like the pebbles in a mass of conglomerate; and it is by constant attention to details, picking up pebbles, so to speak, that they are accumulated. The endless varied details of farming, and the interest attaching to its operations and experiences have made it the subject of observations and of discussions which began with history, and promise to be endless. Most men thirst after agricultural knowledge, and some feel a longing desire for agricultural experience, and a farmer's affection for his art ceases in many cases to have any mixture of mercenary selfish motive. He lingers with the flock, or where labours and tillages are going on! How far he wanders sometimes out of pure affection! What journeys he takes out of mere romance, departing periodically, with cost and pains, to some distant show or sale, like a tame raven that stirs himself in the spring time and hops off, nobody knows where, moved by some curious instinct nobody can define. How earnestly he watches the procedure at distant farms, on spots not so hallowed as his own homestead, but where he hopes to gain a wrinkle! How eagerly he listens when the professor or adept propounds the words of science, or of approved and most recent practice! How instantly he strikes in among neighbours at the market table, or wherever ideas are moving, and likely to be bagged! How he ponders in his mind afterwards by his own fireside, notions old and new—all he has heard or found out rumbling up and down in his head!

Surely something must come of all this

endeavour. Progress — an advance towards something not yet reached — must and does come of it. In agriculture the advance — in knowledge and profit — was always slow, and we believe it always will be; so we cannot afford to lose either in knowledge or effects. The lose of the nine books on agriculture that MAGO the Carthaginian wrote, was a most melancholy thing, which mankind have never ceased to deplore. Nothing can be spared, and nothing should be lost or thrown away, not even the Journal, which may contain nothing but a dish of pseudo-chemico-agricultural twaddle.

This is an age for restorations, and we propose to lay before our readers a leaf of one of the lost books of MAGO, which we are assured related to small economies in agriculture, such as are met with in the poorer districts of England, where agricultural lessons of no small importance may sometimes be learned.

Our earliest experience was on such a spot, far removed from all examples of modern grand farming, with central homestead, factory-like. The portable steam-engines and threshing-machines came to disturb us about the year 1864; till then we had no machinery except turnip-cutters, chaff-knives, and a grindstone. We had nine barns, and as many pairs of flails at work in the winter.

From a bold promontory or "corner" on the downs, with the tableland behind, and the sheepwalk and Furzes around and on the slope, we overlooked our big farm with the eight little homesteads, pictures of comfort for stock; the rich land in the valley, the broad acres of Turnips, the little copses and the "mount," where we grew our hurdles, the trout streams, the distant tower in the village, and a black heath beyond, fringing our domain with as poor and dreary a sand tract as any in Surrey, with Fir-clad sandhills bounding the view, and forming a waste where we have blushed at the blackcock, and been astonished by the capercailzie, which the squire introduced but never naturalised.

This pleasant spot is by no meanas ill-farmed. In the autumn, any time after September 1, the farms around smell of early Turnips, the folds are set, and the sheep bells tinkle, making music as though the country rejoiced in the fold; and no doubt it does, for we have ourselves pitched the finest white Wheat on the waggons—carts we despised; loaded 16 qr. of Oats per acre, and had a hand in Mangel crops of 40 tons for in return for a great deal of sport in the trout streams and copses work was expected from young hands at busy times.

It was easy to make both ends meet, and something more, on the flats and in the bottoms, and it was easy to lose your small gains within a stone's-throw on the "brows," where the deep marls were mixed off to thin chalk or ironstone sand, bearing naturally little but sorrel (sorrow). The neighbourhood is the home of industry and economy of that humbler kind which the wise MAGO informs us is sure to be rewarded.

It always turned out wrong to run a-muck against the old habits and customs; they did not yield easily to new-fangled ideas—an innovator generally burnt his fingers. So when one collected the Mangel leaves and pickled them, the sands cried out, "Plough them in for manure!" and the cattle said, "We won't eat your sour krout!" When another sowed Swedes before June 1, the mildew observed, "Too soon!" and settled upon the leaves about the end of August. When chemists first went about lecturing and recommending "phosphorous for Turnips," our loams answered, "Not here!"-and we learned to gain our practice on the farm and to seek explanations only in the laboratory. In those days little confidence could be placed in chemists and scientific teachers, who generally promised more than they could perform, and were very often too much elated by something they had found out. But we could always rely, then as now, on farmyard manure and the sheepfold. We observed, after breaking up our Furzes by grubbing and ploughing, that Rape and Oats were the best crops; Wheat was peculiarly liable to blight until after some years of high farming. We noticed too that the Whortleberry grew over several miles of country on the left of a certain lane, while on the other side of that boundary, on the same formation of sand, scarcely a plant was to be found. Tares, too, which on Romney Marsh are the best possible preparation for Wheat, even when they have been saved for hay, ruined some of our land for several years, though they were eaten on the ground by sheep. Mangels, sowed afterwards, turned yellow, "stuck up," and refused to grow. Scientific men could not explain these things, and they did not affect to do so, but several pretenders to science pretended to explain them; and in those days —early days for agricultural chemistry — there were more mountebanks and enthusiasts in the agricultural world than there ever will be again perhaps, the word went round, "Another great discovery!" and the answer came back, "Wonderful!"

Caution and observation enabled us to retain those small gains which some people—gaining too fast and innovating too much—converted into losses. Guano was by far the most valuable of the innovations about that time; it started the Turnips, and laid the foundation for corn, that filled the nine barns fuller than they had ever been filled before. We had thought of "centralising" the barns, but, instead of that, they were repaired and rebuilt, and they greatly aid the small economist in cartage of straw, manure, and roots.

When COBBETT called, on his rural rides, and praised our Cabbages, we had not carried out all our economies; we had not then laid open our fields, or formed sheepwalks connecting the downs with distant parts of the farm, and the belt of clay (gault) under the hill—a mere strip, seldom wider than a single field—was, here and there, a little wet. In a light land district draining was not among the economies that were understood; it would have cost a good deal to dig a main drain to carry the water away, and we did not immediately think of digging a hole in the sand below and letting it soak away.

When COBBETT rode by, the selling value of the poorer sands was about £20 an acre. Most of it is now worth four times as much, and some of the knolls, for building on, have sold at £600 an acre. Railways have brought the whole district to the gates of the great metropolis, and many little industries and small gains have now been created in connection with luxuries and the general produce required for a wealthy population.

We propose to give a column on our practice in saving our own Turnip and Mangel seeds, which saved us some pounds a year in seedsmen's bills, besides a considerable gain in the weight and quality of our crops. This is one of those small matters of detail which are important. Mr. HENRY DRUMMOND, the popular member for West Surrey, and a shining light in the agriculture of the county, used, 30 years ago, to end his agricultural addresses with the pregnant words, "Go and buy guano!" Guano has degenerated. Our lives and fortunes change in a moment, and it is not surprising that advice which was good in our youth should be bad after 30 years. Let us conclude with words of more stability, and say, "Go and save your own seeds!" There is nothing in MAGO's lost work that would bring so much gain and satisfaction to modern farmers as the improvement, by selection, of the plants they cultivate.

THE supply of English Wheat at Mark Lane on Monday was small, and sold readily at the previous Monday's rates; and Wednesday's market, prices had a downward tendency.——On Monday, at the Metropolitan Cattle Market, choicest qualities of beasts brought nearly previous prices, and this remark holds good for Thursday's business. Little alteration in sheep and lambs.——For Hops the demand is steady: the plantations are improving.

—— Many of our readers will hear with deep regret of the death of Mr. RICHARD STRATTON, of Burderop, so long known as a successful breeder of Shorthorns, and an eminent agriculturist. We understand that Mr. STRATTON died at Winchester on Tuesday, the 15th inst., after a long illness.

—— When the ordinarily silent AGRICULTURAL LABOURER speaks, it is only fair that we should listen to him. Says a contemporary:—

"A meeting of some significance was lately held at Leintwardine, a village on the borders of Herefordshire and Shropshire. The audience consisted entirely of agricultural labourers, the chairman, Mr. STRANGE, having himself risen from the rank and file of rural industry. The chairman, in a long address, after describing some of the difficulties of the farm labourer, recommended as the main remedy the division of farms into large, middle, and small sized farms. He said—'Let us for a moment look at a large farm, say 600 acres. Now, out of that take a farm of 200 acres, and one of 100 and two of 50 acres each; there you see would be four families living where only one now lives; or, suppose we took another of 600 acres. Suppose we cut that take one of 300 acres, one of 100, two of 50, and three of 33, you will then have seven families where now but one lives.' And though admitting that the large farmer may employ as many labourers as the aggregate body of smaller farmers, amongst whom it is proposed to divide the large farm, Mr. STRANGE contended that with smaller farms there would be more work for the local tradesmen, and that the landlord, notwithstanding the necessity of keeping up more farmhouses and steadings, 'would not have to build such mansions as are called for on gronped farms.'

"Then a discussion followed, and both the chairman and the labourers concurred in demanding better cottages, some of them wishing to rent their cottages directly from the landlord, and not from the farmers for whom they work.

"But the main burden of the labourer's complaint was lowness of wages. One man 'had a wife and two children to keep on 12s. a week.' Another 'thought it only reasonable and right that they should have 15s. per week.' A third remarked, 'that if a man worked two or three hours overtime he ought to be paid for it.' One man had a wife and seven children, with wages of 9s. a week.

"Then one speaker said—'They ought to be bound to give us wages enough to bring up our children properly;' while a subsequent one said—'We get our masters to lower the rent and raise the wages.' And THOMAS GREEN thought they wanted a labourer's club-room. ... Through competition, if one man did not take the work from a farmer another did, and so, through the men not sticking together, they lost ground gradually. If labourers would only stick to each other, and stick out, they might do much, as the farmer could not do without them.'

The labourer then perceives that he ought to be better paid and better housed, and concludes that "they ought to be bound to give us wages enough." Since, however, it must be evident to every thinking man that "they" never will be coerced into giving a fixed wage regulated by Act of Parliament, some better suggestion must be offered. A kind of trade union is, indeed, still possible, whereby "if labourers would only stick together and stick out, they might do much." Much harm and much misery might accrue, no doubt, but eventually little good could be effected in this way. Colliers and workmen in iron works for years past seen many instances of their employers quickly accumulating gigantic fortunes, and this spectacle, together with the sense of their own united power, raised the question why they should not be better paid, and thus participate in a general prosperity. Such, however, is not the case in country districts. Landlords and tenants barely get more than ordinary interest on their capital, and labourers are badly paid. No county class suffers from plethora of wealth, and an increase in labourers' wage would be enough to ruin many an endeavouring tenant. But these labourers urge in their dumb way, "We get our masters to lower the rent and raise the wages." Quite impossible. Competition is too strong a tide to be thus stemmed, and no economist would recommend a compulsory regulation of rent. Two courses appear open to us in this difficult but all-important matter:—First, "co-operation" between labourers and masters, in which mutual help would result in mutual advantage; in which the labourer would rise in prosperity with his master, and in which the well-being of the master would become the aim of every labourer. Secondly, legislation, not direct, but indirect, upon which subject we again have recourse to our excellent contemporary the *Economist*:—

"Now, the first requisite to any general advance of agricultural wages is a better system of managing landed property. Abrogation of game preservation, long and rational leases in place of yearly occupation, and the due performance by the owners of such durable improvements as properly belong to them, are the main points on which the wages question depends. All these are entirely within the control of the landowners and beyond the control of the farmers. Whether the searching scrutiny to which the law and practice of landowning in England is becoming subject will awaken the landowners to something like a realisation of their duties and interests it is difficult to say; but if England is to continue the paradise of landlords they must look about them, and that without loss of time. On the other hand, it should be pressed on the attention of the labouring classes that the reckless way in which they marry very early in life, without having made any kind of provision for a family, has much to do, not only with the pressure which they individually sustain from numerous families, but also with the competition which exists among them for employment."

We have passed over Mr. STRANGE's suggestion of dividing farms as thoroughly unpractical and impossible, however essential it may appear to him and those who think with him.

—— Although farmers cannot fairly be blamed for the many shortcomings of which our RURAL ECONOMY is guilty, yet it is evident that their inertness as a body allows many injurious customs to continue, and hinder reform. Mr. EVERETT spoke correctly before a recent meeting of the Lavenham Farmers' Club, when he said:—

"There were no men in this country that were less public men than farmers, or that took less interest in public affairs. The gentlemen present this evening knew very well how difficult it was on any occasion, and with regard to any questuon, to convene a meeting of farmers in large numbers. There was a good deal of reason in it. The whole tenour of a farmer's life was to make him a quiet, home-loving bird, whom it was difficult to drag out of his cage when once returned to it from his day's labour. He thought that in this matter the farmers had been much to blame. It became every man in a land like England to take some part in public affairs. The want of public spirit, however, seemed to be in some degree

diminishing; and the great progress that had been seen to take place in reference to the formation of Chambers of Agriculture was, he took it, a good augury for the future."

Farmers have paid much attention to the direct improvement of their land and live stock, but there are certain grave questions regarding their position as citizens, and their relations to their dependents, which as yet have not received united action. It is high time that this indifference should be abandoned; and we venture to assert that, if the tenantry of the country, with united and intelligent voice, spoke their convictions regarding tenant-right, leases, security of tenure and capital, game, Poor-law administration, and the obstructive character of our present land-laws, they would not express their opinions in vain.

—— Mr. T. CHANDLER thus writes from Devizes on the STATE of the CROPS in WILTSHIRE, under date of August 16:—

"The harvest is now general, and the farmers are taking advantage of the present glorious weather to gather in their crops with the greatest expedition. By the assistance of the improved machinery for cutting and harvesting, they are enabled to cut the corn before it is too ripe, thereby preventing great waste as well as a deterioration of quality. A fortnight or three weeks of such weather as we are now blest with will leave but little corn unsecured. The journey that I had reserved for my last inspection has been on Salisbury Plain. Getting a lift as far as the 'Bustard,' I took a southerly direction through Elstone to Orcheston, Tilshead, and Lavington. The Wheat on the down land as well as the field is bulky; and, notwithstanding the sheaves are not so heavy as in some years, it may yield a fair crop. It is very much improved in appearance during the last 10 days, and the samples generally are plump, and a good colour. It would be presumptuous at present to hazard a decided opinion as to the yield. This will soon be determined by that unerring standard of truth in such matters, the threshing-machine. The experience of past years may to a great extent serve as a guide as to the probable yield of the present year. In taking a retrospective view of the weather during the past three or four months, and comparing it with corresponding months, in years when the harvests have been very productive, I fear 1871 will not bear a favourable comparison. At the critical period of blossoming and for some little time after, the weather was very cold, boisterous, and unkindly, and although the moisture considerably increased the growth of straw, it was not at all genial for the grain. It is to be hoped the beautiful forcing weather of the last fortnight may to some extent counterbalance the want of heat in June and July. Taking these facts into calculation, I do not think we must expect the yield from the straw to be equal to the average of years. That there is an average amount of straw throughout the country will be generally admitted, but, as in many instances, where the plant of Wheat was thin, the butts of the sheaves are filled with Poppy and Charlock, their appearance is very deceptive. I was sorry to observe, in passing through the district I have named, which is so celebrated for its Barley, that a marked change for the worse in that grain had taken place within the last few days. After rubbing out a great many samples, I unhesitatingly say I did not meet with a really choice one. This remark is not confined to this district only. In the kindly soil from Everleigh through Upavon, &c., the Barley is little better than tailing. Barley is the most deceptive crop that is grown. It may look as promising as the most sanguine could wish till within a few days of its ripening, and turn out badly after all; which I fear will be the case this year. Fields that a fortnight ago indicated a yield of 6 qr. per acre are now more like four, with a quality not so good by 4l. or 5l. a quarter. The Peas, a good crop, well harvested. Beans much improved. The Turnips, &c., on the hills require rain, where they have not been fortunate enough to meet with showers."

—— Respecting the HARVEST in HAMPSHIRE, the *Hampshire Advertiser* informs us that:—

"The work done in this locality during the early part of the week was something enormous. A large portion of the Wheat crop has been cut and got into shock. Steam threshing has also begun here and there in the open field; the yield is no doubt good, but we have heard from the lips of harvestmen, probably full of the idea that they themselves ought to get a larger dividend, that there are 16 sacks to the acre. We do not believe that the average yield is nearly doubled, but the prospects of the farmer at present are very encouraging. Some of the soldiers from our barracks have been allowed to go out and help to gather in 'the kindly fruits of the earth,' and the good humour with which they return after the day's labour shows that they appreciate the liberty to toil. Barley, in many fields, will be an uneven sample, the recent heavy showers having caused a good deal to be laid. The crop of Oats is a splendid one, and though the disease has shown itself rather strongly amongst the Potatos, a few days' sunshine has arrested it, and we hope no very great amount of mischief has been done."

—— Of the POTATO BLIGHT in IRELAND, *Bell's Weekly Messenger* says:—

"We regret to learn that the Potato blight has broken out with great virulence in Tipperary. It is said that in some places fully nine-tenths of the tubers have rotted already, and the remainder is despaired of. In fact, says a telegram, there has not been such a heavy visitation since the great famine 25 years ago; and, were it not for the favourable condition of cereal crops, the consequences might be as disastrous as then to the peasantry. In the neighbourhood of the Potato land the air is most disagreeable from the oppressive odour caused by the blight."

—— The RECENT HEAT is the subject of a letter in the *Times* from Mr. F. NUNES, Heathfield Lodge, Chiselhurst. In this communication the writer says:—

"The following very high temperature, which we have experienced here from the commencement of the present month, may perhaps prove of interest. The thermometers are standard instruments, the one in the sun being in vacuo, and placed on the grass. It will be seen that on three consecutive days—viz., 11th, 12th, and 13th, the temperature in the shade stood at or above 91°, certainly quite the ideal conception of "harvest weather."

Date.	Max. in Shade.	Max. in Sun.	Date.	Max. in Shade.	Max. in Sun.
Aug. 1	78.1	147.0	Aug. 8	81.0	147.0

,, 7	81.8	148.0	,, 14	84.6	145.0

—— We hear of several instances of DEATH in the HARVEST FIELD. The intense heat has for some days made it very difficult for labourers to work in the harvest fields in Devon and Cornwall, and on Monday a man named ROGERS expired very suddenly while at work near Kingsbridge. Two cases of sunstroke are reported from Cornwall.

SOVEREIGN (27,538).

FEW bulls have been more successful prize-takers than Mr. Chaloner's SOVEREIGN (27,538), whose portrait we are enabled to place before our readers, through

FIG. 256.—SOVEREIGN (27,538).

the kindness of his courteous owner. The woodcut (fig. 256) is from a photograph by Mr. Newman, who was employed by Mr. Chancillor, Lockville Street, Dublin. Rather more than a year ago we described SOVEREIGN as he appeared at the Dublin spring show, as follows:—

"A handsome bull of light roan colour, very deep and massive, with rather drooping quarters, and withal an excellent stock-getter. The honours he has won for his well-known owner and breeder have been exceptionally high. On Wednesday, April 20, he was awarded the Towneley or *Irish Farmers' Gazette* Plate, valued at £155, and the Irish Railway Challenge Cup, value £150. The latter prize will be permanently retained at King's Fort, Mr. Chaloner having won it three times consecutively with the same bull, thus removing it from further competition. The Towneley plate is still afloat, owing to BOLIVAR having won it in 1868, thus breaking the continuity of SOVEREIGN'S successes. That this bull's stock are true to their ancestry has been sufficiently proved at King's Fort, and, as an instance, we may mention that of SIR LEOPOLD, the winner of the prize for calves dropped in 1869, at the same show. Although his thighs are a trifle light at present, age will probably supply the deficiency. In general he may be described as a thick-fleshed bull, of rich colour, with much of his sire's style about him, and wonderfully altered since he appeared in the sale ring at King's Fort 12 months since, and was bought in by Mr. Chaloner at 12 gs. The pedigree of such a bull as SOVEREIGN is an interesting study to the breeder. He is now just four years old: he was by Mr. K. Booth's ROYAL SOVEREIGN, and from Mr. Torr's *Village Rose* by BLOOD ROYAL (14,169). The following diagram,

which takes up his pedigree immediately after *three consecutive crosses of* WESTERN COMET (689), according to the fashion of the old breeders, will assist the reader in tracing his lineage :—

A Cow, the result of three consecutive crosses of WESTERN COMET (689). — FREDERICK (1066).

White Fan. — 2D HUBBACK (1425).

Wharfdale Lady. — PILGRIM (4701).

Village Belle. — SIR LEONARD (10,827).

Wharfdale Maid. — CROWN PRINCE (10,087).

Village Maid. — BLOOD ROYAL (14,169).

Village Rose. — ROYAL SOVEREIGN (22,802).

SOVEREIGN.

ROYAL SOVEREIGN was very full of BUCKINGHAM (3239) blood, and traced back directly to that noted sire through his 4th g dam. BLOOD ROYAL, an Aylesby bull, was by DUKE OF BOLTON by GRAND DUKE (10,284), which at once connects SOVEREIGN, not very remotely, with the famous Bates' Duchesses, GRAND DUKE being out of *Duchess 92*; CROWN PRINCE and SIR LEONARD again take us back to the noted sire BUCKINGHAM, through *Charity* and *Cherry Blossom ;* so we see in SOVEREIGN an animal whose pedigree contains the best strains of the two rival families of Shorthorns so long associated with the names of Bates and Booth."

Since then, and during the present year, he further signalised himself by securing the Towneley or *Irish Farmers' Gazette* Challenge Plate, the Purdon Challenge Cup, Gold Medal, &c., at the Dublin Spring Show, where he was greatly admired. The *Irish Farmers' Gazette* then notices the competition in question :—

"In the section of bulls, three-year-old and upwards, there were 24 entries, among which were several well-known winners at previous shows. Mr. Chaloner's SOVEREIGN was again exhibited in this section, and, as formerly, took his place at the head of it. Not only did he win the 1st honours as an aged bull, but he also won the Towneley or *Irish Farmers' Gazette* 150 gs. Challenge Plate, as the best animal in the breeding classes of neat cattle, male or female. SOVEREIGN won the plate first as a yearling in 1867, but he dropped it in 1868 to BOLIVAR, taking at that time, however, at that time the Railway Cup, which he permanently won last year for Mr. Chaloner. The bull, therefore, has now fairly came back to him in 1869 ; and, as he also won it last year, and now for the third time in succession, it, too, would have become a fixture at Kingsfort, were it not that Mr. Chaloner, in his usual generous spirit, has presented it to the Society, to be again competed for under similar conditions as those which have hitherto been attached to it."

OUR LIVE STOCK.

CATTLE.

A SHORTHORN and Hereford Herd Book is in course of compilation in New South Wales, by a committee appointed by the Council of the Colonial Agricultural Society. The revision committee consist of Major Lowe and Mr. Alexander Brace, and the following rules have been constructed with reference to entries :—

1. All stock entered in the English Shorthorn and Hereford Herd Books.

2. All colonial bred cattle descended by an unbroken pure line from those mentioned in No. 1.

3. All stock which can be traced for two generations to pedigree sires and dams.

4. All cattle bred without admixture from stock entered in the Shorthorn or Hereford English Herd Books, but whose pedigree cannot be traced—upon the owner producing a certificate from the breeder, that to his personal knowledge the cattle in question had for three generations at least been bred accordingly.

5. Entrance fees, *2s. 6d.* each.

Several breeders have already furnished contributions to the proposed work.

SHEEP.

THE exceedingly improbable story, related by Mr. Thomas Bell in his newly published "History of Improved Shorthorns," relating to Leicester sheep, is not likely to add to the credit of his volume. He introduces us pleasantly to many worthies of the last and previous generation, and among others to Bakewell, Waistell, Maynard, the Cullys, &c. ; and the book, so far as we have made its acquaintance, is pleasant to read, and doubtless contains much information on dubious points connected with the early history of Shorthorn cattle. We should like to hear the opinion of Leicester sheep breeders on the following anecdote :—"Mr. Bates often mentioned a fact which showed Mr. Waistell's discernment (?), and it was this. 'Mr. Bakewell," he said, 'had concealed from the world how he had produced that wonderful improvement in his flock, but if the truth were known he was sure that it would prove he had done it by the use of a black tup.' Seventeen years after Mr. Bates heard Mr. Waistell state this, he named it to a gentleman who had visited Mr. Bakewell in his early career as a breeder, and he said that, 'While staying with Mr. Bakewell I observed that there was one part of his premises he never showed me, and I got up very early one morning, and went and examined those premises, and I there found a black tup, a most extraordinary sheep ; but as it was a liberty I had taken, I never named it before to any one.' This he told Mr. Bates, which confirmed what Mr. Waistell had said. Mr. Bates stated that he had learnt from good authority that Mr. Bakewell bought this black tup at Ashbourne Market, in Derbyshire, and that the fact was well known there by those who saw Mr. Bakewell buy the black tup. Mr. Bates stated that he had good authority for saying that of late years black lambs occasionally came from Leicester ewes, though none were ever seen in Mr. Bakewell's day, which is a strong proof as can be given that animals breed back even to remote ancestors, &c." It is our opinion that Mr. Bakewell's inquisitive friend found a mare's nest ; that it is exceedingly unlikely that Mr. Bakewell should have used a black ram, and still more unlikely that, had he done so, there should have been no black lambs dropped in his day. That black lambs are now produced occasionally in Leicester flocks is no proof of the truth of the above "cock-and-bull" story, for black lambs will occur in any breed of sheep. We append a few well-considered sentences from the pen of Mr. Darwin, which may throw light on the occasional occurrence of black lambs :—

"There is reason to believe that sheep in their early domesticated condition were 'brown or dingy black,' but even in the time of David certain flocks were spoken of as white as snow. Among the classical writers of ancient Spain are described by several ancient authors as being black, red, or tawny. At the present day, notwithstanding the care which is taken to prevent it, parti-coloured lambs and some entirely black are occasionally dropped by our most highly improved and valued breeds, such as Southdowns. Since the time of the famous Bakewell, Leicester sheep have been bred with the most scrupulous care, yet occasionally greyfaced, or blackspotted, or wholly black lambs appear. This occurs still more frequently with the less improved breeds, such as the Norfolks. As bearing on this tendency in sheep to revert to dark colours, I may state that the Rev. W. Darwin Fox has informed that seven white Southdown ewes were put to a so-called Spanish ram, which had two small black spots on his sides, and they produced 13 lambs, all perfectly black."

—— A correspondent in the *Field* of last Saturday draws attention to the cruelty practised by farmers in docking lambs. This "friend of dumb animals" says :—

"On questioning farmers why they do it, I am informed :—1. That the fat would all go to the tail. 2. That lambs look bigger afterwards. 3. They would get so dirty. 4. They would suffer more from maggots. 5. That it strengthens the back. Where so many bad reasons are given, a good one is generally wanting.

"In reply to the five objections :—1. There is no more fat on a full-grown sheep's tail than on a lamb's tail. 2. There is a great loss of wool by the operation on a flock of, say, 400 sheep. 2. While I could never see that it made them look bigger, I feel no man who would exercise his power for such purposes is fit to own a flock. 4. As for the 4, If getting dirty is the reason, the same argument would deprive them of their legs. 4. Are not tails sent to brush off the flies, which are the cause of the maggot ? 5. If it were to lose my arm, it would not strengthen my back."

We differ from the writer of the above. First, because we think the reasons given by the farmers on behalf of their custom are conclusive ; secondly, we cannot help noticing that the replies to what the farmers urge in extenuation of their practice, indicate clearly enough to what the writer meant to express, probably the result of defective knowledge upon rural affairs. First, then, regarding the statement "that the fat would all go the tail." Having never heard such a reason given for docking sheep, we are inclined to think the farmer or farmers have been "taken up" somewhere. The fat, of course, will handle better at the rump, just where the tail is set on, than a long-tailed sheep. Hence, allowing the tail to grow long deprives the carcase of a good handling point. We do not believe there are facts to warrant the statement that the fat would all go to the tail, but rather that the "tail head" would not handle so well. We pass over the second reason as an insufficient one for continuing the practice of docking, and we quite agree with "a friend of dumb animals," that it is inadmissible. The third and fourth reasons are, however, the best that can be given for "docking." Could sheep be kept on natural food, their tails might be left intact, but being for the whole period of their short existence under artificial conditions, subsisting on Turnips, cake, meal, and other purchased foods, they are very apt to "scour," or, in other words, to suffer from diarrhœa. Under such circumstances if this the shepherd is compelled to trim the wool from the posterior portion of sheep so affected, and if he had to contend with long-tailed sheep, his task would be rendered much more difficult. Were we, however, to follow the suggestions of this mistaken friend of dumb animals, and to leave the matter entirely to Nature, they would speedily be in the most deplorable condition of wet and filth. Unless sheep are kept *clean*—and we hope that this sheep's friend, should these remarks catch his eye, will now understand what is meant by the word—they will in spring and summer, previous to the clipping season, be exceedingly liable to maggots, and, from our own observation, we can state that the tail of a sheep, when allowed to remain intact, cannot be used to brush away flies, but is only capable of movement within exceedingly narrow limits. To leave a flock of sheep undocked would greatly increase the cost of sheep-herding, and instead of a gain there would be a diminution of wool from the increased amount of trimming that would be necessary, and the damage to other portions of wool from the accumulation of filth.

CONSIDERABLE interest has been aroused in South Australia regarding the Angora goat. Since every animal which ministers to our wants is of importance and interest, we abstract from the Journal of the Agricultural Society of New South Wales, a letter from Mr. Binns, which affords more information respecting the various breeds and their comparative value than we are likely to obtain from any other source :—

"So many inquiries have been recently made respecting the flock of Angora goats in South Australia, under my management, belonging to Mr. Price Maurice, that I am induced to publish the same information about them. The locality where they are depasturing is Oladdie, a hilly country, abounding in shrubs, bushes, and varieties of feed, 200 miles north of Adelaide, being a sheep station leased from the South Australian Government. The original stock was procured from the progeny of the celebrated flock consigned by Mr. John Salt to the late Mr. J. F. Haigh, of Hattuckn, which possessed the purest blood obtainable. An increase has been made to the flock by the importation, early in 1870, of eight pure ewes, and two pure bucks, procured by an agent employed by Mr. A. L. Elder, on behalf of Mr. P. Maurice, who purchased them in Asia Minor, and afterwards reported upon them as follows :—"The 10 goats are from Castambuli, which is the most northern district in Asia Minor, situated about 80 miles from the south coast of the Black Sea. The region is mountainous, and abounds with Oak and other shrubs. This is the finest class of Angora goat, and gives the best quality of hair. I never saw a finer lot of goats. September is the best time for purchasing. There are what we term three best breeds, but each varying in class somewhat, and yet more in quality. We class them thus :—Castambuli, for the highest lustre ; Angora —Next finest, but not so lustrous ; Buy Bazar—The lowest in quality and lustre, but the longest in staple and heaviest in fleece. The natives cross the finer qualities of Castambuli goats with the inferior Angora bucks, and sometimes *vice versâ*. This is to keep up the size and increase the weight of fleece. The Angora and Buy Bazar districts are not mountainous like Castambuli, but a country chiefly grass and herb, but lean feeding for goats even. They make this up by growing a little hay now and again, and sometimes a little bran, and at other times Oats. I suppose Mr. Maurice will find that oil cake must be given once a week, and that pure water is indispensable to their thriving. The natives know nothing about treating sick goats. Disease of the liver prevails in this country ; mange is common also." Mr. Maurice wishes a perfect specimen in a drawing of the finest Angora goat, let him take a photograph of any of the ten sent out, which may arrive in healthy condition.' Head, horns, and shape they exist in when procured from goats sent out, short, double, the real and purest breed of our Angora goats. *J. Binns, Constantinople, May* 3. 1870."

RAM SALES, &c.

THE sale of Mr. Horley's flock, founded upwards of 20 years ago, principally upon the farfamed old flock of Mr. Masfen, of Norton Canes, took place on the 8th inst. Although no very high prices were reached, there was a steady demand all through, the 66 rams averaging slightly over £16 per each. The animals, taken as a whole, are fine, having received any artificial food or stimulants, but their blood secured customers for the 60 at from 50s. to 105s. each. The shearling ewes numbered 100, and were a very level lot. The two best pens made 90s. and 105s. respectively, the others going at 80s., 75s., down to 70s., the lowest price paid. The general average was about 77s. 150 older ewes were offered, and for these the competition was very brisk, 120s., 115s., and 100s. per head being paid for the best pens ; the general run was 80s. to 85s., the average running close to the last-named price. The ewes lambs were matchy, and showed a good deal of breed. They ranged from 60s. to 80s., averaging nearly 70s. each.

—— On Thursday, the 10th inst., Mr. Sanday, jun., sold his well known flock of Leicester sheep, through the agency of Mr. J. M. Pott. The flock consisted of 13 rams, 65 ewes, 20 shearling ewes, 36 ram lambs, and 35 ewe lambs. Mr. Pott, as an effective speaker, offered the shearling rams for sale, with the following result :—Shearling rams : By A Y, dam by M M, g.g.d. by C N, g.g.d. by Y N, g.g.g.d. by G, g.g.g.g.d. by T, g.g.g.g.g.d. by A—Mr. Mead, 35 gs. ; by A Y, dam by H, g.d. bred by Colonel Inge—Mr. Massey, 20 gs. ; by A Y, dam by M M, g.d. by X N, g.g.d. bred by Mr. Buckley—Mr. Cranfield, 11 gs. ; by A Y, dam by D X, g.d. bred by Colonel Inge—Mr. Cranfield, 12½ gs. ; by A Y, dam by S T, g.g.d. by S C (prize ewe at Salisbury), g.g.d. bred by Mr. Buckley—Mr. Birchall, 14 gs. ; by A Y, 3-shear ; by Jubi, dam by M M, g.d. by X N, g.g.d. by W X, g.g.g.d. by L N (dam of L X)—Mr. Langdale, 36½ gs. 2-shear : by L X, dam by S T, g.d. by C S (prize ewe at Salisbury), g.g.d., bred by Mr. Buckley — Mr. Allen, 10 gs. ; by D X, dam M M, g.d. by W X, g.g.d. by No. 3—Mr. Mann, 16 gs. ; by L X, dam by H, dam bred by Colonel Inge—Mr. Harrison, 10 gs. ; by L X, dam by

M M, g.d. by X X, g.g.d. by G 3z, g.g.g.d. by A Y (dam of 90-guinea sheep)—Mr. Marshall, Rempstone, 8½ gs. ; by L X, dam by X X, g.d. by G N, g.g.d. by A Y—Mr. Messenger, 10 gs. ; by L X, dam by M M, g.d. by XX, g.d. bred by Mr. Buckley—Mr. Spencer, 9½ gs. Six-shear ; By M M, dam by C N, g.d. by Y N, g.g.d. by G—Mr. Cresswell, 32 gs. The remainder of the lots made fair prices.

—— On Aug. 11 the annual gathering of Leicester ram breeders and farmers was held at Mr. Stamper's, Highfield House, Nunnington, North York, where Mr. Boulton, the auctioneer, let the sheep. The highest shearling was taken at £20 5s. by Mr. Tinsley, of Malton, the average price being nearly £8 each. The 2-shear sheep brought a strong competition. The prize sheep at the Ryedale Show the previous day let to Mr. Greenwood, of Swarcliffe Hall, for £31 10s., and the lot averaged about 10 gs. per head. The aged sheep averaged about £7 per head. The general average throughout the day was over 8 gs. per head, only three sheep being turned back.

—— On Wednesday, the 16th inst., Mr. Wentworth, auctioneer, offered for competition 56 rams, the property of Mr. George Walmsley, Rudston House. The letting began with No. 1 of the shearlings, which realised £8 ; the highest, No. 10, reached £24. Out of 22, four were let at and the average was £19 5s. 4d. Of 18 2-shear, 16 were let, the lowest at £6 5s., and No. 28 for £26 10s., the average being £11 15s. Of the 3 and 4-shear, 15 were offered and nine disposed of, the lowest at £6 5s., and the highest, No. 41, at £14, average £7 11s. 8d. ; the mean average of the whole being £9 17s. 4d., the highest of any ram show in the district.

—— Mr. German, of Measham Lodge, near Ashby-de-la-Zouch, held his annual sale of Shropshire sheep on Wednesday, the 17th inst., when 44 rams and 105 ewes were disposed of. The last three years the sheep from this flock have been sold at the Ashby-de-la-Zouch Smithfield, but from the fact of the spirited determination of the proprietor to make his flock equal to any in the country, and the confidence the public has shown in purchasing his rams on previous occasions, induced him to hold his sale this year at the Measham Field Farm, and we congratulate him on the great success he has achieved. The sale was commenced in a most spirited manner by Mr. John German, of the firm of Davenport, German & Allen, Ashby-de-la-Zouch, commencing with a grand 2-shear ram, which was let to Mr. Rose, Ash, near Derby, at 21 gs.; No. 2, a 3-shear ram, sold to Geo. Moore, Esq., 18 gs. ; No. 3 was let to Mr. Wood, Ticknall, 17 gs. ; No. 4, Mr. W. Princep, 19 gs. ; No. 5, the first shearling, was let to G. Fulton Esq., of Shardlow, 21 gs. ; this sheep was highly commended at the Royal Agricultural Society, Wolverhampton, and took 1st prize at Leicester Agricultural Show, Leicester. No. 6, Mr. Orme, 14 gs. ; No. 7, Mr. Singlehurst, Kingstone, 17 gs. ; No. 8, Geo. Moore, Esq., 18 gs. ; No. 9, Mr. Sale, 10 gs. ; No. 10, Mr. Barber, Bestwood Park, 9 gs. ; No. 11, Mr. J. W. Faux, 12 gs. ; No. 12, Mr. Singlehurst, 14 gs. ; No. 13, Mr. Booth, 16 gs. ; No. 14, Mr. Gardner, 21 gs. ; No. 15, Mr. Everard, Narborough, 14 gs. ; No. 16, Mr. Sale, 8½ gs. ; No. 17, Mr. Fowler, 11 gs. ; No. 18, Mr. G. Sale, 7½ gs. ; No. 19, Mr. Oakey, Packington, 13 gs. ; No. 20, Mr. Hatchett, Lockington, 14 gs. ; No. 21, Mr. Bagshaw, Stretton, 7 gs. ; No. 22, Mr. Hall, Burbage, 18 gs. ; No. 23, Mr. Webster, 8 gs. ; No. 24, Mr. Garner, Willesley, 16 gs. ; No. 25, Mr. Henson, Burton Lodge, 13 gs. ; No. 26, Mr. Geo. Dewes, Willesley, 15 gs. ; No. 27, Mr. Sale, sen., 8 gs. ; No. 28, Mr. Startin, 8 gs. ; No. 29, Mr. Clare, 8 gs. ; No. 30, Mr. H. D. Goodall, 16 gs. ; No. 31, Mr. Smith, Rangemoor, 17 gs. ; No. 32, Mr. Ratcliff, 11 gs. ; No. 33, Mr. Thirlby, Packington, 9 gs. ; No. 34, Mr. T. Ratcliff, 10 gs. ; No. 35, Mr. Booth, Tamhorn, Stafford, 21 gs. ; No. 36, Mr. Wood, Clifton, 18 gs. ; No. 37, Mr. Eaton, Derby, 10 gs. ; No. 38, Mr. F. Walker, 7½ gs. ; No. 39, Mr. John Thompson, 10 gs. ; No. 40, Mr. Lilley, Swepstone, 9 gs. ; No. 41, Mr. Barber, 8 gs. ; No. 42, Mr. W. Bali, 6½ gs. ; No. 43, Mr. Booth, Tamhorn, 12 gs. ; No. 44, Mr. Princep, 10 gs. ; the average price of the rams being over £15 each. The competition for the ewes was most spirited, prices ranging from 60s. to 102s. 6d. per head, or an average of 75s. ; the purchasers were Mr. W. H. Clare, Mr. Savidge, Mr. Fulton, Mr. Barber, Mr. G. F. Brown, Mr. Alcock Mr. Edge, and Mr. Bowler.

—— Mr. Edmund Olding's annual ram sale took place on Wednesday, at his farm, Court House, Lower Woodford. These rams were selected from the improved Hampshire Down sheep, descended from the well-known flock which was brought to great perfection by Mr. Olding during the time he resided at Rattin Farm, near Amesbury. The highest lots in his under :—To Mr. Dibben, lot 3, 28 gs. ; to Mr. Charles Waters, of little Durnford Farm, lot 4, 21 gs., both these lots being lambs let for the season only ; to Mr. Moore (who competed keenly for all the best lots), lot 50, 16 gs. ; lot 16, 14½ gs. ; to Mr. Squarey, lot 46, 13½ gs. ; Mr. M. H. Marsh (Ramridge House), lot 56, 12 gs. ; and lot 55, 10½ gs. ; to Mr. Gay, lot 20, 10 gs. ; to Mr. W. Long, lot 10, 9 gs. Messrs. Cossins, of Somerton, Mr. Miles, Wexcombe, and Mr. Green, Salterton, each purchased several lambs at very fair prices. The average of 58 lambs sold and let was £7 10s. 8d. each.

—— On the 17th inst. a sale of Hampshire Down sheep took place at Bradwell, near Wolverton, at the residence of Mr. W. G. Duncan, of Bradwell House. The breed is not much known in this district, although it is a very useful one, as it is much more hardy than many other breeds, and on cold rough land it will do well when other sheep would degenerate. The bidding generally was not brisk, and the prices, in the majority of cases, were not so high as last year. The following is a return of the sale :—Sheep : Three ewes, £4 5s. per head, Mr. Bull, Newport. Three ewes, £3 5s. per head, Mr. Bull. Three ewes, £2 19s. per head, Mr. Linnell, Great Brickhill. Five ewes, £3 7s. per head, Mr. Craddock, Bradwell. Five wether lambs, £2 9s. 6d., Mr. Checkley, Tyringham. Five ditto, £2 6s. 6d., Mr. Checkley. Five ditto, £2 6s., Mr. H. E. Bull, Tickford Park. Five ditto, £2 5s. 6d., Mr. J. Townsend, Tyringham. Five ditto, £2 7s. 6d., Mr. H. E. Bull. Two wether lambs, £2 6s. per head, Mr. Checkley. One Hampshire Down ram lamb, £3 12s. 6d., Mr. Mills, Newport. One Hampshire Down ram lamb, Hon. Percy Barrington, Westbury. One Hampshire ditto, £4 5s., Mr. Linnell, Paulerspury ; ditto, £5 2s. 6d., Emerton ; ditto, £4 12s. 6d., Goosey, Wavendon ; ditto, £3 15s., Franklin, Haversham ; ditto, £5 5s., Holdham, Fenny Stratford ; ditto, £2 12s., Hockley, Tyringham ; ditto, £2 10s., Holdham, Stratford ; ditto, £11, Clode, Great Linford ; ditto, £9 5s., Captain Borlase Tibbits, Barton Seagrave ; one shearling Hampshire Down ram, bred by Mr. W. King, Hungerford, £14, Major Levi, Woughton-on-the-Hill ; one Hampshire Down ram lamb, £3 2s. 6d., Craddock, Bradwell ; ditto, £3 2s. 6d., Mr. Pike, Castlethorpe ; ditto, £12 5s., Thompson, Hanslope ; ditto, £4 15s., Linnell, Great Brickhill ; ditto, £4, Price, Newport Pagnell ; ditto, £4, Pike, Hanslope ; ditto, £3 12s. 6d., Pike ; ditto, £6 10s., Pike, Hanslope ; ditto, £4 15s., Pike ; ditto, £2 2s. 6d., Ward, Newport Pagnell, Alderneys : A grey and white cow, four years old, in calf, to calve October 23, £21 5s., Hon. Percy Barrington ; a brown and white heifer, 18 months old, in calf, £13, J. Clode ; a self-coloured heifer, 18 months old, in calf, £14 15s., J. Hawkins, Hanslope ; two ditto, in calf, £15 15s. each, Pike ; two ditto, 19 months old, £14 5s. each, Pike ; a barren heifer, 2½ years old, £16, Atkinson, New Bradwell ; a barren cow, £10 10s., Linnell, Great Brickhill ; a ditto, £11 10s., J. Townsend ; a ditto, £11 10s., Mills, Newport ; a barren heifer, 2½ years old, Holdham, Stratford ; ditto, £15 5s., John Fountaine ; a ditto, £11 10s., Walker. A number of pigs were also sold, making good prices.

—— Mr. George Kent's third annual lamb sale at Needham Hall, Gazeley, was held on Thursday, the 17th inst., Mr. Stanley (Newson, Stanley & Co.) officiating as auctioneer on the occasion. Upwards of 78 rams were offered, the highest priced lamb ram making 50 gs., the highest shearling ram 30 gs., and a pen of black-faced ewe lambs made 72s. per head ; the pen of wethers made 45s. ; and a few lots of full-mouth sheep and crones varied from 59s. to 60s. per head.

Britford Sheep Fair. — This, one of the largest and most important fairs in the south-western counties, was held on the 12th inst. The supply of sheep was from 5000 to 10,000 below the average, and the attendance of farmers and dealers was not by any large as usual, owing probably to the progress of harvest operations. Lambs were in short supply, and sellers commenced by asking extravagant prices, which, as usual under the circumstances, led to a slow trade being done as the day advanced. Wethers were not in large supply, and ewes and wethers gave from 1s. to 2s. a head as compared with Weyhill and other recent fairs in the district. The chief demand was for lambs, and prices were altogether from 10s. to 15s. a head higher than last year. Wethers may be quoted at from 50s. to 56s. ; ewes from 50s. to 60s., and lambs 30s. to 50s. a head. Sir E. Hulse obtained 3 gs. each for 100 ewes. Mr. Fleetwood sold a remarkably fine lot at 75s., and 100 lambs, fed without corn, at 53s., Mr. Farker being the purchaser. Mr. E. Rawlence bought a splendid lot of ewes from Mr. Newton, of Dogdean, also at 75s. Mr. Morrison sold 100 ewes at 60s., and obtained 54s. for a second lot of 160. Mr. Futcher, of Fovant, realised 62s. Mr. E. F. Mills sold 100 ewes at 65s., and Mr. Dibben, of Bishopstone, obtained 50s. each for lambs (the third selection from his flock). Mr. Whitway, of Durnford, realised a like figure for his lot, and 43s. for his culls. He sold his ewes at 60s. Col. Heathcote sold two lots of ewes, one at 58s. and the other at 53s. A lot belonging to Mr. Richard Rooke realised 59s. Mr. Read, of Charford, sold lambs which took the 1st prize at Salisbury, at 38s.—Mr. Bennett, of Winkton, sold a lot of lambs made them a month ago ! These were sold again at a profit during the fair. Mr. Higgings, of Wishford, showed a fine lot of lambs, which sold at 50s. a head ; and Mr. Geo. Sidford sold a useful lot at 47s. Mr. Brown obtained 54s. for ewes ; and the Messrs. Marlow bought one lot from Mr. Futcher at 63s. Mr. Compton, of Fisherton Delamere, made 63s. a head for 100 ewes (Mr. Downs, of Basingstoke, being the purchaser), and 59s. for a second 100. Mr. James Read, of Winterbourne, made 49s. a head for lambs.

Great Sale of Lambs at St. Boswells.—On the 15th inst. an extensive sale of Leicester lambs took place at the Southern Central Auction Mart at St. Boswells, on the North British Railway. The weather was exceedingly hot, and there was no wind to subdue the influence of the scorching rays of the sun. The sale was conducted by Messrs. John Swan & Sons, sheep and cattle salesmen, Edinburgh. The number of lambs put through the ring was fully 7000, and the sale was, on the whole, a satisfactory one. Prices, however, were not so high as those obtained at St. Boswells lamb fair last month, but in present circumstances consigners expressed themselves as being well pleased with the result of the sale. Pastures are considerably barer than they were in consequence of the broiling weather of the last few days, and it is almost impossible just now to keep butcher meat. In addition, the lambs disposed of were not so good in quality as those sent to St. Boswells, or those submitted to competition at the last auction sale held there. Generally, lambs may be quoted 1s. 6d. to 2s. down from last month. There was a capital attendance of purchasers from nearly all parts of Scotland, and from the border and midland counties of England, many of whom were in waiting for Melrose Lammas Fair on the 16th. All the stock was sold. The following were the lots sold :—Three-parts-bred : Blainslie lot, 30s. 6d. ; Philiphaugh, 31s. ; Sneep, 34s. 6d. ; Ettrickdale, 34s. 6d. ; Ettrickhill, 27s. 6d. ; Cathpair, 38s. 6d. and 33s. 6d. ; Rawflatt, 27s. 6d. ; Huntingdon, 31s. 6d. ; Castle Moffat, 28s. ; Smailholm Mains, 36s. 6d. and 33s. ; St. Boswells, 31s. ; Fernichirst, 28s. 6d. ; Cornston, 29s. ; Dryburgh, 24s. ; Greenhead, 27s. 6d. ; Minto Knaines, 27s. ; Birkenside, 33s. 6d. ; West Morriston, 26s. 6d. ; Circleton Mains, 36s. ; Boon, 33s. 6d., 33s., 35s. ; ditto ewe, 30s. ; Whitemore, 32s. ; Cunzierton, 28s. and 26s. 6d. ; Sharplaw, 28s. 6d. ; Earlston, 34s. Half-breds : Ruecastle lot, 28s. ; Dolphinton, 31s. 6d. ; Evelaw, 29s. ; ditto ewe, 30s. ; Horsbrugh, 25s. ; Rachan, 30s. ; Bygatehall ewe, 26s. ; Sisterpath, 30s. ; ditto ewe, 34s. 6d. ; Lordscroft, 25s. ; ditto ewe, 29s. 6d., 28s. 6d., 29s., and 25s. ; Purveshaugh, 30s. 6d. ; Newburgh ewe, 30s. 6d. and 29s. 6d. ; Howden Moor, 27s. 6d. The principal purchasers were Mr. Hebden, Durham ; Mr. Somerville, Jedburgh ; Mr. Wallbank, Berwick-on-Tweed ; Mr. Nicol, Littleton ; Mr. Frier, Cathpair ; Mr. Harrison, Skipton ; and Dr. Murray, Kerknowe. *North British Agriculturist.*

Melrose Lammas Fair. — At this old-established and important fair there was a very large attendance of farmers and dealers. The show of lambs was not so large as last year, it being estimated that the number would range from 20,000 to 30,000. The small show is in a manner to be attributed to the sales held in the district and even on the sale ground, also to the plentiful supply of grass. The business of the fair commenced at 4 o'clock, and was pretty dull up to 8 o'clock, when it became considerably revived, by 11 o'clock almost all the lots on the fair ground were disposed of at prices from 6s. to 8s. above the prices of last year, and 2s. above the prices obtained at the sales on the evening previous to the fair. The appearance and condition of the lambs offered for sale have been excellent. Among the principal sales made were :—Messrs. Aitken, Kelso, sold a lot of lambs at 41s. 6d. ; and the Midshiels lot brought 40s. Mr. Smart, Bowshank, sold his lot at 34s., going to Fife. Mr. Hume, Jeaniefield, sold his lot at 32s. 6d.; Mr. Elliot, Harehead, sold his lot of three-parts at 32s. ; Mrs. Hume, Bluecairn, sold a lot at 33s. ; Mr. Elliot, Chapel Mains, sold a lot of three-parts bred at 33s. ; Mr. Gibson, Fernichirst, sold his three-parts at 32s. ; the Newhall lot of half-breds brought 29s. ; the Thornielee (Mr. Roxburgh) brought 30s. ; Mr. Pringle, Nisbet, sold his seconds, three parts bred, at 36s. 6d. ; the Rawflat lot was sold to Mr. Ord, Eastfield, at 29s. ; Mr. Bruce sold the Thirlestane lot at 30s. ; Mr. Hogg, Crammond Hill, sold a lot of threeparts at 30s. ; Mr. Hall, Kilnknowe, sold a lot at 30s. to Mr. Craig, Whitehaugh.

Falkirk Tryst.—The proceedings of this market were brought to a close on the 16th inst. The weather was splendid. On the whole, the market was a very satisfactory one. The police presented a clean bill as regards crime, and at Larbert Station all the trains were got off without any mishap occurring. The next "tryst" opens on the second Monday of next month.

NOTES ON AGRICULTURE.

ANCIENT AND MODERN FARMING—SMALL AND LARGE FARMS—THE STEAM-ENGINE DOES IT.

WHAT a change has come over British agriculture in my time, and I am only 69 last birthday. The primitive and pastoral age is passing away ; so is the small farmer, and so are waste lands, rough pastures, and low rents.

What has made British agriculture ancient in 50 years ? Steam. Steam has made everything ancient that existed before its introduction. It has multiplied power a million of times, for 1 lb. of coal by its aid will raise 1,000,000 lb. a foot high. We talk now of the ancient coaches, coach roads, and hostelries ; post

horses and postillions have departed with the old mail coaches and sailing packets. Distaffs, spinning-wheels, and hand-looms are now antiquarian. Slow coaches of any sort won't do now. Steam has so multiplied and enriched our population, by creating profitable employment, and has thus so disturbed the ancient relation and proportion between population and acres (the latter having no children), and has so increased the value and rent of land, that ancient farming can no longer be profitable.

Steam not only enriches the merchant, manufacturer, or trader, but also transports him so quickly and pleasantly that he can combine farming with his other occupations, so that we often find him competing for farms, either as owner or tenant, sometimes both. This is good for the country at large.

Adam Smith says, in his "Wealth of Nations," p. 167:—"The increase and riches of commercial and manufacturing towns contributed to the improvement and cultivation of the countries to which they belonged in three different ways" (as detailed at p. 440 of my first volume). He also says, "Merchants are commonly ambitious of becoming country gentlemen, and, when they do, they commonly are the best of all landlords. . . . The merchant is commonly a bold, a country gentleman a timid, undertaker. The habits, besides, of order, economy, and attention, to which mercantile business naturally forms a merchant, render him much fitter to execute, with profit and success, any project of improvement."

All-powerful and cheap steam will do for agriculture what it has done for manufactures and commerce. This was my opinion 22 years ago, when I erected the first new fixed farm steam-engine in our county. The steam-engine has taken agriculture by surprise and found it unprepared both as regards landowners and tenants, for the former has hardly yet fully realised the inconvenient necessity of adapting his land and homestead to modern agricultural requirements. Farmers are gradually awakening to the new idea that everything is to be of iron, if it is to be cheap and lasting. The landowners' once beloved timber, as a source of revenue, has lost its value, and now absolutely impedes the advance of rent by what would naturally follow steam cultivation on the great scale.

Great hedgerows and little fields will not be tolerated by men of capital who mean to make steam-power pay to them and their landlords a modern and better profit. Drainage, good hard farm roads, plenty of shelter for increased live stock, and for modern machinery and implements, have become a necessity for which men of capital are ready to pay a fairly increased rent. There is no occasion to expend here the money for all this is to be found, because our modern draining and land improvement companies will do the whole thing, and only ask a security on the land, where there is a real owner of it.

But let us see how it is that small farms become absorbed into large ones, about which we hear such lamentation. It is a mistake to suppose that small farmers have not been replaced by farmers. Of course, there are many cases of town competitors, but the real and true cause is the great general increase of prosperity, which has enabled good small farmers to become large farmers by absorbing the farms vacated by men who, keeping no stock, and taking all out of the land—farming, in fact, without sufficient capital or modern appliances—have beggared the soil and themselves. I speak with authority upon this matter, for during the last 30 years I have seen this change in operation in a vast number of cases, so that it ought to be a subject more of congratulation than of regret, and must be taken as an evidence of our rapidly increasing wealth and prosperity, just as we see in our time, the gigantic growth of commercial, trading, manufacturing, and monetary combinations. I have no belief in the croakers who conclude that our labourers, mechanics, and operatives are the worse for this increase; on the contrary, all the evidence is the other way. Agricultural and general labour was never better employed. The mere implements and machinery of modern agriculture have given employment, and have absorbed great numbers of agricultural labourers. It is true that an exceptional case may here and there be found of a farmer who extends his holdings—having the good will and confidence of some land-steward, who is blind to his agricultural and suicidal shortcomings in the non-employment of labour, but the rule is all the other way. For successful and money-making farmers, of whom I know many, keep plenty of well-fed stock, manure the land well, keep it clean, and not unfrequently chalk and drain it; all this being a direct contrast with the out-going farmer, who has impoverished the land and himself. The ancient farmer who cannot, will not, or, at any rate, has not adapted himself to modern requirements, goes to the wall. In my early days a small farmer did much laborious work himself, and so did his wife and family. He grew his own wood, and had no coal bill, or very small one. He avoided butchers' profits by salting down his own pork, and only had butcher's meat once a week. Eggs and poultry and butter went to market to enable the good wife to procure dress, &c., for the family. It was only on festive occasions that poultry was consumed at home.

There was great and commendable frugality, and much industry in every department. By home-made wine and home-brewed beer he avoided extensive tradesmen's bills; the grocer and clothier were mildly availed of, and schooling was brief (sometimes too brief) and inexpensive. Early to bed and early to rise was the order of the day. In the management of the farm the implements were few and simple; in many cases not even a drill, certainly no horse-hoes or threshing-machines. The man of the flail did nothing but thresh for years. Good farmers kept their land clean and productive by frequent ploughings and long summer fallows, thus cultivating and resting the land. They could have no artificial manure bills or carriage bills to trouble them. Their rents, rates, and tithes were moderate—a most respectable and deserving class they were, and are, and very hospitable, as I know from experience. Like Pope's Sir Balaam—

"Religious, punctual, frugal, and so forth,
His word would pass for more than he was worth."

A piano was an unusual luxury, and the furniture was ancient and scanty; but now that steam has made us rich we are all getting on very fast, perhaps quite fast enough, for wealth begets luxury and refinement, but, I hope, not idleness and extravagance. At all events, during the transition, some worthy ancient yeomen have succumbed to the altered circumstances, and found themselves unable to compete with the modern practice. Landowners should take note of all these things, and adapt their arrangements also to the altered circumstances.

The great old barns and open farmyards should now be superseded by spacious but covered yards with feeding troughs, and for a limited number of cattle. There should be shelter for all the valuable and indispensable implements and machinery of modern agriculture. The land should be drained, and the fields large, rectilinear, and free from timber, and thus suited for steam-cultivation. Farmers of capital, with their £25 per acre, naturally require residence suitable to their means. The old lath-and-plaster and gable-ended farmhouses are fast becoming labourers' or bailiffs' cottages. I think most people will agree with me that steam has done it all, and will do much more, for its power is irresistible. How thankful we ought to be for all the blessings which it has conferred!

I had nearly forgotten to say that our county bridges have also become ancient and unavailable. The following is a proof of it. Not long ago an engine foundered on Battles Bridge, in Essex. I hope and believe that our country authorities will remove this hindrance to improved and modern agriculture.

"Chelmsford, August 16, 1871.

"Dear Sir,—I am sorry we shall not have a cultivator we can send you (very likely at the time you require it). Our cultivator is now in Cambridgeshire, and the bridges are so bad between Kelvedon and Sudbury that we should rather it kept where it is till you have some new ones built. I am, sir, yours respectfully,

"W. Eddington."

I expect that the drawbacks on our farms will also have to be strengthened, to carry the steam monsters.

F. Y. Mechi, August.

P.S.—In my last communication, for "75 feet of iron hurdle to every five sheep," read "15 feet," &c.

THE HARVEST AND THE CROPS.

We extract from the *Times* of the 24th inst. the following communication on the above most interesting subject, from the pen of Mr. James Sanderson:—

Rarely has the result of a year's crops been so anxiously looked forward to as that of the crops of the present year. The light-land farmer had experienced three adverse seasons in succession, while two years of the same kind proved ruinous to the graziers. By midsummer the produce of 1870 was well-nigh exhausted; home granaries were almost totally depleted, barnyards empty, straw nearly all consumed, and cattle in miserable condition. It was therefore not without reason that consumers, as well as producers, eagerly watched the progress of this year's crops.

The year has been characterised by a frosty winter, a backward spring, and a cold and gloomy summer. The frequent naked frosts in winter destroyed a large area of Turnips, and consequently involved on the part of the farmer a larger and a more expensive purchase of cattle foods. The recurrence of naked frosts in spring caused considerable damage to the Wheat crops, and, by retarding the growth of seeds and intermediate crops, deprived farmers of the early use of natural stock food. May was cold and ungenial, and throughout the month pastures made little progress. The weather in June was marked by an almost total absence of sunshine, and a low temperature—usually the best grain-maturing month—was generally gloomy, having only a few days of bright sunshine, and during the month there were frequent heavy rainfalls, accompanied with violent gusts of wind. Up till the end of the month, the harvest prospects were by no means encouraging. Harvest threatened to be fully a month later than usual, the ripening of many fields of spring-corn was doubtful, while with the continuance for another fortnight of such weather as the past a large area of the rain-beaten and wind-twisted crops would be fit only for the dunghill. Happily, with August came brilliant weather, bright sunshine, and a cloudless sky, which so rapidly matured the crops that instead of the harvest being a month later, as was anticipated, than usual, it is only a fortnight later than in ordinary seasons, and three weeks later than the harvest of last year.

Crops throughout England have ripened almost simultaneously, cutting is general in the home counties, one-half of the cereal crop is secured, and with favourable weather for the next fortnight the great bulk of the grain crops will be ingathered. But to notice the different crops in detail. There were early indications that the Wheat crop would not be productive. The severe frosts of spring decimated the plants on undrained land, and on loose soils, especially on black fen land, which had not been recently clayed. The ravages of the wireworm were unusually severe, and, from the wet condition of the land, the only means—heavy and frequent rollings—of mitigating the evils referred to were unavailable; hence a considerable area of Wheat was ploughed up, and a large breadth that was allowed to grow was so thinly planted that it could not yield half a crop. The ear-forming stage was by no means favourable, while the blooming season, from being wet and windy, was the most adverse I ever remember. So early as in the middle of June it was evident that under the most favourable circumstances the Wheat yield of 1871 would be deficient.

The gloomy month of July tended more to the production of straw than grain, and the heavy and frequent rains greatly injured the crop on loose soils.

The extensive fen area, which usually has a greater acreage, yield than any other description of soil in England, has suffered severely from storms. I have seen several fields not worth the cost of harvesting, and I do not hesitate to say that the yield of Wheat in the fen districts will be one-third less of that of last year. Reaching generally, it is the heavy or Wheat soils (barring the chalk-loams of East Kent, the red marls of Worcester, and the red sandstone of Hereford) that are most deficient, while it is the light soils—which have given the inferior crops the last three years—that have relatively produced the best crops. There is fully one-third more straw than last year, but the heads are short, the spikelets are widely apart, many heads are empty, and there is a unusual number of barren ears. Crops, where laid and in sheltered situations, have been attacked by mildew, in a few districts rust has caused considerable damage, and the majority of crops have been shorn by the rain-storms.

The results of threshed-out fields in Kent, Surrey, Essex, Berks, Northampton, and Lincoln have not been satisfactory, and as the greater portion of the laid crops is still uncut I anticipate that, as the process of threshing advances, we will prove more disappointing.

I estimate the Wheat yield at 22 bush. per acre, or 8 bush. under average, or, as compared with recent years, 8 bush. per acre under the yield of last year, 2 bush. per acre under the crop of 1869, 4 bush. short of the great crop of 1868, and about equal to the crop of 1867; or, to take the aggregate yield, and assuming that the area under Wheat will be equal to that of last year, the results are as follow:—In 1868, 102 million qr.; in 1869, 91 million qr.; in 1870, 12 million qr.; in the year 1870, 13 million qr.; and in the year 1871, 9½ million qr.

Barley, which has been appropriately termed the Grape of England, is the best of the cereal crops. Bulky in straw, thickly planted, long and closely set in ear, the Barley crop of 1871, for bulk, yield, and quality, has seldom been equalled. The chief cause of the success of this—as well as of all spring crops—must be ascribed to the favourable seed-bed they secured. The soil was not only baked by summer droughts, but also pulverised by the bare winter frosts, therefore a most favourable seed-bed was obtained. The rainfall during the end of last week—by swelling the kernel, which promised to be somewhat shrivelled and steely—has vastly improved the quality of this grain. I estimate the yield to be 25 per cent. over average.

As in 1869, so also in this year, the Oat crop is the most erratic and variable. In the South this crop, contrary to ordinary years, far excels that in the North, and crops are talked of as being generally considered unsuitable for the production of Oats. The yield in the South exceeds expectations. A field I saw threshed out in Northamptonshire yielded 20 qr. per acre, and the weight of grain was 45 lb. per bush. Taking this crop as a whole, I consider it to be a good average.

The Bean crop is most prolific, thickly planted, strong and lengthy in stem, and closely podded. I consider it nearly equal to the crops of the last three years combined. I estimate this crop to be 20 per cent. over average.

The Pea crop, too, is singularly bulky, and promises an unusually large yield. From the almost total failure of seeds last year, a large breadth of Peas was sown; and, taking the excessive area together with the enormous yield, probably a larger Pea crop was never produced in England.

The Potato crop, so far as number of plants, vigour of stem, and number of tubers are concerned, was never more promising; however, especially in low and sheltered fields, has already caused considerable damage, but with a continuance of dry weather it is hoped something approaching to an average crop of sound tubers may yet be gathered.

Root crops, comprising Turnips, Mangels, and Kohl Rabi, never looked better. The Turnip crop especially—which, when good, is the basis of a successful system of crops, is the best soil-restoring crop, and lessens the farmer's outlay on artificial foods—is singularly promising. Not a patchy nor a blighted field is to be seen, but everywhere this crop is remarkably luxuriance.

The hay harvest was protracted, on account of the frequent and heavy rains. Meadow hay, on the whole, was secured in fair condition, and proved an average crop. From the failure of seeds last year, artificial hay was limited to a small area, and was an indifferent yield.

Pastures were backward in the early part of the season, but rarely have cattle and sheep fattened so rapidly as during the last three months. Those who predicted the destruction of our pastures and finer grasses from severe drought of last year were premature in their opinions, for seldom have Clovers been so abundant, the sward so close and luxuriant, or pastures carried so large a number of stock. The abundance of Milfoil or Yarrow is doubtless caused by the drought of the last three years, which fosters the growth of this plant.

Young seeds are singularly luxuriant. Green crops—Tares, Sainfoin, and Lucerne—are abundant, and the

yield of vegetable produce has not been equalled for several years.

Taking the produce of 1871 as a whole, it may be safely said, notwithstanding the deficient Wheat yield and the general failure of orchard fruit, that seldom has English produce been so valuable and abundant. To quote the words of the Hebrew poet, "The pastures are clothed with flocks; the valleys also are covered over with corn; they shout for joy, they also sing."

With respect to demand for labour, the contrast between this year and the last is remarkable. Last year union-houses were full; there was little or no hay to mow, almost no Turnips hoeing, and unusually light harvest labour. This year there is a scarcity of labourers, and as much as 6*d.* per acre has been paid for simply tying and shocking corn.

It is worthy of remark that every description of farm produce is dear. Breadstuffs command full prices, the prices of beef and mutton have rarely been exceeded, store stock are 30 per cent. higher than in last year, and wool is realising 15 per cent. over last year's prices.

Coupling the high prices with the abundant produce, the year 1871 will doubtless prove a bountiful year to the farmers. *James Sanderson, 11, Pall Mall East, S.W., Aug. 23.*

CARR'S DISINTEGRATING FLOUR MILL.

MR. BARCLAY read a paper at the recent meeting of the British Association in Edinburgh, upon Carr's Disintegrating Flour Mill. The mill reduces Wheat by percussion, while it is unsupported and falling freely, or being projected, through the air. The Wheat, in passing through the machine, is struck by a series of bars moving at immense speed in opposite directions; it is so instantaneously reduced into a state for bolting, that no injurious heat is caused, and the flour produced is of a much superior quality to that obtained by ordinary grinding, while the cost of its production is considerably less. Messrs. Gibson & Walker, of Bonnington Mills, Edinburgh, have now one of these machines in their perfected state in full operation, and they give the produce of two different lots of Wheat passed through it. The first, as follows, is—Old Scotch Wheat, which produced:—Flour, 45 per cent.; semolina, 26 per cent.; bran flour, 4½ per cent.; exhaust flour, 1½ per cent.; seconds, 4 per cent.; pargings, 1½ per cent.; bran, 13 per cent.; black dust, 2½ per cent.; loss, 1½ per cent.—100 per cent. The other was a mixture of Baltic and Ghirka Wheats, and produced:—Fine flour, 35 per cent.; semolina, 36; bran flour, 4½; exhaust flour, 1½; seconds, 3½; pairings, 2; bran, 13; black dust, sick., 3; loss, 1½—100. These statements show the varied effects produced by this novel process on different descriptions of Wheat. The quantity of semolina obtained from hard Wheats, it will be observed, is much greater, and that of flour much less, than from soft Wheats. But what is of most importance for the ultimate results. The quantity of finest flour obtained varies, of course, according to the quality of the Wheat used. Messrs. Gibson & Walker at present obtain from 55 to 60 per cent.; but they expect, when they have a sufficient quantity of machinery for dressing the semolina, that their minimum production will be increased to 60 per cent.; the inferior qualities of flour will then, of course, be proportionally reduced. By this process Messrs. Gibson & Walker are able to produce a very superior quality of flour from good Scotch Wheat alone; whilst by stones, they can only use a very small proportion of such Wheat, mixed with superior qualities. With regard to the quantity produced in a given time, it may be stated that Messrs. Gibson & Walker pass 20 qr. per hour through the machine at present, and they say that they could easily increase this to 25 qr. per hour, or more, if they had sufficient cleaning machinery to keep all their mills going. Estimating the grinding power of a pair of millstones at 6 bush. per hour, 27 pairs of stones would be required, together with at least 3 pairs under stone-dressers' hands, or 30 pairs in all, to grind 20 qr. per hour. Deduct from this estimate the 5 pairs required along with Carr's patent mill, and it would be found that this machine is actually performing the work of 25 pairs of stones with perfect ease. The disintegrating flour-mill, together with the five pairs of millstones in connection with it, and the rest of the dressing and cleaning machinery, are driven at Messrs. Gibson & Walker's with ease by an engine of 100 nominal horse-power, with cylinders of 28-inch high and 36-inch low pressure, 3 feet and 6 feet stroke. In regard to the cost and working of the very much smaller prime cost of the disintegrating flour-mill, compared with that of the 25 pairs of millstones it supersedes, may be mentioned, as well as the very slight and rarely needed repairs it required —making altogether such a saving in the cost of manufacture as millers will themselves be best able to appreciate.

In answer to Mr. Douglas, the PRESIDENT said he had been informed that 5*r.* per qr. more was obtained from Wheat treated in this manner than from Wheat treated in any other way.

Mr. BRAMWELL mentioned that he, along with several other gentlemen, had visited the mills at Bonnington, and had seen the machine in operation. Experiments were made with it, with the following results:—When grinding 20 qr. of Wheat per hour, the disintegrator consumed 145-horse power; when grinding 15 qr. per hour, 123-horse power; when empty, 63-horse power; and when running with the two discs lashed together, only 19-horse power was consumed. In some other remarks, he said that this was absolutely a new principle in grinding material, and was a most ingenious one.

In answer to a question, Mr. WATSON, engineer at the works, stated that the machine created less dust than the ordinary process.

The PRESIDENT pointed out that if they took away the 63-horse power expended in driving the empty machine from the 123-horse power necessary to grind 15 qr. of grain, they arrived at the power necessary to disintegrate 5 qr., viz., 20-horse power, irrespective of the power expended in driving the empty machine.

The thanks of the meeting were accorded to Mr Carr.

FLAX CULTIVATION IN IRELAND.

AGRICULTURAL STATISTICS, IRELAND, 1871.

RETURN, showing, in statute acres, the extent under Flax in each county and province in 1870 and 1871, compiled from information obtained by the Royal Irish constabulary and metropolitan police, who so efficiently act as enumerators; also the number of scutching mills in each county and province in 1870.

Counties and Provinces.	Extent of Land under Flax.		Difference between 1870 and 1871.		Number of Scutching Mills in 1870.

Total of Connaught	6,068	3,448	Decrease, 2,620		31

Total acreage under Flax in Ireland in 1870 and 1871:—1870, 194,910 acres; 1871, 156,764 acres. Total decrease in 1871, 38,146 acres.

Total number of scutching mills in Ireland in 1870, 1518.

Total extent of Flax grown in Ireland in each of the following years:—

	Acres.		Acres.
1851 ..	140,336	1862 ..	150,070
1852 ..	137,068	1863 ..	214,099
1853 ..	174,579	1864 ..	201,693
1854 ..	151,403	1865 ..	251,433
1855 ..	97,673	1866 ..	263,507
1856 ..	106,311	1867 ..	253,257
1857 ..	97,721	1868 ..	206,483
1858 ..	91,546	1869 ..	229,252
1859 ..	136,282	1870 ..	194,910
1860 ..	108,595	1871 ..	156,764
1861 ..	147,957		

The foregoing return exhibits a decrease of 38,146 acres in the total area under Flax in 1871, compared with 1870. This decrease is general. In Dublin and Queen's County there is a slight increase of 9 acres and 27 acres respectively. In the province of Ulster alone the decrease is 33,224 acres. Of the entire number —(1518)—of scutching mills in 1870, 1409 were in Ulster; 39 in Leinster; 39 in Munster; and 31 in Connaught.

I do not apprehend that any important difference will be found in the acreage under Flax now given, and that which will appear in the Tables of the general abstracts which are being compiled, and will soon be ready for publication; they will give the acreage under the various crops, and also the number of live stock, by counties and provinces. *William Donnelly, Registrar-General, General Register Office, Charlemont House, Dublin, August 2, 1871.*

HARVESTING CORN IN WET WEATHER.

MUCH hay has been damaged by rain during the present season, and we cannot yet say how far changes of weather may influence our harvest prospects. It is well, therefore, to hear in mind that the farmer is no longer obliged to sit quietly by while the rain soaks his sheaves and deteriorates his samples of corn. Thanks to Mr. W. A. Gibbs, a simple apparatus has been designed, by means of which the produce of an average half acre may be dried in an hour. As a rule, we are favoured with good harvest weather, and, so long as the sun shines, the farmer will probably be content to trust in Providence rather than purchase a cumbrous and expensive apparatus. Having, however, inspected Mr. Gibbs' hot-blast fan and iron Wheatsheaf, we believe that any farmer having sufficient knowledge as to the principles upon which Mr. Gibbs works, would be able to erect the necessary "plant" at a small cost, and at once be in a position to meet the exigencies of a wet season. Should such an unhappy thing, during our present fine harvest weather, we cannot help thinking that Mr. Gibbs will be deluged with letters from all parts of the country, begging for information as to his process of corn-drying. A full account of this process, and the requisite machinery, appeared some months since in these columns, and it is not our intention here fully to describe either. We wish to remind our readers that there is such a process, and to show that there is nothing complicated about it. An 8-horse power portable engine turns a fan-blast, which blast draws the hot air and products of combustion from the fire-box of the engine, and sends the heated gases through a house or enclosed shed, in which the Wheat or hay is placed. In Mr. Gibbs' own words—

"The engine is the ordinary portable engine of 6 or 8-horse power, now in general use for threshing and other farm work; the smoke-pipe has been taken off at the hinges and a deep fire-box fastened on to the chassis, to carry off the steam. The back plate of the smoke-box having been removed, the engine has then been drawn up and 'butted up' against a corresponding opening in the back casting of the hot-blast; the iron plate mainly interposed between the two openings, intercepts any large sparks that might otherwise be drawn through the fan. A 5-inch driving belt is carried from one wheel of the engine on to a small rigger on the flyer-shaft of the fan, whilst another band can be carried from the other wheel over the roof of the iron shed, so as to work an elevator or a threshing-machine simultaneously with the drying process. The fan absorbs only about one-fourth of the power of an 8-horse engine, so that the remaining three-fourths are available for other work. With this arrangement we were able, on Wednesday last, to dry and Winnow by the threshing-out in fifteen minutes. The drying shed which was used in these experiments was only 12 feet square, and held 32 sheaves in each compartment; but, with a shed of 20 by 24 feet, which is the size best suited to large farms, 64 sheaves could be dried off in a quarter of an hours = 256 per hour. These 256 sheaves represent about the average produce of half an acre of land; and hence, by dividing the compartments into two openings, and working on through the night, between 10 and 12 acres might be cleared in the day and night, at an average cost of 2*s.* per quarter on the Wheat thus dried. As a full description of these experiments and their close cost of costs have already been published, I pass on to the more immediate subject-matter of this report, viz., the work done by a still simpler arrangement of this machinery during the past hay season.

"This re-arrangement of it was put to the test in order to show its capability of being worked by horses in lieu of steam-power.

"The same hot-blast and drying-house are employed, but an ordinary horse-gear has replaced the steam-engine to give the requisite motive-power; a sunk furnace supplies the heat; an old cart wheel has been adjusted to form an excellent fan, and given movement to a set of levers. The advantage of this up and down movement in the making of hay is very great, because it enables the men to use large hay forks, and to lift up heavy masses of the wet 'clinge' from the ground, and expose it to the hot hair without being exposed to it themselves. For hay drying I have hitherto found it best to remove the false floors, the central partition, and the valve, and expose the hay to the direct action of the air as it is blown into the house; with this simple arrangement I obtained the following results, which are taken from my rough note book:—

"*Experiment 1.—On Upland Meadow Grass, estimated at 1½ Load to the Acre, June*, 1869.

"Grass cut by scythe on Friday morning, once shaken out by the hay tedder; winnowed up by evening; weather fair and occasionally sunny. The hay was carried off next day.

"Shaken out by hand on Saturday by noon time, and put into small grass cocks by evening; weather as yesterday.

"Left in cocks all Sunday, weather fine and drying.

"On *Monday* morning from half-past two o'clock to half-past nine very heavy rain fell; remainder of day dull and moist; left the hay untouched.

"*Tuesday* morning. The labourers heavy rain before eight o'clock; between eight and ten o'clock no rain, shook out two rows of cocks; by half-past twelve o'clock a torrent of thunder rain for two quarters of an hour, which drenched both the spread and the unspread hay, so that the centres of the cocks were as wet as the outsides; by half-past three o'clock the sun came out and a wind sprung up; shook out the two rows and dried them partially by five o'clock; then carted up to the drying-house two heavy loads (which weighed when dried rather more than 37 cwt. of hay fit for stacking), and dried them in three hours; coke consumed, 900 lbs. This work was performed in one half of the drying-house only (before the

partition was taken down), and it is recorded chiefly to form a first basis for the estimate of cost of the process, not as any fair indication of the time taken by it. If for the convenience of calculation we call the 37 cwt. 36 *d.e.*, equal to two loads of truss-bound hay, the cost of finishing it in this manner stands at 3*s.* 3*d.* per load, as the following estimate will indicate :—

Estimate of Extra Labour per Diem.

2 Horses and boy to drive	.. ..	.. £0	5 6
1 Boy to pull hay from cart	.. ..	.. 0	0 6
2 Man to feed wet hay on to house	.. ..	.. 0	3 0
2 Man to guide fever-fork ..	.. ..	.. 0	3 0
1 Lad to throw dry hay out of house	.. ..	.. 0	2 0
		£0	14 0

14*s.* for 12 hours, equals 3*s.* 6*d.* for three hours; add to this the 3 cwt. coke at 1*s.* = 3*s.*, and we obtain 6*s.* 6*d.* as the cost of drying the two loads of wet hay, or 3*s.* 3*d.* per load.

"Now, on the same field from which these two loads were taken, there remained three other loads in precisely the same condition of wetness. As the afternoon turned fine we had the opportunity of testing the comparative labour—cost of finishing it by natural means and in the ordinary way ; this required the constant labour for six hours of eight men, which amounted, therefore, in money cost, to the same three shillings per load. Hence the use of the drying-house resulted in rather less cost than the trusting to Nature—besides which, it is still more important to consider that had rain come on during the field-workers' use the hay, all the foregone labour of opening out the cocks, shaking out the hay, forming it into beds, and turning it over, would have been wasted, and worse than wasted, inasmuch as the spreading out would have exposed it with the damaging action of fresh rain ; moreover, if the hay had not dried sufficiently for the carting during that afternoon, it would have had to take the risk of rain in the night, and more labour would have had to be expended on it on the following day."

Home Correspondence.

Our Water Supply.—In your paper of the 12th you reprint, with approval, a letter on "Our Water Supply," signed "Lechlade." Though a short answer of mine appeared in the *Times*, I wish with your permission to comment on his letter rather more at length. It is not necessary to say anything on the importance of the subject ; it might be content with the regret that readers to evidence given by me before the committee presided over by the Duke of Richmond, but Blue Books, we know, are seldom read. That the valley of the Thames possesses abundance of water to meet the demands of its occupants I freely admit, though I cannot admit that the question lies in a nutshell—it is rather, in my judgment, a "hard nut to crack." I admitted that the rainfall might be 28 inches, but I contend that all calculations must be based on a minimum, which may be 16 inches. Nothing can be more delusive than to calculate on areas and rainfall—nothing can vary more than the watershed of the Thames above Oxford. I know that there are valleys well fitted for the storage of water, such as the sites of the reservoirs which supply the summit levels of the Oxford canal ; but such are not now needed for the supply of towns, and I am free to say I have among the water issuing from so called springs, the aggregate of which form the river ; surely these sources are to be preferred to water stored in reservoirs. Take, for instance, the reach immediately above Maidenhead, or Boulter's Lock, where the river receives its last contribution from the waters of the chalk in mass—a quantity, as has been proved, due to the drainage of the chalk into the river bed in its course from Moulsford or Pangbourne, irrespective of the affluents, equal, and more than equal, to the present wants of London from the Thames. But to return to the district above Oxford. Lechlade says "that the quantity of water through Lechlade Bridge is from 200,000,000 to 300,000,000 gall. every 24 hours." I saw the river a short distance below that point a few days since. I feel sure this an over-estimate now ; but I contend, not for one gauging, but a *minimum*. I have before me a series of gaugings of the river above Oxford, taken by a person duly qualified, in winter and summer ; and the lowest, giving the whole river, is 60,408,430 gall., not one-third of the quantity given by Lechlade" under the bridge in whose name he writes. The Windrush and Evenlode, and other smaller affluents giving their waters, swell the total of the gauging in question. It will be time enough to utilise the overflow of the Thames when it is wanted. I think that the existing reservoir, which I saw on Friday last, must contain more than 5,000,000 gall. ; as for its cost, I think that is not duly estimated ; but be it as it may, it must be remembered that all the water is pumped into it from the level of the Thames, and it is in no wise a type of such reservoirs as probably would be constructed in the Thames valley if they were needed, of which "Lechlade" says, "There is no expense, no pumping machinery, no machinery. It is true that part is stopped by the monopoly of the water companies, who now distribute the water." How that is to be done at an almost nominal charge I am at a loss to understand. Some one, I suppose, must pay for the pipes, &c. Then as to the quantity passing under Lechlade Bridge, as compared with that known to pass over Teddington Weir. Allow, all told, 100,000,000 gall. for the abstraction of water by towns and London water companies —less if you please. If 200,000,000 gall. pass under Lechlade Bridge, the Windrush, Evenlode, Cherwell, Ock, Wycombe stream, Kennett, Loddon, Coln, the smaller affluents, and the water issuing into the river's bed in its passage through the chalk stratum, would swell the minimum discharge at the very least to 500,000,000 gall., whereas the known minimum is 350,000,000 gall. If "Lechlade" will have the water passing under his bridge carefully gauged, he will soon see his error, and will be more careful before he writes on an all-important question, which I think he will find does not lie in a nutshell. *F. C. Clutterbuck.*

Steam Cultivation.—I have no doubt that steam cultivation is right, both on Fowler's and on Smith's plans. What we want, in order to get this and many other improvements more generally adopted, is security of tenure. We dare not farm high under the present system of land-holding in England. Many farmers would be willing to lay out their money in steam-tackle and manures if they were certain that their outlay in improving their farms would still remain their own property ; but they know that, under our present laws, the landlord has power to appropriate to himself the tenant's improvements after a six months' notice to quit. Whether the landlord turns him out and obtains the rent to a stranger, or whether he keeps on the same tenant and raises his rent, the effect is the same : the improving tenant's outlay is confiscated. It is this dread of landlord absorption of tenant-right that starves English agriculture. Mr. Mechi at Tiptree and Mr. Mechin at Woolston (to whom we should) are safe in whatever outlay they make in improvements. Both those gentlemen must own that there are hundreds of farmers in England who know how to farm land as well as they ; but then, under the vile six months' notice to quit, not one farmer in a hundred dare spend his money as they do, as there is there is no security for their outlay. I suppose this safety for tenants' improvements must come in time, but it is a weary while in coming. Whoever wishes well to his country should try to hasten that time, when more food can be raised from our soil. *H. H. O.*

Sanitary Arrangements in German Towns.—Reference has been made in the *Agricultural Gazette* to the sanitary arrangements that exist in German towns, and to them they attribute as their chief safety system. I cut the enclosed paragraph from the *Aberdeen Free Press* of August 11. It formed part of a letter from "Our own Correspondent," dated Elberfield, August 7, and explains itself :—

"The cholera is apparently on its way to us from the East. Russia is already suffering severely already in St. Petersburg, Moscow, Rybinsk on the Wolga, Tambov, Riga, Wilna, and many other places in Russia. If it makes its way up to Elberfeld, I am sadly afraid it will reap a harvest equal to its victims, owing to the very defective state of our sanitary arrangements here. It makes a sensible man sick to see the shameful and senseless way in which the Elberfeld manufacturers turn the glorious little mountain stream, the Wupper, into a cesspool exclusively for their own selfish ends, turning it into a common sewer and receptacle for all the dirtiest impurities and offal from their works. The city has no sewers, but there is a cesspool in every house, and the night-carts go about nightly, pumping out the contents, poisoning the air with the most pestiferous stench. The municipal and communal taxes are extraordinarily high here ; yet very little indeed is done by the authorities for the public weal, except a reasonable *quid pro quo*. The lighting of the streets is also execrably bad. As regards one of the chief necessities of life, pure water, this is, in many houses, more especially in certain parts of the town, almost unattainable, notwithstanding the surprising natural facilities of obtaining the article in a state of high purity, which the mountains offer. An English Water Company, with a sufficiently large capital, and with practical knowledge, and energetic chief engineer, might realise large dividends here." *Wm. Nicol, Brigend, Pitcaple, August 17.*

Feeding Stock to Make Manure.—At p. 1023 Mr. Mechi says, "My live stock capital is usually 20 per acre. I could afford it if I would make it £12 or more, and then I would consume all my straw, treading none under foot, and keep all my cattle and pigs on sparred floors." Did it ever occur to Mr. Mechi that to make manure with cattle tied up is not always the most economical plan ? I have gone to look at a good many farm-steadings, and I have seen many well worked, and evidently money-making farms, on which a great many cattle were kept, and which were making manure, some by treading straw under foot in open strawyards, and some by having it littered under them as bedding in tied-up stalls, and some in loose boxes or hammels, as they are called. But amongst all these three plans commend me, so far as good manure is concerned, to the loose box or hammel. But then comes the question of expense. If my landlord is a "brick," and says, "Never mind the expense ; I will build hammels for you and charge nothing for them," it may be all very well ; but if I have to pay interest and wear and tear on the cost of the hammels, I am not quite so clear about it. Mr. Mechi's sparred floors may be very good, for he saves all the urine (the best part of the manure) ; but I rather think that interest and repairs will come to a deal of money. Wood rots very quickly, and, used as Mr. Mechi would use it, would quickly need renewing ; but if I, as tenant, have to replace it, I may buy my manure too dear. As for strawyards and open sheds round them, all the rains of heaven fall upon them, and of course wash the best part of the manure down the gutter ; and as that gutter very seldom indeed is arranged to irrigate a meadow, the best of the manure goes into the neighbouring brook. With cattle tied up in stalls it is a little better, but even then how often do we see the urine (the best manure of all) running down the channel, to find its ultimate destination goodness knows where. Then look at the dung-pit ! It likewise is exposed to all the rains of heaven, and the drainage from it, which may really be called "the cream," filters away and is lost. If we have a hammel or loose box this is not the case, for the urine is absorbed by the thick layer of dung and dry straw below ; but then, as I said before, the expense is enormous. One of my cattle houses, which is fitted up for 48 beasts to be tied up, is 72 feet long and 29 feet wide (clear inside measurement) with a feeding passage down the middle. Now this house cost me about £200, or say £4 per head for each beast tied up, but if it were fitted up for loose boxes, still retaining the feeding passage down the middle, it would have had to be 100 feet long, and would have cost me at least £50 more for extra divisions and extra height in the walls, making £12 10*s.* for each beast in a loose box, instead of only £4, the cost of house-room for a beast tied in a stall. And if we reckon 10 per cent. for interest and repairs, it would be 8*s.* per head for each beast tied up in a stall, and 25*s.* per head for each beast in a loose box, or more than three times as much ! Now, even if I were willing to pay this increased annual expense, where is the first outlay for building to come from ? Landlords are not usually overburdened with spare capital. That straw must be consumed so as to manure the land is admitted by all ; the only question is, which is the most economical way of getting it back on the land as manure ? If it is utilised by feeding cattle, those cattle require houses, and a great deal of attendance ; and, after the manure is made, there is a heavy expense and labour in carting it on to the land, not to mention that the urine, the most valuable part of the whole manure, is, to a very large extent, absolutely wanted. But is there no other stock than cattle that can be used for this purpose ? Why not use sheep ? Sheep will eat straw quite as well (in an open shed) if you only give it to them at the right season, and in the right way. When sheep are on Turnips, eating them off the land, they will consume a large quantity of straw ; and it is not necessary to make it into chaff to make them eat it. If it is given to them in racks, like hay, sheep will use up about 1 lb. of straw per head per day. But if this quantity about 1 lb. is eaten, and ¼ lb. is trampled under foot. But as it is trampled into the land, where it is wanted, and as the whole of the urine of the animal also falls on the land, it is pretty evident that very little is wanted, at the same time that the cost of cartage is saved. Then as to the straw being given to it on the fields, but it is no more trouble to take it there than it would be to take it to the cattle-houses. Sheep, in fact, can be made to use up profitably everything that cattle in houses would consume—hay, straw, roots, and corn ; and, as the sheep folds shifted daily, every part of the land will get its share of the manure. Of course, if it is heavy clay land, the trampling of sheep will not suit it, but even on heavy clay sheep can be used if the roots and straw are given to them on the Rye-grass and clover lea, where the aftergrass has been finished. Then, I think, all "home-made manufactures of manure" can be kept, and if light land be worked on the six years rotation, three years in crop and three years in grass, selling no corn but consuming it all upon the land with sheep, it will pay better than it does at present, and the artificial manure may be reduced to zero. On a light land farm, if the grain is sent away from it, artificial manure, or bought food, must be brought back, or the land will get out of condition. But if all the corn grown in the land is consumed there, and nothing but fat stock sold from it, then neither artificial manure nor bought food are necessary to keep up the condition. *G. A. H.*

Sewage Irrigation : Broad versus Narrow Beds.—Mr. Morgan will not leave me alone. When he shirked my challenge to submit his figures as to quantity to the implement judges of the Royal Agricultural Society, I thought that he would have been a little more cautious for the future, but it appears that I was mistaken. He now attacks the principles that I have laid down for the distribution of sewage, with a view to economising both the water and the manure. Having previously stated that he uses much larger quantities of sewage than I do, he now states that by means of his broad beds he is able to get a much smaller quantity to flow over the ground at one time than I can on my narrow beds. Now, this statement is of precisely the same nature as that of Mr. John Hampden—that the earth is flat. Mr. Wallace found it impossible to argue with Mr. Hampden, and I will not attempt to argue with Mr. Morgan ; but I will undertake to prove, both mathematically and practically, that his statement is nonsense, to the satisfaction of the said implement judges, or of any first-class professor of mathematics or engineering. Will Mr. Morgan accept the challenge ? or is he afraid of this one also ? *W. Hope, Parsloes, Aug.* 14.

Foreign Correspondence.

BERLIN: *Aug.* 15.—*The Liernur Pneumatic System.*—I am sorry to find, on reading one of your recent leaders and Mr. Mechi's communication (p. 1023), that I have been sorely misunderstood. I am, however, indebted to Mr. Mechi for contradicting the statement that irrigation has been abolished in his fields, and am quite sure his German contemporaries would like nothing better than particulars, for they have heard the most contradictory statements about Tiptree Hall proceedings. Perhaps I may, on my side, oblige Mr. Mechi by telling him that I abhor cesspools as much as he. The very reason mentioned in my last for speaking a word in the cause of Liernur's plan, is, that it does away with cesspools. The reason, moreover, why I feel enthusiastic about the pneumatic system is, that it does away with the sewers also. To my sense of recognition the water-carriage is no better than a huge diluted cesspool in the highest degree of development; and as it is incomplete and irrational without irrigation, and as irrigation is an impossibility with the German climate, Liernur is to be thanked for his invention of pneumatic sewers.

I have called Liernur's the inventor's system, which alone would tend to show that there can be no cesspools about them. There are certainly subterranean reservoirs of cast-iron, and of air-tight construction, serving as evacuators for eight rows of houses at the street corners, but these are very far indeed from having anything like cesspools. However, I have heard of Liernur tenders being used in several places for evacuating cesspools, but this is done, I should say, because the pneumatic reservoir and tubes have not been as yet adopted, for various reasons, which I will trouble myself to inquire into, although I should like to drop the subject for good, and never more to offend your admirable prejudice, "Wash and be clean," which is no less my own. In my own defence, however, I may be allowed to add a few words upon this particular washing process, as it goes in connection with the sewerage system. If washing means diluting, generating diseases, and distilling malaria into the very bedrooms, then the sewerage system is washing indeed; but if it means making evil things imperceptible to any and every sense, and inoxious to health, then I can but stick to Mr. Liernur's invention, as to actually but steadily, and that those parts of the town without waterclosets are still by far the healthiest, varying in different parts from 26 to 57 cases per thousand. I won't dwell upon the words of one of your medical authorities, who said that a good drain better than that morbid gas which is distilled into English houses—I won't dwell upon sewage-fevers, sewage-tongues, and what else; I can but say that wells and pumps are no better between sewers than they are between cesspools, perhaps worse. My admiration for English sewers was once openly genuine, and you may have read between the lines. Water is not the thing to quench putrefaction—water is the very element of its growth.

Besides, as to noses: let Mr. Mechi's be the most sensitive organ of smell there ever was, is, or will be, I have got a ladder at home to go up and down stairs with—meaning a nose—which is no less offended by cesspools than by sewers, let alone the irrigation. If this be a question of noses, give me Liernur's plan, his ventilating closets, his pneumatic tubes, air-tight cast-iron reservoirs and tenders, self-acting decantations, and have all those things the nose don't like sent out of town every day, every night, in express trains, well stoppered; let them be put into cesspools in the country, mixed with earth, ashes, lime, gypsum, &c., by thousands of very willing farmers, and used for gardening purposes, or let them be ploughed into the ground by special contrivances, such as you might call barrel-ploughs. But if it be no question of noses, then let England enjoy her sewers and irrigation fields, dilute and spread what other people hide and bury; let her grow Rye-grass, and no end of it, but let her abstain from nasal evidence; let her convert her fields into putrid pools, which to live and work in a new race of Egyptians would have to be born; let her people be the walking habitations of entozoa, and say it pays!

I have not had the pleasure of enjoying the country breezes at Lodge Farm, Barking, but to judge from those infernal smells I could not help enjoying on the irrigation lands south of Berlin, I would prefer not to; and I hope that this also is a healthy prejudice. However, I could not but be astonished that in Great Britain, what with her climate, sewerage, and gentleman farming, there are as yet no more than 13 irrigation farms, with no more than 1630 acres between them,—I mean sewage-irrigation farms, of course. I believe the sheets of paper that have been spoilt in the irrigation question present a larger area than the lands that have been spoilt with the thing itself. There is no doubt about this being the case in Germany, and perhaps some knowing chap would find it easy to state the same for the home of irrigation—for Old England.

Perhaps, as Beetroot growing will go on, in Germany with the Liernur manure and in England with sewage, some facts will turn up to show what is paying, in Mr. Mechi's sense of the word. Taking, as I do, sewerage and irrigation as a unit, and summing up what a ton of manure may cost to the town and what it will produce in the fields on the one hand, and summing up what an equivalent of Liernur manure will not cost, but will pay to the town, and what can be grown by that, I can, *à priori*, not decide in favour of Mr. Mechi, though he obliges us by filling up, with numerals and cyphers, what I leave to mere logic. *O. Beta.*

Societies.

KEIGHLEY.

THE 29th annual show of the Keighley Agricultural Society was held on the 18th inst., and was fully equal to those of previous years.

The *Cattle* were altogether a very fine show. The aged bulls were a splendid class. The 1st prize in this class was taken by Mr. J. Outhwaite, Catterick, with a white bull, two years and seven months old. This was really a magnificent animal, of enormous size, well fed, and sharply, with a beautifully sleek, silky hide. He was the object of universal remark and admiration by the visitors. The 2d prize was taken by an animal belonging to Mr. T. Statter, jun., Stand Hall. This was also a fine beast. For a Shorthorn bull above one year old, the 1st prize was taken by Mr. R. Stratton, of Swindon, and 2d by Mr. R. Pigot, Jun. For the 1st prize for a bull calf, under 12 months old, was awarded to Lady Pigot, Branches Park. Lady Pigot was an exhibitor in almost all the classes of cattle. There was a remarkably good show of Shorthorn cows, in milk or in calf. The 1st prize was taken by a cow of very large size, and finely bred, belonging to Mr. J. Outhwaite. The 2d prize was awarded to Mr. A. Dugdale, Burnley. For the best Shorthorn heifer, under three years old, the 1st prize was taken by Lady Pigot, with a very nice beast; and the 2d by Mr. J. How, Huntingdon. Mr. R. Stratton took the 3d prize for heifer under two years old. Mr. J. How the 2d. Lady Pigot was 1st in the class of heifer calves, and Mr. T. Statter, jun., Stand Hall, 2d. The dairy cows were an excellent show, and the whole class was highly commended by the judges. The 1st prize was awarded to Mr. W. Dodgson, Otley; and the 2d to Mr. H. Crossley, Halifax. In the class of Alderney or Guernsey cows, a pretty cow, the property of Mr. E. Holmes, Keighley, took 1st position; the 2d prize was won by Mr. R. L. Hattersley, Keighley. A special feature of the show was the offering by the Burnley Club of three prizes of £5, £3, and £2 respectively to the exhibitors of the best, 2d best, and 3d best three Shorthorns. The 1st prize was taken by the fine bull belonging to Mr. Outhwaite, winner of the 1st prize amongst the aged bulls. The 2d prize was taken by Mr. J. How, and the 3d by Mr. R. Stratton. A number of premiums were offered to tradesmen and farmers living within a radius of 15 miles from Keighley. In this department the 1st prize for a Shorthorn bull above two years old was won by Mr. W. Tillotson, Marsden Hall; 1st for bull under two years, and 2d for a Devon bull; and the 1st for a bull calf by Mr. J. Dinsdale, Exleyhead. The last was a remarkably large animal for its age. In cows, Mr. H. Crossley, Halifax, took the 1st prize. In heifers, Mr. B. Baxter, Elsiack Hall, took two 1st prizes; and for the best Shorthorn heifer, J. Hird, Skipton, was 1st. The calf with which Mr. Hird took this prize was wonderfully large, and well-fed for its age. The 2d prize for a heifer calf was won by Mr. J. Duckett, West Morton, with an animal that took 2d prizes at the Horton and Allerton shows.

In the *Horse* classes there was a very good show of roadsters, draught horses, cobs, and ponies; but the speciality of the show was the hunters, of which there was a greater number than in any former year, and many of them animals of first-class quality. For a coaching stallion Stirk Brothers, Kildwick, had the 1st prize; and for a roadster stallion Mr. J. Gill, Silsden, was 1st; while Mr. J. Forshaw, Burley, took the 1st prize for a draught stallion. The stallions were rather a poor show. Mr. J. Ellis, Beeston, Leeds, was 1st for a 3-year-old roadster; Mr. J. F. Crowther, Hatfield, for a 2-year-old; and Mr. P. Parker, Barrhead, for a 1-year-old. For the best draught brood mare, Mr. T. Statter took the 1st prize. Mr. E. Holmes, Keighley, was 1st for a roadster brood mare. For a cob under 15 hands, Mr. E. Charlesworth, Rooley Villa, Bradford, was awarded the 1st prize. Mr. Smith, Mamingham, took a 1st prize for a fine display in the single harness competition. The committee, with a well-judged liberality and enterprise, offered a 1st prize of £50 for the best hunter, and the result was that a large number of fine animals were shown. The 1st prize was won by a beautiful bay, five years old, the property of Mr. J. B. Booth, Kilferby Hall, Catterick. The 2d prize was awarded to Mr. J. M. Tattersall, Musgrave; and the third to Mr. E. Nesfield, Scarborough.

The *Sheep* were, on the whole, rather a poor show, and the whole of the first prizes for the Longwoolled varieties, open to the kingdom, were, with one exception, carried off by Mr. T. H. Hutchinson, Catterick. The exception was a first prize won by Mr. R. Surr, Ripley. Mr. M. Lamb, and Mr. G. Greaves, Otley, were the principal district prize-takers. Lonk sheep were considerably below last year's show. The principal prize-takers were Mr. B. Dobson, Ilkley; Mr. J. G. Bridge, Rawtenstall; Mr. J. Pickup, Newchurch; Mr. J. Gill, Silsden; and Mr. M. Lamb, Otley.

The *Pigs* were a large show, and amongst them were many well-fed animals. Mr. C. Roberts, Wakefield, won the silver cup for the best pig in the show. There was a very deserving show of working men's pigs. The silver cup for the best pig in this department was won by Mr. L. Steel, Keighley.—There was a large show of poultry, and the pigeons were of excellent quality.—Three fine stands of agricultural implements were shown. Messrs. W. & F. Richmond, Colne, showed a most extensive and choice selection, and received the first prize. Towards the close of the day a leaping competition took place, and excited much interest. The number of visitors was large, notwithstanding very disagreeable weather. *Condensed from the "Chamber of Agriculture Journal."*

PRESTON.

THE annual show of this young Society was held on the 16th inst., and the entries in all the classes were larger than at the first meeting a year ago—the number being about 250.

Cattle.—There was a first-class collection in both classes, gentlemen's and tenant-farmers. The 1st prize was awarded to Mr. Parker's roan ROYALIST, a fine animal with grand points certainly; but there can hardly be a doubt that had the owner of the 2d prize bull, Mr. Statter, given the age he would have stood 1st. The show was a capital one for bulls of all ages. The bulls under two years were a very fair class, but there was a considerable falling off, in point of quality, between the younger animals and the older ones. The aged bulls were decidedly the best class. There were one or two nice bull calves; but the specimens were not extraordinarily good, especially compared with the fine samples of breeding and condition which had previously paraded the ring. The prize-takers were good and promising youngsters. There was an excellent class of aged cows, and the judges experienced much difficulty in getting them sorted for the prizes. Mr. Statter was again to the front, closely followed by Mr. W. Dodgson, of Plumpton Hall. Under three years, the heifers turned out fairly, and were what may be called a good class. For the best heifers not exceeding two years of age, however, the quality was not remarkably good; and with regard to the calves, they were not so good as could have been wished. The tenant-farmers' bulls were an excellent lot, and it was difficult to make a selection for the prizes; but when the aged lot was left, the young bulls showed a similar falling-off to that experienced in the other class. Mr. Tomlinson's cow and calf were also an average merit, and Mr. Marsland's was fittingly rewarded. The remarks already made may be applied to the cows or heifers—the old ones were decidedly the best; but the display was better than ordinary of the "over two" heifers, where the competition was close. Mr. Marsland again taking the 1st prize with a nice roan. In the class bulls, the young heifers rather fell off in quality, and the calves, too, were scarcely found so good as could have been desired, although there was not much room for fault-finding. The prizes for the three best dairy cows brought out two good groups, each an animal being veritably a picture; and the winners, Mr. Lund, of Hollingshead Fold, and Mr. Dodgson, Plumpton Hall, deserve the highest compliment. In addition to receiving the 2d prize, Mr. Dodgson was highly commended.

Horses.—Unquestionably the horses constituted the strong point of the show, turned out of the reckoning the classes of lesser importance; and the collection, for a local exhibition, merited the high encomiums it received both from the judges and the visitors. In sheer point of numbers it far overtopped other classes, but even this flattering feature was surpassed by the excellence of quality. Five thoroughbred stallions were brought into competition, and these horses included the animals best known and most favoured in the district. The chief prize fell to "Lord Hastings," belonging to Mr. Joseph Tate, of Pole Street, Preston, a fine-looking horse, with splendid legs and hocks, and altogether a good inherently as attractive outwardly. "Lord Hastings" has been exhibited at eight shows, and at seven has carried off the 1st prize decisively. Mr. Brown's fine brown horse "Humdrum," with nothing at all humdrum or ordinary about it, took the 2d prize worthily. Messrs. Lund's roadster stallion "Octavian" won easily in point of quality. In the draught stallions the decision of the judges at the Royal North Lancashire meeting at Blackburn was singularly reversed, and we do not care to venture any explanation. Mr. Cooke, of Much Hoole, carried off the 1st prize with his "Ploughboy," a very good horse, with excellent legs and superior action; and Mr. Edmundson, of Extwisle, near Burnley, had to be contented with a 2d place, although at the show referred to he was placed before his opponent. The brood

mares were a capital show, and Mr. Jenkinson's Natehy mare, "Star," fully deserved the position attained at the head of the list. Mr. Statter's mare, which came in 2d, is a good animal, but she has not the decided quality of the other competitor. The mares for colt or field in foal were also a nice class, and Mr. Fox, of Singleton, took the prize with the handsome chestnut "Pink," a fine goer. The pairs of draught horses were only moderately good, if we except the takers of both prizes, Mr. Brierley's, Middleton, which were far in advance of the rest in all particulars. The draught 3-year-olds were capital, and the winning horses of both 1st and 2d prizes in the next class for other purposes, Mr. W. Jackson's "Singleton," and Mr. W. Coddington's "Blackburn," were nice blood-looking horses. The prize-winner in the 2-year-olds for draught purposes is a nice hay filly, belonging to Mr. Rimmer, of Farington. The "other purposes" 2-year-olds were an average class, and the yearlings for draught fair, but not of first quality. Mr. T. H. Miller carried off the 1st prize in the yearling class for general purposes with a good brown colt, and Miss Aglionby won 2d honours with a lively chestnut. The colts and fillies for draught were a good show—an excellent show, in fact; the leaders being Mr. W. Harrison, Woodplumpton, with a good brown of four months, followed very closely by Mr. T. Cartmell, of Clifton, with an equally promising grey by "British Ensign," three months old. In the succeeding class there were some fair colts.

Sheep.—There was a particularly good show of Leicesters and of Longwoolled sheep, and the Southdowns were of fair character, but only limited. The Fell sheep merited warm commendation. In whitefaced Horns, also, the collection was to be commended; whilst the gimmer lambs were of extraordinary merit, and ranking above an average class. Altogther, the show of sheep was excellent, and several exhibitors from a distance expressed surprise at the high character of several of the pens brought forward from the district. The whole collection was in good order and condition.

Pigs.—These formed a fine show, considering its limited extent; but the chances of local exhibitors were altogether swamped by the porcine wonders forwarded by Mr. P. Eden, of Salford. His two splendid boars of the large breed—without question a couple of the best animals in all England, as recent contests have proved—carried off the 1st and 2d prizes without difficulty; but Mr. Wareing, of Woodplumpton, received high commendation for a fine young boar of 10 months. The result was varied in the small breed boars, Mr. Eden having to contest himself with the 2d place, giving way to Mr. Leigh's, of Lea, fine boar Sam. The Berkshire boars were tolerably well grown, and the 1st prize winner, shown by Mr. Curtis, Garstang, was deserving hearty commendation. In breeding sows, Mr. Eden went again in front for both premiums; and for the smaller kind he again took 1st money, but was closely followed by Mr. Leigh. The Berkshire sows were tolerably good pigs. *Abridged from the "Mark Lane Express."*

DEVONSHIRE.

Savings Banks for Landowners, Farmers, and Labourers.—The following is an address on this subject, lately delivered by the Devonshire Chamber of Agriculture, by the Rev. E. Girdlestone, of Halberton, and since published in a pamphlet form. Mr. GIRDLESTONE said:—

Amongst the many idle tales which have been circulated about me, one is, that my interest is centred in the labourer exclusively, and that I have no care or consideration for the farmer or the farmer's son. This is altogether incorrect. In truth, it is impossible to separate the interests of these three classes from one another. A man must be a fool to make the attempt. One might as well expect that the rainbow would be as bright with one of its elementary colours omitted, or the air we breathe to be wholesome with one of its constituent gases left out, as that the land can be well cultivated in any other way than by the joint and prosperous action of the three classes who are indispensable for its cultivation. Landowners, farmers, and labourers must stand or fall together. The bow is no weapon apart from the string and the arrow. The rifle is useless without powder and ball. The whole human body sympathises in, and is deteriorated by, an injury to any one of its members. That which for profit or loss affects any one of the three agricultural classes, equally affects the other two. In speaking to you, then, this day about savings banks, I propose to consider them with reference to landowners and farmers, as well as with reference to labourers. I define a savings bank to be a depository for savings. I consider that that is the best savings bank which insures the largest amount of profit with the largest amount of safety. Savings banks are equally necessary for landowners, farmers and labourers. On a right use of them by each of the above three classes the proper cultivation of the land, and, in consequence, the prosperity of the whole agricultural interest, in great measure depend.

1. *As to landowners.*—A non-residence on or in the neighbourhood of their property, such as is too common;

* B. Prowse, Newton Abbot, Devonshire.

a very luxurious and expensive life in London, or on the Continent, for a large portion of the year; an abandonment of their estates chiefly to the care of agents, stewards, and bailiffs—these, it is clear, are no savings banks for landowners. However large be the amounts of rent paid into their hands, if they are invested in any of the above ways, they will be money not saved, but wasted. Principal and interest will both vanish together. Horse-racing and gambling, the latter now, unfortunately so, almost always, more or less, mixed up with the former, need only to be mentioned in order to be condemned. To such practices it is owing that many large and even noble landed proprietors, some by their own fault, others by the vices of their sons, are at this moment bankrupt, and many vast landed estates are lying unimproved, to the great detriment of the occupiers and labourers, as well as of the prestige of the whole class of large landowners itself. No one, of course, will pretend that any of these practices are safe, or profitable, or even respectable investments for the produce of the land. I pass on to those which have a right to be considered as such. For instance, there are the Funds, British or foreign, railways, mines, and joint-stock companies for purposes too many and numerous to be enumerated. These, of course, may all be considered as unobjectionable savings banks, as well for landowners as for any other class. There are, and more or less always will be, some even respectable. Still, neither these, nor anything of a like sort are, to my mind, the best savings banks for landowners. The savings bank which I would most strongly recommend to the landowner is the land itself. To where else shall his rents be invested so safely or so profitably. From no where will they return so sure and so large a return. The land is proverbially honest. By those landowners who have been wise enough to put implicit confidence in it, it has been found as honest as by any other class connected with the cultivation of it. Draining; the improvement of farmhouses, farm-buildings, labourers' cottages; the enclosure of useless roadside wastes; the proper repair of gates and fences, including the abolition of those which are useless; the construction of water-tanks, to which the injury inflicted to both crops and cattle by the severe drought of 1870 has given a peculiarly strong special attention, and with respect to which much useful information may be obtained by a reference to Mr. G. Legard's "Farming of the East Riding," published some years ago in the Journal of the Royal Agricultural Society of England; attention to county business, magisterial and otherwise, the administration of the poor, highway, and education rates, resulting in less extravagance, crime, and pauperism, together with better roads and a more instructed peasantry—this is the best savings bank for landowners. The safety of this bank is undoubted. The profit is sure. A landed estate thus managed by its owner, and let to tenants carefully selected tenants, with all proper security against their being deprived of the benefits of any improvements made by them, and due provision against any loss by game, will command such rents from respectable tenants as will be a high rate of interest for investment. It is thus that a mill, a factory, a foundry, a colliery, a mine, a pottery, or even a mercantile or banking business, is made to answer. The misfortune is that so many landowners look upon their land as anything but a business, yet there is no business which, if time, attention, and money be invested in it, is more profitable. In the debate in the House of Commons on April 26 last, Mr. W. Fowler, M.P. for Cambridge, spoke as follows:—"The country needed a large number of improving landlords, who would do their utmost to improve their estates, and thus benefit the community at large. At present the value of capital as an improvement of land was not sufficiently appreciated; but without capital the land was impotent. In the *Times* of November 11 last, a case was noticed of a gentleman who purchased 450 acres of land for £15,750, and laid out upon it £3800 upon it during four years, he netted £1880 on the year of the 1870 from an annual average outlay of £3450. The tenant's profit at a rent of £2 per acre, and 10*s.* for tenants' use be, through this expenditure of capital, £1150 per annum during the four years. Other instances equally trustworthy could be given of greatly increased rent if capital would be increased if capital were employed upon the land in this way." Had a tenant taken this farm at a rent of £2 per acre, and 10*s.* per acre for rates, he would have netted more than 20 per cent. on his year's farming in 1870. For landowners, then, the safest and most profitable savings bank is the land itself, and all has been spent by its owner upon the land which it needs, or is capable of receiving, it will be time enough to look out for some other investment. This, however, will not often be required. For if, on the one hand, the land is not only very honest, but even liberal, as regards repayments, on the other hand it is very exhaustive. It may certainly be added, that there is no savings bank in which deposits can be made by the landowner with more pleasure, health, and comfort to himself, with more domestic and social enjoyment, with a more encouraging sense of duty rightly discharged, obligations faithfully fulfilled, and, under God's blessing, permanent benefits secured to his own neighbourhood and the country at large.

2. *The best savings bank for farmers.*—I have no need, in the case of farmers, as in that of landowners, to advert to such subjects as non-residence or luxurious and expensive living. Expensive living is not a fault which can often be charged upon a farmer, and the difficulty is, not to keep farmers at home, but to move them from home. An occasional visit to different parts of the country for the purpose of seeing modes of agriculture different from their own, a run, for instance, into Norfolk, or Yorkshire, or the Lothians, would, for the specific instruction it would convey, as well as for the general wakening effect it would have upon the mind, be always well worth the money it would cost, and be anything but a bad investment of a few small savings. Farmers, though not to the same extent as landowners, may be tempted to invest their savings in railways, mines, limited liability companies, and other like speculations. These are more or less both profitable and safe according to circumstances, and thoroughly unobjectionable. Still, I cannot recommend any of them, not even the old-fashioned 3½ per cents. themselves, as the best savings banks for farmers. To the farmer, the same as already to the landowner, I recommend the land as the safest and most profitable bank in which to invest his savings. The land is as honest to the occupier as it is to the owner. The owners may force it to be less honest to the farmer than it otherwise would be by refusing a lease, declining to give security for tenant-right, overstocking it with game, or by that general system of carelessness and indifference, or even inability to provide the funds for necessary improvements which in so many cases renders the farm so much less profitable to the occupier than it ought to be, and otherwise would be. Still, under the most adverse conditions, the land is so proverbially honest, as to be always the safest and most profitable savings bank for the farmer. A careful, constant, unremitting personal supervision of the farm; the employment of all the newest and best machinery; unsparing use of the most approved manures, carefully chosen with reference to the crop and soil; care in the selection and rotation of crops; the securing of an ample hay and corn harvests while the sun shines; the improvement of stock, even though the cost be heavy; good wages punctually paid to labourers; and such kind treatment of them and their families, and care for their religious and moral welfare, as identifies the proprietor with, and identifies them with the interests of their employers, and at the some time indisposes them to drunkenness or pauperism; this is the best savings bank for farmers. You will say that to farm on this principle will cost a good deal of money. So it will. But in what way can you make money or profitably invest every penny which you can save after your rent is paid and your household and personal expenses are supplied? Every penny will come back again into your pocket with compound interest. Machinery, for instance, no doubt, is costly. So are artificial manures. So is the breed of horses, cattle, sheep, and pigs. But the farmer who refuses to invest in these novelties, who says he cannot afford a mowing, or reaping, or haymaking, or threshing machine, and stolidly contents himself with such old-fashioned implements as the scythe, reaping-hook, pitchfork, and flail, and persists in supplying the same crop, without exception or distinction, the manure out of his own stable alone, will find that he has very few savings to invest anywhere. He may live, though that is questionable, but to thrive or prosper is impossible. So also it is often pleaded that to give good wages to a labourer will not enable him with thrift, carefulness, and look after his religious and moral welfare, is all very well for gentlemen, but does not pay the farmer. What is it, I ask, in reply to such a plea, which chiefly impoverishes a farmer and deprives him of his profits? Undoubtedly the heavy and almost ruinous charges of local rates, and damage to horses, stock, and other property, through the drunkenness, carelessness, and want of interest in the welfare of their employer, which are so common amongst the labouring class. Is there no advantage, then, for the farmer in so raising the condition of the labourer as to make him, in character, in, and soul, and mortal, and attached servant? Will he not, in diminished poor rates and less damage to property, put into one pocket more than he takes out of the other for higher wages and multiplied comforts? For the farmer, then, as for the landowner, the best savings bank is the land. The land will exhaust all the savings of the farmer, but it will repay him with surer and larger interest than any other investment. As long as a man occupies land, his wisest course is to spend all his time and money in improving it. It will be time enough to invest his savings elsewhere when he gives up business and ceases to be a farmer.

3. *I pass on to the labourer.*—At present, unfortunately, the most popular savings bank amongst labourers is the Poor-law. This may be described as a savings bank without the trouble, self-denial, and sacrifice involved in saving. It is a savings bank in which those who reap no benefit from it—the farmers more than anyone else—to their great cost and detriment, contribute all the funds, while the idle and dissipated reap all the benefit, and are, consequently, encouraged in habits of idleness and dissipation. Young men and women of the labouring class marry in large numbers without having saved a penny beforehand, with scarcely a bed to lie on, or clothes to their backs. They belong to no club, and have no nest-egg in any savings bank. They look from the very first to parish relief as their right. At the first occurrence of

sickness, or other adverse circumstance, they resort to it, and cling to it without the slightest feeling of shame or degradation. In old age they look upon it as so completely their proper source of maintenance that even if, as is often the case, they happen to have children in independent circumstances, and well able to help them, these very frequently are not ashamed to allow their parents to be maintained at the public expense. Neither Queen Elizabeth, who first established the Poor-law, nor those statesmen who, in successive generations, have attempted to alter and improve it, ever intended it to be the gigantic pauperising engine which it now is; for generally speaking, especially in the west of England, the agricultural labourer has at some period of his life been dependent on the Poor-law for relief to himself or family, and in old age has no other source of maintenance. The Poor-law was enacted, not to supplement wages; not to supply the deficiency of industrious, sober, saving, thrifty habits; or to make up for a want of filial duty to aged and infirm parents, and so encourage pauperism, dependence, idleness, and vice; but only to meet exceptional cases, and, when all other proper and legitimate means of maintenance failed, to provide that none should starve.

The sooner the administration of the Poor-law is reformed, though the change can, of course, be only gradually made, and brought back to the principles on which it was originally enacted, and the labourer taught to look to a more wholesome sort of savings bank, the better it will be for all parties concerned. It is chiefly the married labourer, of course, who can follow the example of the owner and occupier, and, on a small scale, make the land his savings bank. This he may do by every means in his power, and send every penny of money he can spare on his garden, Potato-ground, pig, poultry, and cow, if, as in some instances, he has one, than which he will never find a safer or more profitable investment. A co-operative farm also has been tried in several places—by the late Mr. Gurdon, for instance, at Assington, in Suffolk—and found very successful), is a good savings bank for labourers. A certain number of labourers in a parish form themselves into a company, and take a farm. A fund is raised adequate to the rent and other expenses, say in £1 shares. One of them is appointed at a fixed salary as the bailiff or manager of the farm. The labour is equitably divided amongst the shareholders, at such times as suits their convenience, on days when they have no other work, or after other work is done, at a fixed sum per day or hour; and, if these fail, independent labourers are engaged. The profits are divided at so much per share. It is a pity that those landowners who have the power of doing it, do not set on foot, one in a parish or district, co-operative farms of this sort for labourers; or, failing this, have a two-acre and a small piece of pasture attached to a few of their cottages, to be allotted as they fall vacant as prizes to the more thrifty of the labourers on their estate. There cannot be a better sort of savings bank for them, or one which would more efficiently encourage forethought, industry, thrift, and economy. The same may be said of co-operative stores or shops for all sorts of food and clothing. These are founded on exactly the same principle as co-operative farms, and are already to be found, and flourishing, for all, including even the highest classes of society, in London, many large cities and towns, and in numerous large villages. It is almost incredible how large a proportion of the small wages of labourers is, instead of being saved, absolutely wasted by the purchase at small shops of adulterated food and flimsy clothing at high credit prices. A co-operative store in a village, managed by the labourers themselves, in which they lay in their own goods, at wholesale prices, from the best markets; retail them amongst themselves at ready-money prices; are relieved from the profit of the retail dealer; get out of the bad and pauperising habit of always being in debt; and, in the end, have the profit,—a first-rate, most profitable, and instructive savings bank. Young unmarried labourers, and farm servants of both sexes, should begin to save as soon as they begin to work. They would not then, as too many do now, enter on married life without a penny beforehand, and have no resource in sickness or sorrow but the Poor-law. They would, moreover, have contracted a habit of saving which would never leave them, but in after life would lead them to add, as opportunity offered, to the nest-egg laid by in youth, and be one of the best safeguards against yielding to the temptations of intemperance and extravagance. I cannot very strongly recommend clubs or friendly societies as savings banks for labourers. Some undoubtedly are well managed, safe, and prosperous. But a very large number are constituted incorrect statistics; are badly and extravagantly managed; are too much connected with public-houses; are on the eve of bankruptcy, and in very few cases make provision for such an amount of old-age pay as can render the labourer in his declining years comfortably independent of the Poor-law.

There are other savings banks for labourers much better suited than these for the present improved and improving times. That which I would most recommend is the post office savings bank. The post office savings bank is as safe as the funds, is, in fact, identical with the funds, and, unless the whole country were ruined, can never become bankrupt. It is the safest possible investment, and is largely used by all classes, from labourers upwards. The depositors in post office savings banks at the end of the year 1869 were 1,085,785, an increase of 12.49 per cent. over the preceding year. The amount, inclusive of interest of £2 10s. per cent. per annum, standing to the credit of all accounts open at the end of 1869 was no less a sum than £13,524,109. The average amount of deposit to each depositor was £12 9s. 11d. In the year 1870, the ninth year in which the post office savings banks have been in operation, deposits to the amount of £5,995,121 were received, and repayments of principal and interest were made to the amount of £4,758,187. The charges of management and expenses for the year were £67,945. The sums due to depositors at the close of the year 1870, including interest accrued, amounted to £15,099,104, being above a million and a half more than at the beginning of the year. These figures show, not only the high rate of interest which the post office savings bank is used, but also, since the average of deposits in proportion to depositors is so small, that it is chiefly used by the working classes. Not less, however, than 1s. can be deposited in the post office savings bank. It is difficult to suggest a case, especially for agricultural labourers, to spare so much at one and the same time, or themselves to save up so much by degrees; and hence the post office savings bank has been comparatively little used by them. Penny banks, which have been established in a great many places with very prosperous results, are, wherever established, very happily meet this difficulty. Some one person in the parish, say the clergyman, or the squire, or some benevolent lady, receives at a certain appointed time and place every week deposits from a penny upwards, gives to each depositor a bank-book, provided for by the post office, and periodically remits the amount so collected to the post office savings bank, thus facilitating the deposit of even the smallest sums. The Bristol penny bank has been established 10 years. During that time there have been 307,517 depositors, who have deposited upwards of £30,000 6d. The depositors are, for the most part, of the poorest class of the working population, the average of the sum deposited in proportion to the number of depositors being 10d., though a great number deposit only 1d., 2d., or 3d. There are also 1,600 deferred annuities of not more than £50, than which there is no better plan for securing an independence in old age. Thus, to take a single instance by way of example, a man aged 30 by the payment of £1 8s. 4d. per annum till he is 60 years old, may secure an annuity of £20 per annum for life. He may, of course, have a larger annuity by a proportionally larger payment. Or he may secure the same annuity by one payment of the sum of £24 3s. 4d., which would be no bad way of spending the money which he has deposited in the savings bank previously. Full information on all these subjects may be obtained by the purchase of the "British Postal Guide," which is sold at all post offices for 6d., and a new edition of which, with all additional information, is published every quarter. For labourers, then, especially young unmarried farm servants, there is no safer, more profitable, more easily managed savings bank than the post office savings bank, annuities for old age, and insurance of life. The establishment of a penny bank in connection with the post office, as has been shown above, enables many, who otherwise could not, to avail themselves of this most excellent; encourages even young children, instead of wasting, to accumulate their little presents and earnings; lays, in short, and deposits in safe keeping many a nest egg, destined, perhaps, in after life, not only to attract to itself such accumulations as may make an ample and comfortable provision for old age, but, what is much more important, to engender habits of thrift and independence, which may change the whole character and conduct of the man and his family. If, as already has been shown to be the case, it is of the highest importance for the landowners and occupiers of land to encourage habits of thrift and independence amongst the labouring classes, I know of no way in which they can more readily give a helping hand towards this object than by establishing and personally superintending penny banks in connection with the post office savings bank in their several parishes, explaining to the labourers living on their estates, or in their employ, the condition and advantages of Government insurance and annuities. In truth, an improved peasantry is so completely identified with the prosperity both of the owners and occupiers of land, that I believe that every penny of money or moment of time these spend upon the establishment of penny banks for labourers, is money and time safely and profitably invested on their own account. So that a penny bank is as much indirectly for landowners and farmers, as it is for labourers directly, a savings bank.

The paper, which I have now read to you, does not pretend to be exhaustive. It is a mere sketch of only one out of innumerable subjects connected with the improvement of land. The time, in truth, does not admit of anything more than a mere sketch. But, such as it is, this sketch has been drawn under a very deep sense indeed of the vast importance of the whole subject to which in only a very small part it refers. The improvement of land, and of all who are connected with land, is the one thing most important for this country. The land is the backbone of the nation. Landowners, farmers, and labourers are its thews and sinews. The more these are improved, the firmer and more enduring will be the foundation on which the prosperity of the whole country rests. Had the owners and cultivators of French soil been more enlightened and independent, that personal irresponsible rule, which has been the main cause of all the misfortunes of our unhappy neighbours, would have been impossible. In order to save themselves trouble, they suffered themselves to be led on to nurse the snake which has stung them to the quick; for on no class have the misfortunes of France fallen more heavily than upon her landowners, farmers, and peasantry. Yet even now, in her hour of severest trial and deepest distress, when the population of her capital and chief towns has been tried, and found wanting, it is upon her landowners, farmers, and peasantry, and upon the land itself, that the hopes of France for recuperation and restoration mainly depend. Nor, by the blessing of God, will our own country ever decline if only the land, and those who cultivate it, are not neglected. For some time past, it must, I think, be admitted these have not received from the Legislature their proper share of attention. The public mind, however, has of late become more alive to the national importance of this subject, and we may hope that, on public grounds, there is for agriculture a good time coming. This is no reason, however, for landowners, farmers, and labourers to neglect their own interests, fold their hands folded before them, and merely keep their mouths open in expectation, which, after all, may prove vain, that the Legislature will fill them. God does not ordinarily help those who are too idle to help themselves. The maxim which Longfellow puts into the mouth of his great hero, Miles Standish, is as applicable to agriculturists as to any other class—

"That's what I always say: if you wish a thing to be well done
You must do it yourself; you must not leave it to others."

Farm Memoranda.

EAST BARNS.—The literature of agriculture abounds in records of the manner in which natural difficulties have been overcome by farmers; but the methods by which natural advantages have been turned to account have attracted less attention. This feature of agriculture I shall endeavour to illustrate by the following description of East Barns, in the occupation of Mr. James Murray. The farm is 3 miles east of Dunbar, and lies on both sides of the high road to Cockburnspath, between the Lammermuir Hills and the sea. It is wonderfully sheltered from extremes of climate, and the winter temperature is so mild that it makes a great difference in the period at which agricultural operations are carried out. There is, however, something more than degrees of temperature or inches of rain to be noticed. The soil is a rich red loam, which has been formed by the decomposition of the more or less subjacent Old Red Sandstone; it is about 9 inches in depth, and is endowed with remarkable natural fertility. But natural fertility requires to be sustained, and even this is partly done by Nature, for Mr. Murray's lease includes the privilege of hauling "seaware" from about a mile and a-half of coast, which is equal to a heavy dressing of farmyard manure for from 25 to 30 acres of land, according to the season. [For ground plan of farm-steading see fig. 257, next page.]

The farm consists of about 500 imperial acres of arable land. It is held on a 19 years' lease, under Alexander Mitchell-Innes, Esq., of Ayton Castle, at an annual rent of £1,600, and the current year is the second which has been taken by the present tenant. Considering the nature of a small piece of about 19 acres of pasture, and the fact that the arable land includes about 5 acres of "links,"—a poor sandy soil—it is clear that the natural advantages which have been referred to require to be turned to the best possible account to enable the tenant to obtain a profit after paying a rent which averages nearly £5 per imperial acre. From this point of view, it is hoped that the following description of Mr. Murray's farming operations will be invested with considerable interest. The appearance of the farm, which must be seen to be appreciated, bears evidence of the most studied and careful management, the most thorough and even fastidious neatness and cleanliness; and it shows that, great as is the annual expenditure as rent, the item of labour must also be very large in comparison with the acreage.

The following shift is adopted instead of the ordinary six-course that is most prevalent in the Lothians, partly in consequence of the absence of permanent pasture, and partly on account of the importance of the Potato crop:—1. Turnips; 2. Barley (occasionally a little Wheat) with seeds; 3. Seeds—a part mown, and part grazed; 4. Seeds—grazed; 5. Half Oats and

half Potatos; 6. Potatos after Oats, and pulse after Potatos; 7. Wheat.

The pulse in the sixth year, after Potatos in the fifth, consists of Beans on the stronger land, and of a mixture of Beans and Peas on the lighter. As a rule, therefore, the farm is annually divided as follows:—One-seventh Turnips, one-seventh Potatos, two-sevenths seeds, two-sevenths Wheat and Barley, and the remaining seventh is equally divided between Oats and pulse. The stronger land breaks consist of about 65 acres each, and the lighter land fields of about 70. The former yield as much as the latter, and require as much labour, so that the division is fair in each aspect.

Crops.—1. *Roots.*—The Wheat stubble is ploughed from 7 to 9 inches deep, according to the land, when convenient during the autumn; it is then left until after the spring corn has been sown—generally until the middle or end of April, when it is ploughed along the previous ridges. Occasionally cross-ploughing is adopted, but not often. In dry weather, the harrow follows immediately after the plough, to keep the moisture in the soil; and the land is rolled as soon as the surface is dry enough for a roller to work clean. In the interval between the time of ploughing, harrowing, and rolling the land and the preparation of the seed-bed—generally from three weeks to a month—there is time for the nascent crop of annual weeds to make a braird, of from half an inch to double that length, in the well-pulverised and now mellow soil. These weeds are entirely destroyed by subsequent operations, and a weed in flower is rare to see on Mr. Murray's farm. Four or five ploughs are set to open about a dozen drills to begin; they are followed by carts with manure, and by women who spread the manure in the furrows; for Swedes, to the amount of about 25 Scotch cartloads per imperial acre, and 4 cwt. of dissolved bones, or other artificial manure. When there is more farmyard manure available, the quantity of artificial is proportionately diminished. The return ploughs cover the manure, and are immediately succeeded by two following drills, each of which distributes, at a different depth, 1 lb. of seed per acre in drills 27 inches apart, and is followed by a light roller. Turnip-sowing commences about May 10 with Swedes, which are all in by the 20th, and immediately after hybrid and white Turnips follow, the whole being got in by the beginning of June. The young plants are horse-hoed once, and hand-hoed and singled by women working day-work, and the crop is again horse and hand hoed in the course of another fortnight and three weeks.

What with clean land in good condition, a soil naturally fertile, and a growing climate, the Turnip crop is never a matter of anxiety in the commencement of the season. It is, however, the most precarious crop on East Barns; but the difficulty is not securing a braird, nor in the ravages of the "fly." The anxious time is the latter end of summer and the early part of autumn, when, should dry weather set in, the root-crop sometimes falls short. Mr. Murray stated that if he could secure a fair amount of rain in the autumn, he could be certain of a good crop. About one-third of the break on East Barns is sown with Drummond's Purple-top Swede, and the remainder with hybrid and white Turnips. No Aberdeen yellows are grown. Mr. Murray is of opinion that the seed should be two years' old, and his system is to buy new seed, say in 1868, to be sown in 1870, and 1869 for 1871, and so on. His conviction is that the plants bulb better than from new seed, and do not run so much to top.

2. *Barley.*—As soon as convenient after the Turnips are cleared off the light land, it is ploughed from 6 to 7 inches deep, and harrowed down fine as soon as the weather will permit. In this state it remains until the annual weeds have made a braird, when the skim-plough is put over the land, cutting about 1½ inch below the surface, and destroying the pestiferous wild crop. In the course of another day the land is again harrowed, and is then ready for drilling. Usually not more than 24 hours intervene between the harrow and the drill. From 1½ to 2 bush. of seed Barley according to the richness of the land, is drilled, lightly harrowed in, and the land rolled. The seeds are then sown, the land lightly harrowed, and finally well rolled.

The strong land for Barley, or sometimes Wheat, does not require so much preparation, as it is not so likely to produce the adventitious crop of annuals, which is the object of Mr. Murray's especial solicitude. It is ploughed when the roots are cleared off, and, if dry enough, harrowed immediately; but otherwise it is left until fit, when the harrow and drill follow in close succession, and the seeds are sown as before.

3. *Seeds.*—A large quantity of seeds are usually sown per acre, the mixture being:—3 pecks Italian Rye-grass (one-half English and one-half foreign), ¾ bush. perennial Rye-grass,* and not less than 20 lb. of different Clovers, 6 lb. red, 6 lb. Alsike, 5 lb. white Dutch, and 3 lb. Trefoil; also a quantity of Plantain and Parsley, not more than 2 lb. of each. The system of management commences soon after the Barley is carried, by pasturing with sheep to the extent that the young plants are strong enough to bear. The first year from one-third to one-half of the break is mown, and the aftermath is fed. Two-year-old seeds are entirely pastured, the sheep getting white Turnips on them for two or three weeks before they go entirely on roots. Clover sickness is rare.

4. *Oats.*—As Wheat is never taken after seeds, the lea is not broken up until the end of January or beginning of February, when it is ploughed to the depth of 6½ or 7 inches. Immediately before drilling the land is harrowed, and if there is any appearance of annual weeds the crop is also horse-hoed when sufficiently advanced. Black Tartarian Oats are usually grown, the climate being too dry to suit the white sorts, and about 11 pecks of seed is generally the quantity used. The whole of the crop is consumed on the farm, as well as the straw. *Journal of Royal English Agricultural Society*, vol. vii.

(To be Continued.)

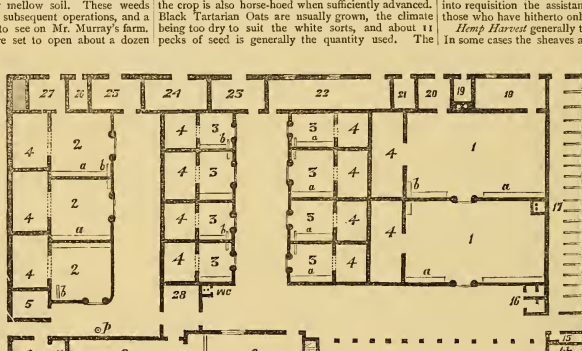

FIG. 258.—GROUND-PLAN OF THE FARM-STEADING AT EAST BARNS.

REFERENCES TO PLAN:—1—3, Fold-yards; 4, Shelter-sheds; 5, Cow-byre; 6, Stable; 7, Harness-room; 8, Large straw-barn; 9, Corn-barn, with fixed threshing-machine and chaff-cutter; 10, Engine; 11, Boiler; 12, Coals; 13, Cart-shed, with granary above; 14, Poultry; 15, Tool-house; 16, Piggery; 17, Stable for farm-horses; 18, Hay-house; 19, Boiling-house; 20, Cake-house; 21, Kilning-house; 22, Servants' cow-byre; 23 and 25, Turnip-houses; 24, Machine and tool-house; 26, Gig-house; 27, Extra stable, with water-cistern at side; 28, Small straw-barn; *a, a*, Food-troughs; *b, b*, Water-troughs; *β*, Pump.

Miscellaneous.

DRY EARTH FOR PIGSTIES.—A friend of mine who has some valuable thorough-bred pigs, which he kept as breeding stock in the country, having to abandon his country property and remove to the city, where from the requirements of the sanitary regulations it was thought the pigs could not be kept, except at considerable risk, has overcome the difficulty through applying the principles of the earth-closet to the use of his pigs. Box sties were put up in a covered building in the rear of the yard of his city residence. A large quantity of well-dried friable loam was obtained and placed under cover, where it would keep dry. At the farthest corner of each sty sufficient straw was placed to make a comfortable bed for piggy to lie on. He never defiles his bed if he can help it. Over the rest of the sty, and especially near the feeding troughs, dry earth was spread over the boarded floor. At first it was thought necessary to clean out the sties every day, and put in a fresh supply of dry earth, but it was soon found out that a shovelful of dry earth thrown every morning and night over what was in the sty, entirely disinfected it of all odours, and so obviated the necessity of cleaning out oftener than once a week. I have visited the place several times, and found no bad smell whatever arising from the sties, nor has anyone, either in the residence or among the neighbours adjoining complained of any annoyance therefrom. The pigs seem to thrive well, are healthy, and quiet. One sty, containing several young pigs, is kept entirely covered with several inches of dry earth, no straw being allowed them, and they appear to delight to roll and root about in it. It might be worth while to try the application of this same principle, on a more extensive scale, in stables, cow-byres, and poultry-houses in the cities and towns. Even in the country, if the earth could be properly dried and stored away for winter use, it might be found of great value as an absorbent of the ammonia in the droppings of stock. This might be done by sprinkling a little over the fresh droppings night and morning, before throwing out the manure heap. By a proper and systematic use of this valuable adjunct, the quality of the manure made on the farm might be largely increased, without adding to its bulk by the admixture of so much useless straw as is customary. *J. M., in "Country Gentleman."*

* Pacey's is never used now, as it was found to get short, dry, and hard.

The Week's Work.

AUGUST 26: *Harvest in Scotland.*—Over the greater part of Scotland the command of labour is limited to a regular staff of harvest hands, so that the whole work has to be done by them; and the task is severe, calling into requisition the assistance of reaping-machines by those who have them hitherto only used the scythe.

Hemp Harvest generally takes place about this time. In some cases the sheaves are allowed to lie open and dry, and when bound up, the crop is stacked like corn, and dew-retted prior to being sent to the mill for breaking and scutching. When grown for both seed and fibre, Hemp is seldom water-retted or steeped. Small farmers who have plenty of spare time on hand, first pull the male plants, which they water-rett and grass-rett as Flax, and afterwards pull the female crop for seed and coarser Hemp; but this mode of separation is slow work, and seldom practicable on large farms with hired labourers.

Trifolium incarnatum.—Sow on a clean stubble about 20 lb. of seed to the acre, after rain, and cover with bush or chain harrows.

Autumn fallows are attended to as soon as the work can be begun. It has become an established fact that ploughing or manuring up land when dry is more advantageous than ploughing it wet. Steam-power has even superseded the old maxim of ploughing clay lands between the wet and the dry. Needless to say that the drier land is ploughed the better, and therefore the first opportunity after harvest should be embraced to prosecute the work of fallowing, with all the force at command, before the weather breaks, and the earth becomes soaked to its maximum with the rains of autumn.

The Teams in harvest require special attention in food, water, grooming, and rest. Corn crops are this year bulky; but the loads, so long as the work lasts, will be as heavy, if not heavier, than usual. A great number of reaping-machines are in the field. "The work must be done," is always the order of the day; and under such an arbitrary rule horses should have an abundance of easily digested food, with plenty of pure, soft, filtered water. Cold hard water to horses in the harvest field is worse than unwholesome, and so is water full of animal and vegetable life. There is little rest for the teams in harvest, and therefore the back of the carthorse should be relieved from the weight of the load when unloading in the stackyard, and at night thorough grooming is essential to refresh the exhaustion of the system that has taken place during the day.

Turnip Hoeing.—This operation must not be neglected even in the time of harvest. Where there is a sufficiency of moisture in the land, the first sown stubble Turnips grow with great rapidity, so that if neglected for a day or two to be singled the loss will be heavy.

Farrow Sows that bring forth their second litter attend to. Dairy porkers and bacon hogs, as the days become colder, will bear moderate forcing, but the diet should be cooling.

Notices to Correspondents.

DISEASED CHICKENS: Your correspondent, "Subscriber," (p. 1088) has not mentioned how his "diseased chickens" are kept, but when I have had some ill in the same way, when kept in the courtyard by the house, with a free run on grass, I have found the best cure to be to send them to the home farm, where the constantly fresh surface of the straw-yard, and the shelter from any cold or wet winds amongst the stacks or sheds, generally restores them to health, at the same time feeding them on broken Wheat (tailings) or barley meal, sometimes mixed with chopped Onions, never giving soaked bread, which will often cause the disease of itself. A new fowl or two next year, by raising a stronger breed of chickens, would probably prevent the recurrence of the disease. *G. E. O.*

MEASURING HAYRICKS: *An Old Subscriber* writes:—Can you inform me the correct scale or manner by which I can ascertain the weight of hay in hayricks, and how to apply it both for square and round-made ricks? [You will find very good information on the above subject in "Ewart's Agriculturist's Assistant," Blackie & Son, Paternoster Row. This excellent little book contains a large mass of information regarding measurements, quantities, prices, &c., connected with rural economy.]

UTILISING PEA HAULM: We give at length the inquiry of "Rusticus," to which attention was directed at p. 1088, in our last issue. He says: "I have just harvested 8 acres of Hogg Peas in the best possible condition, and I shall be pleased to hear how I can best utilise the haulm when the Peas are threshed out. Should the haulm be cut into chaff, and boiling water, treacle, &c., be poured upon it? I trust Mr. Mechi or one of your numerous contributors, will enable me to turn this species of food to good account."

VINEGAR: *Jif.* The following is a recipe:—Put to 10½ gall. of water to lb. of brown sugar, boil it gently till no scum is on the surface, taking what does arise off with a skimmer; put it into an open tub or pail to cool, and when quite so, add a teacupful of yeast, to put into a fermantation; in three days put it into a cask, filling about two-thirds of it, which will cause it to acidify quicker. Place the cask in the sun, with the bunghole open, covering it with a coarse piece of muslin to prevent flies from getting into the liquor.

Markets.

METROPOLITAN CATTLE MARKET.

MONDAY, Aug. 21.

We have a considerable increase in the number of Beasts; there is a demand for choicest qualities, at nearly late quotations; some lots of inferior remain unsold. There are a very few more Sheep than last week, and the trade for them is about the same as then. Lambs are decidedly lower; it is difficult to effect a clearance. The Calf trade continues unaltered. Our foreign supply consists of 1940 Beasts, 10,140 Sheep, 350 Calves, and 5 Pigs; from Ireland there are 250 Beasts; from Norfolk and Suffolk, 700; and 2250 from the Midland and Home Counties.

			Pigs	3	4—4 8

THURSDAY, Aug. 24.

The number both of foreign and English Beasts is about the same as last Thursday; trade is not very brisk, yet there is scarcely a quotable difference in price. The supply of both kinds of Sheep is shorter; although trade is dull, prices are but little altered, if at all. Lambs and Calves are selling lower on the average. Our foreign supply consists of 455 Beasts, 5420 Sheep, 463 Calves, and 25 Pigs.

JOSHUA BAKER.

MARK LANE.

MONDAY, Aug. 21.

The supply of English Wheat at this morning's market was very small, and both new and old sold readily at the full prices of this day se'nnight. There was a good attendance, and a better demand for Russian and American Wheat, and in some instances rather more money was obtained for these descriptions. Barley, Beans, and Peas were without change. Oats were a dull sale, at previous rates. Flour was unaltered in value.

WEDNESDAY, Aug. 23.

A quiet feeling pervaded the Corn Exchange to-day. Business was transacted to a limited extent, and prices in some instances gave way. The supply of English Wheat was small, but that of foreign was large. The demand for all qualities was inactive, at prices tending towards reduction. Barley sold quietly on former terms. Malt was dull, and drooping in value. Oats, the supply of which was extensive, experienced a slow sale, at drooping prices. Beans and Peas were quiet, at about late rates. Flour was dull, and prices favoured purchasers.

SEED MARKET.

Clover seeds of all descriptions are quiet but firm. For Trefoil seed values continue to tend upwards. White Mustard seed sells on former terms. We have a good inquiry for new Rapeseed. Trifolium is in slow request, at the recent decline. Hemp and Canary move off in retail, at unchanged currencies. New winter Tares and Rye are coming to hand, at moderate quotations. In Italian Rye-grass there is as yet but little doing.

JOHN SHAW & SONS, Seed Merchants, 76, Water Lane, London, E.C.

HOPS.

BOROUGH MARKET, Aug. 24.

Messrs. Pattenden & Smith report a steady demand for consumption for both English and foreign. Choice samples are scarce, and rule firm in price. The plantations have improved to some extent, but the result cannot exceed about 3 cwt. per acre on the average. American reports are daily more unfavourable. On the Continent the markets are equal to only about one-fourth of last year's growth.

THE ALEXANDRA PALACE AND MUSWELL HILL ESTATE TONTINE.

(TO TERMINATE ON THE 30th JUNE, 1886.)

THE ALEXANDRA PALACE and MUSWELL HILL ESTATE TONTINE. (To terminate on the 30th June, 1886.)

TRUSTEES—{JOHN CLUTTON, Esq., Whitehall Place.
JOHN HACKBLOCK, Esq., Bolton Gardens.
JOHN HORATIO LLOYD, Esq., Inner Temple.

The Palace is a splendid, capacious, and substantial structure, and the Estate comprises nearly 500 acres of beautiful freehold land within a radius of 6 miles only from Charing Cross.

The object of the Tontine is to complete the purchase and improve the property, and thus to provide for all classes of the inhabitants of the metropolis, and especially of its northern and eastern portions and suburbs, and for the many thousands of country excursionists, a grand institution of healthful recreation and elevating instruction, which will combine the solid advantages of the South Kensington Museum and Schools of Art with the lighter pleasure and pastimes of the Crystal Palace at Sydenham, thus giving effect to the large and enlightened views of the late Prince Consort.

The main advantages of this undertaking may be said to be as follows:—

The holder of a Tontine Certificate for ONE GUINEA or upwards, will become entitled to—

A share in the realisation of the estate in 1886, when the nett proceeds must be of enormous value.

Free admissions in the meantime, on certain occasions.

A share in the Art Unions (proposed to be held once in every three years), when the prizes will be considerable.

To be reimbursed 20*s* for each Guinea paid in the event of the Life nominated, and upon which the Tontine privilege depends, not surviving till June 30, 1886.

Thus the Tontine (besides its other great privileges) presents the opportunity of making, at a very slight cost, an ample endowment for children, or of ensuring a very large return for the capital invested.

If being a "Trust," Subscribers incur NO LIABILITY, and must benefit.

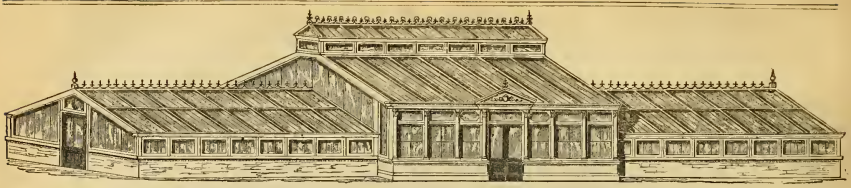
If no issue is made, the Subscriptions will be returned in full.

For further particulars, see Detailed Prospectus.

Admissions to view the Palace can be obtained at the Offices of the Company, 5 and 6, Great Winchester Street Buildings, E.C.

ALEXANDRA PALACE.—The advantages offered to the Public were thus summed up by *The Times*, of July 18th:—"Under the title of 'Alexandra Palace and Muswell Hill Estate Tontine,' certificates representing 850,000 guineas are about to be issued, which will entitle the holders, in proportion as they may possess a single certificate of one guinea or any larger number, to participate in the various objects of the institution, or to take their share of the entire property of the Palace and grounds of 498 acres, should they, 15 years hence, be among the surviving holders. Under an elaborate but ingenious plan framed for the purpose, each subscriber will have several options as to the mode in which he may obtain a return for his investment, and be virtually guaranteed against loss. The Trustees and Board of Directors consist of experienced persons, familiar with the management of London properties and of public establishments, and it may be hoped that the result of their arrangements will be to furnish to the population of the North of the metropolis a place of resort as attractive as that on the other side at Sydenham."

ALEXANDRA PALACE.—In an address delivered by that distinguished lawyer, Mr. John Horatio Lloyd, one of the Trustees of the Alexandra Palace and Muswell Hill Estate Tontine, "Mr. Lloyd explained the principle on which it was proposed to raise the necessary capital, and declared that he was perfectly satisfied that no possible loss could be sustained by any one investing; as, in addition to the value of the property, a system of insurance had been devised which was a practical guarantee against any possible failure. He declared that he would not have accepted the position of trustee had he not been satisfied that the undertaking was one offering many solid advantages to investors, commercially secure against failure, and commending itself in the highest degree to the favourable consideration of all interested in providing for the acknowledged wants of the working classes, and desirous to do so in some more substantial form than by mere words."—*Advertiser.*



HORTICULTURAL BUILDINGS,

COMBINING STRENGTH AND DURABILITY.

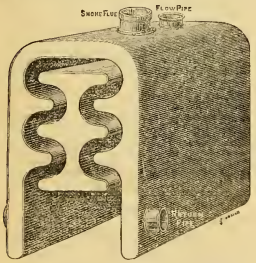
IRON and WOOD CONSERVATORIES of the most CHASTE and ELABORATE DESIGN.

Vineries, Pineries, Peach Houses, Forcing Houses, Glass Cases for Wall Trees, Pits, &c.

Designed and Built, combining all the latest Improvements, so as to answer their intended purposes without risk of disappointment.

Plans, Specifications, and Estimates on application.

ORMSON'S IMPROVED WELDED WROUGHT-IRON CONVOLUTED BOILERS



ORMSON'S PATENT CONVOLUTED BOILER.

Are better than Cast-Iron Boilers, because—

THEY DO NOT CRACK,
THEY REQUIRE NO INSURANCE,
THEY WILL BURN ANY KIND OF FUEL,
THEY ARE SAFE FROM SUDDEN FAILURE.

The internal curved lines of this Boiler giving FOUR INTERNAL CURVED SURFACES to the DIRECT ACTION of the FIRE, which being STOPPED at EVERY PROJECTION or CONVOLUTION, must, to those who understand the Science of Heat, be a convincing proof of the perfect combustion and exhaustion of Heat on the surfaces of the BOILER BEFORE ESCAPING INTO the CHIMNEY. In addition to the foregoing ADVANTAGES, the Fire also acts on the ENTIRE EXTERNAL SURFACE, which undoubtedly gives it the IMMENSE ADVANTAGE of being decidedly

THE MOST ECONOMICAL BOILER KNOWN AT THE PRESENT TIME.

A trial will convince all who use this Boiler of its VAST SUPERIORITY over all others in point of ECONOMY, and being made of the best WELDED WROUGHT IRON, its safety and durability may be thoroughly relied upon. There is no danger of cracking and breaking down, so common to all forms of Cast Iron Boilers.

List of Prices on application; also, "Book of Designs of Horticultural Buildings."

H. ORMSON is prepared to make a Boiler on his Patent Convoluted Principle to Heat WITH SAFETY a larger amount of Pipe than any "One" Boiler in the World can now be found doing.

H. ORMSON also supplies the WELDED WROUGHT-IRON COMBINED SADDLE and FLUE BOILERS.

HENRY ORMSON, Horticultural Builder to Her Majesty,
AND HOT-WATER APPARATUS MANUFACTURER TO THE COMMISSIONERS OF HER MAJESTY'S ROYAL PALACES AND PUBLIC BUILDINGS, AND TO THE ROYAL HORTICULTURAL SOCIETY,

SATURDAY, SEPTEMBER 2, 1871.

MEETING FOR THE ENSUING WEEK.

WEDNESDAY, Sept. 6 { Royal Horticultural (Fruit and Floral Committees), at S. Kensington .. 11 A.M. / Ditto (General Meeting) .. .. 3 P.M.

WE have been induced to lay before our readers a plan of an ARBORETUM and FRUIT GARDEN, proposed to be established at Berlin, in order to call attention, not only to what appears to us to be a very carefully considered and well arranged plan for the purpose, but also to deprecate the astonishing apathy with which a subject of such national importance and, as one would think, of such general interest, is received in this country. Was there a single gardener, or forester, or gardener, who put in a plea for the retention and maintenance of the arboretum at Chiswick, now irrevocably passed out of the hands of the Royal Horticultural Society, and indeed in part destroyed? Of what avail was the protest of a few botanists when they were in no way backed up by the practical men, to whom an arboretum should be of greater value than to the man of science? It is of no use lamenting over spilt milk, however; let us rather rejoice that though the arboretum be lost, the pomological collections at Chiswick, if diminished in extent, will at least be increased in value, and that there at least we shall have what Professor KOCH wants for Berlin—a collection of the best sorts of fruit trees, and illustrations of the best modes of cultivating them.

If of late years little interest was manifested in the arboretum at Chiswick, little more is generally felt for that at Kew. We do not believe that the efforts made by the late director to get together a collection, in spite of great difficulties from the hungry nature of the soil, and the absolute loss from our nurseries of many fine and interesting kinds, have been at all appreciated as they should be. We do not believe that the value of the large collections of hardy

shrubs at Kew is at all generally recognised, and those who note what is in course of carrying out at the present time in the improvement of the arboretum and the formation of a pinetum, seem to us to look at the matter from the standpoint of the landscape gardener rather than from those of the forester or of the botanist. But in a large national establishment, so far as possible, all interests should be studied; and if we now, for the moment, lay stress on the useful rather than the ornamental, it is not that we undervalue the latter, but because the ornamental is pretty sure to be attended to alike in our private and in our public establishments. Moreover, a knowledge of the kinds of trees most suitable for particular purposes, of their habit of growth, the circumstances favourable or adverse to their cultivation, and so forth, is becoming every day of more and more importance. We have cleared so many of our trees, and drained our fields so thoroughly, that there are at least some grounds for fear lest we may not have injured if not killed the goose which lays the golden eggs, and that our climate will suffer from our overweening efforts at "improving the land." Be that as it may, it is a fact that there are thousands of now barren acres, miles of now waste places in the British Isles, unsuitable or almost any form of culture but that of trees, and which might profitably be utilised in the cultivation either of timber or of fruit trees. The amount of capital required to start with would be comparatively trifling; the expense of maintenance would be small; the amount of knowledge demanded is not greater than any manager or forester should, nay, in most cases does, possess.

What then is the reason of the prevailing apathy? We can only attribute it to the subject not being sufficiently kept under the notice of the public. Our country gentlemen want the practice and the precepts of another EYELYN to stimulate them in their turn to exertion.

The complaints which reach us from India, from Australia, from almost all our colonies in fact, of the consequences of the reckless no-management of the forests, should stir up our foresters and gardeners to increased efforts, so that we may turn our wasted treeless tracts to good account, and be spared the humiliation of having to send our would-be Indian forest-officers to France and Germany to learn what, were there a proper system, could be equally well learnt here.

Foremost among our requirements are experimental gardens and collections, such as those advocated by Prof. KOCH, and where the planter might see what is available for his purposes, and where he might resort with the certainty of obtaining information on the subjects in which he is so much interested.

WHATEVER be the fate of the silk culture in Japan, whether it follow the course experienced in India, China, and the other continental lands to its west, or escapes from the frightful risk to which its reckless cultivators have exposed it, by introducing eggs from infected countries, one thing is plain, that it behoves Australia and every other country which has as yet a clean bill of health in the matter of the silkworm disease, to extend the same caution to Japan which they have hitherto given to countries recognised as the abode of the Pebrine. This caution comes well at this time, because the Acclimatisation Society has been vigorously exerting itself to introduce from Japan not only the eggs but the whole system of treatment practised by the Japanese. No harm has been or can have been done yet; but in the future let them walk warily. Dr. BENNETT and Mr. CHARLES MAYNE have been conspicuous by their exertions in this direction; and Sir HARRY S. PARKES, K.C.B., Her Majesty's representative at Yokohama, has, at their solicitation, interested the Japanese minister DATÉ in the movement, and obtained through him not only everything that could be necessary in the way of samples of silks and supplies of eggs, but also a complete set of all the different instruments and machinery used by the Japanese in their *magnaneries*, consisting of upwards of 50 different trays and sieves, feathers and brushes, racks and reels, pans and stoves, baskets and tubs, and all the little implements that can be thought of to save labour and facilitate work. The seed sent consisted of 112 cards of the very best qualities, obtained from mountainous districts at a distance from the sea, which it is thought are most favourable to the production of healthy stock. These cards are more numerous than can be conveniently dealt with by the Acclimatisation Society at Sydney, and several have therefore been dispatched to Adelaide, Melbourne, Brisbane, and New Zealand, for utilisation there; and it would appear a point of no mean importance that this contribution has been made before it was possible that the introduction of European infected eggs into Japan could have affected the natural quality of the eggs in that country.

The above evidence of goodwill on the part of the Government of Japan is more than we were prepared for. It affords one instance of the benefits to be derived from having a British officer to appeal to in a foreign country where the minister understands his duty to his country, and is anxious to perform it.

The intelligence that we have regarding the progress of silk culture in India is derived from a report of the proceedings of a meeting of the committee of the Agri-Horticultural Society of Madras, dated August 3, 1870. In this there is published a letter from Dr. G. BIDIE, the Secretary of the Society, to the Acting Secretary of the Board of Revenue, dated May 21, 1870, from which we are sorry to learn that the SILKWORM DISEASE still prevails in India.

It appears that the Board had asked Dr. BIDIE to furnish them with specimens of the cocoons of silkworms indigenous to the Presidency of Madras, in order to see if they could be procured for acclimatisation in New South Wales; and Dr. BIDIE, in his reply, sends a few cocoons of the only wild kinds which he knew to exist there. He knows of only three. The one belongs to the old genus Saturnia, and seems nearly allied to Attacus Ricini, the castor-oil worm. At Madras it feeds on Zizyphus Jujuba (Bhere tree), Terminalia Catappa (country Almond tree), and sometimes on Nauclea parvifolia; so that no difficulty would be experienced in procuring food for it, should the experiment of domesticating it be tried at Madras. The castor-oil worm itself, indeed, in indigenous to Madras; but it is not cultivated there, although it is reared in some parts of the Hyderabad country. The other indigenous silkworm alluded to by Dr. BIDIE is the Atticus Cynthia, discovered some years ago on the Himalaya, and now cultivated in Bengal, as well as introduced into Europe. Dr. BIDIE mentions that only domesticated worm known in Madras is a variety of the China insect, Bombyx Mori, but in Mysore other cultivated kinds have been introduced from other parts of the world; he does not think, however, that it would be safe to get any from that quarter at present for the purpose of supplying Australia, as the disease which has been so disastrous to sericulture in France and Italy is prevailing there, and it is readily communicated from infected stock either by egg or chrysalis.

It is gratifying to observe that the attention of the Government in the Madras Presidency has been directed to this most important subject, and that the liberality with which they desire to assist in the acclimatisation of silkworms in New South Wales is tempered with a wise discretion; for in the proceedings upon Dr. BIDIE'S communication we find it noted that "it is evident that the greatest care is necessary in selecting worms for exportation, and it appears as the Board are aware that only worms in the Presidency which have been entirely free from epidemic disease are those cultivated to a very limited extent in the Tinnevelly district." It is not, however, known with certainty of what species these are. The Board, however, are not of opinion that the wild worm of their Presidency is of any great value, an opinion in which we entirely concur.

—— A RAMBLE through KEW GARDENS is always a source of pleasure, for there is something there to meet everyone's fancy. For our own parts, although fully concurring in the desirability of doing away with a number of small houses, and of massing the plants in "ranges," we yet can but note that many of our old favourites seem lost in their new abodes, and that many plants of interest, which attracted attention when scattered through several small houses, are now liable to be passed over in the crowd in the larger tenements. The large round bed at the end of the long walk, of which we gave an illustration in our last volume, 1870, p. 1344, is planted in a somewhat similar but less frittered manner than last year. The design is now bolder, and equally or more effective. It consists of a series of elliptical figures radiating from the central vase, triangular spaces fill the intervals between the ellipses below, and the whole is margined by a circular belt of Echeveria secunda glauca. The plants in the upper and lower halves of the elliptical figures are different, which has an odd effect, more pleasurable at a distance than in close proximity to the bed. The upper half of the ellipse consists of a broad belt of Centaurea ragusina, within this a band of Coleus Verschaffeltii, encircling a central mass of Abutilon Thomsoni. Instead of continuing this arrangement, which is effective enough, the lower half of the ellipse consists of plants of larger growth, and has in the centre, below the Abutilon, a patch of plants of Sempervivum ciliatum, edged with Golden Feather, and this encircled with a line of single plants of Echeveria metallica, bounded on either side by a zone of Alternanthera amabilis, and the design completed by a double line of Echeveria secunda glauca, corresponding to the edging of Centaurea ragusina above. The triangular spaces between the points of the ellipses and the outermost border are filled with a centre of plants of Sempervivum velutinum or S. canariense, springing from a carpet of Alternanthera, and edged with the variegated white-leaved Koniga maritima. In some of the other flower-beds it is singular to notice how certain favourite bedding plants maintain their ground in spite of new comers. Not to speak of Mrs. Pollock, Purple King Verbena amply justifies Mr. SMITH'S choice, as also do Duchess of Sutherland and Lady Constance Grosvenor Pelargoniums. Iresine Herbstii is poor, and Mauve Queen Viola, as seen at Kew, no improvement on older sorts. It is a relief to turn from these vulgarisms to the noble Palms. The Arenga saccharifera, one of the finest of the Kew Palms, is now bearing a splendid drooping plume of young fruits. Of quite another character, but noteworthy in its way, is the plant of Dammara australis in the temperate house, and now bearing a few young cones—a very distinct-looking plant. In the same house it is interesting to see the different character which the Vitis (Ampelopsis) tricuspidata (Veitchii of gardens) assumes as it grows older, when it produces deeply-divided leaves, intermediate between those of an ordinary Vine and those of the old Virginian Creeper in form, and quite different from the small neat Ivy-like foliage borne by the young branches. Talking of creepers, those in search of effective plants of this kind should by no means overlook Lonicera sempervirens, which, for bright colour and continuous blooming qualities, may well compare with many better known plants. On the rockery is a plant of Opuntia Rafinesquiana in flower, and a patch of Sedum coeruleum, a little gem; but we urge our readers to go and revel for themselves. We cannot indicate a tithe of the noteworthy plants.

—— THE EAST LONDON AMATEUR FLORICULTURAL SOCIETY has hit on a recipe for filling its exchequer. From a local report we learn that "during the evening large numbers of the fairest of the fair inhabitants of privileged Bow," were assembled on the occasion. "To account for this it is necessary to state that the band of the Royal Middlesex Artillery Volunteers were located on the field, and supplied music to which ere long the youthful feet were tripping merrily over the green sward; their owners elated with the thought that no censorious mamma was at hand to check their vivacity." It is needless for us to remark that floriculture was at a discount, and the only flowers that found favour were the "dancing girls!"

—— The following suggestive passage occurs in Mr. BENTHAM'S Presidential Address to the Linnean Society, lately published. We quote it as illustrative of the aim that societies and public institutions should strive to attain. "The formation of our ZOOLOGICAL SOCIETY and gardens opened a new era in the cultivation of the arts. . . . With an annual income of about £23,000 the Zoological Society is enabled to maintain a living collection of about a thousand species of vertebrata; and although some portion of the surplus funds is necessarily applied for the sole gratification of the paying public, yet a fair share is devoted to the promotion of that science for which all the fellows are supposed to subscribe—the accurate observation of the animals maintained, the dissection of those that die, and the publication of the result. Physiological experiments are either actually made in the garden, or promoted and liberally assisted."

—— A new application of CHARCOAL has recently come to our knowledge. We are told it is now largely used in the manufacture of a permanent enamel, or varnish for coating the insides of casks. The charcoal, which is made from the wood of Salix alba, is reduced to a very fine powder, and mixed with proper proportions of shellac and methylated spirit. When ready for use it is laid on with a brush, and the inside of the cask is fired, so as to remove the spirit and leave only the lining of charcoal and shellac; it is then coated again and fired a second time, after which it is allowed to stand a short time before being used. This composition is said to form a perfect enamel, and while it prevents any chance of leakage it preserves the casks in an extraordinary manner. It answers admirably for beer and acids, and is largely adopted by some of our principal brewers. Its preparation and use is protected by a patent.

—— Amongst the many NEW ANNUALS introduced year after year, there are few that hold a permanent place in our gardens. The majority are rejected on account of the short duration of their flowering season, which seriously interferes with the beauty of a garden

planted in the style almost universally adopted at the present time. Two recent introductions seem likely to prove valuable acquisitions, either for the geometrical garden or indeed borders. I refer to Godetia Whitneyi and Tagetes signata pumila. The former (for figure and description, see *ante*, p. 103) certainly deserves all the praise bestowed upon it. The splendid rose-coloured flowers, with a crimson blotch on each petal, strongly reminding one of those of an Hibiscus, are produced in the greatest profusion for a long period. The plants in the bed I have in view are dense bushes, about 18 inches high, literally covered with flowers. Tagetes signata pumila, and especially the variety florepleno, is a very pretty, dwarf, compact, yellow-flowered plant, suitable for bedding, and much more to be depended upon than the Calceolarias, of which, by-the-by, I have not seen a good bed this season, all being more or less diseased. *H.*

—— The Maximum Temperatures of the Air during the week ending August 26, ranged in England from 78°.7 at Blackheath, to 67° at Newcastle-on-Tyne, with a mean for all stations of 73°.1 in Scotland the highest recorded was that of 82 at Perth, and the lowest 64° at Greenock, the mean value being 65°.6, or 70°.4 lower than the corresponding value for the southern country. The Minimum Temperatures of the Air were more equable over the whole country, the highest value being 52°.8 at Portsmouth, and the lowest 40° at Strathyl, and the means 44°.9 for England, and 43°.8 for Scotland. The mean temperatures ranged from 63° at Portsmouth and Blackheath, to 53°.3 at Aberdeen. The decrease, as shown in Mr. Glaisher's Tables in the present issue, is very striking, the values, with but few exceptions, declining nearly uniformly from south to north. The mean value for England was 59°.1, and for Scotland, 53°.9. Rain is recorded as having fallen at all stations during the week, though much heavier in Scotland than in England, the maximum fall in the latter country being 1.12 inch at Eccles, while at six out of the seven stations in the former the values exceed this amount. At Glasgow and Perth 2.49 inches and 2.16 inches were measured. The mean fall for England was 0.45 inch, and for Scotland 1.67 inch.

—— The Messrs. Dickson & Co., of Edinburgh, have sent us another batch of Seedling Violas, similar to those referred to at p. 772 of our last volume. They are described to be dense and branching in habit, hardy in constitution, and invariably full-flowered blooms from spring till autumn; indeed, as we learn, "they have been almost a sheet of flower throughout the season." The Messrs. Dickson state, that they find Viola stricta a very useful species for crossing, as the seedlings from it have a fine, soft, waxy-looking colour, and a good substance. Of those referred to last year, the deep golden yellow, now called Dickson's Golden Gem, is one of the finest; and those called V. lutea pallida, and V. lutea Grievei, with The Primrose and V. suaveolens major, are extremely showy, and of different shades of pale sulphury-yellow. V. odorata, a creamy white, with violet eye, looks like a useful bedding Pansy. Another smaller-flowered white, V. stricta alba, pure white, with a small orange spot at the eye, if of a suitable habit, must be quite a gem for bedding purposes. Strongly contrasting with these are V. amoena magnifica, a rich mulberry purple with the lower petals pucy-violet, the eye yellow; and Vanguard, like a small self-coloured mulberry Pansy—both charming flowers. Violet Fairy Queen is again quite distinct, having yellow lower petals, and deep violet top petals, evenly bordered with yellow, so bright and cheerful-looking that it must be an excellent massing plant. With these came several highly-promising bedding Pansies, of which one, named Celestial, a deep reddish-purple, and New Colour, a sort of reddish plum-colour, both said to be first-rate in habit, struck us as being likely to be extremely useful.

—— One of the handsomest and most symmetrical plants of Thujopsis dolabrata we have fallen in with, is growing in the pleasure-grounds at Ashridge Park. The plant is in vigorous health, about 5 feet 6 inches high, and fully as much through at the base, and forms a dense cone of perfect symmetry, very different from the abrupt and unfinished appearance so often presented by the leader and uppermost branches of this really handsome and hardy Conifer. An equally well-furnished plant of the prettily variegated variety, of about half the above size, is growing in another part of the grounds.

—— In reference to the names of Oncidium macranthum hastiferum, and Lambertvanum, Professor Reichenbach writes that both are due to M. Linden, of Brussels and Ghent. "I remember very well how he pointed out one day, to Director Funck and to myself, the differences between these varieties from the very bulbs. Every one knows that M. Linden's ability to discriminate species from the bulbs alone is quite unrivalled. The unfortunate name of hastiferum was given, if I remember aright, to the best variety. It gave rise to the suspicion that my 'hastiferum' was the same plant, though that is quite as distinct from hastiferum as a rhinoceros from a hippopotamus, since it bears an erect blade on its anterior lip, while the hippopotamoid macranthum does not rejoice in such an ornament. Now I believe Oncidium macranthum Lambertyanum was, by 'second choice,' named in honour of Monsieur le Comte de Lambertye, the distinguished grower of Strawberries. Finally, Oncidium macranthum itself appears to have been that much inferior variety, bearing much smaller flowers and scarcely any black violaceous ornaments on the lip. The numerous sketches I have at hand show remarkable differences in the side lacinie of the lip. This is, however, perhaps a matter of no great importance, since I do not at all know whether I did not get several of these first flowers, which ultimately often prove to be mere abortions. M. Linden's last catalogue specially attributes a higher value to the two varieties than to what he takes as the type. There is, however, scarcely any doubt that the hastiferum is what was originally intended for macranthum, which was gathered by Ruiz and Pavon, and which I have from Dr. Lindley's own hands. If I cannot give a very accurate answer, I have, however, done my best to make some remarks."

—— Those who have to supply French Beans in any quantity throughout the winter and spring months are strongly recommended by a correspondent of the "Florist and Pomologist" to waste none, but to adopt the plan of preserving them, while there are plenty to be had. When thus preserved, he finds that an immense amount can be had in winter, and not having to grow them; indeed for the last three winters he has not had to force any. The mode of preserving them is as follows:—To 12 lb. of Beans allow 6 lb. of salt. In a pan place a layer of Beans, and then a layer of salt, until the vessel is full, the last layer of salt to be rather thicker than the others; put a plate or anything that will nearly cover the Beans, on the top of the pan, and a weight of about 6 lb. on the top of all. Let them remain thus for two days, when the salt will have turned into brine; then take out the Beans and put them in jars, pour the brine, which must be equally divided, over them, and a small plate on the top of the Beans to keep them under the brine, and then tie a bladder over the jars. If well covered with the brine, the Beans will keep good for 12 months. The Beans should be gathered on a dry day. Before using, they should be put in cold water for an hour, changing the water several times. If properly done it is said to be difficult to tell them from newly-gathered Beans, either as regards appearance or taste.

—— Messrs. Carter & Co. have sent us samples of various forms of French and African Marigolds, grown at their seed farms in Essex. We can pronounce them to be very good examples of their respective sorts. The Africans are represented by the usual orange-coloured and lemon-coloured varieties. Amongst the varieties of French Marigold, those which we prefer are labelled Dunnett's Double Tall Orange, of a clear deep orange hue; Double Gold-striped and Double Dwarf Gold-striped, two handsomely marked gold and brown sorts, and the Double Tall Dark, of a rich Spanish brown. In all these the colours are well marked, and the capitules full and symmetrical, with the florets well developed, and spreading out into a handsome rosette.

—— Judging from the appearance of numerous plants in the nursery at Great Berkhamsted, and from the information obtained from Mr. Lane, we are inclined to accord a very high position amongst ornamental—perhaps even profitable—Conifers to the Vancouver's Island Fir, which Gordon called Picea grandis. Its growth is most rapid and elegant, and in the high grounds of Berkhamsted it is perfectly unaffected by any frosts. We might with safety designate it as one of the most rapid-growing members of the Coniferous family.

New Garden Plants.

Oncidium exasperatum, *Lind., Rchb. f.*

Affine Oncidio coccifero, Rchb. f. Sepalis tepalisque extus valde muriculato - exasperatis; sepalis cuneato ovatis apiculatis; tepalis cuneato-lanceolatis labello triangulo basi unicoque obtusangulo; cullo depresso a basi in discum; apice utrinque unidecratio antice, utroque latere dentibus ternis; carinis tunc geminis; columna sub foves isthmo insiliente constricta.

One of the smaller flowered species, with chestnut-brown flowers, the lip, however, yellowish with brown streaks. The calli of the lip are beautifully lemon-coloured. The specific name, *exasperatum*, is one of the Wallisian discoveries, introduced by M. Linden. Its most extraordinary feature consists in the asperities on the outside of the flower. *H. G. Rchb. fil.*

Odontoglossum crocidipterum, *n. sp.*

Affine Odontoglosso nævio, Lindl. Labello ante unguem erectum angulato usque hastato, antice valde velutino; callis erectis gemiois emarginatis ante basin; columnæ alis plurisetis laceris, angulo in basin foveæ stigmatica insidente.

Much in the way of Odontoglossum nævium and odoratum, but apparently different from either in its many-fringed column wings, which take the place of the single bristles. Its colour is a pallid yellow, with many chestnut-brown spots. The lip has its anterior part covered by a large brown spot, and on each side of the calli a similar smaller one. The merit of introducing this New Grenadian Orchid pertains to Mr. Stuart Low. I have obtained it twice from this invaluable correspondent, the last spike bearing very curious flowers with spreading angles before the base of the lip. Now I have before me a rich spike coming from J. Day, Esq., and who makes some very interesting remarks as to the organs of vegetation. "It is quite different," says he, "as regards the bulbs and leaves, from anything I have seen. The bulbs are nearly elliptical, not tapering to the apex as most do, shorter and rather blunter at the edges than most other Odontoglots. In age the bulbs shrivel and wrinkle all over irregularly, and never get sulcated in deep groves as the others." The flowers are scented, but the scent is disgusting. *H. G. Rchb. fil.*

GLEANINGS FROM CHISWICK.

Few things afford the true lover of horticulture more pleasure than occasional visits to its oldest and most venerated shrines, amongst which dear old Chiswick stands pre-eminent. Approach the old gardens from whatever directional one may, happy reminiscences are recalled to one's mind, and a glow of warmth runs through us as we think of its glorious past and now hopeful future. Where is the gardener, old or young, who has not profited by the lessons in practical horticulture which after much careful and laborious study have been disseminated for the benefit and for the benefit of all? It was here, too, that the lamented and greatly esteemed Thompson compiled the mass of facts which afterwards resulted in the "Gardener's Assistant," and which, whether in the cause of pomology or in teaching of the young gardeners who are in future excellence in their calling, stands out boldly as a sign-post on the road to success. The older members of the profession knew this unassuming but faithful and laborious author, and there are very few of the younger ones who have not a well-thumbed volume of "Thompson" upon their "own" shelves. The reader, I am sure, will pardon me for thus giving vent to feelings which possessed me, in common, I doubt not, with others, who lately made a visit to these old grounds. I had intended only to give the pith of a few useful observations which I gathered a few days ago, and will therefore not digress further.

The large vinery (better known to some as the conservatory), under the present management, points to a present and to a future of very great success. The "huge span" is laden throughout its whole extent with a beautiful crop of Cucumbers, and of young growth a healthy foliage, which affords a prospect unsurpassable in its way in the three kingdoms. Mr. Barron, the undeviatingly courteous superintendent here, as well as at Kensington, may well be proud that his attempt to renovate the old border has thus early proved successful. Having removed a brick wall which was immediately near to the house, he has enlarged and partly renewed the border, and in so doing has considerably elevated it above its former level. Mr. Barron believes, and, I think, rightly, that by elevating a Vine border well above the surrounding natural ground, far more favourable conditions as regards drainage are insured than by the customary method of supplying this by means of rubble at a lower depth. And so far, assuredly, the Vines, huge as they are—some 30 feet long in the rod, are answering in a remarkable manner to the valuable aid given them. The canes of the young growing rods of the current season's formation average 20 feet in length, and are uniformly strong in proportion. The crops upon the true Frankenthal, which Mr. Barron considers the best of all black Grapes, the Black Hamburgh not even excepted, are very fine, many carrying bunches by the score, averaging from 2 to 3¼ lb. weight, and colouring well. The canes of Gros Guillaume (Barbarossa) are carrying a great load. Many of the bunches, which are ripening, or, I should say, colouring, rather earlier than usual, average from 16 to 18 inches in length, and in proportionate in width. Raisin de Calabre, the white companion to West's St. Peter, is very heavily laden. It succeeds well in this cool house, and is one which Mr. Barron values for its hanging capabilities. The Mill Hill, or Champion Hamburgh, is readily distinguished here, as in other places, by the peculiar dagging of its leaves. The Black Monukka, with its peculiar stoneless berries, is also fruiting freely. It is in connection with this Grape that Mr. Barron has effected a cross, of which great hopes may be formed, whatever be the issue. This peculiar variety was used as the male parent in crossing the Frankenthal, and, strange as it may appear, the seeds so obtained have produced seedlings having the peculiar shaped leaves of the Monukka, hence there exists great hopes that the berries may possess the stoneless characteristic of the Monukka, which, it is needless to say, would be a great gain.

I should add that, amongst the many other kinds which are grown and are doing well in this huge house, Trebbiano is especially noticeable, with its large showy bunches, which hang so well.

Mr. Barron, from what I observed, evidently pins much faith upon the capabilities of old Vines; when, as I have before stated, young rods are grown therefrom, as by grafting approved kinds on to old sorts of less repute, not only has so much been attained, but the promises for the future are favourable in the extreme. Whilst upon the subject of Grapes, I must refer to a smaller house, which contains a very fine crop of Muscats, wherein the Madresfield Court, grafted upon the Trovéren Frontignan, is grown, and

in a very limited space. Next the door are some very finely berried bunches, proving it to be a grand Grape, of "the first water." The bunches look solid, heavy, and compact, and fine for exhibition, whilst the flavour, we know, is past question. Its characteristics are found in its producing its fruit unusually near to the main rod, and in the berries having thick, strong foot-stalks, and the usual indications of long-keeping. Much is due to Mr. Barron for having thus ably confirmed the fact that in this variety we possess a most valuable late Grape; indeed, were I going to plant a house to come in late, I should use no other black Grape than this.

There are at Chiswick two orchard-houses, pure and simple, having no assistance from artificial heat, as many so-called orchard-houses have. Here the trees are in good health, and on many there is a heavy crop of fruit. I noticed the Plum General Hand as being a fine showy fruit, of good flavour, very large, and of the true Green Gage type. Pond's Seedling is also a fine large showy Plum for pot work. Amongst Peaches, Royal George and Stirling Castle are particularly noticeable, and have their own against many newcomers; Crawford's Early is also well represented; it has yellow flesh, is a freestone, of good flavour, and a good cropper.

In a long narrow orchard-house in which Grapes, Peaches, and Nectarines have been grown for comparison, and with great and lasting benefit, as many synonyms have been proven for one and the same fruit, are other Peaches, which it will also be well to refer to now. First, I would say that the trees have done remarkably well in this house, the fruit having been fine and abundant. Here Bellegarde was very fine, as also were the evidently near relatives, Violette Hâtive and Galande. Rosanna is a good flavoured, yellow-fleshed Peach; while Shanghai, or Chang-hai, has little save size to recommend it. But of all Peaches, commend me to the Belle Beauce, a good early variety, which is something like Grosse Mignonne; it is a variety of great merit, earlier than the Early York, and of double the size, and has a flattened, showy fruit. Amongst Nectarines, "you can put down Pitmaston Orange as one of the best for pot work," said Mr. Barron. The Bowden and the Victoria are each worthy of being noted down. The Violette Hâtive, Downton, and Rivers' fine-apple, appear prominent; Victoria is like Stanwick, save that it is three or four weeks earlier.

I cannot refrain from mentioning the Fig-house as affording part of the useful information I have gleaned. I refer to two or three prominent varieties amongst a house full of pot plants, all in rude health and abundant bearing. De la Madelaine is there the earliest amongst the early varieties, ripening even in advance of the good and fruitful White Marseilles. But of all the varieties, the true Bourjassotte Grise is Mr. Barron's favourite. I should not omit to mention the Panachée, or Striped Fig, illustrated so well in a late number of the "Florist and Pomologist." It should be known that the ornamental stripes are exhibited by these beautiful fruit onward from their earliest infancy.

The tramway system of orchard-houses, introduced by the Rev. J. Fountaine, is also illustrated in the Chiswick Gardens; and why should it not? The old "City Road" has given place to the modern innovation; and why not old Chiswick? I cannot say that the trees look in any great degree the better for the appliance, quaint and plaything-like as it appears on the surface. Certain it is that the thing is well carried out to the end in view; and well would it be for all gardeners if like conveniences were extended to the many other departments requiring much labour in attending to them. One of the running trucks (rolling stock I should observe, had upon it a fine load of the largest possible Black Diamonds, not the black diamonds from Cannock Chase or Wallsend, but the Plums of that name.

I must pass by the many other subjects of interest, including the beautiful collection of Phloxes and Pentstemons in bloom at the time of my visit, and say finally, that the hardy fruit trees—one and all—are moved into their new quarters, are thriving well, and will yet, in association with the older pyramidal Pears, prove a pleasing feature. The fine pyramidal Pears have many of them been regrafted with more approved varieties, some of them proved to be, and the grafts have taken remarkably well, having made young shoots so vigorously and so plentifully that a casual observer would not have noticed that such a harsh process had been undergone by them. The new, or rather reserved ground, now remaining in the hands of the Society, is far more compact and replete with the symptoms of general good culture than was the old garden. The annuals, bedded-out Pelargoniums, and the fruit trees in pots, call for especial note.

I may further say that, though much has been looked forward to through this curtailment of space, which gives to the able superintendent some chance of doing things as he would, and not as means allowed him, as formerly, we already see an earnest of what may be anticipated in the future in the neat, orderly, and skilful display afforded. Yet we look forward to a still more glorious future, knowing that, however successful heretofore, no man will be found more heartily to join in the emulating acclamation—Advance, than Mr. Barron. *William Earley, Valentines, Ilford.*

CONVERTIBLE FLOWER OR FRUIT VASE.

It must have often occurred to many besides myself, that if they could only procure this or that flower, what a much prettier arrangement they could have made. It must also have often occurred to many that, if the same limited number and variety of flowers had only been arranged in this or that form of vase, instead of the one they happen to be placed in, how much better they would have looked. Some years ago I rarely saw a dinner-table decorated but what some new form or other suggested itself to me as an improvement upon what was already in my collection; and when time permitted the reduction of these ideas into form of working drawings, an order to the zinc-worker or glass-blower was the usual result. In this way I got together a great variety of vases, dishes, stands, &c., and then found it best to wait until the flowers arrived before determining what vases should be used. Before my collection became so varied I used to get out a certain set of vases, as suitable for a table of a certain size, and to order flowers that would look well in those vases; and if the flowers ordered arrived, all went well. But the best-intentioned of florists cannot always supply what they confidently promise; and my experience teaches me, that the least trouble in the end is to get the

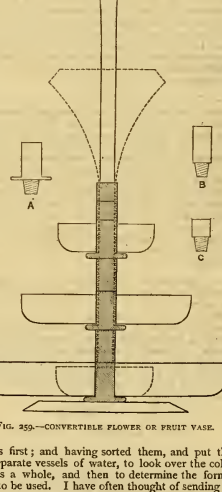

FIG. 259.—CONVERTIBLE FLOWER OR FRUIT VASE.

flowers first; and having sorted them, and put them into separate vessels of water, to look over the collection as a whole, and then to determine the form of vases to be used. I have often thought of sending you sketches from my collection [Pray carry out your intentions still further. EDS.], and now forward you one of a vase which I have found more generally useful for either fruit or flowers than any other form I know of.

This vase consists of the following 11 parts:—a glass foot, half-an-inch thick, into which is fixed a metal tube 2 inches long; six pieces of metal tube, each furnished with a male screw at one end and a female screw at the other, and all the screws alike; of these six, two are 1 inch long, 1, and four are 2 inches long, 4, and 1, two of these four having a projecting flange half an inch wide at the end next the male screw; three glass dishes, of the respective diameters of 5, 9, and 13 inches, and each having in the centre a tubular hole, so that it can pass over any of the metal tubes and rest on a flange: the dishes are about 2 inches deep, and the metal tube is nearly an inch in diameter. The remaining part is a trumpet-shaped piece of glass, having at one end a male screw, like all the others, and at the open end an edge turned in more than half an inch. This inversion of the lip is found to be of great use in holding the ends of the lateral shoots of Fuchsia, which, by thus lying in a natural position, display their blooms without crowding.

When all these pieces are put together it forms a vase 28½ inches high, as shown in the sketch (fig. 259). The dotted lines show that the top piece may be screwed into the foot, without any intervening piece of metal tubing, when the height will be only 18½ inches. It will also readily be seen that by the use of one or more of the metal tubes, the height of the vase may be raised inch by inch to any extent between these extremes. In the same way, by an alteration in the distances between the flanged tubes, the dishes may be brought nearer to each other, or placed farther off from each other. Again, the dishes may be used with or without the rest of the vase, or the vase may be used with only one or with two dishes, or one or more of the dishes may be used on the foot without the top piece. In short, the foot may be used without the top-piece, or with it at eleven different heights, and each dish may be used separately, or at ten different heights upon the foot. Your mathematical readers may amuse themselves by calculating the number of combinations which eight of these vases enable me to effect.

When the dishes are arranged as shown in the sketch, loops of wire may be clipped over the edges of the upper dishes, and thus tall grasses may be made to stand erect amongst a lightly-arranged pyramid of flowers, such as I would prefer to see, but might be better to use the two flanged pieces without any tubes between them, in which case the three dishes would rest one just above the other. Supposing that a ring of Peaches were arranged upon the lowest dish, a ring of Nectarines upon the second dish, and a Pine or a few Plums upon the top dish, then one kind of these fruits may be taken from the group without disturbing the other fruits. I will not occupy your space with a description of any of the other numerous ways in which such a vase can be dressed with fruit, or flowers, or both, but will only add that I cannot too strongly recommend it, particularly to those whose selection of flowers is often very limited. These vases have been made from my drawings by Messrs. James Powell & Sons, of the Whitefriars Glassworks; and I gladly avail myself of this opportunity of testifying to their readiness and willingness in working out new designs, and to their patience and courtesy in troublesome matters of this kind. *W. T.*

A GARDEN OF TREES.

We have had recently the opportunity of inspecting the plans and notes relating to an arboretum and fruit garden proposed to be established at Berlin. The proposal emanates from Professor Karl Koch, the highest authority on all matters connected with Dendrology, and the author of a standard treatise on that subject, already alluded to (vol. iii. p. 225, 253, 1869), and which has but two serious faults, both of which can be remedied. The first is, that we have at present only the first volume—a defect, we are glad to learn, which is likely speedily to be removed; and the next is that it is written wholly in German. While awaiting a full English translation, a Latin synopsis of species, such as might readily be given as a supplement to the whole work, would be of immense service to the busy reader, be his nationality what it might. Reverting however to the subject before us, we may say that we were struck with the importance of Prof. Koch's project, and impressed with the manner in which he proposed to carry it out. Although, says Prof. Koch, here and there in Germany, and especially in England, greater and smaller collections of trees have been made, some of which still exist, and which were called arboretums, at the time when the landscape English style was the fashion, these were but first attempts which, in Germany at least, with the exception of the Royal Botanical Gardens in Berlin, were made by private individuals, with the assistance of Willdenow, and fell to the ground at his death.

Most of Koch's scientific basis, and this is particularly the case in the arboretum at Muskau, which owes its origin to the munificence of H.R.H. Prince Frederick of the Netherlands, and which, thanks to the admirable direction of the inspector of parks, Mr. Petzold, far excels, in a horticultural point of view, any collection in the land, was planted. Thus, in 1772 Duroy, a Brunswick physician, published the first Dendrology, he described 310 kinds of trees, which were at that time cultivated in the garden of Veltheim, judge of the Duchy of Brunswick, at Harlke, near Helmstadt. Since then a hundred years have not elapsed, and the number of trees has been nearly tripled, through introductions from foreign countries alone. For instance, in the above-mentioned work 10 kinds of Maple were described, 24 are now cultivated. Duroy knew 13 wild Plums and Sloes, and only 7 Thorns (Crataegus); we now possess 35. In addition to this it must be remembered that in the course of culture a great many varieties and forms have crept in, which sometimes outnumber the original forms, and that these, being in many cases preferred by amateurs, and fetching a higher price in the trade, have been further propagated.

For more than 30 years Professor Koch has made the plants in question his particular study, and in the course of his researches has made many journeys, especially in western Asia, whence we have received many of our trees. He fixed more especially upon that district as the land of his particular researches, because he rightly imagined he had discovered in it the fatherland of most of our fruit trees. The origin of pomaceous and stoned fruits has

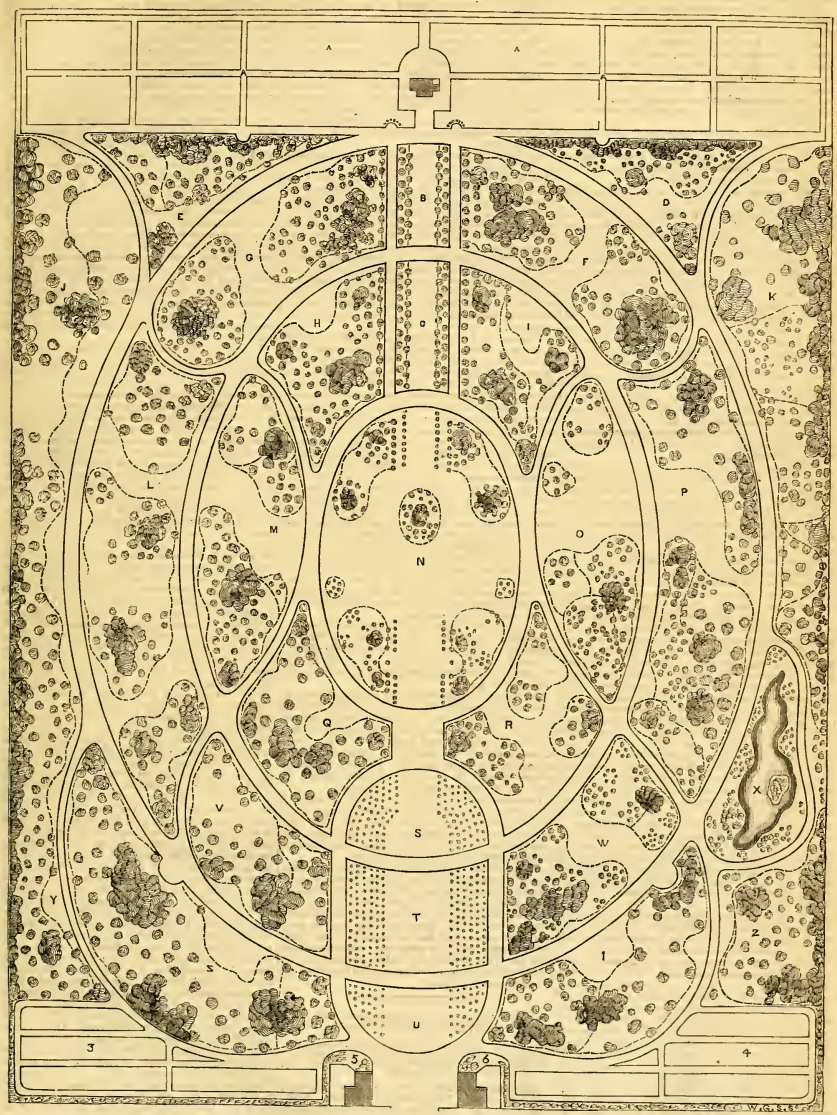

FIG. 260.—PLAN OF THE PROPOSED DENDRO-POMOLOGICAL GARDEN AT BERLIN.

never been scientifically determined. Only long-continued attempts at cultivation, such as can be carried on in some institute set apart for the purpose and secure from the chance of individual change of purpose, will ever lead to a scientific conclusion.

The dendro-pomological garden has, besides its scientific, a practical side. Young men who are making forestry and agriculture their study would there have the opportunity of improving themselves and acquiring a knowledge of the different kinds of trees and of the modes of planting and culture, especially fruit trees, as well as those adapted for planting along roads and highways, &c.

A circumstance of great importance has hitherto proved an almost insuperable obstacle to the acquisition of such knowledge, that is, the great confusion in the nomenclature of trees from which even the best nursery gardens and arboretums are not free.

A true scientific nomenclature of trees will only be obtained when these have been observed for years in Nature. Trees are the more difficult to determine in that they require a long time to blossom, and are in some cases, like the Willow and Poplar, of different sexes. In addition to this our trees—and this is not only applicable to those foreign kinds with which we have been acquainted for hundreds of years, but also to indigenous ones,—often become in the course of culture so altered that their outward form is quite different from their natural uncultivated state, and consequently frequent mistakes arise. Such varieties and forms whose origin is not known have thus been described as independent kinds, and under different names. Not a few foreign trees, whose acquaintance one has made for the first time in the form of a fragment in some herbarium, have been described by different botanists under different names. Were such plants cultivated beside one another, so that they might be contrasted one with the other, such errors would soon be exposed. Gardeners, too, have frequently made use of any sports or chance deviations from the normal form, and propagated them, in order to be able to sell them as something new.

A dendrological garden has still another important object. The effort to beautify our grounds, and make them more habitable and pleasant by planting, has, especially of late years, made great advances. The environs of Berlin and Potsdam rank first in this respect. Those who can look back 30 years can judge what has been done in that comparatively short time to adorn and beautify the country. In Silesia and Pomerania, and even in the distant provinces of Prussia and Posen, the growing spirit has borne fruit. An intelligent observer will note that the beautifying of the land has kept pace with the cultivation and civilisation of man himself. Man becomes the better in proportion to the degree in which he occupies himself with plants and their culture. This moral influence is not sufficiently recognised. Notwithstanding that so much has already been done in this respect, or that the desire of beautifying one's surroundings has been generally aroused, the interest would be greatly increased were we made more fully cognisant of the rich material at our disposal. But this can only effectively be made known by a dendro-pomological garden, such as Professor Koch proposes. Of the importance of this there is still much to be said. The possessor of a garden can always inform himself with more ease of the nature and habit of a tree or shrub which he grows himself. The same principle applies to the more extensive facilities given by a dendrological garden. The number of avenue trees now existing is pretty considerable. We have them for all soils, circumstances, and situations. But, owing to the want of the necessary knowledge great mistakes are often made. Still more difficult is the right choice of blossom and fruit-bearing shrubs. No doubt the reason that the latter are by no means sufficiently appreciated, as a means of adorning our residences, especially late in the season, is, that a knowledge of the abundance of material which is available for this purpose is wanting. Not less charming and instructive would be the effect of plants arranged in geographical groups. In this way a new means of developing the mind and taste of the people would be obtained, which would be of use not only to the young, but also to those of riper years.

Such a garden will, however, only imperfectly fulfil its purpose, unless the better kinds of fruit trees, and such as deserve to be generally propagated, are cultivated in it. In Prof. Koch's opinion every province should have its own particular garden, in which the provincial pomological characteristics might be exemplified; and, in addition to this, there should be a general pomological garden, in which, besides matters of pure practice, strict scientific investigations should be carried on. The sciences are, now-a-days, so blended, that in most researches the co-operation of many learned men, such as may be found gathered together in Berlin or other great towns, is required. But as separate science has now become so extensive, that one man can no longer embrace everything in it. Whoever occupies himself with physiology and the life history of plants is in general so entirely engrossed, that he has seldom time to do anything in systematic botany, and *vice versâ*.

Every year a great number of landed proprietors visit Berlin, especially in the winter time. These gentlemen often seek for instruction in those matters which concern their own lands. Nothing, however, would so entirely minister to the requirements of such proprietors as a collection of the best fruit trees, and they would at the same time have an opportunity of becoming acquainted with the fruits produced by them.

In such a collection not only the best mode of culture should be found from which every one might learn, but both expert and novice alike might gain a knowledge of the advantage of rational practice and scientific theories in pomology. On that account, says Prof. Koch, there should be examples of the different methods of cultivating the high stem, the pyramidal, the wall fruit trees, and such modes of training should be exemplified on the same species, in order that the apparent differences in the results of culture might be seen and tested.

In the arrangement of the garden a museum must not be lost sight of, in which fruits and other interesting subjects of culture should be exhibited for the benefit of the public. The different appearance and various degree of excellence of one and the same fruit, according to the manner of its cultivation, cannot fail to direct attention to more careful culture. The laying out of a dendro-pomological garden, which should provide at one and the same time for the requirements of science, practice, and æsthetics, is undoubtedly a difficult task, which Prof. Koch says (with too great modesty as it seems to us) that he felt himself not capable of superintending in all its branches. On that account he applied to Mr. Mayer, of Messrs. Booth, for assistance, especially as far as the last part was concerned.

The form of a hippodrome was considered by Mr. Meyer to be the best for a dendrological garden. In spite of the regularity of such a form, the visitor would be hardly conscious of it when inside the garden. On the two sides most exposed to the wind it is proposed to plant high trees, to which the name of wind-breakers has been given. An outside compartment is destined for the large trees, the inner one for the next in size, and the middle one for the smallest and most tender plants. The ground slopes on the inside somewhat downwards, so that the piece of ground in the centre which is to be planted with evergreens lies lowest (N). It might also be well were the ground to be undulating, as some trees prefer such a position. Further, the plan is another of Mr. Meyer's, that the regularly set ones, such as Limes, Maples, Nut trees, &c., should occupy the one, and the more irregular ones, as Oaks, Poplars, Beeches, &c., the other side. In order to show the progressive advance in their culture, the wild Roses should be placed first, then the Roses as they were for ages found in the smaller gardens, and lastly the best kinds of the present day. Such contrasts between early methods of culture and those now prevalent should also be made with the Pæonies, Hortensias, and Hibiscus, &c.

Creeping plants should have a place for themselves in another compartment. Wild Vines and the best kinds for wine should be planted; and lastly a hedge composed of all the various kinds of plants capable of being used for the purpose, ought to surround the dendrological garden.

The garden should not only be open at all times to the man of science, the forester, and the agriculturist, but everyone should have the right to seek instruction in it, and both director and inspector should be prepared to impart it. Seeds, grafts, or cuttings, should be presented gratis to proprietors, so far as this may be done without excessive expense. Professor Koch then submits detailed plans of the proposed garden, in which all the trees and groups are laid down.

In addition to this, he gives a scientific catalogue of all the trees which he recommends for a place in the dendrological garden, and indicates the place they should occupy. Next to the catalogue proposed, the trees are divided into scientific classes, which more or less harmonise with the different quarters.

As far as we can estimate the extent of ground necessary for this undertaking, 40 acres would be sufficient for the whole dendrological garden; and, should it be necessary to make special provision for the agricultural and forestry part, space for culture, experiments, additions, &c., Prof. Koch considers that 60 acres would be ample, and that to maintain it, no great annual charge would be required. We hope to hear soon that Prof. Koch's plan, which has received the sanction of the Prussian authorities, will be carried out in the manner he proposes.

THE NATURAL HISTORY OF A FLOWERING PLANT.

[The following remarks are taken from Professor Thiselton Dyer's fifth lecture on "The Natural History of a Flowering Plant," in the theatre of the Royal College of Science, Dublin. The subject treated upon was "The fruit."]

THE essential parts of a flower are the two innermost circles, or whorls. These are, like the outer whorls, equivalent to leaves, but have been very much modified in the course of their development—the stamens, to contain the pollen; the carpels, which occupy the centre of the flower, for the production of ovules. The real nature of these bodies is shown in their occasional replacement under abnormal conditions by true leaves, and also by their reduction in some double flowers to a petal-like state, the analogy of which to the leaf, colour excepted, is more obvious. The upper part of a stamen corresponds to the blade of a leaf; but the cellular substance between its two surfaces is modified in its growth so as to produce eventually a great abundance of isolated cells or pollen grains. In the majority of plants these are discharged as a fine powder by the disruption of the cavities in which they are formed; so vast, indeed, is the quantity shed by cone-bearing trees that it has been sometimes attributed to showers of sulphur. The carpels are formed by the infolding of a leaf, the edges uniting to produce a closed cavity which protects the ovules. These are at first merely small cellular out-growths from the seam where the margins of the carpellary leaf have united, and to which, therefore, they must be looked upon as belonging. The whorl of carpels are either separate or united into a compound body, which may have a single cavity, or as many compartments as there are carpellary leaves, according as they have entered into combination, open or closed. In order that ovules may grow into seeds, it is necessary that they should be subjected to the influence of the pollen. This is shed from the stamens upon the tops of the carpels which are not quite closed in at that point, and the pollen cell then grows down into the carpel at the expense of spongy matter, which it absorbs, till it comes in contact with the ovules. Leaves will occasionally bear buds upon their margins; ovules, on the other hand, sometimes approach the character of leafy buds. Whether they are really their equivalent is not completely ascertained. Pollen grains, however, it is quite certain, are undoubtedly leaves and detached cells. They have even been produced, in rare instances, from the cellular structure of the ovule itself.

It was an old dictum that "Nature abhors a vacuum." Darwin has given a similar expression to another natural law, in saying that "Nature abhors perpetual self-fertilisation." This—which is, of course, out of the question where the stamens and carpels are borne on different flowers, or even on different plants—is constantly obviated even where seemingly inevitable. One frequent mode is by the pollen being produced either before or after the time that the adjacent receptive surface is prepared for it. Access of other pollen is, therefore, necessary, whether wafted by the wind or carried by insects. In Orchids the pollen is coherent and not powdery, and has to be transferred bodily by the latter agent, it is quite certain, or scarcely.

After the pollen has produced its effect, all the parts of the flower, except the carpels, wither away, but the carpels swell and grow into the fruit. If there has been any adhesion between the carpels and other whorls of the flower, then the adhering portions share in the growth of the fruit. The ovules, indeed, form the bulk of the fruit. It may happen that fruit forms, notwithstanding that the ovules are barren, and this is an advantage in many cultivated kinds. The barrenness seems to be caused by the unnatural conditions of cultivation, the elaborated matter unused by the seeds making its way to the fruit or some other part of the plant more succulent. Whatever be the structures that have entered into its formation, the mature fruit consists of two distinct things—the contained seeds and the containing seed vessel. This last may vary infinitely in texture, from yielding pulp to bony hardness, depending upon the degree to which the constituent cells have been indurated by deposits in their interior. These variations are not casual. When the seeds have an edible covering they are eaten by birds, and dropped undigested; Mistleto, Mezereon, and wilding Apples certainly distributed in this way. When here the seed vessel, on the other hand, is very woody, it retains often for a considerable time seeds not at first fit for germination; this is especially noticeable with many Australian plants. The fruit may be provided with winged projections, as in Ash, Elms, and Maples, or with a tuft of silky hairs,—arrangements facilitates its carriage by the wind; there may be appendages of the same kind to the seed. If the surface of the seed vessel is spinous or rough, as with our native Cleavers or Burdock, the fur of animals will be the means of its dispersal. All plants, all living things, indeed, change. Particular kinds of straw from the soil its perhaps minute supply of some substance necessary to them, but not to many other plants, which take the place of those that migrate. What the precise ingredient is may be difficult to ascertain; in the case of land which has become clover-sick it is still doubtful. Nevertheless, it is easy to see that enlargement of a plant's area will, from this and other causes, be often a condition of its existence. Plants of aquatic habit are often quite cosmopolitan; their seeds are, doubtless, widely dispersed by the muddy feet of wading birds, known to be great wanderers. Larger fruits could hardly be distributed, except by water; experimentally, it is found that they often float longer than small ones; still, as might be expected, their areas of growth are comparatively small. The Cocoa-nut flourishes best on the shore, and its nut gets easy access to the waves to carry them to new islands; it is found all through the tropics, but this is rather the work of man than of Nature.

There is a kind of antagonism between ordinary growth and fruit-bearing. Plants continually propagated, not by seed, but by detached buds, like the Potato, rarely produce fruit. The Nuytsia, or Flame-tree of Australia, derives its name from its sheet of blossom, yet never has been known to produce a single seed. Plants whose growth is over-stimulated in warm countries will not flower, except they receive a violent

check. A kind of mean between excess and deficiency in the supply of nutriment is needed. A certain accumulation is required before a tree bears, but anything beyond this defeats its own object.

The prolonged vitality of seeds has been greatly over-rated. The most authentic cases do not carry it beyond 100 years, and these are exceptional. Wheat, for all practical purposes, loses its vitality in seven years. If popular beliefs were true, there would be no temptation for seedsmen to manipulate their old seed for sale.

Home Correspondence.

Hardy Succulent Plants.—Out of a small collection of succulent plants, containing upwards of 250 species, of which about 150 were Cactaceæ, the following sustained the entire severity of the frost of the last winter, although some of them have suffered somewhat; nor have the adults flowered too freely this summer:—Agave americana; A. americana, fol. var.; Sempervivum barbatum, Cereus flagelliformis, C. Martianus, C. tubulosus (on its own roots), grafted specimen killed (how grafted?); C. colubrinus, C. colubrinus var. flavispinus, C. pumilus; Opuntia Rafinesquiana, O. clavarioides, O. corrugata; Echinopsis Decaisneana, E. oxygona; E. multiplex, var. with long spines; E. multiplex, ordinary form damaged; E. flammea, one example; E. formosa; E. Pentlandii, one small example; E. Pentlandi rosea carnea, E. Pentlandi Scheerii, E. P. rhodanthe, E., P. elegans vittata; Echinocactus Monvilei, one specimen; E. Ourselianus, two; E. concinnus, E. mammulosus, E. setispinus, E. gibbosus, E. longihamatus, E. Williamsii, E. ingens, E. corrugatus, and various seedlings from imported seed not yet flowered; Echinocereus pectiniferus; E. pectiniferus var. lævior, E. Scopa, E. cinerascens; Mamillaria Bocasana, M. Wildiana, M. gracilis, M. gracilis pulchella, M. stellaris, M. pycnacantha, one example; M. 7 sp.; M. 3 sp. seedlings; Cereus pentalophus, C. leseens; C. serpentinus, one specimen; Phyllocactus phyllantoides. *John E. Daniel, The Terrace, Epsom.*

The Potato Disease.—The sound advice which you have lately given in a leading article should be followed by all growers of Potatos, namely, to depend upon some of the best keeping early and second varieties for the main crop, and to plant them as early as the season and soil would permit. For the last 20 years I have promulgated this opinion, and in a letter inserted in the *Times* a few years after the mildew first appeared, I stated from experiments I had made in frames with early Potatos, that the disease never appeared to any extent before the end of July, and that the crop would always be safe if ripened early. When the summer is favourable for the development of the mildew it only attacks Potatos in a certain stage of their growth in the end of July and all through August, heat and moisture being its foster-parents. In this district a great many cottagers and farmers now plant their Potatos earlier than they used to do, and having selected some of the best keeping early and second early sorts, they have them already lifted and stored for their winter's supply. Had August this year, with increased heat, been as wet as July, I believe that the Potato crop would have shown more loss from disease than the early year shows it first appearance. In 1868, 1869, and 1870 the summers were too dry for the mildew to show itself to any extent, and many growers of Potatos hoped that it had taken its departure. To show the advantages of early planting and lifting I had this year, at the end of July, a quantity and fine sample of Myatt's Prolific raised for keeping in boxes for seed. They are as yet quite sound, whereas about 12 rows were left in the ground for daily use, and on raising them now about one-half are diseased. The Ashleaf new varieties are quite as much affected here at this date as our old early and second early sorts. The later varieties are likewise beginning to show the fatal blotches on the haulm and foliage, and the peculiar stench from the fields of Potatos at night denotes that the mildew is universal amongst them. It is, however, possible that the cold dry nights now prevailing, and the hot sun in the day may arrest its progress, and should September be dry the loss may not be so serious at lifting time as we now expect. *William Tillery.*

—The electrical and atmospheric conditions to which, at p. 1071, Mr. Fenn ascribes this disease have surely existed, and will continue to exist, from the beginning to the end of the world. The Potato disease, we may hope, may be classed among those things which "have their exits and their entrances." The *onus probandi* lies upon the shoulders of those who advocate the electrical theory, of showing why this supposed destructive agency has not affected the Potato in the slightest degree through the long period of its history and culture previously to the year 1845 or thereabouts. I cannot, therefore, but agree with the Editorial comment on this point of Mr. Fenn's communication. It seems to me far more reasonable to attribute this evil to the fungoid mould which the writer speaks of, and which, like the oidium of the Grape Vine made its first appearance with the disease. The observation which identifies the appearance of the disease with those electrical and atmospheric conditions may be perfectly correct, for these conditions may be exactly those under which the fungoid mould vegetates and thrives. The value of Mr. Fenn's remarks upon the treatment of the Potato, so as to secure abundant light, sunshine, and aëration to the foliage of the plant, cannot, I am convinced, be over-estimated. Mr. Mechi's valuable remarks (p. 1085) on thick sowing and mildew harmonise with this advice. I have acted for years on a set of rules in accordance with the same principle, and have suffered a minimum loss, while I have seen dreadful loss ensue in multitudes of cases from its neglect. Whether or not a fungoid mould is the cause or only a consequence of the Potato disease, the experience of 20 years has fully demonstrated the fact that those conditions under which fungoid growth is the least vigorous are those under which the Potato is most secure from the ravages of disease. The summer rains have prevented my securing these conditions this year so perfectly as usual, and my loss by disease is greater than usual, and especially where the over-luxuriance of growth has produced the most crowded state of the foliage; yet the worst loss in my case has not exceeded one in twenty, while my poor neighbours, who in the endeavour to increase their produce by close planting have subjected their plots to the danger arising from drawn, blanched, immature, and top-heavy stalks and foliage, are losing one-half, and even more of their Potatos within a stone's cast of my garden. The wisdom which profits by experience so far as to choose the driest and well drained spot, free from the shade of hedgerow and fruit trees, is all thrown away, if the system of close planting reproduces the evils arising therefrom, viz., insufficient aëration, darkness, and exhalation of the sunshine. Due to the crop with the top-heavy, unwieldy foliage sinks down like a dense carpet, shutting in damp, and shutting out light, sun, and air. The fertility of the soil, the genial shower, become then evils. I manure abundantly for Potatos, and have never suffered from doing so, because I have given abundant room for growth. Rank-growing kinds, of course, require much more room than the dwarf sorts. From 30 to 36 inches between the drills is not too much for the former, according to the fertility of soil and quantity and quality of manure; in my neighbours' gardens 20 inches for all kinds is the rule, with the result, as a general aim at producing a short-jointed, stout, hardy, well-matured stem, with foliage to match, in our Potato plots and fields, just as we do in training the Vine, wall fruit trees, &c. A day or two's black frost, which made dreadful havoc in low sheltered gardens, has not touched mine

still growing rapidly, and about the right stage for table use, measured 26½ inches in length and 11½ in diameter. Three other fruit measured 35, 36, 37 inches respectively. I must say the Marquis has a beautiful neck, perfectly smooth and straight. Altogether this will make a first-rate exhibition variety. It is a very shy seeder, consequently the flesh is solid and firm. Out of this small space 260 ripe fruit had been cut for seed, independent of quantities weekly cut for market. At the present time there are 120 in various stages of ripening; 70 of these measure from 30 to 35 inches. This fine Cucumber was raised from the Invincible, Needle-gun being the male parent. I must commend the noble Marquis to gardeners generally, and particularly to those whose plants have been diseased, and who would like to procure a healthy stock. *J. Taylor, Rose Hill, Botcherby, Carlisle.*

Mimicry.—As connected with the subject of plant mimicry or pseudomorphism, or whatever may be the most acceptable term for these interesting phases of plant life, it may be worth while to record two instances of variegation which have been recently brought to my notice. In the first a quantity of the common wild Convolvulus had grown up and become thickly intermingled with a Japanese Honeysuckle; the leaves of the Convolvulus, though, of course, retaining their normal shape, had, in places where they were thickest, assumed the variegation of the Honeysuckle. In the second instance the leaves of an Onion which had grown near a mass of the variegated Phalaris arundinacea, had partaken of an exactly similar variegation with the grass. These facts, though having no relationship with the instances of plant mimicry such as have been mentioned before in these columns—namely, that of two plants of widely dissimilar natural affinities and geographical distribution assuming similar external appearances—are, perhaps, worth noticing, with the view of inviting records of any similar occurrences, the cause and effect of which might be made the subject of close observation. Can it be a system of vegetable photography—the originally variegated leaves covering those of the intruding plant, so that by the effect of a strong light or sunshine a portrait of the variegation of the plant should be taken? If such is the case, an exactly similar operation takes place in photography proper, the Honeysuckle being in the position of the negative, the dark blotches upon the leaves of which become light blotches on the leaves of the Convolvulus. In the "Journal of Botany" for August, Mr. J. G. Baker mentions an instance of a singular change in the leaves of a plant of Viola sylvatica, which had accidentally grown amongst specimens of the cristate form of Lastræa Filix-mas. Many of the leaves of the Violet "had become abnormally dilated, and at the same time plaited and crumpled, much after fashion of the pinnæ of the Fern. It produced flowers and fruit, and has been reproduced from seed." *J.* [Does our correspondent infer that variegation in the instances he cites was "catching?" Eds.]

Parsons' Mignonette.—Seeing an inquiry in the *Gardeners' Chronicle* of the 19th inst. respecting Parsons' new Mignonette, and also a reply in last week's number, I am induced, although not an uninterested person, to send you some specimens of the plant, and to offer a few remarks on them. In the first place, it is a well-known fact that the choicest varieties of flowers and vegetables, however distinct, lose their characteristic features and superior qualities under unfavourable culture. Even the common Mignonette varies considerably, according to the nature of the soil it grows in, and a luxuriant specimen of it would compare well with a starved plant of our best strain. There is no secret in our treatment of Mignonette, and yet we are tolerably successful, as numerous visitors to these nurseries can testify during autumn or winter can testify; but we certainly exercise all our knowledge and care in the culture of this as well as other plants. The best horse in the world needs generous diet, and the purer the breed the greater the necessity for food of the best quality. I send for your inspection specimens of our "Improved Tree Mignonette," and also of our variety called "eximia," both from our seed-bed in the open ground, as we have no pot plants in bloom at this season. I may add that we have experienced no difficulty in keeping these varieties pure and distinct, and in pots the variety eximia is much finer, and the flowers of a purer white, than when grown in the open ground. Respecting odour, many persons have expressed the opinion that our variety possesses a most exquisite perfume, exceeding the common as much in this as in any other respect. *W. Henderson for F. Parsons.* [Our own proved to be a very mixed and uneven sample. The selected specimens now sent are fine. Eds.]

What is Tulp?—The enclosed extract, though not answering this question, may be of interest as showing that the herb has long existed in the country near the Cape. The extract is from Joan Nieuhof's "Zee en Lant-Reize," Amsterdam, 1682; and as I only can make out the meaning from its resemblance to German, I copy the paragraph at length. I gather the meaning to be that there grow great and small plants of some sort (I do not make out the word), with knobbed roots, and savoury fleshed herbs; also grow Tulp Tree, Housekeek, and many other herbs (kruiden) in the wild. "Daer groeit grote en kleine zuuring met knobbelige wortelen, en veelerlei geurigh vleesch-kruit: ook grooien aldaer tulpen, boomlinsbloek, en meer andere kruiden in 't wilt." I do not trouble you with this for publication unless, of course, any part of it is useful; perhaps I should beg to be excused in offering it at all, as I do not understand Dutch, but in your hands it may throw some light on the question. The various information before and after make it appear the locality is the near neighbourhood of the Cape of Good Hope, and the extract given is the continuation of a passage mentioning plants growing in "De vlakke velden en dalen." I see "Tulpe" is Tulip in Dutch, as well as German. Can the plant be some bulb, injurious, as the autumnal Crocus here. *E. A. O.*

Yellow-leaved Horse Radish.—I enclose a leaf of white Horse Radish for your inspection. It grows freely, and I think would make a very ornamental bedding plant. It came up in the centre of a bed of Leeks, 6 feet from the main bed of Horse Radish. *George Stork, Gr. to A. J. Binny, Esq., Seweene Hall House, Norfolk.* [The leaf is perfectly blanched. We never saw one so completely so before, though we have often noticed a partial etiolation of the leaves of Horse Radish. We do not suppose it would be constant enough for bedding purposes; moreover, it would be too coarse. Eds.]

How Plants are Destroyed by Frost.—This is a subject of intense interest to horticulturists, and one that I have several times adverted to in your columns. About two years ago I was taken to task by Sir W. Thomson, of Glasgow, for affirming that dew assisted the cold in the work of destruction, and denying that winds, *per se*, were a protection to plants exposed to cold. Experiment and experience still seem to justify the soundness of these views. Plants suffer more from frosts in valleys, where the air is moist, than in upland districts, where the air is drier. The depth of the frost-bite into the tissues of plants may almost be measured by the thickness of the dew-coat or amount of condensed vapour, though amateurs and others still seem to think the contrary. Doubtless heat is liberated when aqueous vapour is converted into water, but we have no proof whatever that such heat is imparted to the tree or plant. On the contrary it is certain that the plant is colder than the dew before the vapour can be condensed upon its leaves. And the question of absolute temperature afterwards must mainly turn upon the relative powers of radiation from wet or dry surfaces, and surfaces dewed over less or more thickly with condensed water. Into that I do not intend to enter at present, but rather to point out what seems like a discrepancy in your suggestive leader on the ravages of the frost among plants. You assure us that the injury wrought by cold is caused by drought, a drying up of juices or loss of water, and likewise that the more copious the dew falls in any given place, the greater the damage inflicted. Either of these theories may be true, but it seems hardly feasible that both can be so. They appear to us practically contradictory, and we will most respectfully inquire with which theory you mean to win our confidence, the wet or the dry? Professor Dr. Mer's theory, differs little in its ultimate effects from the one generally received, that of a rupture of cells by the action of cold. It has long been well known to most cultivators, that actual frost has been by no means unattended with a flow of moisture. Some specimens of frost-bitten tissues has likewise been observed, and the bark often appears too large for succulent shoots that have been injured with cold, and it presents a shrivelled appearance in consequence. But M. Mer assures us that the cells are not ruptured, though how as contrarian by cold can possess the liquid contents of the cells through the cell walls without rupturing them is not very obvious [If you squeeze a sponge you don't rupture it, if you filter a fluid you don't break the filter. Eds.], so that when freezing does take place it mostly happens in the intercellular passages. Well, suppose this is the true theory of plant freezing; it does not appear to prove that the injury is caused by drought, for further on you assure us that all this may happen without injuring the plant in the least. The cell juice oozeing through the side of the cells into passages may be re-absorbed by the general action of heat, if time be allowed before the sun drains out the displaced juices, and all may again be well. We do not find, however, such to be the case if plants have been much frozen, neither do they exhibit the slightest symptoms of desiccation; on the contrary, the tissues are full of sap, but the character of the sap has undergone a change, and the structure seems ruptured, disorganised, and discoloured; indeed, according to M. Mer's theory, the rupture of structure—I use the term advisedly, as including cells and intercellular spaces,—seems as inevitable as on any other. Supposing the sap to be squeezed forth from the cells into the intercellular passages, would the frost not lay hold of it and freeze it there as readily or more so than in the cells [Yes.], and would not the sap expand on the instant of coagulation, and rupture of cell-sides ensue? [Separation of cells, but not rupture necessarily.] Practically it matters little whether an infinity of small vessels are rent asunder from the expansion of fluid from within, or scored or pierced through by innumerable fragments of ice from without. Either way the tissues would be injured, and not simply emptied of juice by the cold. But, again, the dry theory seems quite incompatible with the wet one. If the frost injures or kills vegetation by emptying it of sap, then whatever checks desiccation ought to moderate the power of the frost. The question then seems narrowed to this: Does a coating of dew on leaf, flower, or branch, help to husband or squander the sap within either? If the former, then the wet and dry theories of plant freezing are incompatible; if the latter, then they may be reconciled. To me it seems almost as clear as that twice two make four that if this injury by frost arise from drought, that moisture in the air on the plant, or near to it, ought to prove a mitigator of damage. Experience declares they are not, and therefore I question the theory. I quite agree with you about the injury inflicted by the sun, shining suddenly and fiercely on chilled plants; but this would prove equally injurious on either hypothesis, the wet or the dry. But if both can be held as compatible with truth, then may we also begin to doubt the testimony of our eyes, that fierce sunlight often finishes the work of destruction that the frost began. *D. T. Fish.* [Our correspondent seems to be mixing up several different questions. We may advert again to the subject by-and-by. Eds.]

Bedding Pelargoniums.—I wish, to supplement the remarks of Mr. C. P. Pewis, to say concerning the merits of the true Violet Hill Nosegay, by stating that last autumn I exhibited a very dwarf compact plant of that variety, not more than 20 inches in diameter, having upwards of 60 expanded and partially expanded trusses of flower upon it—literally a mass of bloom. It is one of the most free-flowering and short-jointed of all the Nosegay tribe; colour of the flower, purplish-rose; and makes a charming bed. When I left Shirley, I parted with this plant amongst others to Mr. Elcombe, of Romsey, who is a capital judge of bedding Pelargoniums, and who was particularly struck with its beauty. Certainly he has it true, as always grew my show bedding Pelargoniums in pots plunged in ashes in the open air, where they remained from the middle of May until the middle of August, when they were carried into the house, so as to secure the bloom in that state of finish so characteristic of Pelargoniums grown under glass. As our show always took place on the last day of August, a fortnight's housing just sufficed. I should have scorned to use those accessories to training plants that are so rife aroune London. The finger and thumb did all the business, neither the use of any knife or pair of scissors and, although plenty of larger plants have been shown, yet for size of plants, compared with size of pots they were grown in, dwarf compact habit and abundance of flower, I have never been beaten. *A. D.*

Fungus at the Roots.—We have here a good-sized Double Thorn bush (pink), which has rather suddenly died. Upon examination of the soil about the roots I found a large quantity of Fungus known. Can any of your numerous correspondents inform me if, in their experience, they have known Thorn bushes to be poisoned by such a Fungus growth? *William Parker, Derby.*

Dendrobium chrysanthum.—In the rich collection of Orchids at Fernichurst, several plants of the above named Dendrobium are now clothed with magnificent golden-yellow flowers, the beauty of one of which we noticed two exceedingly strong growths, both of which have just cast off their gorgeous array. One of these measures 4 feet in length and bore 70 flowers; the other was 5 feet 6 inches and bore 80 flowers, forming two splendid strings of bloom. This is a plant which deserves more attention than it generally receives newer introductions having put it a little in the shade. But, although it has been in the country for upwards of 40 years, it is still one of the most lovely and attractive Dendrobes we have. D. chrysanthum is a plant of easy culture; it succeeds best when grown in a hanging pan or basket, filled with peat and Moss, good drainage being provided. It requires a moderate amount of heat and moisture during the growing season, after which it may be removed to a cooler house, where it will amply repay the cultivator by producing in profusion its rich golden flowers. In the Odontoglossum house here are half-a-dozen pans of the lovely Disa grandiflora superba, in excellent condition. Two of the pans measure 17 inches in diameter, bearing respectively 13 and 17 flowers, the remaining four pans, which are less than the above ones, bearing flowers, making a total (for the six pans) of 48 flowers. Two of the growths, or rather flower-spikes, reach the height of 3 feet, and the other spikes average 2 feet 6 inches. Several of the blooms which are in a far advanced state appear, through insect agency, to be setting seed-pods freely. The plants are placed as near the glass as possible, by which means the colour of the flowers, which is of bright scarlet and crimson veined with pink, are brought to the highest perfection. There are not many, I think, who meet with great success in the cultivation of this lovely Orchid, but in the above mentioned house it appears to be quite at home, and better health could not be attained. No must I forget to mention some good specimens of Oncidium macranthum growing in the same house. It will be remembered that "F. W. B.," at p. 618, mentions one of these plants as having a spike 12 feet

in length, bearing 44 flowers. He also treats on the well doing of the others, and it may be gratifying to know that these plants still retain that health and vigour as on the day he saw them. The other day I counted on five plants 100 of its rich flowers, forming quite a mass. Since then one spike has past its best, leaving at the present time 78 flowers fully expanded. Of all Oncidiums yet known, I think this the most lovely and interesting. *N. G. S.*

On Storing Fruit.—The scarcity of fruit for storing this year will add to the anxiety of storing it well, so as to prolong the supply as much as possible. A good deal has been written from time to time on this subject, but perhaps it would not be amiss for those who feel inclined, to state the mode which they may have found to answer best. The greatest secret, however, which has often been pointed out in your columns, is that the fruit must be picked at the proper time, not too soon, nor, in the case of some Pears, left too long. These matters cannot well be particularized without observation on the spot; as a rule, however, this may be known by cutting a fruit in twain, and noticing the pips—if they are brown all over they may be safely gathered. I generally choose a fruit not altogether exposed, but one which will give an idea of the state of those altogether shaded. If the fruit will easily part from the tree by gently raising it upwards, it is another sign of ripeness, or fitness for gathering. It is not necessary nor wise to gather all the fruit at once from large trees, where one-half are by exposure a week in advance of the rest. The same thing applies to trees of smaller pyramids. The fruit on the south side are ripe before those on the north, &c. When the fruit is gathered, the best should be placed by themselves, and so in the case of those having "spot, wrinkle, or any such thing." This will save much trouble afterwards. If the fruit be not gathered dry, it is necessary that it should be well dried before storing; the fruit room also should be well cleaned and aired. Where those rooms are heated it is easily managed, but where it is otherwise a little forethought is necessary. Now, the question is, what is best to store the fruit upon? Perfect ventilation may be obtained, with the necessary twilight dulness, but if the air cannot play around the fruit when wanted, of what use are currents of air above them? I say, therefore, and I have proved it, that nothing besides the bars of the stage is best. Laying down paper or straw is of no use, but is, on the contrary, decidedly hurtful to the fruit. Stages of such a width and divisions of such a height as may be convenient to reach at the farther end, and in any way to my opinion the most useful. Bars with rounded tops and bottoms, placed half an inch apart, are the best, as the air freely finds its way between the fruit. Only one layer of fruit should be laid on, or else the increased weight will make indentations in the lower fruit. Currents of air continuously passing through the room are not needed. If the air is cold and drying, as we get it from the east sometimes, it is wise to shut it all out. Again, if the air is charged with moisture, as we get it very often from the south—if the room is previously dry—I should shut it all out; but if the fruit should "sweat," as it does to, and after, frosty weather, I should allow the air to pass freely, even under the above circumstances, until the fruit is dry. It will require the assistance of fire to keep the air in the room in most situations in a proper state. No fruit should be allowed to enter. Although the outward appearance of the fruit may not be altered by it, yet the flesh will become spongy and flavourless. Attention to these matters, and a constant picking over, have as much to do with success as anything. A thermometer in the room is necessary. Whatever changes in the weather may occur outside, this room must—and can with a little attention—be kept in much the same temperature from October to March. *Henry Mills.*

Orchid Cultivation.—I have very great pleasure in supplying your correspondent "G. H." with the information he seems to desire. In my letter (p. 775) I spoke generally of the "mountain ranges of Southern India," and I think I said the temperatures were taken at an elevation of 7300 feet—an elevation seldom met with in Southern India, except on the plateau of the Neilgherries. *James MacPherson.*

Dwarf Apple Trees.—I read, p. 1069, "Apples have suffered much more on dwarf trees than on large orchard trees, the latter being much more, &c." I cannot quite understand the logic of Mr. Baines, but I do know some dwarf trees, now six years old, which are full of the finest fruit ever seen; while on a large number of standards, from 30 to 40 years old, there is not a peck. So much for the difference that site and soil make. The dwarf trees to which I allude are grafted on two or three kinds of what are called English Paradise stocks; all grow well, and bear well. They had their young shoots shortened in June and again this day (August 21). All the young shoots made since then have been pinched in to three or four leaves. There are eight rows, 18 trees in each row, of the following kinds, one row of each:—Winter Hawthornden, Lord Suffield, Small's Admirable, so like the Ecklinville and Stirling Castle Pippin as scarcely to be distinguished from them; Jolly Beggar, Duchess of Oldenburg, Dumelow's Seedling, Cox's Pomona, very beautiful and good, and Warner's King. It is interesting to observe the difference the stock makes on the growth of Apple trees. These trees, if grafted on the Crab stock, would be making shoots from 5 to 6 feet in length, and bearing but few fruit. The trees I have described are growing at Sawbridgeworth, and permission to see them will be granted to any one interested. *T. Rivers.*

Potato Grafting.—Whilst acknowledging Mr. Simpson's right to indulge in a little banter at my expense anent this subject, I shall not permit his harmless pleasantry to irritate me into the running just now of anything controversial upon a subject that is in danger of becoming hackneyed. If Mr. Simpson has really succeeded in changing the character of the Potato, or that of the Artichoke, by grafting, I shall not challenge his assertions, whatever I may think of the probable value of the results of his experiments. Potato grafting, so far as it has gone, has done next to nothing for Potatos yet that can be esteemed peculiarly advantageous (even Mr. Fenn does not deny that), although undoubted changes accrue. Should Mr. Simpson prove more fortunate in his operations on the Artichoke (and there is plenty of room for improvement there) no one will be more pleased to see his results than myself. As he has expressed his intention of displaying them at one of the September meetings at South Kensington, I trust he will select the 20th inst. for the purpose, as on that date Mr. Fenn fully expects to be there with a collection of his choice seedling Potatos, and which I hope to be enabled to supplement with a number of other varieties. To make Mr. Simpson's acquaintance on that occasion would be a pleasure. Perhaps some of our fellow Potato-growers will kindly take the hint, and assist in the promotion of a large Potato exhibition, without waiting for the stimulus of the small prizes for collections offered by the Society on November 1—although why November 1 should be chosen is perhaps difficult to say. On the 20th or a week or two I may be enabled to give the results of my Potato trials and experiences during the past summer, when I shall enter more largely into some of the points now under dispute. *Alex. Dean.*

Peaches.—There is something uncommonly tempting to the Peach grower in the announcement that Peaches are selling in Covent Garden Market at from 6*s.* to 12*s.* per dozen, but the most remarkable thing of the case appears to consist in the fact that "no one" sells to the market he must be content to accept "next to nothing" for them. I am anxious to dispose of 50 dozen or more of fine rich fruit, but am told on every hand by frequenters of the market that Peaches are fetching "next to nothing." How to reconcile this statement with your quotation of latest prices is to me a mystery. I can but conclude that the fruit salesmen must be reaping enormous profits at the joint expense of both grower and consumer. It would really be a matter of interest if some of your London readers would take the trouble to inquire as to what the price per dozen at which Peaches can be obtained [1*s.* to 12*s.* on Thursday last], as I have a notion (it may be an incorrect one) that the charge is almost prohibitory to all but the moneyed classes. Surely there is room for some one, that for growers if they could devise some other means by which their choice products should be brought within reach of the middle and lower classes more easily than they are at present. The costermonger is by no means a tempting specimen of humanity, or one with whom ladies would have a desire to deal, still less would they care to partake of the contents of his barrow. In the matter of choice fruit a perambulating dealer who possessed a vehicle specially adapted for its conveyance, keeping it clean, cool, and free from dust, would be a great boon to the public, especially if he purchased direct from the grower, and was content with moderate profits. It does seem passing strange that there should be hundreds of thousands of persons in London who rarely, if ever, taste a Peach, and that at the same time the grower, we are told, "next to nothing" should be told that "they are fetching next to nothing in the market." For some years past I have had nothing to do with the culture of Peaches, my horticultural travels having led in a different path; therefore, when I came here and found some 25 trees of varying sizes, the majority having been planted about seven years, and most of them in a rough state, I had but an indifferent anticipation of the fruiting results this year. As most of us like to put off an unpleasant job as long as possible, so in this case was the pleasanter duty of Potato-growing, now six years old, which are full of the finest fruit ever seen; while on a large number of standards, from 30 to 40 years old, there is not a peck. So much for the difference that site and soil make. The dwarf trees to which I allude are grafted on two or three kinds of what are called English Paradise stocks; all grow well, and bear well. They had their young shoots shortened in June and again this day (August 21). All the young shoots made since then have been pinched in to three or four leaves. There are eight rows, 18 trees in each row, of the following kinds, one row of each:—Winter Hawthornden, Lord Suffield, Small's Admirable, so like the Ecklinville and Stirling Castle Pippin as scarcely to be distinguished from them; Jolly Beggar, Duchess of Oldenburg, Dumelow's Seedling, Cox's Pomona, very beautiful and good, and Warner's King. It is a plantation of Strawberry runners. These not being in my line, were turned in roughly with a fork at Christmas, the border being lightly reforked after the nailing. I got a good show of bloom, and more set than I anticipated, but I did not give it the slightest protection, being, of course, a non-cultivator in this respect also. Being perfectly satisfied with the quantity of fruit set, I was more than satisfied with the admirable growth that the trees developed, and, with one or two exceptions, with the general freedom from blight. About the middle of July I had a fine lot of robust wood to lay in. Just before that a friend called in, and, noticing the appearance of the trees, remarked, "I see you have not yet laid in the summer's growth;" to which I replied, "No, it seems to luxuriate and enjoy itself so much in the wind, that I have been loth to do so hitherto;" but I got it laid in soon after, nevertheless. When this was accomplished the trees filled as much space as in the previous year, but with a much better lot of wood, and I had all laid in that possibly could be, in case I may desire to cut out more of the old wood next winter. Since then the trees have made a renewed growth, but this has been left untouched, as the fruit seems to be swelling and colouring to a high pitch of perfection. Perhaps I have staggered for one instant. The exceptions to the general healthiness are two or three small-flowered Peaches, that could not possibly take a white blight or mildew. Next year I propose to try upon them Mr. Fenn's recipe, "hot sewage liquor," applied at night—I hope with success. *A. D.* [The prices of Peaches, retail, in Covent Garden varies, as we know from personal inquiries, from day to day, almost hour to hour, and often from shop to shop. Eds.

Fire Blight and Torch Pruning.—The phenomenon called fire blight may be described as the sudden appearance of withered twigs or boughs in the midst of luxuriant trees (or bushes) that are hedged (healthy and in full vigour), and is chiefly observable at the extremities of branches soon after thunder, or heavy sultry weather seeming to portend thunder. Though sometimes attributable to frost in the preceding winter, there is no reason to doubt that the sudden discoloration of vitality of a bough at midsummer is oftener an effect of electric fluid, which in its passage (with or without detonation) has affected that portion of the tree or shrub with more intensity than the main body of it. The hint thus given by Nature may be taken up by the skilful arboriculturist, and in his forest walks teach him how to apply the flame of a torch to the extremity of an encroaching branch, too lofty to be reached by the pruning-knife, or by any kind of shears or nippers that has been invented. By means of a Bamboo cane, or any long pliable stick, with a couple of rags moistened with oil, he can reach with ease a bough 30 feet above his head, or higher. He can cause its foliage to shrivel up and perish, without taking fire, and without the slightest danger to other branches, or to adjoining trees. This must of course be done with judgment and discretion, and only in situations where a blighted extremity will not offend the eye, as it would do upon a lawn. Let us suppose an encroaching Wych Elm, threatening to overhang an Oak. The two trees may stand too free and widely apart to justify our felling the Elm, if we can only check the growth of the invading branch. But its end may be 30 or 40 feet from the ground, and its direction horizontal, therefore the more inaccessible. With nothing but fire can we readily reach it. Let us, therefore, use that simple means. Take another case. The weeping spray of a lofty and beautiful Ash is descending over a public road. In another year it will interfere with the passage of hay-carts. The mutilation of one whole side of the tree is urged as absolutely necessary. But nothing more is really needed than a skilful application of flame to the lowest portions of the weeping foliage in order to check its descent and keep the headway quite clear. In three or four years the operation will have to be repeated, that is all. If we only cause the foliage to shrivel up without touching the bark, the necessary check will be secured, whether the twigs vegetate feebly the following year or not. And in general it is quite possible to avoid even the causing of any temporary blemish, so small a quantity of foliage being brought under treatment that by ordinary eyes it is unnoticed. In other cases in which this simple process is available, to the great convenience of arboriculture, I will defer, rather than occupy your space further now. *Ralph Carr Ellison.* [A good hint in judicious hands. Eds.]

The Cool Treatment of Orchids.—During two years I made the cool treatment of Orchids my whole study. They are a class of plants most valuable for keeping up a succession of flowers all the year round, and as such at the present day I know of no other class more beautiful either for dining-room decoration or as

cut flowers for bouquets. During the time mentioned I had a very good collection under my charge, consisting of about 40 species and varieties of Odontoglossum, 50 of Cattleyas, 20 of Oncidium, 30 of Dendrobium, &c. I found that some kinds of each of the genera mentioned required to be kept from 8° to 10° hotter than others, more especially the tender sorts of Dendrobiums; also that such as Lycaste and Ceelogyne require to be shifted into a house 10° hotter when they start into growth until their time of flowering, and then be brought back to their former place. I had Odontoglossum Alexandræ in flower in December, 1869, with a spike of ten flowers, and it kept in full beauty for ten weeks. This, too, was the second time for this plant to flower within the twelve months. One morning during the time that this plant was in flower, I found that the thermometer stood at 58°, the glass being covered with frost inside, and I was surprised to see that the flowers were not in the least affected, in fact they kept in full beauty for a month afterwards. There were about 8 inches from the glass. I had over 90 plants of Odontoglossum Alexandræ and O. Blandfordianum, but I saw no other that behaved. I could not, however, get O. Phalænopsis to grow in this house to my satisfaction, so I shifted it to another house, which I kept from 10° to 15° hotter, and in two months I could see a great difference in the growth. It both grew and flowered well, and so also did O. Karwinskii, O. Cervantesii, and O. citrosmum. All of the 40 kinds of Odontoglossum, these are the only four which I took out of the cool house, in which the remainder did well. The temperature of this cool house I kept as near as I could to 45° during the cold nights of winter, and from 55° to 65° by day. During the hot months of summer I kept it as cool as possible. Some days when the thermometer out-of-doors registered from 80° to 90°, I kept this house from 65° to 75°. The only danger that I can foresee in the system of cool treatment, is in having too much dampness during the cold days and nights of winter, and to guard against this I was always very particular not to have any water thrown about the house, but merely a little to avoid too dry an atmosphere. I did my watering between 12 and 1 o'clock A.M. during the cold and frosty weather. There is no greater mistake made to Orchid growing than to either wet the plants, or to syringe or damp the house until the regular heat is up, or to allow cold draughts. Morning and afternoon sun is of the greatest advantage up to a certain extent. The blinds must always be at command, to avoid sudden changes. I prefer using the blinds at certain times to giving much air. During the hot months of summer the houses can scarcely be kept too damp, so as to save over-watering the plants. I object to lean-to houses for Orchids for two reasons—first, because the plants require as much light as possible, by being kept close to the glass in consequence, because the plants in lean-to houses are subject to too much damp during the cold and frosty nights of winter, and they do not get the proper amount of either light or air, especially in winter; when the plants in the lean-to houses are losing their beautiful green hue, and changing to a brown unhealthy appearance, those in the span-roofed house are improving and getting into a vigorous growth. At Mr. Warner's, Broomfield, there is the best constructed house for cool Orchids I have ever seen. It is about 60 feet long and 16 feet wide, half an angle of elevation of 35°; the centre stage is 5 feet, side stages 3 feet, and paths 2 feet 6 inches wide, with a tank in the centre that holds about 4000 gallons of water; it helps to keep the house cool during the hot months of summer, besides furnishing a good supply of water for the season. *M. M., Royal Vineyard Nursery, Hammersmith.*

The Golden Rust or Fungus.—I send you one or two more specimens of this pest. It swept over the Rose-trees in the greater part of the Anglian as with the besom of destruction, and Roses were totally defoliated, and the wood of many was well nigh killed. We cut them back and clear any remaining leaves off, to reduce as far as possible the chance of infection on the young wood. But of course the spreads of spores are very great, and how it is to end it is impossible to say. Unless some anti-fungoid atmospheric conditions set in, it seems as if this pest must kill the Roses. Many were so weakened by the attack that they have not opened half their flowers. It likewise threw some sorts, such as the Persian yellow, out of season. Many of the buds of this variety were arrested, as it were, in the grip of the Fungus, and only lately unfolded their blooms. I have observed one striking peculiarity, that the rougher the leaves the more virulent the attacks. Smooth-leaved Bourbons, Teas, Noisettes, have escaped, as nearly as may be. It is very singular to notice such varieties as Gloire de Dijon, Celine Forestier, Devoniensis, Maréchal Niel, and others interlacing those laden with and crippled by Fungus, while they continue clean. It seems as if a certain roughness was needful to arrest and fix the pest. Would that all our Rose leaves were smooth. If such diseases continue to prey upon our Roses the attention of hybridisers will have to be turned to this point. Even among Hybrid Perpetuals there is a wide range of finish and of smoothness among leaves, from the gloss and polish of Charles Lefebvre to the harsh scouring-paper like texture of Madame Cambacères. The latter bears one of the very heaviest coatings of this terrible Fungus. I don't think for a moment that this scourge enters the plant by means of the roots. If so, how can these partial or complete exemptions be accounted for?—unless, indeed, it be contended that the texture of smooth leaves is so close as to shut the Fungus in: that, however, is most improbable. It seems much more likely that the rough surface arrests, invites, or at least furnishes a suitable nidus for it. Its attacks are so sudden, its development so rapid, that it seems impossible to check or eradicate it. Every leaf, and almost every bud, was attacked, penetrated, destroyed. Even the wood seems pierced through, its stamina broken, its power of growth crippled. I wish the Scientific Committee would take this matter in hand, and try and help us to a remedy. I am sure they would thus earn the undying gratitude of Rose and their myriad votaries. Since writing the above many of our Roses have died, and I hear of great mortality among the large growers. The effect of the disease runs down the wood to the base of the bud, and the plant dies—the wood, in most cases, becoming of a pale straw colour. *D. T. Fish.*

Societies.

METROPOLITAN FLORISTS' SOCIETY: *August 30 and 31.*—The second exhibition of this new society was held at the Crystal Palace on Wednesday and Thursday last. It is confirmed on all hands that the season has been a very adverse one for florists' flowers. Dahlias, owing to the excessively cold spring, are very late, though the plants have generally made a wonderful growth during the last two months; Gladioli are nearly withered up through drought, Asters are small and miserable, badly infested with fly, and the hot sun has taken nearly all the colour out of the Roses. These, with Hollyhocks, were the principal flowers represented, and which, from the causes above mentioned, reduced the general merits of the exhibition to a standard far below that attained at the Society's first venture last year. We have hope, however, for the future, and are sure that all will agree with us whether from such as this, or any other causes, such a really useful institution should not be allowed to degenerate into mediocrity, it will be no fault of the Crystal Palace Company, who generously support the Society by the most liberal terms, and we are glad to state the fact, that of the £165 12*s.* 6*d.* offered in the schedule, £101 is given by the company. Such substantial assistance as this is deserving of the highest commendation.

The leading amateur champion of Dahlias, which brought about such a capital contest last year, the competition for 1st honours was confined to Mr. H. May, The Hope Nursery, Bedale, Yorkshire, and Mr. J. Keynes, of Salisbury, who fought their battle over again, the North countryman this time having considerably the best of it. His flowers were admirable for size, symmetry, and colour, the following especially being remarkably well represented:—Miss Roberts, Toison d'Or, Memorial, Flambeau, James Bennett, Sir G. Smythe, Commander, Juliana, Miss Henshaw, Criterion, Royalty, Leah, &c. Mr. J. Keynes' best flowers were Juliana, Miss Annie Neville, Artemus Ward, Juno, Sir G. Smythe, Mrs. Wyndham, Mary Keynes, Lothair, Memorial, and Paradise Williams. Memorial is one of the finest shaped flowers in cultivation, and remarkably good in Juliana, when well done, but, as an old florist of many years standing remarked, "it takes a lot of doing," and so do many of the others to get them in perfection. No 3d prize was awarded, the 4th being taken by Mr. J. Walker, Thame, Oxon. We should have liked to have seen the right which the judges have to withhold prizes, where the subjects are not worthy of them, exercised a little more vigorously during the day than was the case on this occasion. Some of the exhibits in the Gladioli classes, in particular, much needed a little discretion of this kind. In the class for 36, Mr. Keynes came in 1st, Mr. H. May 2d, and Mr. J. Walker 3d, all showing excellent collections, in which James Hunter, Annie Creed, Victory, Vice President, and Miss Henshaw figured very conspicuously. Messrs. Draycott & Son, Chelsea, exhibited a little more vigorously than usual, and 24, Messrs. Kelway & Son, Langport, coming in 2d, Mr. W. Seale, Sevenoaks, 3d, and Mr. H. Corydon 4th. The flowers most noticeable in the collections from these exhibitors were Mr. Paul of Cheshunt, Fanny Purchase, Vice-President, Edward Spary, Mrs. Boston, King of Sweden, and Lord Derby. In the corresponding class for amateurs, which was well contested, Mr. C. J. Perry, Castle Bromwich, was 1st; Mr. J. Burpitt, gr. to C. Lambert, Esq., Wandsworth Common, 2d; and Mr. Martin, Henfield, Hurstpierpoint, 3d. For 12, Mr. H. Glasscock, Bishop Stortford, was 1st; Mr. G. H. Tewkes, Wimbledon, 2d; and Mr. W. Steer, Eltham, 3d. In the nurserymen's class for 24 Fancy Dahlias, the best came from Mr. Keynes, Mr. H. May coming in 2d, Mr. W. Seale 3d, and Mr. J. Walker 4th; whilst amongst amateurs, Mr. C. J. Perry was best come in 1st, Mr. Perry, followed by Mr. J. Burpit, Mr. J. Beach, and Mr. F. J. Martin. The best flowers were John Sealy, Flora Wyatt, Butterfly, Miss Annie, John Salter, Duke of York, Miss Nelson, Leopoldessa, Sparkler, Galatea, Pauline, Fanny Sturt, Frank Tiffin, Polly Perkins, and Prince of Wales.

The number of Hollyhocks shown was very small, though the flowers were quite as fine as usual. Cut spikes in the class for 12 Hawke, Gainsborough, took the 1st prizes in the open class for 9 spikes, and in the amateur class for 12 cut blooms, in the former with excellent examples of Alba superba, Midnight, Walden Primrose, Fair Ellen, Queen of the Yellows, and four very good unnamed seedlings. Mr. W. Chater was 2d with spikes not quite so large as the former, but very neat, those of Cygnet, Willingham Defiance, Carus Chater, being superbly finished. In the open class for 12 cut blooms, Mr. W. Chater was 1st, and Mr. G. Wheeler, Warminster, 2d. Amongst the several collections of cut blooms, the following varieties were well shown:—Prince Albert, Marvellous, Walden King, Purity, Sanspariel, Fanny, Nobilis, Lady Thynne, Hellipse, Alba superba, Leah, Archbishop, Leviathan, Exhibitor, Standard Bearer, Lord Napier, and Goldfinder. The special prizes, for 9 blooms of seedling Hollyhocks, given by the Rev. Lord Hawke, were taken by Messrs. Kelway & Son, Mr. G. W. Wheeler, and Mr. J. Chater, Cambridge, in the order named; and Mr. W. Chater's prize for the best seedling was won by Mr. Oats.

The Gladiolus classes were much more vigorously contested than was the case in those for Hollyhocks. Messrs. Kelway & Son had the best 36, Mr. G. Wheeler being 2d, and the Rev. H. H. Dombrain 3d. In Messrs. Kelway's group the following were very fine:—Victory, Madame Eugène Scribe, Lord Poltimore, Lacepède, Lucius, Meyerbeer, Celebrity, Picciola, Nestor, Norma, Magnificent, Glow, Felix, and Victory, the latter four being awarded First-class Certificates. Mr. J. Douglas, gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, took the 1st prizes in the open class for 24, in the amateurs' class for 12, and the Chapman's patent show case, offered by Messrs. Eassie & Co., Gloucester, for the best 6 spikes of Gladiolus of 1870. His flowers were quite up to his usual high standard, and included some fine seedlings, two of which, named Fairy Bells, salmon-pink, feathered purple, and Sunbeam; and Fairy Queen, lightly feathered with purple, were awarded First-class Certificates. The other exhibitors were Messrs. Paul & Son, Mr. Walker, Mr. Gold, Mr. Oats, Mr. Glasscock, and the Rev. C. Wolley Dod, Edge Grove, Aldford, who was down for the season, especially by Mr. G. Wheeler, Messrs. Kelway & Son, Mr. Walker, of Thame, and Mr. Matthews, Hoxton. Roses were rather poor, the best coming from Messrs. Paul & Son, and C. J. Perry. The last named exhibitor was also 1st for 24 cut blooms of Verbenas, a beautiful stand; Mr. G. H. Fewkes, Birmingham, being a good 2d. Among the miscellaneous productions were a group of fine-foliaged plants from Messrs. Downie, Laird & Laing, to which an extra prize was awarded; a group of new hybrid bedding Violas (see p. 1230), from Messrs. Jackson & Son, and a French group from Mr. Fewkes; a nice stand of seedling Verbenas from Mr. Eckford; a fine collection of Onions from Mr. Sarndell, Clapham Common; a new flat kidney seedling Potato from Mr. J. Keynes; and some Dahlias from Mr. J. G. Woodlet, Caterham; two large specimen Hydrangeas from Mr. Edwards, Upper Norwood, a collection of Roses from Messrs. Paul & Son, and a stand of bedding Dahlias from Messrs. Carter & Co. Mr. Chapman, Gloucester, exhibited specimens of his new cases, noticed at p. 1098, which, however, did not meet with such a favourable reception as his previous cases. In addition to the certificates above mentioned, First-class Certificates were also voted to Mr. G. Rawlings for Dahlia Maid of Essex, a creamy white ground, tipped with purplish-crimson; and to Mr. Turner for Dahlia Mrs. Turner, a pure white ground, tipped with white, a fine flower, of a colour much wanted; and John Standish, very bright crimson scarlet, good in petal, and a fine shaped flower.

The show of fruit decorations is productive of such a diversity of opinion, that it is a real pleasure to record anything like a unanimous verdict. Yet, thanks to the wholesome restriction of having a clear space of 15 inches around the centre of the tables, imposed by the Honorary Secretary, it was patent to all that on this occasion there was, especially on the part of the amateurs, who greatly outrivalled their professional brethren, such a combination of taste and quaintness as has not been brought together at any former exhibition of the kind. In the amateurs' class the 1st prize was won by Mr. W. L. Buster, and the 2d by Mr. A. Hassard, both groups being equally light, graceful, and refined in arrangement, the former being the most decided in character. It consisted of three epergnes, tastefully filled with Roses, Liliums, Statices, Gypsophilas, &c., the colour of which was nicely relieved with Fern fronds; and four small glasses, in each of which were two or three fronds of the Maidenhair Fern and a truss of salmon-pink Pelargonium, which had a very delicate appearance. Mr. Hassard's group, though a little weak, was much admired. It consisted of three pretty glass stands, filled at the top with the white Gypsophila, mixed with a few flowers of the blue Lobelia, and surrounded with Fern fronds, and at the base with the blue flowers of Agapanthus umbellatus, Lilium lancifolium rubrum, and the common white Clematis, &c., mixed with Ferns. Here also four narrow glasses, each of which contained a sprig of hardy Heath, a very chaste material for such a purpose; Mr. G. Buster, Goring, was 3d, and Miss Blair, Mr. J. Hudson, and the Rev. H. H. Dombrain were commended. For a vase or basket for drawing-room (shown on tables covered with white cloths!), Mr. Seale, Sevenoaks, was 1st, Miss Blair 2d, and Miss Hassard 3d, the others being commended. The exhibits in the professional decorator class were below mediocrity, call for no special commeat.

SEVENOAKS HORTICULTURAL: *August 24.*—This flourishing Society held its annual exhibition in the picturesque grounds of Knole Park on the 24th ult. Plants and cut flowers were fairly shown, but in the matter of fruit and vegetables the display of each was below the average. The best collection of dishes of the former was staged by Mr. R. Godbold, gr. to C. Candy, Esq., Chipstead Place, Sevenoaks, and consisted of capital Black Hamburgh and White Muscat Grapes, Bellegarde Peaches, Figs, Nectarines, Apricots, Jefferson's Plums, and Melons. Mr. Neighbour, gr. to — Wythens, Esq., Bromley, was a good 2d. A very worthy pair of Pineapples, viz., Montserrat and Queen, came from Mr. Hopgood, gr. to J. Goldsmid, Esq., M.P., Combridge. The best three bunches of Black Hamburgh Grapes, fine in bunch, berry, bloom, and flavour, came from Mr. J. Burt,

gr. to R. Mildmay, Esq., Shoreham Place, Mr. Hopgood being 2d. Some excellent Muscat Grapes were also shown. The best, and they showed a cultural skill of no mean order, came from Mr. R. Grant, gr. to J. Rodger, Esq., Hadlow Castle; Mr. Godbold being 2d. Mr. J. Burt had a capital collection of four varieties of Grapes, single bunches, consisting of Black Hamburgh, Muscat Hamburgh, Muscat of Alexandria, and Foster's Seedling. Mr. Sewell was 2d, with Black Hamburgh, Alicante, Bowood Muscat, and Royal Vineyard. Peaches, Nectarines, Apricots, and Plums were grandly shown; in regard to the latter, Kent appears to be favoured beyond other southern counties, as in several places we have recently seen good crops of fine fruit. Such varieties as Washington, Kirke's Victoria, and Goliah, were particularly striking at the Sevenoaks show. Of Morello Cherries fine fruit could scarcely be desired.

In all the classes vegetables were in prime condition, and especially was this true of the cottagers' productions; in fact, the improvement witnessed in this respect since the first exhibition of the Society some four years ago, is such as to show most conclusively in how satisfactory and successful a manner the Society has accomplished the purpose for which it was more particularly established. A splendid example of Cyperus alternifolius variegatus was shown in fine condition by Mr. Godbold; large in size, stout in growth, and splendidly coloured. It gained the leading prize in a specimen plant. Achimenes were capitally shown, Mr. F. Thorne, gr. to K. D. Hodgson, Esq., M.P., Ashgrove, and Mr. W. Dodson, gr. to C. H. Mills, Esq., M.P., The Wilderness, being the successful first. Very meritorious miscellaneous collections of plants and cut flowers were staged by Messrs. Downie, Laird & Laing, John Cattell, J. Searle, and E. Hollamby, that materially enhanced the exhibition. The arrangement was somewhat unfavourable; nevertheless, the show and the added attraction of the splendid band of the Grenadier Guards, brought together a numerous and influential company.

BANBURY HORTICULTURAL: *August* 29.—This is undoubtedly one of the most successful of the smaller exhibitions held in the provinces. It is a fortunate Society in many respects, but in these, that it has not a larger income is variably all that could be desired, and the show is always held in the charming grounds attached to the residence of William Munton, Esq., treasurer to the Society, at the left of the town. The visitors passed by the principal entrance to Mr. Munton's residence, down the sunny slope of radiant green turf, on which is set down one of the prettiest flower gardens one can well wish to look upon, and so to the show ground, in the midst of the grounds, as perfect in keeping as they are unique in design and arrangement, are always thrown open to the visitors, and are a show in themselves.

In the open class for stove and greenhouse plants, Mr. W. Finlay, gr. to Col. North, M.P., Wroxton Abbey, was 1st, with a finely coloured Croton pictum, Rondeletia speciosa major, Acacia metallica, Clerodendron fallax, Allamanda cathartica, and Dipladenia amabilis. Mr. W. Bryant, nurseryman, Rugby, was 2d, having fine examples of Croton augustifolium, Latania borbonica, and Dracæna antarctica, and, what is sometimes exhibited now-a-days as a specimen plant—Mandevilla suaveolens. Mr. F. Perkins, of Leamington, exhibited in his group a specimen of the new Lasiandra macrantha, of good size, but it appears to be too woody to be a very effective show plant. Mr. Finlay had a good group of 6 Ferns, consisting of Adiantum formosum, A. cuneatum, Aspleninm fasciculatum, Hypolepis repens, Thamnopteris australasica, and Davallia canariensis. The best 6 distinct foliaged plants were also staged by Mr. Finlay; and some examples of the purple Cockscomb, from the same exhibitor, were very finely grown indeed. The admirable manner in which Mr. Finlay cultivates Verbenas in pots, has already been referred to in detail in these columns. The six plants shown on this occasion, trained to a flat surface, were well grown, and literally covered with good trusses of flowers; they consisted of Mr. Finlay's fine plum-purple hue, very effective for show purposes; Wroxtoni, Princess of Wales, a pretty striped variety; Rising Sun, Biondin, and Isa Eckford. J. Gillett, Esq., was 2d, with some creditable plants.

Cut flowers are invariably numerous at Banbury, and well done. The collection of bunches of cut flowers staged by Messrs. E. & J. Perkins, Coventry, was a most attractive feature, and comprised a yellow Oncid, Lasiantha macrantha, Anemone Honorine Jobert, a pretty striped Phlox Drummondi, Magnolia grandiflora, Clerodendron Balfourii, Convolvulus purpureus, Euphorbia floribunda, Ixora coccinea, &c. The German Asters shown by Mr. E. Gunthorpe, and the French Asters by Mr. J. Betteridge, were of the first quality; a half-dozen spikes of large-flowering German Stocks shown by Mr. E. Spencer, were finely developed; and the show of double and single Zinnias extensive and good. Mr. C. J. Perry's Verbenas and Dahlias were missed, the near proximity of the Crystal Palace show prevented him and others from exhibiting on this occasion.

There was a good show of fruit. The best collection came from Wroxton Abbey Gardens; so did the best three bunches of White Muscat Grapes, fine in bunch and berry; W. Munton, Esq., was 2d. The three bunches of Buckland's Sweetwater shown by Mr. W. Colegrave were magnificent examples, and the Black Hamburghs from the same exhibitor were of the same quality. Mr. Finlay had three very fine bunches of White Syrian, but unripe, and some very good Muscat Hamburghs in the class for black Grapes. Mr. Colegrave had a bunch of Black Hambughs weighing 7½ lb.

The Onions were a little below the usual quality, still some fine bulbs were shown. In the sweepstakes class for 12 bulbs, in which no prizes were awarded, the best came from Mr. G. Ward, the second best from Mr. S. Taylor. The vegetables shown by cottagers were very good indeed, particularly the Potatos. The staple kinds were Early Emperor and Royal Albert among the rounds; and among kidneys, a fine Ashleaf type, and the Early American Rose—large and coarse. Early Emperor was shown both as a round and kidney; in each case the tubers were of fine quality. Sutton's Red-skinned Flourball was large in size, coarse, and very deep in the eyes, requiring much cutting to waste.

On the occasion of the show at Banbury, a room in Mr. Munton's house is always set apart for the judges, where an excellent luncheon is spread for them. The generous hospitality shown by Mr. Munton on such occasions is always highly appreciated by the judges, and is in marked contrast to the treatment received at some other exhibitions.

Notices of Books.

A Catalogue of the Plants of the Punjaub and Sindh, &c. By James E. Tierney Aitchison, M.D., &c. Taylor & Francis. 8vo. 1869. Pp. 204.

It is not very often in this country that practical men are compelled from force of circumstances to bethink themselves of what plants are best capable of enduring drought and heat. If, however, we had many repetitions of such a season as that of 1870, when the hay crop was almost a total failure, and other things suffered proportionately, we might then have to turn to the botanists to tell us what plants grow in the rainless regions of Peru, or Chili, or of Southern Africa. Then, perhaps, the value of Dr. Aitchison's Catalogue would come home to the practitioner; till then, the list in question will be more valued by the scientific than by the practical botanist. When we recall the fact that Sindh and the Punjaub are among the hottest, driest districts on the face of the globe, it is with some surprise that we find here a list of no less than 1458 species of flowering plants, together with a dozen Ferns (including Actinopteris radiata) and a few other flowerless plants, the list of which latter, however, is obviously very incomplete. Dry and hot as is the general character of this country, the Punjaub is said to being extremely fertile along the river-valley, or wherever irrigation can be practised. Towards the Himalayas, again, a moister climate prevails, and with it a more copious and luxuriant vegetation.

The flora of the dry desert region has much affinity with that of similar districts in Africa, stretching, it might almost be said, from the. Canaries and Cape de Verd Islands, right across the African continent to Nubia and Egypt, on through Arabia, Persia, and Afghanistan to Sindh and the Punjaub. Various species of Capparis extend from Sindh westward to Senegal, Cocculus Leæba and C. villosus have a similarly wide distribution; Ochradenus baccatus, a relative of the Mignonette, extends equally far, so does the Tamarisk (T. articulata), and very many other instances of a like character might be cited. Less is to be distrance, wide be distribution of these plants, the similarity of climatal conditions preclude surprise at the facts.

The catalogue which Dr. Aitchison has prepared with such evident care, will furnish valuable materials for those who wish to work out geographers who wish to work out geographers who wish to work out geographers with the geographical distribution of plants—a subject, the importance of which, as furnishing evidence on the present climatal condition, and on the past history of our globe is now becoming recognised. It is not to be expected that a few questions have been answered by such a catalogue as that before us. We note among Mallows, for instance, the very singular Pavonia ceratocarpa (Dalzell), so different from any of its allies in its fruit, is omitted, as also P. arabica and Hibiscus intermedius (Richard). We may note also that No. 158, Cleome Gibsoni (Stocks), a very curious and well-marked species, is the same as H. pentaphyllus of Ferd. v. Mueller, a species found not only in Africa and Scindh, but also in Australia. This must not be confounded with Roxburgh's H. pentaphyllus, which is the Lagunæa Rheedii.

Among plants of garden interest, we note in Dr. Aitchison's lists the Carambola, which is cultivated in gardens at Jhelum, the Wampi, the Indian Bael, various kinds of Orange, the Jujube, "raised by grafts always;" the Vine, cultivated and wild; the Mango, concerning which we are told that "an excess of moisture in the atmosphere seems to be necessary for the perfection of the fruit;" the Almond, Plum, Apricot, Peach, which, with the flat China Peach and the Nectarine are cultivated throughout the whole Himalaya; various Roses, Pears, Apples, Quince, Loquat, Guava, Pomegranates, numerous Curcurbits, Mimusops indica, of which the author says "it gives the best shade of any tree I know in India;" the Olive, various Jasmines, the Oleander, the Breadfruit which, under cultivation, bears fine large fruit; Populus euphratica, which, the author remarks, "should do well in England," and would be an interesting plant from the protean forms of its foliage.

Only a single Pine, P. longifolia, is marked as native, and only two or three other Conifers as being in cultivation. The four Orchids mentioned are Epipactis veratrifolia, Spiranthes australis, Zeuxine sulcata, and Z. membranacea. As to grasses, we were not prepared to find so many as 168 species enumerated, including Rice, Sugar-cane, Maize, various Millets, and species of Cenchrus and Pennisetum, useful as fodder grasses.

A pretty good idea of the capabilities of the district, when water is at hand, may be gleaned from the foregoing notes; those who wish further information on the useful plants of the Punjaub will find it desirable to consult, in addition to Dr. Aitchison's list, that of Dr. J. L. Stewart, published in 1869, under the title of "Punjaub Plants."

We must not conclude our notice of this unpretending catalogue without expressing our sense of the service to botany which Dr. Aitchison has rendered, a service the more acceptable and the more easily available from the existence of an excellent index. If we must make a complaint it is this, that cultivated plants are not distinguished from the native ones, either by any difference of numbering or of typography. In a list of this character the differences between native and cultivated plants should be so expressed as to catch the eye at once.

Kelly's Post Office Guide to London in 1871. Kelly & Co. Pp. 424.

This is intended, as its title denotes, as a visitor's handbook to the metropolis and companion to the Directory. It contains an immense amount of information of a character more likely to be useful to the stay-at-home traveller for reference on occasion than to the actual visitor. The work is divided into fifteen chapters, devoted to the history of London, its amusements, statistics, local Government offices, charities, colleges, art structures, exhibitions, military and naval depots, and commercial features. The information given under these heads is very varied and necessarily somewhat unequal, great prominence being given to some matters than their importance would seem to warrant, and *vice versâ*: nevertheless, as a whole, we can recommend this volume to the notice of our readers as a good compendium of knowledge relating to our modern Babylon.

—— Those of our readers who can enjoy genuine humour should get hold of a little book lately issued, entitled *My Summer in a Garden*, by Charles Dudley Warner. The difficulties and delights of American gardening, the former comprising boys, birds, insects, and weeds, are amusingly depicted. The weeds which most exercised our author's patience are "Pussley" and "Snake-grass;" the former "a fat, ground-clinging, spreading, greasy thing, and the most propagatious plant I know,"—doubtless the Portulaca oleracea, an introduction from Europe; the latter probably our "Twitch," or "Couch" (Triticum repens), a grass with "a slender, beautiful stalk, and when you cut it down, or pull up a long root of it, you fancy it is got rid of; but in a day or two it will come up in the same spot in half-a-dozen vigorous blades. Cutting down and pulling up is what it thrives on. Extermination rather helps it. If you follow a slender white root, it will be found to run under the ground until it reaches another white root; and you will soon unearth a network of them, with a knot somewhere, sending out dozens of sharp-pointed, healthy shoots, every joint prepared to be an independent life and plant."

Florists' Flowers.

A MOIST, mild, and, on the whole, favourable spring, has helped to bring out somewhat prominently the usefulness of bedding Tulips as decorative agents in the flower garden. Last year, Messrs. Veitch & Sons planted out at their Exotic Nurseries, Chelsea, several beds of Tulips, without attempting to mass them in colours, with a view of acquiring some knowledge of their individual characters. This year, some of the leading varieties were massed in beds, and made a charming and effective display, as well as afforded an excellent idea of the adaptability of certain sorts for bedding purposes.

The red-coloured Tulips give some excellent flowers for grouping in masses. Foremost is Brutus, having an orange-crimson base, and slight edge of yellow. Belle Alliance, brilliant scarlet-crimson, dwarf, and with a stiff, erect habit, early blooming, and a capital bedder; perhaps unsurpassed as an effective scarlet Tulip. Couronne Pourpre, rich dark crimson, and the darkest among the crimson shades; a very fine, high-coloured variety, that blooms at the same time as Belle Alliance, to which it affords an excellent contrast, because of its much greater depth of colour. Scarlet Thol, the earliest of all, and very finely coloured; Vermillon Brillant, very fine, and somewhat larger in size than the preceding; Couleur Cardinal, a very distinct and effective Tulip, with a short and unusually rigid habit, a little late in blooming, but valuable as affording a succession; and Paul Moreelse, a cerise-crimson, a fine and striking hue of colour. Generally, the foregoing are cheap, or moderately so in price, and therefore to be had at a reasonable cost.

The two best yellow self flowers are unquestionably Chrysolora and Golden Prince, the first the earliest, and of a pleasing pale yellow hue; Golden or Yellow Prince has a stiff, upright habit, the flowers large, well coloured, and highly effective. A third yellow Tulip is found in Yellow Pottebakker, a fine bold, showy flower. Chrysolora, being rather new, is somewhat scarce, but the other two can be had at a moderate cost. Thomas Moore, buff yellow, is both distinct and good, and very useful for bedding.

In the way of white self flowers, nothing can be better than Princess Helena and White Pottebakker; the former has a dwarf, erect habit, the flowers are pure

white, and of good size and build; this is deserving of very high commendation for bedding purposes or pot culture. The old White Proserpine, one of the finest built flowers of the section, is too well known to need description. Comte de Mirabeau, white tinged with pink, can be classed with the white flowers, and makes a very useful bed.

Among edged flowers Keizer Kroon is unapproachable for its superb beauty and great size. It is one of the most constant Tulips grown, and it is surprising how it will flourish even in poor soil. A bed of it is a grand picture in a spring garden. Duchesse de Parma is almost or quite as large, and has a narrow edge of yellow. Princessed'Autriche is a broken form of Duchesse de Parma, and has the base striped with yellow; the unbroken is to be preferred to the broken form if the cultivator would have the most effective bed. Le Matelas, having a white ground with stripes and flushes of rose, is both a pretty and distinct flower; but the colour gets pale and muddy in hot weather. Rose Luisante, a lovely shade of pale pinkish-rose; the edges of the petals paler, is also a charming and effective bedder, as well as distinct in character.

The flowers having violet and purple shades are both novel and fine, and extremely effective as bedding plants. Foremost for size, build, and the peculiar delicacy of its lively hue of silken rosy-carmine, is Proserpine, one of the grandest of the early Tulips. Of a paler hue is Queen of Violets, of a pale violet colour, not so large as the foregoing, but it makes a charming bed. President Lincoln and this appear to be identical. Van der Neer, rich shaded violet, is large and very fine, and makes a striking bed: like Proserpine, this flower is of superb build. Wouverman is the darkest of all, and may be described as dark purple; it is not so large as Van der Neer, but very valuable for its colour. Molière is a good and useful pale violet bedding variety, and this, added to the foregoing, gives an admirable lot of violet-coloured flowers.

Two of the prettiest and most useful of the white and crimson striped flowers are Scott's Standard and Bride of Flanders; the latter is the finest, and has more colour; both are dwarf in growth, and are of good stiff habit. Roi Pepin is very pretty, but best suited for pot culture; besides, it is too high in price for bedding purposes. Cramoisie Royale, which is a broken form of Cramoisie, is very handsome also, and makes a gay and showy bed. Van Vondel is a grand Tulip, it is of a showy crimson-scarlet hue, is flushed with white, and occasionally striped with the same. This flower is of fine build, and very large. Fabiola and Globe de Rigaud, have violet and purple and white stripes, are distinct and novel, and make good showy beds.

The foregoing may be accepted as a select list of really suitable bedding Tulips. They are undoubtedly rising in popular estimation, for nothing can compare with them at the particular season when they are in flower. Those who use them for spring decoration cleave to them, and year by year work out charming floral pictures, that, while they brighten with a regal splendour the opening spring months, at the same time delight the eye and gladden the heart. *R. D.*

Garden Memoranda.

The Knoll, Baildon, Leeds, the Residence of C. Stead, Esq.—The traveller in passing from Leeds to Bradford by the Midland route will notice on his right—immediately before reaching Shipley station —a castle-like structure with a prominent tower and flag-staff, standing on a woody knoll, and by its position as well as its architectural features forming an imposing feature in the surrounding landscape. This is "The Knoll," and the residence of C. Stead, Esq., a staunch lover of Orchids and of horticulture generally. To the right of this, and at the farther extremity of the flat table-land, so to speak, which lies at the back, stands Fernehurst, another Orchid establishment that has frequently been noticed in these columns. Looking to the left, the towers, spires and chimneys of one of the most thriving of England's manufacturing villages—Saltaire—are seen for a moment or two as the train rushes onward. The Knoll is reached by passing through the village of Shipley, and thence up the carriage drive as it winds gradually up the well wooded slope. In the early spring this drive is beautifully bordered by great patches of wild Hyacinths and wood Anemones, which are allowed to grow unmolested, and nearly repay the privilege by thousands of sweetly-scented blossoms. During the spring months the place is quite gay with wild flowers, and the feathered songsters being protected in the grounds they repay this kindness by a grand chorus of song.

The Knoll is pretty well known as an Orchid establishment of no mean pretensions, and as such we would now more particularly speak of it. Here, collected together under a few hundred feet of crystal roofing, will be found some of the choicest gems known in the Orchid world—Vandas, Aerides, Phalænopsids and Dendrobes, remarkable alike for beauty and vigour. Here, growing in all the luxuriant freshness of Nature, will be found the finest plant in Europe of the beautiful and rare Vanda Cathcartii, this plant having several times flowered in Mr. Stead's collection, and was, besides, the first plant that flowered in this country. It has been already figured in these pages. Here also may be seen Dendrobium Devonianum with pseudobulbs upwards of 5 feet long; and thick in proportion. Fancy the splendid wreaths of purple-tipped, delicately perfumed blossoms afforded by growths like these! In one corner of the Indian house are upwards of 70 plants of Phalænopsis, doing well, including *P. grandiflora*—a peculiarly long leaved variety, with upwards of 20 leaves; this plant is growing on an oak block plunged ina pot with moss, and when we last saw it, it was one of the most healthy plants in the country; *P. Parishii*, a magnificent specimen, on a native block, just as lopped from the tree in its native habitat—doing well; *P. amethystina*, a remarkable and little known species figured and described last December in these columns; some fine plants of *P. Schilleriana*, and several nice specimens of *P. amabilis*, *P. Luddemanniana*, *P. cornu-cervi*, &c.

In this house is one of the finest examples we have seen of Vanda Batemanii, upwards of 6 feet high, with two fine breaks at its base. This plant annually produces splendid flower-spikes, and remains a long time in perfection as the flowers open gradually in succession. Amongst Angræcums are fine specimens of *A. sesquipedale*, *A. eburneum*, Lindl. (*A. superbum*, Du Pet. Th.), the old but extremely rare *A. caudatum*, a plant we very seldom either see or hear of now in collections; *A. bilobum* (*A. apiculatum*), *A. Leonis*, *A. pellucidum*, and the very pretty little white-flowered *A. falcatum*, a native of Japan and probably Australia. One plant in particular of *A. sesquipedale* is worthy of notice, it having 36 fine leaves with two breaks, and is one of the finest specimens of cultivation. Aerides Schroederi, 2 feet high, with 34 leaves and two breaks; this plant produces very fine branched spikes of large richly coloured flowers. Vanda gigantea (V. Lindleyana) is well represented by a fine vigorous plant, having 26 great, fleshy, gracefully recurved leaves. A fine healthy piece of Cypripedium insigne had 20 leaves and three vigorous breaks: this bears large and deeply coloured flowers, and is a superb variety. Dendrobium crassinode, D. Bensonie, D. Parishii, D. macrophyllum, D. primulinum, D. formosum, D. Falconeri, D. Findlaeniam, &c., are well represented by good examples, while D. cruminenatum is worthy of special notice, its flowers lasting but a few hours; indeed, it is the most fugacious of all Dendrobes. It is an old plant, and peculiar on account of its bulbs being spindle-shaped at the base, and attenuate above the point. They are delicately perfumed, and of the most crystalline whiteness, with a blotch of the faintest and purest lemon-yellow on the disc of the labellum.

In the Cattleya-house are some fresh and healthy specimens of Cypripedium caudatum, C. Lowii, and a very nice plant of the rare and highly scarce Uropedium Lindeni. The rare old Epidendrum sceptrum here finds a congenial home along with the cooler Dendrobes and Oncids, together with the round-leaved Vanda teres, and the still more beautiful Vanda coerulea. The majority of the Cattleyas grown in this house were imported from the Continent some time ago, and, unfortunately, suffered severely during the voyage, but they are now rapidly improving. Here are two or three good plants of Cattleya crispa, and one of its beautiful and distinct variety, C. crispa reflexa marocophylla. One or two plants of Lælia purpurata and L. Brysiana are doing well. A large and remarkably healthy specimen of Trichotosia ferox (Eria vestita?) is growing vigorously, its greenish flowers being highly curious, though far from beautiful from a florist's standpoint. Thæophilia crispa is represented by a splendid pan, which has been divided into two expanded flowers at one time—truly a glorious sight! this being, moreover, a fine variety, quite equal to the T. crispa marginata of "Warner's Select Orchids." In addition, there are plants of T. suavis, T. Galeottiana, T. Cortifii, and several improved species, the names of which have not as yet been determined.

Amongst the winter-flowering Lælias are plants of L. autumnalis, L. furfuracea (true), L. anceps (several fine varieties), and L. albida. The lovely Flor de Maio, L. superbiens, is also represented here, and together with the others is doing well; while in the Indian house we noticed a splendid blooming pan of the rare Utricularia montana (U. alpina), which was figured and described at p. 1039.

Odontoglossums are quite a feature here, and we noticed the pretty little O. erosum (syn. O. stellatum), O. Phalænopsis, O. Pescatorei, several fine varieties of O. Alexandræ, O. luteo-purpurenm, O. candelabrum (O. coronarium), O. læve, O. grande, O. Insleayi, and others. A fine plant of O. Schlimii attracted our attention from the peculiar dark markings on its leaves.

The houses which Mr. Stead has had erected for Orchids are neatly finished, and glazed with the best sheet glass, 14 inches wide, in order to admit a maximum quantity of light. Inside, the houses are fitted with slate benches, which are themselves supported by neat and ornamental iron pillars, the whole being neatly finished with stout wood beading. The advantage of iron over wood in the internal arrangement of Orchid-houses must be evident to all who consider the enormous moisture that is prevalent, and which speedily permeates and induces decay in wood fittings. Beneath the stage and side benches in the Indian house are shallow lead vats or tanks, and these being filled with water are useful in diffusing an equable moistness through the air of the house. Close to the wood beading that surrounds the central table, and passes along the side benches, are fitted small perforated copper tubes, and these being connected with the water supply the whole house can be damped in a few minutes by simply turning a cock at one end, while the whole of the waste water drips into the shallow tanks below.

In order to preclude the possibility of drip from the roof, the glass is cut diagonally, and a groove serves to conduct condensed moisture away. This plan serves the purpose intended very efficiently.

In the preceding account the best Orchid species plants only have been alluded to, and no mention made of the numerous duplicates that exist of most of the species named, excepting the most rare. For example, there are many plants of the commoner Vandas, as V. tricolor and V. suavis, including most of their best varieties; but these and many others are not alluded to particularly because common to all large collections. Again, no mention is made of a great many rare and beautiful species but recently imported.

The grounds are planted tastefully with choice Coniferæ and rare trees and shrubs, Rhododendrons especially doing well. The place is comparatively new, and was formed under the supervision of the proprietor and his gardener, Mr. G. Gilbert, who still retains charge. *F. W. B.*

THE WEATHER.

TEMPERATURE OF THE AIR AND FALL OF RAIN AT DIFFERENT STATIONS,

August 24.—Generally overcast till night; rain fell occasionally in the afternoon, also a heavy gale. Aurora night.

" 25.—Cloudy till about 5 P.M.; a few light clouds prevalent afterwards.

" 26.—Generally cloudless.

" 27.—Light clouds and haze prevalent in the morning; fine afterwards.

" 28.—Generally cloudless.

" 29.—Cloudless. Very fine.

" 30.—Fine in the morning; generally cloudy afterwards.

James Glaisher.

Obituary.

We have to announce, with regret, the death of Walter Beck, Esq., on the 24th ult., at Worton Cottage, Isleworth, at the early age of 32. Mr. Beck was son of the late Edward Beck, whose name was so familiar, and so much endeared, to the florists of the past generation; and by whom the "Florist," now continued under the title of "The Florist and Pomologist," was established upwards of 20 years ago. Though Mr. W. Beck did not take an active part in the floricultural world, the gardens at Worton Cottage have kept up their character for high and successful cultivation, especially in the case of Cyclamens and Pelargoniums.

Miscellaneous.

GATHERED TREASURES.

I Gathered Roses. I gathered gold,
I am weary, but I can sing.
I gathered all in the times of old,
When ev'ry day was Spring.
I treasure the Roses, but where is the gold?
I have known sorrow, but I can sing.
Out and for shame on my wealth untold,
For my riches all took wing.
Oh, treasured Roses! Oh, vanished gold!
I am stout-hearted still, and still I sing.
For the Roses still I hold,
Their perfume brings back Spring.
I gathered Roses! I gathered gold!
I am needy, but I can sing.
And your little hands, that my hands enfold,
Is the sole remaining thing. *Public Opinion.*

Entada scandens is a plant well known as producing the longest pod of any of the Leguminosæ, indeed the longest fruit known, some of them measuring even 6 or 8 feet. These woody pods contain hard, shiny, brown, circular seeds, each about 2 inches across and from half to three-quarters of an inch thick. They are largely used by the natives, where the plants grow, for making snuff-boxes, spoons, &c.; for this purpose the fleshy cotyledons are merely scooped out, leaving the hard woody shell. In the East Indies the seeds are used as weights, and the natives prepare a hair wash from them; they are also used in medicine as a febrifuge, but they are not used either in the East or West as food. In some parts of the interior of Africa, however, the natives regularly eat them. They first roast them for the purpose of removing the hard shell, they then cut the fleshy part up into slices, and cook it for some time in hot water; after being thus prepared it is washed in cold water, and is ready for eating. When so prepared it is said to have a very sweet taste.

Ixia crocata.—This charming little flower is so useful during the month of May and the early part of June, both for decorative purposes in the conservatory, and also as a never-failing source of cut flowers, that it is very much to be recommended, and only requires to be more generally grown to be duly appreciated. The culture is exceedingly simple; and, as the plant will flourish best without any kind of forcing, it is advisable that the bulbs should not be potted from the dry state too early in the autumn. A nice succession may be kept up by potting a portion of the stock early in September, and the remainder a month or five weeks later. The soil I use is about equal parts of loam, leaf-mould, and peat, with a little sharp silver sand. Four flowering bulbs are enough for a 5-inch pot, and six for a 6-inch pot. The small bulbs which are not likely to flower may be distributed amongst and planted with the flowering bulbs, where the plants are to be used for decorative purposes, as they help to produce a dense mass of green foliage; but when grown for cutting purposes this is not necessary, and in that case the surplus small bulbs may be sown rather thickly in seed-pans, and treated entirely with a view to the production of flowering bulbs another season. In potting, the soil should be used in a moderately moist state, but very good drainage must be provided, and the pot filled firmly, without pressure. The bulbs are then to be placed on the top, and pressed down about an inch with the finger and thumb, and the soil pressed down gently, so as to leave it but a little below the margin of the pot. The pots should then be placed in a cold pit, or they may be set on coal ashes, and covered with a movable frame and lights; I prefer the latter until the approach of severe weather, when they are removed to a cool pit, kept moderately dry, and from which frost is entirely excluded. After the bulbs have started water may be applied, but in very moderate quantities through the winter. When, on the approach of spring, growth becomes active, they will require plenty of water; and at that time a portion may with advantage be placed close to the glass on the shelf of a greenhouse, which will accelerate their flowering. The remainder may be left in the pit until they throw up their flower-spikes, and may then be removed to the conservatory as occasion requires. Several other species and varieties of Ixia and Sparaxis are amenable to the same treatment, but I know of none more showy than Ixia crocata, nor one which increases more abundantly, coupled apparently with the great desideratum of a hardy constitution. *John Cox, in "Florist and Pomologist."*

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

Let all plants intended to flower late in the autumn and mid-winter, and which require a larger pot, be shifted without further delay. Give moderate shifts only, however, and pot with moderate firmness as compared with what would be necessary earlier in the season. The second, or other successional batch of *Cape Pelargoniums*, having been cut back and broken afresh, require potting, which must be done quickly. Remove as much soil as possible from the old balls, and then put them into as small-sized pots as the roots can be got into conveniently, without undue pressure, in an open, free admixture of fibrous yellow loam, leaf-mould, and sand. As the sun's rays, taking the day through, lessen in intensity, every advantage should be taken to duly expose all plants the more freely, by dispensing with shading more and more, if any be used, until it is removed altogether for the season. These remarks apply especially to *Orchids*, which have many of them now nearly or quite completed their growth. Give them less water as well as less shade, and, by admitting the sun more freely, ripen off the more fully the growth made. With a proper distribution of the plants, that is, the necessary removal of all such as have tender growing leaves into more shaded positions, the thermometer may be permitted to run up freely to 85° or 90° by sun-heat alone. By these means these plants can be induced to go to rest kindly. Those who have not yet placed their *Camellias* out-of-doors should now do so; also *Indian Azaleas*. They receive much benefit by a free contact with the buoyant air. The conservatory should now be gay with *Neriums, Balsams, Cockscombs, Zinnias, Lilium, Lycoris, Hæmanthus, Vallotas*, &c., which in admixture with various foliaged plants will be as gay as need be. It will be well now, save during very bright fine weather, to give to all such a more limited supply of water, and to the *Liliums* especially, as these may be said to have perfected the major part of their growth, and to have the blooms are fully expanded. Regulate the shoots upon *Climbing Plants*, pinch back the points of the grosser shoots, and so endeavour to equalise the sap more generally between them and the weaker ones. If the weather proves hot and dry, see that the atmosphere is duly charged, in particular to defend the balls of all valuable plants against the fluctuations of extremes of moisture and dryness.

FORCING HOUSES.

Pine-apples must now have air freely during genial periods. Maintain around them an even temperature, averaging from 83° to 85°, with the customary increase after shutting up, and encourage by every possible means the newly potted plants to form fresh roots abundantly. Make the necessary arrangements to insure the usual supply of new tan by the time it will be wanted finally to make up the bark beds for the winter starting. Syringe the *Vines* and surroundings freely, whilst the Grapes are engaged in the swelling process, in the case of vineries. Keep the foliage healthy and so aim at assuring those conditions by the aid of which alone a good result is attained. Give to *Pot Figs*, now commencing the final swelling, copious waterings with wholesome liquid manure, and afford frequent surface sprinklings over all the internal surroundings within the structure. Attend well to the *Peach* and *Nectarine houses* from which the fruit has been long gathered, and assist the roots, by means of a watering if necessary, to perfect efficiently both bloom and wood buds for another season. Those *Orchard-house Trees* which have just yielded their crops of ripened fruits should now be watered with clear soft water only. Already the roots no doubt have in the majority of instances been over-gorged with manure-water, the sedimentary remains of which existing in the pots will serve for all further purposes.

HARDY FRUIT GARDEN.

Remove the leaves somewhat from the fruit of late kinds of *Peaches* and *Nectarines*, and so encourage betimes the ripening process. Gather early kinds of fruit rather by anticipation than otherwise, and by laying them by in a dry, cool, airy situation, determine their safety against insect-pests, which, in some counties, are very abundant. Thin the leaves which surround bunches of outdoor Grapes a little, which may under more than usual favourable circumstances tend to ripen them somewhat by the advent of winter. Protect late varieties of *Plums*, such as the Blue Impératrice, &c.

HARDY FLOWER GARDEN.

Bedding plants will now need to be kept within proper bounds. This, and the removing of decayed blooms, the necessary mowing, sweeping, &c., will tend to afford a more beautiful aspect to the parterre than any of us could have looked forward to in the cold earlier summer months. Sow again if necessary, either in pots or boxes, or on the open sheltered border, such annuals as *Collinsia, Erysimum, Nemophila, Ten-week Stock*, &c. Place early *Mignonette* in pots in favourable aspects, to encourage a strong, sturdy growth. Old plants of *Pinks* and the like, from which "layers" have been taken, should, if two seasons old and a sufficient stock exists, be removed to the rubbish heap, or at the best pinned in somewhat closely and neatly, so as to enhance the beauty and size of the blooms of another season.

KITCHEN GARDEN.

Finally thin out the last sowing of *Turnips* for winter use, and use the hoe freely between rows. Continue progressively to earth-up the earliest and successional *Celery*, freely supplying with water such as need it. The same remarks apply to *Cardoons*. Earth-up forward *Broccoli*, and finish planting late varieties. Transplant all *Lettuce* and *Endive Plants* sufficiently advanced for the purpose; make also another sowing of each upon a sheltered sunny aspect, and continue to blanch by the usual processes according to the demand. Make permanent plantings of *Cabbage*, planting them thickly in the rows, so that every other one may be pulled up for early consumption, and so increasing the supply as much as possible. There is never any danger of having an excess of this useful vegetable. That the sun may exert its beneficial influences, remove all young shoots frequently as they form upon *Tomatos*, and cut away any gross leaves which too greatly shade the fruits, as these are rather late this season. *W. R.*

TOWN GARDENING.

The *Chrysanthemums* will now begin to show their flower-buds, which should all be removed with the exception of the terminal one on each shoot, if large blooms are required. *Earwigs* will become troublesome to the plants, and should be trapped either by placing lobster-claws on the sticks [how ornamental!], or by twisting up a piece of greasy paper and placing it among the shoots, shaking out into hot water every morning all those which are thus trapped. As the *Annuals* and other plants are cleared off, *Pompons* should be removed to their places. These as well as the large Chrysanthemums should be kept well supplied with liquid manure, and be frequently syringed over the tops with clear water. *Carnations* and *Pinks* that are struck should be planted out into an open border, and be kept well watered; they will then make strong roots to stand the winter, and bloom freely next season. Now is the best time to increase the *Lily of the Valley*, which does well in town, if not disturbed after once planting. The method of propagation is to lift the old roots with a fork and divide them into as many separate pieces as may be required, planting them with a trowel about 3 inches below the surface. Most of the *Herbaceous Plants* will now have done flowering, and where an increase in the stock is required, they should be propagated by dividing the roots. *J. D.*

Notices to Correspondents.

Bananas: *E. N.* writes to know how long the Banana takes to ripen after the fruit has set. Will some correspondent who grows them kindly answer the question?

Bedding Verbenas: *M. H. R.* The following varieties have been tested for bedding purposes, and found to answer well:—Annie, carmine and white stripe; Crimson King, crimson with white eye; Countess of Radnor, pale ruby; Eclipse, brilliant reddish crimson, with a dark centre; Exquisite, delicate pink; Firefly, vivid scarlet, with white eye; James Bridges, scarlet, dark, very effective; La Grande Boule de Neige, pure white; Leah, pink, with crimson centre; Lady of Langleybury, purple and white stripes, a sport from Purple King; Mrs. Holden, clear lavender; Mrs. Robin, bright pink, with white eye; Pearl, pure white, a fine bedder; Richard Dean, bluish-purple, with large white eye; Princess of Wales, pink and white stripes; Sensation, bright scarlet with large white eye; Sir Colin Campbell, scarlet, shaded plum-purple; and Triomphe de Massifs, pale blue, with dark centre.

Budding Hollies: *C. P.* Hollies may be budded either in spring or autumn. Now is a good time. If you are a skilful budder, a thin slice of the wood may go in with the bark, but it is better to remove the wood, taking care not to injure the bud in so doing. Keep the shoots of the stock pinched back in spring, so as to induce the dormant bud to break. It is unfortunate that your Maréchel Niel buds have broke into shoots, as they are more liable to be injured by the frosts in winter than if they had lain dormant. Bud later next year.

Clematis: *Y. Nelson.* Your Seedling No. 2 is a very handsome thing, no doubt, but is no improvement on, and does not seem to be distinct from, some of the varieties of Jackman's strain.

Diseased Larch: *J. Jeffries & Son.* We have had the same affection in Larch before. The condition was in that case owing to there being a cake of hard impenetrable conglomerate beneath the roots, in consequence of which the growth was slow, resin was discharged, and the trees gradually grew sickly. It is scarcely probable that the Penza is the cause. It is abundant everywhere on fallen Larch twigs. Anything which checks growth might produce the same effect as the cone-generate pan, which can sometimes exist in the damp and low ground where the disease is worst. We should rather expect in such a case the disease known under the name of frumping. *M. J. B.*

Grapes: *Devizes, Bedford.* Having syringed your Vines with the lime water, you will be unable now to remove the white powder settled on the leaves, even hard spring water would have had the same effect.—*A Subscriber.* Your Grapes are attacked by a minute parasitic Fungus belonging to the genus Glæosporium, and closely allied to *G. fructigenum*, but with apparently shorter spores, which are however very variable in size. Species are figured in this journal in 1856 and 1859, the one on Apples the other on Peaches and Nectarines. All the six seeds of the three berries

sent are diseased. In the diseased spot on those which are of a dark brown, we find abundance of raphides. *M. J. B.—A. R.* We are afraid that you have got some new noxious Fungus. The spots are full of mycelium, but in an early stage of growth. We have at present seen only a single spore, oblong with three septa, but with a single leaf only we cannot even determine the genus. Please to send two or three more leaves, and perhaps we may be able to give you a better opinion. *M. J. B.*

LEAFY FLOWERS OF CLOVER: *M. N. & Co.* The change in question is not uncommon, and is more frequent after a wet season than a dry one, leaf growth being favoured by the moisture. It is much more common in white Clover than in any other kind. A great deal has been written on the botany of the subject, a full summary of which is given in Dr. Masters' "Vegetable Teratology," p. 276.

MARECHAL NIEL ROSE: *A. V.* Let the shoot or shoots of your Marechal Niel Rose run till they reach the length you require them. This Rose should do very well in a late vinery. We will answer your other questions in our next.

MORELLO CHERRY TREE GUMMING: *Don Juan.* You can do but little. Cut away as much of the gummed portions as you can, and encourage the young shoots. Prune them back tolerably hard, and your tree may yet recover.

NAMES OF PLANTS: *E. C. C. D.* From the scrap sent apparently Verbascum Blattaria.—*Globe.* Flea Bane, Inula dysenterica, formerly used in dysentery.—*W. O. B.* Cherodonta Ferox.—*G. F.* Pine Cone.—*Constant Reader.* —*E. P.* The white variety of St. Dabeoc's Heath, Dabeocia polifolia, wild in Ireland.—*Mas.* Common Hart's-tongue, Scolopendrium vulgare.—*T. McKenzie & Son.* Polypodium vulgare semilacerum; it has been previously found in your country.

PEACHES WITHOUT FLAVOUR: *J. Wardle.* The fruits when received were smashed and quite rotten; over-cropping and starving, starving of the wood, will produces the result you describe.

PEAT EARTH: *W. R.* You cannot do better than apply to Mr. Epps, of Lewisham, who supplies peat earth of excellent quality, specially selected for the growth of pot plants. We hear that he has just now been fortunate enough to meet with a new supply, of the very finest quality.

RAPHANUS CAUDATUS: *C. W. S.* Cook them like any ordinary vegetable, and serve with white sauce, *à la* Salsafy.

SELECTIONS OF PLANTS: *R. S. T.* Twelve Roses—Hybrid Perpetuals: Alfred Colomb, Baroness Rothschild, Comtesse d'Oxford, Duke of Edinburgh, Edward Morren, Lonis Van Houtte, Marie Baumann, Sophie Coquarel, and Xavier Olibo; Tea-scented Gloire de Dijon, Niphetos, Marechal Niel, and Souvenir de Mme. Rennes. Six Nosegay Pelargoniums: Amy Hogg, purplish-rose; Eclat, rich magenta, suffused with purple; Le Grand, rosy-orange; Lizzie, soft salmon, suffused with orange; Pink May Queen, deep pink; and Stanstead Rival, bright glowing crimson. Six Double Pelargoniums: Andrew Henderson, bright scarlet; Emile Lemoine, deep pink; Gloire de Nancy, deep rosy-pink; Marie Lemoine, soft carmine; Victor Lemoine, intense scarlet; and Wilhelm Pfitzer, brilliant orange-scarlet. Six Zonal Pelargoniums: George Peabody, brilliant deep crimson; Jean Sisley, fiery scarlet; William Soden, pink, pale bright orange centre; Friendship Lucas, deep salmon; Mrs. William Paul, soft rosy-pink; and Bouquet Blanche, pure white. Six good useful Camellias: Alba plena, Dr. Boisduval, Jenny Lind, Lavinia Maggi, Matchless, and Valtevaro.—*Kent.*

VINES DISEASED: *D.* We have very carefully examined the various examples of the leaves and fruit sent, and can discover no disease to lead us to a solution of the question. There is no mildew as we expected. The Vines, as you state, have grown well, and got damaged quite suddenly. We must then look for the cause in the atmosphere of the house. Have you over-heated your flues and had an escape of sulphurous gases? We are inclined to think so. The leaves seem to have been rather flabby, through growing fast in a humid atmosphere and damp bottom, then to have been scorched with something—not all at once, but to have been subjected to it for some time.

WASPS: *Mr. East* writes to recommend a preparation to destroy wasps, the name of the which we see in the advertisement, and should be inserted as such. The most efficient wasp trap we know is the French trap figured at p. 461, 1870. With this we catch the wasps daily by scores.

WHITE PASSION-FLOWERS: *Subscriber.* P. alba, P. punctata, P. vespertilio, P. arborea, a white form of P. coerulea, and many others.

CATALOGUES RECEIVED: Wm. DIED.—On August 24, at Worton Cottage, Isleworth, WALTER BECK, aged 32 years.

Markets.

COVENT GARDEN.—Aug. 1.

We have very little alteration to notice this week. supplies being about equal to the demand, and trade continues very steady. Pines are not quite so plentiful as they have been, and prices have gone up a little. The Spanish and Portuguese Grapes, the first consignment of which arrived during the week, are realising but very low prices. We have good supplies of Potatos, at slightly advanced prices.

WANT PLACES.—Letters to be Post Paid.

MR. JAMES FRASER (of the late Firm of J. & J. Fraser, Lea Bridge Road), undertakes HORTICULTURAL VALUATIONS of every description; SALES by AUCTION, &c.—Maylands Farm, Romford, Essex, E.

ITALIAN ALP or LIGURIAN QUEEN BEES.—The autumn importations of these beautiful bees are now commenced. GEO. NEIGHBOUR & SONS are offering QUEENS, warranted bred and fertilised in Italy, at the following low prices:—One Queen, 10s.; three, 25s.; six, 60s.

GEO. NEIGHBOUR AND SONS, 149, Regent Street, W.; or 127, High Holborn, London, W.C.

WANTED, THREE or FOUR ACRES, good holding soil, for Trial Ground, with Cottage or Small House for Gardener. Must be within half-an-hour by rail from Charing Cross, Waterloo, or Cannon Street Stations. Apply, by letter, to Messrs. MINIER AND CO., 60, Strand, London, W.C.

WANTED to RENT, from FIVE to TEN ACRES of GOOD LAND, either established as, or suitable for, a Market Garden. No objection to a little Glass. Near Liverpool or Manchester preferred.

A., 107, Scotland Road, Liverpool.

To Nurserymen and Gardeners.

TO BE SOLD, in consequence of the death of the Proprietor, the LEASE and POSSESSION of a NURSERY and FERN WAY, fronting to Hagley Road, Edgbaston, Birmingham, excellently situated for business. There is a good Villa Residence on the ground, let off for a term.

J. LEA SMITH, Solicitor, 19, Cannon Street, Birmingham.

FOR IMMEDIATE DISPOSAL, the entire STOCK and GOODWILL, or a PARTNERSHIP in the thoroughly prosperous NURSERY and SEED BUSINESS. The Nursery Grounds extend over upwards of 30 acres, and the Trade has had it desired; and the Seed Business is extensive and increasing. This is a first-rate opportunity for any one desirous of really practical and business men, who can command a moderate amount of capital, as a large portion of the purchase money can be paid in instalments, extending over a series of years, by paying a moderate rate of interest.

Applications to be made to B. S., *Gardeners' Chronicle* Office, W.C.

Important to Nurserymen, Florists, and Others.

TO BE DISPOSED OF, by Private Treaty, the LEASES, with possession, of the old established and well known CHISWICK NURSERIES, comprising a substantial 14-roomed Dwelling-house, with Seed Shop and Offices annexed, two Cottages in occupation, 12 Greenhouses and several Sheds of Iron, heated with hot-water piping, with the whole of the choice Stove and Greenhouse Plants, also about 18 acres of rich and productive Land, cropped with first-class general Nursery Stock. Held under two Leases at low Rents. The whole to be sold as a fair valuation in the usual way.

For further particulars apply to Messrs. PROTHEROE AND MORRIS, Auctioneers and Valuers, Leytonstone, E.

SALES BY AUCTION.

SALE THIS DAY and MONDAY NEXT.

Dutch Bulbs.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY and MONDAY, September 2 and 4, at half-past 12 o'Clock precisely each day, a fine lot of DUTCH HYACINTHS, TULIPS, CROCUSES, NARCISSUS, IRIS, ANEMONES, and other Bulbs, in fine condition.

On view the mornings of Sale, and Catalogues had.

Periodical Sale of Poultry and Pigeons.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, September 5, at half-past 12 o'Clock precisely, a fine lot of choice POULTRY and PIGEONS, from the yards and lofts of the Rev. A. C. Brooke, J. A. Fordham, Esq., Mrs. Evans, and other well-known Breeders and Exhibitors.

Choice Orchids.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, September 7, at half-past 12 o'Clock precisely, a large importation of PHALÆNOPSIS GRANDIFLORA, a consignment of choice ANGRÆCUMS, and other rare ORCHIDS, just received from an importation of various ORCHIDS from the West Indies, and a large number of established plants of CYPRIPEDIUM INSIGNE, and healthy, well established plants of PHALÆNOPSIS of sorts.

On view the morning of Sale, and Catalogues had.

Holker Hall, Lancashire.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has the honour to announce for SALE by AUCTION, without reserve, on WEDNESDAY, September 6, at 1 o'clock precisely, Selection from the Holker Herd, belonging to His Grace the Duke of Devonshire, which will consist of about FIFTY YEARLING BULLS, CALVES, and HEIFERS. Amongst them will be found some Oxfords, Wild Eyes, Blanche, Cleopatra, Alva, and other Kirklevington families. The young stock are chiefly by Grand Duke 10th (21,848), and Grand Duke 17th (21,064). Rosedale (25,806), of the same blood, is now in full use in the herd, and the whole will be found well worthy the attention of purchasers of Shorthorns. Mr. W. Strafford can, therefore, with confidence strongly recommend gentlemen to attend the sale of the present favourable opportunity, such as may not occur again for some time.

Catalogues, with Pedigrees, may be had on application to Mr. STRAFFORD, 13, Euston Square, London, N.W.; or of Mr. DREWRY, Holker House, Grange-in-Cartmel, Lancashire.

Beaumont Grange, Lancaster.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions to SELL by AUCTION, without reserve, on the Premises at Beaumont Grange, near Lancaster, on THURSDAY, September 7 next (the day following the Sale at Holker Hall), a choice selection of BULLS, COWS, and HEIFERS, from Mr. W. W. Slye's Herd, principally of Kirklevington and Oxford descent. Amongst them will be found descendants of the Crarina, Duchess, Garland, Lady Spencer, Moss Rose, and Red Heart families, also some very valuable specimens of Bates blood in Grand Duke of Kent 2d, Lady Tregunter Fourth, and Barrington 3d families, the whole of which can be strongly recommended to the favourable notice of purchasers.

Catalogues, with Pedigrees, may be had on application to Mr. SLYE, Beaumont Hall, Lancaster; or, of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Killhow, near Wigton, Cumberland.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to intimate that he is instructed to announce for SALE by AUCTION, without reserve, on FRIDAY, September 8 next, at Killhow, about FIFTY HEAD of very superior SHORTHORN BULLS, belonging to Robert Esq., that have been selected and bred with the greatest care from some of the most fashionable and pure strains of blood, to which have been used Bulls of the first class. 17th Duke of Oxford (25,094), from the famed Holker Herd, is now in service, and the young stock are chiefly by him. The animals will be found on inspection to possess all the qualifications of high-bred Shorthorns: they have robust constitutions, are well grown, rich in colour, with good hair and quality of flesh, and are in a fine healthy breeding state; as such they are well worthy the attention of purchasers of first-class Shorthorns.

Catalogues, with Pedigrees, may be had on application to Mr. FOSTER, Killhow, near Wigton, Cumberland; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Important to the Trade.

EXTENSIVE SALE of WINTER FLOWERING HEATHS, EPACRIS, CYCLAMENS, TREE CARNATIONS, &c.

MESSRS. PROTHEROE AND MORRIS are instructed by Mr. John Fraser to SELL by AUCTION, on the Premises, The Nursery, Lea Bridge Road, Leyton, Essex, on THURSDAY, September 21, at 12 o'Clock precisely, without reserve, about 25,000 winter-blooming HEATHS, in various sizes, and including the best varieties, viz.:—Hyemalis Wilmersiana, gracilis, and gracilis vernalis, grandiflora melanthera, regerminans, Sindriana, colorans, rubro-calyx, and others. 2000 EPACRIS, of the choicest varieties, viz.:—MISS LINDSAY, LADY PANMURE, and others. CYCLAMENS, of the finest strain of persicum, profusely furnished with bloom-buds; TREE CARNATIONS, WHITE WORTH, and others, in bloom, and in pots; 2 quantity of SOLANUM CAPSICASTRUM, full of berries, TREE CAMELLIAS, in bud, LARGE BOXES of ROSES, and a number of miscellaneous Greenhouse Plants.

May be seen and Catalogues had on the Sale. Catalogues may be had on the Premises, and of the Auctioneers and Valuers.

N.B.—Intending purchasers are respectfully invited to inspect the Stock, the whole of which is in the finest possible condition.

Tooting, S.W.

IMPORTANT SALE of EXTRA STOCK of STOVE & GREENHOUSE PLANTS, rare ORCHIDS, choice FERNS, selected PALMS, &c.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, Nursery, Tooting, Surrey, on TUESDAY, September 26, at 11 for 12 o'Clock precisely, by order of Mr. A. Henderson, retiring, a large quantity of extra stock of STOVE and GREENHOUSE PLANTS, rare ORCHIDS, choice FERNS, selected PALMS, hardy HERBACEOUS PLANTS, &c. Full particulars next week.

LARGE SALE by AUCTION.—On account of the illness of the Proprietor the very extensive collection of STOVE and GREENHOUSE PLANTS, as well as the whole of the valuable NURSERY STOCK of the Horticultural Establishment of Mr. H. Cannell, Swanley, Kent, will be DISPOSED OF on SEPTEMBER 17, and following days.

Catalogues may be had on application at the above Nursery. In consequence of the extent of the Sale, and the large collection, the days of the Auction of each of the respective branches are fixed for the convenience of purchasers.

Dover.

NOTICE of SALE of the WELLINGTON NURSERY and Adjoining FREEHOLD RESIDENCE.

MESSRS. CRIPPSFOLD AND HAYWARD have received instructions from the representative of the late John Dyer, Esq., to SELL by AUCTION, at the Mart, on TUESDAY, September 5, at 2 for 3 o'Clock in the afternoon (immediately after another Sale of Property), at Dover, in two lots, the following valuable PRIVATE DWELLING-HOUSE and FREEHOLD LAND, situate on the Folkestone Road, at Dover, in Two Lots, which will be numbered 12 and 13 in the Sale, viz.:—

Lot 12. The commodiously arranged Private Residence, known as "Conservatory Cottage," and being No. 19, London Road, Dover, for many years in the occupation of the late J. Richardson, Esq., deceased, but now in hand. The House, which is fitted up with every convenience and regard to comfort, contains Dining and Drawing-rooms, Five Bed-rooms, and capital Domestic accommodation, and has a pretty approach from the road under an enclosed Verandah, with garden in front and at the side.

This Lot is held under Lease from the Trustees of the Borough Charities in Dover, for a term of 21 years, from the 29th September 11, 1869, at an apportioned annual ground rent of £9 10s.

A valuable piece of FRUIT GARDEN with this Lot is included in the hiring of the adjoining Freehold Land by Mr. Thomas Clark, and is subject to the Lease of the Land to him, and to the Lease granted by him, which will be entirely chargeable upon the said Freehold Land.

Lot 13. All that valuable Plot of Freehold Land, known as the "Wellington Nursery," adjoining Lot 12, new and for many years in the occupation of Mr. Thomas Clark, containing three acres. This Lot, which has a frontage of about 178 feet to the London Road, is in a state of high cultivation, and forms a first-rate Nursery Establishment, adapted for the successful carrying on of the Business of a Florist or for Building Purposes.

The above property will first be offered in One Lot, and if not so sold will be offered in Lots as up in the Sale by the Auctioneers. The House may be seen on application to the Auctioneers.

Further particulars and conditions of Sale may be obtained of Messrs. WORSFOLD AND HAYWARD, Auctioneers, Surveyors, and Estate Agents, New Bridge, Dover; or of Mr. THOMAS LEWIS, Solicitor, Dover.

Brockton House, Eccleshall, Staffordshire.

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on TUESDAY, September 12, at Brockton House, Ecclesshall, about 3 miles from Stafford, 50 SHORTHORN HORNS, the property of Mr. Thomas Bell. 11 numbers above Fifty years old, which have been very carefully bred for upwards of forty years from the far-famed Kirklevington blood, Mr. Bell's long association with the late Mr. Bates being the best guarantee for their excellence and purity. Among these will be found the Duchess of the "Peach Blossom" (or Place), "Georgianas," and other fashionable tribes. The Bulls are in full use in the Duke of Thornley's 8th Duke of York, and this celebrated young Bull will be offered at the Sale.

Catalogues, with Pedigrees, may be had of Mr. BELL, Brockton House, Ecclesshall, or of JOHN THORNTON, 15, Langham Place, London, W.

Extensive Sale of Pure-bred Shorthorns in Lincolnshire

MR. JOHN THORNTON will SELL by AUCTION, without reserve, on FRIDAY, September 14, at Panton House, Wragby, Lincolnshire, the celebrated HERD of PURE-BRED SHORTHORNS, numbering about 100 Head, belonging to Messrs. Spedding.

The success that has distinguished the Panton animals at the Royal, the Yorkshire, and other leading Shows—the unrivalled character of the Herd, and the first-class bulls of Booth blood which have been used—Mr. C. Booth's Manfred (26,281) and Belvedere (25,728), now being now in service—is the best evidence of the high standing and exceptional merit of the Herd, which contains a large number of heifers of great substance and quality, as well as several prize winners, including some choice young bulls.

Catalogues, with Pedigrees, may be had of JOHN THORNTON, 15, Langham Place, London, W.

NOTICE of SALE of the HERD of SHORTHORNS belonging to J. N. Beasley, Esq., of Chapel Brampton, Northampton, announced to take place on FRIDAY, September 22, NOTICE IS HEREBY POSTPONED.

London, August 30, 1871. JOHN THORNTON.

Milcote, near Stratford-on-Avon.

HIGHLY IMPORTANT SALE of the MILCOTE DOWN SHEEP.

MESSRS. HUTCHINGS has been honoured with instructions from the Executors of the late J. C. Adkins, Esq., to SELL by AUCTION, at Milcote, on WEDNESDAY, September 13, at 2 o'Clock prompt (Luncheon at 12), the whole of the celebrated FLOCK of MILCOTE DOWNS, comprising 148 superior Ram Lambs, Ewes and Theaves, 360 very superior Ewes and Wether Lambs, 22 grand symmetrical Shearling Rams, and 24 ordinary Shearling Rams.

The great celebrity of this Flock demands a few words as to its formation. With Oxfordshire Downs as a foundation, the late Mr. Adkins, for many years, blended occasional strains of the best Cotswold and Leicestershire blood, and by judicious management and careful selection succeeded in producing a distinct type of Down Sheep. With the Milcote Downs combine good size, hardy constitutions, the Milcote Downs are remarkable for their heavy weight of fine meat and wool, and for their early development and maturity. The rams will be brought forward in a natural and unforced condition. The Auctioneer can, with great confidence, call attention to this Sale; and can assure Flockmasters that an entire Flock of such high character is seldom offered to Unreserved Public Competition.

Catalogues will be circulated in due course, and may be had of the Auctioneer, 28, Bridge Street, Stratford-on-Avon.

Trains stop at Milcote Station as under:—From Paddington, Oxford, Banbury, Leamington, Warwick, and Birmingham, 8.49 and 11.8. From Paddington, Oxford, Moreton, Evesham, and Worcester, 8.25, 11.0, and 1.15.

Shropshire Sheep.

ELFORD PARK, TAMWORTH.

MR. MAY'S IMPORTANT ANNUAL SALE of PURE-BRED SHROPSHIRE RAMS and EWES.

MESSRS. LYTHALL AND CLARKE inform the Breeders and Feeders of Blackfaced Sheep that they will SELL by AUCTION, on TUESDAY, September 12, at Mr. May's, Elford Park (Luncheon at 1 o'Clock), about FIFTY First-class RAMS, and ONE HUNDRED large-sized healthy EWES and THEAVES.

Elford Park is one mile from the Haselour and Croxall Stations on the Midland, and two miles from Alrewas Station on the South Staffordshire Railway.

An omnibus will meet the 11.4 A.M. down train, and 12.10 and 12.18 P.M. trains at Tamworth.

The above are a portion of Shropshire Sheep—pure in blood—very large in size—full of wool and mutton—and very suitable for improving the stamina of a Blackfaced flock, or for crossing with other breeds.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, at New Farm, Sutton Maddock, Shifnal, on FRIDAY, September 8 next, at 1 o'Clock punctually (Luncheon at 12), the SUTTON MADDOCK FLOCK, consisting of FIFTY RAM-SHROPSHIRE RAMS, and ONE HUNDRED SHEARLING and STOCK EWES, the property of Mr. Henry Smith.

The Sutton Maddock Flock has attained a reputation second to none among the Shropshires. It has secured the highest honours at the Royal Agricultural Society of England, the Birmingham, Smithfield Club, and numerous other important Shows, where no fewer than 130 prizes, value £500, and upwards of 200 cups, have been awarded to it. The leading Flockmasters have acknowledged its superior merits, and the last three Rams have been selected from the Flock to occupy the positions obtained by Lord Chesham's and Mrs. Beach's Rams and Ewes.

Conveyances will meet trains at Shifnal and Cosford Stations. An omnibus will also leave Shifnal at 11.30, and return after the Sale.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Holly Bank, near Burton-upon-Trent.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, on TUESDAY and WEDNESDAY, September 12 and 13 next, the ENTIRE FLOCK of THREE HUNDRED PURE-BRED SHEEP, HOMES, PIGS, IMPLEMENTS, POULTRY, CHEESE, &c. (the property of Willoughby Wood, Esq., who is giving up his farm).

Conveyances will meet the trains at Burton and Walton Station, on the Midland Railway, and at Wichnor Junction, on the South Staffordshire Railway.

ORDER OF SALE.

TUESDAY, September 12.—Sale at 10 o'Clock of Sheep.

WEDNESDAY, September 13, Implements, Cattle, Horses, Pigs, Poultry, &c.

Luncheon on Tuesday at 11.30; Sale at 1 o'Clock.

Luncheon on Wednesday at 12; Sale at 12 o'Clock.

The Rams are of great size, excellent Wool Cutters, and possess plenty of muscle. The Ewes are remarkable for their character, with great scale, and very prolific. Among them will be found, in addition to the carefully bred ones belonging to the flock, many purchased at a high price from Messrs. Minton, Bibby, and Boden.

The Dairy Stock are remarkably well bred, many having three or four crosses of pure blood.

They are of great size, rich colour, and good milkers.

The Sheep and Stock are well worthy the attention of gentlemen wishing to procure well bred stock.

The Auctioneers would recommend this Sale as a first-rate opportunity to any one desirous of founding a high-class Flock of Shropshires or Shorthorn Herd. As Mr. Wood is giving up his farm, the whole of the lots will be sold without the slightest reserve, and it is seldom a better bred or more useful lot of Sheep and Cattle are disposed of.

For Catalogues, apply to the Auctioneers, 39, New Street, Birmingham.

Shropshire Sheep.

THE THIRTEENTH GREAT CENTRAL SALE, at BINGLEY on WEDNESDAY, September 13.

MESSRS. LYTHALL AND CLARKE will SELL by AUCTION, on THURSDAY, September 14 next, at 11 o'Clock punctually, TWO HUNDRED AND EIGHTY SHROPSHIRE RAMS, and SIX HUNDRED EWES, from the noted Flocks of

The Right Hon. the Earl of Bradford.	
The Right Hon. Lord Wenlock.	
Sir Charles Slingsby, Bart.	
The Right Hon. Lord Willoughby de Broke.	
Mrs. Beach.	Mr. S. C. Pilgrim.
W. C. Firmstone, Esq.	H. J. Sheldon, Esq.
Mr. Glover.	Mr. Deakin.
W. Lort, Esq.	Thomas Walker, Esq.
Mr. Lythall.	E. Stubbs, Esq.
Mr. Evans.	Mr. Yeo.
And Others.	

The above will include Prize Rams and Ewes at the Yorkshire and other important Shows.

Auctioneers' Offices, 39, New Street, Birmingham.

F.S.—Further entries should be sent to the Auctioneers before September 1.

ALTRINCHAM AGRICULTURAL SOCIETY.—A THE TENTH ANNUAL SHOW will be held on THURSDAY, September 28, when FIVE HUNDRED POUNDS and SILVER CUPS will be offered in PRIZES for Horses, Cattle, Sheep, Pigs, Dogs, Poultry, Roots, Grain, Cheese, Butter, Implements, &c. ENTRIES CLOSE SEPTEMBER 16. Schedules, Rules, and Forms of ENTRY, can be had on application to the Secretary,

28, Church Street, Altrincham. JOHN SPROT.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

AGRICULTURAL EDUCATION.

The Examination of Candidates for the Society's Prizes will take place in the WEEK COMMENCING TUESDAY, APRIL 16, 1872. The age of Candidates for the Society's Prizes must not be above 21 years on March 1; but Candidates, irrespective of age, may Compete for the Society's Certificates.

Copies of the Form required to be sent in by March 1 may be had on application to

H. M. JENKINS, Secretary.

12, Hanover Square, London, W.

The Agricultural Gazette.

SATURDAY, SEPTEMBER 2, 1871.

THERE are two ways of GROWING TURNIP and MANGEL SEEDS, a right and a wrong way, or, not to be dogmatical, there is a cheap and a more costly way. Seeds are grown for maket on the cheap plan, which, to say the least, we do not recommend. Good land is required for heavy crops, and the best for the purpose

deep, rich alluvial soil, with a subsoil that becomes good top soil as soon as it is exposed. There is a tract of this kind of land and of strong loam resting on free chalk between Gravesend and Cliffe, on the banks of the Thames, where 300 acres of Turnip seed are sometimes grown on a single farm. In the market garden districts of Bedfordshire, by Biggleswade, Sandy, and adjoining parishes, cheap seed growing is carried on, and there are small plots of Turnip and other seed, on all the little garden farms.

We will mention one other district, the most famous of all. About 25 years ago a farmer tried the experiment of ploughing up some turf in Romney Marsh, which is, as our readers know, a deep deposit of mud, well drained, and forming some of the richest pasturage in England. The experiment was extremely successful. The soil proved "inexhaustible," yielding enormous crops of Turnip and Mangel seeds, corn, Clover, and Potatos in constant succession, on the single condition that before corn could be grown, several crops of seeds should be taken to tame the soil.

Romney Marsh has become one of the most famous cheap seed-growing districts. The crops of Turnip and Swede seed frequently exceed 40 bush., and those of Mangel 30 cwt. per acre. At 2*d.* per lb., 40 bush. of Turnip and 1 ton of Mangel would give nearly £20 an acre in each case. Seeds, therefore, are grown wholesale at a very small cost; but unfortunately they are grown from imperfect roots; or rather they are not grown from roots at all, but from shreds of plants about the size of quills or radishes. In order to produce these parent plants, the seed is sown in seed-beds about the end of July; and in November the wretched little biennials are pricked out in the fields; except in the case of Mangel plants, which are more tender, though not too tender in the shred form to be wintered in sheltered seed-beds. They are pricked out in spring.

In both cases an iron dibble is used, about as broad as a carving knife, and somewhat thicker. This tool is driven into the ground, the shred is lipped into the crevice, and is fastened by closing it with the blade, shifting it so as to squeeze the soil tightly to the plant. The little medicines, which cannot be called roots, are planted in rows about 30 inches apart. On soils that are both friable and strong they branch vigorously, and should be hoed early in spring to encourage them to do so. On hard land of insufficient strength, they are inclined to "run" prematurely, and instead of the ground being covered with a dense mass of haulm, self-supporting, and covered with seed-bearing pods, it is only half covered, and the stalks are then liable to be broken by the wind; a weakly crop is also more liable to attacks of worm, and by the time the linnets and doves have taken their tithes, the grower's share is so small as to convince him by experience that the seeds cannot be profitably, grown from these little biennial shreds, except on suitable land.

The degeneracy consequent on breeding from starved sheds is remarkable, though not more so than might be anticipated as the result of such a complete setting at defiance of the physiological laws relating to the reproductive system in plants. Assuming that the starved shreds are the offspring of full-sized roots, we should not expect the degeneracy to be very great in the first generation, though one would certainly choose seed from well-grown roots, in preference to that from starved sheds. But, unfortunately, it is only certain painstaking seedsmen who are so careful as to supply their growers uniformly with "stock" seed. A very large quantity of seed is grown for the general market that is of shred-parentage in the second or third generations. Let such seed be sown by the side of honest seed, and an extraordinary difference in the weight and quality of the roots will be observed. Clear-skinned, firm, and sweet-fleshed, shapely bulbs, with a single tap-root, and not too much neck and leaf, with very few stragglers running to seed, will contrast with rough bulbs, fanged, stringy, and coarse, and evidently reverting to the primitive form of the sea-side Beet—a stout-stemmed, sprawling plant, with a wiry tap-root fixed in the sand; or of the cliff Cabbage, or rather of some primeval Rape, from which the Turnip tribe may have descended.

We leave this branch of seed-growing, and the biennial shred system, to those who may be interested in it. It is unnecessary to go further into the question of "How not to do it?" Our readers are fortunate if they cannot appeal to their own experience, or to that of their neighbours, in confirmation of our view on the subject of cheap seed-growing. We will now give the details of a more approved practice, and endeavour to show how seeds ought to be grown.

Our first experience was with a Purple-topped Swede, originally selected by a friend more than 30 years ago. It may encourage young beginners, showing how attractive a fixed pursuit may become, if we mention that this gentleman, a large and very successful farmer, used sometimes to vanish from our side during the excitement of the chase, when the scent was warm and the game close at hand, for the purpose of marking a promising Swede that had caught his eye. Latterly there were comparatively few roots that wandered far from the selected type, but we never saw a field of Purple-tops that did not contain some green and otherwise undesirable roots, showing the necessity for constant selection to obtain pure types, and the large quantity of bad breed (blood) that there must have been when the process of elimination commenced.

With respect to the shape of roots we preferred them globular, or slightly wide shouldered without being flat at the crown, with half the bulb out of the ground and the other half buried, and good quality was indicated in the case of Swedes by firm, clear flesh, slightly tinged with pale yellow. Turnips for early folding may, however, be tankard shaped, standing far out of the ground, and Mangel may be long or oblong, instead of round. In the matter of shape the breeder should select good models and adhere to them. He can achieve any shape he pleases by a few years' selection.

The principle to be observed in selecting parent roots, whether of Swede, Mangel, or any other kind, is to choose perfect specimens. They should be neither small nor overgrown, but sound, hard-fleshed, keeping roots, grown without too much artificial manure, or any other kind of forcing which may be supposed to injure their powers of keeping, or to impair their vitality. Swedes should be set up in their necks in the best land that can be found for them, somewhat from the refuge of birds. The best way is to dig them in with a spade a yard apart. A large farmer may obviate all risk of losing the seed by birds, &c., and get rid of the whole of the care, except that of selection, by contracting with one of his cottagers, delivering the roots to him and paying a liberal price for the seed. Mangel and Swede seed will cost about 3*d.* per lb. in favourable years.

Mangels selected for seed must be kept through the winter without heating, and planted without blemish, early in March, in the same manner as the Swedes. Both should be set rather deeply, for protection, and they should be moulded up subsequently to support the haulm. Stakes and string may be used for the same purpose.

We could give many examples of the advantages of growing seeds at home; but it seems needless. We will only add that it is the only way to secure the best seed, inasmuch as the cost of cartage, &c., and two years' rent, prevents seeds "for market" from being grown from fair-sized roots.

—— There was a better supply of Wheat at Mark Lane on Monday than for some time past, but though the attendance was good, there was a slow sale, at the previous Monday's rates. On Wednesday the tone of the market was steady, the demand healthy, and prices well maintained.——At the Metropolitan Cattle Market on Monday a small supply of English beasts, and a good demand, sent up the average of prices; prime sheep also advanced, with a ready sale. On Wednesday only the very choicest lots could obtain to Monday's figures, the average for all others being lower.

—— Referring to the Potato Disease in Ireland, the *Irish Farmers' Gazette* of Saturday says:—

"In consequence of the conflicting reports which have appeared in different journals relative to the extent of disease in the Potato crop of this country, we addressed letters of inquiry to correspondents in various parts of Ireland. We may with safety say that, from the general tone of our reports, there is no reason at present to be apprehensive of what might be termed a failure of the crop. Very few reports speak despondingly, whilst the great majority are most favourable, and if the fine weather continue it will go far to check the disease where it has already appeared. We attribute the cause of alarm which has been widely circulated to the blighted appearance of the stalks, the state of the tubers not being taken into account, and this opinion is confirmed by most of our correspondents from every part of Ireland."

—— At the late Cheshire Quarter Sessions, at Knutsford, Sir Harry Mainwaring, in his charge to the grand jury, said he was sorry to inform them that the Foot and Mouth Disease had increased in the county during the hot weather with great rapidity. At the July sessions there were only eight animals under treatment in the county. There were now 581 under treatment. Pleuro-pneumonia seemed to be at a standstill, and there were 21 present only to cases under treatment. Captain Smith, the chief constable of the county, submitted to the court a return under the Contagious Diseases Acts, from which it appeared that from August 23, 1869, to August 5, 1871, there were attacked with foot and mouth disease in Cheshire 31,699 animals. Of that number 17 were killed for market, 30 for burial, 433 died, 30,637 recovered, and 582 remained under treatment.

OUR LIVE STOCK.

CATTLE.

An eminent breeder of Bates cattle writes to us as follows:—

"While I yield to no one in my admiration for the genius which Mr. Bates displayed as a breeder, I cannot admit that no good blood existed outside his herd. Of the soundness of his general principles there can be no doubt, and the correctness of his judgment has been fully vindicated by the ever increasing value of the animals descended from his herd. He was, however, a man of strong prejudices, and doubtless not seldom viewed facts through a highly coloured lens. It appears to me most injudicious at this time of day to revive the bitterness of bygone controversies, and especially to throw aspersions which admit of no proof on the honour of men such as Mason, Coates, &c. It would do immense harm to the Shorthorn cause if, on the authority of individual assertion, doubts were thrown on the authenticity of our first established pedigrees. Of such authority there is no need—who can tell but that some future writer may attack the pedigrees of Mr. Bates? In my opinion the sooner such useless gossip is forgotten the better. Let us take the animals and their pedigrees as they have been delivered to us, and use them to the best of our judgment."

—— The coming week will witness three important Shorthorn sales in the North of England. Space precludes a lengthy notice of each of the herds in question, but as few sales as possible we may state that 33 females and 12 bulls, the property of the Duke of Devonshire, will be sold at Holker on the 6th; that 19 females and 11 bulls, the property of Mr. W. W. Slye, will be disposed of on the 7th; and that 52 females and 4 bulls, from the Killhow herd, will be offered on the 8th inst. The Holker catalogue comprises 11 Wild Eyes, three Cleopatras, tracing from *Cleopatra* by Earl of Dublin, and back to Young Wynyard (2859), two Asias, 10 Blanches, direct descendants of *Blanche* by Belvedere; eight Oxfords, going back to 2d Duke of Northumberland and Short Tail; two representatives of *Lally* by Earl of Derby, and the Countess of Barrington strain, besides Elviras and Minstrels, going back to Phenomena and Favourite and Hubback, which will give them grace, even in Mr. Bell's eyes. Sires inheriting the Kirklevington blood of the highest name have been used, such as the pure Bates bull, Lord Oxford (20,214), Grand Duke 10th (21,848), and Grand Duke 17th (24,064). The stock are chiefly by these bulls, and Baron Oxford 4th (25,580), a son of the celebrated prize-winner, *Lady Oxford 4th*. The Beaumont Grange catalogue opens with *Lady Spencer 2d*, by Grand Duke of Lancaster (19,883), of Chilton extraction, and further on we meet with her daughter by Barrington Oxford (25,607). The catalogue also contains some pedigrees of rare merit, including a few animals of Bigsby descent crossed with Kirklevington bulls, resulting in that favourite strain Bates upon Knightley; others are closely allied to Royal winners, the dam of *Duchess 9th* (lot 8), and *Duchess 10th* (lot 16), being own sister to the dam of Colonel Towneley's Baron Hubback, a winner at the Royal, Oxford, and Baron Hubback 2d, the 1st prize yearling at Wolverhampton. Among these we notice several descendants of *Fair Francis* by Sir Thomas Fairfax; Red Duchesses going back to Hubback; Duchesses from Cleveland and Duke of Norfolk; Charmers of Milcote extraction; *Lady Tregunter Bates* by the 2d Duke of Tregunter, and of the Lady Barrington blood; *Fawsley Duchess*, combining Bates and Knightley in perfection; and among the bulls a Grand Duke of Kent, Duchess bull, and Prince of Oxford, of the Gwynne blood.

With reference to the Killhow herd, we cannot do better than quote Mr. Strafford's remarks at the commencement of the catalogue, in which he informs us that the cattle are principally from the renowned herds of Lord Lonsdale, Sir Curtis Lampson, Bart., Messrs. Bowly, Howard, Leney, Rich, Slye, and other eminent breeders, and comprise specimens of the much-admired "Blanche," "Carolina," "Charmer," "Cleopatra," "Fillet," "Florentia," "Gwynne," "Surmise," "Sweetheart," and "Ursula" families, with other good and favourite sorts. The sires of these are of the highest breeding and character; six of the lots are by 7th Duke of York (17,754), one of the most remarkable sires of modern days; the Duke of Devonshire's 10th Grand Duke (21,848), 14th Duke of Oxford (21,605), bred at Holker, and Royal Cambridge (25,009), from *Moss*

Rose by 4TH GRAND DUKE (19,874), are each the sire of four lots; whilst others are by 2D DUKE OF COLLINGHAM (23,730), 2D DUKE OF CLARO (21,576), 3D DUKE OF CLARO (23,729), 2D DUKE OF THORNDALE (17,748), GRAND DUKE 13TH (21,850), DUKE OF GENEVA (19,614), 9TH GRAND DUKE (19,879), LORD OXFORD 2D (20,215), MAY DUKE (13,320), HOUGHTONS (20,986), KNIGHTLEY (23,051), and other valuable and well-known bulls. Several of the young stock are by 17TH DUKE OF OXFORD (25,994), bred by his Grace the Duke of Devonshire, and the cows and heifers are chiefly served by this very superior bull.

—— On the 25th ult. the well-known Castle Grove herd of Shorthorns, the property of J. G. Grove, Esq., was sold by Mr. John Thornton. We have previously noted the fact that the herd consisted of eight families—all of Booth origin: this told in the sale, though the company attending it was limited, the results were excellent, as will be seen by referring to the prices realised. The cattle were in good healthy condition, and had been running out night and day. The cows were of great substance, rich colour and fine hair; and throughout the herd there was great uniformity and evenness of character. Fourteen animals of the "Fame" tribe averaged £139 2*s.* 7*d.*; four of the "Lady Sarah" tribe averaged £143 6*s.* 6*d.*; and three of the "Campanula" tribe averaged £96. We can only refer to particularise a few of the prices made: Thus, the very fine *Norman Lady* by SIR ROGER (16,991), went to Mr. J. Downing for 200 gs., and the great milker and good breeder *Cinderella* by SIR JAMES (16,980), went to Mr. J. Whyte for 270 gs. The Rev. T. Staniforth secured *Hyacinth* by BRITISH CROWN (21,322), for 305 gs., *Gertrude* by SIR JAMES (16,980), for 70 gs., and *Lady of the Manor* by BRITISH CROWN, for 260 gs. Mr. H. Aylmer secured *Ringlet* by BRITISH CROWN (21,322) for 280 gs.; and *Northern Lady*, by the same bull, became the property of Mr. R. Jefferson, at 170 gs. *Countess* and *Maid of the Mist*, both by THE SUTLER (23,061), fetched, the former 310 gs., and the latter 255 gs. *Cynosure*, a grand calf, by GREAT HOPE (24,082), went to Mr. E. J. Smith for 110 gs. Among the bulls we note the acquisition by Messrs. Dangar, Grant & Co., of COMMANDER by THE SUTLER (23,061), a very fine bull, of great character, for 93 gs.; CATO, a square, good calf, by GREAT HOPE (24,082), went to the Rev. J. Micklethwait for 86 gs.; and another of GREAT HOPE's progeny, COUNSELLER (calved June 9), sold to Mr. G. Allen for 42 gs. But for the complete list we refer to the annexed Table :—

Name of Animal.	When Calved.	Price.	Purchaser.
Cows and Heifers.		Gs.	
Coquette	1854	40	Mr. T. Rose.
Ciboulette	1859	60	Mr. J. Downing.
Collerette	1860	70	Mr. R. Jefferson.
Rosalie	1862	40	Mr. R. M. Gumbleton
Nonsense	1862	30	Mr. T. Rose.
Norman Lady	1862	200	Mr. J. Downing.
Vanity	1863	..	Not offered.
Ruth	1863	40	Mr. T. Rose.
Lady Martha	1863	85	Mr. W. Barnes.
Patience	1864	50	Mr. E. J. Smith.
Lady of the Lake	1865	130	Mr. W. Barnes.
Ruth wife	1865	35	Major Elliott.
Gertrude	1865	70	Rev. T. Staniforth
Cinderella	1865	270	Mr. J. Whyte.
Vaudeville	1865	85	Mr. J. Carson.
Chemisette	1866	41	Mr. W. Scott.
Ruth wife	1866	61	Mr. W. Fox.
Hyacinth	1866	305	Rev. T. Staniforth.
Gity Lass	1867	62	Mr. E. K. Cox.
Nicety	1867	63	Archdeacon Clyde.
Ruth 2nd	1867	53	Mr. D. Mesham.
Northern Lady	1868	170	Mr. R. Jefferson.
Novelty	1868	90	Mr. P. Whalley.
Ringlet	1868	280	Mr. H. Aylmer.
Pursity	1868	49	Messrs. T. & J. McEldeery.
Nepentha	1869	125	Mr. W. Barnes.
Lady of the Manor	1869	260	Rev. T. Staniforth.
Ruth 24th	1869	55	Mr. J. J. Gaitskell.
Countess	1869	310	Mr. J. Downing.
Maid of the Mist	1869	255	Mr. J. J. Gaitskell.
Noteworthy	1870	30	Earl of Castlestuart.
Ruth 25th	1870	51	Mr. R. M. Gumbleton
Cantatrice	1870	180	Mr. A. Ashworth.
Cynosure	April, 1871	110	Mr. E. J. Smith.
Familia	April, 1871	42	Mr. J. Whalley.
Nemesis	June, 1871	95	Mr. R. M. Gumbleton
Lady of the Valley	June, 1871	61	Mr. W. Barnes.
Bulls.			
COMMANDER	1870	93	Messrs. Dangar, Grant & Co.
VICTOR	Feb., 1871	38	Mr. S. Watt.
ROLLO	Mar., 1871	31	Messrs. F. & J. McEldeery.
NESTOR	April, 1871	17	Mr. J. R. Boyd.
REFORM	May, 1871	80	Earl of Bective.
CATO	May, 1871	86	Rev. J. Micklethwait.
GANYMEDE	June, 1871	17	Mr. D. Olen.
COUNSELLOR	June, 1871	42	Mr. G. Allen.

Summary :—

36 cows at	.. £4111 15	5 =	£4018 7 0
8 bulls at	.. 44 17	9 =	359 2 0
44 animals averaged ..	£99 9	9 =	£4377 9 0

—— The sale of the late Mr. Barnes' Shorthorns took place at Westland, Kells, Ireland, on the 25th ult. The cattle were suffering from foot-and-mouth disease, and many of them were almost too lame to walk. They were consequently in poor condition, and yet such is the esteem in which the blood is held, that these serious drawbacks to the sale of ordinary stock did not appear to affect the spirit of bidders. The sale commenced with *Medora*, which was sold to Mr. T. Rose, of Wymondham, Norfolk, for 31 gs. The three daughters of *The Nun*, *Speranza* by BRITISH FLAG, *Brilliant*, and *Bright Eye* by LEVEQUE (20,025), were sold for 58, 81, and 80 gs. respectively. *Grand Duchess 3d*, by ROYAL SOVEREIGN, and out of *Grand Duchess* by Mr. Bolden's GRAND DUKE 3D, g.d. *Sylph*, of the Booth Mantalini tribe, was sold to Mr. E. J. Smith, Ishanmore, co. Limerick, for 220 gs.; *Bracelet* by ROYAL DUKE (25,014), and also of the Mantalini family, became Mr. J. Downing's at 310 gs.; *Necklace* by KING RICHARD (26,523), and of the same Bates upon Booth cross, was sold for 325 gs. to Mr. G. Allan, for 325 gs.; *Brunette* by KING RICHARD, and a daughter of *Brilliant*, lot 4, was sold to Mr. J. White, of Aberdeen, for 105 gs. Then came the crack of the day, in *Mantalini* by KING RICHARD, g.dam *Alpine* by BRITISH PRINCE, g.d. *Sylph*, of the "Mantalini" tribe, by HOFEWELL. This pure Booth yearling heifer was sold at the extraordinary price of 750 gs. to Mr. W. Bolton, of Tipperary. *Richard's Rose*, another of KING RICHARD's stock, was bought by Mr. A. Ashworth, Bolton, Lancashire; and the remaining heifers sold, with one exception, at from 50 to 80 gs. In the bull sale WHITE DUKE was secured by Mr. George Atkinson, of Seaham, for 170 gs., and FAVOURITE by ROYAL PRINCE, and a grandson of *Grand Duchess* by GRAND DUKE 3D (16,182), became Mr. H. C. P. Gell's property at 190 gs. A summary and price list is appended. In these sales it is curious to notice the much higher price given for the uncrossed Mantalini heifer than for *Necklace* with the Bates cross, but it is also worthy of attention that the union of the two families should be so highly valued as in the case of the last-named heifer. At this time, when we are being astonished by the statement that 99 out of the 100 entries in Coate's Herd Book should never have been made, and that the only Shorthorns are those with the HUBBACK blood in their veins, it is curious to find 750 gs. given for a heifer without such an "all essential" cross.

Name of Animal.	When Calved.	Price.	Purchaser.
Cows and Heifers.		Gs.	
Medora	1862	31	Mr. T. Rose, Norfolk.

11 bulls at	.. 71 4	2 =	783 6 0
44 animals at ..	£100 14	1 =	£4431 0 0

RAM SALES, &c.

Shropshires.—Mr. R. H. Masfen's sale of Shropshire sheep took place at Pendeford. The stock comprised 60 superb Shropshire rams, and about 100 Shropshire stock ewes, all in capital condition, and the auctioneer was Mr. W. G. Preece. Sufficient time having been allowed for an inspection of the stock, the visitors were invited to partake of luncheon, which had been provided, as usual, in first-class style, in a large marquee erected on the ground, over which Mr. Horley presided. At the conclusion of the repast, the company adjourned to the ring fence outside, where Mr. Preece briefly noticed the merits and special excellencies of the animals he had been entrusted to dispose of, relying chiefly upon the high reputation which this particular breed of sheep has maintained during a period of more than a quarter of a century. The selling of the rams was then commenced, the bidding for many of the larger animals being very spirited. The following are the names of the principal buyers, and the prices :—No. 1, Preserver, a magnificent animal, Mr. Coxon, 29 gs.; No. 3, Noble, 30 gs., Mr. Sunday, of Holm Pierrepoint; No. 4, Marcus, 28 gs., Mr. C. Wilkes, Knowle; No. 5, Nimrod, 23 gs.; Mr. Horley; No. 7, My Lord, 25 gs., the agent of Sir John Chetwode; Nos. 9 and 24, the agent for Lord Hatherton, 13 gs. and 11 gs. respectively; No. 10, Chieftain, 23 gs., Mr. S. Leather, of Delamere Forest, Cheshire; No. 11, Rupert, 30 gs., Mr. Forrester, of High Ercall, Wellington; he also purchased a second ram, No. 50, for 9 gs.; Nos. 13 and 16 were purchased by Mr. Civis for 15 gs. and 7 gs. respectively; No. 14, shearling, and 7 2-shear, at 11 and 10 gs. each, Mr. Briggs, of Hadley; No. 20, The Captain, 16 gs., agent for Mr. Jukes, of Colwall, Wellington; the same purchaser also bought a second ram, No. 29, for 7 gs.; Nos. 26 and 27 at 20 gs. and 16 gs. respectively, were purchased by the agent of Mr. John Peel, of Middleton; No. 28, Nobleman, the Rev. B. Botfield, of Decker Hill, 20 gs.; No. 31, Commander, the agent of Macclesfield; No. 33, Noble Boy, and No. 3, a 2-shear, were purchased for the Earl of Beresford's farm in Ireland, and three others were bought by the agent of Lord Wenlock, to be sent likewise to improve the breed in the sister country; No. 49, The Colonel, was let for 20 gs., to Mr. T. Nash, No. 51, Actty's No. 2, Actty's No. 1 was purchased by Mr. H. Rogers, of Wolgarstone, for 13 gs.; No. 8, The Baron, and 32, The Peer, bought for 20 gs., by the agent of Mr. H. C. Vernon, of Hilton; No. 46, a shearling, and No. 8, 2-shear, knocked down for 20 gs., to Mr. Weber, of Ashton Hall, near Albrighton. Of the other older rams, No. 1, Roh Roy, a 2-shear, was let to Mr. John Crane, of Shrewardine, for 30 gs.; No. 2, The Monarch, was purchased by the agent of Archdeacon Clyde, for 16 gs.; No. 4, Conqueror, bought by Mr. Booth, of Lilley, for 12 gs.; No. 5, Cantab, let to Mr. Wall, of Shocks, near Coleshill, for 21 gs.; No. 47, was also let for 8 gs. to Mr. Bradburne, of Pipe Place, near Lichfield, who was likewise the purchaser of the highest priced ewes. The remaining rams were knocked down at prices varying from 15 gs. to 5 gs. each, and the four were sold, to the following purchasers :—Messrs. Taylor, Robinson, Gresty, Morrey, Croydon, Rotchell, Lowe, F. Keeling, Yates, H. Lovatt, Nock, Harris, G. Keeling, Bennett, Brown, Snaresdon, of Leicestershire; Nevett, and C. H. Clark. The ewes were next brought forward, and a most superb lot of 100 head of these were brought into the ring in lots of five. Lot 1 was purchased by Mr. Stubbs, of Preston Hill, for the remarkably good price of £5 each. Lot 2 was, however, superior both in form and build, and after some spirited bidding they were secured by Mr. Bradburne, of Pipe Place, near Lichfield, at the price of £6 5*s.* each. The remaining lots were disposed of as follows :—Lot 3, at 87*s.* 6*d.* each, Mr. Milward, of Thurgarton Priory, Nottingham; lot 4, 82*s.* 6*d.* each; lot 5, 80*s.* each; lot 6, 82*s.* 6*d.* each; lots 7 and 8, 75*s.* each; lots 9 and 13, 80*s.* each; lot 10 (H. Lovatt, Wolverhampton), 62*s.* 6*d.* each; lot 11 (E. Bradburne), 105*s.* each; lot 12 (the Rev. B. Botfield), 90*s.* each; lots 14 and 16 were purchased by Mr. Griffiths, of Tillington, for 65*s.* and 75*s.* each respectively; lot 15, Mr. Bennett, for 75*s.* each; and lots 17 and 18, by Mr. Gresty, for 65*s.* each. The average price realised by the rams was £13 7*s.* 5*d.* each, and for the ewes £4 12*s.* 10*d.*

—— Messrs. Oates, Perrens, and Woolridge held their annual sale of Shropshire sheep, on Monday week, at the Lyttleton Arms, Hagley. The first lot offered were six 1-shear rams, by Crane's No. 6, belonging to Mr. Hall, of Finnstone, and the first of these was purchased by Mr. R. Cox for 13 gs.; the second by Mr. Pitt for 5½ gs.; and the sixth by Mr. Lett for 5 gs. Nos. 3, 4, and 5 were not sold. The next lot were nine 1-shear rams, by Beach's No. 1. The first was not sold; the second was purchased by Mr. S. Mobberly for 10½ gs.; the third by Mr. B. Brooks for 7 gs.; the fourth by Mr. Mobberly for 7½ gs.; and the seventh by Mr. Birch for 7½ gs. Numbers 5, 6, 8, and 9 were not sold. Three shear rams, by Evans' No. 16, were not sold. A shear ram, by Paddy, was purchased by Mr. Lett for 8½ gs. A ditto by Mr. Simpson for 5 gs. A 3-shear ram, Evans' No. 16, by Nonpareil, dam by Chieftain, was sold to Mr. Millinchip, for 6 gs. The next lot, the property of Mr. J. Harward, included

16 1-shear rams, six of them being by Caractacus the 2d, nine by a ram of Mr. Crane's, and one by a Montford ram, and a 3-shear ram, Caractacus the 2d, by Caractacus. The six by Caractacus fetched 52 gs.; the nine 60½ gs.; and the Montford sheep, 7 gs. A sharp competition took place for Caractacus, which was knocked down to Messrs. Webb for 174 gs. The next lot were from the flock of Messrs. E. Webb & Sons, of Kinver Hill. Two 1-shear rams by Son of Mainstay, went of for 11 gs. Four 1-shear rams by Beach's No. 1, realised 25 gs. Three 1-shear rams, by Son of Pride of Weston, fetched 19 gs. Forty ewes, belonging to Mr. W. C. Firmstone, realised £111 15s. A similar number, belonging to Mr. John Harward, were sold for £119 10s. The whole of the animals sold realised over £500.

——Mr. William Baker's sale was held at Moor Barnes on the 23rd ult. Messrs. Lythall & Clarke were the auctioneers, and some remarkably good prices were given. Forty rams were offered, and the average of £11 11s. 9d. was obtained. Ewes were offered to the number of 70, in pens of five, and realised the high average of £5 13s. each. The following are among the principal prices given:—No. 3, shear, Hero, 15 gs., Mr. W. Coundon; No. 5, 2-shear, Young Brevet, 14 gs., Messrs. Scriven, Newport Pagnell; Nos. 13 and 14, Twins, 13 gs., Mr. Vergette, Drayton; No. 20, 18 gs., Mr. Lucas, Rugby; No. 24, 17 gs., Mr. Watson, Gillsmoor; No. 28, 18 gs., Mr. Spencer, Appleby. Ewes sold as under, in pens of five each:—Lot 1, for £34 7s. 6d, the pen; Mr. Walker, Odstone; 2, £23 15s., Mr. T. Jowitt; 3, £25, Lord Polwarth; 4, £28 15s., S. Ashton; 5, a pen of 6, £42, Mr. Jowitt; 6, a pen of 5, £25, Mr. G. Woodcock, Shearling ewes; 7, £26 5s., Mr. Jowitt; 8, £24 7s. 6d., Mr. T. Ashton; 9, £28 2s. 6d., Mr. Woodcock, Coventry; 10, £31 5s., Mr. Jowitt; 11, pen of four, £14, Mr. Pegge; 12, pen of four, £25, Mr. Jowitt, Hereford.

Southdowns.—Mr. Rigden's annual sale of Southdown ewes, and letting and sale of rams, took place on Wednesday week. Previous to the sale, the company partook of an excellent luncheon, over which Mr. Thomas Brandlock presided. At the conclusion of the repast, the Chairman proposed the health of Mr. Rigden, and that gentleman, in returning thanks, said his ewes still felt the effects of last year's drought. They were in rather low condition, and not quite in their accustomed bloom. He had not kept his shearling rams high, so do which he considered was a mistake. The company then returned to the pens, and Mr. Edward Drawbridge, auctioneer, commenced business. The sale realised £600 10s. The ewes were put up in lots of five; the highest price obtained for fullmouthed ewes was £5 7s. 6d.; for shearling ewes the top price was £5 5s. A 3-year-old ram, by a grandson of Archbishop, was let to Mr. Smith for £16 16s.; a 2-year-old, which obtained the 2d prize at Wolverhampton, was let to Mr. Gorringe, Kingston, at £23 2s.; and a 1-year-old to Lord Newbury for £27 6s. Among the rams that were sold, a 2-year-old, by son of Hempo, went to Mr. Field, Ashurst Park, Tunbridge Wells, for £17 6s. 6d.; another for £11 11s. to Mr. J. Moon Stevens, Winscot, North Devon; and a 1-year-old for £22 1s. to Mr. Bradshawe, Belgrave, Leicester.

——On Thursday week the Westdean Southdown flock, so long bred by the late J. A. Pinnix, Esq., was brought to the Hammer at Messrs. Tribe, Wyatt & Sons, of Chichester. A large number of the leading flockmasters of Sussex and neighbouring counties, as well as others from greater distances, repaired to Westdean, in spite of the unfavourable weather. The following are among the principal prices given:—

YEARLING EWES.—Lots of five 4-tooth ewes were sold to Messrs. Heasman, at £6 10s., 8s., and 6s. per head; to Mr. Clark (for the Duke of Richmond), at £5 5s.; to Mr. Fowler (Whitehawk), at 84s.; to Mr. Hamlin (Donnington), at £5 and 7s.; and to Mr. Carew Gibson, at 75s. Lots of 10 ditto were sold to Mr. Green (of Herefordshire), for 80s., 72s. 6d., and 70s.; to Mr. Goodwood (Chailey), at £6 6s.; Mr. J. Woodhouse, at 65s. and 62s.; Mr. Sparkes (Wittering), at 63s.; Mr. Gibson, at 60s.; Mr. Woodbridge (Goodwood), at 57s. 6d. and 67s. 6d.; and Mr. Bunbury, at 60s.

TWO-YEAR-OLD EWES.—Lots of five 4-tooth ewes were sold to Mr. Fookes at 90s. per head; Mr. Gibson, 84s.; Mr. Homer (Ashtilhampton), 84s.; Mr. Pitts (Hove), 75s.; Messrs. Stone (Lancing), 67s. 6d.; and Mr. Whitcher (Stoughton), 65s. Lots of 10 were sold to Mr. Woodbridge at 62s. 6d.; to Mr. R. H. Ellman (Landport), 67s. 6d. and 62s. 6d.; Mr. Fookes, 72s.; Mr. S. Beard (Southgate), 75s. and 67s. 6d.; Mr. Green, 72s. 6d. Pens of five were bought by Mr. Gorham at 70s., and Mr. Disbury, at 62s.

THREE-YEAR-OLD EWES.—Lots of five 6-tooth ewes were bought by Mr. Carew Gibson at 90s. and 77s. 6d.; Mr. Fowler, 85s.; Mr. Fookes, 82s.; Mr. Dearling (Dodsworth), 75s.; and Mr. Padwick (Thorney), 70s. Lots of 10 were bought by Mr. Homer at 70s.; Mr. T. Harris, 75s.; Mr. G. Drewitt (Ving), 77s. 6d.; Mr. Stone, 70s.; Mr. Green, 75s. and 70s.; Mr. Woodbridge, 67s. 9d.; Mr. J. Saxby (Northease), 70s.; Mr. Davis (for Lord Dacre), 69s. 6d.

FULL-MOUTHED EWES.—Lots of five were sold to Mr. Green at £7 10s.; Mr. Woods (Crows Hole), £6; Mr. Woodbridge, £5 5s.; Mr. Stone, 77s. 6d.; Mr. Dearling, 75s.; and Mr. Carew Gibson, £5 5s. Lots of 10 were bought by Mr. Fookes at 72s. 6d.; Mr. Porter (Foxhole), 72s. 6d. and 70s.; Mr. Marshall (Godshimig), at 72s. 6d., 67s. 6d., and 65s.; Mr. Dearling, 70s.; Mr. R. Lucas (East Marden), 67s. 6d. and 62s. 6s.; Mr. Davis (for Lord Dacre), 70s.; Mr. Woodbridge, 65s.; Mr. Stone, 67s. 6d.

BROKEN-MOUTHED EWES.—Lots of six were bought by Mr. Bird (Sutton), at 77s. 6d.; and Mr. Dearling at 67s. 6d.

YEARLING RAMS.—Lot 1, a yearling ram, by a son of No. 10, a Goodwood sheep, Mr. T. Cooper, Norton, 32 gs.; 2, Mr. Barclay, Leatherhead, 23½ gs.; 3, by I. Eliman's No. 3, Mr. T. Harris, 23 gs.; 4, by a Westdean sheep, son of No. 10 from Goodwood, Mr. Tickner, Boreham Street, 25 gs.; 5, by a Westdean sheep, No. 6, son of No. 16 from Goodwood, Mr. Green, 24 gs.; 6, by No. 9, a grandson of T. Ellman's No. 16, Mr. Stone, 25½ gs.; 7, by No. 9, Mr. Styers, 17½ gs.; 11, by lot 79 in this sale, grandson of Mr. T. Ellman's No. 9, Mr. Richards, Wimbourne, 15 gs.; 12, by No. 9, a Westdean sheep, son of No. 10 from Goodwood, Mr. Hodson, West Blatchington, 23½ gs.; 14, by do., Mr. Ashby, Eastdean, near Lewes, 16 gs.; 15, by do., Mr. Elliott, Broughton, 24½ gs.; 16, by do., Mr. Tickner, 20 gs.; 18, by lot 64, son of No. 10 from Goodwood, Mr. Hipkin, 15 gs.; 19, by No. 10, from Mr. J. Pinnix, Walderton, Mr. Homer, 28½ gs.; 20, by do., Mr. Fookes, 20 gs.; 21, by do., Mr. Whicher, Stoughton, 15½ gs.; 24, by No. 10, a Goodwood sheep, Mr. Ashby, 23 gs.; 25, by do., Mr. Hamlin, 14½ gs.; 26, by do., Mr. R. H. Ellman, 15 gs.; 27, by a Westdean sheep, Mr. Hodson, 19 gs.; 28, by do., Mr. Richards, 15 gs.; 29, by No. 10, a Westdean sheep, Mr. Woodbridge, 17½ gs.; 30, by No. 9, a Westdean sheep, son of No. 10 from Goodwood, Mr. Ashby, 30 gs.; 31, by No. 9, a Westdean sheep, son of No. 10 from Goodwood, Mr. T. Harris, 21½ gs.; 32, by No. 10, a Walderton sheep, Mr. Fookes, 18 gs.; 36, by lot 64, son of No. 10 from Goodwood, Mr. Woods, 20 gs.

TWO-YEAR-OLD RAMS.—Lot 37, by 64, son of No. 10 from Goodwood, Mr. Barclay, 44½ gs.; 38, son of lot 70, a Walderton sheep, Mr. Stenning Bartlett, 45 gs.; 39, son of No. 10 from Goodwood, Mr. Carew Gibson, 74½ gs.; 41, do., Mr. Wheeler, 17½ gs.; 42, do., Mr. Fookes, 20 gs.; 43, do., Mr. Parlett, Bury, 15 gs.; 44, do., Mr. Lucas, Westhampnett, 30 gs.; 45, do., Mr. J. Saxby, 20 gs.; 46, do., Mr. Tickner, 15½ gs.; 47, do., Mr. J. Saxby, 14½ gs.; 48, do., Mr. Ashby, 29 gs.; 49, by No. 4, a Westdean sheep, Mr. S. Beard, 23 gs.; 50, by lot 80, son of No. 10 from Goodwood, Mr. Tickner, 13 gs.; 53, do., Mr. Green, 20 gs.; 54, do., Mr. Wheeler, 18 gs.; 55, by No. 3, son of No. 10 from Goodwood, Mr. Woodbridge, 15½ gs.; 56, do., Mr. Woods, 21 gs.; 58, do., Mr. Saxby, 14 gs.; 63, by No. 10, a Walderton sheep, Mr. Ashby, 24½ gs.; 64, No. 10 from Goodwood, Mr. Clark, from the Duke of Richmond, 41 gs.; 65, do., Mr. Green, 24½ gs.; 66, by son of T. Ellman's No. 2, Mr. Barclay, 14 gs.

Lincolns.—The celebrated flock of longwool Lincoln rams, belonging to Mr. C. Clarke, of Scopwick, was submitted to public competition on Thursday week by the Messrs. Briggs. Notwithstanding the unfavourable weather, a considerable number of the hundred of the leading ram-breeders and agriculturists of the county attended the sale, and numbers of buyers were also present from Yorkshire and Nottinghamshire. The sheep were not in show condition, but their quality and symmetry were undeniable. The pick of the lot was undoubtedly lot 30, a magnificent 2-shear, which, after a spirited competition, fell to the bid of Mr. T. Kirkham, of Biscathorpe (who used him last year), at 150 gs. There were 33 shearlings. Mr. Byron secured No. 7, for £38 17s.; Mr. Clarke, Ashby, No. 9, a grand sheep, with beautiful coat, and a good forequarter, for £63; and Mr. Lockett, No. 22, for £49 7s. Mr. C. Clarke, Ashby, became the fortunate possessor of No. 43 (a magnificent 2-shear, with nice coat and beautiful flesh), for £65 2s.; the following lot was knocked down to Mr. Kemshall at £42; and Mr. Maynard secured the fifteen last of the shearers, at a like figure. The 3-shear and aged sheep were wonderfully good, the best in a prime lot falling to the bid of Mr. J. H. Caswell at £89 5s. Mr. Paddison, of Ingleby, bought lot 61 for £67 4s.; Mr. Smith secured lot 59 for £46 4s., and two others were each knocked down at 50 gs. each. Sixty-nine sheep were offered, and one was withdrawn, the 69 realising an aggregate of £1639 11s. 6d., being an average of £23 15s. 1d. The 33 shearlings averaged £19 18s. 6d.; the 25 2-shears, £24 2s.; and the 11 3-shear and aged sheep reached the extraordinary average of £32 13s. 9d.

PARASITISM IN RUMINANTS.

[The following deeply interesting remarks upon our food-producing animals, their parasites, and disease in them, from a lecture delivered before the Society of Arts, by T. Spencer Cobbold, M.D., F.R.S., may not be unacceptable to our readers.]

In the further pursuance of our plan, I propose this evening to give you an account of the common liver fluke, which takes up its residence in the sheep. At the same time, we shall have an opportunity of incidentally studying several allied forms.

I have already stated that flukes constitute a distinct and natural group of entozoa, termed "trematodes," or flat-worms. For the most part they reside in the ruminants, but some of them attack other quadrupeds, and also man himself. The liver-ducts of the ox and sheep constitute their head-quarters, so to speak.

If you glance at this list, representing the entire parasitic fauna, in each case you will see that a considerable variety of flukes occupy these two hosts. The first-named, or Fasciola hepatica, is the form which we have to deal with especially, this species being common to the ovine and bovine quadrupeds. Fortunately, it is an extremely rare parasite in man, only 18 instances being on record of its having been found in the human host, but for otherwise it is with the fasciolæ and sheep. Now, what sort of a creature is this entozoon?

Without going into the anatomical details of the fluke itself, we must now glance at one of the most intricate points connected with the study of entozoology, viz., the eggs of the flukes. They are very large indeed—when compared with those of other forms of parasites. The eggs of the common tapeworm measure no more than the 1-70th of an inch in diameter, and will, it has been said, pass through an ordinary charcoal filter. The eggs of the fluke, however, are so large that they measure as much as 1-180th of an inch lengthways. These eggs are scattered over the field by millions, passing from the hosts or bearers in a way which it is quite easy for you to understand without its being particularly described. When thus scattered, they require for their further development a certain amount of moisture. A good shower of rain is, of all agencies, the one thing needful in their favour; for the rain carries them down into ditches, and streams, and lakes, and into other artificial or natural collections of water, where the further development of their contents will be rapidly accomplished.

Consider, I pray you, what takes place when an egg is conditioned in a manner suitable to its further development. The egg is furnished with a lid, so that when moisture is supplied, this part forming the anterior pole of the shell, rises up and a locomotive animalcule immediately emerges from its interior. This little creature is furnished with a dense covering of vibratile cilia, and it swims about with extraordinary rapidity.

Let me tell you that I have frequently experimented with the eggs of certain flukes, and it is really a beautiful and instructive sight to watch the behaviour of these minute organisms as they disport themselves, darting across the field of the microscope with astonishing activity. But they do not long retain the simple ovoid form assumed within the shell. They change into a conical figure, the larvæ of the common fluke bearing a mark, in the shape of a cross, on its back. This pigment spot has been called an eye, but whether it sees or not with this organ is quite another matter. The spot consists of a number of minute granules collected together. I have also not seen this spot in any of the other forms of trematode larvæ which I have examined.

What is the subsequent history of our fluke? For years past ento-zoologists—abroad and at home—have been trying to work out the genetic relations of the common species; but I fear we have not yet succeeded in fixing all the phases through which it passes. It is difficult to make out clear evidence nevertheless, by putting together the changes which obtain in other forms of fluke larvæ, we are enabled pretty accurately to determine the phases of life-changes which these creatures undergo.

At the risk of being a little tedious, I will now endeavour to open out the principal data by which our definitive conclusions have thus far been arrived at.

Speaking of flukes generally, the ciliated larva loses its cilia, and at the time of the decay or falling off of the cilia another small body is observed inside the original ciliated larva, which, according to the usual organisation, grows rapidly at the expense of the primary larva. The little organism inside—you may call it the germ if you please—increases in size until it assumes a form similar to that of the original. The odd thing is, that it has no sooner arrived at this stage of development than another organism appears in its interior; so that we have the ciliated animalcule producing a germ in its interior, the germ itself increasing in size, until it becomes what we call a germ-sac. First a germ, and then a germ-sac. Now, the germ-sac developes within itself numerous other larvæ. These again, emerging from the sac, become what is termed a redia, and the still stranger thing is, that these redie develope other larvæ inside themselves. This process is essentially a kind of budding, only, instead of being carried on outside, as in a plant, it is produced internally. We have, therefore, two varieties of sacs, two kinds of sacs, simple and organised, or, in other words, sporocysts and redie.

In many of the flukes those germ-sacs contain in their interior an enormous number of buds, and the buds again, in their turn, during certain favourable seasons, go on multiplying, practically speaking, *ad infinitum*. One cyst will thus form a series of new germ-sacs, and these also will multiply indefinitely. Notice, however, if you please, that in the case of the redia, which is only a more highly organised form of germ-sac, the larvæ developed in its interior have a different history to that of the preceding. Take the simple, original, unorganised germ-sacs. They are furnished with tails, and are termed cercariæ. I must also tell you that all kinds of sacs, whether simple or compound in character, are collectively termed nurses. When, therefore, I use the term nurse, I mean some kind of sac which contains larval flukes in its interior. The redia has a structure something like the adult fluke, for there is a sucker and a mouth at its base, leading into the stomach, which is a simple unbranched tube or cavity.

The whole history of the larval development of flukes, the cercariæ play a most conspicuous part, and it is they that are chiefly concerned in bringing about the epidemics of rot. You, doubtless, understand that the rot is an endemic disorder, produced entirely by the Fasciola hepatica. When this highly-developed form of nurse, termed the redia, bursts, the cercariæ are liberated, and, escaping into the water, they swim about with great rapidity. But my hearers will say, "You have not told us where the larvæ dwelt whilst all these changes took place?" My reply is, "They were for the most part ensconced in the bodies of water snails belonging to the well-known genera, Lymneus, Paludina, Planorbis, and their allies."

Some of the cercarian forms are very peculiar. The true cercariæ have no eyes, but the larvæ of certain kinds of flukes have visual organs. Thus, the larvæ of certain Polystomata, of Monostomata, and also of Tristomata have eyes. "But," you will say, "what is the meaning of all this?" I shall endeavour to explain the point immediately, but I have scarcely done with

other matters, which I must make clear before proceeding further.

I have said that during certain seasons the larvæ are much more prevalent than at others. Atmospheric changes involve the reproduction of a greater number at one season than at another. In point of fact, not only does a favourable season increase the number of these larval forms, but it increases the degree of their organisation. It is a strange thing, but it is nevertheless perfectly true, that if the heat be excessive, and there be abundance of moisture, the number and character of the larvæ will be altered accordingly. Speaking generally, it may be said, in short, that under these atmospheric and other favourable and peculiar conditions, one germ-sac may become a thousand, and this thousand may produce other thousands; and all these collectively will finally involve, if the season is prolonged, the production of innumerable forms of cercariæ.

So extraordinary are some of these larvæ, that in the case of the form termed Bucephalus polymorphus, the creature is furnished with two tails. There is something yet more remarkable about this Bucephalus. The head and body will develope into a fluke like an ordinary cercarea, whilst the tail, which presents a beaded or jointed appearance, developes in its interior a large number of larvæ. Every joint, in fact, becomes, as it were, a nurse, developing in the interior so many sacs; these latter, again, in their turn, being capable of producing Bucephali. Thus the tail of the animal is a concatenation of germ-producing sacs, whose developmental phenomena are practically without a limit.

I dare say you may think I have made the subject appear sufficiently complicated, but what I have said is, in truth, not half the story, for not only do the larvæ of flukes undergo these various changes, but the nurses themselves will split up into several other nurses, and all these divisions will go through the same transformations, after the manner I have described.

Then you will say, "What of the snails?" Well, it is very difficult to generalise on so complicated a subject; but I think, with the aid of Dr. Pagenstecher, who has written a valuable monograph on this subject, one can advance a certain number of statements which are true, even though they may not embrace all the data we should like to collect before making definitive propositions. As a rule, one larval fluke will only select one molluscan host. You know the ultimate destiny of nearly all these larvæ of the common fluke is to attach to the sheep in the ox, as the case may be. They have to pass a part of their time sojourning in the territory of snails. We call the snails the intermediary bearers, because they supply a habitat between the free condition, when the larvæ swam about, and the ultimate bearer, which is the sheep.

It is usually the prerogative of the snail to have its own particular set of larvæ, belonging to one species; but that is not invariable, for some of the snails will harbour a limited number, two, three, four, or five, and, I think, as many as six in one case. However, at least three or four juvenile trematodes may be found in one kind of snail.

Having traced their development as far as the cercarian stage, what is the final outcome? The cercaria developed inside the snail makes its way out into the water, and swims about in a perfectly independent fashion. And here a slight difficulty presents itself, for some have supposed that they went back again into the snails, others maintaining that they remained in the water until they were swallowed by the sheep or ox drinking. It is quite clear that in many cases the flukes are conveyed to their hosts as actively swimming cercariæ; but it is also extremely probable that many forms of fluke larvæ are passively transferred to their ultimate bearers whilst occupying the bodies of molluscs or other aquatic intermediary bearers.

Our desire has been to find out what particular species of snail plays the part of intermediary host to the larval form which developes into the common fluke. Manifestly, if you or I were in a position to say "that is the culprit," pointing out a particular Lymnæa, Paludina, Planorbis, Succinea, or other species, the molluscs might put a stop to outbreaks of rot by getting a number of children to collect and destroy all the snails of the particular species thus known to act in the capacity of intermediary bearers. But this is the very thing we have not been able to find out. Statements there are, it is true, have been put forward by some persons to the effect that they have discovered the snail which harbours this larva; and they will tell you that it is the little mollusc called Succinea putris. This little mollusc is peculiar in many respects. In the first place, it cannot hide itself altogether within its shell. It is seldom seen in the water. It goes to the very brink of ditches, ponds and rivers, being an inhabitant of marshy grounds, where there is plenty of moisture. Never being away from such localities, it is exactly the kind of snail in which you would naturally expect to find the particular cercarian form we have so long been looking for. As regards epidemics of rot amongst sheep, it is notorious that they occur principally in the spring; and you may get a notion of the extraordinary amount of disease which is induced by this parasite, when I state that every year hundreds of sheep are destroyed by it. During certain years, indeed, tens and hundreds of thousands of sheep are cut off. Thus, in our own country, the injurious effects of this parasite were most clearly exhibited during the epidemic of 1830 and 1831, when between 1,000,000 and 2,000,000 sheep perished from the rot disorder. In the year 1812, in the neighbourhood of Arles, in France, 300,000 sheep perished; and, in 1824, an epidemic occurred in the Isle of Thanet. So acute was this local outbreak, that Mr. Cramp, a sheep farmer on a large scale, lost £3000 worth of sheep in less than three months.

It has been observed that cattle, sheep more particularly, are only affected when grazing in low pastures. And the reason of this is obvious; for, unless the sheep can only get access to snails residing in such localities, the sheep in like manner can only be infected by devouring the snails and the parasitic larvæ frequenting these situations. Consequently, as is well known, when the slightest symptom of the disease appears, if the sheep are removed from the marshes to high ground, the disorder is at once checked. The sheep soon recover, unless they happen to have swallowed a large number of the larvæ.

Everybody who has to do with cattle and sheep, is familiar with the appearances presented by animals thus affected. Even butchers' boys can tell a rotten sheep, as they call it. They examine the eye, and find that it has lost its lustre; whilst there is a peculiar paleness about the membrana nictitans. The conjunctiva loses its ordinary bright colour, and the vessels contain fluid which, instead of being a bright red hue, is pale and watery. There are, also, many other characteristic indications. I have myself repeatedly tested sheep for flukes by simple manipulation. If you run your fingers or thumb down the spine of a rotten sheep, it winces when you come to the region of the loin.

Another matter of some interest is, as to how these animals should be treated. Not only should they be removed from moist localities and placed on high and dry ground, but they should also have cereals mixed with their ordinary food. Peas, Beans, and other seeds of that nutrient class, should be given with grass, taken from uninfected districts; whilst, speaking generally, the animals should be kept apart from all other influences calculated to promote the disorder.

ROASTED TURF.

WHERE any process has been found beneficial to the garden it is quite right that it should be turned over to the farm, and although the greater extent of the farm prevents many gardening processes from being applied, yet there are some of such immense importance that they should be handed over to the agricultural side at the earliest opportunity.

In large towns, such as Manchester, the sawdust formerly wasted is now economised by being used in stables to absorb urine, and thus convey in the solid form that richest part of the manure direct to the land, for the sawdust holds it with such a firm grasp that nothing less than the earth itself can get the filth out of it, and sawdust being a vegetable substance, the compost of sawdust and urine makes an excellent manure; but I need scarcely remark that the bulk of sawdust is unsuitable in proportion to the need of it in this way in all the cow byres, pigsties, stables and privies where watery manure is made, and it becomes therefore necessary to get an absorbent material in bulk sufficient for the occasion. Gardeners and florists have their various composts—heaps, and they ingredients with great precision—silver-sand, turfy loam, sandy peat, leaf-mould, stable dung well rotted, and the like. Many years ago one of the crack composts for the florists' Carnations was turfy loam roasted, and for small concerns a few sods could easily be roasted over an iron plate laid upon three brick props, having a fire of wood or of cinders underneath. During the process of roasting, wireworms and the like were destroyed, and the turves became more or less impregnated with the wood smoke, and this was more particularly the case when the turves were roasted in a kiln of the usual hollow piles, about the size of haycocks, with a fire of faggot-wood inside; for, by means of this slow fire, turves containing rushes, and soured with stagnant water, became friable and sweet, and fit for immediate use in potting plants and the like, that otherwise would have taken months, if not years, to be available for the like purposes.

In the extreme West of Scotland, before the Potato disease appeared, it was the custom of the Islesman to strip his hut, for it was hardly worthy of the name of house, annually, and with the sooty thatch and still smoking turves, called in the North "divets," that lay between the wood of the roof and the straw thatch, to manure his Potato land, and he usually got an excellent crop, as the land was seldom poor, having a good neighbour in the sea for wrack or seaweed as manure for grass, &c. Now, unless roasted turf is friable, as sand or sawdust, it is not cooked enough, and it must on no account be burnt like clay for bricks or pottery. When a gardener lets his Heaths and Epacrises potted in peat and sand get thoroughly dry, the usual phrase employed is that they will not take water, and we see the water run off the dry peat just as it would run off the back of a waterfowl; it is, therefore, clear that peat turves are not to be roasted when we want an ingredient to absorb water and hold it. The top spit of clay soil or loamy soil, about 4 inches deep, with the grass on it, will roast nicely, and as it roasts it will get full of open chinks, to let out smoke, in all directions, for as is well known the wet earth will shrink as it dries, and occupy less space than it did before; and therefore in roasting turves the kilns should be watched as one would watch wood when burning for charcoal, to regulate the openings on the windward side, by closing them with a patch of wet clay, to get the fire to act evenly and all round. Of all the agents employed by man there are none more powerful than fire, and few so variable in action. It was fire that forged for man in the olden time the murderous war weapons that terrified the unarmed into subjection, and prophets announced a blessed time of peace coming, when the deadly steel of the spear should glow on the anvil to form the harmless pruning-hook, while the weightier metal of the battle-axe should steel the harmless coulter, and help to till the land, or, as the poet hath so eloquently expressed it—

"And the broad faulchion in a ploughshare end."

Passing over the strong arm of steam, which has caused the venerable flail, as an instrument of torture, to be consigned to oblivion, not only does fire plough the field and thresh and winnow the corn, but it carries away the produce by rail to market, and brings back manure, coal, and building materials. By force of fire one shire or another excites rare rent, stormy seas traversed, mines of all sorts made available, and their contents hauled to the surface. Almost all the food we eat is prepared by the agency of fire for our use, converting animal and vegetable substances into a state of tenderness fitted for the teeth to masticate. Fire, therefore, in this case cannot be said to be a destroyer, for when human food has been well roasted, it is not to be confounded with being burnt, and it is this grand division that has to be kept in view in roasted turf.

Few will understand that the ingredients wanting in the soil must be supplied before any crop can be got, but the rain alone might give the answer for other ingredients as well as for water, and tough rushy sods, that are usually pared and burnt, might be given as an example of food in very great need of dressing, but certainly free from being burnt to ashes; but if roasted only be cooked or roasted until it was friable, as if for Carnation culture, it would be available as food for plants, or to be used as an absorbent for watery manures as above stated. In cases where no turves can be had, loam, or even clay, can be roasted, but these must be cut and turned before they are piled up for roasting; slightly puddled, any garden earth will bear piling up like sods or turves, and may be smoke-dried as above stated, and when pounded and riddled, will give solidity to watery manures.

Where is there a farm of the old *régime* where the duck pond, draining pond, and general open cesspool draining the dunghill is not one of the most conspicuous institutions of the household? In Denbighshire, last year, a child, under two years of age, toddled into this pit of dirty water and was drowned; but the filth of the water gave the doctor no chance to resuscitate, for the little fellow was poisoned as well as drowned by the water of this deadly pit.

By the proper use of roasted soil manure would not run any more, and, therefore, the pond would only contain water, and the bulk of dry dung available for crops would remain dry. Burning the heaps of weeds is certainly a very ready way of disposing of them, but it is the destructive principle; whereas, they being vegetable, like the sawdust, should not be destroyed, but converted into manure for growing crops: the very Dock roots can be smoke-dried until they are as dead as the Turkey Rhubarb of the druggist's shop, and Couch-grass roots, if only buried 1 foot deep, will die a natural death and yield vegetable mould,—the best known medium in which to grow plants, for it is said by cultivators of exotics that no plant refuses to grow if planted in vegetable mould. Loam roasted and roasted is, moreover, the most practical disinfectant for the farm, as well as the cheapest; it is no foreign or costly article, coming by sea from foreign parts, and coming inland by railway; it is indigenous to every farm and holding, whether great or small, for only soil that will puddle will always stand up to be roasted, but nothing can be done with dry earth. A square hole, by way of ashpit, should be dug in the earth, and an iron grating or a few iron bars laid over it, on which to make the fire, and this ashpit should communicate with the outer air, and when rightly started the fire will burn with such a calm glow that it will be quite a pleasant sight to peep through at it. Long ridges of clay burning, or great stacks of turf pared with the floating spade to be reduced to ashes, have nothing to do with this kind of roasting, for who would pot a plant in the red ashes of burnt clay? or who plant could live in the alkaline ash of burnt turves? and whether for the garden or for the farm, the principles must ever be kept distinct. *Alex. Forsyth, Islington Square, Salford.*

HARVESTING CORN IN WET WEATHER.

As an addendum to our remarks on this important subject last week, we place before our readers some very practical suggestions from the *Yorkshire Post* for saving corn in wet weather by a system of protection from the weather in the field or in sheds. We would

direct special attention to the ingenious plan of forming small stacks in the field, of such a form that setting a current of air plays over all the heads of the sheaves, they are, at the same time, secured against rain :—

"There are many other ingenious modes of preventing injury to corn in an uncertain or wet season, which have been adopted by different experimenters. In the districts of Kent and Sussex, where Hop oasts or kilns are near enough to the Wheat fields to render one of them handy for from practicable, wet Wheat in the straw has been dried in these buildings with some success. One trial showed that on a kiln floor, the area of which was 540 feet (less than 8 yards square), the produce of 45 acres could be dried in six days, the average time required for each charge of sheaves being 24 hours. This would be rather slow work on a farm of any size, and can only be adopted in Hop-growing localities. A gentleman in Sussex some years ago had 30 acres of Wheat cut and placed under cover, using for that purpose every barn, hovel, cattle or implement shed on his farm, and setting the sheaves upright as closely packed together on the ground, each acre of sheaves occupying thus 400 superficial feet. This Wheat was cut whilst the weather was dry, and carried dry to its shelter, and he found that in 10 or 12 days it was ready to be threshed out. Afterwards, as an experiment, two waggonloads of Wheat, that had been cut and carried during heavy rain, were also brought in and placed under shelter in the same manner, and these were reported dry enough for threshing in 16 days. If these results have been verified by subsequent experience, they would seem to indicate a valuable and partially available means of saving at least some portion of a crop. Possibly the chief reason why this method has not been extensively adopted may be found in the fact that the large area of roofed-in space requisite for the purpose is not often to be found on a farm. To accommodate 30 acres, each acre of which needs 400 feet of standing room, a farmer must possess and be able to clear out 12,000 superficial feet of shelter, that is, equal to 30 sheds measuring 27 feet by 15 feet each. The different modes of carefully stooking and hooding Wheat used by English farmers are too well known to need description. They are none of them effectual preventatives of damage from rain. In continuous wet weather the sheaves grow at the bands and the ends of the stooks, and the top sheaves are liable to sprout in a few days of damp weather. With corn reaped by the sickle a good workman could so arrange the stook as to prevent injury to the four or six middle sheaves for some time. Mown corn is, however, soon wet and soon dry, but the tails of the sheaves sprout in damp seasons. Corn cut by the reaper is soon wet and soon dry, like that mown by scythe, but the sheaves stand better, and have no ears in the tail, and, consequently, if kept up in stook, it will bear much rain before it becomes sprouted. The very best men in the field should therefore follow the reaping hands, and 'set up' the sheaves in stook or 'haddock.' Good workmanship in this department of the reaping work is one of the most efficient auxiliaries we have in preventing damage to grain from wet; and when thus stooked they should be carefully watched, and fallen sheaves immediately lifted up. In the west of Ireland, where the climate is wet and fickle, the cottier farmers put their Wheat as soon as cut, or when the clouds threaten, into pikelets, containing perhaps 50 or 60 sheaves. These are carefully built in a conical shape, and the top protected by being thatched with the last sheaf. They are secure from anything but extraordinary downfalls of rain. In Sweden the farmer avails himself of the abundant supply of wood to form, out of the thinnings of the forest, useful arrangements for partially securing the cereal crops from the inclemency of the climate. One mode is by staking from the ground at intervals poles 6 or 7 feet high, and on the sharpened points of these poles the sheaves are spiked, and slid down one after another like Normandy Pippins on a string. The top sheaf protects the remainder to a certain extent, but it will be evident that wind and rain will have free access to the sides of the sheaves. The merit of the system in such a country is the very short time in which they will become dry again after a shower. It is said that one man can set up 500 of these poles in a day. In Russia a species of rack with broadened roof is used, on which the grain is hung; but this is simply applicable to where Wheat is scarce and wood redundant. The only mode of securing grain in rather a damp state, or as soon as it is cut, or before it is ready to stack in the ordinary manner, as a safe step in the prospect of wet weather, which we have mentioned previously, is the following. For many years we have tested its efficacy on a large scale, and secured Wheat in very difficult seasons without a sprout. In the Wheat of a field of Wheat place two hurdles or stack-bars parallel to each other, at 2 feet apart. The taller and stronger the hurdles are the better they will act. At the centre of each hurdle a stay may be put across to the opposite hurdle, or, what is better, a forkful of Thorns may be thrust into the passage, so as to be held by the top bars of the hurdles as in a vice. The heads of the parallel hurdles should not be placed opposite to each other, as, by so doing, one portion of the double fence would bear much more lateral pressure than the other. An old clipped hedge split will furnish the very best sort of Thorns for inserting between the bars at the intervals specified. A small bed of straw or Thorns, 4 feet wide on the outside of each of the parallel rows of hurdles, is made; and upon this soft grain may be stacked, roofed, and secured from rain by tye bands of thatch or of unthreshed Wheat. The *modus operandi* is as follows:—Stack the sheaves in rows with the heads to the hurdles, with a few sheaves to fill up placed longitudinally. After reaching a little higher than the top of the hurdles, the walls of sheaves may be carried up about a yard more, the sheaves being so placed that the 2 feet space is gradually closed up; after which, the two rows of sheaves and the passage are to be roofed with sheaves, drawing in quickly, so that on the ridge a small quantity of short straw or rakings may be immediately placed, and the roof made secure against weather by opening out thatch and tying down with two rows of pegs and string. On each side of the parallel rows of hurdles 105 sheaves may be laid, viz., seven rows of 12 sheaves, at right angles, and three parallel to the bars; five additional courses up to the roof, each being now a double row, will take 120 sheaves; and the roof will swallow up 100 more; so that, to complete the erection for the length of 9 feet we shall require (105 + 120) × 2 + 100 = 550 sheaves, or about the produce of an acre of ground. Twenty hurdles only are thus required for 30 acres of Wheat; and the length of the safety stook will be 30 yards in such a field. It will have a flue 2 feet wide through the whole length, through which the air will circulate, and as the sheaves are placed one row thick at right angles, the wind will pass through and between them, to the central flue, drying the corn thoroughly. Thus we have a stack with all the external surface necessary for drying, but without any solid inside, which becomes sodden and impenetrable to the air if stacked when damp or soft. It is, in fact, simply a straw wall without any 'filling,' through which the air can pass freely. On several occasions we have tested the method, and we have frequently recommended it. And we do so again, because we have not as yet met with a more successful mode of practice under such circumstances. The idea was suggested to us by the Roman poet's recommendation to stack the damp grain over a Quickthorn hedge."

MILK COOLERS.

From the article on American Butter Factories in vol. vii. of the Journal of the Royal Agricultural

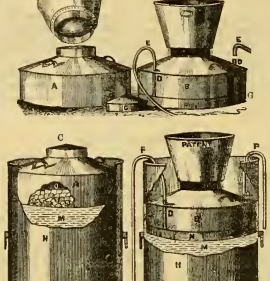

Fig. 261.—"National" milk-coolers.

Society of England, we take the following description and illustrations of milk coolers and carrying cans. It

Fig. 262.—cover and bottom for milk-can.

is there stated that, for properly preserving milk in its transit from the farm to the factory, milk coolers

Fig. 263.—carrying-can for milk, with its appurtenances.

have been introduced among the farmers to cool the milk at the farm as fast as it is drawn from the cow. We give figures of two devices which are used in the carrying cans hauling milk to the factory. Cold water or ice may be used for the purpose indicated.

In fig. 261 (the "National" milk cooler), A represents the cooler, for water (N), and ice (O). B shows the cooler arranged for introducing water by means of syphons E, E, fixing on tubes D, D; and C, the cover. F, on both sections, is the strainer; G, body of the cooler; and H, H, the carrying cans with coolers floating on the milk (M).

In the next illustration (fig. 262), A represents the cover of the carrying can (fig. 263), and E the iron bottom.

Fig. 263 shows the carrying can for milk, with its appurtenances—A and B in fig. 262, forming part thereof. In the present illustration A shows the can with cooler and strainer set in place; B, the cooler; and C, the strainer. The illustrations are so clear as to render further description unnecessary.

INTERNATIONAL EXHIBITION.

Australian Meat Preservation and Importation.—Owing to the vessel with the Australian goods for the International Exhibition having been lost, only two meat-preserving companies exhibit, viz., Towns & Co., a Sydney company, and Whitehead & Co., also of New South Wales. In our report we shall notice in the first place, the statistics of meat imported into the United Kingdom during the past five years, which we take from Messrs. John McCall & Co.'s circular, with some remarks quoted from the *Melbourne Argus*, so as to bring up this head to the most recent date; (2), the various methods of preserving meat; (3), the Australian companies now represented in London; (4), the dietetic value of this new branch of industry to the mother country; and (5), the pecuniary influence of this new trade on the price of fat stock, home and colonial.

1. Statistics of meat imported into the United Kingdom from 1866 to 1870, from John McCall & Co.'s circular, viz. :—

1866.—	91 cwt.; declared value,	£321
1867.—	5,721 ,,	18,800
1868.—15,337 ,,		45,749
1869.—28,306 ,,		80,385
1870.—77,842 ,,		203,874

It will be seen from this Table that the increase is progressive, and somewhat remarkable, and from the *Argus*, a Melbourne newspaper of the highest colonial authority, dated April 22, 1871, it continues: "The number of sheep slaughtered by the company during the six months was shown" (at the seventh half-yearly meeting held on the 21st—April 5, 1871) "to be 1,161,264; and of oxen 3115. The value of the meats consigned to London was £47,595, and of the tallow £34,425." It may be added that this company are enlarging their works.

"The Victoria Meat Preserving Co.," quoting the same paper, "who commenced operations in October last (1870), have been able to present a favourable report. Over 240,000 tins of meat were preserved up to the close of the half year ending March 24 last (1871), and the advices from London stated that very fair prices had been offered for the meat." The capabilities of the plant were 1000 sheep a week; the value of the shipments was £11,674."

An equally favourable report is given of the half-yearly meeting of the Warnambool Meat Preserving Company.

Besides the above and other companies at work the *Melbourne Argus* refers to the prospectuses of several new companies starting, viz., of "The Meat Preserving Company of Echuca," of "The Metropolitan Meat Preserving Company" (an old company with a new name), of "The Sydney Company," and of "The Central Queensland Meat Preserving Company." The first shipment of the Sydney company has been received by the agents, the Messrs. Crosse & Blackwell, of Soho Square. To this we shall return.

(2). The preservation of beef, mutton, pork, fowls, fish, &c., is an old affair, based no doubt on the experience of our ancestors, who slaughtered their cattle in autumn, and salted their flesh for consumption during the winter season. Fed for the long months on salt meat, a relish for something less salt was natural. Hence numerous patents were obtained. We shall quote the first on record, viz., No. 278, October 7, A.D. 1691, obtained by Thomas Porter and John White, as follows, viz. :—

"A grant unto them of the sole use, exercise, and benefit of their new invention of keeping and preserving, by liquors, or otherwise, all sorts of flesh, fowls, and fish, and many other things, either in pieces or in whole bodies, at a cheap rate, for many years, in all climates, without changing the nature, quality, taste, smell, or colour

thereof, as good, palatable, and wholesome, to be eaten and made use of for any intent and purpose whatsoever, as when first killed or put into such liquor; to hold and enjoy the same for 14 years, according to the statute."

No specification of this invention has been enrolled, so that some degree of mystery hangs about it. Since the above date about 650 applications for patents have been made for the preservation of animal and vegetable food. An abridgment from 1691 — 1866, covering 497 patents, has been published by the Commissioners of Patents, and may be had for 10*s*. Those for flesh may be divided into six classes, thus :—1. Freezing or preserving with ice; 2. Salting with various saline substances; 3. The introduction of gases into the meat; 4. The injection of gaseous or liquid substances into the blood of living animals, or immediately after they are slaughtered, so as to prevent decomposition; 5. The preservation of cooked or raw meat in hermetically sealed vessels or canisters, technically termed "cases" or "tins;" and, 6. The combination of the 2d and 5th.

Of the above methods the fifth is the only one that merits notice. True, one or two companies use a very small quantity of common salt, or some other saline substance, but the propriety of using any antiseptic is annually losing popularity, whilst the practice of the exclusion of air, is, on the contrary, daily gaining ground. It must be borne in mind that Australia is not in advance of the mother country in the art of preserving meat. The investigations of the Society of Arts —since 1810 (Durant's patent)—point the other way. And the *Melbourne Argus*, in its report on meat preserving, informs its readers that "some cases of meat from the establishment of Messrs. Forbes & Co., Aberdeen, preserved by Mr. Richard Jones' (a London merchant) vacuum process, and received from London, were, on being opened at Melbourne for inspection, found to be of very superior quality; and that a Mr. Brown, late of Forbes' establishment, Aberdeen, had gone to assist the Queensland Meat Company in carrying out this method of preservation." Such facts prove that our Australian colonies appear determined to profit by practical information wherever they can find it, and to go a-head in the preserving of meat accordingly.

Mr. Jones' last process is under patent, sealed Sept. 25, and dated March 31, 1869. There is very little novelty in it, but into details of this kind our limits will not permit us to go. His claim, which we quote from his specification, No. 978, A.D. 1869, will give a general idea of his process :—

"I am aware that it has heretofore been proposed to operate on animal and vegetable matters for the preservation of them for food by the employment of exhausting means in connection with the heating means; but by such method the exhausting means was employed after cooking has been effected, and also the effecting of such cooking entirely under vacuum, substantially as described."

Prior to 1869, Mr. R. Jones had obtained three patents for preserving animal food in a raw state, viz., No. 1859, A.D. 1860; No. 1523, 1864; and No. 2952, 1865. The two latter specifications met with considerable approbation from the Society of Arts about 1862. It belongs to the third class, or method of curing meat by means of gases; and the less said about the introduction of gaseous substances into raw meat the better. The fact that the patentee in his last patent, 1869, returns to the cooking process, leaves the practical conclusion manifest. True

"The Victoria Meat Preserving Company" have adopted an intermediate course. They first slightly cure the meat, which is then packed in the tins; the interstices are then filled up by melted fat, and the tins are hermetically sealed. But this is only an experiment, and, as the *Argus* reports, "Nothing further was to be done with the preserving of meat in fat until the result of the latest shipments of other companies in that line was ascertained." The principal shipments of this company consist of cooked food. In short, at the present time, there are numerous experiments on trial with the view of determining their respective merits. They are all based upon what is generally designated "M. Appert's" (a Frenchman) process, patented in England by Augustus De Heinzelin, No. 3310, A.D. 1810, and Peter Durand, No. 3372, 1810; and as all three patents were anticipated in this country by prior examples, they were never acknowledged good. The following will give a general idea of the Australian practice.

The first start was evidently based upon the old practice of boiling down the meat for the sake of the fat and bones. The meat was boiled until it separated freely from the bones, no more water being used than was absolutely necessary. The lean, fat, and jelly were then put into the tins in proper proportions, a lid soldered on with a small hole. The tin was then placed in a hot-water bath to drive out the air. This done, the tin was hermetically sealed by closing the small hole with a drop of solder. (2.) Instead of boiling the meat (parboiling, as in some cases), it was stewed before it was put into the tins. Under this plan, when too little water was used without a hot-water bath, the meat was liable to scorch or singe, and we have had some tins taste accordingly. (3.) The next plan was to put the raw meat into tins, and to stew in the tins placed in a water-bath, and then hermetically seal when the surplus water and gases were driven off in the form of steam. (4.) The next may be termed the roast meat processes, *i.e.*, the meat is cooked in its own juice and fat, either before it is put into tins or after. According to the latter plan, the fresh meat has to be unboned; according to the former, it may be done in a cauldron until the meat separates from the bone, adding a little hot water at times, to supply what is carried off by evaporation, so as to prevent scorching; but with a close lid to the cauldron very little water is required with fat meat. As soon as the meat separates from the bone, the lean, fat, and jelly are proportioned into the tins, which are then placed in a water bath, to drive off the air, which done they are hermetically sealed. (5.) When the raw, unboned meat is cooked in its own juice in tins in a bath of pure water, it is done without a pierced lid, in order to prevent evaporation, and when the meat is done to a certain degree the tops of the tins are pierced, to let off air and gases; they are then hermetically sealed, and again heated, to do the meat thoroughly. If the water bath consists of a solution of muriate of lime, or other liquid whose boiling point is different from that of water, the tins are sometimes placed in such a bath with holes in the lid. Mr. R. Jones, whose patent claim we have quoted, proposes not only to place the tins with the meat in a solution of muriate of lime, but also to exhaust the air in the tins, so as further to alter the boiling point. Under each of these practices there is considerable diversity, according as they are carried out.

3. "The Australian Meat Preserving Companies represented in London are :—

a. "The Melbourne Meat Preserving Company, Limited," Victoria; importers, Messrs. Robert Brooks & Co.; sole agents, John McCall & Co., 137, Houndsditch, London. (We have referred to this company already.)

b. "Australian Meat Preserving Company, Limited," Charles Gunn, manager, 52 and 53, Crutched Friars, London, E.C., manufactory, Melbourne, New South Wales. The committee of the Society of Arts, 1867, speak very highly of the preserved meat of this company. This company have also introduced Ramomie extract of meat, prepared according to Baron Liebig's specifications, which is very highly reported on by Dr. Parkes, Professor of Hygiene in the Army Medical School, and others.

c. "The Victoria Meat Preserving Company;" J. A. Huxtable, agent, 24, Laurence Pountney Lane, London, E.C. We have already referred to this company.

d. "Sydney Meat Preserving Company;" London agents, the Messrs. Crosse & Blackwall, Soho Square. "The site of the works," quoting the *Argus*, "is 8 miles from Sydney, on the Parramatta River, and the company have a permit of a 1000 sheep being tinned in a day." They exhibit beef and mutton in the International, and the first shipment has given very general satisfaction. We have had a trial of two tins, and both were excellent.

e and *f.* "Ballarat and Warnambool Meat Preserving Companies" are represented by Kaltenbach & Schmitz, 1, Alderman Walk, London; and 12, Albert Buildings, Liverpool.

g. "Whitehead & Co., Broadwater, Clarence River, New South Wales," London office, 8 and 9, Lime Street Square, and Bod Street, Lambeth, exhibit in the International solid essence of beef, *extractum carnis*, in skins and in squares, or cakes in boxes. It obtained a prize medal at the International Exhibition in Victoria, 1866, and another at the Universal Exhibition, Paris, 1867, and since then it has met with an increasing sale.

h. "Central Queensland Meat Preserving Company;" factory, Rockhampton, on the Fitzroy River, Queensland; London office, 30, Palmerston Buildings, Old Broad Street, E.C.; secretary, C. H. Allan, Esq. We have only one prospectus of this company, in which we are told that "Queensland, with a population of about 100,000, possessed in March, 1868, 1,000,000 cattle and 9,000,000 sheep, with unlimited powers of increase." The district is doubtless one of the best grazings in Australia, being well watered all the year round; and as they are starting with a well-organised directorship and management, under Jones' patent, with all the improvements which experience may suggest, every success may reasonably be expected.

4. "The best proof of the pudding is in the eating," it is said, and the old maxim applies to the dietetic value of Australian beef and mutton. The increase in the consumption is a conclusive argument. Much has been said about its being "over done," "boiled to rags," and so on. But groundless prejudice can never stand out against the *£ s. d.* argument. So long as the Australian companies can send our hard-working meat-eating people cooked beef and mutton ready for use at 7*d.* per lb.—more than equal to 1½ lb. of butcher's meat with the bone and uncooked, at the present high prices of English meat—the consumption of Australian meat will go on increasing. As to prejudice against its cooking, What is overdone? If people would only look seriously at their own joints—fully 25 per cent. bone, from 20 to 30 per cent. sent up in the chimney in cooking, the outside burnt black, red at the bone, and neither one thing nor the other half way—they will find the Australian factory system of cooking in advance and not behind. That Englishmen get accustomed to their own modes of cooking is true enough, and that it has become a second nature is generally granted, and that is about the most that can be said in favour of English cooking and taste. But if meat cooking factories shall prove—as they doubtless will—what cheese factories have done, the sequel need not be told.

5. The *Argus*, and all the Australian newspapers we have seen, report that, great as the productive resources of the colonies are, better prices are being realised for fat stock; and as the companies improve in the manufacture, and as the consumption in the mother country increases, there is every reason to aver that the price of preserved meat will rise nearer to the English level. We do not therefore apprehend that the increase in the importations of Australian preserved meat will have much effect upon the price of English fat stock. On the contrary, the prosperity of this branch of trade will find a profitable source of employment and investment of capital for our surplus agricultural population, and thus relieve the over competition for farms at home. *W. E.*

ESTIMATION OF PHOSPHORIC ACID IN SUPERPHOSPHATES.

The fact to which Mr. Purser has called attention in a recent number of the "Chemical News" (vol. xxiii., p. 178), is one only too well known to those concerned in the manure trade. There are, unfortunately, considerable discrepancies in the reports of analysts of superphosphates; a little ventilation of the subject cannot but prove wholesome.

In the first place, are analysts agreed as to what they understand by soluble phosphates; do they understand phosphates soluble in hot or cold water?

Exhaustion of the superphosphate with hot water may give, according to circumstances, more or less soluble phosphate than exhaustion with cold water. If the superphosphate contains soluble compounds of alumina, it will yield less soluble phosphate when boiled with water than if the exhaustion is conducted in the cold, and the difference between these two modes of operating may be very considerable. A simple experiment will satisfy any one on this point. If a cold solution of superphosphate be treated with alum, or other soluble compound of aluminium, the solution appears unchanged. On applying heat turbidity commences, and when the boiling-point is nearly reached a copious precipitation of phosphate of aluminium takes place; on cooling, the precipitate, if not too considerable, entirely re-dissolves. This reaction is certainly remarkable, and the cause not very apparent: one is tempted to think that the aluminium is, in the case assumed, combined in the cold with sulphuric acid, and in the hot with phosphoric, and that a change of temperature effects a change in the degree of affinity of aluminium for these two acids. The practical result is, however, very plain: superphosphates containing aluminium in a soluble form will yield less soluble phosphate to hot water than to cold.

Most superphosphates yield less to hot than to cold which contain traces of alumina; when, however, the superphosphate has been made from Navassa phosphate, or other of the native phosphates rich in alumina, the amount of aluminium salt soluble in the cold may be very considerable; the quantity depends, however, in great measure, on the manner in which the superphosphate has been manufactured. The presence of aluminium in the solution is, of course, at once indicated by the formation of a precipitate on boiling.

Before leaving this part of the subject, I may just mention, that the reaction of ferric salts with solution of superphosphate is wholly different from that described above. Soluble ferric salts produce an immediate precipitate in the cold, and are, consequently, never found, save as traces, in a soluble superphosphate.

From the above considerations, it seems evident that the removal of the soluble phosphate should always be effected with cold water. The maximum amount of phosphoric acid appears to be dissolved when, after thorough exhaustion with cold water, the residue is lastly boiled. In this case, the hot water probably effects a partial decomposition of the reduced phosphates. The increased amount of phosphate rendered soluble by the hot water is by no means considerable, and can hardly be fairly reckoned as soluble phosphate, which, by its character of a manure to field crops, must surely be understood as a phosphate soluble in rain water.

The best mode of extracting the soluble phosphate is, I believe, the following :*—10 grammes of the carefully mixed sample are placed in a mortar. A flask, marked to deliver 1 litre of water, is filled, and fitted as a wash-bottle. The superphosphate is moistened with some of the water, and rubbed smooth

* This method is, I believe, of German origin; I became acquainted with it at Mr. Lawes' laboratory at Harpenden.

with the pestle; more water is added, the whole well stirred, and the solution and fine particles decanted into a bottle. The residual superphosphate is brought to a finer state of division by means of the pestle, and is again treated with water as before. This rubbing and washing are repeated until the whole of the manure has been transferred to the bottle in a fine state of division. The rest of the water is next added, and the bottle shaken at intervals during three hours. 100 c.c. of the solution correspond to 1 grm. of the superphosphate.

The estimation of the phosphoric acid in the watery solution may, of course, be effected by any of the trustworthy methods with which chemists are acquainted. The most usual plan is to precipitate the phosphoric acid as tricalcic phosphate by means of ammonia, with or without the addition of chloride of calcium, according to the proportion of lime present in the solution. The other methods which seem specially applicable, are precipitation by magnesia, and by uranium.

The usual plan of estimation as tricalcic phosphate, is of quite sufficient accuracy for commercial purposes when properly conducted, but lies open to several distinct sources of error. Thus the "high analyst," by precipitating with a considerable excess of ammonia from a solution containing excess of lime, obtains a phosphate containing notably more calcium than tricalcic phosphate, and his result is, consequently, above the truth. This error is met by some by re-dissolving the phosphate containing excess of lime, and re-precipitating it; the error may, however, be avoided in the first instance, by limiting the amount of ammonia employed. If ammonia is only used in just sufficient quantity to distinctly turn turmeric red, tricalcic phosphate may be successfully precipitated from cold dilute solutions containing much lime in excess. An error of a different kind arises from the difficulty of washing all the sulphates out of the gelatinous phosphate, and from the fact that the washing must not be pressed too far, as loss of phosphate occurs in the later stages of washing. Since success in this mode of analysis depends so much upon the conditions under which it is used, it is much to be regretted that commercial analysts who always estimate soluble phosphate by precipitation with ammonia, would test their results a few times by duplicate analyses executed by the magnesia method, and thus ascertain whether the conditions they habitually employ are consistent with accuracy.

The following results, obtained with two superphosphates, show the amount of agreement that may be expected from the different methods described:—

	Estimation as tricalcic phosphate.	Estimation as phosphate of magnesium.	Estimation as phosphate of uranium.
(1). ..	24.65 24.55 ..	24.19	24.90
(2). ..	17.3	16.82	16.50

The determinations of insoluble phosphate in superphosphate are, I fear, more generally inaccurate than those of soluble phosphate; they are usually greatly in excess of the truth. The manufacturer can tell very nearly the total amount of phosphate present in his manure. Thus, if he makes superphosphate with equal weights of Cambridge coprolite and sulphuric acid, he knows that, allowing for the loss of weight in mixing, the product will contain almost exactly 32 per cent. of phosphate reckoned as tricalcic; and any mistakes he may have had to make as to the materials will only diminish the percentage of phosphate. What, then, is his surprise, on receiving the report of the scientific chemist, to find that the soluble and insoluble phosphate added together, give a total of over 40 per cent.: a result not very uncommon. If commercial analysts would remember that only high-priced superphosphates, made entirely from Sombrerite or bone-ash, can possibly contain 40 per cent. of phosphate, they would save themselves from many mistakes.

The origin of this error is that less care is taken in determining insoluble phosphate than in the estimation of soluble: that the portion of the superphosphate undissolved by water is dissolved in acid, and the solution precipitated with a large excess of ammonia, without any attention to the nature of the substances precipitated.

It is best to determine the total phosphate present in the superphosphate by one operation, and then, by deducting the soluble phosphate, to find the insoluble. If the superphosphate has not been made from ferruginous or aluminous materials, the solution of the superphosphate in hydrochloric acid, and the precipitation of the phosphates by the limited amount of ammonia already referred to, will give sufficiently accurate results. In all other cases, the hydrochloric solution of the superphosphate should be neutralised as far as possible without causing a precipitate, and then treated with excess of oxalate of ammonium, and subsequently with citric acid and magnesia mixture, as already described.

In conclusion, it must not be forgotten that the faulty processes in use by commercial analysts are to no small extent due to the pressure put on them by the public. When the fee given is reduced to the lowest possible point, the analyst is forced to regard the number of his analyses as of more importance than their quality, and to adopt methods, the main object of which is to enable him to snatch a result in the shortest possible time. *R. Warington, F.C.S., in the "Chemical News."*

Home Correspondence.

Carts versus Waggons.—It would be very unreasonable, and contrary to all evidence, to suppose that the public mind can be speedily removed from a rut in which it has travelled for ages. One of those ruts may be called "the waggon rut;" and yet if we test the question by the reliable expedient of comparative trial and self-interest, the agricultural mind ought to come out of that rut immediately; but I write this for the next or rising generation. This question was long ago settled in favour of the carts, as recorded in early numbers of the Royal Agricultural Society's Journal (vol. ii., p. 73; vol. vi., p. 156; vol. vii., p. 73). Every one interested should read Mr. Hannam's admirable paper, illustrated by diagrams, in vol ii., p. 73. I wonder how much is the annual loss inflicted on British agriculture by the use of waggons, for although the question was settled by comparative trial, very few farmers either knew about it or believed in it, for still waggons continue to be the order of the day, although a farmer seldom drives to market on four wheels. As there are 23,000,000 of acres of arable land in the United Kingdom, in addition to 23,000,000 of permanent pasture, there are probably many more than 500,000 waggons, costing (as an average proportion of road and harvest waggons) £30 each, or £15,000,000, whereas the best made harvest carts would cost less than half that amount, and thus effect a saving of capital of probably £7,500,000. Mr. Bowly, of Cirencester, in his prize essay, Royal Agricultural Society's Journal, vol. v., p. 156, found his waggon to be worn out of every £100. But it is not alone in loss and interest of capital, but also in wear and tear of horse-flesh, and loss of time in horse and manual labour. Let me give an instance of this, first observing that although some 25 years ago my men were all in favour of waggons, they would now look upon them as heavy encumbrances, prolonging their labour, and thus causing deductions from their harvest earnings. We use long, wide, and low carts, about 12 feet long, 7 feet wide, and 3 feet 6 inches high; weight about 12 cwt. Mr. Hannam's dimensions will be found given in vol. ii., p. 73, of the Royal Agricultural Society's Journal. The cost varies from £13 to £15—they were formerly cheaper. We use one horse at harvest, and a boy to drive; they carry about 150 large Wheat sheaves. They carry to market 10 to 12 qr. of Wheat with one horse. A small quantity will fall out. The carts do not press upon the horse either up or down hill; they are convenient for coal, but cannot be tilted. Two good men will pitch and load from 60 to 80 qr. of Wheat in a long harvest day, and one man will unpitch them. Three carts and three horses will convey this quantity, with one boy to drive; but an extra cart and one more boy are required when the distance is greater. There is no binding the load. No such satisfactory practice could be done with waggons, and the cost would be in every way much greater. *J. J. Mechi, August, 1871.*

Legislation on Utilisation of Sewage.—Will you allow me space for a few remarks on the account given in your number for August 19 of the discussion which took place at the Social Science Congress on legislation on the utilisation of sewage." It is not that I in any way doubt, so far as it has gone, the full success of Mr. Hope's experiment. From all the accounts which I have read of it, the irrigation of his sewage the example of Romford reflects the greatest credit on that gentleman's spirit, skill, and intelligence. His effort is beyond question the most successful which has been made to overcome the enormous difficulty—created by the water drainage system—of disposing with advantage to the town itself and with safety both to the land and the water-courses, of the refuse of a town, after it has been augmented in volume sixfold by water and the whole mass has been brought together into one body. Still neither the two years of the Romford experiment, nor the five years of that at Barking, will afford a safe ground for legislation, which should render such a system of sewage disposal compulsory on every town population of this country. For in the first place by whom has "this carrying away of the refuse of towns into rivers, and the pollution of those rivers, and the spreading disease amongst their neighbours, while only beneficially employed in doing the countless service at all,"—by whom has all this been done but by the originators and abettors of the water sewerage system?—who also have been to a great extent the originators or supporters also of those 45 sanitary Acts, on which during the discussion such severe remarks were made. In twenty years sanitary inspectors and civil engineers either did not foresee or did not care about the pollution of rivers. They promised us "immense advantage in the introduction of waterclosets." There was to be no fever (nor small pox I suppose) in a town properly drained. What, however, does Mr. Bailey Denton say of Hitchin, sewered 20 years ago by Mr. Rawlinson? At the close of that period the death rate had been reduced to 23! The river had long been so polluted that, for some distance below the town, it was not safe for the cattle to drink of it; and the sewage, bayed back by the floods, had conveyed offensive and deleterious matter into the cellars of houses. And, now, can those gentlemen give us any guarantee against similar evils in the course of 20, 10, or even seven years, arising from the pollution of our fields by sewage irrigation? I am confident that they can give no such guarantee; nay, I can perceive strong misgivings on this point in their own minds. For instance, Mr. Bailey Denton, in proposing to relieve the evils arising from the sewage of Hitchin, by pouring that sewage over 60 acres of land, sees only one objection to a certain piece of ground, which is this—that it is within 1 mile of the town. And a remark, made at the discussion by so high an authority as Mr. Chadwick, in which he stated an advantage in Mr. Hope's system over the Edinburgh meadows ought carefully to be noticed. "Those meadows cost £30 an acre, while Mr. Hope's system, which was of course the most efficient—and not by any means so dangerous—cost from £8 to £12 an acre." Will the town population of England, then, submit to have a nuisance, and that probably of a dangerous character, established in their immediate neighbourhood? Will they not inquire first whether there be not some more effective and some safer remedy for this "great national evil" of the pollution of rivers, and some more effective mode of preventing the waste of that manure, the value of which is estimated by millions? I abstain from any remark on the just observation of Mr. Watlington, that the profit to be made by sewage irrigation must depend greatly on the position of the town. But, in illustration of it, I would adduce the case of this town of Dorchester, in which I write. We have below us several hundred acres, into which the sewage of 7000 persons, if we shall ever be compelled to withhold it from the little stream, which barely passes through the water-mead, according to recent calculations, to receive it all. But these acres are full of springs; they are underlaid, in fact, by a bed of water. Few of them could be used as arable land. The absorption by the soil, then, of the extremely offensive other corrupting matter would be very small, and the exhalations, especially in hot and sultry seasons, would soon of necessity be offensive and deleterious. Further, the owners and occupiers of the land could not be expected to give anything like its value for that which the Board of Health may find itself compelled to dispose of. On the other hand, there are within my parish some 2000 acres of arable land, either on a level with the town or considerably more elevated, which, if it could be conveyed to them, would entirely absorb, with vast profit both to the farmer and to the inhabitants, all the refuse of this town, especially if unlimited water, even five-sixths of water. This, on the dry earth system, might be done without offence or injury to any one." Not the slightest nuisance need be created—not an approach to anything dangerous. The occupiers of the land would require no compulsion to adopt the use of so valuable a manure. Extend this idea from one this one town to the whole country. Consider the high downs, the dry and light heaths, the lofty hills which crave this manure of the 15,000,000 of our town population, and say, while this is the case, and the farmers of those districts would gladly purchase such manure if at a fair price it could be conveyed there, is it philosophical, is it scientific, is it just to the country, under the misnomer in such cases of "the utilisation of sewage," to withhold it from such localities, and pour it over a limited space, that frequently has little need of it? I have observed with some attention the proceedings of associations and commissions; and as opportunity has presented itself I have followed out my own investigations on this subject; and I am now prepared, on the proper occasion, and under fair consideration, to convince any unprejudiced body of men that by the adoption of the dry earth system, and by the adoption of the principles laid down in "The Science of Manure as the Food of Plants,"† and of that mode of action set forth in "The Advantages of the Dry Earth System," ‡ all the refuse of this town of every kind be given up to the board of management of the system, can from this refuse, rightly but easily used, manufacture a manure the market value of which shall be worth £1 a-head of the whole population. Allow me to add one or two words on the important communication in the issue of August 26 on the use of "Dry Earth in Figstyes." The plan adopted by "J. M." is almost exactly the same with that which, in my pamphlet, entitled "The Science of Manure as the Food of Plants," I two years ago proposed for horses, cows, pigs, and fowls, and which is now about to be carried out, as to pigs and fowls, in 10 cottages, with the sixth of an acre attached to each, just erected by the Industrial Improvement Society, of which the Rev. J. Venn is, I believe, the president, in the city of Hereford. In my paper on "The Advantages of the Dry Earth System," ‡ read at the Social Science Congress at Newcastle, will be found the following passage:—

"If horses and cows kept in the metropolis should be bedded on dry sifted clay, with a thin covering of chaff, five-sixths of the urine now used for litter, and an equal proportion of carriage, would be saved; the escape of ammonia being prevented, the animals would be kept in better health; the urine would be withheld from the sewers; and, being absorbed in the clay, would yield a vast amount of manure for fertilising the neighbouring heaths."

* See Appendix to Twelfth Report of Public Health.
† Published by W. Macintosh; and by Cassell, Petter & Galpin, London.
‡ Mackintosh, publisher.

To this I would now add a remark, which is somewhat enlarged in "Science of Manure," that there is the opportunity here as in the earth closet, through the capability which the earth or clay possesses of repeated action, of condensing the manure so manufactured, and so of increasing its power by repeated use of the earth for the same purpose. Should this plan be adopted in the stables, cow-stalls, and pigstyes of farmers, five-sixths of the straw, now almost wasted as litter, would afford food to cattle, and admit of the keeping a much larger amount of stock; and if to the manure, which might thus be manufactured on every farm, some addition should be made through my proposed mode of utilisation of the refuse of towns, a ton of manure, equal in value to 19 or 20 tons of that which even in these years is commonly scattered over the land might, with vast increase of produce, be drilled in with every crop. *Henry Moule, Fordington Vicarage, August 21.*

Thinner Sowing.—I continue my comparative trials of thick and thin sowing, and send you this year's results. The field was drilled on November 10, 1870, with my usual quantity, 4 pecks per acre of Clubheaded Rough Chaff White Wheat. Four lands in stetches towards the centre of the field were drilled with only 2 pecks per acre on the same day as the other portions of the field. It was on a Clover lea, first mowed for hay, and the second growth folded with sheep, eating cake, &c., as is my usual custom. In the early growth of the crop the thinner-sown was distinctly visible, but as the spring advanced the two pieces became equally thick, and no difference was perceptible, either during ripening, cutting, or in the stubble after cutting. This was the opinion of all those numerous farmers who inspected it during its growth. Two exact portions were measured off, cut and threshed, weighed and measured. There was an equal number of sheaves from each portion, and an equal weight of grain. The straw and grain were both brighter from the thinner sown, and this I have always found to be the case, with a single exception. The thin-sown sample would command 1 or 2s. more per qr. than the thicker sown. Weight per bush: thick-sown, 60 lb.; thin-sown, 61 lb. Wheat this season does not weigh so well as in drier seasons. The name of the field is Ash Field; the comparative lands were opposite the stable door, which will be remembered by those who saw it. The whole field was measured from 6 to 12 per acre —the trial square (16 roods) gives a return of 54 bush. per acre. When the whole field is threshed and dressed the quantity shall be accurately given. I sold some white Wheat yesterday at 57s. per qr. This is independent of rather a poor quality, and would probably command 58s. or 59s. The result of my long-continued experiments proves unmistakeably that where the farming is good on well-drained and deeply cultivated soil our usual quantity of seed is a very great and wasteful mistake. I lay down no particular rule, but recommend each farmer to satisfy his mind by comparative trials which quantity of seed is most profitable to him under his peculiar circumstances of soil, climate, and style of farming. By comparative trials I found that by putting in 1 bush. as against 2 an increase per acre return is Wheat 3cr. per acre. The average of Great Britain is stated to be 3 bush. of seed Wheat per acre; this must be far too thick sowing: as a general rule, the higher you farm the less seed is required. Much Wheat this year was raised from the ground by winter's frosts, and some was injured by spring frosts. Although heavy land, I Crosskilled this field well. This not only re-bedded the roots of the Wheat, but also arrested wireworm. Salt on the lighter land after Crosskilling saved the plant, and gave me an abundant crop. I think it is wrong to go on sowing the same quantity of seed as our forefathers did when broadcasting, without taking into account the altered circumstances, such as the drill, drainage, and higher farming. Every farmer should make comparative trials. Two visitors from Liverpool assured me yesterday that as much as 4 and 5 bush. of Wheat sown per acre in that neighbourhood, the return being only about 4 qr. per acre. The average of the kingdom is stated to be a return of 10 kernels for one; mine is an average of 40 for one. I sow 6 pecks of Barley and 8 pecks of Oats per acre. In many foreign countries, where the weeds are allowed to grow with the corn, the return is only five or six for one. My Wheats are always once or twice horse-hoed, and hand-hoed in the rows. If the land is loose we Crosskill once or twice before hoeing. Much corn gets diminished in crop and injured in quality by too thick sowing, which causes an early falling of the crop. *J. J. Mechi, Tiptree, September* 1.

Societies.

GLOUCESTERSHIRE.

THIS meeting was held at Pittville, Cheltenham, on Tuesday, Wednesday, and Thursday. The weather was fine, and large numbers of visitors, including many ladies, visited the ground. The number of entries in live stock were much below last year's show at Stroud. Then there were 206 entries of cattle, sheep, and pigs, and 104 horses and ponies, while on the present occasion there were in these sections respectively 123 entries of cattle, sheep, and pigs, and 112 horses. There was a more imposing show of implements than appeared last year. In the Shorthorn classes Mr. R. Cliffe, Over, of Sholetbrook, took the 1st place with LORD OF THE FOREST (26,704), a large, nice-looking bull, not too wide over the crops, but with good thighs and flanks. Mr. F. Leybourne was placed 2d with a light-fleshed, leggy bull, of fair quality, but with very coarse shoulders. The executors of the late Mr. Stratton showed some good cattle from the Burderop herd, characterised by squareness, levelness, and other good points, but in too many cases hard to the touch. Bulls from this herd took prizes in the yearling class and bull calf class, also in the yearling heifer and heifer calf classes. The prize for the best bull, any age, offspring, also went to Burderop; but we must say we greatly preferred the family group exhibited by Lord Fitzhardinge, consisting of LORD WILD EYES 5TH, *Rose of Gloucester*, and calf, all of which handled like velvet, and were in fact the only animals in the yard which entirely pleased us in this important point. In the class of breeding cows Mr. W. Bradburn was 1st with *Miss Chesterfield*, a level enough cow, and Miss Strickland's *Vote 10th*, a cow with a good deal of character, but hard, was placed 2d. The commended cow, also belonging to Miss Strickland, was patchy. In the class for 3-year-old heifers, Mr. W. Bradburn showed a wide, nice heifer, which was placed 2d, and the late Mr. Stratton's *Flower Girl*, a heavy good-looking square cow, which fulfils her early promise in these respects, was placed 1st. The show of Herefords was poor, and a prize was awarded to the animal exhibited. Messrs. John Walker, William Taylor, E. J. Morris, Thos. Cadle, and Thomas Hewer were the successful exhibitors. There was a fair show of long and short wooled sheep. In the former classes prizes were taken by the executors of the late Mr. Thomas Gillett, Kilkenny Farm, and Mr. Henry Cox, of Ashbrook. In the shortwoolled classes Mr. H. S. Waller, Farmington, Colonel Kingscote, Sir William Throckmorton, Mr. F. Gillett, and Mr. W. Playne, of Minchinhampton, divided the prizes; and in the classes for Oxfords, Mr. Hobbs and Mr. George Waller were successful. There was a good show of Berkshire pigs, and the prizes were divided among Mr. H. Humphry, Mr. R. Swanwick, of the College Farm, Cirencester, Lord Fitzhardinge, Messrs. Wheeler & Son, and Mr. Elwes, of Colesbourne. The horse show was fully equal in numbers to that of last year, and some good animals were shown.

A very agreeable feature of the show consisted in a loan collection of pictures, porcelain, and other works of art. A flower show also added fresh attraction to the scene.

The following is a list of the awards :—

CATTLE.

SHORTHORNS.

The best Bull above two years old.—Mr. R. E. Oliver, Tarenter; 2d, Mr. J. Popham, Bristol.

The best Bull above one year and under two years old.—1st and 2d, Mr. R. Stratton, Swindon.

The best Bull Calf, bred by exhibitor, and under 12 months old.—Mr. R. Stratton; 2d, Mr. C. Hobbs, Maisey Hampton.

The best Bull, Cow, and their offspring.—Mr. R. Stratton.

The best Cow, in calf or in milk, having had a calf at its full time, within 12 months of the day of exhibition.—Mr. W. Bradburn, Wolverhampton; 2d, Miss F. Strickland, Tewkesbury.

The best Heifer in calf or in milk, under three years old, bred by exhibitor.—Mr. R. Stratton; 2d, Mr. W. Bradburn, Wolverhampton.

The best Breeding Heifer, under two years old, bred by exhibitor.—1st and 2d, Mr. R. Stratton.

The best Heifer Calf, bred by exhibitor, and under 12 months old.—Mr. R. Stratton; 2d, Mr. T. Morris, Gloucester.

HEREFORDS.

For the best Bull, above two years old.—Mr. J. Walker, Hereford.

The best Bull Calf, bred by exhibitor, and under 12 months old.—1st and 2d, Mr. W. Taylor, Ledbury.

The best Bull, Cow, and their offspring.—Mr. E. J. Morris, Winchcomb.

The best Cow, in calf or in milk, having had a calf at its full time within 12 months of the day of exhibition.—Mr. E. J. Morris, Winchcomb.

The best Breeding Heifer under two years old, bred by exhibitor.—Mr. E. J. Morris.

The best Heifer Calf, bred by exhibitor, and under 12 months old.—Mr. T. Cadle, Westbury-on-Severn.

SHEEP.

LONGWOOLS.

The best 5 Breeding Theaves, not more than 23 months old.—Mr. S. W. J. Harris, Northleach, Farringdon.

The best Ram of any age.—1st and 2d, Executors of T. Gillett, Faringdon.

The best Shearling Ram.—1st and 2d, Executors of T. Gillett.

The best 5 Ewe Lambs of the Cotswold breed.—Mr. H. Cole, Cirencester.

The best 5 Ram Lambs of the Cotswold breed.—Mr. Cole.

SHORTWOOLS.

The best 5 Breeding Theaves, not more than 23 months old.—1st and 2d, Colonel Kingscote, M.P., Wotton-under-Edge.

The best Ram of any age.—Colonel Kingscote, M.P.; 2d, Mr. H. S. Waller, Farmington.

The best Shearling Ram.—Colonel Kingscote, M.P.; 2d, Mr. W. Playne, Minchinhampton.

The best 5 Ewe Lambs.—Mr. F. Gillett, Burford.

The best 5 Ram Lambs.—Sir W. Throckmorton, Bart., Farringdon.

OXFORDSHIRE AND SHROPSHIRE.

The best Ram of any age.—Mr. G. Wallis, Farringdon.

The best Shearling Ram.—Mr. G. Wallis.

PIGS.

The best Boar Pig under a year old.—Mr. R. Swanwick, Cirencester; 2d, Lord Fitzhardinge, Berkeley Castle.

The best Boar Pig more than a year old.—Mr. H. Humphrey, Shrivenham; 2d, Messrs. J. Wheeler & Son, Long Compton.

The best 3 Sow Pigs of the same litter, under 9 months old.—Mr. R. Swanwick, Cirencester; 2d, Mr. J. H. Elwes, Colesbourne.

The best Sow Pig for breeding purposes.—Mr. A. Stewart, Gloucester; 2d, Messrs. J. Wheeler & Sons.

The best Sow and Pigs (not less than six) her own produce, the Pigs under 12 weeks old.—Lord Fitzhardinge, Berkeley Castle; Mr. R. Swanwick.

HORSES.

The best Stallion for agricultural purposes, above two years old.—W. Wynn, Grafton; 2d, Mr. J. Manning, Orlingbury.

The best Mare and Foal, her own offspring, for agricultural purposes.—Lord Sudeley, Toddington; 2d, Duke of Beaufort, Badmington.

The best Gelding or Filly for agricultural purposes, under three years old.—Mr. S. Davis, Woolashill; 2d, Mr. J. Swill, Longford.

The best Stallion calculated to get Hunters or Hacks.—Mr. H. Brown, Swindon.

The best Hunting Mare or Gelding of any age.—Mr. J. B. Jones, Cheltenham; 2d, Mr. W. R. Holman, Cheltenham.

The best Hunting Mare or Gelding under 5 years old.—Mr. C. Cook, Toddington; 2d, Mr. C. Harland, Cheltenham.

The best Mare calculated to breed Hunters, with her foal at foot, got by a thoroughbred horse.—Mr. W. Slatter, jun., Cirencester.

The best Hack not exceeding 15 hands.—Mr. R. N. Hooper, Cowbridge; 2d, Major G. A. E. Quentin, Cheltenham.

The best Pony above 12 and under 14 hands.—1st and 2d, Major G. A. E. Quentin.

The best Pony not exceeding 12 hands.—Mr. E. Philimore, Cheltenham; 2d, Mr. G. Houghton, Tewkesbury.

WORCESTERSHIRE.

THIS society's annual meeting was held last week at Malvern, in close proximity to the railway station and the Imperial Hotel. Considerable dissatisfaction was expressed, exhibitors having to unload their animals from the trucks two miles from the yard, instead of on the spot; but, with this exception, the arrangements were good.

Cattle.—There were some well-known show animals brought together in the Shorthorn classes, among which appeared the Marquis of Exeter's TELEMACHUS, Mr. Outhwaite's ROYAL WINDSOR, and Mr. G. Garne's ROYAL BUTTERFLY 20TH, who was regarded with much favour on account of her quality and good masculine head. These three bulls competed for Lord Sudeley's Toddington Challenge Cup and the Earl of Beauchamp's piece of plate, both of which, together with the 1st prize of his class, were awarded to TELEMACHUS.

In the same class MARMHULL DUKE was placed 1st, and Mr. Stratton's MASTER GLANVILLE 2d. We abridge the following notes from a contemporary :—

Mr. Outhwaite's *Vivandière* beat Mr. How's *Windsor Butterfly*. The latter gentleman's *Vesper Queen* easily disposed of the other competitors in the heifer class, in which Mr. Bradburne stood 2d, with a purchase at Mr. C. Stubb's sale. The beautiful coat of the Rev. Walter Sneyd's *Maid of the Mist* secured her the victory in a capital class of yearling heifers, in which Mr. How was 2d.

There were about as many Herefords as there were prizes offered for the breed; but some of the best men were represented—notably Mr. P. Turner, who won 2d with his aged bull, and two 1sts with heifers, the 2-year-old being in high enough condition for a Christmas show, and also the President's prize for the best Hereford. Mr. Tanner secured the 1st prize for bulls, with MONAUGHTY 3D. Mr. R. Tanner won both prizes for cows, and 2d for yearling heifers, with his three entries. The other honours fell to Messrs. Twinberrow, Rogers, and Morris. The prizes for dairy cattle were all given to highly descended Shorthorns and their crosses.

Sheep.—The Shropshires were allowed precedence in the classes. In ewes, Mr. Firmstone's pen had been got into much better condition since Wolverhampton, and were placed before Mr. Baker's and Mrs. Beach's pens, which there occupied first and second positions. In the class for shearling ewes, Mr. Pulley's were placed 1st, and Mr. Baker's and Mr. Firmstone's highly commended pens at the Royal Agricultural Show 2d and 3d. Mrs. Beach won with a shearling ram, to which the extra prize as the best male animal in the sheep classes was also awarded. Mr. Pulley was 2d and 3d. In the aged ram class, Mr. Feno's Bath and West of England winner was 1st, and Mr. Tanner's 2d; although we prefer the sheep bred by the late Earl of Aylesford, and exhibited by Mr. W. Baker, which obtained a high position at Wolverhampton, to either prize winner. The longwoolled sheep were confined to a few pens of good Leicesters, from Mr. Harris, of Stoney Lane; some Lincoln Leicesters, from Mr. T. W. D. Harris, of Wootton; and a couple of Cotswolds from Messrs. Wheeler & Son, of Long Compton; amongst which the prizes were divided.

Horses.—A spacious ring was made to show the horses, with the usual arrangements for seats and fences. The Earl of Coventry's "Umpire" was considered the best thoroughbred stallion, with "The Mallard," bred by the late Lord Glasgow, 2d. Mr. Tomlinson's "Young Lofty," winner in the agricultural stallion class at Birmingham, added another to his numerous victories. Mr. Percival took the principal prize for hunters with his chestnut gelding "Melton," Mr. Cook's 4-year-old "Misfortune" being 2d.

Pigs.—Messrs. Duckering and Wheeler were almost the only competitors in the classes for white pigs; the former gentleman taking most of the honours. There was a good show of Berkshires, Messrs. Joseph Smith, Swanwick, Humfrey, and other well-known breeders putting in an appearance. Mr. Humfrey won the 1st prize and extra cup, with his only entry, a 4-year-

old boar. Mr. Swanwick was the 1st for sows and gilts, and Mr. Humfrey, 2d for sows.

On Tuesday and Wednesday the weather was very fine; but on Thursday, the day for the people—the "shilling" day—the rain came down freely, accompanied by a hurricane, which blew directly across the field, and unfortunately carried off the canvass covering of several of the sheds. That was not all, for a sudden gust blew down the large tent in which were placed the plants and flowers exhibited at the horticultural show, and a portion of the dinner marquee shared the same fate.

The following is the list of awards in the several classes:—

CATTLE.

SHORTHORNS.

Best Bull in Shorthorn classes, £25.—The Marquis of Exeter. The Toddington Challenge Cup, of the value of 50 gs., given by the Right Hon. Lord Sudeley, was also awarded to this animal.

Best Hack, not exceeding 15 hands.—W. Lee.

Best Pony, above 12 and under 14 hands.—W. Godsall.

Best brood Mare, for producing hunters.—G. B. Jones.

LEINTWARDINE, NORTH HEREFORDSHIRE.

The Condition of the Labourer.—We give this week a more extended account of Mr. STRANGE's address on this subject at the meeting of the Agricultural Labourers' Improvement Society. The following are extracts:—

If you really wish to have your condition bettered, you must act faithfully, honestly, temperately, and dare to be men. Be sure to do your employer no injustice, for he that does his employer an injustice does himself an injustice; while an honest man is a noble man, and belongs to the highest order of nobility. Now, speaking of the cottage question, I believe still that in all cases where practicable the cottage should be held direct of the landlord; for a commission before the House of Commons, when speaking on the question, said there was no doubt whatever that it was better for the cottager, because it placed him in a more independent position; and a thing which makes a man feel more independent I believe makes him more manly. Artemus Ward said we want female women; I maintain we want manly men. It may suit small men or tyrants to be surrounded by a cringing multitude, but servility is not courtesy, and it is not good, socially or morally. Now the thing has been fairly worked out concerning the cottage question by a gentleman, in the *Times* of last year, and has never yet been answered. He shows how cottage property can be made to pay a fair percentage with the rents at a low standard. I believe it is the wish of many to keep from being a burden to the parish, and I would say that he or she who needlessly throws him or herself on the industry of others, lowers himself in the scale of human beings, and acts dishonestly. I fear this is working an evil in the country at the present time. It is far more acted on in England than in Scotland. But perhaps you will say, "Yes; but the Scotch labourers are better paid." Yes; but when I tell you that it is far more acted on here than in Ireland, what think you of this? I have seen myself a man shirking about receiving parish pay because he had no work, he said, when he might have had work, and leaving his garden unplanted.
