From Mr. E. S. Williams, Trichomanes auricularium.

From Messrs. Fisher, Holmes, & Co., Thymus citriodorus aureomarginatus.

From J. E. Mapplebeck, Esq., Pteris aequilina, vars. incurvam, grandiceps, cristata Gloveri; Lastrea Filix-mas var. revolvens; Athyrium Filix-femina, vars. dilatatum, Mapplebeckii, rectangulare, caudiculatum, cerstophyllum, flabellifolium tenue, Gillsoniæ, Craigii glomeratum; Blechnum spicant var. crispatum.

SILVER FLORA MEDAL.

CLASSES 1, 3, 4, 7, 8, 25, 28, 35, 46, 59, 60, 62, 63.

In the above Classes a Silver Flora Medal was awarded to the winners of the First Prize.

BRONZE MEDAL.

CLASSES 3, 13, 15, 19, 20, 21, 23, 27, 29, 31, 39, 40, 61, 65, 66.

In the above Classes a Bronze Medal was awarded to the winner of the First Prize.

The Gardeners' Chronicle

SATURDAY, JULY 1, 1871

MEETINGS FOR THE ENSUING WEEK.

MONDAY,	July 3	Entomological	7 P.M.
		Royal Horticultural (Fruit and Floral Committees), at S. Kensington ..	11 A.M.
WEDNESDAY,	— 5	Ditto (Scientific Committee)	1 P.M.
		Ditto (General Meeting)	3 P.M.

NOTHING seems wanting, at the moment we write, to secure the full success of the ROYAL HORTICULTURAL SOCIETY'S VISIT TO NOTTINGHAM, but a continuance of the glorious weather of the opening day, when a large and fashionable company was drawn together to regale upon a feast of flowers. To say it was a thoroughly good display, would convey but half the truth, for we may fairly add, there has been no more effective show than this since the great International, which we all look back upon with so much pride and pleasure. The capacious tent under which the main part of the exhibition took place, permitted a picturesque plan of arrangement, which only needed to be appreciated and seconded by the exhibitors themselves, to have been a paradise of flowers. Here, however, was the greatest defect of the exhibition, from an æsthetic point of view, and we feel the exhibitors need only to have it pointed out to remedy the evil for the future. What we refer to, and specially deprecate, is the sloping of the plants, a plan which has come into vogue through the plants having in most cases to be staged in narrow lines with a background, but which is utterly and entirely inappropriate when, as in the present case, the plants come into view in all directions. In some instances the effect of the mode of staging was painful in the extreme, whereas a more natural grouping had been adopted, the picturesque effect which MR. GIBSON aimed at in his design would have been secured, and the plants, instead of looking well from one point of view only—which seems to be the main object of sloping them—would have looked well from every point. This was especially evident in the case of some Ferns with fine spreading fronds, and which, had single plants been brought forward and elevated on pedestals near the prominent points of the ground, would have added wonderfully to the effect.

Of the plants themselves, we cannot speak too highly. Foliage plants, Palms, flowering specimens were alike good, and by no means too elephantine in their proportions, though many of them were of great size. Ferns of all kinds were extremely well represented, both as to the selection and the cultivation. Fruit was not so plentiful as might have been expected and could have been wished, which is probably to be attributed to the duration of the show. For the rest, our detailed report, and the view and plan of the tent which Mr. SMITH has prepared for us, will give all further necessary information.

The show was opened with due honours by Lieut.-Col. SCOTT, R.E., C.B., in the absence of the President, the Duke of BUCCLEUCH, and in presence of the Mayor of Nottingham and the representatives of the Corporation; and the Mayor gave a promenade concert to the season ticket holders in the show grounds on Wednesday evening. Tuesday evening was taken up by the Gardener's Dinner, a truly important feature, but into which we would gladly have seen more life and reality infused. It certinly did not strike us as so successful as it should have been, though doubtless the committee and the chairman did what they could to make it so.

WE may supplement our recent remarks on the EFFECTS OF FROST ON VEGETATION by the following notes, extracted mainly from a recent publication by Prof. GOEPPERT, of Breslau. It appears that during the unusually severe winters of 1828-9, and 1829-30, the Professor made many observations and experiments on the influence of low temperature on vegetation, and published the results of his researches in a pamphlet of 244 pages, with numerous statistical tables. The winter of 1869-70 offering another good opportunity, he resumed his labours in this direction, of which the following is an epitome.

1. All plants in the open air would eventually be killed by continued frost, according to their bulk, or the more or less fluid contents of their cells. Cellular tissue, therefore, sooner than ligneous tissue, and herbaceous plants sooner than shrubby plants.

The cell-contents, or protoplasm, as confirmed by NÄGELI and SACHS, manifests great changes. The cell-walls and vessels, on the contrary, are not torn or fractured, even in plants killed by cold; hence the extravasation of sap on the surface of frozen plants. Chemistry is everywhere active. Cellulose and chlorophyll are decomposed, hence the discolouring and ultimate blackening of leaves—the commencement of humification. This change takes place also in the medullary rays, subject to a higher degree of frost, causing the trunk to split through to the medullary sheath; and, as these clefts never unite (merely grow over), the process at length extends to the wood fibres and vessels. Naturally, all the other organic constituents of the cell-contents suffer like changes, as, for example, the change of starch to sugar in frozen Potatos.

2. Individual constitution alone governs the different degrees of susceptibility evinced by plants, for which we have at present insufficient explanations.

Plants never become accustomed to an absolutely lower temperature than is natural to them in their homes. We often see plants of this description in cultivation, but we have never succeeded in habituating them to frost. Witness Dahlias, cultivated for upwards of sixty years, and even now as tender as when first introduced. Even plants from countries equally cold, or colder, than ours, but with later or earlier seasons, do not readily adapt themselves to her change. For instance, Robinia Pseud-Acacia (Pennsylvania) has been cultivated in Germany some 200 years, but has not become thoroughly acclimatised.

Our spring is earlier than in Pennsylvania, but the Robinia does not vegetate so early as our native trees, and does not lose its leaves until the frost kills them, and in consequence of this they are often killed by a degree of cold that would not injure it in its native habitat. Gleditschias and even young Planes occasionally succumb from the same cause.

3. There are many local and occasional causes to which this susceptibility of plants may be ascribed.—(*a*), difference in fluid contents; (*b*), winds; (*c*), changes of heat and cold; (*d*), degree of frost; and (*e*), situation.

Brassica oleracea and Helleborus fœtidus (with perhaps Crambe maritima), are the only native German plants with herbaceous stems that withstand the ordinary winters.

Winds injure, as is well known, through cold currents, and also, which is not so well known, through the drying up or evaporation of the ice or frozen fluids of the cells, which in the frozen condition cannot be replaced.

Frequent changes of heat and cold are ultimately fatal to very hardy plants. Such plants as Lamium purpureum, and Senecio vulgaris, will bear rapid changes of freezing and thawing five or six times, but not more frequently.

The degree of frost which vegetation is capable of withstanding has not been satisfactorily proved, chiefly owing to the neglect of modifying conditions. MIDDENDORF estimates it at 23—19° F.; ROBERT KANE, in lat. 78° 37' N., measured —43°.5 R.; and MCCLURE even—47° R. Beyond this latitude, up to 82° N., KANE found luxuriant vegetation, though only herbaceous. The limits of trees are much lower—the highest latitude in Siberia (Taimyrlande), 72° 30' N., for Larix sibirica; Europe, 70° N.; North America, between 68° and 69° N.

Great importance must be attached to the fact that the lower parts of trees and seeds and herbaceous plants altogether, are protected by snow. KANE found, in 78° 50' N., a temperature of 27° in snow, at a depth of 2 feet, 17°; at 4 feet, 13°.03; at 8 feet, 1°.06; probably ground only 1°. Prof. GOEPPERT made the first connected series of observations on the temperature of snow in the cold winters—1829-30—of the present century, and again in February of 1870. With the snow very equally distributed at about 4 inches deep, after three of the coldest days (2° to 21°) it was 5° to 6°; 4 inches in the ground 2° 12 inches below the surface 0° Reaumur.

From all these observations it appears that plants in high latitudes, and also on the higher Alps, are not exposed to very intense cold, for snow invariably in quantity before severe frosts set in, preventing radiation and ensuring a gradual and more uniform degree of cold. And it may be inferred that luxuriant vegetation exists even at the North Pole.

Snow practically is the best covering for alpine plants in gardens, the absence of this may explain the cause of many dying in our gardens. Nevertheless, the snow covering does not prevent the roots from being frozen. Growth takes place in winter only when we are free from frost for some time, and then slowly. Bellis perennis and Helleborus niger freeze and thaw without injury whilst the roots remain frozen.

Lastly, it may be mentioned that plants can bear different degrees of temperature at different parts without injury. MIDDENDORF saw Willows in North Siberia (Taimyrlande) in flower whilst the lower portions were still frozen.

—— THE DELPHINIUM NUDICAULE, recently introduced by MR. THOMPSON, of Ipswich, proves to be a much finer garden plant than was at first supposed. It is a tuberous-rooted and hardy species, with the usual finger-lobed leaves; but what is most remarkable about it are the brilliant scarlet flowers, which contrast so strongly with the usual blue tint which pervades the genus. We have indeed already had a scarlet Larkspur in the D. cardinale, but in that the flowers were of a dull red only, and the plant itself seemed unmanageable. Here, on the contrary, the colour is bright and effective, and the plant appears to grow freely when planted out in moderately light soil. The flowers with these rosy spurs are very suggestive of some brilliant Tropæolum, such as T. tricolorum, only that the mouth of the calyx is more widely spreading than in the flowers of that plant, approaching in size and form very nearly to those of D. sinense. Everyone should try if this fine novelty will thrive under the conditions which his garden affords; and those who find that it will do so, will discover that they have added a gem to their collection. There is an opinion abroad, formed possibly from the exhibition of indifferent examples, that the plant is far less meritorious than it really is seen to be when growing in the garden; and MR. THOMPSON informs us that he has himself been surprised at the different effect produced by bringing the plant into an ordinary sitting-room. In the open ground, whether in strong or weak light, the colour is glowing, and in a mass very striking, but in a room it is dull. Our own opinion, formed from watching the development of the plant in the open ground, is that it is really a good garden plant.

—— At the dinner given to the judges after the Rose show at the Crystal Palace on Saturday last, the Rev. H. H. DOMBRAIN presented to MR. WILKIN-

* MIDDENDORF enumerates all trees and shrubs found in North Siberia, in his work, "Reise durch Sibirien."

son, the General Manager of the PALACE, a very beautiful silver claret jug and cup, bearing the following inscription :—"Presented to ISAAC WILKINSON, Esq., by Judges and Exhibitors at the Crystal Palace Flower Shows, as a mark of their appreciation of his unvarying kindness and courtesy." Mr. DOMBRAIN, on behalf of the subscribers, tendered their thanks to Mr. WILKINSON, and expressed their regret that, owing to the increased duties devolving on him as General Manager of the Palace, they should not be brought into such close contact with him as formerly. Mr. WILKINSON acknowledged the gift in suitable terms.

—— A few weeks ago some specimens were sent to us of CAMELLIAS, which very unaccountably lost their leaves. As it seemed possible that something might be made out of the case if we had an opportunity of watching the recovery of the plants which not be brought good root might go on if re-potted, the attempt was made; but the remaining leaves fell, no fresh roots were made, and as the plant was evidently slowly dying, we thought it well to examine its condition before death had made the several parts undistinguishable. Accordingly on making a section we found that in consequence of death of the portion of the wood of the stock in contact with that of the graft, disease had extended downwards, quite sufficiently to account for the unhealthy state of the plant. This adds confirmation to the views stated by Mr. ANTHONY WATERER, in a late communication to the Scientific Committee of the Horticultural Society,—a communication which well deserves the attention of all propagators. *M. J. B.*

—— The extreme MAXIMUM TEMPERATURES in England during the week ending June 24 ranged from 72°.9 at Blackheath to 65° at Leeds, with a mean for all stations of 68°.8, and in Scotland from 73° at Perth to 64° at Dundee, with a mean for the several stations of 67°.5. The extreme MINIMUM TEMPERATURES in England were 38° at Hull and 40°.9 at Wolverhampton, and in Scotland were 39° at Edinburgh, 39°.5 at Paisley, and 40° at Dundee and Perth: the means for the two countries being, for England 47°.9, and for Scotland 41°.8. MEAN TEMPERATURES, 58°.2 at Portsmouth, and 56°.2 at Blackheath, were the chief of these values recorded in England, and 54°.9 at Greenock, and 53°.9 at Perth were the chief in Scotland, the means for the two countries being 54°.1 and 51°.6, respectively for England and Scotland. RAINFALL in some parts of England was very heavy during the week, and thunderstorms, accompanied by vivid lightning, occurred at most of the stations, particularly those in the midland counties. Wolverhampton is credited with the largest fall at any of the stations, viz., 2.11 inches, Birmingham and Salford being next with a fall of 1.74 inch at both places. In Scotland, where the mean for all stations was 0.38 inch, the largest falls took place at Glasgow (with 0.76 inch) and at Perth (0.73 inch). The mean for all stations in England was 1.37 inch. (See Mr. GLAISHER'S Tables in our present issue.)

—— The second annual exhibition of the METROPOLITAN FLORAL SOCIETY will be held at the Crystal Palace on August 24 and 25, when prizes to the amount of £170 will be given. Schedules are being prepared, and may be had on application to the Hon. Sec., the Rev. BLUNDELL-WOOD DOMBRAIN, Westwell Vicarage, Ashford, Kent.

—— We give the following statement, attributing a FUNGOID ORIGIN TO WHOOPING COUGH, and which appeared in the *New York Tribune*, for what it is worth :—

"Dr. LETZERICH, the pathologist, who some time ago published his observations on a Fungus, supposed by him to produce diphtheria, has more recently made a series of experiments with another form of fungoid growth, which he believes to be the cause of the very infectious disease, whooping-cough. The spores found in the expectorated mucus, causing the irritation and coughing, were allowed to vegetate into large masses, and small portions were then introduced into young rabbits by an opening in the windpipe. The wounds thus made soon healed, but the animal became affected with a violent cough. Several animals thus diseased were killed, and the air-passages in each were found to be very large quantities of similar Fungus. These observations, so important to the advocates of the germ theory, have not, as yet, been confirmed by other investigators in the same field."

—— Mr. TILLERY records in the "Florist and Pomologist" an interesting cross between Rhododendron Aucklandii and the Veitch's Stella Azalea, Stella being the female parent. The pollen from the short anthers of Aucklandii was used in effecting the cross. The young plants from seeds so produced are now growing vigorously, and are expected to flower next year. At present all the difference visible is that they are stronger in growth and with larger leaves than those of other young seedling Azaleas sown at the same time. Stella was selected for experiment in this case, on account of its being a very strong-growing variety and of fine habit.

—— Africa appears to be capable of supplying the wants of all our PAPER-MAKERS, since it furnishes, besides the Esparto-grass and the bark of the Adansonia, a fibre-producing plant called Diss-grass, which, though difficult to work and not so valuable as the better-known Esparto, can yet be obtained in such quantities and at such a price as will render it a useful luxury. The dwarf Palm can be obtained in almost any quantity in Algeria, but the cost of collection is rather more than that of Esparto, as each leaf is picked separately, and its manufacture into paper is more difficult and expensive, the texture of the fibre varying in different parts of the leaf, one portion of which contains some yellowish wax or resin, extremely difficult to kill, and almost impossible to detect till it is discovered on the hot rollers and the paper is spoilt. The rivers of South Africa are in many places choked with a plant known as the Palmete, a kind of large rush, 8 or 10 feet in height, of which large quantities can be obtained, and which in all probability will be found of use in the fabrication of ropes and paper.

New Garden Plants.

MASDEVALLIA ATTENUATA, *n. sp.*

Affinis Masdevallie floribundæ Lindl. Foliis longe petiolato-attenuatis linear-ligulatis acutis (apice scilicet minutissime tridentato), pedunculos bece excedentibus; pedunculo tenui; bractea vaginata ovariam pedicellatum longe non æquante; mento angulato, papulo subcylindraceo; sepalorum parte libera a triangula basi caudata, candis carnosulis crassiusculis deflexis; petalis supra basin angueicebatim antice semihastatis ligulatis acutis anneveis; labello ligulato antice subacuto crenulato carinis depressis a basi in discum anticum ibi in lineas callosas subparallelas excurrentibus; columna apice postice in dentem retusum extensa, utrinque juxta antheram rotundata.

A small-flowered little plant, with whitish flowers, having orange-yellow tails, and a greenish hue on the white of the flower. The sepals, white, with a green middle nerve. The column is greenish. The lip yellow, with an orange-coloured base and apex. It is one of the recent introductions from Costa Rica, obtained by Messrs. Veitch.

We must state a very surprising fact, viz., that our wild flowers are quite even inside, while the fresh ones have a very thin but quite obvious cover of velvet inside. We should not have been astonished so much if the dry flowers had been scabrous, the fresh ones quite glabrous, for we have observed that very often, and particularly in Masdevallias. *H. G. Rchb. fil.*

ONCIDIUM CUCULLATUM DAYANUM, *n. var.*

I have lately obtained this lovely variety from J. Day, Esq. It has quite white flowers, with beautiful violet blotches on the sepals and petals, and on the inferior part of the lip. The crest is beautiful, much like Oncidium Phalænopsis. That, however, is widely distinct by the three long reeds at the base of the lip. It appears to be very rare. *H. G. Rchb. fil.*

THE NATURAL HISTORY OF A FLOWERING PLANT.

[The following is a report of the second of Professor Thiselton Dyer's course of lectures on "The Natural History of a Flowering Plant," in the Theatre of the Royal College of Science, Stephen's Green, Dublin.]

IN the course of his remarks on "The Root," the lecturer said :—

The transition from the consideration of the leaves to the root of a plant is less abrupt than it appears at first sight. The leaves are specially adapted to the atmosphere so as to bring the largest possible plant-surface into contact with it; the leaves are feeding organs, and their food is taken hold of in the gaseous form. The roots are also widely spread, and expose in their aggregate a considerable surface, though not all equally efficient: they are, in fact, another feeding system, complementary to that formed by the leaves. The two are joined together by the axis, or main stem, which breaks up, therefore, above and below, into ramifications terminating in parts specially adapted to collect plant food from the different media in which they are placed. External circumstances have given each their special character. A somewhat perverse experiment made by Duhamel, an industrious investigator of plant life, will illustrate this. He bent down the stem of a young Willow, and buried the crown of branches in the ground. The leaves proceeded to produce leaf-buds, but developed rootlets. Willows are tenacious of life; the internal resources of the young plant supplied for a time the want of leaves. Finally, when Duhamel disinterred the original roots and elevated them into the air, the inversion became complete, and they produced leaves. In this instance, not quite so complaisant as this; but the great majority of them will develope from fragments of the stem, more rarely from fragments of the root, the parts needed to make the plant complete. It is a great part of the skill of the gardener to make use of this interchangeableness to multiply plants which it may not be convenient or possible to raise from seed; not that the process can always be effected in the same way: individual peculiarities of constitution intervene, and various artifices have to be employed to get a successful result. As a general rule, cutting a root with less facility in proportion as the stems they are taken from are hard-wooded and old; the vitality of such portions is less active. Plants which are propagated on a large scale for sale are often made to produce, by exposing to heat while diminishing the light, a number of young shoots which can be easily rooted. The study of plant life is a science, while the practice of horticulture is an art involving no very recondite scientific principles, but requiring often in their application no small amount of skill and ingenuity. The immense amount of destructive friction which would otherwise be involved, confines the growth of roots to their extremities, just within which the formation of new cells takes place. The tip of every rootlet has this growing point protected by a kind of cap, which is continually abraded and renewed, but which is easily to be seen in many water plants, such as Duckweed. The newest parts of the roots are covered with delicate hairs, formed by tubular prolongations of the cells forming the surface; these become inserted between the smallest particles of the soil, and are bathed by any matter in solution it contains, and consequently, passes by absorption into their interior, and, by a repetition of the process, from one cell to another. Generally speaking, roots will not grow unless a plant has also active leaves: this is not universally true, as the colourless protoplasm of the root cells can nourish itself on the nutrient material stored up in the plant, and in plants the result of nutrition is growth. The points of growing rootlets once destroyed, they will not grow again, but new rootlets have to be formed; this is the cause of the shock plants sustain when they are transplanted, and of the often irreparable injury a plant sustains from having its supply of water neglected. A great deal has been stated as to the direction of plant growth; one observer thought all roots were directed by centripetal force towards the earth's centre. The true explanation would seem to be that roots travel in the direction where they can feed most easily. It is easy to see this in the case of a hedgerow timber of cultivated fields. The roots of an Ash have been found running beneath the well fed surface for 95 feet; in the same way they will develope enormously in water-pipes and drains. The roots of an Alder stopped completely the main of the Berwick waterworks. Roots, it must also be remembered, are organs of support. The habit of taking a deep hold upon the ground will, of necessity, be impressed upon them; and this will operate disadvantageously in the end, if, as sometimes happens, they strike too vigorously into a bad soil. Fruit trees, which are to have their roots kept superficial, so as to be well fed, must, as a consequence, be grown of small size. The extent of feeding ground occupied by roots is very great. In a tree, it far exceeds the spread of the branches. Schubert traced the roots of Wheat to a depth of 5 feet. The access of air to roots has been found essential to their health. Trees, the roots of which are too deeply buried when any change is made in the surface of the ground, are apt to die in consequence; and, when trees are planted in towns, a space should be left unpaved immediately round them, which will allow them also to be watered in very dry weather. While the leaves are the means by which carbon is introduced into the plant, it is by the root that the other elements of its food are secured. These are dissolved, as saline and mostly highly oxidised substances in the water which permeates the soil, and in this form they pass by a purely physical process into the roots; thence, by means to be traced hereafter, they are transferred to the upper parts of the plant. In the leaves the excess of water is got rid of by exhalation. Hales found that a Sunflower with a leaf surface of 39 square feet exhaled 22 ounces of water in 24 hours; and in the Pea every 100,000 grains of water which passes through the plant carries about 40 grains of solid matter with it. The sulphur, phosphorus, and nitrogen contained in these matters are, in the leaves, torn from the oxygen with which they are combined. But the disposition of the plant food would again be treated of in the next lecture.

EARLY PEACHES IN ORCHARD HOUSES.

THOUGH the season is too little advanced to speak decidedly on early Peaches in unheated orchard-houses, and, in spite of the heavy rain which has been falling lately, I cannot refrain from expressing my admiration for that most valuable Peach, Early Rivers. Well did my friend know its value when he adopted it by his own name. I have now some half-a-dozen trees of each of his earliest seedlings, and among these—up to this—there is none I like so well as Early Rivers. It has all the merits a Peach should possess; it is handsome, hardy, and highly prolific. It was raised from the Early Silver Peach, which with me is delicious, but not a first-early, rather a second-early, and which was itself raised from the white Nectarine. Any one purchasing Early Rivers should note that it has large flowers and kidney glands, and is not very liable to mildew. This adverse season it has actually ripened on the 15th of the present month, on a diagonal cordon against the back wall. In 1869 it ripened on July 1, and in 1870 on the 10th, so that this is an enormous advance. Accustomed as I am to see my fruits advance, from 10 to 20 days in 10 years or so, this is considerably more. The fruits are not so large as last season, there being too many on the trees.

Thus, in an unheated house, we have Peaches at a time when they are half-a-crown each at Covent Garden, and, as to Algiers, there are not generally say as early in the Paris market in the very best of seasons. In 1869 Early Beatrice ripened here on June 12, but as the tree subsequently died, this was an abnormal case. It is, however, quite coloured, but small, and not ripe this season yet. At Sawbridgeworth, Early Rivers is ripe at about the middle of July, so that here we are just one month in advance. Has any one ever

ripened Early Beatrice as early as the 12th, and Early Rivers as early as June 15, in an unheated house before this?

If any one could witness our generally late and cold springs, he would be speedily disabused of the fallacy that our climate is the sole cause of early ripening. Cornwall sends Potatos, Strawberries, and Khuharb to the Londoo markets quite as early as do the Channel Islands. Though our winters are comparatively mild, they are often severe, and always stormy and damp, while our springs are notoriously late. To what, then, is this early ripening of this Peach due? I answer without hesitation, after a longer experience than any man in England or in these islands in pure cordon training, that it is due chiefly to the peculiar advantages of the diagonal cordon on the back wall of a solid lean-to orchard-house. These houses are more than a week earlier than the span-roofed. The diagonal cordon is so easy to train and expose to the sun's rays, and the roots are so naturally restrained, that a just balance is established between root action and the parts in bearing which is eminently favourable for fruit culture. Thin out rigorously, water freely, and no other system of training can surpass—I think excel is the right word—the diagonal cordon.

I may add here, that Early Louise presents a very fine appearance, and is colouring freely. My half dozen trees of this sort are all very well cropped. It is a prolific variety evidently. Early Leopold seems a second early at present. Rivers' Early York will be an acquisition, for, side by side with Early York, while the last is slightly mildewed the seedling is perfectly free from it.

On the whole it bids fair to be a good season under glass, but on the walls we hear many complaints. *Th. C. Bréhaut, Richmond House, Guernsey, June 17.*

DARLINGTONIA.

ONE of the plants which attracted most attention at Nottingham, was the singular Darlingtonia exhibited by Messrs. Veitch. This plant is a native of California, where it was recently met with by Mr. Robinson, who communicated an account of it to the Linnean Society a short time since. The plant had, however, been previously well known to botanists, and had indeed been exhibited by Messrs. Veitch at the Royal Horticultural Society. It is a near ally of the Sarracenias, but differs in several technical points, and amongst others in the singular tails which spring from the mouth of the pitcher. The floral conformation is like that of the Sarracenia, but the stigmas are comparatively small, and do not present the large umbrella-shaped expansion so characteristic of the Sarracenias. Moreover, as lately pointed out by M. A. De Candolle, the five lobes of the ovary alternate with the sepals, instead of being placed opposite them. We have not ourselves yet had the opportunity of verifying this statement, of the correctness of which, however, we entertain no doubt. The leaves of this plant are 12—18 inches long, tubular, twisted, veined, of a dull reddish colour above, and curved at the apex into a hood, from which proceed the two curious processes before alluded to. The flowers are borne singly at the end of a long stalk, and are bent downwards, each one about 2 inches across. The sepals are greenish-yellow, the petals purple. The stamens are 15—20 in number, the ovary is 5-lobed. It is one of the most interesting plants in cultivation, and, as it naturally grows in damp places, exposed to extreme cold, or extreme heat, according to the season, it would hardly seem to need the coddling treatment to which it is sometimes subjected in this country.

THE LORANTHACEÆ OF ANGOLA.

[The following paper was read by Dr. Welwitsch before the Scientific Committee at the last meeting of the Royal Horticultural Society.]

THE singular beauty and richness of the gay-coloured flowers of the numerous species of Loranthus, which enhance in so considerable a degree the variety and charm of tropical forests, is noticed and acknowledged by every attentive traveller in the torrid zone; and the introduction and culture of these interesting parasites form worthy objects of attainment by skilful and persevering horticulturists. I beg, therefore, to offer some brief observations on the occurrence and distribution of the species of this order in south-west tropical Africa, and to add a hint to encourage, and perhaps to facilitate, their future introduction into Europe.

During my travels in Angola I collected about 30 species of Loranthus, but only one species of Viscum. The number of species, and also that of individuals of the same species, I found to increase progressively from the sea-coast towards the highlands of the more distant inner regions, and to culminate in the mountainous forests of the districts of Pungo Andongo and Huilla, at an elevation of between 4000 and 5000 feet above the sea.

Nearly all the species I encountered are erect, or more or less spreading shrubs, from 1 to 2, or 2½ feet high, with the exception of one species, which forms a pendulous bush, with slender branches, 4 to 6 feet long.

Most of the species of Loranthus, and also the single species of Viscum I met with, were growing on the lower or higher, or even on the top branches of evergreen trees, less often on trees with deciduous leaves; but a few of the most brilliantly flowering species I encountered in the burning and treeless coast region, growing at the base of small low shrubs of Barlerias and Sidas, very much in the same manner as Cytinus hypocistus occurs on Cistuses in the sandy plains of Portugal. Sometimes in the hot littoral region, a beautiful Loranthus is met with, growing, not at the base, but on the middle branches, or even on the main stem of low slender twiggy shrubs; and in such instances the natural combination of the bright green and broad-leaved parasite and its gay crimson flowers with the more tender and differently shaped foliage of the foster plant, forms one of the most striking features of parasitic vegetation along the sea coast of Benguella and Mossamedes; so in one instance I was most agreeably surprised to find a small bush of Gossypium microcarpum, only between 2 and 3 feet high, bearing several stems of a pink-flowered Loranthus, nearly a foot long, on its slender branches: whilst on another occasion I met with several low shrubs of the intensely glaucous Tamarix articulata,

FIG. 171.—DARLINGTONIA CALIFORNICA.

of which nearly every main branch was adorned by dense patches of a pretty Loranthus, with splendid yellow flowers.

The greater number of the Angolan Loranthus glitter with flowers of a more or less pink or scarlet hue, but about half-a-dozen of the species are adorned with golden or orange-coloured blossoms, and nearly all the species are exceedingly free flowering. The principal flowering season of the Loranthaceæ coincides in Angola with the spring, that is, from September till November, but many of the finest species continue their blooming almost during the whole summer, when they may be found not unfrequently covered with ripe fruits at the base while they are still in full bloom at the top of one and the same branch of the respective foster tree. The yellow-flowered kinds, however, seem to begin their season much later, for I met with several golden-blooming species in the months of June and July, which time in Angola is the very middle of the dry and chilly winter season.

All the species have fleshy and rather broad leaves, which, however, vary considerably in colour, being on some species of a dark shining green, in others glaucous green, and, in a few species, they are covered with a greyish tomentum. Although some few species evince a decided predilection for particular species of trees, I not unfrequently found the same species of Loranthus growing on trees pertaining to very different species, genera, or even orders of plants; but the pendulous species of Loranthus I observed exclusively on species of Ficus, whilst the Viscum I found constantly growing on an arborescent Composite, a species of Tarchonanthus. The forest trees most frequently inhabited by Loranthuses are the Adansonias, several of the larger trees of the orders of Mimoseæ, Combretaceæ, Sterculiaceæ, and Sapindaceæ, as well as most of the different Fig trees, whilst in the southern parts of Benguella, and near Cabo Negro, many beautiful Loranthus may be observed on the Tamarix articulata; on the contrary, I seldom or never saw a Loranthaceous parasite on trees belonging to the orders Anonaceæ, Hypericaceæ, Zanthoxyleæ, and Euphorbiaceæ, although every one of these orders is rather copiously represented by large and mostly evergreen trees in the woods of the Angolan highlands; but I have frequently seen some scarlet flowering Loranthuses investing introduced trees of Citrus Aurantium and Citrus Limonum, and also those of Ficus Carica; and it seems to me that this curious parasite immigrates with a kind of predilection from the original habitation to the neighbouring fruit trees, for on one occasion I saw a whole orchard of Orange trees invaded with a blood-red flowering Loranthus, and in another instance I met with a plantation of Fig trees (Ficus Carica), most of them covered not with Figs but with a grey-leaved Loranthus, with yellow flowers. It seems also that the quality of the sap or juice of a tree exercises little or no influence upon the vegetation of Loranthaceæ, for in one instance I found on the same tree two species growing, equally vigorously, on Adansonia, which has a watery juice, and at another time on Fig trees, of which the sap is milky and glutinous.

These two latter circumstances seem to hint at the probability and perhaps even facility of the future culture of these pretty parasites in European gardens, wherein such an introduction would vary the rather wearying "Pelargonism" and "Orchidism," or, at any rate, these plants would be contrasted with many new and graceful forms and strange-looking productions of the tropical zone, never yet seen in a living state in Europe, and until now only admired and praised by travellers.

THE AMATEUR GARDENER.

The Strawberry.—The amazing difference which often appears at this season between the Strawberry beds of one gardener and another, and even between two beds in the same garden, is matter of notoriety, and leads to inquiry as to the cause. We want to know how it is that one man has such a profusion of fruit, while another is disappointed and vexed by the scantiness of his crops; and when, in some instances, there may be reasons of an apparently arbitrary kind, which even science cannot discover, the cause which produces such diverse results are sufficiently patent. Sometimes half the plants in a bed may be barren, and if the cultivator lets them remain, in the hope that next year the loss will be made up by increased fruitfulness, he may again be disappointed. Our own method of guarding against this, is at once to pull up every barren plant, and to take fresh runners only from those which have borne well. We have generally found this plan effectual, though not to the extent of making every plant in a row prolific. Three years ago we had a new bed of Chiffik Hautbois, and only three of the plants bore fruit. We took early shoots from these, and the next year they all bore as well as their parent stocks.

Some growers lay stress on the second or third shoot in summer, but we always take the first. It is a common practice to let the runners root as they will, and in the autumn to take up promiscuously as many plants as are wanted for new beds; but this is a careless mode of proceeding. We are now getting shoots rooted as fast as we can, and we remove them immediately they are ready, to a nursery bed, where, in about six weeks, they are fit to be planted out where they are to remain. They have thus four or five months to perfect their growth, and will be finishing plants next year. A whole season is thus saved. As soon as a runner has a plant at its terminus, we peg it down or confine it in a fixed position by a stone or oyster-shell; the latter is the best, because the white shell indicates the place in the path where the runners are, and in gathering the fruit they need not be disturbed. The runner is prevented from growing any further, and all the possible strength is thrown into the young offset. We hope to have our new beds filled in this way by the first week in August.

There is a great temptation to allow too little room for growing Strawberries, but it should be resisted, and not less than 4 square feet should be given to each plant. This will seem too much when the plants are young, but, by the second year, when they will be in their perfection, it will be found not to be too much. In some cases we allow runners to root as they please the third year, and the year following dig up the bed as soon as the fruit is gathered and sufficient offsets secured for a new plantation. The soil should be rich, and deeply dug before planting, after which there should be only a surface stirring, as disturbance of the

roots is to be avoided. We find the barbarous custom is not yet obsolete of cutting off all the foliage of Strawberry beds in the autumn. If there were no other objection to this, it would be sufficient that the crowns of the plants are thus deprived of their natural protection during the winter, and barren plants will be very common. If all runners are removed as they grow, the plants will need very little trimming up. The old leaves will gradually die away as the young foliage advances in the spring, until all marks of decay will be gradually obliterated.

A thin layer of short rotten manure, such as an old Cucumber bed furnishes, should be spread over the plants in the late autumn, and worked among the leaves with the fork. We place the same in the alleys also, and, if the proper kind of dung is selected, it will, when the time of fruiting arrives, be found sufficient to keep the fruit clean. In the very heavy rains we have had in the last fortnight, the fruit lying on this stratum has seldom been soiled. There are many contrivances to secure the same object, but we know no better one than this. The fruit may be forwarded in the ripening by tiles or slates placed under it. Slates, about 5 inches wide, put in a row on each side of the plant, make a tidy and effectual protection from the splashings of the rain in wet weather.

We will say little about the sorts of Strawberries which best repay cultivation, for they are very numerous, and the best plan is for a grower to visit the beds of his friends when fruiting, and make his own selection. More things have to be considered than the kinds of fruit, some kinds having a more compact and dwarf habit, which makes them more suitable for small gardens. We have been for some years contented with Keens' Seedling, British Queen, Underhill's Sir Harry, and a late Pine, of which we have forgotten the name. We must not omit to mention that Strawberries often do well along garden edges, and when so planted the fruit is easily gathered. *H. B.*

Home Correspondence.

The Condition of the Peach and Nectarine Trees.—I fear the statement made in your leading article at p. 770 is but too true of the above trees out-of-doors. Such as I have seen and heard of are in a miserable condition, some describing their trees as in a moribund state, and others as in the condition described by Mr. Barnes, namely, "blistered, covered with green aphis, and spiders." None of this is the case here out-of-doors. I live on the apex of the parish, wholly open for miles to the south and south-west, unprotected towards the east, and with only a low, 5, 6, or 7 feet brick wall to keep off the west wind, and the north wind, which latter comes from the Wiltshire hills some 20 miles off, with nothing but here and there an Elm tree to defend my trees. The winter here was Siberian, and the spring very severe, but I had not to cut from 112 of the above trees more damaged wood than would amount to 1 foot. This arises mainly from being a short-pruner in summer. I have seen long-pruned trees this spring with as much dead as living wood. The crops of Peaches and Nectarines are excellent on south walls, very good on the west walls, but, with four or five exceptions, bad on the north walls, owing to the severe May frosts, accompanied by the biting east or north-east wind. The trees are all in most vigorous health, the foliage is free from blister, curl, aphides, and red spiders; it is as good as could be desired. Between 600 and 700 people have been here in the last two days, chiefly to see the Roses, but amongst them several gentlemen's gardeners. To them the Peach and Nectarine trees were the great attraction, and subject of astonishment. Their account of their trees put me in mind of Milton's lazar-house—

> "Dives' oft the tossings, deep the groans,
> Despair the sick doth tend."

There is no wonder connected with it. I look after them myself all the year round, and I will not suffer severe winter or spring, red spiders, or aphides to blister, curl, or afflict my trees. The miserable state of the Peach and Nectarine trees out-of-doors in England is a disgrace to science, and the result of neglect and gross ignorance. I hope some of the readers of this article will come and review my trees. *W. F. Radclyffe, Okeford Fitzpaine, Blandford.*

Marechal Niel Rose.—In the Belfast Botanic Gardens I saw a sample of this Rose under very good culture. It was growing in a square tub at one end of a show house, and was trained under the glass for a considerable distance. During the time of my visit at the first North of Ireland Flower Show, held in the gardens in May, not the first show of the year, but the first show of the kind held in May in these parts), the roof was literally covered with flowers. There could not be less than a couple of hundred expanded at one time, and you would require at least to multiply that by two to get at the sum total of the blooms at that period. The Lord-Lieutenant and party formally opened the show, and the Countess Spencer was so delighted with the "Maréchal," that a bouquet of the flowers was presented to her. My principal object in notifying this is to state that the Rose had been budded on the Brier, and, not contented with the food supplies which that stock sent up, had taken root itself, and quite eclipsed in time its foster parent. One might judge from this it would do best on its own roots, but Mr. Johnson, the curator, observed that it seemed to prefer the help of the Brier stock in its younger stages, and that by earthing it up past the junction of stock and scion it would set away roots for supplies on its own account. The Manetti does not seem a good stock for it at all; it would soon die were it forced to live upon the resources which that stock can supply, and it would seem that the proper way to grow it well is to treat it as Mr. Johnson has done. The pale yellow shade of colour is not shown to advantage against "blinded" glass of the ordinary character. It would be better, therefore, to have a screen of, say, light blue, which is an agreeable eye colour against bright white. This would, in such a case as that we have described, exhibit its beauties to much greater perfection. It is really a grand Rose, seen under such culture as I saw it. I know there are a few other places where it has been equally well done, even in Ireland, but your readers generally may be none the worse of hearing of this particular case, and some of them may profit by the information given. *Jas. Anderson.*

Watson's Lawn Sand.—I think few can form any conception of the wonderful effect that takes place after a dressing of this sand on a bad lawn. When I say bad, I mean that the lawn contains every kind of weed that can be named, and where such was the one here, with the exception of about 2 acres, until I obtained Watson's lawn sand. Being somewhat doubtful of the effect, from the flowing description given in a circular sent, I only tried the smallest quantity sent out by the vendor, namely, 14 lbs., the result of which is as follows:—I selected a place in the middle of the lawn where the grass was as bad as it was almost possible to be, giving it a dressing at the rate of 4 oz. to the square yard; and at the first appearance everything seemed to have been burned, the grass became brown while the weeds kept their hue; but as soon as rain came everything seemed to change, the coarse grass and Daisies giving way to grass of a far finer character, Clover also making its appearance; and although the whole of the Daisies did not disappear after the first dressing, yet, after applying about 6 oz. more to the square yard, they did so—the result being so highly satisfactory that I have used 6 cwt. of it, and we have now as fine a lawn of grass as could possibly be wished for as far as the dressing has been used, but where none has been used it is nothing but moss and filth of almost every description. *James Stewart, Bellisfield House, Windermere.*

Viola cornuta Perfection.—Permit me to say that I have grown this plant to perfection for three years, and it is now covering a "star" bed with a 3 feet band of Violas, which are a complete mass of bloom. One can hardly put a finger between the blooms without touching them. It is undoubtedly a first-class bedding plant, and I shall be happy to show my flowers to any gentleman who may favour "pilgrimage" to the quaint old church of pious George Herbert, only a few yards distant. *E. Lampard, Gr. to Rev. W. P. Pigott, Bemerton, Salisbury.*

Buds below the Seed-leaves.—These are produced very quickly in the common Pimpernel—Anagallis arvensis. When the top of the young stem with the cotyledons is cut off, minute protuberances arise on the sides of what was before the smooth and naked stem, and from these issue buds which, in the seedlings of Dodecatheon Meadia, I find that the cotyledons remain for a considerable time fully expanded without the least trace of a bud showing itself in the axil; but at length a bud breaks forth through a longitudinal cleft in the apparent stem, just above where the cotyledons enter the earth. In this case, which is quite different from that of the Anagallis, the stem which supports the cotyledons may be only their united prolonged bases, in which the bud is immersed, as it is in some American Compositæ, which expand their cotyledons above the surface of the earth supported upon an apparent stem, which is, however, tubular, and the bud really arises from a point below the surface of the ground, and pushes its leaves up through the axil. *W. Mitten, Hurstpierpoint, June 27.*

Pear Grafted on Apple.—M. Carrière's statement respecting the Pear growing on the Apple is quite correct. Last summer, while budding some young seedling Apples, the thought occurred to me, Why should not the Pear grow on the Apple? I then inserted buds, viz., Marie Louise and Fondante d'Automne, on the Apple, both of which are growing vigorously. This season I intend carrying the experiment into a wider field. Last spring I grafted a St. Michael's and Blood Oval Oranges on seedling Shaddocks, to see what influence the stock will have on the scion. The foliage is looking remarkably healthy. *A. Hosack, Ashburnham Place, Battle.*

Ivy.—Allow me to add a word to the testimony of "H. B." at p. 772. Ivy does harm to growing timber. I cut down some large Larch this spring, some of which were tightly compressed in folds or coils of strong Ivy, and the boles of the Larch could not swell. When sawn, the grain of the Larch was remarkably close and fine—like pitch Pine, while that of trees free from Ivy was coarse. This, I conceive, would arise partly from suppression of the Ivy not permitting the bole of the tree to enlarge itself, partly, perhaps, from robbery of nutriment at the roots of the Larch by the roots of Ivy. Ivy does good and not harm to good walls—adds to their dryness. *Mem.* It must be a good wall to be entrusted with Ivy upon it. My old vicarage barn gable was covered with Ivy of a century's growth. On re-roofing the barn I found the gable leaned over inwards so much that it was necessary to rebuild it. We could not understand why the gable had got out of the perpendicular in this way, till we discovered the roots of the Ivy had got into the wall, and, as it were, wedged up the stone-work. The mortar was very bad. The roots had not come through the wall, or the lift would have been uniform throughout. Some 25 years ago we had an archdeacon who was under the impression that Ivy injured all walls, and so ordered the churchwardens everywhere to remove Ivy from our old Norman church towers around. As the walls are 6 and 8 feet thick, and the mortar like adamant, the Ivy could do no harm, and we have lost a very picturesque feature of neighbourhood. *W. M. R., Bishop's Castle Vicarage, Salop.*

Phormium Flowering.—Two years ago I flowered in my nurseries the Phormium tenax fol. aureo-marginatis, a fine plant, with a stem of about 4 yards high, and with many flower-spikes, but which did not give me any seed. I kept the plant all the time indoors, in a well-aired cool span-roofed house shaded with laths. This year the Phormium Colensoi fol. argenteo marginatis, is about to flower. The stem is upwards of 14 yards high. It is a fine plant, healthy, and at present is kept in a span-roofed house devoted to cool Palms, as Latania borbonica, Corypha australis, Chamærops Fortunei, Phœnix reclinata sp. *P. de G., Steenbaugge.*

The Setting of Grapes.—Within the whole range of horticulture nothing can be of more import than the proper setting of Grapes. Mostly setting freely of themselves, at times a failure occurs that ruins the crop. I regret that amid those experimented upon (see p. 737) one or two of the most irregular setters are omitted. These are, Lady Downe's, in certain places; West's St. Peter's, now and then, and especially the Canon Hall Muscat. Should an opportunity offer, perhaps, the latter especially will be subjected to careful examination. The most striking and, at the same time, most provoking irregularity is, that while a few of the berries seem over-set, the majority are not set at all. What I mean by over-setting is this—some berries, or parts of berries, have one or more seeds abnormally developed, so much so that these seeds press against the rind of the berry so forcibly as to induce premature decay. In these instances of excessive development the seeds are likewise unsound and of a darker colour than usual. The flesh of the berry also adheres to them, almost as tenaciously as the flesh of a clingstone Peach or Plum does to the stone. Moreover, these berries are frequently misformed, bulged out of shape by the size of the seed. It is seldom that such berries have the usual number of seeds; more frequently only one or two of such monstrous seeds are found. Can these malformed seeds be the result of compound fertilisation, or do they admit explanation of their origin? Again, is their unusual size the cause or product of their unsoundness? Also, why are they most frequently found on Vines that are shy setters, such as, pre-eminently, the Canon Hall Muscat, and the Lady Downe's, Hamburgh, on Vines that set much less freely than the common Hamburgh? There is another curious coincidence connected with these monstrous berries. It is this, that they are generally, if not always, found on the same bunch with unset and seedless berries. How often, for instance, are the bunches of Canon Hall Muscat Grapes such as a few large berries like Golden Champion at their largest, only rounder, and all the other fruit on the bunch about the size of the Corinth or Currant Grapes? It seems as if the large berries had absorbed all the seed-bearing power of the plant, and concentrated nearly all into one or two monstrous growths. Can there be such a thing as an intercommunion of seed-bearing force between different portions of the same bunch? Explain it as we may, the coincidence of abnormally large and small seedless berries on the same bunch is well nigh constant, and is perhaps most constantly seen in the Wilmot's Hamburgh and the Canon Hall Muscat varieties. But the abnormal growth of particular seeds is likewise common among Muscat of Alexandria. Wherever found it proves injurious to the quality of the Grape. I have scarcely ever met with an abnormally large seed without the quality of the fruit being lowered thereby; the flesh is coarse, or incipient decay is set in, and, as already stated, these big seeds are mostly unsound. There are exceptions, however, to this. But there is another peculiarity about large seeds of Grapes, which is constant as far as my experience goes. They are scarcely ever found in their right position. Of course it may be held, that their size must needs throw them out of place; but their displacement is greater than can be thus accounted for. It almost seems as if the displacement were the cause of their extraordinary development, rather than that

their mere size was the reason of the altered position. It would be interesting to inquire into the effect of a change in the position of seeds or stones in reference to external influences upon their size and quality. Would the mere bringing of them out from the centre of the fruit and placing them close to the rind affect the changes we find in misplaced seeds or stones? Are the instruments of change—external or internal accidents from without or vital alterations of structure springing forth from within, the offspring of external errors or injuries or the legitimate development of misformed or differently formed gemmules. These queries have an important practical bearing upon the setting of Grapes, for the variations of normal structure proceed from some latent power of variation implanted in vitality itself: we may not alter them. But if not, greater knowledge, higher skill, especially of the mysteries of setting time, may enable us in future to prevent such freaks, and all other accidents to the critical moment of the plant's life. That is a most suggestive saying in your leader (p. 737), that the gardener wants the Grapes, not not the Vine itself. And doubtless this shy setting, or not setting, or setting a few berries only on a bunch, are all fair weapons given to the Vine by Nature to enable it to protect itself from our grasping greed and short-sighted improvidence. Probably a moderate crop is almost the best antidote to shy setting. *David Tell Fact.* [Among the causes of bad setting not mentioned at p. 737 may be set down the following: the formation of a gummy substance on the stigma, and the presence of a small dipterous insect, which eats up the pollen which may gain access to the stigma. EDS.]

— When reading your leader on this subject, at p. 737, I was struck with the theory there laid down, viz., that syringing at last would do no harm" [under the particular circumstances alluded to], such being opposed to an opinion in which I felt to have been educated. It brought to my mind a fact which came under my notice some 16 years or more since: I was passing through a vinery with the gardener at the time of thinning, and, speaking of the tedious straight-jacket affair it was, he took me to another house, more forward, and on which little or no labour had been bestowed in that matter, at the same time remarking, "These I gave a good syringing at a certain stage of thinning, which is usual with me, and save the trouble of thinning." Now the result here obtained would prove it a great risk, and probably the total failure of the crop, if syringing was the constant practice during the flowering period. I have always looked on a rainy time, when trees or flowers were blossoming, as be detrimental to a crop of fruit or seed; and I am further reminded of boyhood days by hearing a fruit grower, of near fourscore years, say, after three or four rainy days at the time of Peaches, &c., blossoming, "Not much fruit this year; too much wet." *Josiah Ekemble, Gardener Nursery, Southampton.*

Bats.—My church is infested by these creatures. We never see them, but their droppings are swept up a quart measure at a time. How could I attack them with any hope of expelling or destroying them? Could I fumigate them? With what? or how? The roof where they lodge is very lofty. *W. M. R., Bishop's Castle Vicarage, Salop.*

A Cool Orchid-house.—I now propose to lay before your readers a practical illustration of the home element of which I wrote, by giving a short description of the cool house of which I have the charge, also the names of many of the plants grown in it. The Odontoglossum house is a lean-to; it is built on the north side of a wall running east and west, or nearly so. The house is a rather large one, being 45 feet long, 10 feet wide, 9 feet high at the back, and 4 feet 6 inches in front. It is heated by four 3-inch pipes. They go along the front only, and there is no other pipe, flue, or anything of the kind in the house except this 180 feet of piping. The back table is 3 feet 6 inches in width. It is simply a pit filled with rubble, and finished with a presentable surface. The path comes next—2 feet 6 inches wide; the front table is 3 feet 10 inches wide. It is not carried close up to the wall in front, but a space of 2 inches is left all along the front for free circulation of warm air from the pipes below. Under this table and close to the pipes there are a number of shallow (cemented) water-tanks running the whole length of the house, and presenting a surface of about 80 feet of water, thus forming a constantly moist atmosphere in the house under all circumstances. There are 18 ventilators, six of them opening on the pipes, and these last are opened a little when the outside temperature is 50°. More air is given as the outer temperature increases; and, when it rises to 65°, not only all the ventilators, but the door also opened, and an outer canvas door closed to break a rush of air, keep out insects, &c. The plants are carefully shaded from the sun; but, as both ends of the house are glazed down to the tables, and there are front sashes 1 foot 6 inch deep, there is plenty of light, and, owing to the position of the house, no shades are required from the third week in October to the second week in March, and it is during this time that the young leaves acquire the ruddy brown and Copper Beech colour mentioned by me at p. 677. Your readers will see from this rough description that his house very nearly agrees with Mr. Bateman's idea of a cool house, mentioned by Mr. Anderson at p. 741, and six years' experience convinces me that it is very nearly correct for the plants named below. The collection of Orchids grown in this house is a rather large one, numbering upwards of 550 plants, and more than 70 distinct species, 64 of which are here given, and about 100 plants have not yet bloomed. Allow me to add that, in the present letter, and in that given at p. 712, you will be found much of the information asked for by "G. H." at 615, when he desires to know "what this cool treatment really consists of?" and I am sure it would be very interesting to many of your readers if he will tell us how many of this list he grows in the Liverpool. *T. Statter.*

The Past Winter.—I think we may safely consider all trees and shrubs that stood the past winter without protection as hardy. At this place there are a great number of Conifers which have been planted at different times within the last quarter of a century. With a few trifling exceptions they stood the past winter uninjured. The soil varies considerably. In some places it is a sandy or gravelly loam, resting on a gravelly subsoil; and in others, a clay loam resting on a subsoil of strong retentive clay. The plants do well in all situations where the soil is not too light or strong. They do remarkably well where there is a good depth of gravelly loam, and many of them are now beautiful specimens. The last three hot dry summers have been very favourable for ripening the wood. They have broken finely this season, and are now making splendid growths; and most beautiful objects they are, the newly born foliage contrasts so strikingly with the old. The few that suffered a little were either too near other trees, or the soil a little too wet; the injury done was trifling—a little browning of the foliage on a few of the branches. As it would take up too much space to give the names of all the kinds, I may mention that all the more ornamental and hardy kinds are planted, some by scores and others by hundreds. Of evergreens and shrubs have stood little. Laurustinus, that in 1860-61 was killed to the ground, was very little hurt. Berberises have stood well, with the exception of Wallichii, which seems very tender, it being much injured in every situation. Hares are very destructive to B. japonica at present, it is scarcely worth planting where hares have access to it. I noticed among standard Roses one or two have had their heads killed, but the stocks are alive, and one has put out strong shoots. Fruit trees were not in the least injured by the frost of last winter. In 1860 and 1861 much of the fruit tree was killed. One valuable lesson we may learn from the past, and that is, whatever we plant, or in whatever situation we plant anything, to secure well ripened wood. If we do this, we have little to apprehend from the severity of our ordinary winters; but if we plant in such places, and under such conditions as cause late growths and succulent unripened wood, then we may expect serious injury from the first severe frost that sets in. Formerly Conifers were planted in confined, sheltered situations, which caused late growths and unripened wood, which the first severe frost invariably injured. These matters are now better understood, but still there is always a desire to see trees grow away freely and vigorously, and sometimes people are tempted to plant in circumstances favourable to rapid strong growth in as we cannot expect the hot weather always to ripen such growth, it is much better to be content with moderate growth, well matured. *M. Saul, Stourton, Yorkshire.*

Grafted Potatos.—When last I wrote to you upon this topic, I believed Potato grafting to be all "leather bottel;" but I am neither afraid nor ashamed to confess that my views on the subject are now somewhat altered, and that experience has convinced me that changes are produced in the Potato by means of grafting, thus showing physical connection between the scion and the stock, but whether these changes are likely to prove beneficial or otherwise time alone can show. My conversion began when, last August, I paid a visit to that persevering apostle of the Potato grafting theory, Mr. R. Fenn, of Woodstock, who pointed out to me such certain differences and divergences of character produced by grafting that I at once threw up the sponge and cried "peccavi." But Mr. Fenn meant that I should become well grounded in my new faith, and to this intent he sent hither to me, that I might grow them under my own eyes, some 12 tubers or so each of five grafted kinds that were originally worked in 1869, consequently this is the third year of trial. All the sets were large and plump, and very equal in started growth and appearance, and were planted in two lines side by side, so as to bring the respective kinds into close comparison. The kinds worked originally were Lapstone Onwards, Yorkshire Hero, Milky White, and Fluke—several tubers of each of these kinds being also sent to make the test of growth and character more perfect. The whole were planted in the first week in May, and the notes taken of their growth on June 3 and 17 respectively will tell their own tale. 1. Earliness in growth of grafted sets are Yorkshire Hero in Onwards, having Lapstone foliage a shade lighter than Yorkshire Hero; through the ground as early as Onwards and several days before Hero. A further comparison on June 17 showed that the leafage of the grafted was narrower and more pointed than that of the parent Hero. 2. Yorkshire Hero grafted into Fluke showed a growth about equal to Hero, and with no special divergence. 3. Onwards in Yorkshire Hero presents a marked change of character, the growth on June 3 was not only several days behind Onwards, but on June 17 it is made apparent that the haulm is not only not more than one-half the height of the parent, but also that it is very short-jointed, leafage about the same. 4. Milky White, grafted into Yorkshire Hero on June 3, was in growth nearly as early as Milky White; and after comparison on June 17 shows that the leafage is smaller than is that of Milky White, and that the haulm in its growth exhibits that upright character so peculiar to the Lapstone tribe. 5. Milky White, grafted into Fluke June 3, about even in growth with the Fluke, June 17 showed a haulm less robust than either parent, and having an intermediate shade of green also. These are my latest observations, and I doubt if I shall find any other special peculiarities until the time of maturation arrives. Any differences that may be observable in the tubers shall also be carefully noted. *Alex. Dean, Bedford.*

Horticultural Boilers.—Many of your readers have been misled by the expression, turning the flow into the return, and it will be well, I think, in reference to the sketch accompanying Mr. Cannell's letter, that the pipe rising from the top of the boiler is (as it must always be) the flow in both cases, the only difference being, that in one case, that on the left hand side, the water rises to its highest point soon after leaving the boiler; and that on the right hand side, it gradually rises to its highest point, and then descends quickly into the boiler by the return-pipe. I had a short and rather hurried conversation with Mr. Cannell at Woolwich, and quite agree with him in what he says to a certain point. He does assert, in my opinion, errs in the opposite extreme, and impedes the circulation nearly as much by making the water rise continuously through too many yards of pipe, as those do who make the highest point on the flow-pipe too near the boiler. The whole motive-power of the horticultural boiler is due to the difference of weight between equal volumes of water at different temperatures. As every one knows, water when heated is lighter than cold water, because under the action of heat it expands; but it is not generally known that the difference in the rate of expansion is greater the nearer the water approaches the boiling point; thus 1000 parts of water at boiling point when cooled 36°, or at a temperature of 176°, occupy only the bulk of 986 parts. When cooled 144° F. below boiling, or at 68°, these 1000 parts will have become 960 in bulk, that is, it is reduced $\frac{26}{1000}$, while losing 36° of heat, and $\frac{26}{960}$, while losing the next 108° of heat, the difference in contraction being twice as rapid during the loss of the first 36° as it is while losing the next 36°. Mr. Cannell is quite right, therefore, when he says it is a quick circulation to have the flow and return pipes nearly equal in point of temperature, and the higher that temperature is maintained the more perfect is the command that the boiler has over the system of water in circulation, though it is not precisely so much an object to have the temperature of pipes too high. Any person who has ever studied the laws of radiation of heat will know that Mr. Fish (p. 710) is wrong when he says that it is a proof of rapid circulation to find the return much colder than the flow. Heat radiates off equally in every direction, and under similar circumstances each foot of piping will radiate off the same amount of heat from the water in the pipes during equal periods of time. The rapidity with which the water flows through the pipes will not in any way affect the amount of radiation from the pipes, but the greater the motion through the pipes the colder the water will be on its return to the boiler, because the iron pipes, acting as conductors of heat, have conducted so much more heat away from it in proportion to the time it has been in the pipes; the only difference being, that it parts with its heat more rapidly the greater the difference between the heat of the water and the heat of the house in which the pipes are placed. The

reason, I think, Mr. Cannell has erred in making his pipes continue to rise too far is this:—Supposing the water to leave the boiler, we will say, at 180°, and to return at 120°, after passing through 300 feet of piping, it will have cooled 60°, or 1° on an average for every 5 feet of piping. The specific gravity of the water has gone on increasing as the water has contracted by cooling in about the ratio, roughly at those temperatures, of .980 to .960, so that the difference of the water at the last is not to rise but to fall back, and so impede the circulation. It is far better to make the pipes rise gradually till they reach a point half way of the total length of pipes, and then gradually to fall again till they reach the boiler. It is better to avoid confusion in the meaning of words, not to call the actual junctions at the top and bottom of the boiler the flow and the return, and to consider the rest of the pipes merely as so many yards of pipe to be heated, or to convey the heated water. Many persons make a great mistake in thinking that the pressure of water in the pipes has anything to do with the motive-power. The water in the old system of boiler and pipes is in a state of equilibrium or rest before the heat is applied by the fire at the boiler. When the heat is applied, the water in the boiler gradually expands and rises as its specific gravity becomes less, and other water supplies its place below. "A Practical Haud," p. 712, is wrong if he thinks, because the bottom of Mr. Cannell's boiler is hottest, that consequently the water there is hotter than the water at the top of the boiler, and in consequence the latter water would be to rise up the return. As water must rise when heated, and as the return is at the bottom, it cannot, after once it begins to rise in the boiler, find its way again into the return, but as it continues to rise so it acquires additional heat both by convection and also by direct conduction from the inner superficies of the boiler; and will continue to acquire additional heat so long as the temperature of the heated air in the flues of the boiler is greater than that of the water. I am not going to say much on the merits or demerits of Mr. Cannell's boiler, I think it is a good one in its way, but it does not seem in my mind to encourage the heat which might be given to the outside of the boiler, and also in the drawings the connecting pipes are too small. Too many persons consider that water in horticultural boilers is heated by convection only, just as water is boiled in a pot, not considering that in a proper boiler forgetting that the water in a horticultural boiler is always in a state of motion, that colder water comes in at the return and rises hotter through the flow, and during its passage through the boiler is continuously impinging on the iron sides of the boiler, and will obtain heat by direct conduction from the iron, whether that heat is transmitted by vertical or horizontal flues on the upper or under surface of the boiler; in short, in whatever way you can heat the iron sides of the boiler, and the more thoroughly you can surround it with flues, the greater the heating effect, and the more thoroughly will the boiler do its work. Again, it ought to be borne in mind, that as the whole circulation in boilers depends on the difference of the specific gravity of water, under different temperatures, the motive-power is by no means great, so that no obstruction should be put in the circulation, by using small pipes as junctions to the boilers, or by sudden bends, such as going up and down under pathways, or again by running long lengths of pipe continuously at the same level. Pipes do not vary in the measure of their capacity in the direct ratio of their diameter, or radius, but as the squares of their radius; thus, a 4-inch pipe does not contain only twice as much water as a 2-inch, but four times as much water; and if an inch pipe is used as a junction into the boiler, and 4-inch pipes used in the heating system, the water has to pass 16 times as quickly through the inch pipe as through the 4-inch. As a rule, whatever sized pipes are used to heat the houses, the same sizes ought to be used for all bends, junctions, &c., and no unnecessary impediment should be placed in the circulation. I do not know what Mr. Fish means when he says he is not prepared to give up specific gravity, which costs nothing, in favour of inertia, which costs so much. Does Mr. Fish reflect that the difference in specific gravity cannot be produced without this costly caloric? It is the common mistake of confusing cause and effect. Motion in hot-water pipes is caused by the difference of the effect of specific gravity, which difference of specific gravity is due to the expansive powers of heat. The boiler which heats most rapidly will not necessarily cool most rapidly; that boiler which secures the most perfect and rapid circulation, and in which the difference between the heat of the flow and return is least, must be the best for many purposes, because, if (as Mr. Fish wishes to make out) a hot flow and a cold return is a proof of rapid circulation, the water when it returns to the boiler must be acted on by a very hot fire, if it is to be heated to this difference between flow and return during this its rapid transit through the boiler; whereas if the circulation is good and the difference between flow and return is small, less fire is required to bring the water again up to the heat it has lost, and the slighter the difference between flow and return the better will be the boiler for night purposes. A boiler which can be heated quickly will full force of fire will keep up its heat best with a small amount, the great secret of success being to have a boiler large enough to work the pipes with a small amount of fuel. A cheap and small boiler is generally the most costly in the end. I suppose nearly every one has his pet boiler. I like Ormson's concentric and convoluted boilers when properly set, and one of the best cheap boilers is one which I have recently put up for a friend, and which does its work perfectly—Jones's "Double L" saddle boiler. The first boiler I ever set, I set on the principle which I now advocate, of making the highest point of the pipes half-way in the length of the pipes; the next boiler built on the same principle, always making the pipes rise gradually about 2 to 3 inches in 10 feet, sometimes more. I see nothing consequently very novel in Mr. Cannell's plan, except that of making the water rise up to the furthest point, which, as I have before tried to explain, is a mistake; and in his sketch, unless he surrounds his boiler with a flue, he is wasting a great amount of heat from the external radiating surface of his boiler. *C. P. Peach.*

A Visit to the Gardens of Manley Hall.—It was my good fortune to be in Manchester during the Whit-week exhibition, and hearing that the famed garden of S. Mendel, Esq., could be seen by any one connected with the profession, I availed myself of this opportunity to see what is undoubtedly one of the finest gardens in the three kingdoms; and it occurred to me the few notes made during my visit might prove interesting to those who have not had the advantage of a personal inspection. In the first place there are 44 houses, with an area of 75,000 feet of glass. Entering the conservatory from a charming light which the view before is what I consider the *beau-idéal* of what a conservatory should be,—large ornamental-leaved plants, such as Araucarias, Tree Ferns, Aralias, Dracænas, Yuccas, &c., are planted at intervals, and make a basis for the general arrangement. Between these are placed various flowering plants, which are brought from the other houses, and which are removed as their beauties fade. The adjoining house is called the stove fernery, and here a magnificent sight meets the view—deep rocky chasms and large boulders of rock, beautifully covered with Ferns and Lycopods in great variety, with water trickling over and about them, the whole relieved by Ferns of larger growth, which prevent it having too rough or rugged an appearance, altogether quite a fairy scene Amongst the finest plants thus placed were beautiful examples of Cyrtodeira chontalensis, and Philodendrons, Alsophila contaminans, Dicksonia antarctica, and Todea africana; a few Palms also were luxuriating here, such as Seaforthia elegans, Areca lutescens and Baueri, Caryota ureus, with its large bipinnate leaves, and the beautiful fan-leaved Thrinax elegans. In another house, devoted to ornamental-foliaged plants, were many grand specimens, the most striking of which were a pair of Anthurium Scherzerianum, with upwards of 30 of its curious flower-spathes on each plant, the spathes large, deep brilliant scarlet, and measuring nearly 6 inches in length. Another fine Anthurium, called acaule, is far too little grown, its large, bold, dark green leaves, making a noble ornament; and, as it can be used with advantage in the subtropical garden, it is doubly valuable. Alocasia intermedia, one of the Messrs. Veitch's hybrids, was in grand condition, with beautiful green leaves and stalks upwards of 4 feet high. Another Alocasia, for which we are indebted to the energy of Messrs. Low (A. metallica), was represented by a superb plant upwards of 8 feet in diameter, its large deep bronzy leaves contrasting beautifully with the variety of its numerous rhizoa variegata and A. Jenningsii, Caladiums, Anthuriums, and various Marantas; but the crowning plants of this house were three Palms of surpassing beauty: first a glorious Cocos Wedelliana, and with some 30 of its beautifully arched, pinnate, dark green leaves, which were about 5 feet in length, giving it a most graceful Palm at present in cultivation; next, a very fine grown plant of Phœnicophorium sechellarum, bearing 10 leaves, which were in the blade alone 5 feet in length; and a very fine Geonoma Seemanni, with its bold, bushy, dark-green, spreading leaves. Here also is a house devoted to the genus Gymnogramma; it was, however, a little too early in the season to see this at its best, but the hundreds of young fronds just unfolding gave promise that these alone would amply repay a visit in the course of a month or two. Next came a house devoted to miscellaneous plants, remarkable for the beauty of their leaves. Here, amongst good examples of Dasylirions, Yuccas, Dracænas, and Cordylines, was a truly grand plant of Phormium tenax variegata, measuring about 14 feet in diameter, with the broad leaves beautifully variegated, and the remains of an enormous flower-spike which it produced last year. Gleichenias, which are looked upon as the aristocrats of the Filices, have here a house devoted to their culture, and all the kinds in cultivation are to be found in this collection, among them some extremely well-grown plants, such as G. speluncæ, 10 feet diameter, 6 feet high; G. flabellata, 8 feet diameter, 6 feet high; G. dichotoma, 8 feet diameter; G. rupestris, 6 feet diameter; and many others, all of which were in the most robust health, and a sight of which would fill the heart of any lover of Ferns with rapture. Amongst the many fine greenhouse flowering plants the following were blooming most profusely:—Erica Massoni major, geminiflora superba, tricolor rosea, eximia superba, and a very fine Cavendishiana, in which a pair of thrushes had built a nest and reared a brood of four young ones this spring. Elandfordia nobilis was also very fine, although it had been flowering some two months, a fact which speaks volumes for its decorative properties. Several plants of Darwinia tulipifera and fuchsioides were in superb health and denisely flowered. A grand plant of Acrophyllum venosum, with flowers and foliage to the pot, measuring 5½ feet in height and 5 feet in diameter, but which showed no sign of being worn out, although of such elephantine proportions. An immense plant of Dracophyllum gracile was also charming, with hundreds of its pure white heads of bloom contrasting beautifully with the rich colours of the many finely grown and flowered Azaleas by which they were surrounded, but these I was just a few days too late to see in all their beauty. Again we pass into some warm houses, and really it seems that the collection of plants is inexhaustible; here were some very fine plants of Crotons, such as manumum, Veitchii, and interruptum, besides richly coloured examples of the commoner kinds; a magnificent Cycas revoluta, and the curious but rarely seen Vriesia Glazouiana in flower. Several varieties of Pandanus, whose peculiar spiral growth render them very attractive, were growing vigorously, as also was a very fine collection of all the best Dracænas in cultivation, including the curious Darlingtonia californica, all showing signs of being handled by a thorough master of his art; the new and beautiful Cochliostema Jacobianum, and many grand Ixoras, amongst which was a specimen of I. coccinea, with a prodigious mass of bloom. Allamandas and Dipladenias were lending a profusion of their large trumpet-shaped flowers to complete the grand effect of this glorious display. Achimenes and Gloxinias are grown here largely, and, I need scarcely say, they are grown well; they are lovely plants for decoration or for cutting for vases, and I sincerely hope they will not be discarded from our stoves, although I have sometimes thought there is a growing tendency to neglect them. Leaving these, we turn to the Orchids, which are such a speciality at Manley Hall, and, taken as a whole, they seem to be growing well, although some still retain the evidence of having been in bad health. The collection comprises, as far as I could see, the majority of the best species and varieties, the following of which were blooming during my visit:—Lælia majalis, bearing three spikes; a fine variety of Cattleya dianæa Backhouseana, a superb plant, with 16 of its beautiful yellow and creamy-white flowers fully expanded; a fine variety of Cattleya Mossiæ, bearing 16 flowers, known amongst Orchid growers as the Manley Hall variety; it has large and broad sepals and petals, and a rich purple-purple lip; Cypripedium barbatum-glossum hastilabium, a fine plant with extra large flowers; many plants and numerous varieties of the charming Barkeria spectabilis; Oncidium crispum, bearing large branching spikes and an immense quantity of its large flowers; Oncidium Lanceanum, Cattleyanum ampullaceum, with eight fine spikes; a grand plant of Epidendrum prismatocarpum, with fine long spikes of its curious and sweet scented blooms; the old but very showy Promenæa citrina, Trichopilia crispa, Anguloa uniflora superba and Clowesii, the latter with six flowers; a grand and beautiful Cypripedium Lawrenceanum, Miltonia festiva, Dendrobium formosum giganteum, a grand specimen of Vanda teres, literally covered with its large rich rosy blossoms; Aerides crispum, Oncidium Lanceanum, Kenauthera Lowii, bearing two long spikes, but with a paucity of flowers, so that the two flowers nearest the base of the spike are yellow instead of cinnamon-brown; Dendrobium M'Carthiæ (of which there are several good plants, one of which had 26 of its superb cherry-coloured flowers fully expanded; a superb variety of the rare Dendrobium Wardianum, and smaller but fine plants of Dendrobium Paxtoni; a nice plant of Phalænopsis Luddemanniana, bearing upwards of 40 blooms; Saccolabium guttatum, a plant which bids fair to be a giant in its family, it has 13 growths, and although not well established, had produced six good sprays; a good Thunbergia, with six good heads of flowers; Vanda tricolor Leopoldi, which is one of the very best, its rich deep violet-purple lip rendering it most distinct; Epidendrum vitellinum majus; and some fine Cypripediums, amongst which were caricinum, Stonei, and barbatum grandiflorum, the latter of which was shown as one as specialities for winter blooming, the Calanthes Veitchii and vestita (both red and yellow eye), hold first rank, for the large specimen pots of these may be counted by dozens, and are said to yield a fabulous quantity of blossom, which can be used for vases or for bouquet making, and always with a pleasing effect. The last but not the least house which I shall notice is the tropical and temperate fernery, the former being 70 feet long, 26 broad, and 17 high; and the latter 96 feet long, and the same breadth and height as the tropical one. They are separated by a glass partition, and the interior has been most artistically laid out with large and massive boulders of rock, and winding walks and small lakes, in which aquatics thrive beautifully. Between the crevices, and in the niches, Ferns, Lycopods, and many Mosses are growing luxuriantly; and larger plants, such as Ferns, variegated Begonias, and coloured-leaved Dracænas, occupy positions more suitable to their proportion. Large specimens, also, stand in various places throughout the place, and comprise splendid examples of Cyathea medullaris and princeps,

Angiopteris evecta, Sciadocalyx pulcher, Theophrasta imperialis, and Alocasia violacea, &c. Before passing into the temperate fernery one is introduced to a little rugged rocky recess called the Todea and Filmy Fern house, which although but recently established bids fair to become the gem of the establishment. It has a beautiful little waterfall, and in the water which runs along the floor are large stepping-stones, so that one may easily imagine they are really in a rich Fern valley in a state of Nature. In and about the tufa rocks, of which this is composed, are fine specimens of the filmy fronded Todeas, such as superba, pellucida, pellucida compacta, and Fraseri, as well as numerous Hymenophyllums and Trichomanes, the gems of which are certainly T. auriculatum and T. Laschnathianum. The larger plants occupying prominent positions are a good Marattia Cooperi and Thyrsopteris elegans, Asplenium myriophyllum, Cyathea dealbata and Dicksonia squarrosa. The cool fernery is entered by crossing a rustic bridge over a small stream, in the vicinity of which are fine examples of Todeas, Trichomanes reniforme, radicans and pyxidiferum, Jungermannias, Marchantias, and a great variety of British Mosses clothe the masses of rock, from amongst which many seedling Ferns have sprung, forming beautiful groups. In various recesses are good plants of Hymenophyllum caudiculatum, crispatum, sericinosum, demissum, multifidum, tunbridgense, and many others; and among the large specimens are many Dicksonia antarctica and squarrosa, Cyathea dealbata and medullaris, Alsophila australis and excelsa, and the largest plant of Asplenium caudatum I ever saw; it has a stem, and its long fronds are beautifully arched, and fall gracefully, looking very much like a broad-leaved Weeping Willow. Of the forcing houses and kitchen garden I shall say nothing more than that the latter in particular was in the highest state of cultivation I ever saw—the crops good, and not a weed of any description to be seen; in fact, the whole of this privately established is in a first-class condition, and reflects the greatest credit upon Mr. Petch for the skilful and systematic manner in which everything is done. Everything is neat, clean, and polished, indoors and out, from the tool sheds and stokehole to the conservatory and fernery; indeed, no matter where one looks, every place is fit for inspection, even by the most severe disciplinarian. *W. H. G.*

Societies.

Royal Horticultural, at Nottingham.

June 27 to July 1.—The first independent visit of the Royal Horticultural Society to the provinces, so far as we can judge up to the time at which we write, must be looked upon in no other light than as a decided success; for we are quite certain in our own minds that, with the notable exception of the famous International Exhibition of 1866, there has never been held such a fine one as that which commenced with great *éclat* on Tuesday and concludes to-day, in the ancient and picturesque town of Nottingham. The weather on Tuesday was as brilliant as could be desired, and the ceremony attending the exhibition brought together a brilliant crowd of visitors. A procession of the Mayor, the Sheriff, the Council of the Society, accompanied by a guard of honour of the famous Robin Hood Rifles, and the band of that corps, was formed at the Castle Lodge, near to the show ground, at a quarter to 1 o'clock. The mayor and other local officials took off their robes of office, and the procession slowly defiled into the show ground, and marched to the lawn in front of the archery pavilion. The Robin Hoods were drawn up in line on a slight eminence 50 yards away, and a ring was formed, the spectators standing quietly around.

The Mayor then read the following address:—Colonel Scott, my Lords and Gentlemen, Members of the Council of the Royal Horticultural Society,—It is my pleasure and privilege, as Mayor of the borough of Nottingham, to offer you, in the name of the inhabitants of this district, a hearty welcome on the occasion of your exhibition in this park. The horticultural pursuits of our manufacturers have been the means of creating and fostering amongst our artisans a love of horticulture, as in its principal branch, periods of work, followed by corresponding periods of leisure, have furnished them with opportunities of cultivating this taste. The result has been that in the immediate neighbourhood of Nottingham more than 10,000 gardens of small size are held principally by the workmen of the borough and suburbs, who find during the cessation of their toil such a relaxation that is at once invigorating to the body and elevating to the mind. We trust that your meeting in Nottingham Park may strengthen and elevate this taste still further, and while the Society will be benefited pecuniarily, we may gain a corresponding advantage by serving and trying to emulate the brilliant specimens of horticultural excellence which your Society's influence collects. I trust you will open an exhibition brilliant in character and satisfactory to us all in its results.

Colonel Scott, in reply, said: Worshipful sir, and ladies and gentlemen—In the name of the Council of the Royal Horticultural Society I thank you most sincerely for the kind welcome which you have given us to-day. You have received us with such great honour, that we cannot suppose it is paid to us as individuals, but only because we represent the principle of those numerous societies which have of late years sprung up in this country, and which give so much delight and satisfaction to all engaged in gardening. When first the idea of holding country shows was mooted, we feared to make the attempt single-handed, and for the last four years we have supposed it unwise to separate ourselves from the Royal Agricultural Society; this year, however, we decided to adopt a bolder policy, and determined to do what we could of our own strength. Amongst the towns which invited us for this year was the town of Nottingham, and I assure you that we did not hesitate for one moment to accept the offer. It is well known that whatever Nottingham undertakes she carries out with vigour and determination. Whether it is manufactures or horticulture it is the same, and I may perhaps even venture to say that in politics you show the same vigour. I believe that in horticultural matters some of your "lambs" become something like lions. I have noticed that among your allotment gardens—which are so well managed, and make such a noise in the world —the chief man is a Knight of St. Anne's, and the best budder of roses a General Jack. All these symptoms are indications of vigour, which we thought would lead to success if came amongst you; and, from what I have seen again, I believe our success will be great, and the weather is glorious. I regret that the task of opening the exhibition has not fallen into worthier hands. His Grace the Duke of Buccleuch, the President of our Society, would have been present to-day, but he is prevented by his military duties. The Royal Prince connected with our Society, whose visit we anticipated with so much satisfaction, has been commanded by her Majesty to attend a State ball at Coburg; and Mr. Wilson Saunders, one of our most honoured members, and, as we consider him, the father of horticulture, is too much indisposed to attend. I am quite certain, however, that both of these would have taken part in this respect, you will more than make up for any deficiences on our part. From the vigour displayed by Mr. Lowe, who, we are glad, is now a member of the Council, and from the conviction that he is about to be made the name of the Duke of Buccleuch and the Royal Horticultural Society I have great pleasure in declaring it open.

Following this announcement there was a general rush of the assembly, the immense marquee, which had been laid out as a model garden, and which contained as fine a lot of plants as could well be brought together. The general arrangement and the principal features of the display will be given next week, as will be also describe from the annexed views and plan of the ground.

Comiog now to more detailed particulars, we must commence with the *Stove and Greenhouse Plants*, which were a very prominent feature of the large marquee. In the first-class for 20, distinct, in 12-inch pots, the competition was confined to Messrs. Jackson & Son, Kingston, and Mrs. Pope & Sons, Nottingham, Mr. Sandiford and the prizes being awarded in the order named. Nothing remarkable was shown in either group, the former of which consisted of young half specimens, fairly grown, of Ixoras, Dracænas, Dipladenias, &c. The best of the most notable examples from the Messrs. Cole being a nicely flowered plant of the rarely seen though very beautiful Roella ciliata, and a similar one of Ixora amboinensis. The best 9 plants, in the amateurs' class, fell to Mr. T. Baines, gr. to H. L. Micholls, Esq., Southgate House, Southgate, and a very good lot they were, though certainly not so fine as the collection which he staged at the Crystal Palace at the first spring show. His most perfect specimens were those of Dipladenia amabilis, well grown and fairly flowered, these being of excellent colour; a capital plant of Dracophyllum gracile, well flowered, and the Dipladenias splendidly grown and trained and immensely attractive; Ixora coccinea, well bloomed and large; Erica Cavendishiana, E. æmula, a fine example of Darwinia tulipifera, and a grandly flowered Allamanda Hendersoni. Mrs. Pope & Sons, Bolton, showed their collection containing a very good example of Ixora salicifolia, well grown and well bloomed, and a very nice Dipladenia amabilis, &c. In the amateurs' class for 12 there was a fine collection by Mr. J. Douglas, Great Hill, Timperley, Cheshire, who had, amongst others, a very good Ixora coccinea, and Clerodendron Balfouriauum, a healthy plant, well flowered. In the 24 prize class Dipladenia amabilis, &c. In the 24 prize class Mr. W. Worswick, Esq., was a well-finished specimen of Rhynchospermum jasminoides. The special prize, offered by G. E. Paget, Esq., for the best specimen stove flowering plant, also won by Mr. Baines, with a wonderfully fine specimen of Ixora javanica, 5 feet high, and 3 feet through, well clothed with foliage to the pot, and superbly bloomed; a remarkably well shown Bougainvillea glabra, from Mr. W. Bolton, coming 2nd. Specimens of Anthurium Scherzerianum were staged by Mr. Baines and Mr. B. S. Williams, in competition for the prizes given by C. Paget, Esq., Ruddington Grange; the first going to the former, with specimens from Messrs. Jackson & Son, who had, amongst others, E. jasminiflora alba, E. tricolor coronata, E. Vernonii, E. tricolor speciosa, E. Paxtoni, and E. depressa, &c., in the collection. What is termed a lot came from Messrs. Cole & Son, whose collection, though uneven in size, had much merit to recommend them. The finest single specimen in the show was a wonderfully fine one of E. obbata, in very healthy, well perfectly bloomed, and staged by Mr. Baines to compete for the prize given by C. Seeley, Esq., M.P., Brookhill Hall; Messrs. Jackson coming in 2nd with a very good example of Victoria regia. The prize for 9 stove and greenhouse plants, given by Mr. B. Walker, Lenton, was won by Mr. J. Stevenson with a very good group, including very fine examples of Allamanda Hendersoni, and Dipladenia, both well flowered and of good colour, and a remarkably fine plant of Ixora alba, &c. The 2d prize, given by the local committee, was taken by Mr. J. Bolton, who had a first-rate specimen of the old Cassia corymbosa, and another of the beautiful scarlet Clerodendron fallax.

Fine-foliaged Plants, including *Ferns*, were very numerously contributed, and of excellent merit too, more especially the Ferns, which were altogether much better than we have seen at any exhibition for a long time. The best four Dracænas, or Cordylines, came from Mr. B. S. Williams, as well as the best collection of 9 fine-foliaged or variegated plants amongst nurserymen, which contained remarkably handsome specimens of Palms, Cycas revoluta, Encephalartos latifrons, probably the finest specimen in the country, a good example of Pandanus elegantissimus, and the same of Cordyline indivisa, &c. Next to Mr. Williams came Mr. W. E. Dixon, showing, amongst others, one of the finest specimens of Phormium tenax variegata we have ever seen, a handsome plant of Cyathea dealbata, and a specimen of Gleichenia Mendelii, about 5 feet through. Messrs. Bell & Thorpe were a good 3d. In the corresponding class for amateurs, Mr. Baines again stood 1st, having large handsome fronded specimens of Stevensonia grandifolia, Croton variegatum, Dasylirion acrotrichum, &c. Mr. W. Cruickshank, gr. to Lord Belper, Kingston Hall, was 2d, with an excellent group, comprising some grand tree Ferns, a splendid specimen of Phormium tenax, Ferns, a splendid specimen of Phormium tenax, a gigantic plant of Alocasia gigantea, a remarkably good A. metallica, and a beautifully coloured Croton angustifolium, &c. Mr. J. Woodfield, gr. to J. S. Foljambe, Esq., was 3d with notable examples of Sanchezia nobilis variegata, a fine bush about 5 feet through, suffering a little through the cold, and Dieffenbachia maculata, &c. The best specimen Croton, one of C. angustifolium, about 5 feet high and 4 feet through, splendid both in foliage and colour, came from Mr. Baines; the next best being a large, well grown and coloured C. variegatum, from Mr. J. Stevenson; Mr. J. Bolton being 3d with a good C. angustifolium. Mr. J. Woodfield, Osberton, sent a beautiful pyramidal trained plant, about 8 feet high and received an extra prize. From Mr. B. S. Williams came the best 12 Ferns, grand examples of Gleichenia burmianum, Areca lutescens, Latania borbonica, Thrinax elegans, Phœnix sylvestris, &c.; Messrs. Bell & Thorpe being 2d with smaller but well furnished specimens of Dicksonia Baueri, Davallia pulchra, &c., and Messrs. G. and W. Yates, Manchester, 3d. Mr. Baines took the prize given by Henry Smith Wright, Esq., Lenton Hall, with a grand example of Sarracenia Drummondii, about 3 feet high, Mr. Stevenson being 2d with a grand Alocasia Lowii, about 3 feet high, and finely developed. Mr. Baines also staged the best 3 Pitcher plants, as well as the best single specimen; Mr. B. S. Williams being 2d in the latter class.

Orchids were not by any means so numerous or so good as might have been expected. Mr. B. S. Williams took the 1st prize for 9 and 6 in the former class with Oncidium incurvum, a nice plant with 5 spikes, Cypripedium barbatum, Cypripedium superbiens, with 16 fine flowers; and a nice example of Angulua Clowesii, &c.; and in the latter with Sobralia macrantha, a large, very healthy plant, sparsely flowered, Saccolabium Calthæ, Cypripedium superbiens, and Lycaste Skinneri. Messrs. Rollisson & Sons were 2d in this class, with, amongst others, a plant of the rarely seen Brassia Wrayii; while in the former the 2d and 3d awards were taken by Messrs. J. Broome & Co., Fairfield Nursery, Manchester, and Mr. W. E. Dixon. The amateurs were only represented by Mr. E. Mitchell and Mr. J. Stevenson.

Exotic Ferns were remarkably well shown. The best 6 amongst came from Mr. J. Stevenson, amongst which were a very large and handsome specimen of Gleichenia semivestita, another of G. flabellata, and capital examples of Leptopteris superba, Acrophorus nervosus, and Lindsæa cultrata, &c. The best 24 prize was taken by Mr. J. E. Mappiebeck, Moseley, near Birmingham, with a collection containing nice specimens of Neottopteris australasica, Dicksonia squarrosa, and Osbeckiana, and in the collection of 12 hardy exotic kinds, contributed by Messrs. R. Edwards & Son, were very fine plants of Struthiopteris pennsylvanica and S. germanica. Mr. Baines took the prizes given by H. Sherbrooke Cox, Esq., Nottingham, for a single fern, a plant of Gleichenia rupestris, over 4 feet in height and the same through, an exceedingly well-grown specimen; and Mr. G. Daniells, gr. to A. M. Mundy, Esq., came 2d with a fine Gymnogramma peruviana and G. chrysophylla. The best specimen of Adiantum was a handsome plant of A. farleyense, shown by Mr. T. Allsop, gr. to C. S. T. B. Reynardson, Esq., Holywell Hall; Mr. Cruickshank being placed with a good specimen of A. tenerum. In the amateurs' class for 12, Mr. T. M. Shuttleworth, Golden Hill, Preston, came first with Cyathea princeps, very handsome, beautiful large specimens of Alsophila australis, Schidea, Lomaria gibba, Todea superba, Gleichenia dichotoma, Todea superba, &c.; Mr. Baines being 2d, and Mr. Bolton 3d. Mr. J. Bolton had the best 6 Lycopodiums, and Mr. B. S. Williams the best pair of Tree Ferns. In the amateurs' class Mr. Baines took the last-named exhibitor was 1st again, with handsome specimens of Cyathea, Cibotiums, Gleichenias, Todeas, &c. Mr. G. Cooper, Derby, being 2d, Mr. W. E. Dixon 3d, and Messrs. Bell 4th. Twelve distinct Maidenhair Ferns were contributed by Mr. T. M. Shuttleworth and Messrs. Bell & Thorpe, in the former of whose collection was a pretty pair of Adiantum assimile.

Of *British Ferns*, a magnificent collection was exhibited by E. J. Lowe, Esq., F.R.S. In the nurserymen's class for 12, Messrs. R. Edwards & Son, Nottingham, came in 1st, and the best 10 new varieties not new in commerce were shown by Mr. Mapplebeck; Mr. F. Thompson, gr. to T. Charlesworth, Esq., The Hollow, Leicester, coming in 2d.

A collection of subtropical plants, suitable for the summer decoration of gardens, consisting of medium-sized Palms, Dracænas, Musas, Azaleas, Beaucarneas, and others, was contributed by Mr. B. S. Williams, Messrs. Lane & Son, Berkhampstead, sent a most admired group of neatly trained pyramidal plants of Yiex, which are exceedingly useful for decorating halls and corridors in the summer time, and even the conservatory in winter. Mr. B. S. Williams also exhibited 6 good specimens of Agaves, especially A. Victoriæ major, A. betancurtha, A. geminiflora, and A. americana variegata, &c., for which he was awarded the 1st prize; and the best collection of hardy and half-hardy variegated and ornamental foliaged plants, which included some fine young Palms, Yuccas, Conifers, Eurya latifolia, and Euonymus alboinarginata, and E. japonica aureo-variegata—both very handsome, and useful subjects for the flower garden. Messrs. Barron & Son, Borrowash Nurseries, Elvaston,

FIG. 172.—INTERIOR OF "MODEL GARDEN" AT THE NOTTINGHAM SHOW. (Looking South).

exhibited a very excellent assortment of hardy trees and shrubs, for which they received the 1st prize. For four specimens of Lilium auratum, Mr. Turner was 1st, with fine plants, Messrs. Rollisson & Sons coming in 2d, and Messrs. Yates 3d. The only exhibitor of 6 Pyrethrums was Mr. B. S. Williams, and to him the 1st prize was awarded. Messrs. Veitch & Sons had a remarkably fine group of *New* and interesting *Plants* which was much admired, they also took the first prize for 6 new plants, with a beautiful specimen of the elegant Paullinia thalictrifolia, and Dieffenbachia Bausei, one of the handsomest of its class, Dracæna amabilis, Aralia Veitchii, Croton Wisemani, and a nice little plant of the beautiful Todea Wilkesiana. In their large group were many Orchids, new Dracænas, Marantas, Dieffenbachias, Palms, some beautiful Darlingtonias (see p. 825) and Sarmentas, a collection of succulent plants, and a charming specimen of the handsome Davallia Mooreana, figured at p. 964, 1869.

In that department of the exhibition including the classes for *Florists' Flowers*—a designation which, as the Rev. S. R. Hole justly asserts, denotes a little restrictiveness that is not true in fact, but which it is expedient to retain for the sake of convenience—some of the points were rather weak. Fuchsias, for instance, were very inadequately represented; so indifferent were they in the amateurs' class for 6 varieties that one would not have been surprised if the leading prizes had not been awarded. Mr. Bolton, gr. to W. Warwick, Esq., Leicester, had the best group; and in the nurserymen's class for the same number, Mr. George Edward, York, staged very fairly grown and bloomed plants of Vesta, Avalanche, Encounter, Rose of Castile, Schiller, and Blue Beauty; and there was no other competitor. It is really too bad that Fuchsias were so poorly shown, seeing how easily they can be cultivated. Some fine young pyramidal plants would have filled up several places at the sides of the great tent that were occupied by small plants dwarfed almost to insignificance. The best 9 show Pelargoniums also came from Mr. George Edward, of good size, and trained after the usual fashion. They consisted of Beacon, Royal Albert, Desdemona, Clarissa, Virginie, Mary Hoyle, Lord Clyde, Pericles, and Charles Turner. Mr. Turner, Slough, had the next best group, consisting of nice young upright plants of about the second season's growth, that were beautifully bloomed, and comprised such fine new varieties as Regent, Eldorado, Sunshine, Magnificent, Emperor, Nabob, Lady of the Lake, Example, and Congress. The quality of the flowers borne on these small plants was something remarkable. The show Pelargoniums for amateurs

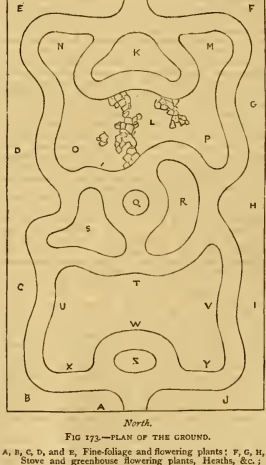

FIG 173.—PLAN OF THE GROUND.

A, B, C, D, and E, Fine-foliage and flowering plants; F, G, H, I, Stove and greenhouse flowering plants, Heaths, &c.; J, British Ferns; K, Pelargoniums, Lilies, &c.; L, Rockwork; M, N, Exotic Ferns; O and P, Orchids; Q, Fountain; R, Pelargoniums and Orchids; S, New plants (Veitch); T, New plants (Williams); U, V, W, X, and Y, Fine-foliage plants and exotic Ferns; Z, Group of British Ferns, &c.

were so indifferent that only a 3d prize was awarded Mr. T. Mitchell, gr. to Thomas Cross, Esq., Ruddington Hall, had the only 6 fancy Pelargoniums. They consisted of Marginata, Queen of the Ocean, Ann Page, Evening Star, Matilda, and Mr. Horner; they were fairly grown, and received the 1st prize. Mr. George Edwards had 6 nicely grown plants, and received the first prize in the open class, with Madame Sainton-Dolby, Juliet, Tormentor, Brightness, Zoe, and Ann Page. A 4th prize was awarded to Messrs. G. Small & Son, for some apologies for specimen plants. The Zonal Pelargoniums furnished by amateurs in class 17, were so indifferent that no 1st prize was awarded. H. Smith, Esq., Nottingham, received a 2d prize for six huge specimens, that might be 4 or 40 years of age. There was something better in the nurserymen's class for the same number, and here Messrs. Bell & Thorpe, Stratford-on-Avon, were first with the Queen of Beauties, John Thorpe, of a dull orange-red hue, Fairy Princess, Lord Derby, Indian Yellow, and Mrs. William Paul, very prettily flowered. Mr. George Edwards was second with Glow, Mrs. William Paul, Enchantress, Shirley Hibberd, Clipper, and Alphonse Karr; these bore excellent quality of flower, but were not well grown. Messrs. Bell & Thorpe had the best 6 double varieties, consisting of Delight, Marie Lemoine, Wilhelm Pfitzer, Miss Evelyn, Victor Lemoine, and Madame Lemoine; strongly grown, but not particularly well-bloomed plants. In fact, there was a marked falling off from the excellent quality of the double Pelargoniums shown at Oxford last year. Mr. F. Perkins, Leamington, was second, with Capitaine L'Hermitte, Madame M. Buckner, and four of the foregoing. Variegated Pelargoniums in the open class were of moderate quality. J. E. Mapplebeck, Esq., Woodfield, Birmingham, had the best, consisting of Miss Kingsbury, Flower of Spring, Silver Star, Queen of Queens, Stella variegata, and Oriana.

There was a considerable quantity of *Cut Flowers*, and they made a very effective display in the fruit and Rose tents. In class 39, for 24 bunches of cut flowers, each bunch distinct, Mrs. E. Cole & Sons, Withington, Manchester, were 1st with a very choice collection, comprising Succolabium Blumei Dayii, Allamanda grandiflora, and A. cathartica; Erica jubata rubra, E. Exquisite, E. Vernonii, E. ventricosa Bothwelliana, Dipladenia amabilis, Ixora coccinea, I. amboinensis, I. Colei, Phalænopsis grandiflora, Cypripedium Stonei, C. barbatum, Dipladenia crassinoda, Laelia purpurata, Oncidium leucochilum, and Bougainvillea glabra. Mr. J. Bolton, gr. to W. Worswich, Esq., was made equal 1st, his stand being

nicely set up, the bunches were backed with Maidenhair Fern, and rested on green Moss. Among his flowers were Cattleya Dowiana fallax, Stephanotis floribunda, Begonias, Pentas rosea, Plumbago capensis, Salvia patens, &c. Mr. F. Perkins, Leamington, was 2d, his stand containing Petunias, Kalosanthes coccinea, Bouvardia jasminoides, Tacsonia Van Volxemii, Statice purpurea, &c.

In the class for 24 bunches, Mr. D. Lumsden, The Gardens, Bloxholm Hall, Sleaford, was 1st with Sobralia macrantha, Aerides odoratum, Aphelexis macrantha purpurea, Stephanotis floribunda, Gloxinias, Brassia verrucosa, Cattleya Mossiæ, Calanthe vestitofalcata, Pimelea Headersoni, Erica ventricosa superba, Allamanda Henderson, and Æschmea fulgens. 2d, Mr. Peachey, gr. to H. E. Hill-Eley, Queendon, who had Dendrobium magnifica, Bougainvillea glabra, Dipladenia amabilis, Rhododendron fallax, &c. Mr. Bolton was 3d, and in his stand were some glorious blooms of Hibiscus sinensis, Stevensia elegans, Francisceas, &c. There was an excellent competition in this class, and it is a matter for surprise, inasmuch as it is educational in the matter of taste in elegant arrangement. The best 12 Pinks came from Mr. G. Turner, and consisted of Rev. Geo. Jeans, Marmion, Christabel, President, Dr. Maclean, Prince Frederick William, Eustace, Delicata, Attraction, Bertram, Lord Kirkcaldy, and a seedling. Mr. D. Pizzey, gr. to Sir E. Perry, Highgate, was 2d, with good flowers of Disdem, Lord Herbert, Victory, Peppy, Genevieve, and some of the foregoing. Mr. J. Taylor, Sneinton Road, Nottingham, was 3d. Messrs. G. Small & Son, Ilkeston, were 1st for 12 cut trusses of Pelargoniums, which comprised J. F. Nunn, Blue Bell, Hydrangea, Arthur Pearson, and others, the best part of the names being lost. Some very fine flowers were in this lot. Mr. Peachey was 2d, his varieties consisting Blue Bell, very fresh coloured; Mrs. William Paul, Hecla, Clipper, Charlotte Corday, Le Grand, and Violet Hill Nosegay. Mr. Turner also contributed a capital stand, which appeared to have been disqualified through containing 13 varieties. They were remarkably fine, and included some of the newer Continental varieties, such as Mons. Gibbard, Madame Hoste, pale Nosegay; Gambetta, very dark orange scarlet; Mons. Joinville, Wilhelm Wick, Mons. Ricul, George Sand, Victor Milo, La Tousaine, Marie Stuart, Marquis de Hufford, and Gladiator. The best 12 double Zonal Pelargoniums came from Mr. Thomas Laxton, Stamford, who had The Beacon, a seedling pink variety; Wilhelm Pfitzer, Victor Lemoine, very fine; Gloire de Nancy, The Marchioness, a seedling pink; Madame Lemoine, Victor Lemoine, Victoire, of very fine shade of violet, but does not expand well; Emille Lemoine, Madame Lemoine, and E. J. Lowe, vivid red, very distinct in colour, and as double as can be; quite as double as it is a single-flowered variety needed. 2d, Mr. F. Perkins—Madame de St. Jean, scarlet; Madame Rudolph Apell, deep pink; and Madame Michel Buckner, bright pale pink; in addition to some of the foregoing. Messrs. Hill, Bedford, and H. Cannell also competed, the latter staging some very fine trusses of the high-coloured Zonal Jean Sisley.

On the whole the *Roses* were very good, considering what a trying season it has been. Mr. Thomas Laxton, Stamford, was 1st in the amateurs' class for 24 varieties, having capital blooms of Devoniensis, Maréchal Niel, Coupe d'Hebe, L'Enfant Trouvé, Le Pactole, Anne Laxton, a seedling of a pale rose colour; Gloire de Santenay, Madame Knorr, Baronne de Noirmont, Oliver Delhomme, Marguérite de St. Amand, Maréchal Vaillant, Madame Rivers, Madame Julie Daran, Souvenir de Mons. Potteau, Madame Francois Lacharme, Mrs. Laxton, Mr. Ker, Francois Arago, Général Jacqueminot, Pierre Notting, Thorin, Madame Bonnaire and Sénateur Vaisse. The Rev. E. N. Pochin, Silsby Vicarage, Loughborough, was 2d, the best flowers being Céline Forestier, Souvenir de Bosanquet, Xavier Olibo, La France, Horace Vernet, John Hopper, Sénateur Vaisse, and Madame Bonnaire. Messrs. Paul & Son were the only exhibitors of 24 Roses in the amateurs' class, having very fine examples of the Souvenir d'un Ami, Sénateur Vaisse, Madame C. Wood, Modèle de Perfection, Abel Grand, Xavier Olibo, Nardy Frères, Baronne de Rothschild, Dr. Andry, Centifolia roses, La France, Marquise de Mortemart, Jules Margottin, Miss Ingram, La Fontaine, Général Jacqueminot, Marguérite de St. Amand, Dupuy Jamin, Camille Bernardin, Marquise de Mortemart, Madame C. Joigneaux, Duke of Wellington, Charles Lefebvre, and Madame Boutin. In class 48, for 12 cut Roses, for amateurs, some fine flowers were staged. Mr. George Johnson, 28, Peas Hill Road, Nottingham, was 1st, with capital flowers of Elie Morel, Madame C. Wood, La France, Charles Lefebvre, Jean Goujon, Maréchal Niel, Horace Vernet, Princess Mary of Cambridge, Abel Grand, Duc de Rohan, John Hopper, and Exposition de Brie. The Rev. E. N. Pochin was again 2d, the best flowers being La France, Maurice Bernardin, Souvenir de Malmaison, Gloire de Dijon, and Laurent Descourt, the nearest approach to a purple Rose exhibited; 3d, Mr. T. Green, Nottingham.

Turning to the *Prize Lists*, for the best 12 Golden Tricolor Variegated Pelargonium in class 85, Mr. C. Turner was placed 1st, with Baroness Burdett Coutts, a small but finely-coloured plant. Messrs. Bell & Thorpe were 2d, with Macbeth; and Mr. C. Frisby, Blankney Hall Gardens, with Magnet. Mr. Turner had the best Silver Tricolor in Mrs. Rousby, well grown and coloured; and Mr. Frisby was 2d with Lizzie Frisby, a very promising Silver variety. The best 12 Herbaceous Calceolarias came from Mr. Smith, Nottingham, the varieties pretty good. The prizes offered by Mr. T. W. Evans, for 6 Clematises, did not bring any competition, notwithstanding the adaptability of these plants for pot cultivation in pots. The leading prize, given by Lord Belper, for the best 6 Tricolor Zonal Pelargoniums not yet in commerce or sent out in 1871, was taken by Mr. C. Turner, who had Miss Norris, Miss Rutter, Baroness Burdett Coutts, and Mr. Rutter, golden-edged; and Mrs. Rousby and Mrs. Brooke Brydes, silver-edged. These were nicely grown and well-coloured plants. Mr. C. Frisby was 2d, with Magnet, Lady Folkestone, Hermit, and Reine des Beautés, golden-edged; Miss H. Bouverie, and Lizzie Frisby, silver-edged. The best 6 Zonal Pelargoniums, shown under the same conditions, were staged by Messrs. Bell & Thorpe, but they did not call for any particular remark. The best 6 new Nosegay varieties came from the same exhibitors, and were a poor lot also. These new Nosegay variety, David Garrick, standing by the side of the group, was much superior to anything it contained. The best 6 new show Pelargoniums came from Mr. Turner, and consisted of Sunset, Black Prince, Charlemagne, Imperator, Brigand, and Zephyr—every plant containing some very finely formed flowers. J. Fellowes, Esq., Beeston, had 6 very nice forms of erect flowering Gloxinias, and Mr. J. Bolton the same number of pendant flowering kinds. Mr. Turner had the best group of 5 Liliums, carrying over 50 flowers. Messrs. Rollisson & Sons, Tooting, London, were 2d; Messrs. G. & W. Yates, Manchester, 3d; and Mr. Geo. Edwards, York, 4th. It will be seen each group was a considerable distance, but they had travelled well, and greatly helped the exhibition. Mr. B. S. Williams had the best collection of succulents in class 117, Messrs. Bell & Thorpe being 2d. These comprised Aloes, Agaves, Echeverias, Sempervivums, Cacti, &c. The best hand bouquet came from Mr. F. Perkins, Leamington, elegantly arranged and handsome; a nice one from Mr. Peachey, Queendon House, Dartford. The gentlemen's "button-holes" were a very attractive feature; Mr. J. House, Peterborough, was 1st with a sprig of a delicate Erica, another of scarlet Bouvardia, and a bit of Fern; the 2d to Mr. Peachey, from Mr. Bolton, and consisted of Erica, two blossoms of a pale Fuchsia, and Fern; Mr. Cruickshank, Kingston Hall Gardens, was 3d, with a beautiful flower of Gardenia Fortunei. In several cases the button-holes were very fine.

The handsome Silver Cup, given by the Rev. S. Reynolds Hole, for 12 cut Roses, was won by Messrs. Paul & Son, who had magnificent blooms of Léopold Hausburg, Duke of Edinburgh, Marie Baumann, Miss Ingram, Maurice Bernardin, La France, Marie Baumann, Centifolia rosea, Joseph Fiala, Nardy Frères, Camille Bernardin, and Dr. Andry. The next best 12 came from Mr. H. Bennett, Shrewsbury, who had fine examples of John Hopper, Madame C. Joigneaux, Jules Margottin, Marguérite de St. Amand, Céline Forestier, Exposition de Brie, Gloire de Dijon, Sénateur Vaisse, Charles Lefebvre, Prince Camille de Rohan, Duke of Edinburgh, and Boutin. Six collections competed for this handsome Rose trophy. The best 48 cut Roses in class 137 also came from Messrs. Paul & Son, a very fine lot, that were much admired. The best 24 were from Mr. Turner, Madame Hector Jacquin, Madame Marie Rady, La France, Annie Wood, Marquise de Mortemart, Léopold Hausburg, Miss Ingram, Dupuy Jamin, Madame C. Joigneaux, Duke of Edinburgh, Jules Margottin, Madame Charles Wood, Camille Bernardin, &c. Mr. Merryweather was again 2d, and Mr. George Edwards 3d. The leading special prize for 12 cut Roses, to be shown by artizans, given by Mr. H. Bennett, Shrewsbury, who had also offered 2nd, St. Ann's Well Road, Nottingham, who had remarkable examples of Charles Lefebvre, Dr. Andry, La France, Camille Bernardin, John Hopper, Marquise de Mortemart, Comtesse d'Oxford, Duke of Edinburgh, Miss Ingram, Madame Marie Cirodde, Francois Lacharme, and Gloire de Santenay. 2d, Mr. H. Biddles, Park-lane, Loughborough; the flowers unnamed. 3d, Mr. R. Rodgers, Watford Street, Nottingham. The best 24 blooms were La France, Charles Lefebvre, Madame Vidot, Madame Hector Jacquin, Mons. Noman, John Hopper, Gloire de Dijon, &c. There were 9 capital collections in this class, and it served to show in a remarkable way to what extent beautiful Roses can be produced by the artizans in the allotment gardens round Nottingham, as well as at Loughborough. The premier Rose, shown as a single flower, was competed for by seven, Mr. Turner's G. T. Laxton, was a fine example of Duke of Edinburgh, shown by Messrs. Paul & Sons. The next best was Marquise de Mortemart, shown by Mr. George Burnham, of the Gardens, Elm Park, Hornsey, by the President, from Mr. J. Brown, Sneinton the 4th, Elie Morel, from Mr. W. Wise, Newcastle Street, Nottingham.

The desire to possess the patent plant protectors, offered by Mr. W. Paul, Waltham Cross, for 24 trusses of each, appeared to have awakened no ambitious desires in the breast of any rosarian, as no competition took place, or at least no signs of it could be found. It was much too early for Mr. Jas. Douglas's prize for the best Picotees staged was a stand of 12 blooms of Prince of Orange, from Mr. Perkins, Leamington.

A very fine stand of Verbenas came from Mr. C. Turner, also a very large one from Mr. Laird, who also contributed Verbenas, and Messrs. Downie, Laird & Laing stands of English and fancy Pansies, the superb colouring of the latter exciting much admiration.

The chief of the novelties shown for certificates consisted of two fine groups of seedling Ferns, from Mr. E. J. Lowe and Mr. J. E. Mappleback. A few other subjects were, however, selected from the fine miscellaneous collection of Messrs. Downie, Laird & Laing, amongst which were Dracænas which will be welcome additions to this fine decorative genus, namely, D. Wisemani, a bronzy-leaved plant, with red margins, and breaking out into white in the younger growth; and D. amabilis, a broader-leaved form than D. Guilfoylei, and much superior to it, the leaves green, variegated with pink and white. These came from the South Sea Islands. Dieffenbachia Bausei, another of the same genus, is perhaps the finest of all the Dieffenbachias. It is a stocky-growing broad-leaved variety, of hybrid origin, with leaves of a yellowish-green, irregularly edged and blotched with dark green, and also spotted with white, the markings very distinctly effective. Begonia Chelsoni is another pretty hybrid form, with light red flowers of a different tint from those of the related B. Sedeni. In Mr. Williams' group was a nice plant of Trichomanes auricularium, a very elegant creeping-stemmed tropical filmy Fern. Mr. G. F. Wilson had cut specimens of four rare Lilies, namely, californicum, the flower reflexed, deep red with dark spots, a broad-leaved kind, the leaves somewhat whorled; puberulum, of Torry, orange-red reflexed flowers, spotted with black, and whorled broad leaves; pendulifolium, with the flowers of puberulum, but having narrower scattered leaves; and canadense flavum, a very pretty bell-shaped flower, tawny-yellow, spotted with black. All the foregoing received First-class Certificates. Messrs. Veitch had also a very curious Orchid, Epidendrum ciliare, apparently a species with leafy stems and small panicles (in this case two-flowered) of very remarkable flowers, the sepals and petals being a deep green, and the lip expanded and deep orange-coloured, appearing to stand on a long stalk. Mr. E. J. Lowe had also a curiosity in the shape of a variegated Rose (? Gen. Jacqueminot) which, if thoroughly fixed, would be a real acquisition, the leaves being handsomely marked with creamy white, and the younger ones also stained with red.

Mr. Turner, of Slough, staged several of the fine new Pelargoniums which had been already exhibited at the London meetings, and the following amongst them were in a condition to receive first-class awards, viz., Achievement, a lovely tint of rose, with blotched upper petals; Pompey, Cæsar, Zephyr, all high-coloured sorts, and Charlemagne, a soft rose; and Imperator had remarkably high-coloured lower petals.

Of *New Ferns* the name is legion, and we can only indicate some of the more striking. The following forms of Scolopendrium, a genus which Mr. J. E. Mappleback were particularly good :—Fellowsii, with tall, recurved subpyramidal fronds; Smeei, tall and erect, with a narrow sculpturate line within the smooth undulated edge, perfection; the apiculate variety, laxum; Kelwayanum, dwarf, broad, multifidly-lobed and sculpturate; Davyi, narrow, erect, and sculpturate; præcinctum, dwarf tufted growth, sculpturate, with a frilled excurrent line; vigilante, bold and sculpturate; dichotomum, dwarf, crested and ramose; cochleatum, undulate, with the top spirally twisted; Moonize, a very well marked supralineate form; innocuum, broad arching fronds, transversely plicate, and deeply crenate-lobed; the apiculate variety, apiculatum, very broad and bold, somewhat frilled at the end; thaumaston, dwarf and undulated, the apex recurved and divergently lobate; tumulum, narrow base, broad, spreading, flat terminal area; bicuspidatum, dwarf, broad, with a pocket-like apex, and forked excurrent horns; omnilacerum Lowei, one of the obtusidentate set, but broader and more deeply cut. Lastrea dilatata calomelanos and its varieties, two pretty, finely cut, dwarf forms, in the way of cinca; Lastrea Filix-mas Belperi, a narrow, irregularly fringed form of crista, analogous to Craigii, amongst Athyriums; L. F.-m. depauperata Padleyi, dwarf, crested and dilated; L. dilatata plumosa; L. F.-m. variegata, greyish white, as if invaded by thrips; Polystichum angulare aripreppes, a deeply toothed form, in the way of grandidens; P. ang. transforme, a drooping variety of the foregoing; P. ang. cristatum Thompsonize, the gem of the whole collection, with fine, symmetrical bipinnatifid fronds; A. m. admirabile, dwarf, and very ramose; A. m. capitatum, dwarf, and finely crested; A. m. Adiantum Victoriæ, a very admirabile, a fine, spreading-habited sort, with cuneatetrapeziform pinnules; A. C. daphnites, dwarf, and crested with very large concave pinnules; A. C. perfectum, a very free-growing crested variety; A. C. pulcherrimum iridioides crista, a grandly multifid cristate form of this well-known stove Fern; and the following forms of Athyrium Filix-femina :—Gullsonæ, with the fronds grandly cristate; Alexandræ, a subsymmetrical form of Victoriæ, fimbriately toothed, and crested; invincere, in the way of Pulleri, very neat; decorum, a large, subsymmetrical form, with laciniate pinnules; trossulum, like a robust flabellifolium, but with the pinnules dilated; Victoriæ, full, deeply-toothed, and symmetrical; Triumphale, a dwarfish and somewhat irregular form of Victoriæ; Bellairsiæ, large and subsymmetrical, and laciniate; Lawsoni, a very elegant and symmetrical form, with the pinnules pinnate and cristate apex. These, with a Hymenophyllum Khasiani, said to be intermediate between unilaterale and tunbridgense, but with the habit and aspect of the former, all received First-class Certificates, as were shown by Mr. E. J. Lowe. A smaller, but select collection, came from Mr. J. E. Mappleback. The most remarkable amongst them were the crested forms of Pteris aquilina, namely, Jackii, with the pinnules deeply encurved; cristata Gloveri, regular, with the pinnæ nicely crested at the ends; and grandiceps irregularly dilated into large crested heads, and without symmetry. Asplenium Trichomanes was

Messrs. Lane & Son of Berkhampstead, in competition for the prize offered by the local committee.

For the prizes offered for a collection of *Fruit*, 12 dishes, 6 distinct kinds, there was only one exhibitor, Mr. Miles, gr. to Lord Carrington, Wycombe Abbey, Bucks, and to him the 1st prize was awarded. He had two very handsome Queen Pines, weighing about 5¾ lb.; 3 bunches of Black Hamburgh, fine in size, if deficient in colour; a fine dish of Foster's White Seedling, excellent Violette Hâtive Peaches and Murray Nectarines, Mr. Radclyffe and Sir Charles Napier Strawberries, and Black Circassian and Bigarreau Napoléon Cherries. A collection of fruit was also staged by Mr. Brown, fruiterer, Nottingham, apparently not in competition for these prizes. Pine-apples were not very numerously shown, but they were of excellent quality. The best came from Mr. Miles, gr. to Lord Carrington, consisting of a very large Providence, weighing 11 lb. 5 oz., and 2 Queens, averaging 5¼ lb. each; Mr. Simpson, gr. to Lord Wharncliffe, Wortley Hall, contesting in 2d with handsome Queens, fine examples, one about 4 lb. 12 oz. In the next class, for a single fruit of any variety, Mr. Simpson came in 1st with a beautiful Queen, Mr. Miles being 2d with a capital specimen of the same variety. In the class for a specimen, Mr. Miles was again 1st, taking the special prize offered by the late S. T. Cooper, Esq., with magnificent Queens, Mr. Simpson securing the 2d prize, given by the local committee, with admirable representations of the same variety, the one about 4 lb. Grapes made a very interesting exhibition. The best single dish of Black Grapes came from Mr. R. T'Anson, gr. to T. Statter, Esq., Stand Hall, Manchester, good Alicante in bunch, berry, and colour, and more noteworthy still from the fact that they were cut from Vines 27 years old, and grown on the restrictive system. The second honours were secured by the veteran Mr. Henderson, gr. to Sir George Beaumont, Bart., Cole Orton, with examples not over large in bunch, but perfection in size of berry and general finish; Mr. Sage, gr. to Earl Brownlow, Ashridge, 3d, with a very good sample. A very good sample was also contributed by Mr. G. Daniells, gr. to A. M. Munby, Shipley Hall, Derby. A very good dish of Muscat of Alexandria, perhaps hardly as ripe as they might be, from Mr. W. Holah, gr. to H. Saville, Esq., Rufford Abbey, Notts, was 1st in the class for White Grapes, Mr. W. Peachey, gr. to H. E. Hole, Esq., Quorndon Lodge, Loughborough, being 2d with Golden Champion, of splendid size but bad colour; and Mr. H. Henderson 3d, with nice examples of Buckland Sweetwater. Mr. Smith, gr. to the Earl of Gainsborough, Exton Park, Oakham, sent the best basket of Grapes, which consisted of six very handsomely finished bunches of Black Hamburgh, Mr. Henderson coming in 2d with smaller but equally well finished examples, and Mr. W. Broadbridge, gr. to Sir C. Mordaunt, Bart., Walton Hall, Warwick, was 3d. Mr. Forman's prizes for six bunches of one or more varieties of Grapes, the produce of Vines more than 25 years old, brought out a most interesting display. The 1st prize was awarded to Mr. R. T'Anson, who had large bunches, well finished berries of excellent colour. These also were cut from Vines 27 years old, grown on the single rod system. Mr. M. Henderson came in 2d with small but highly finished examples of Black Hamburgh cut from Vines 39 years old, planted and grown on the extension system; Mr. Lynn, gr. to Lord Hatherley, Hedsor, being 3d with handsome bunches of Black Prince, Black Hamburgh, Buckland Sweetwater, and General de la Marmora, an early White Grape of considerable merit—they were, however, scarcely ripe enough, and no information was given as to which of the rival systems they had been grown upon. From Mr. Simpson, Wortley, came some capital Black Hamburghs, cut from Vines more than 40 years old, which are restricted to one rafter, and pruned to the best bud. Mr. G. Craddock, gr. to Lord Willoughby de Broke, Compton Verney, Warwick, sent admirable specimens of Muscat of Alexandria, White Frontignan, and Black Hamburgh, from Vines which were grown on the restrictive system, on their own roots, and which have produced Grapes that have regularly taken a 1st prize for the last 12 years. Mr. A. Meikle, gr. to Lord Ducie, Tortworth Court, Wotton, had Black Hamburgh, and a small Red Grape cut from Vines grown on the moderate extension system, and there were several other productions of which no particulars were furnished. Mr. Bunyard, gr. to Colonel J. C. Wright, Stapleford Hall, for 6 kinds of fruit, Pines excluded, there was only one competitor—Mr. W. Holah, who had good-shaped bunches of Canon Hall Muscat, with Raspberries, Nectarines, fine Golden Hamburghs, Ruddington Hall Seedling, and King of Melons, a capital dish of Apples, and the same of Lee's Perpetual Figs, Peaches, Nectarines, &c. Peaches and Nectarines were not shown numerously, but of excellent quality. The best single dish in the former class was a handsome dish of Bellegarde, shown by Mr. P. Hope, gr. to F. C. Clarke, Esq., Vinery House, Allerton, Liverpool; Mr. Sage, gr. to Earl Brownlow, Ashridge, coming in 2d with the same variety; and Mr. Lamb, gr. to G. Davy, Esq., Colston Basset, 3d, with very fine Galande. Mr. Jack, gr. to the Duke of Cleveland, Battle Abbey, Sussex, also sent admirable specimens of Bellegarde; Mr. Brown, Gopsal, and Mr. Lynn had Royal George, and Mr. Miles had Violette Hâtive. Mr. P. Hope was also 1st for Nectarines, with Elruge, wonderfully fine in size and colour; Mr. Lynn being 2d, with exceedingly handsome Violette Hâtive, and Mr. Brown 3d, with the same variety. The same kind was also shown by Mr. Brown and Mr. Henderson, and Mr. Lamb and Mr. Miller, gr., Worksop Manor, competed with good specimens of Elruge. Capital dishes of Brown Turkey Figs were shown by Mr. Brown, Mr. Sage, and Mr. Miller, the prizes being awarded in the order named—Mr. D. Lumsden, gr. to the Hon. R. C. Nesbit Hamilton, Bloxholm Hall, also competing with the same variety. The best single dish of Cherries was one of Black Circassian, of excellent quality, from Mr. Miller, Mr. Miles coming in 2d with Bigarreau Napoléon; and Mr. Garland, gr. to Sir T. Dyke Acland, Bart., Killerton, was 3d, with capital specimens of Elton. The same exhibitor also sent a dish of the Black Tartarian; Mr. Miles had another one of Black Circassian; and Mr. J. Woodfield, gr. to F. J. S. Foljambe, Esq., Osberton, and Mr. Lydiard, Bathaston, had May Duke. In the class for 6 dishes of Strawberries there was only one exhibitor, Mr. Miles, and he received the 1st prize. The best green-fleshed Melon came from Mr. G. Lamb, Colston Basset, a handsome high-flavoured fruit, named Colston Basset Seedling; Mr. T. Middleton, gr. to G. T. Cross, Esq., being 2d, with Ruddington Hall Seedling; and Mr. T. W. Shuttleworth, Golden Hill, Preston, 3d, with Gilbert's Improved Victory of Bath. The best scarlet-fleshed variety was a small fruit of Scarlet Gem, shown by Mr. Gilbert, gr. to the Marquis of Exeter, Burghley; Mr. A. Meikle coming in 2d, and Mr. J. Mitchell 3d; Mr. Woodfield, Mr. Holah, Mr. Miller, Mr. Cox, Mr. Calder, and Mr. D. Lumsden, also competed. Mr. Frisby, gr. to H. Chaplin, Esq., Blankney, sent three dishes of Apples, and from Mr. Garland, gr. to Sir T. Dyke Acland, Bart., came three nice dishes of Currants and Raspberries. Mr. Henderson, Cole Orton, exhibited the Black Mammoth Grape, a large variety, raised in Australia; and Mr. Miles had a Providence Pine-apple, weighing 10 lb. 14 oz., and an Enville, 8¾ lb. in weight. Mr. Tillery, Welbeck, sent a collection of Strawberries. Mr. G. Lamb had a brace of the Sooly Qua Cucumber, of immense size; and Mr. Woodfield, Osberton, exhibited fruit of Vanilla planifolia, of the years 1870 and 1871.

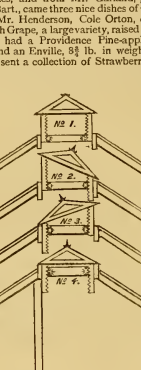

FIG. 174.—VOICE'S PATENT HOTHOUSE.

At no previous provincial exhibition of the Society have *Vegetables* been shown in such magnificent condition as they were here. Indeed, considering the season we have had, we doubt if a larger, cleaner, and better grown lot could be brought together. The great centres of attraction were the splendid collections shown in competition for "The Gardeners' Prize," subscribed amongst the gardeners of Great Britain and Ireland, with £5 added by the Marquis of Exeter, and the handsome silver cup given by Messrs. Carter & Co. for a collection, including Laxton's Supreme, Carter's Hundredfold, Laxton's Quality, Dwarf Waterloo, and two other varieties of Peas. This prize was won in the most satisfactory manner by Mr. J. Garland, gr. to Sir T. Dyke Acland, Bart., Killerton, Devon, who staged a collection which roused to enthusiasm the admiration of his brother gardeners, and which, besides splendid examples of the specialities mentioned, contained 50 beads of Asparagus, weighing 7¾ lb., and of an average length of 8 inches, the largest sample we ever saw from the garden of an English amateur, though at the same time we do not consider it the most useful size for satisfying the requirements of a gentleman's table; and perfect examples of Cabbages, Kidney Onions, Parsnips, Celery, Carrots, Broad Beans, Turnips, and Beet, &c. It is only fair perhaps to state that Mr. Garland procured the seeds of these remarkably fine vegetables from the firm who gave the prize. The 2d prize was taken by Mr. D. Lumsden, also with a capital lot, in which were admirable Globe Artichokes, Onions, Broad Beans, Cabbage, Leeks, Potatos, and a fine dish of the Rat-tailed Radish. Mr. Gilbert, gr. to the Marquis of Exeter also competed in this class, though unsuccessfully, he having thrown his greatest efforts into the competition for the Gardeners' Prize, which was suggested by him in these columns some months ago, and which he now won very cleverly. When he made the suggestion, Mr. Gilbert made some observations upon the generally rough and primitive manner in which the "cook's favourites" were staged, and we have much pleasure in stating that Mr. Gilbert set an admirable example here, by showing them with a shallow box, with a garniture of beautifully curled Parsley, an arrangement which we should be pleased to see generally followed on all future occasions. There is an old proverb, that "good wine needs no bush," and so in the matter of good vegetables many gardeners hold the opinion that they require no other setting off than that which is afforded by white plates; but the production of good vegetables is, or ought to be, a matter of the first importance with every gardener, we think it strange that those gardeners should have such a poor regard for their hardly gained productions. Mr. Gilbert's box of vegetables and salads contained, in the first place, the cleanest and most perfectly developed Cauliflowers in the show, and the same may be said of his dish of Orangefield Tomatos, which were excellent in size and perfect in colour; a capital dish of Mushrooms, the same of Globe Artichokes, and Fulmer's Early French Bean, as well as a nice dish of Laxton's William the First Pea, &c. His salading materials consisted of a beautiful piece of Telegraph Cucumbers, Beet, Cabbage and Cos Lettuce, and Mustard and Cress. The competition for the other prizes was particularly close, the Rev. C. C. Ellison taking 2d honours with a collection deserving much praise. Following him came Mr. Miles, gr. to Lord Carrington, and Mr. Craddock, the latter of whom secured the patent exhibiting case, given by Mr. Chapman, of Gloucester. First-rate collections were also staged by Mr. Hinsden, Mr. Frisby, Mr. T. S. Mitchell, Mr. F. Soar, Mr. W. J. Holah, Mr. W. Peachey, and Mr. A. Meikle. The prizes given by the Loughborough Horticultural Society were also very well contested. More cucumbers were shown than is usually seen at an exhibition, and among them were excellent representatives of most of the leading kinds. For the prizes offered by T. R. Stavey, Esq., and the local committee, there were 12 competitors, the 1st prize being won by the Rev. C. C. Ellison, Bracebridge, Lincoln, with a very nice brace of a white-spined variety, aptly named "Lickemall," Mr. J. Bolton coming in 2d, with very good specimens of Telegraph, and Mr. Mitchell 3d, with Berkshire Challenge. Mr. J. Allan, Norton Hall, Sheffield, had a brace of Hamilton's British Challenge, over 20 inches long. Mr. D. T. Fish sent a nice brace of Telegraph, and so did Mr. A. Meikle. Pearson's Long Gun was represented by Mr. A. Farr, and Mr. H. Hinsden sent an immense brace of the new Chinese Cucumber, Sooly Qua. There was also a brisk competition for the prizes given by Mr. W. Edgcombe Rendle, but nothing calling for special comment was contributed.

First in importance among *Horticultural Buildings* are hot-houses, though the field seemed left to the provincial builders—Messenger, of Loughborough; Denman, of Norwood; Foster, of Beeston; Wheeler & Humfrey, of Nottingham. These are well known, and call for no special remark. Ayres' imperishable boxes, which have previously noticed in these columns, appeared in much better condition than at Oxford, and now seems a business-like, useful structure. It is of iron, zinc, and a composition hard and, said to be, durable as stone, the stages and side walls being thus rendered imperishable. Ample provision is made for ventilation, and the inventor says the cost will not exceed that of the best wooden houses; if so, these houses ought to take. It must be a boon to have imperishability and cleanliness combined in structural facilities and structural merits of the highest order.

Mr. Bickley, of Birmingham, likewise exhibits an ingenious mode of glazing. He reverses the usual order of the roof bars, and runs them across the rafters. On narrow slips of wood, deeply serrated strips of zinc are nailed; a few of these saw-like teeth are reversed, so as to hold the glass firmly, and the squares abut side or lengthways. Each contains about a square foot, and even on those of ordinary character, it is said, the attraction of the two edges prevents drip. If the immunity from drip at ordinary angles can be ensured, these roofs will prove exceedingly light and cheap.

Another novelty in ventilation is exhibited by Mr. Voice, of Hareross in Sussex. The house is furnished with a centre cap or lantern, one or both sides of which can be elevated rapidly with a rack and screw at pleasure (fig. 174—1 to 4). By this mode ventilation can always be given on the end side of the wind, while, by lifting up the entire top, the heated air can escape at once. Side ventilation is given in the ordinary way through the wall-plate (fig. 174—5 and 6). Mr. Foster seems to have brought the mechanical contrivances for the movement of ventilators to a high state of perfection. By a peculiar arrangement of a rack, pinion, and screw, the heaviest ventilator can be moved with the utmost facility. The open ventilator is elevated by a horizontal movement which throws it up, so that air is given while the rain is kept out. The houses and pits of this exhibitor have wooden sides and iron feet, which makes the tenant's fixtures removable at pleasure.

Mr. Richardson, of Darlington, likewise exhibits models of his patent hothouses. The improvements shown by Mr. Rendle in his plant protectors bring some of them almost within the category of houses. The old forms are still retained, while new facilities for the removal of the glass are afforded by a movable coping, that is simply laid on the upper edge of the glass. Nothing could be more simple. The protectors are also shown in more pretentious size and form; glass walls and miniature houses,

in which zinc is used for grooves and wood for sides, instead of bricks and tiles. The Peach-case and amateur's plant-case have folding backs of wood, which are let down to tend the trees or plants, while the top is also movable. The cordon frame has a hole at the end, to admit the tree, and there can be little doubt of their worth, with the efficient shelter these cordon cases provide. We have a good character of these protectors on all hands, and no one can doubt their special adaptation for the purposes intended. As lately remarked in these columns, the great want of modern gardening is more glass, and we shall every attempt to provide it cheaply and in useful forms.

A good specimen of Beard's glass walls, strong, substantial, and business-like, was also shown here.

From glass structures we naturally turn to the means of heating them. Boilers were not numerous, and there is no great novelty among them.

Mr. Weeks showed his upright tubular, and Mr. Ormson put up some substantial-looking convoluted saddle and fluted saddles, and a new form in which the fire is swept through the centre and four spaces around it. There can be no question of the power and the durability of these boilers.

The Witley Court boiler was likewise shown, with its furnace door and everything complete. Its chief features are the semi-detached end, to receive the full force of the fire, the deep flue to take ash-pit to be kept supplied with water, and the fact that it is not proposed to carry the fire around the outside. It looks capable of heating any amount of water that may be required; but the semi-detached end seems a defect.

Mr. Ormson showed a double-flued saddle—with the water carried under the bars, and a solid end that seems to combine most of the advantages without the complications of the Witley Court Boiler.

Among miscellaneous exhibits, a fine lot of pottery, including vases, fountains, baskets, and pots, was shown by Mr. John Matthews, of Weston-super-mare; garden chairs with shades, in endless variety; engines, mowing machines, garden tools, fancy stationery, carriages, perambulators, *ad libitum*; rollers, vases, and even reapers; steam-engines—and, last, though in many respects by no means least, as an adjunct of the time, a printing machine, driven by steam-power, to print the Guides and Prize Lists of the Royal Horticultural Society on the grounds.

The Dinner at the Exchange Hall.—On Tuesday evening a public dinner was held in the Exchange. The Rev. S. R. Hole, M.A., vicar of Caunton, presided, and among those present were the Mayor, Colonel Scott, Major Trevor Clarke, Messrs. Barron, of Chilwell; Stevens, of Trentham; Stevenson, of Timperley; Fish, of Bury St. Edmund's; Ingram, of Belvoir; Cole, of Withington; W. Barron, Elvaston; Rollinson, Tooting; Veitch, London; Turner, Slough; Lane, Berkhamsteed; Laing, Forest Hill; Barron, Chiswick; Williams, Hollo-way; Dickson, Chester; Baines, Southgate; Dean, London; Paul, Cheshunt; Gadd, Wollaton; W. Paul, Waltham Cross, &c.

The Chairman gave "The Health of the Queen," and afterwards proposed "The Prince and Princess of Wales, and the rest of the Royal Family." He remarked that, as an invalid, he was glad to see that the Royal Highness had missed 12 pigeons in succession. He trusted that his Royal Highness would seek healthier pursuits, and among them horticulture, especially Roses, and among them the Hotspur of Shakspeare. He should like, in connection with this toast, the amiable and excellent Prince who presided over the dinner of the Gardeners' Benevolent Institution. He then proposed the toast "The Prince and Princess of Wales and the rest of the Royal Family."

The Chairman again rose and said, he had never said grace with more satisfaction than he had done that day. He was not an epicure, he felt sometimes as the writer expressed it—"Fate canot harm me, I have dined today." Englishmen used to have no difficulty about dining; but somehow or other there had been some difficulty about holding a gardeners' dinner without these annual meetings. They had previously wanted the presence of those who were at the head of the Society, but here they were to-night. They had had the best show to-day that ever the Society had had in the provinces, and there had been no want of harmony in making it a happy one throughout. The gardeners who came to these meetings had great sympathy and fellowship with each other; they wanted to renew old friendships, and to meet men they had heard about all their lives. Did not our painters wish to know a Millais, or a young soldier a Napier? He had known the time when he would have gone 40 miles to see Messrs. Rivers, of Sawbridgeworth. What they wanted was unity, and they had it to-day more than they ever had it before. He gave them the "The Health of the Chief Magistrate of the Town," who had done so much to make success of the new institution. He might congratulate him on the happy day this had been for Nottingham and on the grand exhibition over which he had, so to speak, presided. (Cheers.)

The Mayor, in reply, said he felt that, as one who filled the honourable office of Mayor of Nottingham, he should have been a recreant to the trust confided in him if, when an important Society like this paid the town a visit, he had not done all he could to promote the harmony and success of the meeting. The Mayor then proposed the Council of the Society, coupling with the toast the name of his friend Colonel Scott.

Colonel Scott, in reply, said it was a great honour to reply to the toast, and went on to observe that the Society had done much to humanise mankind. Mr. Hole had made some comments upon the difficulties in connection with this dinner. He did not know the ins-and-outs of the question, but he reminded them that the Society had a great many difficulties to contend with. It was made up of heterogeneous elements. There was first the florist, who looked at a flower in relation to its regularity; then they had the horticulturist proper, who delighted in looking at everything in the light of colour or beauty of form; then there was the botanist, who thought that it was the most important thing that a flower should have its right name given to it; and then the physiological horticulturist, who thought of nothing but the scientific point of the question. Besides these classes, however, they had the outside public to consider. Horticulture was like painting, there were wanted not only the artists, but the people to admire the works that were produced. Many of those present were men of business, and they were pretty well aware that a hundred pounds out of the pockets of the public would be the worst thing that could befall them. Still, he did not think the Horticultural Society needed any apology; they were doing their duty manfully and well. He dwelt on the progress the society was making, and said the show in Nottingham was one which would bring thousands to see it. He could not help referring to the local committee, who had worked so hard to secure success, and he wished also to acknowledge the efforts of those who had brought together so large a number of plants, also to those who had judged them so well, but who, for the next three or four days, would not have a very happy life of it. Last, but not least, they returned their thanks to the Mayor for the honour he had done them, and also for the courtesy and geniality and all those qualities for which he (the Chairman) was indebted to him personally for the success of the exhibition. He thanked them from his heart for the way in which they had been received, and hoped this would be one of a series of meetings at which they would meet together. (Cheers.)

The Chairman, in giving the next toast, proceeded to refer to a few names which had not been previously mentioned in the first list of "scientific persons" attending the meeting in Nottingham, mentioning Mr. Grumbley, Mr. Thomas Baines, Mr. Cole, Mr. Stevenson, and also Mr. E. J. Lowe. With reference to the latter gentleman, he remarked that, whatever differences might have arisen, he thought they should do all honour to his enterprise and energy and activity in bringing about this great success. He then mentioned Mr. George Eyles and Sergeant Johnson, and concluded by saying that the show of flowers and plants he had seen that day could not be had except in his life. He then called on Mr. Baines to reply to the toast of the exhibitors.

Mr. Baines, in reply, made some practical observations upon the growing of plants.

The Mayor, in proposing the health of the Chairman, referred to the part he will be had shown in promoting the meeting, also to his being an excellent clergyman and an excellent gardener, who looked from Nature up to Nature's God. Mr. Hole was really and truly, and in the highest sense of the word, a gardener, who cultivated not only his own garden, but the souls of those who lived in his parish, and he was glad of his presence that night. He hoped he would long continue in his Christian labours, and in the promotion of horticulture, and grace by his pleasant and agreeable presence many such meetings as this.

The Chairman, in reply, said he should look back upon this day as one of the happiest in his life. This was the first day in which they had bridged over a little chasm which had existed between science and practical gardening. He did not pretend to be anything but a lover of flowers. He had encouraged flower shows because such his idea. The man who could not admire every flower in a wood as well as any Orchid was not a true gardener. If he did so, however, he was a true florist. The Chairman then referred to the speeches in the train as they came from Nottingham there lived a clergyman, and there also used to live a clerk. We were getting rather tired in this age of the conversational duet between the clergyman and the clerk, but the latter race was not quite so flourishing. But there lived in this village a clerk, and he did not think he was offending against propriety when he stated that his predecessor, old Mr. Kemp, used to play delightfully on the violin. All things went very happily, the clergyman employing the clerk to make clothes for himself and livery for his man, and he (Mr. Hole) thought a right shilling the talent which he had to encounter. Unfortunately, one day there came to the clergyman a new groom, who declared that he would not have his clothes made by Kemp. The clergyman weakly and unadvisedly allowed him to go to another tailor, and allowed him to go to a very excellent man and tailor, whom they all liked—Mr. Finn. The man went to Mr. Finn, and the next Sunday when the clergyman gave out the hymn the 100th Psalm, to the tune of Kent, he was astonished to hear the clergyman gave out the hymn, repeating the first verse, but the fiddle made no sign. There was consternation in the heart and countenance of the parson, and he turned to the groom, and in a whisper asked him why he ought to have proceeded for an explanation, and after a pause there was a messenger sent, and the reply was, "If you please, sir, Kemp says as Finn may fiddle." He hoped that in the same way the new gardening would not be put on one side for science, or they might reply "Science may fiddle." He said to the Council of the Royal Horticultural Society, "Come to us, as you have done to-night, in a kind and friendly way, and be the friends with the British gardener." He then warmly thanked the company for the way in which they had drunk his health.

Major Trevor Clarke and Col. Scott both denied that the council of the Royal Horticultural Society was in any way inimical to the practical gardener.

Mr. Baines proposed the Judges, to which Mr. Fish replied, and said the Council of the Society might be pardoned occasionally, because they had a great desire to understand the gardeners, nor did they understand them. The only way to get out of the difficulty was to put their Chairman on the Council, and there would then be an end of the difficulty for ever.

The Chairman proposed the health of Mr. E. J. Lowe, and said the success which had attended this day's proceedings must have entirely obliterated any objection anybody might have held to any particular view he had taken. They must all feel grateful to Mr. Lowe for the energy he had displayed in bringing this meeting to so happy a issue.

Mr. Lowe, in reply, said any little labour he had bestowed was amply repaid by the promise of success which he saw before him, for he always noticed that when the first day started well they were sure to go on prosperously to the end. He assured them that he had both the Horticultural Society and the success of the gardeners equally at heart. He pointed to his production of British Ferns as a proof that he was a practical gardener—(Cheers) —and after some further observations resumed his seat amid applause.

Mr. Fish in proposing the next toast, said that practical men laid the elements of science, and the difference between them and the bookmen was, that whilst the latter put their science into books, the former put it into plants and flowers. He proposed "Success to Horticulture," to which Mr. Ingram, of Belvoir, replied in an appropriate speech.

The Chairman gave the Horticultural Press, and coupled with it the name of an old gardener—Mr. W. P. Ayres. Mr. Ayres might have been a little venturesome in his zeal for horticulture, but if they looked through his writings, they would find him an advocate of the gardener. Mr. Ayres had made many valuable suggestions both in print and in private about this show, and his (the Chairman's) only regret was, that he had not been working with them, when his heart lay so much in the cause.

Mr. Ayres said there was no one living who was willing to do more for horticulture than he was, and he really thought he was doing good, although some might think he was doing harm. He was happy to be should always pursue an independent course, and do that which he considered to be right.

The Mayor then proposed the ladies, to which Mr. Pearson, of Chilwell, replied in a humorous speech.

The proceedings shortly after terminated.

CRYSTAL PALACE ROSE SHOW: *June* 24.—The extremely unfavourable state of the weather, was the reason assigned by many of the most noted rosarians, who flocked to this popular place of resort on Saturday last, for the circumstances of the exhibition. In the first place, it was not so large as usual, and, in the second, the blooms, as a whole, were below the average merit, being, with the exception of those sent up from the south-west country, remarkably small and poor in colour—an attendant consequence of the late heavy rains. In the first four classes, which were confined to nurserymen, the honours may fairly be said to have been between Messrs. Keynes, Williams and the veteran florist from Salisbury, Mr. John Keynes, seeing that the former came in 1st for 72 distinct varieties, and the latter for collections of 48 and 24, three trusses of each, and 12 and 6 of each. The blooms were of Centifolia rosea, Alba rosea, Général Jacqueminot, the best of the lot; Dupuy Jamin, a Rose which was shown well in all the leading groups; Jean Goujon, a beautiful red; Lefebvre Hautaburg, very fine; John Hopper, Charles Rouillard, Madame Rivers, Felix Genero, Madame Julie Daran, bright red, a fine, globular-shaped variety; Marie Baumann, and that old favourite, Comtesse de Chabrillant, a variety which, like Général Jacqueminot, Charles Lawson, Jules Margottin, and others, will probably hold its own as long as Rose shows are in existence. Mr. Keynes came in 2d in this class, and a good one too. His flowers were, in the case of some of old, if we were not quite so even, especially those of Madame Clémence Joigneaux, a first-class show Rose; Mdlle. Eugène Verdier, Nardy Frères, a new variety, of excellent merit, rose, with a shade of violet, large and full; Baron Morel, Dupuy Jamin, Alfred Colomb, very fine, Camille Bernardin, and Maréchal Niel. Next to Mr. Keynes came Mr. J. Mitchell, of Pitdown, followed by Messrs. E. P. Francis & Co., of Hereford. Messrs. Turbin, English-combe, near Bath, was also a competitor.

Mr. Keynes had his revenge in the class for 48, three trusses of each, Messrs. Paul & Son being here placed 2d. His collection contained large and well-coloured examples of Fierfield Queen, Devonensis, Madame Willermoz, Maréchal Niel, first-rate, Alfred Colomb, also excellent, La France, Louise Peyronny, Souvenir d'Elise, and Edward Morren, finer and of better form than we have seen it before, but a little deficient in colour. Messrs. Paul & Son had the following in capital order :—Beauty of Waltham, Dr. Andry, Dupuy Jamin, Modèle de Perfection, John Hopper, Camille Bernardin, Centifolia rosea, and La France. Mr. Turner was 3d, and Mr. Mitchell 4th.

In the next class, for 24, three trusses of each, the first three prizes were taken by the same exhibitors, and in the same order. Mr. Keynes' flowers were splendid, and were examples of Marguérite de St. Amand, Madame Clémence Joigneaux, Marquise de Castillane, Abel Gand, Duke of Edinburgh, Léopold Hausburg, Nardy Frères, Miss Ingram, Camille Bernardin, and Baron Bonet, a new variety, staged by Mr. Turner, delicate rose, large, and of good form.

For 24 varieties, one truss of each, Mr. Walker, Thame, Oxon, was 1st; Mr. G. Cooling, Bath, whose collection was very unsatisfactorily labelled, 2d; Mr. Parker, Rugby, 3d; and Mr. Knight, Hailsham, 4th,—four others also competing.

The freshest and brightest Roses in the exhibition were contributed to the amateur classes by Mr. R. N. G. Baker, Heavitree, Devon, who was pre-eminently first, for 48, 36, and 24 varieties respectively. Amongst his 48, of which all were large and good, the following especially were splendid in colour:—Madame Marie Rady, Alfred Colomb, Maurice Bernardin, Marie Baumann, Madame Rothschild, Centifolia rosea, Mrs. Charles Wood, and Antoine Ducher. In this class Mr. W. Ingle, gr., Round Hall, Colchester, was 2d, with, amongst others, grand blooms of Maréchal Niel, Rubens, Madame Crapelet, Maréchal Vaillant, Gloire de Dijon, and Cloth of Gold; Mr. Ebard, Clarendon Park, Salisbury, 3d, and the Rev. G. Arkwright, Pencombe Rectory, Bromyard, 4th. In

the class for 36, Mr. Baker beat fifteen other competitors with a collection of great excellence, comprising especially good blooms of Dr. Andry, Duc de Wellington, La France, Duke of Edinburgh, Louise Peyronny, Fisher Holmes, and Charles Lefebvre. Mr. Chard came 2d, Mr. Excell, gr. to J. Hollingshead, Esq, Maidstone, 3d; and Mr. J. Davis, Wilton, Salisbury, 4th. Next to Mr. Baker, for 24, came Mr. T. Gravely, Cawfield, Mr. J. Davis, and Mr. Sandall, gr., Wivenhoe Park, Colchester. The best 12 single trusses, distinct, were contributed by Mr. J. E. Cavell, Walton Manor, Oxford.

In the open class for 12 trusses of any new Rose of 1868, Mr. Keynes staged Marquise de Castellane; Mr. J. Durbin, Madame Rothschild; Mr. Turner, Duke of Edinburgh; and Messrs. Paul & Son the latter and Marquise de Mortemart. Messrs. Paul & Son had the best collection of 24 new Roses of 1868-9, one truss of each, including a fine seedling from Duke of Edinburgh, named Robert Marnock, deep maroon; and staged excellent representatives of the former variety and Centifolia roses, in the class for 12 blooms of any single variety. Mr. Keynes was 2d in the former class. In the latter class Mr. Ingle staged Jules Margottin; Mr. F. May, Braintree, Essex, Devoniensis; Mr. F. W. Bridge, of the same place, Maréchal Niel and Souvenir d'un Ami; Rev. G. Arkwright the last named variety, and Mr. Keynes La France. The best collection of yellow Roses also came from Mr. Keynes, a very fine lot of Maréchal Niel; Messrs. Paul & Son coming in 2d with Céline Forrestier and Gloire de Dijon.

In addition to the Roses, prizes were also offered by the Metropolitan Floral Society for Ranunculuses and Pinks, two classes each; the Rev. H. H. Dombrain winning both first prizes for the former flowers, Mr. Turner having the best Pinks. Mr. Hooper, Bath, and Mr. A. Evans, Marston, Oxford, took second honours for Ranunculuses, and the first named, and 2d for Pinks. Mr. Peiarger. gr. to Sir E. Perry, Fulmer, Slough, being 3d. In the class for miscellaneous productions were 11 fine boxes of Roses from Mr. Turner, a large and effective group of finefoliaged and flowering plants, including some well grown pot specimens of garden Phloxes from Messrs. Downie, Laird & Laing, boxes of Pinks and Ranunculuses from Mr. Hooper, Bath, a nice group of pot Roses from Messrs. Paul & Son, and a group of cut Pinks, Rose Pelargoniums, including Lord Lorne, bright scarlet, pip large, round, and smooth, and Frances, Countess of Waldegrave, a lighter scarlet, with a white eye, from Messrs. Burley & Martin, nurserymen, Brentwood.

Notices of Books.

The Honey Bee, its Natural History, Physiology, and Management. By the Rev. George Bevan, M.D. Revised, enlarged, and illustrated by William Augustus Munn, F.R.H.S. London: Van Voorst. With 21 plates, 8vo, 1870.

The common hive bee, Apis mellifica, together with its various local or geographical varieties, and a few other distinct species, found in tropical countries, have, from the earliest ages, attracted the attention of mankind; and probably there is scarcely any subject on which more or greater amount of ingenious trifling has been bestowed than in inventing and modifying receptacles for their domicile, with greater or less facilities for robbing the inmates of their honied stores. Dr. Bevan's work, published in 1838, has ever since that period been the standard English work upon the bee; but, after 32 years it has been deemed advisable to publish a new edition of it, in which it was intended that the many new and curious facts relating to the physiology and economy of the insect, which have lately been recorded, as well as the various improvements in the construction of the hive itself, should be brought together and described.

This task was undertaken by Major Munn, an enthusiastic bee-keeper, and inventor of a peculiar kind of hive, which attracted much attention in the Great Exhibition in Hyde Park, where so many differently constructed hives from various parts of the world were brought together.

We regret that it is our conscientious duty to state that this task has not been satisfactorily performed. That the arrangement of the various chapters has been transposed is not very material, although we think that Dr. Bevan's plan of giving the description of the insect at the commencement of the work was more judicious than placing it in the middle, where we find it in the new edition; but we are justly entitled to complain that throughout the work the editor has thought it proper to introduce words and passages and even chapters into the text, omitting also the original text in many places, without the slightest indication of what was original, or what has been altered or added by the editor.

We will confine ourselves in this review to the description of this hive (as illustrating the practical portion of the subject comprised in Part I.) and to the manner in which the editor has treated the physiological or scientific division of the work (Part II., to which, however, he has injudiciously transposed several of Dr. Bevan's practical chapters).

With reference to the origin of bar and frame hives we read in the original edition (pp. 106, *et seq.*):—

"It has been said that Huber borrowed from the Candiotes the first idea of his leaf-hive. These *descendants of a highly intelligent* people, *without being aware of the principle of their proceeding, continue the practice of their ingenious predecessors, in so far as simply surmounting* their hives with loose bars *can be considered as a continuation of it*, and are thereby enabled occasionally to raise artificial swarms and sometimes to practise partial deprivation, in a very easy and simple manner, but there is much casuality in their proceedings, little of science, *for in answer to enquiries, which I have repeatedly instituted through the medium of persons residing in the Archipelago, I have learned that the attainment of either of the advantages referred to is liable to great uncertainty; the mere removal of loaded combs among the Greek apiarians, so far from being at all times a simple and easy process, to use the language of one of my informality, often involves a very delicate and difficult operation.* Huber extended and *dimunished the system he has adopted.* As to the quality and thickness of the wood, &c."

Then follows a description of Mr. Golding's hive, with its various bars or leaves, and which the author concludes by saying, that it will "constitute what, I think, will be found an improved modification of the hive of Huber."

The portions of the passages printed above in italics have been left out by the editor, who thus sacrifices an instance of Dr. Bevan's careful research, as well as the doctor's appreciation of Mr. Golding's success. He has altered the passage commencing above with a "thus—" Later experiments, however, have proved this hive has admitted of still further improvement, and the hives of Du Beeuwois' construction [exhibited in the Great Exhibition in 1851] are the best and most useful," and then instead of describing De Beauvois' (not Du Beauvois') hive, he copies the whole of Dr. Bevan's description of Mr. Golding's, commencing "I have also found the thickness" "as wood," &c., pp. 305, 306. We see, therefore, that the idea of compelling the bees to store their honey in separate leaves of frames, capable of being removed for examination or deprivation, has been known in all ages, and several modifications of the principle were exhibited by Mr. Bevan, Golding, and Munn, in the Great Exhibition in 1851. The last named, however, claims (p. 37) to have first used his hive in 1834, to have patented it in Paris in 1838, and to have published a description of it in 1844, but unfortunately no copy of this description can now be found. As existing hives are one of the best suggestions, and at the same time most complicated of the hives then assembled, resembling rather "a lady's work-box with a stand and ornamental fittings," as was said of it by Prof. Hamet in his report on the Paris Exhibition of 1867, than a working beehive. It was in fact a triangular box of mahogany enclosing seven movable frames, each fixed by a hinge at one of the angles, so that it could be drawn up, when the top of the box was lifted off and received into a larger sized "observation frame" with glass sides of the same triangular shape. Not only, however, has Major Munn omitted, as he admits, that the triangular form is inconvenient, but that for practical purposes the glass observation frame is an incumbrance, and hence the hive which he exhibited at the horticultural show in Oxford in 1870, was square in shape, inclosing square frames without any "observation" frame whatever, the bees scarcely ever, except on some slight details, from those of De Beauvois and Golding. In his work the editor dwells much on having made the floor of the hive slant downwards from front to back, which enables any dead bees or other refuse to fall out of the hive at the entrance, which extends from the whole width of the back of the hive, and to reach which entrance the bees have to crawl up a second and lower alighting board of the whole width of the hive slanting upwards in the opposite direction from front to back. We consider this arrangement a very unnatural one, as bees invariably select a hole with a more level entrance, never left to themselves in swarming and choosing a place of abode; moreover, they certainly have the instinct to clear away any objectionable matter lying within the hive.

As to the name "honey-trough," which the editor has applied to his hive, it is a simple delusion, being equally applicable to a flat tin box, with a sloping glass cover extending over the greater portion of it, used for feeding the bees from a bottle placed neck downwards in communication with the perforated portion—and which is placed on the top of the bars when it is necessary to feed the bees.

In his description of the plates representing his hive, the editor says that the "bar-frame principle consists in having a 'bar with a frame' to carry each separate comb in a hive where the combs can be attached by the bees to the sides of the frames, and not to the sides of the hive, *as in all Grecian and other bar-hives or boxes.*" This statement is not, however, correct, since De Beauvois' hive consisted of nine four-sided frames, for as many combs enclosed within a square box of wood with a movable roof, which is precisely the principle of Major Munn's hive, although he triumphantly remarks, on p. 45, that "a law suit in America has quite decided the question of the bar-frame hive being the invention of an Englishman, and not French, German, or American, as has been supposed; and I am rejoiced to revive the question with such evidence in favour of the 'bar-and-frame hive.'"

Turning now to the scientific, or second part of the work, we find that the editor has adopted various opinions quite at variance with those of the more advanced and philosophic naturalists of the day. Thus his description of the young larva of the bee, and the manner in which it is nourished, is a strange jumble of fact and fiction, the fact being found in the reprinted description of Dr. Bevan (pp. 9 and 10), and the fiction being the additions of the editor (pp. 175, 176). Take, for instance, the following passage from the latter:—

"It is a question which will be fully explained when treating more fully of the larva state, whether it is not supported, in combination with vital force [!], by *endosmosis*; for the quantity of food left by the queen [!] in the larva cells, whilst the young is in the pupa [!] state, is nearly twice as much as the whole weight of the larva, and it seems to be the more solid parts of the food left from the mere [!] bee bread and honey (by the result of capillary attraction), according to the theory of Johns. Dutrochet), taking up the sugar and water and more liquid parts of the mixture."

And yet, although adopting this idea of endosmosis, or nourishment by absorption through the pores of the skin, he tells us in the next line that the larva is fed with farina or bee-bread; and in the next page (p. 176) how any one having learned that it opens the mandibles [mandibles] when in want of food, of which a most liberal supply is given to it by the nursing bees, which calculate the quantity which will be required so nicely that none remains in the cell when the larva is transformed to a nymph. Again, at p. 346, he reasserts the principle of endosmosis, stating that "*there is no mouth* developed in the larva, but the point of the spinnaret [*sic*] at the head, which enables the larva to spin itself into its own cocoon." This spinnaret is the nipple at the extremity of the labrum or lower lip, the action of the mandibles is above alluded to, and a careful examination with a lens clearly shows the rudimental upper lip (labrum), and a pair of rudimental lower jaws (maxillæ). This completes the parts of the growth of a mandibulated insect. In fact, how is it possible for a larva to feed upon bee bread without a mouth? The structure of the bee larva is, indeed, precisely similar to that of the wasp—larva which has no means of feeding on honey or sugar and water, but only on solid food. The question of endosmosis is far too difficult to be treated in the cursory manner adopted by Major Munn. We had further marked the long passage descriptive of Plate 21, at the end of the volume, in which a magnified figure is given of the larva of a male bee, as every line exhibits either an error in grammar or science; it is, however, too long for extract.

The doctrine of parthenogenesis, or the power of the queen to deposit eggs which produce male insects, without any previous fecundation by the male, is as easily discarded as that of endosmosis is accepted by the editor. Every entomologist, however, knows that female insects occasionally produce fertile eggs under similar conditions, and every bee-keeper knows that queen bees only produce male eggs if not impregnated by the twentieth or twenty-first day after having hatched from the eggs, or if not impregnated at all; so is it equally certain that the queen must have the power of depositing male or female (worker) eggs at will on arriving at male or worker cells. All these facts are explained by parthenogenesis, which principle has now been further applied to explain the singular anomalies exhibited in the propagation of other insects, such as the Polistes amongst wasps, and the Strepsiptera. Major Munn, on the contrary, believes that in all these cases impregnation had really taken place. If such, however, had been the case, the anomaly in the production of nothing but male eggs would not have occurred. We have not space or inclination to enter into further detail on this subject, but would advise Major Munn to study Signor Bulbiani's paper on the development of the aphides in the last published part of the "Annales des Sciences Naturelles," and its beautiful figures, where he will be able to discover the proper name, structure, and functions of the organ which, in the description of Plate x, he has misnamed the "spermatheca," and then, perhaps, he will also be ashamed of having given to the world such a set of caricatures as are to be found in some of his own plates.

—— Under the title *Beiträge zur Systematischen Pflanzenkunde* (Observations on Systematic Botany), Professor Reichenbach has recently published a series of articles chiefly relating to Orchids, and specially interesting as containing a descriptive catalogue of the Orchids of Brown's "Prodromus."

Obituary.

WE greatly regret to announce the death, in his 71st year, of M. CHARLES LEMAIRE, till lately editor of the "Illustration Horticole," a gentleman distinguished for his special knowledge of succulent plants and well versed in general botanical knowledge, as also in classical literature. M. Lemaire died in Paris, where he remained throughout the siege, suffering from a painful disease, and, we are sorry to add, in impoverished circumstances. We have received from his successor, M. André, a feeling tribute to his memory, which we shall have the melancholy satisfaction of publishing in our next issue.

June 22.—Overcast throughout. Rain fell continuously from 3 P.M. till midnight.

" 23.—Rain fell from midnight till 5 A.M. Generally cloudy during the day.

" 24.—Cloudy till slight. Fine and nearly cloudless after 8 P.M.

" A few drops of rain fell occasionally.

" 25.—Variable amounts of cloud prevalent. Generally fine.

" 26.—A very fine day. Generally cloudless after 7 P.M.

" 27.—Variable but fine throughout. A cloudless night.

" 28.—Showers of rain fell in the early morning. Variable amounts of cloud were prevalent. Fine after noon.

JAMES GLAISHER.

Miscellaneous.

JUNE, 1871.*

Month of delights!—so poets tune
Their lyres to make them all appear;
But all these pleasant things, this year,
Were of the scantiest kind in June.

Sheep-bells did tinkle as of yore,
And scythes were whetted to cut hay;
But when in swathes, O, lack-a-day!
No chance to shake or turn it o'er.

June, in whose course we look with hopes,
And watch the tender swelling fruits;
But grubs and aphis on the shoots
Have this year nearly spoil'd the crops.

Month set apart for bedding out
The tenderest of our gaudy flowers;—
But cold east winds, and some hail showers,
Did all their carliest beauties flout.

Few midges danced above the streams,
Nor dragon-flies show'd on the wing;
And beetles nestled, shivering,
For want of the sun's brightening beams.

Snow-capp'd, at times, the higher hills,
And hoar frosts glitter'd in low sites.
With heavy rains and chilly nights:—
So June has brought us many ills. *W. T.*

The Asplenium lucidum of New Zealand is regarded by the natives as a sacred plant, and Dr. George Bennett gives some interesting details of its superstitious uses. It is used by the Tohunga or priest when he is praying over a sick person, and

* See page 811.

endeavouring to avert the anger of the gods, to whose influence the illness of the individual is attributed; he waves a frond of this Fern over the patient, and, should it happen to break, it is regarded as a fatal omen. When the Tohunga consults the gods, previous to engaging in any war enterprise, he also waves a frond of this Fern whilst he offers up prayers to the spirits: if it breaks, it is supposed that the gods are averse to their engaging in war, and the enterprise is abandoned. It is also used by the natives as a badge of mourning: when a wife mourns for her husband, she sits wailing in her hut, with a frond of this Fern bound as a fillet around her head; and a husband performs the same ceremony when he loses his wife. They are careful not to burn these plants, as it is said that when the chief has his hair cut: after the operation is performed, the chief holds a frond of this Fern in his hand, meanwhile the priest prays over him, taking the frond and shaking it; after which it is dipped in water, and shaken over the chief: if it breaks, it is regarded as a sign that he will not live long; and if one of the leaflets should break off, it is regarded as an omen that one of the family of the chief will soon die, but should the frond remain entire, it indicates success, health, and long life.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

The earliest flowering plants of *Cape Pelargoniums*, whether of show or fancy varieties, will have passed their best, and will now need attention in regard to pruning back, as a preliminary to another season's active campaign. Cut them down somewhat severely, but with an eye to secure as many well-placed eyes on the old matured wood as possible. After this operation has been performed place them in a cool house for similar position, and where rain cannot reach them. They should be kept somewhat dry at the root for two or three weeks to come, and until some little progress is made in the formation of young shoots. Seeds of that very showy greenhouse biennial, the *Schizanthus*, should be sown within the next week or two. Sow the seed in a rich nuctuous fibrous loam, with a little sand, peat, and thoroughly pulverised cowdung intermixed. Seeds of *Herbaceous Calceolarias* should also be sown now, if not already done. Place the pans in a cool, shady frame, and where drips or heavy rain-showers cannot reach them. *Chrysanthemums*, where intended to bushy specimens are formed, may be again pinched back, though it is not desirable to pinch any back very severely after the first week in July, as this not unfrequently tends to decrease the size and beauty of the blooms. Afford manurial waterings alternately, and proceed with staking and tying so as to be prepared for any wind storms that may occur. Repot *Vallotas* in equal parts of good peat, fibrous loam, with a dash of silver sand and well decomposed manure intermixed, in all instances where the roots require fresh soil or larger pots. Generally speaking, with moderate freedom during the next few months, and, indeed, until they push forth their blooms in or about August. Be particular at this season to keep *Tuberous Tropæolums* which are at rest dry at the root. The best way is to turn the pots containing the tubers upon their sides in a cool, moderately dry situation. Let me again draw attention to the fact that when bright sunshine does come, shading should be resorted to in most glass structures to which but a moderate quantity of air is admitted. This is the more necessary, owing to the fact that we have had so much dull weather of late. As soon as the weather becomes at all settled, it will be well to attend to any repairs, and painting and glazing that may be needed in greenhouses, cool pits, &c. Proceed with the potting of all plants requiring that process. The many delicate or newer varieties of plants that we have been unwilling to risk at an earlier date, may now be operated upon with greater freedom from risk, as these will now have time to make fresh roots, and re-establish themselves before the dull autumn months set in.

FORCING HOUSES.

Pines which are now advancing to the fruiting condition, or such as have undergone the preliminary stage to an early show, must now be regularly attended to, in regard to root-watering. It is difficult to say how frequently individual batches may need such attentions, as so very much depends upon the size of the pots they may be in, the texture of the loam, bottom-heat, &c. Should the weather prove dry and hot, however, they will need moderate supplies every three days or so, according to the dryness of the air and the amount of actual sunheat. Those *Pines* which are about to ripen their fruit must be kept rather drier, from the time when, by imparting an agreeable odour to the air, and by a slight change of colour, they exhibit symptoms of ripening. Give air always during mild periods as freely as possible, but maintain such a degree of heat as has been suggested in past Calendars. *Vines* which are ripening their crops evenly and kindly may be permitted to grow a few young shoots, if they push forth freely and are not likely to give too much shade to the older and more matured foliage. By so doing, the necessary preparations for the future season's wood supply may be more successfully carried out. It has been previously suggested that late Grapes should be thinned more than those which may be termed mid-season ones, in view of their keeping better during the winter months, when a cold and necessarily damp atmosphere will often pervade the most carefully attended structures. Attend to the "root wants" of all *Young Vines* that are planted out. By neglecting to give periodical surface-waterings to such when they are planted out within-doors, we induce them to root too deeply, when, by greater attention, the roots may be maintained nearer the surface. *Orchard-house Trees* should now have a good mulching with rich, thoroughly-decomposed manure, and should be watered very frequently. Many fruit trees, such as *Peaches, Nectarines*, and *Plums*, will now have finished stoning, and should be treated very liberally in regard to syringing, so as to aid them as much as possible in the final swelling process.

HARDY FRUIT GARDEN.

In any case where the usual pruning, nailing, and thinning operations, connected with wall fruit trees, and which generally demand our earnest attention during the month of June, have not been completed, bring up all arrears with the utmost dispatch, for although the weather continued cold so long, and many things are backward in their growth in consequence, the year nevertheless does not loiter, and our routine of operations must keep pace with the seasons if we are to be prepared for the arrival of winter. The *Aphis pests*, especially black fly, seem to increase with amazing rapidity, even now when the young foliage has attained to a greater amount of consistency, and is more matured to withstand their attacks. Thin out the strongest breast wood or young shoots upon wall, espalier, and pyramidal *Pears, Apples*, &c., and shorten the points of the stronger ones remaining for a future season's tree increase.

HARDY FLOWER GARDEN.

Proceed with the layering of *Pinks, Carnations, Picotees*, and *Clove*s. Pegs should be prepared from old birch brooms, or similar material, some 3 or 4 inches in length, and nicely pointed. Provide a rich open compost, consisting of three parts loam and one each of decayed leaf-mould and sand. Clear away all litter from around the old plants, breaking the soil deeply subsequently. Place a moderate mound of fresh soil around the plant, and proceed to prepare the shoots selected. First, pull off, without injury to the shoots, all old or injured leaves at the base of the young leaves of the current season's growth; then shorten the points of those young shoots selected. Now with a sharp knife make a slit from beyond a well matured joint upwards to the next one, which is nearer the growing point, and slanting inwardly at least half way, if this can be done without injury to the other half of the shoot. Having made the fresh soil moderately firm, make an opening therein some 2 inches deep, and place the shoot therein, choosing a peg and fixing down securely in such a manner as to leave the wound open, and so that some of the finer soil may fall within the cut, which is done by raising the point of the shoot gently upwards as the peg is being fixed firmly over its lower portion. Whilst the shoot is being held in its position place more soil firmly over and around it, and so proceed until all are done, when a nice gentle soaking of water from a fine-rosed watering-pot will nicely settle the soil amongst the whole. I have been somewhat more explicit, from a desire to aid those who, being uninitiated in the practice, nevertheless would like to perform this simple operation. Seedlings of either of the above may likewise be planted out permanently now. Be careful in doing so not to bury them too deeply, yet plant them permanently, notwithstanding. Bring *Box Clipping* to a close. Should a dry period follow the late cloudy weather, remove the temporary lights from *Auriculas*, clearing from around their base any decaying leaves, and giving them every requisite attention in regard to root-watering during dry weather. *Belladonna Lilies* may now be transplanted where necessary, though it is not advisable to do so oftener than every three or four years. Propagate *Double Rockets* and *Scarlet Lychnis* by aid of the matured growths at the base of each bloom-spike, and, when properly prepared, dibble them into a cool, shady border.

KITCHEN GARDEN.

Following the late rains, transplant permanently more *Celery, Endives, Autumn Cauliflowers*, such as *Walcheren, Coleworts*, &c., for early winter supply. Plant out *Cauliflowers* in rows about 30 inches asunder, the plants being at a like distance apart in the rows. Thin out finally all *Salsafy, Scorzonera, Beet, Hamburgh Parsley*, grown for the roots, and *Rampion*, to the customary distances apart. Make sowings of *Cabbage* and *Colewort Seats* for use, by means of successional transplanting during the months of October, November, and December, when they will prove very useful. Seedling plants of *Thyme, Sweet Marjoram, Savory, Hyssop, Burnet, Borage, Angelica, Sorrel*, and all similar *Herbs*, for which a demand occurs, may likewise be permanently planted out on to a sheltered favourable border. Make an effort to master all weeds thus early, and so insure immunity from them during the season. *W. E.*

Notices to Correspondents.

ASPARAGUS SPINACH: *Taylor.* Chenopodium Quinoa. Certainly different from ordinary Spinach, or from Goosefoot, and acceptable for variation sake.

CHINESE MUSTARD: *Taylor.* We believe this to be a variety of the White Mustard, Brassica alba. Nos. 2 and 3 are also forms of B. alba. No. 4 is B. nigra, the Black Mustard.

FUNGUS: *W. M.* We have little doubt that your Fungus is that state of Agaricus disseminatus which occurs occasionally in grass plots. It is doubtless very near Coprinus, but dries up rather than melts. *M. J. B.*

—*W. M.* The latest memoir on Penicillium that has fallen within our notice is that by E. Low, in "Jahrbucher fur Wissenschaftliche Botanik." Pringsheim. Vol. vii., part 4, p. 472—511. 1870. *M. J. B.*

GUN LICENSE: *H. R. V.* Yes, he must have a license to do so.

INSECT ON LAWN: *H. E., Greenawoy.* The insect is the common tick, Ixodes Ricini. Their profusion on the lawn is probably due to the sheep which fed on it having been much infested, and then scattered them partially around. For the sheep, the best remedy is careful washing with any good sheep wash, such as Girdwood's, or carbolic acid of proper strength. For the lawn we do not think you can use a better application than that you propose, a good dose of slack lime.

INSECTS: *T. M.* The insects on your Verbenas are one of the many species of Thrips. *J. O. W.*

MASDEVALLIA: *K. V.* You do not state the temperature, nor describe the atmospheric conditions or treatment. Probably the decay may arise from moisture hanging too continuously about the young tender growths. Masdevallias are essentially "cool" Orchids.

MEAN TEMPERATURE: *P. G.* For your purposes it will suffice to take the maximum and minimum twice a-day, add the sums together and divide by four, which will give you sufficiently nearly the mean temperature of the day; or, simpler still, observe the temperature between 9 and 10 A.M., at which time the thermometer indicates nearly the mean temperature of the day.

NAMES OF PLANTS: *G. M.* Orphis conopsea. We do not recognise the Fir.—*K. & L.* If wild, Geranium pratense.—*Marsh.* Geum urbanum.—*D. A.* Deutzia scabra.—*A. G.* Sisymbrium officinale.—*C. W. S.* Oncidium trigastrum.—*E. C. C. D.* Scrophularia aquatica.

PASSION-FLOWER: *R. B.* There are some 200 species—which is the one you mean? None are poisonous, but only a few worth eating.

PITCHERS ON CABBAGE: *T. W.* These are not uncommon.

ROSES: *W. F.* Your Roses seem to have a complication of disease. We observe Coleosporium pinguæ and Lecythea Rosæ, two leaf parasites, against which no remedy has been discovered. It is possible that there may be other fungal pests, but the specimens did not arrive in a good condition. *M. J. B.* We have also received, without any comment, specimens of the rootlets of some Moss (the old Conferva castanea), directed to King's Cliff instead of Sibberforth.—*A. Mc M.* It would not be right to exhibit Noisette Roses for Tea Roses.

TRAVELLER, CORRESPONDING CLERK, or SALESMAN.—Thoroughly competent; has a practical knowledge of Plants, their Value, Culture, Propagation, &c. Well acquainted with the country.—TRAVELLER, *Gardeners' Chronicle* Office, W.C.

SHOPMAN (Head), in the Retail Seed Trade.—A Young married Man, of the highest respectability and full experience.—H. H., 7, Highfield Road, Walton, near Liverpool.

BUTLER, where one or more Footmen are kept.—Age 36, married; good character, height 5 feet 9½ inches. Country preferred.—C., 7, Vine Street, Dursley, Gloucester.

REES AND CO.'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in fine condition. It is believed to be the best Artificial Manure yet produced. Its base is Peruvian Government Guano; it contains 21 per cent. of Soluble Phosphates, 4 to 5 per cent. of Ammonia with Salts of Potash. See reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Ogston, and Mr. Sibson. Delivered in 2 cwt. bags, each of which is secured by a tender seal bearing the Company's Trade Mark. The analysis is guaranteed so long as the seals remain unbroken.

REES AND CO. (Limited), 39, King William Street, London, E.C.

REPORT and ANALYSIS by DR. A. VOELCKER.
Consulting Chemist to the Royal Agricultural Society of England.
"Analytical Laboratory, 20, Salisbury Square, Fleet Street, E.C.
"London, January 15, 1870.
"SIR,—Enclosed you will find the results of a careful analysis of a sample of your Biphosphated Peruvian Guano. These results speak for themselves. I need therefore hardly add anything in recommendation of the high quality of this valuable Artificial Manure.
The samples examined by me contained only 10 per cent. of moisture, and fully the proportions of soluble and insoluble phosphates which I understand you guarantee to furnish, and was in a fine state of preparation. The more generally this Manure will become known to Agriculturists, the more, I am convinced, will it be appreciated by them.—Believe me, Sir, yours respectfully.
(Signed) "AUGUSTUS VOELCKER.
"The Secretary, REES AND CO. (Limited), 39, King William Street, London, E.C."

ODAM'S NITRO-PHOSPHATE or BLOOD MANURE.
ODAM'S DISSOLVED BONES.
ODAM'S BIPHOSPHATED PEA & BEAN MANURE.
ODAM'S NITRO BI-PHOSPHATE (or prepared) GUANO.

MANUFACTURED BY THE

PATENT NITRO-PHOSPHATE of BLOOD MANURE COMPANY (Limited), consisting of Tenant-Farmers occupying upwards of 80,000 Acres of Land.
Chief Office—109, Fenchurch Street, London, E.C.
Western Counties Branch—Queen Street, Exeter.
Irish Branch—49, Westmoreland Street, Dublin.
DIRECTORS.
Chairman—John Clayden, Littlebury, Essex.
Deputy Chairman—John Collins, 255, Camden Road.
Edward Bell, 48, Marine Parade, Brighton.

Managing Director—James Odams.
Bankers—Messrs. Barnetts, Hoare & Co., Lombard Street, E.C.
Solicitors—Messrs. Kingsford & Dorman, 23, Essex St., Strand, W.C.
Auditor—J. Carter Jonas, Cambridge.
This Company was originally formed in 1857, and is under the direction of Agriculturists, circumstances that have earned for it another title, viz., "THE FARMERS' MANURE COMPANY."
Several Hundred Thousand Tons of the Manures have been supplied to the Agricultural Public, and the increasing demand that existed for them is the best proof of the appreciation in which they are held.
Particulars will be forwarded on application to the Secretary, or may be had of the local Agents.
C. T. MACADAM, Secretary.
109, Fenchurch Street, London, E.C.

THE LONDON MANURE COMPANY
(ESTABLISHED 1840), have now ready for delivery, in fine dry condition,
PURE DISSOLVED BONES.

or PLANT CLEANSER, destroys Scale, Mealy Bug, Red Spider, &c., without injury to Plants; 6d. and 1s. per bottle.
The NEW SHOWERER, for applying the above, 6d., 1s. and 3s. 6d. each.
Wholesale of T. A. POOLEY, Sussex Wharf, Wapping, E.; and Retail of all Nurserymen, Seedsmen, and Florists.

TO CURE TISSUE,
for FUMIGATING GREENHOUSES.—Will destroy all the Insects, and not injure the Plants, and burns without the assistance of blowing. 1s. 6d. per lb., carriage free. A reduction in price for large quantities.
To be had of Messrs. R. ROBERTS AND SONS, 112, St. John Street, Clerkenwell, London, E.C.; and of all Seedsmen and Nurserymen.

MR. JAMES FRASER (of the late Firm of J. & J. Fraser, Les Bridge Road), undertakes HORTICULTURAL VALUATIONS of every description, SALES by AUCTION, &c.—Haylands Farm, Kendal, Essex.

To Market Gardeners and Others.
TO BE LET, on a 20 years' Lease, from Michaelmas next, 135¼ ACRES of good LAND, very favourably situated, close to the London and South Western Railway Station, Aldershot, Middlesex. B. B., Post Office, Staines.

TO BE SOLD, by Tender, pursuant to an Order of the High Court of Chancery, made in a cause of Meldrum v. Hayes, with the approbation of the Vice-Chancellor Bacon, at the Office of Mr. John Bolton, 6, Kendal Terrace, in the County of Westmorland, Solicitor, on TUESDAY, the 25th day of July, 1871, at 3 o'Clock in the afternoon precisely (unless previously disposed of by Private Contract), the GOODWILL and STOCK in TRADE of the BUSINESS of NURSERYMAN and SEEDSMAN of the late JAMES MELDRUM deceased, carried on by his Executors, at the Nurseries, 18, Castle Street, Mints Feet, Canal Head and Skewbarrow Garden, at Kendal aforesaid, and at the Shop and Premises situate in the Market Place, Kendal. The said Nurseries consist of about 14a. or 15a. of Land laid out as Gardens and well stocked.
Particulars of the Stock, and particulars and conditions of Sale and Forms of Tender may be had gratis of the said Mr. JOHN BOLTON, of Kendal, aforesaid, and of Mr. JOHN WILSON, Solicitor, Kendal.
Dated this 23d day of June, 1871.
JOSHUA BIRD ALLEN, Chief Clerk.
NICOL & SON, 88, Queen Street, Cheapside, London,
Plaintiff's Solicitors.

Important to Nurserymen, Florists, and Others.
TO BE DISPOSED OF, by Private Treaty, the LEASES, with possession, of the old established and well known CHEWICK NURSERIES, comprising a substantial 14-roomed Dwelling-house, with Seed Shop and Offices annexed, two Cottages in occupation, 12 Greenhouses and several ranges of Pits heated with hot-water piping, with the whole of the choice Stove and Greenhouse Plants; also about 12½ acres of rich and productive Land, cropped with first-class general Nursery Stock. Held under two leases at low rentals. The whole to be sold at an extremely low figure in the usual way.
For further particulars apply to Messrs. PROTHEROE AND MORRIS, Auctioneers and Valuers, Leytonstone, E.

SEED BUSINESS, in Yeovil, Somerset, for SALE: Of worth £500 per annum. Situate in the best corner shop of the town, and opposite the Market House. Carried on for the past two countries in the West for Farming and Gardening. It consists of Stock in Trade, Fixtures, and Lease 3 years unexpired, at low rent. The Books, Trade Lists and Books for the last 12 years can be examined. Reason for sale is that the present Manager, who has been for the last 12 years, is about to retire; and the Proprietor having an extensive Nursery business, has not the requisite time to attend to the Seed Department. Price £1,000.
J. SCOTT, Merriott, Somerset.

Pine-apple Place, Maida Vale, Edgware Road.
MR. J. C. STEVENS begs to announce that he has received instructions from the LESSEE, by Private Contract, the LEASE (38 years unexpired), STOCK, and GOODWILL of the old and well-established NURSERIES of Messrs. WILLIAM PAUL & SON & CO., which have been established upwards of a century.
Full particulars can be obtained of Mr. J. C. STEVENS, Auctioneer and Valuer, 38, King Street, Covent Garden, London, W. C.

SALES BY AUCTION.

Imported and Established Orchids, Palm Seeds, &c.
MR. J. C. STEVENS will SELL by AUCTION, at his Great Room, 38, King Street, Covent Garden, W.C., on TUESDAY, July 4, at half-past 12 o'Clock precisely, several COLLECTIONS of IMPORTED ORCHIDS, including many fine plants; an importation of ORCHIDS and BULBS from India; 112,000 SEEDS of PALMS, and other Plants, from Petropolis; and a variety of choice ORNAMENTAL FERNS.
On view the morning of Sale, and Catalogues had.

Rare Orchids.
MR. J. C. STEVENS has received instructions to SELL by AUCTION, at his Great Room, 38, King Street, Covent Garden, W.C., on THURSDAY, July 6, at half-past 12 o'Clock precisely, a small COLLECTION of ORCHIDS, including Vanda Cathcarti (rare), V. Roxburghi, V. Roxburghi cœrulea, V. cristata (rare), Cypripedium Spicerianum, C. barbatum, Aerides Lindleyana, A. Warneri, Saccolabium giganteum, S. Harrisoni, fine new Aerides in the way of maculosum, with spotted leaves; Cattleya Aclandæ, &c., all in fine condition.
On view the morning of Sale, and Catalogues had.

Orpines, Wateringbury, Kent.
IMPORTANT SALE of SHORTHORNS.
MR. STRAFFORD has received instructions to announce for SALE by AUCTION, without reserve, at Orpines, on WEDNESDAY, July 5 next, at Head of First-class SHORTHORN PURE-BRED YOUNG BULLS, from Messrs. F. Leney & Son's renowned Herd, which has been bred with great care and judgment for the past 30 years, and is of the highest class, are chiefly by Bulls of the unrivalled Duchess and Oxford blood, and from Cows of the Duchess, Oxford, Blushby strains, including Charmers, Fawsleys, Sweethearts, and other very choice tribes. Fully half the Stock are by 15th Grand Duke 7050, who has proved himself a first-class Sire, and they do credit to this favourite line of blood. Amongst the Bulls will be found a very promising rich roan Calf, from the magnificent Cow Sunshine, bred by himself in Herd.
Catalogues, with Pedigrees and other particulars, may be had on application to MR. MURTON, Seedsman, Nurseryman, and Florist, Epsom; or of Messrs. LENEY AND SON, Orpines, Wateringbury, Kent.

Smeeth, near Ashford, Kent.
IMPORTANT SALE of SHORTHORNS.
MR. STRAFFORD has received instructions from Mr. Thomas Hobbs, Smeeth, near Ashford, Kent, to announce for SALE by AUCTION, without reserve, on THURSDAY, July 6 next, the whole of his valuable SHORTHORN HERD, consisting of about 40 Head of Bulls, Cows, and Heifers, that have been bred from good and fashionable Herds, such as Messrs. Thompson, Cave Clayden, Wragby, Wells, and other noted breeders. The Young Stock are chiefly by King Oberon (16,521) and Safeguard (17,490); the latter is now in Mr. Hobbs's Herd. Also will be offered a very valuable KENTISH RAMS, for which Mr. Murton is so famed as a breeder.
Catalogues, with Pedigrees and other particulars, may be had on application to MR. MURTON, Smeeth, Ashford, Kent; or of Mr. STRAFFORD, 15, Regent Street, Waterloo Place, S.W.

Biddenham Annual Sale.
MR. STRAFFORD is instructed by Mr. Charles Howard, of Biddenham, near Bedford, to announce that the ANNUAL SALE of SHORTHORNS will take place FRIDAY, July 28, and will consist of about FIFTY AYCROFTSHIRE DOWN SHEARLING RAMS, and a few OLDER RAMS and EWES.
Luncheon at 1 o'Clock; the Sale immediately afterwards.
Biddenham is within a mile of the Midland Station at Bedford, where conveyances will be in attendance.
Catalogues: 13, Euston Square, N.W.—July 1.

Important Shorthorn Sales.
MR. JOHN THORNTON will SELL by AUCTION the following HERDS of PURE-BRED SHORTHORNS, several of which are of a very first-class and choice character.

THURSDAY, August 3, the second day of the Yorkshire Show, in a field adjoining the Railway station at Harrogate, at 12 o'Clock, the Stray, York, about FORTY HEAD, from the Rev. J. D. Jefferson's herd, including the Duke of the Waterloo, Daisy, J, and other choice tribes, all crossed with bulls of Duke blood.

WEDNESDAY, August 23.—The celebrated and first-class HERD bred by the late Thos. Barnes, Esq., at WESTLAND, Kells, Co. Meath, Ireland, now the best Booth blood Herd in the last 30 years. The small select HERD, the property of R. W. Reynell, Esq., will be SOLD at the same time and place.

FRIDAY, August 25.—The first-class HERD bred by J. G. Greve, Esq., at CASTLE GROVE, Letterkenny, Ireland, including several of the Fame family, crossed with Mr. Booth's bulls for many years.

TUESDAY, September 12.—At BROCKTON HOUSE, Eccleshall, Staffordshire, Mr. T. Bell's entire HERD, bred for 32 years from the first-class Booth blood.

THURSDAY, September 14.—Mesrs. Dudding's entire HERD, at FANTON HOUSE, Wragby, Lincolnshire, comprising about 100 head, including several prize winners. Mr. Booth's Manfred (50,801) is sire of the Bulls.

FRIDAY, September 22.—The first-class herd at CHAPEL BRAMPton, Northampton, the property of J. N. Beasley, Esq., consisting of the favourite J tribe, crossed with first-class Bates blood.

TUESDAY, September 26.—About 40 HEAD, including several of the Blanche and Nonpareil tribes, crossed with Duke blood, belonging to Mr. Wm. Ashburner, at NETHERHOUSES, Ulverstone.

The late Sir John Rolt's HERD will also be SOLD during the autumn at OZLEWORTH PARK, Wootton-under-Edge, Gloucestershire.

JOHN THORNTON, 15, Langham Place, Regent Street, W.—July 1.

The Royal Agricultural Show, Wolverhampton, 1871.
STAND 348.
SUTTON AND SONS,
SEEDSMEN by appointment to the Queen and H.R.H. the Prince of Wales, will exhibit their—
SEED MUSEUM, AGRICULTURAL, HORTICULTURAL, and FLORICULTURAL PRODUCE,
Including 1000 Separate Varieties of Seeds, 250 Specimens of Dried Natural Grasses, and some of Sutons' Improved Italian Rye-grass 6 feet 3 inches in height.
All Goods Carriage Free. 5 per cent. allowed for cash payment.
Priced Descriptive CATALOGUES on application to
SUTTON AND SONS, Stand 348, Show Yard, Wolverhampton; and Royal Berks Seed Establishment, Reading.

THE LANDS IMPROVEMENT COMPANY,
(Incorporated by Special Act of Parliament.)
Drainage, Reclamation, Farm Buildings, Labourers' Cottages, &c.
DIRECTORS.
John Clutton, Esq. Granville R. Ryder, Esq.
Frederick L. Dashwood, Esq. Granville R. H. Somerset, Esq., Q.C.
Henry Farquhar, Esq. Harry W. Verney, Esq., M.P.
Lord Carlisle, M.P. Charles Watkin Williams Wynn, Esq., M.P. (Chairman).
John Horatio Lloyd, Esq.
The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy in respect of their Glebe Lands.
Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.
UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.
The whole outlay may be liquidated by a rent-charge upon the land, redeeming principle and interest, over 25 years.
No investigation of title is required.
Further particulars, and information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S. W.

Agricultural Land Improvements.
DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.
THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY,
(Incorporated by Act of Parliament in 1849.)
DIRECTORS.
T. Chapman, Esq., F.R.S. The Right Hon. Viscount Combermere
George Thomas Clark, Esq. Edward John Hutchins, Esq.
John C. Cobbold, Esq. Sir William Hart Dyke, Bart., M.P., D.C.L.
Henry William Peek, Esq.
Principal Engineer, Mr. J. Bailey Denton.
Agricultural improvements of every kind are executed by the Company, or the outlay thereon advanced to Landowners or Trustees, who prefer carrying out the works by their own agents.
Tenant Farmers may obtain the requirement with their Landlords, procure the execution of such Improvements.
The capital so laid out on Land may be charged upon the Estate, and paid off by a Rent-charge of about 6 per cent., in 31 years, or at the option of the Landowner in a shorter period.
No investigation of title necessary, and no legal expenses incurred.
UTILISATION of SEWAGE.
Special arrangements with the Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, together with all requisite Engineering. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, discharging in a fixed period the principal amount with interest thereon.
Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 4, Great George Street, S.W.

MANCHESTER and LIVERPOOL AGRICULTURAL SOCIETY.—Prize Lists for the Show at Liverpool in SEPTEMBER NEXT may be had on application to the Secretary. Upwards of THREE THOUSAND POUNDS are offered in PRIZES, including £100 for the best Heifer, £80 for the best Shorthorned Bull, upwards of £200 for Hogs, £200 for Poultry, upwards of £275 for Pigs, and £300 for Sheep. ENTRIES CLOSE AUGUST 1.
THOMAS EGERTON, Secretary.
Winsford, Cheshire.

ROYAL AGRICULTURAL SOCIETY of ENGLAND.
WOLVERHAMPTON MEETING, 1871.
SHOW OF HORSES, CATTLE, SHEEP, PIGS, and IMPLEMENTS,
SATURDAY, July 8, to FRIDAY, July 14.
Admission—Saturday (Implement Yard only), 5s. Entire Stewards' Holiday, 5s.; Tuesday and Wednesday, 2s. 6d.; Thursday and Friday, 1s.
Season Tickets, price 10s. 6d., available from July 8 to July 14, may be obtained of Messrs. CLOUGH AND HARNETT, Wolverhampton; or of
H. H. JENKINS, Secretary,
12, Hanover Square, London, W.

The Agricultural Gazette.
SATURDAY, JULY 1, 1871.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

July 3 to July 8	Agricultural Society's Meeting at Wolverhampton—Trial of Steam Cultivators.
July 10 to July 14	Agricultural Society's Meeting at Wolverhampton—Showyard open on Monday for open judging.

IT is a curious illustration of the way in which an engrossing subject gathers food from every quarter, that a recent article in the *Daily News* on the Census of 1871 ends in a discussion of THE SEWAGE QUESTION as its proper issue and conclusion. The population is more and more massing itself in towns. Rivers—the natural drainage system of the country—are thus becoming more and more polluted. The town which robs the country of its power for cultivation robs it also of one great means of its fertility. Man, the best "farm stock" in the world, is, by the force of circumstances, being more and more turned to wasteful and even to mischievous account. The water supply of our great towns is being perfected—the water-closet is everywhere adopted, and the sewerage of house and street is carrying valuable manure to waste—and the whole evil is growing with the growth of population and of improved town management.
Meanwhile the hopes of those who imagine

that from the ton of sewage which, in ordinary circumstances, proceeds every ten days from each member of a town population, it may be possible to precipitate the small quantity of fertilising matter which it contains, so as to obtain a solid manure suitable to ordinary farm management, have been aroused by the announcement of a company using Dr. FORBES' patent for this purpose. A phosphate of alumina, insoluble, and therefore useless in its natural condition, has been found in large quantities in a West Indian island. This is decomposed by sulphuric acid, and the mixture of phosphoric acid and alum thus obtained is passed into the sewage as it flows from the mouth of any town drain. The alum, decomposed by the lime in the dirty water, throws down its clay, and this flocculent precipitate carries with it all the suspended matter of the sewage, which is thus clarified and dismissed in a clear and an apparently clean condition. Moreover, as the stream in which the mixture of alum and phosphoric acid flows to mix with the sewage, a small trickle of milk of lime is added ; and this unites with the phosphoric acid, and the neutral phosphate of lime, in extremely fine division, also falls, and thus helps both to hasten the precipitation of the sewage and to increase the value for agricultural purposes of the precipitated material. A sediment composed of the mud of sewage, to which 20 to 30 per cent. of phosphate of lime has been added, is a valuable manure, even though it has been hitherto true that the mud of sewage as thrown down by the "A. B. C." and other precipitating processes has been of little value, yet now that the precipitant contains a large quantity of phosphate of lime, it is probable that sewage mud may have a considerable marketable value. If this result should be obtained along with a purification of the sewage, enabling it to run with impunity into any stream or river, the gain would certainly be of the great importance towards the achievement of a satisfactory plan of sewage utilisation. Unfortunately we are not yet able to say that it is. The effluent water goes off clear, but not necessarily—and, indeed, not probably—clean. Unless some result very different from all hitherto known results of alum precipitation be in this case obtained, the effluent water, though clear, will not prove to be clean—it will be still putrescible. Containing organic matter in solution, this will putrify in hot weather, and the nuisance will not be abated.

We fear, therefore, we are no nearer, even yet, to the achievement of any success in sewage purification by precipitation. The only plan by which sewage can be utilised at the same time that it is purified, is by offering it to the roots of growing plants. They will feed on its filth, converting it into useful food, and the water will thus go from them purified. The supremacy of sewage irrigation, including within its single agency as it does all the methods, whether of treatment by mass of earth, or treatment by intermittent mixture in the earth with air, or treatment by bringing to bear upon its contents the influences of the various chemical substances which the soil contains—at the same time that all the while the main and leading agency of using the filth directly as plant food is in full operation—seems to be more and more established. Every other scheme results more or less in failure. This alone has always been more or less a success, and towns, large and small,—Norwich, Bury, Chelmsford, Croydon, Norwood, Worthing, Reading, Merthyr, Birmingham, Blackburn,—are being gradually driven to its adoption. In this way, ultimately, we may hope that some return may at length be made by the town to the country for that process of depletion and exhaustion which, our census returns show to us, have been for so long a time in constantly increasing operation.

WE shall not be able to give our readers any serviceable account of the proceedings of the great agricultural meeting at Wolverhampton until Saturday next. These proceedings have, however, really begun this week—and a staff of stewards, judges, and officials have been engaged, at first under difficult, but latterly under more favourable circumstances, in subjecting the various steam-cultivating machinery which has been entered in competition for the Society's prizes to the preliminary trial, which will no doubt have the effect of weeding the list of the less efficient implements, so as to enable a concentration of the testing process next week upon the smaller number which survive the trials that are now proceeding. The prolonged examination these given cannot fail, we should think, to increase the confidence of those who are intending to adopt steam cultivation, and who may be waiting for an authoritative verdict for their guidance. The competition for Lord VERNON's prize of £100, offered for the best combination of machinery for the cultivation of the soil by steam-power, the cost of which shall not exceed £700—the engine to be locomotive, and adapted for threshing and other farm purposes—is not a very extensive one: Messrs. HOWARD and Messrs. FOWLER alone having entered for it ; but it is an extremely interesting one, and no doubt many are waiting the issue of the trial.

The prizes offered by the Society are (1) for the best combination of machinery for the cultivation of the soil by steam-power, £100 and £50 ; (2) for the best combination of machinery for the cultivation of the soil by steam-power, the weight of the steam-engine not to exceed 10 tons, £50 and £25 ; (3) for the best combination of machinery for the cultivation of the soil by an ordinary agricultural engine, whether self-propelling or portable, £50 and £25 ; (4) for the best windlass, £20 ; (5) for the best snatch-block, £10 ; (6) for the best plough suitable for steam cultivation, £25 ; (7) for the best subsoiler suitable for steam cultivation, £20 ; (8) for the best digger, £25 ; (9) for the best cultivator, £25 ; (10) for the best steam-plough or scarifier, £20 ; (11) for the best roller suitable for steam cultivation, £10 ; (12) for the best harrow, £20 ; (13) for the best drill, £10 ; (14) for the best root or stone extractor, £10 ; (15) for the best combination of those implements not qualified to compete in classes 1, 2, and 3, £10 ; (16) for the best implement or part of tackle suitable for steam cultivation of any other description not qualified to compete in the preceding classes, £20 ; (17) for the best agricultural locomotive engine applicable to the ordinary requirements of farming, £50 ; and (18) for the best waggon for agricultural purposes, to be drawn by an agricultural locomotive engine, £20. For these several prizes there are entries in the various classes varying from three to thirteen in number.

No one will deny the merit of great completeness to the scheme by which it has been thus attempted to cover the whole field of steam cultivation with motive to improvement : and we are glad to see that a very large number of the agricultural machine-makers of the country come forward to compete. Messrs. FOWLER & Co., and Messrs. HOWARD & Co., are, of course, the largest competitors. Messrs. RANSOME, TUXFORD, AVELING, AMIES & BARFORD, BARROW, BURRELL, COLEMAN, HAVES, ROBY, WILLIAMS, and others, in alphabetic order, are also present ; and the list of judges, including names both new and old—Messrs. BRAMWELL, HEMSTEY, HICHIN and SHERBORN, among the former, Messrs. MENELAUS, of Dowlas, Major GRANTHAM, Messrs. KAY, of Darlington, and KIMBER, of Abingdon, among the latter, is ample and strong enough to give confidence in their decisions.

The trial is being held on the farm of Mr. TAYLOR, Barnhurst, rather more than a mile from Codsall Station, and nearly three miles from Wolverhampton. It commenced on Tuesday morning with Messrs. FOWLER's two 20-horse power engines and their 13-tine cultivator, by which, after some little difficulty, owing to the quantity of Couch in the land, 3 acres of land were torn up and cultivated 9 inches deep within an hour. Another pair of engines of less power afterwards did some good work with a smaller cultivator, and a single engine subsequently worked a 7-tine balance cultivator, taking a width of 6 feet. There was a fourth set of FOWLER's tackle tried later in the day, in which a 7-tine turning cultivator was worked with an 8-horse power double-drum engine and disc anchor.

The Ravensthorpe Iron Company then exhibited at work FISKEN'S patent process, in which, as our readers know, a light rope driven at 10 times the rate of the implement that is being drawn, gives the requisite speed to the plough or cultivator, which thus makes its way to and fro across the field with a comparatively small strain on any rope or anchorage on which it pulls. These occupied the judges on Tuesday. On the following day Messrs. HOWARD's double engine set of tackle and Messrs. BARROWS & STEWART'S roundabout tackle were submitted to similar tests, in the presence of Messrs. MENELAUS, C.E., and Messrs. HEMSLEY and SHERBORN ; and the other judges were engaged in testing the ploughs and other implements in classes 4 to 16. An accident to one of Messrs. HOWARD's engines has had the effect of postponing a portion of the competition in which they are engaged, until the final trial on the stiff land provided for it near Stafford.

The whole of these trials will be described in detail next week, when we hope also to lay before our readers some account of the other contents of the showyard.

A NORTH LANCASHIRE correspondent supplies us with a satisfactory explanation of that NON-INCREASE of the AGRICULTURAL POPULATION which successive census returns reveal. The decrease of the agricultural class in England may to some extent be attributed to the introduction of farm machinery — threshing, mowing, reaping, hay-making, pulping, and turnip-slicing machines. The greater part of these are now in general use, not only on large holdings, but almost on every farm, from 30 acres upwards, throughout the country. Before the common use of these machines, which are now regarded as an indispensable part of the equipment of a farm, all the uses to which they are devoted were performed by hand labour. By their aid the holder of a few acres, who kept but two men-servants, is now enabled to work his little farm with the assistance of a boy ; and whatever his acreage may be, the agriculturist is enabled to dispense with a proportionate amount of manual labour. Some years ago, in the districts of North Lancashire and Yorkshire, where the time of hay and grain harvest varies a little, the harvestmen used to go in large companies from one county to the other ; and a farm of 500 or 600 acres required from 50 to 100 additional hands to get in the harvest, the time employed varying from a fortnight to a month or six weeks, according to weather, and every room and available outbuilding was brought into requisition as a lodging. Those drones of harvestmen are now things of the past, and by the aid of machinery harvest operations are usually now completed in a very short time. The old adage, "As one door shuts another opens," has had its application here. North Lancashire, from an isolated agricultural district a few years ago, is now become one of the most important iron-mining and iron-producing districts of the kingdom, and the agricultural labourer, driven from his legitimate employment, finds better wages and shorter hours of labour at the mines and the blast furnaces.

The above reasons for the decline of the agricultural population apply with equal force to the counties of Yorkshire, Westmoreland, North Lancashire, Cumberland, and some of the border districts of Scotland. At the recent agricultural hirings, held in these counties, the following have been the average rates of wages paid for the half year :—Best men, £13 to £16 ; second class, £9 to £11 ; boys, £4 to £6 ;—first-class women, £6 to £10 ; second class, £5 to £7—(domestic servants, ranging from girls of 16—maids of all work—to experienced cooks, varied from £4 to £15) ; to this, of course, is added a good dietary, all found by the master. The food in farmhouses is plain, but of the best and most substantial kind : breakfast of good milk porridge, and bread and cheese—bread and cheese and beer in the forenoon—substantial meat and Potato dinner, with pudding and bread and cheese and beer—supper of milk porridge, and bread and cheese, or, very frequently, bread and meat (cold from dinner) and beer : tea on Sundays. On these terms the utmost difficulty is experienced in procuring farm servants. It is thus only that the agricultural labourer can be kept in the fields and homesteads of the North. How much easier is it not to account for the phenomenon of a reduced agricultural population in the South, where agricultural wages are so much lower.

—— PRICES have been unchanged, with, however, rather a downward tendency, in Mark Lane during the past week. There has been a very small supply of English Wheat offered, but the receipts from abroad were more liberal. —— In the Metropolitan Cattle Market the number of beasts has been larger, that of sheep shorter, than usual ; a fair clearance of both has been effected, and prices have been maintained.

—— The Act of last session, requiring a TEN SHILLINGS LICENCE to be taken out yearly by every

person carrying a gun, came into operation last August. Before the close of the financial year on March 31, 1871, 93,679 licences were issued—83,048 in England, 7615 in Scotland, and 3016 in Ireland. 965 cases were reported to the Excise of guns without licences, and 710 prosecutions were instituted.

—— Messrs. Sutton, of Reading, send us a single ear and straw of their Italian Rye-grass, 5 feet 6 inches long, together with a note from Mr. J. Snook, of the Irrigation Farm, Norwood, in which he states that the average weight of the first cut there this year is no less than 28 tons per acre!

—— If any one would appreciate the conservative effect upon the soil of a vegetable coating, whether of grass or cultivated crops, by witnessing the extraordinary Power of Ordinary Rainfall under circumstances fatal to the growth of plants, he should visit the neighbourhood of Swansea. The sulphurous gas from the copper smelting works in that neighbourhood has involved woodland, crop-land and pasture in one common destruction. The visible plant has disappeared, and the root accordingly is dead and gone. The consequence appears in fields, once cultivated and yielding large and valuable produce, now entirely bare; while, even where the slopes are not excessive, the whole surface is furrowed and seamed so as only an excessive flood or waterfall could, under ordinary circumstances, have shown its power. There is nothing to hold the soil together, and the fine particles are washed away. The gravel in the midst of the soil at length is bared, and, by-and-by, the fainfall collecting into rills upon this gravel surface, furrows out deeper channels for itself, until at length that which was a fertile meadow, or a market garden, is scored and seamed, and covered with *débris* of rock, as if the victim of an avalanche of stones, such as one sees in upland Alpine valleys. When the slopes are greater the result is even more extraordinary; and it appears as if the tender shoots of grass, which are here destroyed, were the only safeguard which hinders in our climate the conversion of our hill sides into cliffs, and our lower slopes into barren wastes of gravel.

—— The Rev. M. J. Berkeley would be much obliged if Mr. Odams' friend, whose specimens of diseased Wheat have reached him after considerable delay, would be good enough to forward further specimens to him at the Horticultural Society, South Kensington.

OUR LIVE STOCK.

CATTLE.

The sale of Alderneys at Buckhurst Farm, Berks, noticed in a recent impression, came off on the 23d ult., when Mr. Thornton sold 13 pure-bred animals. One lot, *Minnie*, brought £20 10s.; a lot 2 brought £18 10s., and other heifers made from £10 10s. to £15, according to age.

—— The following Booth cattle were shipped from Liverpool on board the Magellan, last May, for Messrs. Delgado Brothers & Sons, of Callao, Peru:—Viscount, calved April 8, 1870, bred by Mr. E. J. Smith, Islandmore, County Limerick, got by The Earl (27,623), and out of *Lancelot* by Best Hope (23,413); *Charming Nell*, bred by Mr. Jefferson, Preston Hows, got by King Charming (22,033), and of the "Gwynne" or "Princess" tribe; and, lastly, *Dainty Dame*, also bred by Mr. Jefferson, by Charming (22,033), and descended from *Duchess* by Cleveland Lad (3407). Viscount won the 3d prize in a class of 135 animals at the Royal Dublin show this year. His sire, The Earl, stood 2d at the same show three years in succession, and was out of the dam of the well-known Sovereign. *Charming Nell* is in calf to Mr. Booth's Vain Hope (23,470), by Lord of the Valley (19,637). The sire of *Lady Fragrant*. *Dainty Dame* is in calf to Knight of the Shire (26,552) by Commander-in-Chief (21,451), the 1st prize bull at the Royal Agricultural Society of England's meeting in 1868.

—— The Smeeth sale takes place on Thursday, July 6, the day after the Wateringbury sale, and will be conducted by Mr. Strafford. *Myra*, lot 1, the first cow in the catalogue, is by Photograph (20,492), and from *Star* by Captain Shafto (6833). She is a strain, which traces through such well-known names, as *Titania*, *Zinc*, *Roguery*, and *Pageant*, to stock long bred by Mr. Mason of Chilton. Four heifers and a young bull, all from this cow, will be sold. Lot 2, *Kentish Lassie* by The Don (18,989), is the first of a group of 16 individuals which owe their origin to *Miss Beau* by The Beau (12,182), a son of Belleville (778), from Mr. Bates' *Cambridge Rose 6th* by 3d Duke of York. Lot 3, by The Don (18,980), is the first of four representatives of *Twentieth* by Lockley (4240), and *Twentieth* by Stanhope (5315); *Princess* by the Don, and out of *Red Empress* by Cambridge Grand Duke (15,722) comes of the *Verbena* by Cedric tribe; *Wanton*, by Kentish Lad (22,027, is a grand-daughter of *Wanton* by Mameluke (13,289), and the female section of the catalogue contains other well bred animals. In the bull section are Safeguard (27,409), by Grand Duke of Essex 4th (24,068), and out of *Surmise 4th* by 2d Duke of Kent, and some young bulls of the tribes above noticed. Most of the cows and heifers are in calf to the last named bull, and he is included in the sale. Smeeth station adjoins the farm, and is four miles from Ashford, a central station on the South-Eastern line from London to Folkestone and Dover.

—— The Farnley Hall sale, in which the entire herd, so long bred by the late F. H. Fawkes, Esq., is to be disposed of, takes place on August 1. Mr. Strafford informs us that the present herd has been bred with "great care and judgment" for 40 years, and that it commenced with animals from the herds of Messrs. J. Whitaker and R. Booth—"Norfolk (2377) by Mr. Bates' 2d Hubback (1423) was purchased from the former in 1832, and was followed in the succeeding year by Mr. Booth's *Medora* and *Verbena*." Other ancestresses of the herd were *Laura* by Boughton (2868), bred by the Duke of Bucleuch; *Spots* by Garton (2052), and *Thornaine* by Stillington. Upon examining the catalogue further we find these good strains of blood have been further improved by the use of Norfolk (2377), Sir Thomas Fairfax (5196), Laudable (9282), Borrowby Boy (9980), Beaufort (9943), Lord Marquis (10,459), Reformer (18,687), Lord Cobham (20,164), and Reformer (24,930). The young stock are principally by Lord Harleston (26,633), a son of Duke of Darlington (21,586), and *Anemone* by Duke of Kent (19,619), and of the *Acomb* by Belvedere tribe.

ON FACILITATING THE TRANSFER OF LAND.

The heavy expense of investigating the title to real estate has long been felt; and though Parliament has often made attempts to remedy the grievance, nothing effectual has yet been done.

I have drawn, in outline only, a scheme which would, I think, reduce to a minimum the labour, and consequently the expense, of investigating titles. The substance of it is far from new, and may be stated in a single sentence. It is simply to give absolute power of sale to the person or persons in whom the legal estate vests. The purchaser, then, would need only to see that this estate really vests in the vendor.

Now the proposition will be met, at the outset, by two objections, viz., 1st, That it will annihilate trust property; 2d, That it will injure the lawyers.

In reply to the first, why should trustees be more likely to deal fraudulently with land than with consols? No one fears putting consols into trust, though the trustees have absolute power of sale, and the sale of consols is more public transaction than the transfer of stock. I have, however, endeavoured to give security against a wrongful sale by trustees.

The second objection is founded on truth, for what the parties gain the lawyers will lose. But for the comfort of the latter I would state that my plan is not one which, like magic, is to convert bad titles into good. Though it sows the seeds of a better state of things, it will not produce its full fruit for many years.

Now then for details. Let a "Commissioner of Landed Estates" be appointed, with deputies where needed. The use of this Commissioner will appear hereafter. His office may, by fees, be made self-supporting.

The first case of transfer which presents itself is the sale by a freeholder. This can hardly be simplified. But he would, however, give a form (No. 1), containing, 1st, the names of the parties; 2d, the consideration; 3d, description of the land; and, 4th, notice of fee-farm rents or other liabilities. A copyholder would convey by a similar deed, specifying heriots and alienation fees.

Perhaps it would be convenient to hold, in accordance with the principles of Roman law, that a deed executed according to the prescribed form implied covenant for good title, and that vendors who wished to avoid this liability must enter into a separate agreement with the purchaser.

The second case is that of mortgage with power of sale. Here the form (No. 2) would differ from No. 1 only in reciting,—"In consideration of £——, secured by a mortgage deed of even date herewith." If it be objected that two deeds will thus be required instead of one, I reply that the transfer of mortgage effected from the Act will cause no appreciable expense, and that the two together are not to bear more stamp duty than is now levied on one. Most mortgage deeds contain a clause that the mortgagee may sell without proving to the purchaser that the mortgagor has made default, so that, practically, the mortgagee will lose no power by the change. Mere equitable mortgages, where the legal estate remains with the borrower, would not be within the purview of the Act. Upon repayment of a mortgage, the reconveyance would be by form (No. 3), differing from No. 1 in reciting "in consideration of the repayment of £—— advanced on mortgage."

The third case is that of trustees. Here the transfer deed (No. 4) would recite "In consideration of a deed of trust of even date herewith," and the trustees, if they finally sold, would adopt form No. 1, or if they made over the property to any one named in the trust, would only have to recite, instead of a pecuniary consideration, "In conformity with the provisions of a deed of trust under date," &c.

If the parties beneficially interested chose to take an invidious security against the dishonesty of their trustees, they might be empowered to compel the latter to deposit with the Commissioner the deed under which they hold the legal estate, until certain events shall have taken place. Deprived of the possession of this deed, the trustees could not sell.

The fourth case is that of land inherited or bequeathed. I propose that when any one dies, seised of land, the legal estate should not pass direct to the heir or legatee, but, like personal property, to the executors or administrators, and that they should by a deed (No. 5), bearing only a nominal stamp, transfer it to the proper party. In the case of a will, where there may be some patent or latent ambiguity, it is easier for executors to decide, or to bring the point to a decision, than for a purchaser, who is a stranger to the family, to investigate the subject in after years; and such deed by executors should bar action of ejectment against a purchaser for value, the claimant being left to his remedy against the executors.

In the case of intestacy, the argument for throwing the *onus* upon the administrator is still stronger. For we have, in England, three distinct rules of descent. In some places all sons inherit equally, in others the eldest alone, in others the youngest. To prove any one to be the youngest, that is, that there is none younger, is like proving a negative. Surely, then, it is for the administrator, while the heir or heirs are living, and the facts recent, to obtain and register those facts, by making the land over to the legal claimant.

When a testator creates an estate tail, the executors could not, of course, transfer the legal estate absolutely to the life tenant. The law therefore should require, that in order to effect an entail a testator must appoint trustees, to whom the executors can transfer.

The above four cases comprehend the commonest transfers. Others, such as the transfer of a bankrupt's estate to assignees, may suggest themselves, and be disposed of in analogy with the preceding cases, and so to any peculiar case not provided for by the Act, the Commissioner might have the power of sanctioning a form.

No person should be compelled to adopt the new forms in the case of ordinary sale, mortgage, or trusts. It will take time to reconcile the public to them. But a gentle pressure might be put on by charging higher duties on all other forms.

Next, let us see the practical working of the scheme. You have purchased land with the condition that the title shall commence with A., who died, at a reasonably remote period, intestate, leaving sons, B. C. administered to the estate; B. mortgaged to D., who put the mortgage into trust with E. and F. Subsequently B. repaid the loan, and now offers the land for sale. He produces—1. Letters of administration to C.; 2. Transfer from C. to B.; 3. Transfer from B. to D.; 4. Transfer from D. to E. and F.; 5. Transfer from E. and F. to B.

To look over these short deeds would not take half an hour, and any one of moderate intelligence, with sufficient knowledge of the stamp duties, might trace the title himself. If a professional man were employed, the charge would be a mere trifle compared with an ordinary bill of the present day.

The above scheme differs from most others in not requiring registration or parish maps, the continual alteration of which would be a source of great expense. I would, however, allow the Commissioner to enrol deeds drawn in conformity with the Act, and provide that in the event of the originals being destroyed, copies attested by him should be received as evidence.

While desirous of avoiding matters extraneous to the scheme, I would just remark that the present mode by which copyholders can compel enfranchisement is too expensive to be generally useful. An Act should lay down principles on which might be valued not only fixed annual payments, as quit-rents, but also more uncertain dues, as heriots and alienation fees. The chance of escheats is perhaps too small to have an appreciable value. The Commissioner, having calculated, according to the Act, such charges on his estate as were therein specified, and having added, for any particular charges not so specified, a reasonable sum, should tender the same to the parties interested, and upon their offering, either actively or passively, any opposition to the proposed enfranchisement, the copyholder might petition the Commissioner, who, after hearing the other side, should have power to determine both as to the subject-matter and as to costs. Freeholders might be allowed to extinguish fee-farm rents in the same manner. *G. Sparkes.*

AGRICULTURE AND CHEMISTRY.

In the year 1866 I made an experimental trial of the plan lately proposed by Mr. Marshall Hall. I then commenced a series of 40 lectures to a class of farmers' sons at Kingscote, a village about 15 miles from the Agricultural College. The lectures were given under the auspices of the well known Kingscote Agricultural Association, a thriving and enlightened farmers' club. The class, numbering something like 20, was quiet, regular in attendance, and passed a fair examination at the close of the course, which extended over two years. The lectures were devoted to inorganic, organic, and agricultural chemistry, the subjects being taken in this order, that a good scientific basis for the agricultural application of chemistry might be secured. At the same time an agricultural bias was

given, even to the earlier lectures, by illustrative experiments, made, as far as possible, with substances produced on the farm or useful to the farmer, with plants, soils, and manures. More than this, the pupils of my class were encouraged to repeat the chief experiment shown in the lectures, and several of them actually fitted up little laboratories of their own at home. I regret that I have not been able to repeat so encouraging an experiment, but the great difficulty was in the distances which both students and teacher had to travel in order to reach the place of meeting. My own journeys, during this course, give a total length of 1200 miles, and, owing to the absence of a railway, had to be performed under peculiar difficulties. But I am convinced that the system which I carried out in 1866-7, and which Mr. Marshall Hall has just suggested in his letter to the *Devizes Gazette*, may, when suitably modified in accordance with local circumstances, be carried out with immense advantage to the general farming interest. I ought to add that the scheme above described owed much to the suggestion and help of the Principal of the Agricultural College. I hope, on another occasion, to develope further a method of scientific instruction for young farmers, and to describe a plan for the creation in England of agricultural experimental stations where chemistry might be brought to bear upon agriculture in several directions.

I would now ask for a little more space, in order to describe briefly one of the most obvious aspects of the manure question. How is it that unanimous need manures, such as the different varieties of superphosphate of lime, are often sold to farmers at a price so much higher than that at which their crude constituents can be purchased? We know that the process of manufacture is not tedious or troublesome, and that its cost is small. And we know also that many manufacturers of superphosphate supply manure dealers wholesale with fair qualities of this manure on terms which allow the latter a broad margin of profit, but that the farmer has to pay not the manufacturer's charges only, but those of the dealer as well. I little has pointed out one of the ways in which a farmer may get a manure for, say, £4 per ton, which shall be guaranteed to contain 26 cent. of "soluble phosphate," and for which he would have to pay, in the ordinary course, from 5 to 6 guineas, if not more. But it is only fair to point out that two manures may analyse equally well, and yet differ in their effectiveness very considerably. This remark applies with especial force to nitrogenous manures, in which the nitrogen may exist in various degrees of availability. It is, on the other hand, highly probable that the soluble part of a mineral superphosphate, provided some decomposing carbonaceous matter be present, is as useful as the corresponding constituent of bone superphosphate. Thus, the argument for difference of price, which manufacturers urge by reason of their employment of the best materials, must not be pushed too far. An instance in point may serve to illustrate my meaning clearly.

In the spring of this year some samples of manure were sent to me for examination. I was subsequently informed that the price charged for them was £8 8*s.* per ton. Now, on analysis, I could only rate them at about £5 5*s.* per ton, assuming their several manurial elements to have been derived from the most valuable crude materials. But what was the argument against my valuation which Messrs. A. & Co., the well-known manufacturers of this manure, urged with the farmer who had purchased the manure? It was to the following effect:—"Our manures are the final result of long-continued thought and experiment; they have been successfully submitted in the field to the severest trials by numerous farmers; we have sunk thousands of pounds in arriving at our present processes of manufacture, &c., and, moreover, our manures are compounded and mixed in such admirable proportions, and with such exquisite skill, that they must not be judged of by the inadequate test of chemical analysis." Let us pursue this admirable argument a step further: let us apply it to an animal's food instead of a plant's food. Only mix stones with bread, with a sufficient amount of exquisite skill, and anxious thought, and long experience, and the innutritious stone or other rubbish becomes a most useful material for sustaining life!

Unfortunately, the farmer has not only to deal with mixed manures (which too often justify descent to the epithet "nostrum" which Mr. Little uses in this connection), but he has to suffer from the gross frauds of purposed adulterations. We shall not easily forget the revelations as to the ochre-grinding machine at a Liverpool guano works, nor the *exposés* which are continually made in our agricultural journals. The unscrupulous are tempting subjects for adulteration. After all, they won't crystallise and won't distil, and so come under the great class of "dirts." Here is an analysis of a very dirty dirt indeed, which was analysed in my laboratory last week, having been purchased for a good superphosphate, at a good price, by a deluded agriculturist.

Analysis of Superphosphate, from Mr. ——, May 24, 1871.

Water	17·33 per cent.
Organic matter and combined water (containing nitrogen equal to 0·372 per cent. ammonia) ..	16·31 ,,
Monocalcic phosphate (corresponding to 2·31 per cent. bone earth made soluble)	1·74 ,,
Tricalcic phosphate	5·02 ,,
Calcium sulphate	12·92 ,,
Common salt	16·82 ,,
Sand	19·30 ,,
Alumina, ferric oxide, and alkaline salts ..	10·86 ,,
	100.00 ,,

It is evident that in making this exquisite mixture the zeal of the operator had outrun his discretion: he had evidently scraped the floor a little too hard. *A. H. Church, Royal Agricultural College, Cirencester, in the "Chemical News."*

SEWAGE IRRIGATION AT RUGBY.

THE question of sewage irrigation, after being long regarded by the public at large as the hobby of a few enthusiasts, has of late years taken to a greater extent its proper place as a subject of national importance—indeed, as one which can no longer with safety be neglected. The public, ever slow to adopt new ideas, has come to see and acknowledge the necessity of dealing with the sewage of cities and towns upon recognised principles. These are, that impurities of all kinds shall be removed from the centres of population in a prompt and effectual manner, and without contaminating our rivers and streams. Legislation has made the latter point imperative, and no excuse will now be accepted for the continuous pollution of streams. This being so far settled, the question presents itself how sewage impurities can be prevented from becoming a nuisance, and their fertilising properties preserved and used for the best. This question I now propose to consider, assuming, in the first instance, the necessity of dealing with sewage in a strictly sanitary point of view, and viewing the subject by the light of the experience acquired at Rugby. The subject seems to divide itself at the outset into three propositions:—

1. The application of natural principles indicates water as the readiest and best means of removing animal impurities.

2. Dilution, within certain limits, presents the fertilising properties of sewage in the best possible form for assisting the growth of vegetation.

3. The medium of communication between the fertiliser and the plant, namely, the soil, at once extracts all valuable properties, and affords the only effectual means of purification.

The question would therefore appear to shape itself into an inquiry how these natural principles can best be carried into effect. And here it may be said that no "hard and fast" line can be drawn, no "rule of thumb" laid down, which shall apply to any and every case. General principles being agreed upon, they must be subject to modification according to locality and surrounding circumstances. It will be well to indicate the conditions which are requisite, and the causes likely to render modifications necessary.

The first requisite is an ample and regular supply of water. In considering the quantity of water, it should be noted that while 20 to 25 galls. per day for each unit of the population will suffice for sanitary purposes, it may become necessary, for the purposes of irrigation, to increase the quantity to 35 or 40 galls. Happily, we have been enabled at Rugby to secure an abundant and unfailing supply from the river Avon.

And here we reach the important question of separation of rainfall from sewage. It is an immense advantage in every way when the quantity of sewage to be dealt with day by day can be ascertained and provided for. In a warm, dry season, like that of last year, when greater dilution would be desirable, the rainfall fails to accomplish it; while in a rainy season the fall upon the land may make it advantageous to reduce the dilution. This is essentially the case in winter, when vegetation is nearly or quite at a standstill, and when excessive dilution by rainwater reduces the temperature of the sewage. The balance of advantages would seem to be in favour of separation when required.

Nothing in the shape of storage is permissible. The sewage must be distributed at the earliest possible moment, to prevent decomposition and consequent nuisance, as well as to secure its full value to the land. Mechanical filtration is necessary to remove the solid parts. This is readily effected by tanks, with screens through which the liquid flows. A simple mechanical contrivance for agitating the more solid parts of the sewage before it enters the tanks would, I think, add materially to the value of the liquid.

Next in order would appear to be the question of suitable land. It may be laid down as an axiom, that the better the land in the first instance, the better the results to be looked for from irrigation. Sandy or gravelly soils are a mistake if better can be got. A good loamy soil, 15 to 18 inches deep, with some admixture of clay, and a gravelly subsoil, may be said to be the best. It will produce a greater variety of crops, of finer quality, and will more readily absorb and retain the valuable ingredients of the sewage, than any other soil. It must not, however, be understood that only this description of land will produce good results. Experience tends to prove that irrigation may be employed with advantage, under proper arrangements, on almost any kind of soil. The most important consideration, in an economical point of view, is to select land upon which the sewage can be made to flow by gravitation. Unless this can be accomplished, I consider it more than doubtful if sewage irrigation in ordinary seasons can be made a source of profit.

Ordinary pasture land is not fit for irrigation, nor is any other land without more or less of special preparation. This fact having been ignored, has led to most of the so-called irrigation failures. Due consideration must be given to the natural formation of the land, and all inequalities of the surface carefully levelled, or carried to the formation of the sewage, which means destruction of the crop, will ensue.

The distribution is generally recommended upon one of two different systems—the "Catch-water," or the "Pane and Gutter" system. Much has been said for

and against the catch-water system, but my experience leads me to regard it as by far the best system for distribution.

Under the catch-water system, the sewage is brought to the head of the field or section of land to be irrigated. "Carriers" are then laid out across the fall of the land, at distances apart regulated by the gradient and general contour. Then, by means of sluices and stop-boards, the sewage in the carriers is made to overflow at such points as may be requisite, or along the whole line of carrier. Some distance below it is received into a smaller carrier or "catch-water," from which precisely the same process is repeated, until the bottom of the hill is reached, and the effluent water thoroughly purified.

The "pane and gutter" system consists of a main carrier running at the head, and small ones or "grips" running with the fall of the land. In these latter the sewage is intercepted by stop-boards, and made to overflow right and left, until it finds its way to the lowest level.

Under almost all circumstances, a modification of both systems is to be preferred. Under the first system, pure and simple, the section next the main carrier always gets the first dressing of sewage, the next section always the second dressing, and so on, until by the time the lower levels are irrigated, nearly all valuable properties have been absorbed by the higher land. To remedy this obvious defect it is necessary so to lay out the land that each piece in turn can receive a first dressing. This I have done in several instances, with the best results. This being done, the width of the sections should be progressively increased, the widest being at the lowest level, to ensure proper purification. Unless the land is of very slight gradient, this system is to be preferred to the "pane and gutter." Where the latter system is necessary, the "grips" or downward carriers should not be of great length, but should be crossed by intercepting carriers, to admit of the advantages of first dressing, and consequent proper equalisation.

The advantages to be derived from these modifications are, that a smaller quantity of sewage is necessary, a shorter period of application suffices, and the crops are equalised over the whole surface.

Next in order will come the consideration of the kind of crop, and the times and modes of planting. The results of my experience show that Italian Rye-grass must be the staple, at least in our part of cultivation. The best season for sowing is early in September. The land must be first well irrigated, then ploughed, and properly levelled. This being done, and the best seed selected, about 6 bush. to the acre should be sown. In an open season the grass will spring in eight or ten days, but no sewage should be applied until there is a good growth over the whole surface. A slight irrigation will then suffice. Another dressing in the spring, preferably in mild weather, will prepare the crop for the first cutting. After cutting a copious dressing of sewage should be given at once, and again after each cutting during the season. It is usually considered that one sowing suffices for three years; but, if the sewage is properly applied, and the seasons reasonably favourable, the growth will be so luxuriant as to exhaust the plant, or nearly so, in two years. After Rye-grass a root crop should be substituted on land of a flat gradient, but on a steeper surface cereal crops may be best grown, due regard being paid to the nature of the soil, and the aspect. My experience is that all root crops should be sowed on ridges, high enough for the sewage to be carefully applied in the intervening furrows without touching the plants. The number of dressings must be varied, according to the season and the dictates of experience. The rule of ridging applies to all crops, except Rye-grass and cereals, and almost any vegetable may be advantageously grown, as Cauliflower, Cabbage, Carrots, Mangel Wurzel (which gives a specially good result), Onions, &c.

After one root crop the land may again be laid down in Italian Rye-grass. If the land is poor, and of steep gradient, successive sowings of Italian Rye-grass may be made, with no root crops between.

The solid deposit from the filtration tanks is of great service, if applied to the land immediately after removal. It will very much enrich poor soils, and increase their capacity for retaining the more valuable parts of liquid sewage.

It is a great point in favour of irrigation, that, in growing large crops and selling them to be consumed off the land, a sewage farm directly promotes, to a very large extent, the fertility of the surrounding district.

It must be borne in mind, in conclusion, that the mere application of sewage to a given quantity of land will not of itself ensure success. In this, as in every other pursuit in life, watchful care and untiring perseverance in applying the results of experience will be needed to secure the great benefits to be derived. Granted these are given, then experience proves that sewage irrigation may be made to yield the most astonishing and lucrative results. *John E. Palmer, Town Surveyor, Rugby.* [We understand that Mr. Taylor, tenant of Barnhurst, on which the Agricultural Society's trials are this week being held, is to receive the sewage of Wolverhampton on his land; and Birmingham is about to lay out large sums in the purchase of land for the abatement of the nuisance it creates. All these places have to come to Rugby, Croydon, Barking, and the other pioneers, to learn their lessons. Mr. Palmer's opinion is therefore of great value.]

LABOURERS' COTTAGES.

Messrs. Baily Denton, Son & North's Cottages.

The above cottages (the design for which appeared in your issue of May 13) are a very fair sample of the modern style, and unquestionably contain all the conveniences you mention. But to my mind there are one or two slight defects which might be easily remedied without additional expense.

The primary objects in designing a labourer's cottage ought to be comfort and convenience, both of which are, in a great many instances, sacrificed to external appearance. I do not allege that this has been done to any great extent in the design under criticism, yet I think that without much detriment to outward symmetry the internal arrangements might be improved.

In illustration of my meaning I submit to you a design for a pair of cottages (of which fig. 175 is an elevation, and fig. 176 ground and chamber plans), occupying almost precisely the same space as those above referred to. In comparison with them I admit that mine are less pleasing to the eye, but, estimated by success in attaining the main purposes of such erections, I think that they have more than counterbalancing advantages. It will be seen at a glance that the door being placed at the extreme side, and the omission of a second upper window, are faults in point of taste; but my contention is that the designer of labourers' cottages must be prepared to forego the

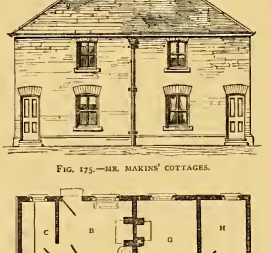

Fig. 175.—Mr. Makins' cottages.

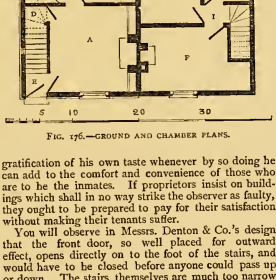

Fig. 176.—Ground and chamber plans.

gratification of his own taste whenever by so doing he can add to the comfort and convenience of those who are to be the inmates. If proprietors insist on buildings which shall in no way strike the observer as faulty, they ought to be prepared to pay for their satisfaction without making their tenants suffer.

You will observe in Messrs. Denton & Co.'s design that the front door, so well placed for outward effect, opens directly on to the foot of the stairs, and would have to be closed before anyone could pass up or down. The stairs themselves are much too narrow and awkwardly twisted. They cannot fail to be inconvenient for general use, and on exceptional though inevitable occasions will, I fear, be useless. I remember a case in the North, in which it was necessary to lower a coffin from a window in the upper room. Possibly this might be avoided by dexterity, but I see no necessity for the stairs in their present form, when, by a different arrangement, they can be made more convenient.

The windows appear to be casements, which are preferred by many for the sake of appearance, but are never so convenient as sashes, and are seldom, if ever, made water-tight. I have already noticed the omission in my design of a second upper window, another could be added if thought desirable, but it is not necessary, as I have appropriated the space over the entrance to the front bedroom, which is already well lighted.

Messrs. Denton & Co.'s pantry is much too small, and, taking into consideration that it has to serve the purpose of larder as well, it is placed too near the living-room fireplace.

I would also point out there is no provision made for cupboards, and there is not a single bedroom completely rectangular, the landing robs them all.

I have omitted in my design a fireplace in one of the bedrooms. The third room being necessarily small is better without one, if well ventilated in the ceiling. Messrs. Denton & Co. in giving three have exceeded the requirements of the Inclosure Commissioners, who only stipulate for two.

Below I give comparative Tables of cubical space contained within the cottages. Owing to the larger size of my fireplaces, my total amount is less than Messrs. Denton & Co.'s by 20 feet, but by the space saved in staircase, landing, &c., I still gain 351 feet in the rooms, distributed thus—living-room, 91 feet; scullery, 34 feet; pantry, 136 feet; bedrooms, 90 feet.

By making the cottages deeper I save a great deal of frontage, and in consequence economise in various expenses incidental thereto, such as road-making, superior workmanship, material, &c. Of course wherever (as is often the case) eligible frontage is limited, there would be the additional advantage of being able to build a greater number by one-fourth :—

Home Correspondence.

Quantities of Sewage Applied per Acre by the Metropolis Sewage Company at Barking.—I am surprised that one who is so ready to attack others should complain of my vindication of my statements as an unjustifiable attack on himself. Mr. Hope publicly—and, as I submit once again, without reason—asserted that my statistics were totally incorrect, and I publicly, and after inviting investigation by independent practical engineers, brought forward the results of Mr. Hassard's tests in support of what I had stated. In opposition of this, Mr. Hope desires your readers to believe that, owing to the lengthened experience which he claims to possess, his simple contradiction is sufficient to negative any statement he disapproves—very especially those which emanate from the secretary of the Sewage Company, who, in his letter of June 24, he speaks of as his pupil—and that should anything more be necessary to cast doubt upon my figures, it is to be found in an occasional possible interference with the working of our machinery. Mr. Hope must not, however, rely too much upon the help which this last affords him, because we have little or no interruption from the causes he cites, and should any arise to interfere with the proper delivery of sewage on to the farm, or cause a temporary suspension of the flow altogether, it would be at once detected and attention given to it. Neither can Mr. Hope be permitted to shield your readers without my offering a distinct denial to his statement as regards my pupilage, since it is perfectly well known that when this farm was taken and placed for the purposes of experiment in the hands of Mr. J. C. Morton, both Mr. Hope, the manager of the International Financial Society, and I, the secretary of the Sewage Company, were alike ignorant, in common with most others, of everything connected with practical sewage farming. However much, then, I may regret to deprive Mr. Hope of the honour attaching to the position, I must say that I do not understand in him to plume himself upon having been ever my master. With regard to the use of decimals, to which Mr. Hope attaches so much importance, as to admit that had I confined myself to round numbers he would probably not have questioned my figures, I am quite ready to admit that, although the breaking of gross quantities into common subdivisions necessarily entails fractions, the use of the one place in decimals, of which I was guilty, might have been dispensed with without really affecting the general results, although no doubt the want of exactness exhibited by the figures would have led to hypercritical objections similar to those which Mr. Hope now takes. I do not propose to trespass further on your indulgence than is necessary to express my thanks to you for the opportunity you have afforded me of endeavouring to show your readers that the statistics we have collected are practically correct, and to suggest that Mr. Hope's claim to superior practical experience in sewage farming, so constantly asserted, requires to be supported by detailed statements, such as we have annually presented, extending over and through those years in which he states that he had the start of me. *Henry Morgan,*

Lodge Farm, Barking, June 21. [The discussion seems to us to have been permitted long enough. Our readers may now be safely left to draw their own conclusions as to the risk of inaccuracy attendant on the methods by which successive managers of the Lodge Farm have honestly endeavoured to report the quantity of sewage which they have annually used, and the proportionate quantities which reached the different plots to which the sewage was applied during the year.]

Nature's Enactments and Acts of Parliament. —By reading your late articles on land tenure (in which I am glad to recognise the handwriting of one of your oldest and ablest correspondents), I am forcibly reminded of the old distich :—

"Of all the ills the human race endure,
How few that laws or kings can cause or cure!"

and have been led to think that if the owners and occupiers of land would study the laws of Nature more, and Acts of Parliament less, they would come to the conclusion that of all the remedies offered to us as panaceas by the different land doctors the most homeopathic would prove the best, in short, that all artificial barriers are more or less erroneous. And first, as regards ownership : When the inhabitants of these islands emerged from barbarism, and the population had become sufficiently numerous to occupy and cultivate all the land in the hills, it became a matter of necessity that the occupier who had reclaimed, fenced, and tilled the land, and perhaps built a house for his family and houses for his cattle, should have a permanent property in his outlay,—a fixity of tenure subject only to the services, quit-rents, tithes and other charges which the feudal laws, wherever they prevailed, or the Saxon customs in other places imposed on landed property, that being the only property that existed in a tangible shape. Hence the law of inheritance became also a necessity, and the power of making wills and settlements, otherwise no one would have taken the trouble to make these permanent improvements; the desire of founding and perpetuating a family being one of the most natural passions, and most conducive to the improvement of property. True that in times of civil war and uncertainty these improvements were multiplied by the invention of entails and uses to an extent now become unnecessary, and which have been to a great extent repealed; and I doubt whether any further removal of restrictions would have much effect in bringing more land into the market, or in reducing the price, in the face of the difficulty I just alluded to, by which rich men are tempted to give 30 or 40 years' purchase for a property—a price no person of moderate income could afford. At the same time there is no lack of land to be purchased in small quantities in the neighbourhood of towns and railway stations, where land jobbers, either individuals or companies, are universally buying up properties and subdividing them into small occupations, either for building suburban villas or for market gardeners and cowkeepers. Near these centres of population and industry the present owners are easily tempted to part with their land; at a distance from them small occupations are not so easy to any owner or occupier. So that, as far as I can see, any law that interfered with the natural law of supply and demand would be either inoperative or mischievous. 2dly, The laws which govern the occupier are more simple. His security should be ample so long as he farms with justice to the farm and with profit to himself, in the interest both of his landlord and himself; when he loses his capital and when he deteriorates his farm, this security should cease. His rent must be something more than the owner could make after paying the expenses of a bailiff or steward, allowing he would farm himself. The size of his occupation is limited by his means. He must not hold less than will produce him the means of livelihood according to his station after paying all outgoings. He must not hold more than his capital will enable him to stock and manage to the best advantage. Other things being equal, the larger the farm he can thus take, the larger in proportion will be the profit. The modern and expensive appliances, such as steam cultivators, &c., will be often remunerative on 1000 acres, while they would be ruinous upon only 100 acres. Nevertheless the size of farms in England is, from the natural causes above named to, gradually decreasing—the proportion of tenants holding 5 acres and under being one-half, and of those holding less than 100 acres being four-fifths of the total occupiers of land. And if the wealth of England continues to increase the size of farms must go on diminishing. More land will be taken every year for villas, for pleasure farms, for market gardens, &c. ; and from the same causes continuing to act on a lessened area, it will follow that the value of land must increase irrespective of any farming profits. Gentlemen will continue to purchase and rent land regardless of the interest it pays, for the sole pleasure of occupying, as they do now in the neighbourhood of London and large cities. This natural law will, I apprehend, gradually prevail, whether we like it or not, whether we try to modify it by Acts of Parliament or not. It has already cut up one-half of the area of England into plots of less than 100 acres, and will flow like a tide, gradual, but resistless, over the remaining half. In the meantime, let neither owner nor occupier of land be discouraged, but make the most of their present opportunities. Prices keep up, especially of meat and all perishable produce. High farming is paying very fairly. Let us cease to pester Parliament for new laws, or agitate for what is unattainable, while we neglect the advantages within our reach. *J. B. M.*

Gardening and Farming.—I could never understand why there should be any difference between the two as regards draining, deep cultivation, and abundance of manure and produce. I have asked why there should be any difference, and I am told by farmers :—1. That it would not pay to treat the garden as they do the farm—they would not grow enough. 2. When I say that is the strongest argument for gardening the land, I am told by the same parties that they have neither manure nor capital enough ; they don't mean areable capital enough, but, in plain English, they admit that they hold too much land in proportion to their capital. Now there is nothing so easy as to double a farmer's areable capital. I often say to my farming friends who have 600 acres of land, and complain of want of capital, "Take a farm of only 300 acres, and you will at once double your areable capital, and from my practical experience I can assure you that you will thus considerably increase your percentage of profit." That question of increased areable farm capital is one of the questions of the day, undergoing revision and solution, and the time is fast approaching when the important question will be, not how many acres do you farm, but how much is your areable capital. I am daily more and more convinced that from £16 to £30 per acre is not too much on arable farms. I know several who have that amount, and whose farming pay more than the average rate of profit. A cottage gardener who fattens his one hog on 20 rods of ground, absolutely makes at the rate of 640 lb. of meat per acre, or eight times as much as an ordinary farmer, therefore he also thus makes eight times as much manure. The result must be obvious. Therefore the quantity of meat a farmer makes on his farm, especially with food not the production of his own land, is a measure of his crop-producing powers. Britain is not half farmed, nor will it be until the areable capital of both landowner and tenant is vastly increased. *J. J. Mechi, Tiptree, June*, 1871.

Agricultural Experiences. — I got two roots to-day of Rye-grass, each the produce of a single grain, on one of which I counted the stems—193 ; the other had 150. I suppose it to have become 150. It grew in a place manured for Parsnips, which failed. I enclose a stem. I had last season, and have it still, a root of Wheat which grew in a thin place in the field, the produce of one grain, that had 55 stems, and of these 42 had good ears, another had 37. I could send this will not be credited ; but I have them, and would send them if I had an opportunity. I consider both cases a most extraordinary increase—beyond anything I have ever seen. *J. M. E.*

Co-operative Prices of Phosphate Manure.—Will you kindly grant me space to answer the questions asked by Mr. W. Gurdon in your number of June 17? Mr. W. Little, of Heckington, Hull, is the representative member on our Council of the Lincolnshire Association, and the price named by him is quite correct. The price of mineral superphosphate of lime ordered by members of the Lincolnshire Society (and of our allied Association) in the preceding autumn, and delivered in bulk anywhere within a given area (of which I shall be glad to give Mr. Gurdon a map). The manure being ordered in advance, and paid for before delivery, the Society only puts 1*s.* per ton profit upon it, to cover cost of analysing and other expenses. The higher price quoted by Mr. Gurdon, from the May number of the *Agricultural Economist*, is a price for manure ordered out of stock at the busiest time of the year. To supply orders the Association has to incur considerable expenses of warehousing, &c., and the rule, therefore, is to charge the current market price of the day, and then return to the members all the surplus profits after providing for working expenses and payment of 5 per cent. interest on capital. If Mr. Gurdon will refer to the June number of the *Agricultural Economist* he will see that the price has already been reduced to £5 per ton, and if he deducts from this price 12*s.* per ton for the average return to members, and 5*s.* 6*d.* per ton for the bags, he will find the nett price below £4 per ton, exclusive of carriage to rail. The price named by Mr. Little is for the delivery in bulk at the railway station. Having thus fairly quoted Mr. Spooner at length, I now assert that the entire aim and scope of true co-operative societies (not omitting our own) is of a totally opposite nature, both in theory and practice. Their object is not to pander to the "craving for cheapness," but in all cases to supply an honest article at a fair and reasonable price, of reliable quality, and without adulteration or trickery of any kind. They promote the true interests of producers as well as consumers, all honest interests being identical. The rule of our Association is to buy the best articles of each kind, and we refuse to deal in inferior or adulterated ones. As regards cheapness, all we do is to economise the cost of retailing the goods. An agent or broker adds nothing to the quality or value of goods, whether he is paid 1*s.* or £1 or £2 per ton for selling them ; and if by the union of our members we can distribute manures, and at an average 4 per cent. instead of 20 or 25 per cent. profit, that is a clear gain to the public—all political economists from Adam Smith to the present time proving it. Nor do we seek to attract customers by such pleas, as the "cheapest" articles are in most cases entirely excluded from our list. Thus genuine (second quality), (third quality), marked and unmarked oil cakes, we do not deal in, only the pure article. Then as regards superphosphates, if we want a mineral superphosphate for our members we act on Dr. Voelcker's advice, "Pay only for soluble phosphate ;" but we stipulate for the highest percentages obtainable, the use of the best materials by the contractors, and perfectly dry condition. What is more, we take care that we get what we bargain for, and Mr. Spooner will not venture to deny the force of the following statement. Of our analyses by Dr. Voelcker and Professor Sibson of our stocks of mineral superphosphate, taken at different times from September, 1870, to April, 1871, showed an average of 27.60 of soluble phosphate and only 14.37 of moisture. Mr. Spooner knows as well as I do that it would be impossible to get such high results of so permanent a nature out of the low-class phosphates he speaks of. I may add, that when we want dissolved bones we stipulate for the insoluble phosphates and ammonia as well as for the soluble phosphates, and tie the contractor to make the manure out of pure steamed bones. We pursue the same policy in all our contracts, and so far from stimulating the taste for spurious cheapness, we claim for our co-operative system that it induces a demand for high-class goods ; our members know that they get unadulterated articles when they pay for them, a certainty they cannot always have when they buy in the outside markets. *Edward Owen Greening*, 35, *King Street, Westminster, S.W.*

Professors Gamgee and McBride.— Having given insertion to "A Practical Farmer's" letter in yours of the 3d, you will probably think it only fair to give insertion also to so much of the enclosed, from the *Wilts and Gloucestershire Standard* of to-day, as shows that Professor McBride is not sought to be shelved. Professor Gamgee of any honour that is due to him, but, on the contrary, has spoken highly of him, as he deserves. I observe in your paper of to-day, that Professor McBride does not allude to this point, thinking, no doubt, that it is sufficiently stated that he is not honestly liable to "A Practical Farmer's" charge ; but all persons may not know this, and the charge having been made, its refutation should have equal publicity. *George Walters, Clifton, Bristol, June* 24. [The following is the extract referred to :— "We are very pleased to see 'A Practical Farmer' stand up so bravely for one who has deserved so well of his country in general and of agriculture in particular, as Professor Gamgee, and we much regret that he should be left to experience in his own person that 'virtue is its own reward,' but it is rather hard upon Professor McBride to attack him on this subject, since there are few men in the kingdom who more heartily appreciate the benefits which Professor Gamgee has conferred upon the farmers ; and perhaps the best answer to the above will be to print an extract from Professor McBride's lecture on Cattle Diseases at our Cirencester Chamber of Agriculture, as reported in the *Wilts and Gloucestershire Standard* of May 14, 1870, in which he said—

'Many veterinarians have drawn the attention of those interested to this subject, but none to the extent of Professor Gamgee, or with the same originality of thought. Since 1858, till the cattle plague appeared, he never failed to point out that most alarming fact—the result of the traffic in foreign cattle. Strange to say, one of the most influential agricultural bodies in this country would hardly listen to him ; they put him down as an enthusiast, a theorist, an idle dreamer. When he told them that if they persisted in introducing foreign stock, we should be certain to have a visit from dire destroyer, cattle plague, he was laughed at. In fact, he was said to be suffering from a peculiar form of madness —his hallucination being that this country would soon suffer from a plague which would destroy nearly all our cattle. Agriculturists said it could not occur—it was sensational—a myth—a mere shadow ; and further, when he informed you how cattle plague could be stayed, I firmly believe if Lynch law had been an English custom, the cattle dealers and others interested would have made an example of one who was, and is still, your best friend. Such has been the recompense that one of the most talented members of our much-abused profession received at your hands ; and why? Because he knew more than

'It is the aim of co-operative societies also to pander to this craving for cheapness, and to supersede it in this place. A superphosphate of lime is wanted to contain so much per cent. of soluble phosphate, and nothing more, save that it must be low in price. A manufacturer who wishes to supply it, of course, in order to secure some profit, buys a very cheap and low class phosphatic material, and treats it with sufficient acid as to secure the amount of solubility required ; and it is a fact that raw materials vary to the extent of 45 to 75 per cent. Thus undue stimulus is given to the inferior material, and the fair-dealing manufacturer is injured to the extent of the business he is deprived of."

his contemporaries, and because stock-holders were not sufficiently educated to receive the truths he communicated. I take this opportunity of saying that he has the most comprehensive view of all that pertains to epizootics. What did he do for Wiltshire? Stopped small pox. I am not aware of anyone, who has written or lectured upon this subject, advancing anything that he did not advise years ago. They but echo his words, without giving him the honour of being the first to suggest such measures. Government adopted his suggestion for cattle plague, after the loss of millions, but neither agriculturists nor the Government have either recognised or remunerated his valuable services. Every profession has had its martyrs, and I expect ours is no exception to the rule. However, gentlemen, it is satisfactory to know 'that it is never too late to mend.'

Could any recognition of Professor Gamgee's services be more complete, or any appreciation heartier? 'A Practical Farmer' has probably not seen this, or he would hardly have dragged Professor McBride's name before the public as an individual depreciator of Mr. Gamgee, because he is not perpetually acknowledging in every word that he writes how much veterinary science is indebted to that gentleman. Let it suffice to say, that if every one did Professor Gamgee as much justice as our worthy veterinary professor here, he would not have gone so long unrewarded. *Wilts and Gloucestershire Standard.*"]

Utilisation of Sewage.—Taking, as I do, a great interest in this question, in common with so many who advocate the use of town sewage, and to ask Mr. Mechi to add to the obligations we already owe him, by informing us whether the sewage of Romford, about which there appeared a paragraph from him in the *Times* of June 26, averages as much as 100 tons per head of the contributories, and whether in that case it nevertheless pours over the farm in a black state? Taking the figures set down, nearly 600,000 tons of the sewage are delivered in one year on to a farm not exceeding 120 acres, and when a deduction is made on account of buildings, yards, roads, gardens, &c., it will be near enough for the present purpose if we assume that 100 acres are under sewage irrigation—that each would, on an average, receive 6000 tons per annum. The population of Romford, as regards the farm, is said to be no more than 6000, so that each acre of land receives the sewage of 60 people, which is paid for at the rate of 2*s.* per head, or £6 for 6000 tons—something less than a farthing per ton. I lately noticed in your journal a statement by Mr. Hope, the lessee of the Romford sewage farm, that the pump upon it was worked continuously night and day; but whether this is so always or not, Mr. Mechi tells us that the results are the same as regards the annual quantity of sewage pumped and disposed of. I also noticed that, in Mr. Hope's opinion, the value of the sewage of each head of our population is 8*s.* Now, what I would ask Mr. Mechi is, whether, in his opinion, one-fourth of the value of sewage is all that I were I to become a sewage farmer to-morrow, would afford to pay for or whether, in other words, I must have the benefit of three-fourths of it to recoup me for the expenses attending the working of a sewage farm? Unless I am altogether wrong in my quantities, and I do not think I am, I cannot reconcile them and the price paid for the Romford sewage, with the price which I have always been assured sewage will fetch, namely, 1*d.* per ton, and at which price the Romford farm would now be paying £2500 a-year, or £25 per acre. The value of the Romford people, 6000 by 8*s.* per head, nearly approaches this sum, being £2400; but that the quantity of sewage which Mr. Hope is obliged to take is double that which it is considered safe to estimate as the average due to the population of towns generally. *F. P., June* 20.

Societies.

HIGHLAND AND AGRICULTURAL.

At the general meeting, held in the Society's Hall, George IV. Bridge, Edinburgh, on Wednesday of last week, Sir JAMES GARDINER BAIRD, Bart., in the chair: 194 new members were elected.

Mr. MURRAY, of Dollerie, moved the adoption of the byelaw No. 2, altered as follows:—"That proprietors farming the whole of their own lands, whose assessment on the valuation roll does not exceed £500 per annum, and all tenant-farmers, office-bearers of local agricultural associations, resident agricultural factors, land stewards, foresters, agricultural implement makers, and veterinary surgeons, none of them being also owners of land to an extent exceeding £500 per annum, shall pay at admission, and afterwards annually in advance, the sum of 10*s.*, with the option and power of redeeming the same by payment of £5, as the purchase of life subscription, and which life subscription may be so purchased, under deduction of any annual payments that the member may have previously made, with this limitation, that at no time shall a member have the power of redeeming the annual payments for a less sum than £3." The alteration was agreed to.

Mr. KINLOCH, yr., of Gilmerton, said he had to report that he had been given to understand that the arrangements for the next show at Perth were progressing satisfactorily. The following was a comparative statement of the entries:—

	Perth, 1871.	Perth, 1861.
Cattle	580	335
Horses	180	155
Sheep	630	616
Pigs	70	77
Poultry	290	300
Dairy produce	72	91
Implements	1500	850
	3120	2484

Mr. KINLOCH said he had to state the result of what the directors had agreed to in reference to the following motion, which was proposed by Mr. Munro, and seconded by Mr. Ord last January: "That a class of implements for competitive trial be annually fixed on, the implements to be exhibited at the show, and the trial to be held at the time of year best suited for testing the strength of the implements and the work performed. That the trial be extended over a longer time than has hitherto been the practice, and that it be remitted to the directors to make arrangements with the manufacturers as to the manner in which the trials may be most satisfactorily carried out." Mr. Munro was kind enough to withdraw his motion on the assurance being given that the subject would receive the consideration of the directors. The directors sent the matter to the general show committee and to the machinery committee. These committees had had a meeting with Mr. Munro, and at that meeting they went over the whole of the ground on which the present system was founded, which was embodied in a report and approved of by the Society in January, 1862. They resolved unanimously to adhere to the present system, but they agreed, as an experiment—and only as an experiment, which they did not at all approve of—to recommend that it would be competent for the local committee of the general show to select any description of machinery for special trial, the competition to be held when and where they might appoint. One year the implements chosen might be reaping machines, another potato lifters, another double-furrow ploughs, and so on. The directors undertook to give prizes for the competition, but they washed their hands altogether of the competition otherwise. They had very good reasons for doing that, inasmuch as they found it exceedingly difficult to manage on previous occasions. The report of the committee was approved of by the directors, and it was remitted to Mr. Menzies to submit the matter to the local committee at Perth. He did so when he had told them that the local committee at Perth declined the responsibility of choosing the implements, but they were willing to do so with the aid of the machinery committee. The local committee also undertook the management of the competition.

The Chemical Department.—Dr. ANDERSON gave in a verbal report on the experiments carried on in this department. In the first place he had to thank the Society for the leave of absence they had granted him during his protracted illness. He might mention, however, that during the period referred to he had personally conducted the whole of the correspondence of the laboratory, which was not little. During the last six months the business of the laboratory had been unusually large—the number of the analyses had been greater than in any previous half-year—and it had embraced analyses of all kinds. He had had an unusual amount of adulterated and inferior manures brought under his notice, while there had been two or three cases of suspected poisoning of cattle, sheep, and dogs, which had been examined into, but in only one case did he find poison. Specimens of water had also been examined, and he had seen enough to satisfy him that care was required in the erection of new farm buildings, and that attention should be paid to the position of wells, so as to provide against the possibility of their becoming contaminated. With reference to the adulterated and inferior manures, Dr. Anderson stated that he would not have brought them under the notice of the Society had it not been that the specimens examined were bought from manufacturers of the highest reputation, gentlemen who were making thousands a year from the business. In conclusion, he mentioned that he was at present engaged in an investigation of the scab in Potatos—a disease which had of late occasioned very considerable loss to the farmers.

Mr. MENZIES said, with regard to the minutes of the special committee of the Chemical Department, that the board approved of the following suggestions, and resolved to act upon them as opportunity occurred, in any re-arrangement of the Chemical Department:—"1. That the chemist should have his laboratory at the headquarters of the Society in Edinburgh, and reside there. 2. That in fixing the salary of the chemist the scale of prices for analyses should be revised, with the view of reducing the rates. 3. That the field experiments carried on by the Society should have the chemist's special attention. The publication of the results to be periodical, and under his entire charge and control."

Mr. HARVEY wished to know when the re-arrangement was likely to occur? The minute said "When an opportunity occurs." He had been speaking about it for the last ten years. In other ten years he might be somewhere else.

A long discussion followed, but no resolution was put on the subject.

Mr. MENZIES reported that the following premiums had been awarded since the general meeting in January:—1. The gold medal or £10 to A. H. Church, Professor of Chemistry, Royal Agricultural College, Cirencester, for a Report on the Cultivation of Sugar-Beet; 2. The gold medal or £10 to W. J. Moscrop, agent for the Earl of Zetland, Oliver, Richmond, Yorkshire, for a Report on the Best Modes of Housing Fattening Cattle.

Steam Ploughing.—Professor WILSON laid on the table the following memorandum as to ploughing at Dunmore, by Thompson's traction engine and Gray's balance plough, on February 28:—

"The ploughing took place in a large field at Dunmore Park, which had lain about 40 years in grass, and was nearly level. The soil was a strong clay, and in good order for ploughing. The engine is of 8-horse power, and weighs 7½ tons, with vertical boiler and cylinders. It runs on three wheels, with indiarubber tyres, each 2 feet broad, and covers a space 7 feet wide. The steam-gauge, when the engine was drawing the plough, indicated a pressure of from 120 lb. to 125 lb. per square inch. Five cwt. of coal and 700 gallons of water are stated to be consumed in a day of nine hours. The plough is a balance-plough, made by Gray of Uddingston, and is the first of the kind which has been constructed. The plough had three mouldboards. The engine travels on the unploughed land, dragging the plough behind it. The length of the furrow was 22½ chains, or 275 yards. The furrows made by the plough were 6 inches deep by nearly 9½ inches broad, and were fairly turned, considering that the ploughman had not much experience of the work. A braiding 20 yards wide was left at each end of the field for turning the engine. To travel the distance of 275 yards and to turn the engine, and attach it to the plough ready for the return journey, occupied a space of eight minutes; and this required considerable activity on the part of the engine-driver when turning the engine. The engine was driven by one man, with a boy to attend the fire and watch the pressure and water-gauges. The engine carried a store of coal sufficient for four hours' work, and four hours' supply of water. The plough was steered by one man, whose duty also was to hook and unhook the engine to the plough at the commencement and end of each furrow. At the end of each day's engine and plough were working, viz., three furrows 28 inches wide and 275 yards long, or 214 square yards, in eight minutes, the time required to plough an imperial acre was within a small fraction of three hours; and supposing the plough to work nine hours a-day, which, taking the average length of days in the ploughing season, is a full allowance, it would turn over 3 imperial acres per day, or about what two pairs of horses would do single-throne. It was observed that while the three ploughs turn over a space of 28 inches wide, the engine-wheels cover a space of 7 feet wide, so that the wheels of the engine pass three times over the land before it is turned by the plough. It was also noticed that the engine passing over the land depressed the surface about 1½ inch, and the soil was also compressed to this extent. The Highland Society's self-registering dynamometer, made by Messrs. Easton, Amos & Anderson, of London, was tried on the engine and three-furrow plough, and indicated a draught of 21 cwt. A common swing-plough, drawn by two horses, was tried to ascertain the difference in draught on the land in its natural state and where the engine had passed over, and it was found that the land, where compressed by the engine, required an additional power equal to the draught of 1 cwt., the engine ploughing 6 cwt. on the unpressed land, and 7 cwt. on that which the engine had passed over. The committee were desirous of seeing the engine and plough at work on stubble or ploughed land, but Lord Lansdowne had not land on which it could be shown. The committee would also wish to see the engine and plough tried in a field with a considerable slope. Lord Dunmore handed to the committee the following statement of the cost of his apparatus and of the daily expenditure in working it:—

Cost of engine, 8-horse power	£700	0 0
Cost of ploughs, three-furrow	70	0 0
Cost of water-tank..	30	0 0
	£800	0 0
Interest on 8-horse power engine at 5 per cent..	£35	0 0
Depreciation in value and wear and tear, 7 per cent..	49	0 0
	£84	0 0

Allowing engine to be under steam four days a week = 208 days, which gives 8*s.* 1*d.* as daily cost for engine £0 8 1
Ploughs, cost £70, at 5 per cent. on outlay, and 5 per cent. for wear and tear = £7 per annum, and for 100 working days that would be 1*s.* 5*d.* per diem .. 0 1 5
Tank would cost £30, which at 10 per cent. = £3 per annum, would give for 100 days 0 0 7
Engine-driver's wages at 24*s.* for 6 days 0 4 0
Boy, at 1*s.* per diem 0 1 0
Ploughman, at 2*s.* 6*d.* per diem 0 2 6
Coal, at 4*d.* per cwt., 5 cwt. 0 1 8
Oil and waste 0 0 6
£0 19 9

Autumn stubbles—in 10 hours ploughing we could do 7 acres easily—equal to 2*l.* 9*d.* per acre; spring ploughing lea, 5 acres—equal to 3*l.* 10*d.* The committee cannot close their minute without an expression of thanks to Lord Dunmore for his kindness when they went to inspect his lordship's apparatus, and the gratification that it gave them to see his lordship interesting himself in such an important subject as steam cultivation, in which they trust he may be successful."

Professor WILSON submitted the undernoted report on Fisken's system of steam-tillage :—

"Having, together with Professor Macquorn Rankine, been appointed by the Society as a deputation to inspect the working of the 'Fisken system' of steam tillage, we proceeded (April 20) to the farm of Offerton Hall, near Sunderland, in the occupation of Mr. H. M'Laren, where the 'system' has been in operation during the past winter, 440 acres, of very different quality, having been ploughed or cultivated on the farm since October last. Professor Macquorn Rankine was unfortunately unable to attend. The farm is of an undulating surface of about 600 acres in extent, and lying on the magnesian limestone. The fields appeared to have been deeply tilled, and the soils, of varying textures, were in a dry and friable condition. When wet, their tenacity would be greatly increased. There were no steep slopes or other obstacles met with while the work was under our observation. Before giving the results of our inspection, it will be well briefly to describe the peculiarities of the 'Fisken system' of working : as, although it has been before the public for several years, from various circumstances it has not hitherto taken a prominent position in the competitive trials of steam tillage which have from time to time been held. The 'system' differs materially from the other 'roundabout' modes of applying steam-power to tillage purposes. The engine which gives off the power may be placed in any convenient spot adjoining the land to be ploughed, on a roadway, or by a pond of water, for instance, and the power given off is conveyed by means of a light hemp rope (⅞ inch diameter) travelling at a high velocity—say 25 to 45 miles per hour—round the area to be operated upon, and communicating with the windlasses placed on opposite sides (headlands) of the land to be tilled. This high velocity, when communicated to the windlasses, is, by a simple mechanical arrangement, reduced to any desired velocity per hour. The reduction of the change of velocity being necessarily associated with the corresponding increase of tension of the ropes in the exact ratio of the rate of reduction of velocity (less, of course, the amount consumed by friction, &c.) Thus with an initial velocity of 30 miles an hour, when reduced at the windlass to 2 miles an hour, would correspond to an increase of tension (hauling power) equal to the rate of reduction—or 15 to 1—or pull of 1 cwt. on the engine's travelling rope at the engine is therefore increased to a strain of 15 cwt. on the hauling rope (steel wire) working between the windlasses. In the transmission of power from the engine to the implement a loss will always take place, greater or less in proportion to the extensibility and elasticity of the travelling rope, and to the friction of the various moving parts of the engine and tackle. The implement—a plough, cultivator, or harrow—is drawn by the steel wire rope backwards and forwards between the windlasses at any speed that may be desired. The mechanical arrangements of the windlasses enable the man in charge of the implement to turn forward at the end of each 'bout,' and also to stop and start the implement at work the required distance with perfect precision, without communicating with the engine-driver. Owing to some delays in reaching the ground, we found the work already commenced on a 14-acre field, of an irregular parallelogram shape, with a slight but increasing gradient along the line of working. The engine was placed near the entrance gate to a water-course, from which it pumped its own supply. The engine was one of Clayton & Shuttleworth's 12-horse power double cylinder traction engines, with 8.25-inch cylinders, and a 12-inch stroke, and working 'grooved' fly-wheels 5 feet in diameter, round and by which the travelling rope was driven at the same speed as that of the periphery of the wheel itself. The engine consumed about 13 cwt. of coal per hour when at full work. The 'travelling' rope was half inch in diameter, and made of the best Manilla Hemp expressly for the work, in lengths of 250 yards, each length weighing about 112 lb. Five lengths were required for the 1,250 yards, amounting to 5 cwt. in length, and weighing about 5 cwt., was carried round the field at a height of about 3 feet from the ground on light porters, with friction pulleys placed at distances apart of 50 yards on the light and 30 yards on the slack side of the windlass. The proper tension of the rope was regulated by a tightening pulley under the control of the engine-driver. While at work we timed the speed of the travelling rope, and found it varying from 35 to 40 miles an hour. The hauling rope was of steel wire, 3 in. thick, and 800 yards long, equal to a straight draught (furrow) of nearly 400 yards long. The implement at work was one of Fowler's reversing cultivators, working 7 tines, and covering 5 feet 6 inches, and set at a depth of 8, increasing to 11 inches. The field had been steam-ploughed with a 10 by 8 furrow in autumn, and was now being cultivated for Potatoes. The distance between the windlasses (headlands) was about 200 yards, and the average length of furrow was 190 yards. The double 'bout,' including the turning at both ends, took from 4½ to 5 minutes, according to the depth of working, giving a working rate of about 2 miles per hour. (The were-hauling rope, we noticed, was allowed to trail on the ground, Mr. M'Laren considering that the friction and extra wear and tear of rope was not equivalent to the cost of porters and attendants.) The work was done in a perfectly satisfactory manner; no hitch or difficulty was experienced in any of the movements of the implement or of the machinery. The fly-wheel made from 180 to 200 revolutions per minute, and the pressure increased from 60 lb. to 75 lb. per square inch, as the depth of working was increased. Every part of the machinery appeared to be under perfect and immediate control. At our request, the implement was stopped several times while working 11 inches depth, and started immediately, without any apparent difficulty or strain on the machinery. The number of persons engaged was four—two windlass men, one ploughman, one engineman. From these data it is seen that (at 70 lb. pressure) the engine was giving off a power equal to about 20 horses, while the cultivator was at its work. Not having any means (dynamometer or friction breaks) at our command to see how this power was consumed—that is to say, divided between the working of the engine itself, of the 'travelling' and of the 'hauling' rope, and of the windlasses, we could only obtain information from our Mr. M'Laren, who gave us the following as the result of his practical observations :—The engine, when working at the rate of 160 revolutions per minute, required a pressure of 8 lb. per square inch to set its own parts in motion, and an increasing pressure of 12 lb. per square inch, or 20 lb. in all, to give motion to the full length (1600 yards) of the 'travelling' rope. This would be equivalent to a consumption of rather more than 2-horse power by the engine, and of 3-horse power by the rope, or a loss of at least 5-horse power before the strain or pull reaches the windlasses. These details require to be tested by direct and careful experiment, as also does the power consumed by working the windlasses, before any just estimate of the effective force or actual working efficiency of the steam-power can be arrived at. Another important element for consideration, which has a direct money equivalent in the calculations, is the time required to set and adjust the tackle, to take it down again, and shift it to another locality. Mr. M'Laren informed us that they could begin to work in two and a half hours after the engine and tackle reached the spot, and that they could take all up again in one and a quarter hour, or altogether four hours in all. Mr. M'Laren also informed us that he had ploughed a field of 33 acres without having to shift the tackle at all, and another of 55 acres without having to move the engine, which was placed advantageously close to a supply of water. We were also informed that the engine and the whole of the tackle had remained out in the fields during the whole of the winter, and certainly without any appearance of deterioration in the engine or machinery. The advantages claimed for the 'system,' simplicity and economy of working arrangements and of first outlay, and general adaptability to fields of varying size and shape, appear to be fully established by the practical success it has achieved on Mr. M'Laren's farm. Until, however, it has been ascertained by direct and careful testing what amount of power is consumed by friction, &c., and what amount is consumed in the economic management of the tackle, it is not possible to give any judgment as to the practical efficiency of the 'system,' or its comparative economical application. If the verdict on these points be satisfactory, the system should have come out by practical success a powerful competitor for public favour in the field of steam tillage, and Mr. Fisken will be entitled to the thanks of the agricultural community for having successfully worked out a new mode of applying steam-power to the mechanical forces of the farm.

"P. B. SWINTON, Holyn Bank.
"JOHN WILSON, Edinburgh.

"Edinburgh, April 28, 1871.

"*Note.*—Although we have said that the rate of working of the apparatus when under our observation was about 2 acres per hour, it is right to mention, that having left the field for about an hour, on our return we found that the amount of work done in that time was only equal to one and a quarter acre per hour. From whatever cause this arose, there did not appear to be any want of steam-power, as when the engine was stopped steam immediately blew off from the safety-valve.

"P. B. SWINTON."

Mr. MITCHELL (Alloa) reported that a proposal by the Marquis of Tweeddale to form a committee on the general improvement of land in Scotland was approved of at a meeting of the board of directors on February 1, when the following gentlemen were appointed :—The Marquis of Tweeddale, Mr. Jackson, of Corsiephine; Mr. Smith, Whittingham Mains, Mr. Swinton, Holy Bank; Mr. Young, Keir Mains; Mr. Elliot, Laighwood; Mr. Stephens, Redbrae; Mr. Mitchell, Alloa; Mr. Hunter, of Thurston—the Marquis of Tweeddale, convener. The committee had a meeting on February 15, when a memorandum on the subject prepared by the Marquis was read. After some conversation as to how the committee should take action, it was resolved that a copy of the memorandum should be sent to each member of committee for consideration, and that the meeting should be adjourned for a fortnight or three weeks, when the bordships, by which time it was hoped that each member would be prepared with his own views of the best mode of improving land, and of the course to be recommended to the directors.

Miscellaneous.—The memorial of the Privy Council anent the transit of animals, the report on prizes offered by Lady Burdett Coutts with reference to humanity to animals, appointment of committee to consider as to a register for farm servants, publication of Corn Returns in regard to the gun-tax, and the appointment of committee with power to form an entomological collection, were agreed to. In submitting the petition anent the gun-tax,

Mr. HUNTER, Thurston, said he had had some correspondence with the authorities in London as to the definition of game. From the correspondence, it appeared foxes, badgers, dogs, polecats, &c., could be shot without a gun licence, but no bird whatever could be killed without a licence.

Cutting Turf by Steam-power.—The following communication, by Mr. Henry Trench, of Cangort Park, Roscrea, Ireland, was laid on the table :—"It is proposed that a premium be offered for a machine by which steam-power may be used to supersede the use of the slane in cutting turf or peat for fuel—the machine to cut sods of turf similar to those cut by the ordinary upright or breast slane, and to leave them spread on the bank in the usual way. The operation of cutting and spreading is at present more than half the total cost of turf, and is therefore the chief thing to be economised. It is not proposed to make any change in the method of drying the turf, which could be done by natural means, as at present. The time for saving could thus be largely extended, and the cost of turf lowered to such a rate as to limit the use of coal, which is now superseding turf in many public and private establishments. This plan seems never to have been yet attempted, in this country at least, previous efforts for the economical manufacture of peat fuel having been chiefly directed to the process of drying it by compression or by artificial heat. I am in hopes the matter may be considered sufficiently important to be taken up by an agricultural or other scientific society. Meantime, I am willing to offer a premium of £10 (if you will kindly award it), for the best machine, if any can be produced, having practical merit. The machine to be exhibited in Dublin next August, at the same time as the Royal Agricultural Show, and I will gladly double the amount in case the judges of the Royal Agricultural Society may be good enough to relieve you of the trouble of the award."

A vote of thanks to the Chairman terminated the proceedings.

NORFOLK.

At the annual meeting and show of the Norfolk Agricultural Society last week, at Dereham, Mr. C. S. Read, M.P., presided, and spoke upon the administration of the Cattle Diseases Act in Norfolk. The show was well attended—the receipts at the showyard having much exceeded the average of the last few years. We have not room for the prize list. There were good classes of Norfolk cattle, and a fair show of horses. The 1st prize for yearling Shorthorn bulls, including the Prince of Wales' prize of £10 10s., was taken by Mr. Upson's PRINCE BISMARCK. The Swedish horses suffered from the absence of Lord Walsingham's usual contribution.

After Mr. C. S. Read's speech on the Veterinary Department of the Privy Council, Mr. W. Jones and Mr. J. T. Mott spoke for the successful and unsuccessful candidates.

Sir W. JONES, Bart., in responding to the toast of the "Successful Cattle Exhibitors," said : We may divide the pastures of Norfolk into two categories. The rich pastures in Marshland and in the valleys will grow Shorthorns extremely well, and there I have often found specimens reared ; but I do not think that your light land grasses would enable you profitably to breed Shorthorns. Fat them we can, and better than any other people in the world, because we know better how to use Turnips and cake. But it is quite a different thing to breed animals upon thin and very grasses. Moreover, I do not think it would be possible to satisfactorily breed Shorthorns upon our upland farms. You would have to keep a succession of Vetch crops growing in summer, for somehow a cow will have succulent food or she will not give her calf the milk which it requires. Where a county has a specialty, as there is in any particular class of stock that bears its name, that is known to be found within its borders, and is a marketable commodity which elsewhere obtains an advanced price, that stock ought to be cultivated. If our Norfolk stock becomes fashionable, as I believe it will—if it be taken up by the high and mighty—and the Prince of Wales intends to have one of the principal herds in Norfolk,—we may depend upon it that many people will come here for bulls and cows, and we shall drive a profitable trade, which, after all, is most important. I think we should not do well if we were to dispense with the prizes we give to cattle and sheep. The use of prizes is that by competition it affords persons who want animals, either male or female, the opportunity of knowing where to find the best, and the best will achieve supremacy, for to that buyers will resort. Therefore I say that if any of these shows were dropped it would become a question as to where the best Southdowns, home-breds, or Shorthorns could be found, a great advantage would be taken from the purchaser, and a man would not get the profit he deserves for the care and expense he has bestowed upon his flock or his herd. I am altogether opposed to the removal of the rewards now given for the successful breeding and rearing of animals, because I am far from thinking that we have yet reached perfection. I am a great believer in Darwinism ; I think that you may modify an animal to almost anything. I will just throw out a subject to be solved by the next meeting, namely, who will tell us of a plant that will give us a good crop of hay, and afterwards a sure crop of Wheat. We know that if we have a good plant of Clover we get a good plant of Wheat, but then we do not get a good plant of Clover afterwards. There is also a nut which I will give the members of Parliament to crack. The farmer and the labourer both produce genuine unadulterated goods ; but the groceries bought by the one and the oilcake and manures purchased by the other are sadly adulterated ; and, therefore, I suggest to the hon. members around me that they should find out some means of checking this state of things. It is checked in America, where adulteration is made a penal offence, the consequence being that the oilcake there is worth £2 a ton more than the English cake. Many of you would not object to buy a ton of American cake without seeing it, but would not like to buy a ton of English cake without seeing a sample.

Mr. J. T. MOTT gave "The Unsuccessful Exhi-

bitors." In the course of a humorous speech he said: I will not stop to tell you how I burnt my fingers in dissolving bones, or how many big-bellied carboys of sulphuric acid I consumed—that did not pay—and the stench was not agreeable. So I determined to purchase my superphosphate from a manufacturer; my first 10 tons were so satisfactory that the following year I took the trouble of carrying a pot of this savoury compound to Professor Voelcker in London; the analysis cost me 20*s.*, but that was no object to an enterprising farmer. The report was most favourable; the analysis was printed on the handbills of the manufacturer as a voucher of quality. If gave an extensive order, everything promised well, the Turnip ground was like a garden, the season was most favourable; but, alas! by some mysterious process, the article, which was called genuine, had lost its virtue, my turnips never came to the boe, I dunged 5*l.* an acre, and my bullock account did not look quite so well probably as the return of my friend, the manufacturer of manures. This was, as I said, many years ago, and it taught me never to deal with advertisers, and I have never been victimised since; but I think we must all allow that in no article is there so much deception, so much difficulty in securing your money's worth, as in the purchase of manures. I am sure that the old proverb, "Muck is the mother of money," does not apply to all the infallible specifics which are puffed in the farmers' every market day. I am not going to produce my balance-sheet, but I will say that after holding 1200 acres for twelve years I let 800 to one of the best tenants in the country at double the original rent. He has now held it for eight years, and has just taken a new lease, so I don't think farming such a bad business after all. Before I sit down I would make one more observation. A showyard is very much like a public school, where a cocky boy gets well licked, and soon finds his level. An exhibitor here soon discovers that his own animal is not the perfect beauty he imagined, "not all that fancy painted her, so lovely, so divine." He comes here to have the conceit knocked out of him, and goes home a wiser if not a happier man. This is one of the most wholesome practical results of these exhibitions. After what he had said he would candidly understand that he felt considerable sympathy with the toast that had been placed in his hands—that of the unsuccessful exhibitors.

HANTS AND HERTS.

THIS Society held its tenth meeting the other day at Portsmouth, under very difficult circumstances. The weather was extremely unpropitious, and a very excellent show was thus unable to attract the usual number of visitors. The following is the list of judges and their awards :—

JUDGES.

SHEEP.—Mr. Henry Fooks, Whitechurch, Blandford; Mr. E. Olding, Woodford Cottage, Salisbury; and Mr. H. Bone, Avon, Ringwood.

HORSES.—Mr. J. B. Spearing, Kilburne Lodge, Hurst, near Wokingham; Mr. W. Wheatly, Reading; and Mr. W. C. Spooner, Eling, Southampton.

BULLS and COWS.—Mr. A. Craddock, Lambourne, Berks; Mr. William Champion, Reading; and Mr. Garne, Church Hill, Chipping Norton.

PIGS.—Messrs. Craddock, Champion, and Garne.

POULTRY.—Mr. J. Baily, 113, Mount Street, Grosvenor Square, London.

MOWING-MACHINE COMPETITION.—Mr. W. Chalcraft, Liphook; and Mr. Chas. Bartlett, Dunfield, Horndean.

PLOUGHING.—Mr. John Turvill, Hartley, Mandit, Alton; and Mr. George Pittis, Wymering.

SHEEP.

HAMPSHIRE AND WEST COUNTRY DOWN.

Rams of any age.—1st, 25*s.* A. Morrison, Esq.; 2d, 15*s.* Mr. James Sawkens, Bulbridge.

Shearling Ewes.—2d, 15*s.* Mr. Anthony Budd, Overton, Hants (only entry).

Shearling Ewes of the same flock, which have never been housed and clean shorn.—1st, 10*s.* Mr. W. E. Fitt; 2d, 5*s.* Mr. John Elsom.

Ram Lambs.—1st, 8*l.* A. Morrison, Esq.; 2d, 5*l.* Mr. John Moore; 3d, 4*l.* Mr. W. F. Bennett, Chilmark, Salisbury.

Ewe Lambs.—1st, 5*l.* Mr. F. S. Schwann; 2d, 4*l.* Mr. A. Budd, Overton, Hants.

The whole of the animals in this class were commended.

SOUTHDOWN.

Shearling Rams.—1st, 10*l.* Mr. J. E. and A. Heasman; 2d, 5*l.* Messrs. Heasman; 3d, 3*l.* Mr. H. Penfold, Selsey, Chichester.

Ram of any age.—1st, 8*l.* Mr. H. Penfold, Selsey; 2d, 5*l.* Mr. H. Penfold; 3d, 3*l.* Mr. A. T. Newman, executor of the late Mr. J. A. Finnis, Westdean, Chichester.

Shearling Ewes.—1st, 5*l.* 10*s.* S. W. Seward, Esq., Weston, Petersfield; 2d, 5*l.* Mr. G. Pittis, Wymering, near Cosham.

OXFORDSHIRE DOWN.

Shearling Rams.—1st, 5*l.* Mr. George Wallis, Old Shifford, Bampton, Farringdon; 2d, 5*l.* A. F. M. Druce, Esq., Burghfield, Reading.

Shearling Ewes.—5*l.* A. F. M. Druce, Esq. (only entry).

SHROPSHIRE DOWN.

Shearling Rams.—1st, 4*l.* 10*s.* Lord Chesham; 2d, 5*l.* H. Wood, Esq., Woolley House, Romsey.

Shearling Ewes.—1st, 4*l.* 5*s.* Lord Chesham.

COTSWOLD.

Shearling Rams.—1st, 5*l.* 10*s.* the Executors of the late Mr. T. Gillett, Kilkenny, Faringdon, Berks; 2d, 5*l.* do.

LEICESTER.

There were two classes for shearling rams and ewes, but no entry was obtained.

SOMERSET AND DORSET HORNED.

Shearling rams.—Both 1st and 2d prizes were awarded to Mr. Henry Mayo, Coker's Farm, Dorchester.

HORSES.

CART HORSES.

Stallion, foaled before 1869.—No prize awarded.

Stallion, foaled in 1869.—1st, 4*l.* 10*s.* Mr. John Butler, Sherfield Court, Basingstoke; 2d, 5*l.* Messrs. J. E. and A. Heasman, Angerstein.

Mare and foal.—1st, 4*l.* 10*s.* S. H. Terry, Esq., Western Patrick, near Aldham.

Three-year-old Filly.—1st, 4*l.* Mr. A. P. Martin (only entry).

Mare or Gelding.—1st, 5*l.* Mr. J. Lancashire, Warren Farm, Micheldever; extra prize, Mr. J. Stubbs, West Tisted, Alresford.

HUNTERS.

Mare or Gelding, of any age.—1st, 4*l.* 10*s.* Mr. T. R. Hulbert, Old Alresford, Hants; 2d, 5*l.* Mr. J. Canning, Sutton Scotney, Micheldever.

HACKS.

Mare or Gelding, not exceeding 15 hands high, and calculated to carry 12 stones.—1st, 4*l.* 10*s.* Mr. E. W. Snook, Middleton House, Bognor; 2d, Mr. J. Turvill, Hartley Park Farm, Alton.

PONIES.

Mare or Gelding, not exceeding 14 hands high.—1st, 4*l.* Mr. W. Perkins, Southampton; 2d, 3*l.* Mr. W. D. King, Chitley Farm, Liphook.

Mare or Gelding, not exceeding 14 hands high.—1st, 4*l.* Mr. S. Warrell, Portsmouth; 2d, 3*l.* Mr. A. Ede, Swarthing, near Southampton.

BULLS AND COWS.

Shorthorn Bull.—1st, 4*l.* 10*s.* Mr. R. Soffe, Hams, Eastleigh, near Southampton; 2d, 2*l.* 5*s.* W. Nicholson, Esq., Basing Park, Alton, Hants.

Shorthorn Bull, under 3 years.—1st, 4*l.* 5*s.* John Walter, Esq., M. P., Bearwood; 2d, 2*l.* 5*s.* Marquis of Aylesbury.

Shorthorn Cow in milk, or if in milk, having had a calf within 6 months next preceding June 21.—1st, 4*l.* 10*s.* Mr. J. A. Mumford, Bolton Park Farm, Hurstbourne; 2d, 2*l.* 5*s.* W. Nicholson, Esq., M.P., Sussex Bull, any age.—1st, 4*l.* 5*s.* Messrs. Heasman; 2d, 2*l.* 5*s.* Mr. John Turvill, Alton.

Sussex Cow in calf, or if in milk, having had a calf within 6 months.—1st, 4*l.* 5*s.* Messrs. Heasman; 2d, 2*l.* 5*s.* Mr. J. Turvill.

Devon Bull of any age.—1st, 4*l.* 5*s.* Mr. W. Taylor, Westham, Sussex (only entry).

Devon Cow.—1st, 4*l.* 5*s.* Mr. W. Taylor, Glynley, Westham (only entry).

Channel Islands Bull, any age.—1st, 4*l.* 5*s.* Lord Chesham; 2d, Mr. H. Drewitt, Millvill, Titchfield.

Channel Islands Cow.—1st, 4*l.* 5*s.* Lord Bolton, Hackwood Park, Basingstoke; 2d, Mr. Henry Drewitt, Millvill, Titchfield.

Channel Islands Heifers.—1st, 4*l.* 5*s.* Lord Chesham; 2d, 2*l.* 5*s.* Mr. Henry Drewitt.

PIGS.

Boar, any age.—1st, 4*l.* 5*s.* Mr. H. Humfrey, Kingstone Farm, Shrivenham; 2d, 2*l.* 5*s.* Mr. C. Barton, Sherborne, Basingstoke.

Breeding Sow, any age.—1st and 2d, Mr. H. Humfrey. The whole class generally commended.

Pair of Sows, under 6 months.—1st, 4*l.* Mr. H. Humfrey; 2d, 2*l.* 5*s.* Messrs. Wheeler & Sons.

Boar of any age, large breed, not being Berkshire.—1st, 4*l.* Messrs. R. E. Duckering & Sons; 2d, 2*l.* 5*s.* Messrs. J. Wheeler & Sons.

Breeding Sow, any age.—1st, 4*l.* 5*s.* Messrs. Duckering; 2d, 2*l.* 5*s.* Messrs. J. & S. Wheeler.

Boar, any age, small breed, not being Berkshire.—1st, 4*l.* 5*s.* Messrs. Duckering & Son; 2d, A. F. M. Druce, Esq.

Farmers' Clubs.

EAST LOTHIAN.

Injury Done to Grain in Threshing.—At the late monthly meeting of this Club, held on Friday, the 2d ult., Mr. DOUGLAS, Athelstaneford, presiding, said Mr. Cunningham, brewer, Athelstaneford, had kindly sent a detailed communication with reference to the deteriorating effect for malting purposes of bruising or breaking grain in the process of threshing. On the same point, Mr. Punton, Aberlady Mains, wrote :—

"As regards the overdressing of Barley, a serious loss is the consequence in malting, particularly in the spring months. Barley that has been thus damaged they do not germinate, and when only a few days in operation they become quite mouldy and sour. The damaged grains also contaminate the sound ones, and the whole 'floor' has to be thrown up the kiln before the malting process is half-finished, and the quality of the malt is consequently very much deteriorated. I observe that Barley threshed with the English high speed mills is very often a good deal broken and bruised, but I cannot say whether it is caused by the action of the drum, or by having the hummeller too close set, possibly both of these may have something to do with it. I may mention the machinery we have here the old style of (pins and hummeller) threshes the Barley without breaking or injuring a single pickle, and the weights during the past season ran from 57 lb. to 59 lb. per bushel. I have no experience of Wheat. No doubt overdressing will not signify much, but not to such an extent, I should think, as with Barley."

With regard to the mechanical aspect of the question, Mr. Bridges, engineer, North Berwick, wrote :—

"This evil has been brought on by the introduction of drums running at high speeds. First, there were the peg mills, by which I erected in this county about 1850, and were discontinued principally on this account. Then immediately followed the present high-speed drums, which are not free of the same fault. From 1852 to 1860, I made a considerable number of them in this county, and tried various plans to overcome this defect, but had not at this period availed myself of any of the English patents, but rather avoided them. The greatest advantage I found was in making the concave as open as possible, particularly at the entrance, where the bulk of the grain was knocked out, so as to allow it to escape more readily the instant it was out of the bar. For the last 10 years, the concaves I have been using has carried out this principle more effectually than before, having substituted malleable for cast iron. I have used drum beaters of various kinds, and for several years past have used only the patent serrated beaters, which are now made of steel as well as of iron, and during this period—viz., the last ten years—I have had no complaints made. As an evidence of the effects of the improved concave, there were lately complaints made of two mills I had erected in 1858 bruising the grain. The old beaters on the drum were replaced by the patent serrated beater without making any material improvement. The concaves were next replaced by new ones, which entirely remedied the defect. But beside this construction, a careful milliman is indispensable for the proper working, and keeping these mills in the best order. Several cases of bad management have come under my notice, considerably affecting the bruising of grain. In putting Barley through the mill a second time, in cases of smut, when the hummeller cannot be used, it is highly needful to screw back the concave a little; also, when rough elevators discharge into the drum, no more grain should be allowed to come up than is necessary. I do not recollect of any case where the hummeller was at fault in bruising grain, where it was not found to be running too close at some part of the casing."

On the same branch, Mr. Munro, agricultural engineer, Dunbar, wrote :—

"The subject you name has had a great amount of my attention for several years back, namely—the evils arising from the breaking of corn by machinery. The causes of the same are not few, from which I may mention two or three. 1st, the kind of drum used; 2d, the way the drum and concave are adjusted and kept in order. 3d, the state the corn is in when threshing. In dry seasons, the drum must be kept in first-rate order to prevent breaking. The thing suggests itself to me, that if the farmers would get their millwrights at shorter intervals to examine and adjust their drums, instead of their own men shifting them, we would see less broken corn than at present. In this district, where the drums are not meddled with, there are no complaints of the corn being broken in malting; in addition I do not mean to blame the men in charge of them. On the contrary, I think they deserve credit for the way that they manage them. The only kind of drum I use is Goucher's patent drum, with spikes and beaters."

Mr. CUNNINGHAM, Athelstaueford, after a few introductory remarks, said :—First, then, as you are aware, the object sought in malting is to change the starchy substance of the grain into grape-sugar. This is accomplished by steeping the Barley in water, for a longer or shorter period, to produce fermentation. When the grain begins to vegetate, it is extended on the floors, and kept there from 10 to 20 days, the time varying with the condition of the grain and the temperature of the atmosphere. During this period the plumule or acrospire, which springs from the root end of the seed—the future stem of the plant—gradually ascends until it emerges from the seed at the end opposite the root. Now, it is found that the chemical change effected by the gradual extension of the acrospire—viz., that of changing the starch into sugar—is limited to the portion of the corn up which the acrospire has crept, and no further—the upper part of the corn not covered with the acrospire still retaining its starchy consistence. It is evident, then, that the secret of malting consists in promoting, by natural and regular process, the growth of the acrospire until it reaches the end, or very nearly the end, of the corn, because when it extends further it extracts the substance of the seed. Now, it will be evident, I think, from what I have stated, that when grain is damaged to any extent, it is more than useless for malting purposes. In the first place, the broken and crushed corns not only do not grow, but they change colour, and become mouldy. The crushed corns, by absorbing moisture internally, rapidly decompose and putrify when exposed long to the temperature of the working floor; whilst those grains that are rubbed, although they do spring, rapidly discolour and become mouldy when under the kiln. The loss thus sustained in malting damaged Barley consists first in paying duly for a portion of grain incapable of undergoing the necessary chemical change for producing malt, in the loss of quality and flavour by the damaged corns becoming mouldy with decay; and, lastly—and this is the greatest loss connected with the handling of the article—in being obliged to hurry the floors to the kiln before the sound grains have had time to mature, thereby leaving the acrospire only half developed, and a considerable part of the corns still retaining their starchy consistence, giving the malt hard and flinty, in place of coming out crisp and flowing in texture, as good malt should be. I may remark here that these observations are applicable to all Barley which has sustained damage in the way indicated, when used for malting; but the extent of the evil is modified by the degree to which the evil has extended. Some of the Barley may be only slightly rubbed, while some may be both broken, crushed, and rubbed, and the results I have explained will follow in the proportion in which the damage has extended. Let me say, that a good deal of damage may be sustained by grains which can only be discovered by looking somewhat closely into it. And buyers, on some market days, have little opportunity to inspect the grain as it should be. A number of farmers, with the view of improving the colour of their Barley, when they had much smut, were in the habit, in the early part of the season, of putting their Barley twice through the mills—a most pernicious practice, as the Barley was so damaged as to be very unsuitable for malting purposes. I have on more than one occasion bought parcels of Barley coloured to some extent with the dust of the smut, and I have found that by putting the water into the steep first, and giving the Barley an extra water, a considerable quantity of the smut came off. So long as the body of the corns have sustained no damage, something may be made of them. The evil maltsters above all things deprecate is the damage of corn by breaking or bruising it. I men-

tioned in the first part of my letter that the evils resulting from damaged Barley date from the introduction of high-speed mills into East Lothian. Such is my experience. The particular phase of the complaint was contemporaneous with their introduction into the county. I am quite aware that the high-speed mill, with all the necessary apparatus for finishing the grain for the market as it comes from the machine, is a most desirable implement. It thresches quicker, it thresches cleaner, it turns out the straw in a whole state, it has many recommendations, and, I believe, cannot be dispensed with now. I consider, however, that much of the evil resulting from their use is the result of faulty construction or mismanagement. I often put Barley threshed with high-speed mills perfectly free from any damage whatever. If one farmer can use it to good purpose, it is surely possible for all to do it; the effort is worth trying. I know that parties whose grain is known to be sound and good not only command a more ready sale in the market, but invariably get, I believe, a higher price. My object in writing this is more to point out the evils resulting from defective threshing, leaving to others the task of devising the remedy; but I may remark that I think the damage is often sustained by the grain passing through the mill, the concave of the drum being screwed too close to the convex of the frame. I cannot otherwise account for the rubbing and crushing of the corn. It is the opinion of some that the hummeller is the cause, but the grain runs through the hummeller in a thin stream. The knives, indeed, are sharp, and may possibly cut the grains. They sometimes appear as if they had been cut, so clean across does the division appear, without a dimple or break on either side of the grain. If such should be the case, is it not possible to alter the hummellers as they are connected with the old threshing drum, viz., to have the machine placed vertically instead of horizontally, the knives blunted, and the speed very much reduced? There would then be a solid body of grain to act upon, and although the inlet and outlet would require some nicety of regulating, that might be accomplished. Another defect with some high-speed drums consists in their being screwed without any guage to regulate the distance of the drum from the frame. Consequently the space for the grain and straw to pass between is regulated with no certainty —sometimes it may be closer and sometimes wider, as inclination or accident may determine. The great bulk of the Barley grown in East-Lothian being bought for malting purposes, and the climate, soil, and means of the farmer combining to produce a first-class article, so far as the raw material is concerned, I think there can be no doubt that it is greatly the interest of farmers to study the requirements of the trade (the malting trade), and prepare the grain in such a way that its value may be in no way deteriorated by the process of preparing it for the market—I repeat, the interest of farmers. I might suggest as regards your professional reputation, and say that while East Lothian can boast of a class of farmers who have led the van in the march of improvement, and been foremost in utilising any discovery in science applicable to their particular domain, it seems like a stigma on its character—their professional character —that grain of such superior quality should be spoiled in the dressing. But I feel persuaded that, were buyers assured of greater security against damaged grain, coming as they now do from all quarters, a spirit of confidence would be implanted, and they would be the more prepared to give the utmost value for the article. I know, from conversation with parties in the trade, that the feeling has been that rubbing is one of the drawbacks to East Lothian Barley. As I remarked, in many cases it is very slight, in some there is no rubbing; still where mills have been a considerable amount of mischief when the feeling extends to the whole district. Had there been no such feeling, it is probable prices might have been better. I must say that when I have pointed out the evil to any of my friends engaged in farming, they have invariably admitted it, and expressed a most earnest desire to remedy the evil did they know how. The difficulty lay in applying a sufficient amount of friction to separate the awn without damaging the grain. I hope that some wiser heads will be able to devise a remedy, and that no such subject will need to be discussed next year. In these remarks I have confined myself to Barley as applied for malting purposes. Other kinds of grain are broken and bruised, but I would suppose that, unless used for seed, or stored for a length of time, the damage sustained is nothing like so great in the way of destroying the value of the grain as in the case of Barley making into malt, the rest being all manufactured in a dry state.

The Chairman (Mr. Douglas) said that after the statement of Mr. Cunningham, it could not be doubted that an evil connected with the dressing of both Wheat and Barley did exist, which in the one case deteriorated its value as seed, and in the other for malting purposes. Farmers would be glad if practical men could fall upon some expedient to remedy the evil. It was their desire not only to get the best price for their grain but that the purchaser should have the full value from it, and not be subjected to the waste which it had been shown had sometimes to be borne by the maltster. A threshing-mill should, above all things, thresh clean, for they could not afford to throw away any of the grain, seeing that they had little enough of it on the straw. A good deal of the evil complained of, he thought, arose from the hummeller, to which much attention should be paid. Some of the hummellers were too horizontal. He considered the upright action the best, because it was more under control. There ought also to be some scale for regulating the speed of the drum. As showing the importance of a thoroughly working mill, he mentioned a case in which a farmer threshed a portion of a stack, and its weight in the market was 16 st. 11 lb. His mill then underwent some alterations, and the rest of the stack was threshed. This portion only weighed 16 st. 6 lb., but in consequence of the improved mill not having broken so much, it sold 3*s.* per quarter higher than the heavier sample.

Mr. Hope, Fenton Barns, as bearing out the statements of Mr. Cunningham, said he had been told by an extensive brewer in Edinburgh that he frequently put over the fingers by buying Barley from parties he did not know. There were some farmers, this gentleman said, from whom they could buy with perfect security; and when the Barley was unbroken, he had no hesitation in giving 2*s.* or 3*s.* more a quarter for it. Sometimes, too, he had been told, that when severely bit, brewers had recourse to laying in a quantity of foreign Barley. These things showed the necessity for farmers paying attention to this subject. For his own part, he believed the evil had arisen in a great measure from the high-speed drums; but at the same time he thought it arose often from the inattention of the farmers themselves. They left the matter to men who, in order to get through a good day's work, put too much grain in the hummeller, which he found always caused broken grain. A good portion of the injury arose from want of tuning. As to smut, he might mention that the first sample of Barley he threshed in his high-speed mill was quite white when it went into the hummeller, and quite black when it came out. He stopped the mill at once, and put the Barley through the fanners, and he found by that process that the smut was blown away, and the sample came out quite clean.

Mr. Harvey said he had no wish to speak disparagingly of high-speed drums; but about 30 years ago it was an uncommon thing to see broken grain coming into the market, and there was no doubt that improved machinery had much to do with producing it. He admired the fine action of the high-speed drums; but when the grain came out broken where was the benefit? Mismanagement had been blamed for this; but what did that mean? It meant that these mills needed to be superintended by men accustomed constantly to handle mill.

Mr. Halliday, engineer, said he commenced to make high-speed threshing-machines 16 years ago, and before doing so he had gone to England to see the machines in use there. After inspecting several at Newcastle, he came to the conclusion that they had all the fault of breaking the grain. The result of what he saw made him think that the system of regulating the concave by six or eight screws was a very awkward thing to put into the hands of farm servants. He had therefore constructed a system of regulating the concave, by which a man could regulate it with his foot as he dress-coat on, and without stopping the mill. If the mill was not threshing clean, the attendant had nothing to do but to turn a small handle, and the whole concave was regulated from one point. He found this expedient of great benefit. He had now used it with success for about 12 years ago, and after it was in operation they had to search the whole "bing" over to try to get a broken pickle. He thought there was a good deal in the width of the concave. He made the concave of Mr. Tod's mill pretty wide, to allow the grain to fall through before being struck, and thus it to escape from the drum whenever the grain was taken from the ear. He found that with the concave being so wide there were portions of the heads which went down without the pickle being taken out. He therefore commenced making the straighter concave to prevent these heads getting through the concave; but this, he thought, had a greater tendency to break the grain, and he therefore agreed in the concave being wider to let the corn get out. He believed, also, that the speed of the drum had something to do with the breaking of the grain. When the grain was very dry the velocity of the drum would cause this breakage—the mere contact of the drum would break very dry corn. The drum acted as a disintegrator when the speed was very high. To obviate this he had put two speeds on the drum, so that in threshing Beans the velocity of the speed of the drum could be reduced, while the rest of the machine was going at the full rate. He had done this to several mills, by putting on another pulley for threshing Wheat, and he believed that since then there had been a great improvement. As to the hummeller, his were all horizontal, and delivered on the top instead of the bottom. They were not worked full. The velocity of the drum keeps the grain always on the outside. I admit that it does not look very natural, but nevertheless it is the fact. When it stops there is no more grain in the hummeller than there would be if it was delivered at the bottom.

Mr. Paton believed the complaints made by Mr. Cunningham to be well founded. For his own part, he thought the whole fault lay in the setting of the drum. If farmers would look well after that, and see that the drum was equally set, there would be less breakage. He had seen mills working with one side quite open and the other quite close; and in such a case it was impossible that the Barley could be threshed properly. He held that, with a well-set drum, nothing could beat the high-speed mills.

Mr. Durie was still working with the old Scotch mill, and he was never bothered with either broken Wheat or Barley.

Mr. Halliday—I neglected to say, with regard to the Goucher beater, that I believe it is far too closely grooved, and that if it were wider it would have more tendency to let the grain get through undamaged.

The Chairman summed up the discussion, which he said had brought out some very valuable information, and that upon the whole it had shown that it was not desirable to dispense with high-speed drums. Speed and safety, he believed, were both quite attainable in the use of these mills; and by the application of skill and the results of experience on the part of engineers, and careful attention on the part of farmers, they might hope in the course of time to get a stop put to the evil which had given rise to the discussion.

Farm Memoranda.

Harvey's Dairy, Port Dundas, Glasgow.—The establishment about to be described is situated on the very top of Garnethill, in the west end of Port Dundas, Glasgow. Whatever *rôle* Nature may have intended for Port Dundas, it is now about the most unlikely spot in the world for the locality of a monster dairy. Rope-walks and anchor-foundries, dirt and dry docks, seem in their element. But the dairy is also there, and, despite the outbreak of the cattle plague, a very notable establishment it was. From 800 to 1000 cows in milk were then the usual number, and were the *raison d'être* of a series of long wooden sheds that stand, as black as coal-tar can make them, in long parallel rows, with their gables abutting against an open space in front of an engine-house. The latter structure belongs to a distillery, to which the dairy is most extensively indebted. By means of its engine, liquid manure from the cow-sheds is pumped into tanks erected on the highest eminences on the farm belonging to the Dairy Company, and the distillery refuse is a nutritious and milk-producing food, which is used in considerable quantity.

The following description, extracted from the late Mr. H. H. Dixon's "Field and Fern," will give an idea of what this dairy was a few years ago:—

"Mr. Harvey's byres are distinguished by different names—'The Parlour,' 'The Thistle,' 'The Halloween,' 'The Waterloo,' 'The Malakoff,' and so on. There were some 1700 cows and queys in all, and about 1000 of them in milk, and feeding on Turnip, cut straw, and distilled grains. The Bulls, which stand with them, are mostly Shorthorns, and so are 300 of the milch cows; the rest are Ayrshires, with the exception of a few polls, and recently a sprinkling of Dutch. They stand in long ranks tail to tail, and the scourings fall into the gutters behind them, which are duly flushed down. Hence each beast has to be very accurately told off, on her arrival, into a byre, whose stallage exactly suits her length. In some of the byres there is only one line of cows, and the calves are in small partitions opposite them.

"About 50 of the queys are kept each year, and go as yearlings and 2-year-olds to parks down the Clyde, and the rest are dismissed as 'stirk veal' (to adopt the term of the trade) to the butcher soon after they are calved. Thirteen cows are allotted to each milker, seven of whom live on the spot, and the rest of whom arrive at milking hours from Glasgow."

Since the cattle plague the dairy has dwindled but not decayed. Not more than 150 cows are now housed in the home shippons; but the Company contracts with the neighbouring farmers for the supply of a very large quantity of milk, which raises the total amount of the saleable commodities up to the estimated produce of 800 cows. Ayrshire cows and Shorthorn bulls are preferred at the homesteading.

Cows are bought just previous to calving, to replace those which have gone to the butcher; and in 1869 about 50 passed through the manager's hands in this way. Those of their own breeding are kept for four, five, or six years; and those that are bought are retained according to the age at which they come in. March, April, and May are the months most preferred for bulling, as they suit the winter trade; but great care is taken to have a sufficient number of late calvers, as many of the earlier cows run dry suddenly towards the fall of the year. A cow should become dry at least five or six weeks before calving, and the late calves should all be dropped by the middle of May. No cows are put to the bull in September and October, nor in the early part of November, as June and July calves are not wanted; therefore the season preferred commences about the end of November or beginning of December.

Calves get 2 galls. of milk each every day for about five or six weeks, and then skim-milk for the same length of time. In summer they are turned out very early, but a large proportion are winter-calves, and require the above treatment, especially as the Ayrshire and Shorthorn cross gives a heavy calf that requires a good deal of feeding.

In some years, when food is plentiful or milch cows

are dear, a certain number of stirks are bought; and similarly when feeding-stock is cheap the cows are kept longer.

The cows are milked three times a day, and about one-half of the produce is set for cream. As the Dairy Company do a "family trade," a large quantity of cream is sold in the ordinary course of things; and there is a good demand for skim-milk among the working classes. On an average, the quantity of milk to be dealt with is 1500 galls. daily, of which about 800 are set for cream. The morning milk is all sent away warm, the afternoon yield is about half set, and cream is taken away from the whole of the evening produce. This practice is necessary because, although 12 salesmen are employed, there are but two deliveries daily, although there are three milkings, and the last delivery is over by 4 o'clock in the afternoon. Wooden tubs, as shallow as possible, are preferred to set the milk in; and it is liked to let the milk remain as long as possible, in the shallowest possible tubs, so as to obtain the maximum yield of cream.

In June and July, a certain proportion of the produce is churned, as about this time of year there is a slack demand for milk during six weeks or thereabouts. Milk, cream, and skim-milk are mixed together before churning, this being considered the most profitable method. All the milk is soured, and about 1 lb. of butter to 3 galls. of milk is regarded as an average return. Three of the old-fashioned Scotch churns are used, if necessary, and about 300 galls. can be dealt with at once. The butter comes in about an hour and a-half, including the time occupied in taking off the butter once or twice and brashing; the actual churning, therefore, does not occupy more than about an hour.

About the first ten days of October it is reckoned that the grass land requires the cows to be taken off, and after that time they remain entirely in the shippons until about the latter end of April or the beginning of May. During these seven months the daily food commences with draff (distillery refuse) about 4 or 5 o'clock in the morning, and with bean, pea, or Indian meal, but preferably the first-named, unless Beans are too dear, when mixed kinds of meal are substituted. Linseed cake is occasionally given at this time to cows beginning to run dry, and also in spring to those that require a little laxative. After the first thing, viz., about 9 o'clock in the morning, as much distillery refuse as they can take is freely given; and at 8 o'clock either oat-straw or hay (if possible). The latter is generally Rye-grass hay off the irrigated fields to be described presently. The next feed consists of raw Turnips and Swedes, given about 10 o'clock, and at 11 the cows are milked for the second time. The afternoon meal is given at 2 o'clock, and consists of steamed meal, Turnips, and draff. At 4 o'clock some fodder, generally straw in the afternoon, is placed in the mangers, and between 4 and 5 more draff is run in. Some Turnips are always put in the steamed food. At 5 o'clock the cows are milked for the third time, and are afterwards made up for the night.

During the summer the cows get nothing in the shippons except a little draff in the morning, when they come in to be milked, except towards the fall of the year. They are then allowed some fodder at midday; and in a bad season they get a little meal with their draff in the morning. They are kept on the pastured land by night up to the time for sending to be milked at about 11 o'clock, as well as at night.

The solid manure from the shippons is sold to the neighbouring farmers; but the liquid manure is pumped to a fountain-head a few feet above the highest part of the farm, and distributed by gravitation to auxiliary tanks by two branches, which run east and west from the main receptacle. The pipes ($2\frac{1}{2}$ inches in diameter) run underground, and are furnished with stopcocks, so that the manure may be shut off from any portion of the farm and diverted to any other. The engine begins pumping in the morning after cleaning, and continues as required. Irrigation is done on the well-known Kennedy system, which at one time took some hold in the south of Scotland, and is probably better known, as it is certainly more favoured, in France and Belgium than it is in England. The method is briefly as follows:—An iron pipe is connected with the nearest tap to the portion of land to be irrigated; and to this $\frac{1}{4}$-inch iron pipes, in lengths of 6 feet, with spike and fancet joints, are connected so as to reach the farthest point to be dealt with. To the last piece of tubing a hose can be attached, the sewage is turned on, and the land "watered" by the man in charge, who has a boy with him to carry pipes to and fro, lay them in their places, turn taps on or off, and do other odd jobs. When the land within reach of the hose has been sufficiently watered, a certain number of lengths of pipe, generally about 100, are detached, and the terminal length with the hose shifted accordingly. By this system a man and a boy can irrigate 2 acres per day of 10 hours, the expense for this portion of the work being 1s. 6d. per acre.

The great objection to the Kennedy system is the large initial outlay in underground pipes, and laying them down. Another objection, which would be more serious on an ordinary farm than it is there, is the expense of pumping the sewage every day to the fountain-head. The interest on the first outlay, added to the continuous expenditure inclnded under the second head, probably requires a larger margin of profit to cover them than can be reckoned upon, except under special circnmstances.

Nearly 500 imperial acres are held in connection with the dairy, and are farmed under the following rotation: (1) Oats, (2) roots, (3) Wheat, and (4) seeds left for two or three years, or sometimes four. There are about 300 acres of seeds and grass, and the extent of land in corn and roots ranges from 160 to 170 acres. The Wheat crop is sold, and the straw used for litter. A large quantity of the Oat crop is required for the horses, of which about 25 are kept, on dairy and farm; the remainder is ground and sold as oatmeal, and the oat-straw is used for fodder.

Irrigation commences with the Oat stubble, which gets two runnings in the autumn, one before and one after the autumn ploughing. In the spring a running is again given after the spring ploughing, and for Turnips another at seed-time if possible. Potatos are not irrigated after autumn, as it tends to make them soft. The root corse is generally one-sixth Cabbages, one-half Turnips, and one-third Potatos. The latter crop is sold off the farm, with the exception of the small and diseased tubers.

The green crop being grown on the ridge, the last irrigation is done by running the liquid manure down the furrows. The Turnip land is generally left strong enough for Wheat; and even the Potato land, unless it happens to be a very poor field, gets nothing from the last crop before the land is again planted until the February after the Wheat is harvested.

In February the liquid manure is turned on the Rye-grass for cutting, say about 50 acres; it is then sent on to the land being cropped, and during the summer irrigates the pasture land in succession, the two fields being done at a time. From 30 to 50 acres of hay are got every year, three cuttings being obtained if required; but pasturing is always preferred as far as it is practicable. The mixture of seeds generally sown is about 3 bush. of perennial Rye-grass, and from 3 lb. to 4 lb. each of red, white, and Alsike Clovers per imperial acre. Italian Rye-grass is too soft for dairy cattle, and is therefore never sown. *Mr. Jenkins' Report on some Features of Scottish Agriculture.*

Obituary

We sincerely regret to announce the death of Mr. J. C. Adkins, of Milcote, Stratford-on-Avon. Few men in the midland counties were more widely known and more universally esteemed. His portly form and manly bearing, his cheerful smile and apt and wise sayings, will long live in the memory of many sorrowing friends. He was the thorough type of the English gentleman—straightforward, courteous, hospitable. Of an eminently social disposition, he delighted to gather his friends about him. In his quiet, rural sanctum, during many pleasant and instructive hours, his privileged friends have listened to the outpourings of his powerful and well-cultivated mind, and felt the influence of his great and kindly heart. He certainly possessed in a high degree the power, which many owe, of moulding the opinions and character of those with whom they come in contact. He was well-read in a wide range of varied subjects, including literature, art, science, and the current topics of the day—no subject came amiss to him. He was possessed of great clearness of perception, and much readiness and humour. He was an uncompromising enemy of deceit, hypocrisy, and cant; and with good-humoured satire would often raise the laugh against humbug, folly, and empty pretension. He was equally at home amongst agriculturists, mechanics, racing authorities, medical men, and *savants*. On endless subjects connected with farming, with Shorthorns, and even on commercial matters, he was applied to for advice. His sound sense and varied experience were ever at the service of his neighbours; and as a clear-headed judicious adviser he will be missed by many. He was too diffident of himself to meddle much with public affairs; he eschewed farmers' clubs, meetings of Chambers of Agriculture, and other such gatherings. Although no man was better qualified, he persistently refused to act as Judge at the Royal or any local shows, but with considerable persuasion was, some years ago, induced to become one of the directors of the Stratford-on-Avon Railway. His admirable powers of observation, and his determination to do well and thoroughly whatever he undertook to do, have long made Milcote one of the best-managed farms in the midland counties. He early made use of steam cultivation; he was a great advocate for modern and efficient farm implements and machinery; thorough and clean cultivation he considered prime essentials of good arable farming; in the selection of his seed-corn he was particularly careful, and by employing pedigreed sorts he had recently greatly increased the quality and yield of his barley. Ever since he followed his elder brother as tenant of Milcote, now nearly forty years ago, he bred Shorthorns. Robert Colling's favourite strains were his early choice; his Charmers and Sweethearts at his own and other Shorthorn sales have realised such prices as abundantly testify to the judgment and skill of their founder. The Milcote down sheep, which have occupied a large share of the breeder's attention of late years, now promise to be almost as celebrated as the Milcote Shorthorns.—*Stratford-on-Avon Herald.*

The Week's Work.

July 1.—*Buckwheat* or *Vetches* may yet be sown, where other crops have failed. Anything is better than the exposure of the earth's surface to the wasting influence of the weather. What is it but the scorching sun that has turned immense tracts of Africa and Asia into barren deserts of drifting sand, &c.? Brankmeal makes excellent seasoning for cattle food, and the Vetch is one of our best forage plants.

Cabbage, where Buckwheat and Vetches do not suit, may be planted. The weather has been favourable, in some districts, for planting. If too late for Drumheads and the hearting sorts, try the leaf-producing varieties, with plenty of manure, if possible, in a liquid form.

Turnips sow after forage crops of Rye, Vetches, &c. The practice of preparing the land for the seed is as diversified as farm practice generally is in different places and on different soils, much depending upon the condition the land is in, the manure to be used, whether the crop is to be grown on the flat or in stetches, and, last of all, the weather. If the land is clean, and the crop to be grown on the flat, with farmyard manure, and if the weather is dry, well soak the manure from the liquid manure-tank, pond, or river, before it is carted; and, after it is spread, keep the water-cart going ahead of the plough. Plough in with the sap, harrow fine, sow, and roll down before it. If the weather is rainy, the water-cart will not be needed. If to be grown on the flat with superphosphates, in dry weather, well water the land before ploughing, and sow as above, remembering that water is the best manure that can be applied in dry weather. If some means could be devised for throwing in a good stream from a hose, just behind the furrow horse, it would be much superior to sprinkling it over the surface, as all poaching would be obviated, and the newly turned furrow-slice would drink up the water by capillary attraction, and thus supply the roots of the plants at a very early stage. It would not take many water-carts to keep a plough going, and, where there is plenty of water at hand, why not thus manure the land?

Turnip Hoeing.—The early sowings prosecute as soon as the plants will stand singling. In some places the braird is equal, in others patchy, but, upon the whole, complaint, this year, is below an average. Where there are gaps, they should be re-sown with a gaping drill, well watering the ground before sowing if the weather is dry. Keep the horse-hoe going, is an old familiar rule, but unless the plants will stand it up to when they meet in the drills. The thicker the plants braird in the rows the sooner they require to be singled, for, when they are allowed to spindle, the stem takes a set from the injury it receives by blanching and pulling, and the crop consequently comes bulb well, and the bulbs thus produced are of inferior quality. There is great art in growing a Turnip, and to begin training early is the sure road to success. In the northern counties, where sowing is earlier, the second hoeing may by this time be finished. As you remove weeds, well loosen the soil about the plants. All the Brassica family are grateful for fresh air at the bottom, if there is anything in the land to work upon. When done by the drill or acre, by task, the work is too frequently skimmed over, doing more harm to the plants than good to the land. As soon as the leaves begin to lie off the ground, and the bulbs to form, the last horse-hoeing should be given, the double-mouldboard plough following, which concludes the work. When the land is thoroughly drained, and the crop to be eaten off with sheep, or to be pulled and stored, some do not set up with the double plough, or, if they do, only very lightly.

Haymaking, which commenced here (Surrey) about the middle of last month, will, in some places, be later than was at one time expected. The season has been favourable for the growth of "Buttercup," "Sorrel," and other weeds, so that the making of the haystack will be attended with greater difficulty; and, when overtaken by rain in the making, more loss will be sustained. Where there is a command of town sewage or river water, the hay stubble should be irrigated the moment the hay crop is carried, so as to get a rapid growth, either for pasturage or a second cutting for soiling or hay.

Mangels, Sugar-Beet, and Kohl Rabi should receive an early second hoeing, more especially when much rain has fallen, so as to loosen the soil and let in fresh air to the roots. The work will be effected by the surface should be dry. Practically speaking, the hoes should keep themselves clean. In wet weather, when weeds grow plentifully, the work is attended with no little difficulty; but just so much the more need is there to persevere. If the land is clean, it is better to defer the hoeing until the surface dries sufficiently to leave the soil open behind the hoes. Hoeing the land immediately after a shower when it sticks to the hoes, consolidates it, thereby excluding air and favouring the growth of weeds where seed is present, as it too generally is. And even when the land is clean and free from the seeds of the ordinary weeds, by poaching the surface with the hoes and the feet of the hoers the land gets into an unhealthy state, forming a favourable nursery for the growth of plants whose spores float in the atmosphere. In common language, the surface of the ground becomes covered with a green coating of

moss—the worst class of weeds in the world, as they readily take root in all decaying animal and vegetable matters in the land. The season at the time we write is extremely favourable for their production, and therefore their growth should by every means be guarded against. They are the sure ruin of all our root crops, their presence indicating the very reverse of what Turnips require.

Sheep Washing and Clipping continues into this month in the Cheviot and Blackfaced flocks of the North. A pool in a clear running stream, with a pebbly shore, is chosen for washing, a large fold being made on each side to hold the flock. From being annually washed for four or five seasons old sheep become accustomed to it, take the water freely, the younger following, jumping in between the shepherds as first one is loosed, or as they swim across and walk out into the fold on the other side. A few times across the pool completes the operation of washing without a hand being put upon the sheep. Shearing commences immediately the wool is dry. In the large hill flocks of the North it is common for shepherds to join, shearing first one flock and then another, each flock being thus put through the shears in less time than were they to be shorn each by its own shepherd.

Sheep Folding on all forage crops attend to. If compelled to eat the fold large, and are consequently turned into a fresh break of Vetches, Rape, or Clover when thus hungry, the flock may sustain very serious injury. In warm, moist weather, the best plan is to mow such crops, cut them into chaff with a little dry hay or straw, season with a sprinkling of corn-meal and salt, and feed in troughs. In dry weather the newly mown forage may be allowed to dry sufficiently in the sun before it is cut into chaff alone, and then seasoned as above with meal and salt. If all three crops are grown they should be mixed together, and if Sainfoin and Lucerne can be added, so much the better—sheep like savoury food. Our down and hill pastures, that yield the healthiest flocks and best mutton, furnish a practical recipe at the present time what they require. *W. B.*

Markets.

ENGLISH WOOL.

During the last week Wool has been in good demand, and prices are still gradually hardening, and we anticipate considerably higher rates after the bulk of the clip has come to market. Colonial Wools are 25 per cent. dearer than this time last year, and sometimes even more, and fully 10 to 15 per cent. dearer than last month. The Americans, who have not been in the market to any extent for some years, are now buying largely, and must have taken 15,000 bales of Australian, weighing about 400 lb. each, within the last three months; this new competition alone will account for part of the rise.

HOPS.

BOROUGH MARKET, June 29.

Messrs. Pattenden & Smith report that the accounts this morning from all parts of the plantations are decidedly worse, and on the Continent the prospects for the coming crop are as unfavourable as our own. The market is very firm, without any great amount of business passing, but good healthy Hops are gradually becoming absorbed.

METROPOLITAN CATTLE MARKET.

MONDAY, June 26.

We have a larger number of Beasts than on Monday last, and a fair average quality; trade is active, however, and prices not lower; a fair clearance is effected. The supply of Sheep is unusually small for the time of year; choicest qualities are readily disposed of, and in some instances our top quotations are higher exceeded. Trade is rather better also for choicest Lambs and Calves. Our foreign supply consists of 1920 Beasts, 8500 Sheep, 410 Calves, and 35 Pigs; from Scotland there are 70 Beasts; from Norfolk 480 Sheep, 1500; and 540 from the Midland and Home Counties.

Beasts, 4030; Sheep and Lambs, 21,550; Calves, 445; Pigs, 130.

THURSDAY, June 29.

There are a few more Beasts than on Thursday last; choicest descriptions, however, are by no means plentiful, and make about the same as on Monday. Inferior qualities are rather lower, but a fair clearance is effected. The supply of Sheep is much shorter, the falling off being principally in foreign. The trade is not so brisk as on Monday, and prices on the average are not quite so good. Choice Lambs and Calves fully realise Monday's quotations. Our foreign supply consists of 280 Beasts, 2700 Sheep, and 733 Calves.

MARK LANE.

MONDAY, June 26.

There was a very small supply of English Wheat to this morning's market, which was sold at the prices of this day se'nnight. The attendance was good, and holders of foreign Wheat were not disposed to accept lower prices, and a fair consumptive business was done on last week's terms. Barley was dull, Beans 1*s.* per qr. cheaper, Peas unchanged in value. Oats were 6*d.* per qr. cheaper; inferior qualities sold at very irregular prices. There was no change in the value of Flour.

WEDNESDAY, June 28.

The grain trade to-day was exceedingly quiet, the tendency of prices being unfavourable. The show of English Wheat was small, but the receipts from abroad were more liberal. Transactions in red and white produce were restricted, but no material change took place in value. Barley sold quietly, on former terms. Malt was dull, but unaltered in value. Oats, the supply of which was large, declined a slow demand at declining prices. Beans were dull, at Monday's reduction. Peas were in limited request, at about late rates. Flour was depressed, and generally cheaper to sell.

LIVERPOOL, June 27.—At this day's market there was a fair attendance of the town and country trade, but owing to the more genial weather little disposition to buy, except for the supply of immediate wants. Wheat and Flour met with a slow retail sale, at the rates of this day week. In Oats and Oatmeal there was little done, and no quotable change in value. The same may be said of Barley, Beans and Peas.

SEED MARKET.

The weather during the past week has been changeable, but more favourable on the whole to the growth and maturity of seeds. Our trade is still in the same unsettled state noted in our last report; holders seem inclined to raise their pretensions, and buyers being unwilling to accede to their demands, transactions are in consequence limited to the few articles actually required for present use, such, for instance, as Mustard and Rape seed, both of which are firm. Bird seeds move off steadily, at unaltered rates.

FOLLOWS & BATE'S

PATENT "CLIMAX" BACK-DELIVERY

LAWN MOWER FOR THE MILLION.

Price 25s.

THE TIMES, *December* 10, 1869.

"FOLLOWS & BATE, of Manchester, bring out the latest little wonder in Lawn Mowers, which is a machine cutting only 6 inches wide, being propelled with surprisingly little force, and costing almost a fractional price as compared with the large machines."

These Machines having no roller in front of the knives, cut LONG or short Grass just as it grows, do not miss the bents, and never choke, however wet the Grass may be.

They are specially applicable for Slopes and Steep Embankments, and are the only Lawn Mowers that can be used effectually with or without the Box.

Between **3000** and **4000** of the "CLIMAX" have been Sold this season. Every Machine is warranted, and a trial allowed.

CATALOGUES, with Testimonials and full particulars of other sizes, on application to any respectable Ironmonger or Dealer in Horticultural Machinery, or sent Post Free from the PATENTEES and MANUFACTURERS,

FOLLOWS AND BATE, MANCHESTER.

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER.

The only Lawn Mower that Cuts Wet or Long Grass (as well as dry) without Clogging,

Leaving the Cuttings in small particles, evenly scattered, never looking untidy, serving as a Mulch to Protect the Roots from Heat and Drought, and Fertilising the Sod, which cannot fail to invigorate and beautify the Lawn. Perfectly adapted to SLOPES, UNDULATING LAWNS, RIDGES and VALLEYS; and for the CROQUET GROUND is invaluable.

NOTICE.—GREAT REDUCTION in PRICES for 1871.—We have great pleasure in stating that owing to the unprecedented success our "Archimedean" Lawn Mower met with last year, we have increased our facilities for manufacturing, and notwithstanding that several important improvements have been made in the machine, yet we have made a large Reduction in Prices for 1871.

"Far superior to any of ours."—Vide *The Field.*
"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—Vide *Floral World.*
"Remarkably easy to work."—Vide *Gardeners' Magazine.*
"The quickest, most simple, and most efficient Mower ever used."—Vide *Gardeners' Chronicle.*

Numerous Testimonials from the highest authorities in horticulture have been received.

ILLUSTRATED CATALOGUES and TESTIMONIALS Post Free on application.

MANUFACTURERS and PATENTEES—

WILLIAMS AND CO., 1, CITY ROAD, FINSBURY SQUARE, E.C.

EXHIBIT AT THE

ROYAL AGRICULTURAL SHOW, WOLVERHAMPTON, JULY, 1871,

FIVE DIFFERENT SETS OF STEAM PLOUGHING AND CULTIVATING MACHINERY,

Adapted for all circumstances and conditions of the Soil; with their

NEWEST PLOUGHS, CULTIVATORS, HARROWS, ROLLERS, VANS, WATER-CARTS, &c.

TRACTION ENGINES, of various horse-power; and **WAGGONS**,

of corresponding strength and size.

Some of these Engines will be fitted with INDIA-RUBBER TYRED Wheels, and others with Plain Wheels.

THE HYDRONETTE
(ROBIN'S PATENT).

For Gardens, Greenhouses, Conservatories, Hotbeds, Washing Windows, Carriages, &c.

Unrivalled ease of action, simplicity, convenience, and force.

The HYDRONETTE is a more useful, easy-working, reliable, and convenient water-throwing machine than any other in use. In five sizes, viz.:—No. 1, with 4 feet of Suction Hose, Strainer, Jet and Rose, 12s. 6d.; No. 2, 15s. 6d.; No. 3, £1 12.; No. 4, £1 5s. 1. No. 5, £1 10s. Extra Hose and Union Joints to order.

PATENT WATER BRINGER.

HAYNES AND SONS' PATENT WATER BRINGER, price 21s.—This simple Machine will draw water from a pond or well to feet below the level of garden, and 100 feet over the surface, with the Hydronette or any other Garden Engine.

HAYNES AND SONS, 227, 229, and 231, Edgware Road, W.

CAUTION.—None are genuine unless labelled "HAYNES & SONS, Proprietors, London."

Estimates given for Conservatories or Greenhouses to any Design.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "Patent Double L Saddle Boiler" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and, being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	5 0 0

14, TICHBORNE STREET, REGENT'S QUADRANT, LONDON, W.

GRAY'S OVAL TUBULAR BOILER.

INTERNATIONAL EXHIBITION, CLASS IX., NO. 2119.

MR. GRAY begs to call the attention of the Nobility, Gentry, Nurserymen, Gardeners, &c., to his

NEW OVAL TUBULAR BOILER.

Acknowledged by practical judges to be a great improvement on every form of Tubular Boiler yet introduced. It has proved itself superior to all other Boilers for quickness of action and economy of Fuel, doing its work with one-third less the amount required by any other.

Extract from Report in GARDENERS' CHRONICLE *of International Exhibition, May 24, 1862, page 476.*

"The upright form of Boiler is usually made on a circular plan, but the oval form given to Mr. GRAY'S variety of it is said to be preferable in consequence of its bringing the tubes in closer contact with the fire. The usual form of a furnace being a parallelogram rather than a square, it seems feasible that the Boilers on the oval plan should bring the tubes more completely within range of the burning fuel; and this being so, the change, though a slight one, is no doubt an improvement."

☞ *They are made of all sizes, which, with prices, may be had on application.*

JAMES GRAY, HORTICULTURAL WORKS,
DANVER'S STREET, PAULTON'S SQUARE, KING'S ROAD, CHELSEA, S.W.

J. C. & J. S. ELLIS,
HORTICULTURAL ENGINEERS,
NORFOLK FOUNDRY, SHEFFIELD,

MANUFACTURERS and ERECTORS of HOT-WATER APPARATUS

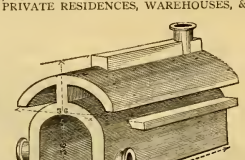
OF EVERY DESCRIPTION, FOR

HEATING GREENHOUSES, CONSERVATORIES, HOTHOUSES, CHURCHES, PUBLIC BUILDINGS, PRIVATE RESIDENCES, WAREHOUSES, &c.

The great advantages of these Boilers are:—

The fire acting directly under the flow pipe, the water begins to circulate immediately.

The Flues all being formed by a continuous water-way, the fire and all the hot gases are brought in direct contact with the heat-absorbing surface of the Boiler, thereby giving a greatly increased amount of power, and by which an immense saving of fuel is effected.



PATENT DOUBLE-ARCH BOILER.

These Boilers offer great facilities for banking-up the fire, and will burn easily from 12 to 14 hours without attention.

The arrangement of Soot-doors in the brickwork is such that all the flues can be cleaned in a few minutes.

TESTIMONIALS.

"The Gardens, Chatsworth, January 19, 1871.

"DEAR SIR,—After using your Patent Double-Arch Boiler for the past 12 months, enables me to speak with a practical knowledge of its merits; and I have no hesitation in saying, out of many Boilers, of all sorts of construction, we have in use, it is the most efficient, and I believe it to be the best Boiler extant; neither do I think there is another that exposes so much surface to the direct action of the fire. Its efficiency, economy in fuel, and the minimum of attention, renders this Boiler a valuable improvement in Horticulture, and it reflects great credit on your good sense in designing it. I shall be glad to show the one I have in use to any person calling at Chatsworth. I remain, dear Sir, yours truly,

"Mr. Ellis." "THOMAS SPEED.

"Westbourne Gardens, Sheffield, October 27, 1870.

"DEAR SIR,—Your Patent Double-Arch Boiler, that you have put down for us lately, to heat the whole of our houses, answers admirably. Its heating surface exceeds all others which I am acquainted with. The small amount of fuel required, the way it is set, and the arrangement of soot-doors, renders it the most complete and economical Boiler I have had to do with.—Believe me, Sir, yours truly,

"Mr. Ellis, Norfolk Foundry, Sheffield." "W. H. BIRD.

CONTENTS.

IMPROVED THICK-LEAVED DANDELIONS.—The above may be sown now, and blanched similar to Seakale.

"In our opinion this is equal to, if not superior to Endive."—*From the Editor of the Gardeners' Chronicle.*

"The leaves sent are 18 inches long, and broad in proportion, and the midrib is nearly half an inch broad and a third of an inch thick. As the common Dandelion when blanched is one of the most delicate-flavoured and wholesome of Salads, this vigorous growing fleshy-leaved variety of Messrs. Stuart & Mein must be a desirable plant for the kitchen garden."—*From the Editor of the Gardeners' Magazine.*

New Seed, 1s. per packet.

STUART AND MEIN, Seedsmen to the Queen, Kelso, N.B.

New Turnip Seed, 1871.

Caution.

F. J. DRECHSLER'S ADDRESS is now, and has been for several months past, No. 63, ARLINGTON STREET, LONDON, W., and not North Street, Stoke.

See this year's PORTABLE WINNOWING-MACHINES, FUMIGATORS, SEMINARIES, &c.

No. 1, Peel Street, Manchester. 1871.

OUR HORTICULTURAL SHADINGS form a thorough Protection from Winds, Frost, and Hail, whilst at the same time they admit Light and Air. They are used and strongly recommended by the most successful Exhibitors and Scientific Horticulturists in the Kingdom, as well as on the Continent; in fact, many pronounced the only "proper shadings" ever offered to the public against Birds, Mildew, Blight, &c. As a covering for Strawberries, Tulips, Hyacinths, Seed-Beds, Greenhouses, &c., they have no rival. The price, being very reasonable, brings them within the reach of every one. With ordinary care they will last for many years. Samples post free on application. DANIEL LILLIE AND SON.

Great Reduction in Prices for 1871,

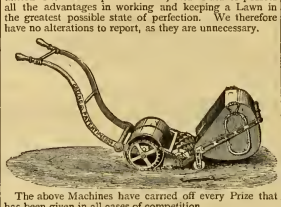
OF

GREEN'S PATENT SILENS MESSORS

OR

NOISELESS LAWN MOWING, ROLLING AND COLLECTING MACHINES.

During the last few years our Machines have been submitted to numerous practical tests, and found to possess all the advantages in working and keeping a Lawn in the greatest possible state of perfection. We therefore have no alterations to report, as they are unnecessary.



The above Machines have carried off every Prize that has been given in all cases of competition.

They are warranted to be superior to any others. We guarantee them to give entire satisfaction, otherwise they can be returned, free of cost to the purchaser. With the increased facilities we possess for the Manufacture of Lawn Mowers, we are enabled to Sell them at a reduced rate on former years, as will be seen from the following Scale of Prices:—

To cut 8 inches .. .. Price	£	s.	d.	
,, 10 ,, ...	3	0	0	Can be worked by one person.
,, 12 ,, ...	4	0	0	
,, 14 ,, ...	5	0	0	
,, 16 ,, ...	6	0	0	This can be worked by one person on an Even Lawn
,, 18 ,, ...	7	0	0	By Man and Boy.
,, 20 ,, ...	7	10	0	,,
,, 22 ,, ...	8	0	0	,,
,, 24 ,, ...	8	10	0	,,

T. GREEN & SON have pleasure in announcing that the demand for their Lawn Mowers this season far exceeds all previous ones, and from this fact they are led to believe that the machines of their manufacture are held higher in the estimation of the public than ever.

Prices of HORSE, PONY, and DONKEY MACHINES on application.

☞ *Repairs executed with efficiency and despatch, both at Leeds and London Establishments.*

GREEN'S IMPROVED

PATENT ROLLER,

FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS, Suitable for Hand or Horse-power.

PRICES of HAND ROLLERS.

Diameter.	Length.	£	s.	d.	Diameter.	Length.	£	s.	d.
30 in.	32 in.	7	10	0	20 in.	22 in.	9	10	0
24 in.	26 in.	4	10	0	16 in.	17 in.	2	15	0

PRICES of ROLLERS, fitted with Shafts,

Suitable for Pony or Horse-power.

Diameter.	Length.	£	s.	d.	Diameter.	Length.	£	s.	d.
30 in.	32 in.	10	0	0	30 in.	60 in.	15	10	0

30 in.	42 in.	11	15	0	30 in.	84 in.	19	10	0
30 in.	48 in.	13	10	0					

These ROLLERS possess many advantages over all others; they are made in two parts, and are free to revolve on the axis, affording greater facility for turning, and the outer edges are rounded off, or turned inwards, thus avoiding the unsightly marks left by other Rollers. They are manufactured of the best materials, and are got up in a manner surpassing any ever yet brought out.

The ROLLERS, 24 by 26 inches, 20 by 22 inches, and 16 by 17 inches, can also made in one part, at a reduced price; and for Rollers of that size, will be found to answer many requirements, as the handle can be reversed to either side of the Roller at pleasure.

HEATHERSIDE NURSERIES, BAGSHOT, SURREY,

Invites from the Country Trade a visit to the extensive Nurseries here, the most convenient Station to which is Farnborough, on the London and South-Western Railway, where Conveyances will be sent to meet Visitors on receipt of an intimation of their intended arrival.

The stock is in very fine condition, and includes large quantities of LARCH, SCOTCH, SPRUCE, AUSTRIAN, LARICIO, and other PINES; CONIFERÆ of every description, FOREST TREES in great quantities, ORNAMENTAL TREES and SHRUBS, RHODODENDRONS in great quantity, ROSES, FRUIT TREES, LAURELS, PORTUGAL LAURELS, and other EVERGREENS; a large stock of Green and Variegated HOLLIES, VINES, &c.: all at moderate prices, and everything has been well transplanted and is well rooted.

A SPECIAL OFFER to the TRADE of MANY THINGS will soon be ready, and can be had on application.

ROYAL HORTICULTURAL SOCIETY

SHOW OF ROSES AND TABLE DECORATIONS, &c.

July 5, 1871.

AWARDS OF THE JUDGES.

CLASS 1.—Group of three PLANTS, suitable for Dinner-table Decorations.

1st Prize, Mr. J. W. Chard, Gr. to Sir F. Bathurst, Bart., Clarendon Park, Salisbury, £3.
2d, Mr. W. Bull, Nurseryman, King's Road, Chelsea, £2.
3d, Messrs. E. G. Henderson & Son, Nurserymen, St. John's Wood, £1.

CLASS 2.—Three Groups suitable for the Decoration of the Dinner-table, to consist of either Flowers, or Fruit, or Flowers and Fruit combined, at the option of the Exhibitor.

1st, Messrs. W. P. & G. Phillips & Pearce, 155, New Bond Street, £5.
2d, Mr. J. W. Chard, £3.
3d, Miss Hassard, St. Roman's, Church Road, Upper Norwood, £2.
Extra, Mr. W. Saul, Gr. to O. Hanbury, Esq., Howe Hatch, Brentwood, £2.

In the above Two Classes, the Prizes are offered by His Grace the Duke of Buccleuch, K.G., F.R.S., President of the Society.

CLASS 3.—72 ROSES, distinct, 1 truss of each. (Nurserymen.)
1st, Messrs. Paul & Son, Old Nurseries, Cheshunt, £6.
2d, Messrs. E. F. Francis & Co., The Nurseries, Hertford, Herts, £4.

CLASS 4.—48 ROSES, distinct, 3 trusses of each. (Nurserymen.)
1st, Messrs. Paul & Son, £5.
2d, Mr. C. Turner, Royal Nurseries, Slough, £4.

CLASS 5.—24 ROSES, Hybrid Perpetuals only, distinct, 3 trusses of each. (Nurserymen.)
1st, Messrs. Paul & Son, £3.
2d, Mr. J. Fraser, The Nurseries, Lea Bridge Road, Leyton, N E., £2.
3d, Mr. C. Turner, £1.
4th, Messrs. E. F. Francis & Co., £1.

CLASS 6.—24 ROSES, distinct, 1 truss of each. (Nurserymen.)
1st, Mr. C. Turner, £3.
2d, Mr. J. Walker, Nurseryman, Thame, Oxon, £2.
3d, Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, £1.

CLASS 7.—48 ROSES, distinct, 1 truss of each. (Amateurs.)
1st, Rev. C. H. Wilkinson, Bromyard, Worcester, £6.
2d, Thomas Laxton, Esq., F.R.H.S., Stamford, £4.
3d, Mr. J. Walker, £2.
4th, Mr. R. N. G. Baker, 9, Salutary Mount, Heavitree, Exeter, £2.

CLASS 8.—36 ROSES, distinct, 1 truss of each. (Amateurs.)
1st, Mr. W. Paul, 12, Mrs. Round, Birch Hall, Colchester, £5.
2d, Mr. J. W. Chard, £3.
3d, Mr. C. G. Linzee, £2.
4th, Mr. P. Stoddart, Gr. to H. J. G. Rebow, Esq., Wivenhoe Park, Colchester, £1 10s.

CLASS 9.—24 ROSES, distinct, 1 truss of each. (Amateurs.)
1st, Mr. J. Skinner, Gr. to Capt. Christy, Westerham Hill, Kent, £4.
2d, Mr. W. Soder, £3.
3d, Mr. J. Wakely, Rainham, Kent, £2.
4th, R. B. Postans, Esq., Brentwood, Essex, £1.

CLASS 10.—12 ROSES, distinct, 1 truss of each. (Amateurs.)
1st, Mr. J. C. Quinnett, Brentwood, Essex, £3.
2d, Rev. C. C. Ellison, Bracebridge Vicarage, Lincoln, £2 10s.
3d, Mr. J. W. Chard, £2.
4th, Mr. W. Soder, 10s.

CLASS 11.—12 ROSES of 1869 or 1870, single trusses, distinct kinds. (Open.)
1st, Messrs. Paul & Son, £3.
2d, Mr. C. Turner, £2 10s.

CLASS 12.—12 ROSES of any ROSE of 1869-70. (Open.)
1st, Messrs. Paul & Son, £2 10s.
2d, Mr. C. Turner, £1.

CLASS 13.—6 Trusses of any ROSE of 1869-70. (Open.)
1st, Messrs. Paul & Son, £1.

CLASS 14.—Collection of YELLOW ROSES, not fewer than 12 trusses. (Open.)
1st, Messrs. Paul & Son, £3.
2d, Mr. P. Stoddart, £2.
3d, Mr. W. Paul, Waltham Cross's Farm, Stisted, near Braintree, Essex, £1.

CLASS 15.—12 Tea-scented and Noisette ROSES, single trusses. (Amateurs.)
1st, Mr. H. Thornycroft, Flours, Weedon, Northampton, £2.
2d, Mr. P. Stoddart, £1 10s.
3d, Mr. J. Tranter, Upper Assindon, Henley-on-Thames, £1.

CLASS 16.—12 Tea-scented and Noisette ROSES, single trusses. (Nurserymen.)
1st, Messrs. Paul & Son, £1 10s.

CLASS 17.—6 Tea-scented ROSES, single truss, in bud. (Open.)
2d, Mr. J. W. Chard, 10s.

CLASS 18.—6 ROSES (Tea and Noisette excluded), flowers, good of their kind, to be judged for their perfume. (Open.)
1st, Mr. J. W. Chard, 15s.
2d, T. Laxton, Esq., F.R.H.S., 10s.

CLASS 19.—6 Tea or Noisette ROSES, flowers, good of their kind, to be judged for their perfume. (Open.)
1st, Mr. J. W. Chard, 15s.
2d, Mr. H. Smith, 7, Cloverton Place, Lycombe, Bath, 10s.

CLASS 20.—12 ROSES, distinct, single blooms. (Open.)
1st, Mr. C. Turner, £1 10s.

CLASS 21.—24 ROSES, in pots, not fewer than 10 varieties, the pots not to exceed 8 inches in diameter. (Open.)
1st, Mr. C. Turner, £6.
2d, Messrs. Paul & Son, £4.
3d, Messrs. J. Veitch & Sons, £3.

Prizes offered by Mr. Wm. Paul, F.R.H.S.

CLASS 22.—Three Blooms of ROSES, Princess Christian. (Amateurs.)

Prizes offered by Messrs. James Carter & Co.

CLASS 23.—Six Blooms of VEAS, to include Laxton's Supreme, Carter's Hundredfold, and Laxton's Quality.
1st, Mr. W. Cox, Gr. to Earl Beauchamp, Madresfield Court, Great Malvern, £2 2s.
2d, Mr. C. Frisby, Gr. to H. Chaplin, Esq., Blankney Hall, Sleaford, Lincoln, £1 1s.

MISCELLANEOUS.—EXTRA PRIZES.

Mr. W. Denning, Gr. to Lord Londesborough, Grimston Park, Tadcaster, York, Collection of Orchids.
Mr. W. Bull, Group of New and Rare Plants.
Mr. C. Turner, Group of Seedling Pelargoniums.
Messrs. J. Veitch & Sons, Group of Roses in Pots, and Collection of Cut Roses.
Messrs. W. Rollisson & Sons, Nurserymen, Tooting, Group of Plants.
Messrs. E. G. Henderson & Son, Group of Tricolor Pelargoniums and Petunias.
Mr. H. Hooper, Vine Nursery, Widcomb Hill, Bath, Cut Blooms of Pansies, Carnations, Cloves, and Fiaks.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a GENERAL MEETING of the MEMBERS of this INSTITUTION, held on WEDNESDAY, July 5, for the purpose of ELECTING THREE PENSIONERS on the FUNDS, the following was the result of the Ballot :—

CANDIDATES.

NAME.	AGE.	VOTES.
JOHN GIBSON	72	922
WILLIAM GATES	68	645
WILLIAM BROWNE	73	747
DANIEL DEWDNEY	78	145
OWEN OWENS	64	372
CHARLES WHITEHURST	71	781
WILLIAM CAWLEY	74	56
RICHARD HUSSEY	68	305
JOSEPH ODELL	71	57
FRANCIS FRITCHARD	59	209

The Meeting then declared JOHN GIBSON, CHARLES WHITEHURST, and WILLIAM BROWN, as having the greatest number of Votes, duly elected Pensioners.
EDWARD R. CUTLER, Secretary.
14, Tavistock Row, W.C., July 6, 1871.

The Gardeners' Chronicle

SATURDAY, JULY 8, 1871.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY,	July 11	Royal Horticultural (Examination of Gardeners)
WEDNESDAY,	" 12	10 A.M.
THURSDAY,	" 13	Royal Botanic (Exhibition of Plants, Flowers, and Fruit).

THE most COMMON OBJECTS in NATURE are often those which are the least generally understood. This is certainly the case with the grains of such everyday plants as Wheat, Oats, and Barley. Few questions are more frequently set in examination papers than "Describe the structure of a grain of Wheat and the process of germination," and yet it is very rarely that one gets a tolerable answer. We have ourselves lately looked over upwards of 300 papers, in not one of which was there any true account of the structure. It is quite certain that many of the teachers must themselves have a very imperfect knowledge of the case, which certainly is not pardonable, as there is an excellent account, with diagrams, in LINDLEY'S "Vegetable Kingdom," with the different views which are entertained on the subject.

The fact is, that there is in these grains either a peculiar organ, or a peculiar state of the cotyledon, which for a long time imbibes nutriment from the starch contained in the seed, and which has been sometimes considered as a part of the primary root, a view which was held by RICHARD, while NEES VON ESENBECK regarded it as a special organ. We were ourselves at one time inclined to RICHARD'S view, as we believe the terms exorhizal and endorhizal greatly misunderstood. In the greater part of monocotyledons the primary root is quite as naked as in dicotyledons, the secondary roots being adventitious; and we were therefore inclined to an opinion that in Gramineæ the representative of the naked root in other monocotyledons was the organ in question. On considering, however, the germination of an Onion, and the mode in which the albumen conduces to nourish the young plant, we find something so analogous to what takes place in cereals, that we are now inclined to Dr. LINDLEY'S views, and to consider the organ in question a true cotyledon, with the peculiar function of absorbing nutriment from the storehouse to which it is joined. What takes place in the germination of an Onion is simply this: the seed, as is well known, is carried up by the cotyledon, which assumes the form of a loop. If a spot of any colouring matter which will not injure the young plant is placed at the point where the cotyledon bends, it will be found that it remains stationary. The tip of the cotyledon remains immersed in the albumen, and is very tender, and as long as it is wanted conveys nourishment downwards to the young plant. We have here then a cotyledon performing the same function as the peculiar organ in grasses, and the obvious inference is, that that also is a cotyledon. If this is true, the grasses alone are truly endorhizal.

It was stated some time since, at one of the scientific meetings of the Royal Horticultural Society, that the seed of Tropæolum is endorhizal. This surprised us so much, that we immediately sowed some seed to ascertain how the case really stands. If a section be made in the seed through the thick cotyledons when it is just ready to germinate, it will be found that the base of the cotyledons united below extends beyond the primary radicle, which is perfectly distinct, forming a sort of coleorhiza. This indeed is indicated in the vertical section of Tropæolum majus in the "Vegetable Kingdom." *M. J. B.*

THERE ought to be appointed without delay a public officer to be called CONSERVATOR of TREES, if London is to be supplied as it ought to be with healthy thriving examples of arboreal vegetation. Pending such appointment, the vestries ought to charge themselves in their respective districts with the duties indicated by the above title. Ought, we said, but they do not. What, for instance, have the local authorities of Chelsea—if there be any—been doing to suffer a gas company to risk the destruction of those beautiful trees—beautiful for London, if not equal to those in the country—which convert Cheyne Walk into a luxurious shady promenade on a summer's day? The public roadways are, in all conscience, sufficiently bored with drains and conduits to make it a hard struggle for the poor trees which have the ill-luck to be planted near; but here in Cheyne Walk the footway has been invaded, an old, small, shallow gas-pipe taken away, and a big one sunk some two or three feet lower, the excavation cutting through the roots which before had escaped, and had laid bold of the undisturbed soil. Here and there big roots, as thick as one's arm, have been cut off within a few feet of the trunk; at other points masses of fibrous roots have been remorselessly torn up and cleared away. The adornment of this riverside thoroughfare, soon to form part of the great metropolitan northern esplanade, with fine old trees like this, is, of course, altogether beneath the notice of such "enlightened" bodies as gas companies; but there should be some official whose duty it should be to look to the preservation of such relics of the good old times, or, if not, the omnipotent local Parliament—officious and meddlesome enough in matters of far less consequence—should stir itself, and put a *veto* on all such vandalism.

The office we have indicated would be no sinecure if the officer did his duty, for, not in Chelsea only, but on every hand, the same kind of ruthless destruction is from time to time to be met with; and though the necessities of the population may be pleaded as an excuse for the new works, in which engineers and surveyors and contractors seem leagued together to kill every green thing, yet, as in the present case, for example, and doubtless in many others, there is no necessity to break up fresh ground when the consequences are likely to be so disastrous, and by all means is so costly—in this case going to have laid the pipes on the other side of the trees. If the local Parliament will not arouse itself, and act, the Imperial Parliament should abridge its power, and get such necessary work done for it. By all means let us have a public conservator of trees, armed at least with as summary powers as those of the officer of health or the inspector of nuisances. Most large towns and cities need such an officer, fully as much as the metropolis itself.

WE are now able to add to our previous remarks on the ROYAL HORTICULTURAL SOCIETY'S SHOW at NOTTINGHAM that it has been in every way a grand success. The receipts at the doors exceeded £1900, and this, with some £600 for season tickets, made a total of £2507 *1s. 2d.* received from visitors to the show. The several days receipts were as follows :—

June 27	Tuesday	..	£150 7 6
June 28	Wednesday (2*s. 6d.*) ..	..	395 2 0
June 29	Thursday (1*s.*)	..	694 0 9
June 30	Friday (1*s.*)	..	343 17 10
July 1	Saturday (6*d.*)	..	393 13 3

Such a financial success was due partly to the splendid weather which prevailed during the greater part of the time the exhibition was open, and partly to the fact that the inhabitants of Nottingham are enthusiastic supporters of horticulture.

ONE of the floral treats to be met with in the neighbourhood of Nottingham, during the period of the recent show, was Mr. PEARSON'S splendid strain of ZONAL PELARGONIUMS, some of which are of a most remarkably attractive character. They are mostly of the semi-nosegay class, but with particularly large flowers, and immense trusses freely produced on plants of stocky growth—a feature which seems to be inherent in the breed. Miss Sanders, a crimson with a strong blue shade, resplendent in colour, is particularly rich; and Rose Peach, a deep, bright rose, is a highly attractive flower. Corsair, a rich scarlet, of faultless form, is so fine in habit, truss, and substance, as to leave Lord Derby far behind; and Amaranth, a free, plain-leaved, compact-trussed, blue-tinted deep rose, seems likely to take the lead as the highest colour in the Christine class. Rose Bradwardine, a lovely rose, is remarkable for the abundance of its cheerful-coloured flowers; and Thomas Adams, a large, bright carmine, has a noble truss. There are others of equal merit, perhaps, but these struck us as decided advances in the class of decorative plants. Mr. PEARSON has also been paying particular attention to the breeding of the Golden Variegated Zonals, and has succeeded in gaining not only brilliant colours, but a remarkably even border of colour. Lady Manvers is a particularly fine variety in this way, and another, called William Sandys, has not only high colour, but a remarkably free habit of growth.

We understand that it was proposed amongst the exhibitors assembled at the Royal Horticultural Society's show at Nottingham to present a testimonial to Mr. GEORGE EYLES, the Superintendent of the Show, with some mark of their esteem, and also of their appreciation of the courteous and able manner in which he has always discharged the somewhat onerous duties which fall to the lot of a manager of flower shows. No one is more entitled to such a public mark of recognition than is our friend EYLES, as the very effective and efficient arrangements at Nottingham bear testimony. We need, therefore, scarcely add that the above-named resolve has our full sympathy, and we trust it will be carried out with energy by such a committee as will command the general support of horticulturists interested in flower shows. The movement is all the more opportune at this moment, as Mr. EYLES has recently retired from the general superintendence of the South Kensington Gardens, and will confine his attention more exclusively to the departments of flower shows and landscape gardening.

—— A meeting of market gardeners, nurserymen, and farmers, was held at the Bedford Head Hotel, Covent Garden, on Tuesday morning last, for the purpose of receiving a sub-committee from the MARKETS IMPROVEMENT COMMITTEE of the City of London, and inspecting plans of the proposed improvements at Farringdon. There were a large and influential attendance of large growers. The chair was occupied by Mr. HENRY MEYERS, the President of the Market Gardeners' Association, who, in introducing the business, alluded to the great inconvenience which he and other growers had had to put up with in consequence of the want of accommodation at Covent Garden, and the decided refusal of the Duke of BEDFORD to offer greater facilities to the producers using the market. Mr. RUDKIN, of the Corporation, produced drawings of the new market proposed to be constructed in place of the present inconvenient and filthy market at Farringdon, and the meeting was engaged for nearly an hour in discussing and advising upon the necessary alterations. A motion was eventually passed to the effect that the meeting approved of the scheme so far as it had been put before them, and pledged itself to assist by all means in its power the efforts of the City committee in establishing the new market. The plans are to be definitely settled at a meeting to be held at the latter end of this month.

—— A most unfortunate circumstance happened during the removal of the plants from Nottingham. It appears that Messrs. BELL & THORPE, from motives of kindness and disinterestedness, took charge of a specimen plant of Croton, belonging, as they thought, to Mr. BAINES, and which they supposed to have been left by an oversight. On reaching home they informed Mr. BAINES of what they had done. It turned out, however, that the plant was the property of some other gentleman, who took such stringent measures to secure the return of his property that Messrs. BELL & THORPE (who acted, we are assured, with perfect *bona fides*) naturally felt much aggrieved. Messrs. BELL & THORPE, who had previously written to Mr. BAINES, but not posted their letter, express great regret for their unlucky mistake, and we trust that their explanation may be accepted as amply satisfying the justice of the case.

—— From the "Gartenzeitung," we learn that HERR ARNOLDI, of Gotha, the celebrated modeller of fruits and flowers, has just commenced issuing a series of sets of FUNGI MODELLED in PAPIER-MÂCHÉ, accompanied by printed descriptions, and all necessary information respecting the properties and habitats of each species. Each species where desirable will be represented in different stages of growth, and all the models will be of the natural size and colour of the species they represent. Indeed those already exhibited by ARNOLDI are said to be so true to Nature, that it is impossible, without handling, to distinguish them from living specimens. Each set or issue will consist of models of 12 to 18 species, with printed matter, and three or four sets will

appear in the course of a year. The sets will contain alternately specimens of edible and harmless species, and suspicious, hurtful, and poisonous species. The ostensible object of these models is to familiarise the masses, who have neither time nor opportunity to study descriptions and plates, with this class of plants, and enable them to distinguish and use the really good sorts, without any risk of confounding them with the noxious species, from which many uninformed persons have suffered. The models will be made under the supervision of Dr. GONNERMANN, Dr. DANNENBERG, and other well-known German mycologists. The price of a set of 12 specimens, with printed matter, will be about 7*s.* 6*d.*, and they may be had through any foreign bookseller. The whole, or any part of the specimens, may be had. If these models prove to be as exact as reported, we think it would be well that local museums and other establishments should be provided with them.

—— The MAXIMUM TEMPERATURES in England during the week ending Saturday, July 1, ranged from 74°.2 at Leicester to 68°.6 at Birmingham, with a mean for all stations of 71°.2, or about 5° above the mean of the several stations in Scotland, where the extremes were 70° at Perth, and 64° at Greenock. The MINIMUM TEMPERATURES in England were, as a rule, lower than those in Scotland; in the former country, 34° (at Hull) and 36°.8 (at Nottingham) were the lowest; and in the latter 39° (at Edinburgh), 39°.2 (at Aberdeen), and 39°.3 (at Paisley), formed the same respective means for the several stations in the two countries were 40° (for England), and 41°.6 (for Scotland). MEAN TEMPERATURES.—The mean for the southern country is about 1°.7 above that of the northern, the values being 55°.2 and 53°.5, respectively. In England, Manchester, with 56°.3, was the highest, closely followed by Blackheath and Liverpool, with 56°.6, and Portsmouth, with 56°.5; and in Scotland, Perth, with 55°.9, was nearly 1° higher than the second, viz., Greenock, with 55°.1. RAINFALL.—The principal falls which took place during the week ending July 1, were chiefly in Scotland, the largest in amount being 0.66 inch at Greenock, and 0.92 inch at Glasgow; the mean for the country was 0.54. In England, 0.56 inch at Salford takes first place; with 0.48 inch at Hull, second; and 0.43 inch at Bradford, third. The mean for the whole country was 0.27 inch. Saturday last was the commencement of another month, and, let us add, we hope also of summer, for up to the present the weather has been most unseasonable, showers of a March and April character having been experienced at the beginning of July. The month of June, 1871, will long be remembered for the low temperatures which prevailed all over the country, and in many of the districts in the north of England falls of snow are reported to have taken place. During the present century there are only seven occasions on which the mean temperature of the month has been as low or lower than in the month which has just passed, they are:—June, 1860, with 54°.8; 1824, with 55°; 1821, with 54°.1; 1816, with 53°.1; 1814, with 53°.4; 1812, with 54°; and 1805, with 54°.5. The mean temperature of the month under discussion was about 55°.

—— The *Scientific Review* notices a metallic paint for the PRESERVATION of WOOD and IRON SURFACES, brought into use by Messrs. TARR & WONSON, of Gloucester, U.S. They take about 40 gall. of wood tar (preferably the best Stockholm tar), to which they add 40 gall. of naphtha, about 0.7 Benzoline specific gravity, or so much naphtha as shall render the tar of the consistency, or nearly so, of boiled linseed oil. The fluids are mixed carefully, and about 24 hours are allowed for subsidence. The purified tar mixture is then drawn from the dregs, which may be drained. To 40 gall. of this purified tar they add about 30 lb. of dry ochrey iron ore (commonly known as bog iron ore) in very fine powder, which must be thoroughly incorporated with the tar. When this has been done they add about 40 lb. of commercial white arsenic and 160 lb. of white lead, and when the whole is reduced to a thick paint by a mill or otherwise, the preparation is ready for use as a protective paint.

—— Those of our readers interested in SCHOOLS and SCHOOL TEACHING, should make a point of visiting the Swedish School House in the International Exhibition. The comfort and physical welfare of the scholars are evidently sedulously cared for, while the appliances for teaching, and the apparatus, models, diagrams, &c., are admirable. It is quite clear that if this is a sample of how children are taught in Sweden, that their education is far more thorough and useful than that of the students at our great public schools or universities, if we except classics and mathematics. Instead of being made to learn from dry and often badly compiled books unintelligible abstract propositions, the Swedish child is so taught by eye, ear, and touch, that comparatively abstruse matters are rendered intelligible to the child's comprehension, and he is put into possession of a mass of facts, the value and importance of which he is made at once to appreciate, instead of being crammed with an ill-arranged farrago of hard words, conveying no meaning to his mind, but which he has nevertheless to learn by heart. Botanists would do well to inspect the beautifully prepared collections of common plants and the accompanying diagrams. These things make us wish it had been our lot to have learnt our rudiments in a Swedish school.

—— A brilliant *conversazione* was held on Tuesday evening last in the great conservatory of the Horticultural Society. The company was distinguished and numerous, including most of the foreign delegates to the horticultural section of the Exhibition. One extraordinary omission occurred,—so extraordinary that, did we not know it for a fact, we should have deemed it incredible—we allude to the absence of hosts! Hosts of guests, truly, but no one to receive them.

—— The WATER RICE (Zizania aquatica) is abundant in Wisconsin, and other parts of North America, on the swampy margins of streams in shallow water. A gently flowing current, where the water is from 2 to 6 or 8 feet deep, is the most favourable *habitat* for this plant, which forms an important article of food among the Indian tribes. They obtain it by paddling a canoe among the plants, when, with a hooked stick, they draw the stems over the canoe and beat off the grain. The harvest only lasts for a very few days, as when ripe the grain is shaken off by the slightest touch, and if the wind should blow hard for a day or two the Rice is all lost. It is gathered both "in the milk" and after it is mature. The Indians take it to their camp and put it into pans, when it is roasted until the husk becomes dry and reddish; they then place it in sacks and pound it by striking on the outside, so as to separate the grain from the husk. It is winnowed, and is then ready for use. Those who have tried it prefer the Zizania to the ordinary Rice of commerce.

—— The accompanying woodcut (fig. 177) represents a contrivance which will be found extremely useful for the application of liquid insecticides. It is called the HORTICULTURAL VAPORIZER, and is, in fact, a modification of the vaporizer used at the toilet for the

FIG. 177.—HORTICULTURAL VAPORIZER.

dispersion of scented liquids, but adapted by these modifications for horticultural use. By means of this apparatus, any kind of liquid may be diffused over plants in a state of minute division, or fine spray, in sufficient quantity to thoroughly moisten them, without ruffling or disturbing the most delicate flower or foliage; and at the same time with a great saving of the liquid as compared with the ordinary process of syringing. It is said that a table-spoonful applied by the Vaporizer is equal to a pint applied by means of a sponge, or the ordinary methods in use. The Vaporizer may be used either by blowing, or by the use of a pair of bellows, fastened by means of a small piece of indiarubber tube to the mouth-piece. As a disinfectant distributor for sick rooms it is also useful. Messrs. PARR & ATHERTON, of Nottingham, are the inventors.

CHARLES LEMAIRE.

CHARLES ANTOINE LEMAIRE (whose death on the 22d ultimo we noticed in our last issue) was born in Paris in 1801. His parents, who were in humble circumstances in the university of that city, where he remained Professor of Classical Literature for some years. On two separate occasions he endeavoured, without success, to establish a school; one of these establishments happened to be in the Rue Buffon, near the Jardin des Plantes. Here the love of botany was kindled in him, and here he made the acquaintance of M. Neumann, the elder *chef des serres* at the museum, and who exercised a great influence on his scientific career. A nurseryman, M. Mathieu, whose establishment was close by the portion of the Jardin des Plantes now superintended by M. Carrière, began to get together, with the aid of M. Lemaire, a collection of Cacti, which the latter studied with ardour, and which became the dominant passion of his life. About the year 1835 M. Cousin, a Parisian publisher, conceived the idea of establishing a horticultural journal, and he entrusted its editorship to M. Lemaire. For many years the "Jardin Fleuriste" and "L'Horticulteur Universel," were almost entirely the work of his pen. He there passed in review the plants newly introduced into France, and which were more numerous in those days than at present. This descriptive talent recommended him to M. Van Houtte, who had recently established at Ghent the "Flore des Serres et des Jardins de l'Europe." After several years passed in the publication and description of the plants introduced by M. Van Houtte, M. Lemaire undertook the editorship of the "Illustration Horticole," a horticultural and botanical journal, then belonging to M. Ambroise Verschaffelt, of Ghent, which post he occupied for 16 years, until M. Linden became the possessor of M. Verschaffelt's establishment, and with it of the above-mentioned journal, the editorship of which was then confided to the present writer. From that time (January, 1870) to the time of his death, M. Lemaire lived in Paris with his devoted daughter, who never left him until his death. In addition to the editorship of the journals we have already mentioned, M. Lemaire collected the materials for a systematic monograph of the Cactaceæ, of which fragments only have been published owing to the want of a Mæcenas to undertake the publication of the book. Latterly, however, the Librairie Agricole de la Maison Rustique of Paris commissioned him to draw up two little volumes, one on Cactaceæ, the other on succulent plants. These two books (reviewed in these columns, pp. 140, 994) were of too restricted a character to allow their author to devote much space to his favourite subjects; but the book on Cactæ contains a synonymy and a reformed nomenclature very useful to botanists studying these plants. Lemaire paid but little attention to the minute anatomy and physiology of plants. With the exception of broaching a theory concerning pollen tubes, which he brought before the Congress at Amsterdam, and which found but few adherents, his studies were principally confined to descriptive botany. His determinations were often accompanied by lengthy dissertations of a very learned and detailed description, appreciated by classical scholars, but having little attraction for those not devoted to philological studies. Lemaire was somewhat of a purist as regards nomenclature; he never ceased to call attention to the numerous barbarisms and solecisms committed by his colleagues, and in general he was right, though he complained much at the indifference with which his complaints were received. If he did not succeed in reforming everything that is erroneous in the orthography and etymology of botanical names, he at least called attention to many errors, and pointed out the right path to be followed by young students of the science. Unfortunately, 40 years' devotion to botany did not lead him on to fortune. Devotees rarely live by science—they often die for it. The example of M. Lemaire is not a solitary one, and we might cite many others equally unsatisfactory. The only compensation for such privations lies in the satisfaction experienced by the discovery and contemplation of so many of Nature's marvels. Posterity will esteem M. Lemaire more highly than did his contemporaries. Man passes away, his work remains. M. Lemaire's name will be honoured and respected by all the botanists who have occasion to consult his numerous publications, and who will reap the benefit of the materials laid up for them during a long career wholly passed in the study of those charming creations which furnish a compensation for many of the misfortunes incident to human nature. *Edouard André.*

New Garden Plants.

HUMATA TYERMANI, *Moore, n. sp.*

Fronds deltoid, acuminate, glabrous, coriaceous, tripinnate; basal pinnæ obliquely-deltoid, the posterior portion larger, and again divided; pinnules very numerous, narrowly oblong, deeply pinnatifid, the lobes oblique, bearing usually a single sorus, with an external tooth: sori transversely oblong, terminal or solitary at the forks of the veinules; indusia creeping: clothed with white, narrow, tapered, slightly-toothed scales: stipes semiteretc.—*Hab.* West Coast of Africa.

This elegant little Davallia, which has been received by Mr. Tyerman from the Western Africa, bears in many respects a close resemblance to D. bullata, the size, outline, and division of the fronds being very similar to those of that plant, but the fructification is quite different, being that of the Humata, not that of the Eu-Davallia, group, while the rhizome, instead of being clothed with rich, golden-brown scales, as in D. bullata, has the scales of a silvery whiteness. The fronds, moreover, are not deciduous, as in D. bullata, but persistent, as in the related Davallia dissects, and D. decora of Java. The African plant bears, indeed, a striking first-sight resemblance to the Indian Davallia Griffithii, which has fronds of the same form, combined with a white-scaled rhizome, but it is altogether larger, and the fructification is different.

The plant now before us (fig. 178), though a small-growing species, is much the largest of the Humatas, and with its elegant form, evergreen fronds, and bloom-scaled rhizomes, will be quite an acquisition for our Fern stoves, being especially suited for basket culture. The fronds measure about 7 inches in length from the setting on of the basal pinnæ to the apex, and are about 7 inches in width across the base; the basal anterior pinnule of the lowest pinnæ is barely an inch long, the basal posterior one an inch and a half, while the average length of the pinnules on the second pair of pinnæ is about half an inch. The stipes, which is reddish-brown towards the base, is, as well as the rachides, and both surfaces of the frond, quite glabrous, rounded behind, flat, with a rim at each margin in front. The veins are prominent on both surfaces, and the position of the sori is marked by boss-like protuberances on the upper surface. The short broad sori are covered by scale-like indusia, attached by the base only.

Mr. Tyerman, the excellent curator of the Liverpool

Botanic Garden, himself a pteridologist of long standing, who has been the medium of introducing this charming plant to our gardens, well merits the compliment of having his name associated with it. Though technically a species of Humata, it is in a wider sense a Davallia, and will no doubt become best known to cultivators as Davallia Tyermanii. *T. M.*

FRUIT-BEARING CONIFERÆ AT LINTON.

[The following paper, which accompanied a very interesting collection of Conifers in fruit, exhibited by Mr. Robson, and to which an Extra Prize was awarded at Nottingham, and which, moreover, was sent in anticipation of a Horticultural Congress, has been handed to us for publication by the local secretary, E. J. Lowe, Esq.]

THE collection of Conifers from whence the fruit exhibited was taken occupies a position about mid-way down the southern slope of a ridge of hills of about 400 feet elevation, the ground occupied by the Pinetum being from about 220 to 290 feet above the sea level. The soil is a dry loam, of good depth, and more or less mixed with stone partaking of the Kentish rag character, but that stone is not found in quantity near the surface, but a partly decomposed substitute of it, locally termed bassock, forms the principal ingredient in the subsoil, and is of so inviting a nature to the roots of most kinds of indigenous trees, that they find their way to a great depth amongst it, and grow quickly and attain a great size. The surface soil, however, though good, would not be regarded by a farmer as being remarkably so, being better adapted for the growth of trees, hedges, and plants of established character than such farming crops as depend on the surface soil alone for their subsistence. Nevertheless, most things thrive tolerably well, especially those having a liking for calcareous matter, with which it is charged. It may be added that it is dry, but not sandy, water being only obtained at the depth of 50 or more feet. With these preliminary observations, and a further remark that the Conifers are mostly scattered over the dressed grounds, some 25 acres, surrounding the mansion, and pretty well sheltered from the north, but in a general way open to the south-west, from whence we have our highest winds, I may leave other points to be indicated when the individual species are treated of. It may, however, be proper to mention that, with the exception of the Araucaria bearing fruit, which has been planted about 40 years, none of the others have been more than 27 in their present position, and all were small when planted. It will thus be seen that the site suits many of them, *Pinus insignis*, for instance, being nearly 60 feet high, and others exceeding 50 feet.

Pinus excelsa.—There are evidently two varieties of this, if not two distinct species, included under the name, one having its spring leaf-buds covered with green scales, the other with the same of a deep rosy-crimson hue. The fruit seems alike, but the habit of growth is different, one being much more spreading than the other, the largest specimen at Linton having a spread of branches of 47 feet, although only 38 feet high, the branches resting on the ground to within a yard of their tips. The other variety has a height and width of about 35 feet. Both have the same long hanging foliage of a glaucous hue, and neither of them have been at any time injured in the least by our hardest winters.

Pinus insignis.—The largest tree is 59 feet high, with a spread of branches of 49 feet, and doubtless this tree would have been higher, but it lost its leader about 20 years ago, and remained four or five years without one; this perhaps accounts for the great spread of its lower branches, for the upper part of the tree is more conical. Its growth, after again forming a leader, was, I need hardly say, most rapid, and the bole, now that it has attained timber-like proportions, does not show that it had ever lost one. Its circumference at 4 feet from the ground is 7 feet 8 inches, the bark very rugged, more so than either the Stone Pine or Pinaster. I may further add, what may perhaps surprise many, that it does not appear to have suffered in the least from any of the hard winters we have had, although a smaller tree of the same species, not more than a stone's-throw from it, was much cut in the winter of 1866-67, and has been slightly injured again in the present winter; but I may observe that the rich, dense, deep green hue, which enhances the beauty of this tree when in a young state, or, say up to the height of from 30 to 40 feet, seems to leave them then—the great number of abortive blossom buds of a dull yellow colour, and the husky remains left after they fall, detracting much from the rich emerald-green the tree previously possessed; it is, however, a tree of fast growth. Near to the largest example of P. insignis a belt of common Scotch and Spruce Firs was planted at the same time for protection to the Pinetum, but none of them approach by long odds the size of P. insignis. I may farther add, that amongst some of the latter species that were planted in 1855, one that I incidentally measured is 40 feet high, healthy and vigorous, and, like all the other Pines we have, excepting P. ponderosa, clothed to the ground with foliage.

Pinus austriaca.—A deserving species, more upright-growing than P. insignis, and when young more densely clothed with foliage than P. ponderosa, or macrocarpa, but as it gets older, its lower limbs, like those of the two kinds mentioned, get thinner of leaves. In outline, however, it is a fine tree, and in colour next to insignis. It grows fast, outstripping some Scotch Firs in the same plantation; but I should doubt if its timber is as good. It appears to like a dry stony soil, stands the wind better than the Spruce tribe, and in many respects is deserving of more extensive planting, being certainly one of the hardiest of the long-leaved class. Our best tree is upwards of 50 feet high.

Picea Webbiana.—The beautiful colour of the cones of this species seems to be its principal merit, for it is seldom that a healthy, vigorous specimen is met with. Amongst several we had here, planted at the time alluded to, viz., 1844, only one has attained the height of 36 feet, and is moderately healthy, with a spread of branches of 25 feet. Its great fault is that it commences growth so early in the season that its tips get destroyed by our spring frosts; hence, rival leaders are formed, and distorted branches, to be repeated, perhaps, the next year; otherwise its broad fine foliage, of a rich green above and fine silvery whiteness below, would render it a great favourite. As it is, it can only be recommended for particular situations, P. Nordmanniana being its superior in many respects, especially so in point of hardiness.

Picea nobilis.—Much as this has been praised, I do not think too much has been said in its favour, for its thickly set foliage, of a rich sea-green colour, gives it a character quite its own, so that in most places it is a favourite. Unfortunately, the best one we have at Linton, after being planted some five or six years, accidentally lost its leader, and remained seven or eight years without one, when it formed two, one of which being removed, the other has rushed up very rapidly, and as straight as a gun-barrel, and is uniformly, but not thickly, furnished with branches, forming a fine tapering cone, very handsome and effective. It is now 38 feet high, and might probably have been 15 more but for the mishap in its early days. Like most of the Piceas, young trees of it do not start very quickly into growth, so that patience ought to be exercised in the case of their remaining a year or two in a round stumpy form. All the Silver Fir tribe, more or less, seem to do this.

Picea cephalonica.—A sturdy species, much inclined to spread its branches, and liable to form several leaders. It seems, however, to be very hardy, and its timber may also be good. In outline it is more irregular than any other Picea I know, but its branches are thickly set with foliage of the darkest green, and these being much longer and more pointed than those of P. Pinsapo, it may be easily distinguished from that species, with which it has been sometimes compared; it contrasts strongly with P. nobilis, and, in fact, with most others. In a collection it well deserves a place, combining as it does a sort of a feathery outline with a dense foliage. The tree from whence the cones were taken is 46 feet high, and nearly 36 feet in the spread of the branches.

Cryptomeria japonica.—A fine tree of this was broken by the wind in 1867, and had to be removed, the tree at the time it was broken being 36 feet high, as upright as it was possible to wish, and clothed to the ground, forming a beautiful cone, slender and tapering, the diameter of its branches at the bottom being not more than 12 feet. As will be seen by the section, which has been lying outdoors since 1867, it has begun to form heart timber, so that there is reason to believe it may be a useful tree in this respect. Its great drawback is the liability it has to turn a sort of sickly brown in some cases; but it is not to this much at Linton. It is, however, too prone to produce fruit, which checks its growth, otherwise it is a fine-looking tree when well grown. C. Lobbii seems to be only a variety of this, if it be not identical with it. I have not been able to detect any difference, the compressed more robust habit of the last-named being more ideal than real; and I believe situation and other circumstances have much to do in preparing the plant to stand our winters.

Cryptomeria elegans.—If the two above-named be identical, there can be no question about this one being distinct, and a great acquisition to the Pinetum, as the rich brown hue it assumes in autumn increases its beauty rather than otherwise, especially when (as is often the case) it is associated with other trees, as the reddish-brown tint comes on long before cold weather sets in, and here at least it has stood several winters without the least injury, and fully exposed. This is the first season it has fruited here; but as none of our plants much exceed 10 feet in height, there is plenty of time yet. It also seems to withstand the winter pretty well, and is in many respects a desirable plant.

Cupressus Vervaeneana.—A graceful, pretty-looking addition to this comprehensive genus, but the plants are yet too small to offer an opinion upon it.

Cupressus Lambertiana.—If it were not for one great drawback, this would be a more desirable species, but the liability it has to be torn up by high winds is sadly against it. The largest one we have at Linton has attained the height of 38 feet, although only planted in 1854, being then not more than a foot high—the best size to plant this tree, as I believe the best safeguard it has against high winds is a good tap-root, to the formation of which the soil here is favourable. The winter of 1860-61 did not in the least affect it, but that of 1866-67 browned it, the tree not showing it until April or later. The past winter has not taken any effect whatever. Its heavy massive foliage, of the darkest shade of green, entitles it to a place in every collection. In outline it is more of a bulbous cone than a pyramidal one, as its greatest diameter of branches is at some distance from the ground, the one here being 23 feet across at 5 feet up. I fear, however, it must be admitted that this tree is more handsome in a young than in an old state, specimens of 20 feet high or thereabouts looking better than when double that size; the foliage gets thinner, and the presence of fruit is no improvement to its appearance.

Cupressus macrocarpa.—A synonym of the last. I cannot perceive any difference. Both transplant badly.

Cupressus funebris.—The flourish of trumpets with which this was ushered in was speedily hushed; for, instead of a handsome graceful tree, it was found to form a kind of unwieldy bush, never likely to exceed 20 feet in height, and, in addition, hard winters cut it up in exposed places.

Cupressus Lawsoniana.—I expect to be found fault with when I say that this has been over-praised, for beautiful as some trees or parts of others may be, there are comparatively few that do not show a defect somewhere—a nakedness of branches in some place or other; out of upwards of 200 trees we have here, there are not many but are faulty in that respect. Another evil is, that they seem so persistently covered with fruit that I fear they will never attain anything like the proportions they are expected to do. Neither will they endure the wind so well as the two Thujas, Lobbii and borealis; but the foliage is handsome, and the tree generally admired. We have no large trees of this species, 15 or 16 feet being the highest, and these do

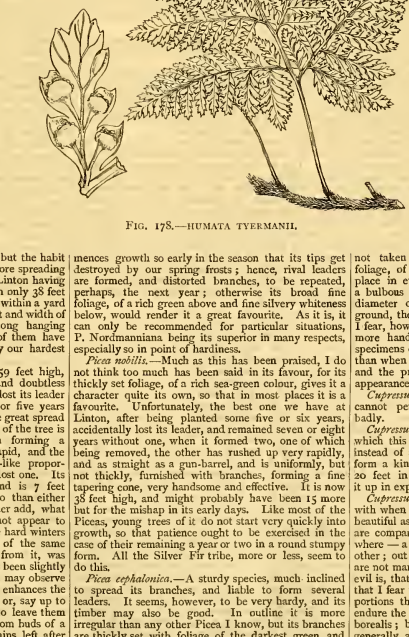

FIG. 178.—HUMATA TYERMANII.

not improve by age. The tree however appears to be quite hardy.

Cupressus Knightiana.—This differs widely from the last, but it is not so hardy. It is, however, a fast grower, but, like the Italian Cypress and some others, is addicted to forming a multitude of leaders; and, while deserving a place in a large collection, it may be omitted in a small one. Quickness of growth is its principal merit. A small tree, planted here in 1865, is now 18 feet high and 7 feet through the branches; but it is no easy matter to keep the number of its leaders down—for not only two or three strive for the honours, but a host of them.

Cupressus Corneyana.—This seems to differ much from the others named, its branches, or rather branchlets, being pendulous rather than upright, while it seems to confine itself to one stem generally. In a collection it forms a distinct feature, and is well worth growing. Its average yearly growth exceeds 2 feet, and its outline is good.

Abies Morinda (*Smithiana*).—A fine pyramidally-formed tree, upwards of 45 feet high, and feathered to the ground, as are all the specimens of this tree, which is more symmetrical in this respect than even the common Spruce. It grows also quite as fast, and promises to retain a good appearance longer than that species, for with us Spruce Firs look shabby at 30 years old. It is also widely distinct from that Fir, its foliage being more copious, and the contrast between the new shoots and the old wood very pretty in early summer.

Abies Menziesii.—A silvery form of the Spruce with the outline of Morinda, but differing from both, as will be seen by the cones; nevertheless, I am far from certain whether this is the true A. Menziesii, as I have seen another one of different character under that name; but I believe it to be correct. The tree is 29 feet high, and 16 feet in diameter of branches.

Abies canadensis (Hemlock Spruce).—This is only introduced to add variety to the collection. The tree is not so much patronised as it deserves to be, growing as it does very well in the shade of other trees, and contrasting well with the Yew in such a position.

Araucaria imbricata.—If this tree could be induced to grow as rapidly as some others do, and to withstand the cold of our late winters, there is no question but it would it be a prince amongst its class, but its hardihood was severely put to the test in 1866-67, and found wanting in so many places that it has not been so popular since. None of our trees suffered at that time, neither before nor since, and the largest ones in the country are those that were not cut down, but having a male plant with flowers on until the present year, the seed did not mature, although the cone, as will be seen by the example of 1869, attained a good size. The tree producing these cones was planted upwards of 40 years ago, and is a fine specimen, being about 40 feet high, and pretty well furnished with branches; some of the lower ones are gone, and some few more show an inclination to follow ere long, but the top of the tree is as healthy and vigorous as can be wished for, the outline being more cylindrical than conical, the top being somewhat flattened, and growth has hardly begun, as will be seen by comparing the young with the old—the latter not so large as some we have had. The tree producing the male cones is much younger and smaller, not more than 20 feet high; these cones are also not half-grown; but I believe, from what I have seen at other places, that the male plant produces flowers at an earlier age than the female, a common occurrence with other things, as was evinced the past spring with a seedling Aucuba, several male plants but no females flowering amongst a batch raised here.

Retinospora pisifera.—The promise which this plant gave of becoming a large tree by its free and tree-like growth, has been marred by its propensity to produce seed-vessels—it being loaded more freely than even Cupressus Lawsoniana, otherwise it is, I think, destined to be a useful tree, its dark green foliage and graceful form entitling it to a place in most collections. As it has not been introduced long into this country there are no large trees of it; the one from which the fruit exhibited was taken is 12 feet high, and about 7 feet through the branches.

Retinospora squarrosa.—Of dwarfer habit than the foregoing, and perhaps more graceful in outline, the colour a bright pea-green. I should expect this tree to be more likely to spread laterally than to get upwards, but in small gardens it may be pronounced a gem.

Retinospora leptoclada.—A slow-growing pyramidal plant, in habit similar to Abies nigricans, or a small stunted Juniper, and well adapted for a position in small geometric gardens, and where it is not likely to outgrow the required size, as the one the accompanying fruit comes from has been planted four or five years, and is now only 4 feet high.

Wellingtonia gigantea.—Much difference of opinion seems to exist as to the merits of this tree. In one respect I may coincide with those who decry it, and that is on the score of its timber not being likely to be of any use; but on the score of beauty, hardihood, and adaptability to all kinds of soil, I have not a word to say against it; on the contrary, much in its favour. There is, however, one point which I am not quite satisfied about, and that is its constitutional vigour. True it grows fast enough, withstands the winds when in an isolated position better than any evergreen tree I know of, and grows quicker than most trees; but the fact of the finest tree we had at Linton dying in 1869, and some other trees I have seen elsewhere showing a sickly condition, implies a doubt whether it is destined to be so long-lived a tree as could be wished. The specimen from which the accompanying section is cut was planted in 1858, being then about 2½ feet high, and the site a favourable one; it made good progress, and towards the middle of the hot summer of 1868, when it ceased growing and showed signs of distress, it was 26 feet high, and the circumference of the bole at the collar was 5 feet 9 inches. Thinking it might be suffering from the extreme drought of the summer, a good watering was given it, but it only lingered on, and died the following year. All the other trees, however, that we have are very healthy, and none of them disposed to form cones but that from which the accompanying sprigs are taken, which is a perfect model of the pyramidal form of tree, 23 feet high, and upwards of 16 feet in diameter of branches. We have larger trees, but not in fruit. One peculiarity of this tree consists in its very shallow rooting, and on that account the ground ought not to be disturbed when it is growing, for although it will succeed pretty well on poor ground, it does better in a more generous soil. It is not the best tree to transplant when it has attained some size, but it is unquestionably the best of all the Pines for making a fresh leader when one has got knocked or destroyed. It is well adapted for an avenue, but I would not recommend its being planted as a memorial tree until its constitutional capacity has been more tried, though as a symmetrical tree, in an open situation when the soil is good, it has few equals, and certainly no superiors.

Taxodium sempervirens.—In the Wellingtonia I would regard this as the most important addition made to our Pinetums during the last quarter of a century, as it promises to be something more than a mere shrub; in fact, it bids fair to eclipse the mammoth tree of the far West in rapidity of growth, upwards especially. It is distinct from the latter in its long, trailing, like a fishing-rod, and its slender graceful growth is still further enhanced by the bright green Fern-like spray with which it is clothed, not standing vertically, like so many of the Arbor-vitæ class, but horizontally, curving over very gracefully, being also of a lighter shade of green, so that I imagine the tree must be a general favourite. It is also very hardy, as our severest winters do not seem to have taken any effect on it, and, as before observed, it grows very fast; our largest specimen is 31 feet high, its yearly growth averaging 3 feet, and on two occasions since its leader was lengthened 7 feet 8 inches: it has certainly a sheltered position, but other trees fully exposed grow almost as fast. I would recommend it as one in a collection that was limited to six species.

Thuja Menziesii.—I can only look on this as being a synonym of the last, and I believe it is now generally regarded as such.

Thujopsis borealis.—A very deserving species of the tree type, and, although not so fast-growing as the last named, it is quite as hardy, and its extremely dark green hue contrasts well with plants of a lighter colour. The tree the fruit was taken from is 20 feet high, and about 7 feet in diameter of branches.

Taxodium sempervirens. Athough hardy, yet the tips of its leaves in most cases show an injured condition. The peculiar spongy character of its bark, and the branches spare, very much resembles, in fact, a sort of pincushion-like feel. The tree seems strongly inclined to spread out laterally, its lower branches resting on the ground and spreading out some distance, but when surrounded by other trees it gets up; the specimen here being in the open its width is nearly the same as its height, 35 feet each way, and the circumference of the bole at 3 feet from the ground is about 5 feet 11 inches. Where the number of trees are limited to a small quantity I would not recommend this to be one, but in a collection it is indispensable, having features peculiarly its own.

Picea Pinsapo.—This tree, certainly the finest in the collection at Linton, is 40 feet high, and its branches spread above 28 feet, resting on the ground, from whence to the height of 20 feet there is only one place where the bole of the tree can be seen, the branches aside, so densely is it clothed, and so upright and faultless is it, as a pointed cone pyramid. It has only once had cones upon it, a circumstance not to be regretted, as the too early fruiting of such trees denotes an early maturity, and consequently a limited growth. This however, is but a fair one of its rival native ones. The short stout leaves, thickly set all around the shoots, instead of only on two sides of them, gives it a distinctive character, added to which its dense green hue and symmetrical form are all that can be desired. A small sprig of it is in the collection, having the cone without fruit.

In a paper of this kind it would be wrong to conclude without saying something as to the absence from the collection of some three or four popular members of this family. First of these is the deservingly favourite Douglas Fir, *Abies Douglasii*, which somehow has never done so well at Linton as most other kinds; the cause I attribute to the large quantity of calcareous matter in our soil, as I have seen this species do best where Rhododendrons and such-like plants grew well, which they will not do where the bulk of our Pinuses are. *Picea Nordmanniana* does better, and we have some good-sized trees of it, but none of them have fruited, neither do I wish to see them do so for some years to come, as the tree cannot be improved by being checked in growth by bearing cones. *Picea lasiocarpa* is too young yet, our largest plant not being more than 12 feet high, and growing very fast, with long leaves. I believe this to be identical with P. Lowii, and, perhaps, P. Parsonsii; but several of the species (so-called) of this genus run into each other so gradually that it is likely when they become old the number of names will be much reduced. My purpose, however, is not to go into this question just now, but to apologise for absentees; and the next is *Cedrus Deodara*, of which we have several approaching 50 feet in height, and between 30 and 40 feet in width, but none have yet shown fruit-bearing cones, though male catkins have been produced for many years. Some healthy, vigorous Cedars of Lebanon several years older have never yet shown cones. I attribute this to their vigorous growth, as smaller trees are often met with in a fruitful condition, but the trees in question are exceedingly healthy. I may here remark, what has been already stated elsewhere, that these two varieties, for they can only be regarded truly as such, are gradually blending into one; in other words, the Deodar will become a Lebanon in course of years. Some trees that we have here are difficult to distinguish at any time, while one is a Deodar in summer and Lebanon in winter; another is a compound of the two at all times—one part of each kind, while others retain their Deodar character still, and may do so for a few years longer than the others. If I were asked which of them I gave the preference to, I would not hesitate a moment giving it to the Lebanon. The fine old specimens to be met with in different places give a dignity to all around them, and a fine old Cedar of Lebanon and an equally noble Scotch Fir will not be easily excelled amongst the host of new trees of recent introduction. Both have been tried and proved good, and I am not sure but the Lebanon will do the best service in most places in the south of England, and perhaps the other in the far North.

Pinus ponderosa is also amongst the important trees of which there are no cones. This is, in my opinion, the best of all the long-leaved class, its tufts of foliage resembling a shaving brush; a mad brush; it bids fair also to become a useful timber tree. The one we have at Linton is 50 feet high, with an expanded top, something like the Scotch Fir when settling into the condition of an aged tree. It has never yet borne fruit, but is a tree much admired; as is also *Pinus Cembra*, an upright, cylindrical-shaped tree, of moderate diameter, but very beautiful, owing to its silvery foliage. This is also nearly 50 feet high, and has never shown symptoms of fruiting. Neither have I noticed any on *Libocedrus chilensis*, which, by-the-by, suffered with us in the winter of 1868-69, having lost many of some 12 feet high shows no signs of fruit of any kind.

Amongst those of which I cannot give a favourable report is *Araucaria brasiliensis*, which, although surviving some twenty-six winters out-of-doors, is not by any means happy in its position there, although it is one of the best we have. The first in point as outdoor tree, *Abies Pinsapo*, has struggled on and attained the height of 31 feet; its only merit is in showing its capability of living outside. As to thriving, it has no pretensions thereto; at all events, it does not thrive well. One or two Mexican Pines are also in much the same condition, the severe cold winters of 1867-68 suffering more than the Araucaria does on these visitations.

In fact, I am not sure but the want of success in the Araucaria arises from the soil not suiting it, for a severe winter makes no more change in it than a mild one.

In conclusion, I may be allowed to apologise for the imperfect growth of many of the cones exhibited, the fact being that it is a month too soon for them. Some of them, as Picea nobilis, Webbiana, and cephalonica, have not attained half their proper size; and as they had to be cut on June 21, some may doubtless be shriveling up ere the exhibition is over; whereas at a later period their appearance is better, and it is needless to say they keep better. This will be readily understood by all who take any interest in such matters, and to such the collection is more especially dedicated, and not to ordinary sightseers. *John Robson, Linton Park, Maidstone.*

BOTANY FOR BEGINNERS.—XI.

In selecting our illustrations we have been guided, first, by the desire to call the student's attention to such plants as may be in bloom at the time the articles are published, and to such as are readily accessible to all within reach of a garden or a field; and, in the next place, to select those which afford the best illustrations of the leading principles of floral construction.

For these reasons we began in spring with *incomplete* flowers of the simplest construction, such as those of the Willow, Elm, Poplar, and Ash; and from these we proceeded to flowers of gradually increasing complexity, such as those of the Tulip, Hyacinth, Apple, Rose, &c., pointing attention in each case to the particular circumstances which produced the modification or complexity of structure. We began thus with flowers of the simplest construction, proceeded to those, such as the Poplar, in which a slight degree of modification was produced by the mere *addition* of parts, till we came to the Tulip, in which the flower

is said to be *complete*, because it possesses all the constituent parts which a perfect flower should have, viz., a *perianth* of two rows, the outer one called *calyx*, the inner one called a *corolla*; then the stamens, surrounding the central pistil. Our next step was to show how the parts of the flower were modified by what is termed *cohesion*, which is, as previously explained, more generally want of separation than absolute union of previously separate parts. *Adhesion*, or union of dissimilar organs, was exemplified in the case of the Apple, p. 581; *irregular growth* by the stamens of the Wallflower, p. 645; or the petals of the Laburnum; *suppression* of parts was exemplified in the case of the pistil of the Laburnum, p. 676, and the flowers of the Willow or Ash, p. 480, destitute as these latter are of perianth. *Multiplication* of parts was illustrated by the Rose, and also the *substitution* of one part for another—of petals, for instance, for stamens, as in so many double flowers, while the St. John's Wort, p. 805, yielded an illustration of *compound stamens*. Incidentally in every case we have alluded to any salient features that the plant presented; but our special object was to show the student how flowers are constructed, and to induce him to ascertain for himself what are the leading structural peculiarities in any particular flower he may happen to gather. Of course when we use the words complete or incomplete, perfect or imperfect, we do so for convenience of arrangement only. So far as the plant itself is concerned, the simplest and least complex flower is as complete as one of greater complexity. What it has pleased the Creator to make is assuredly complete for the purposes for which it is designed. A complex symmetrical flower, then, in a botanist's sense, is very often merely an artificial device constructed by the botanist for his own convenience as a standard of reference. Nevertheless, very many flowers do really conform almost precisely to the standard in their infantile condition, though, as they emerge from babyhood they become altered in some one or more of the ways we have above alluded to. Again, some few flowers do throughout their whole life maintain their original *symmetry*. As this word symmetry is used in different senses, it may be well, before proceeding further, to state that the symmetry we here mention is the due proportion of the parts of a flower one to the other, thus we have a *symmetry of form and size* in which all the parts of the same kind, all the sepals of the calyx, all the petals of the corolla, and so on, are alike in shape and dimensions; a *symmetry of number*, according to which all the parts are in certain multiples, as five sepals, five petals, five stamens, or some multiple of those numbers, as five petals, ten (twice five) stamens, and so forth; a *symmetry* of arrangement, according to which all the several parts are separate one from the other, and disposed in their proper order. In our previous articles we have given several illustrations, showing how this symmetry of form, number and arrangement may be interfered with in various cases, and it may now be well to put before the student a flower in which the symmetry of form and number is perfect, or nearly so, but which presents some deviation from the symmetry of arrangement. Such a flower is offered to us by the common Stonecrop, *Sedum acre* (fig. 179). The branches of this hardy little perennial are round or cylindrical, throwing out here and there fine thread-like roots, and bearing a number of closely set *alternate sessile* leaves. Funny things, too, these leaves are to look at—little fat conical masses of spongy tissue filled with watery sap. In truth the Stonecrops belong to what the French call *plantes grasses*, fat plants. Our term succulent, though longer, is much more correct, for the tissues are filled with watery sap not with fat. These leaves are covered with a thick rind, or skin, which does not allow the juice to evaporate very readily from the surface, and so we find these succulent plants can grow and thrive in hot dry situations, where plants with a more scanty provision of watery sap in their storerooms, or with a thinner rind, would perish from drought. Our particular Stonecrop is obliging enough to live in almost any situation, but, when truly wild, it will be found on dry walls or rocks where little else will grow. The student must not imagine that all succulent plants are Sedums, or even near relatives of Sedum. Cactuses, Spurgeworts, indeed a very large number of the family groups into which plants are divided, have some succulent representatives, which keep up the honour of the family name in quarters where the ordinary representatives could not do so—another hint, this, not to trust to external similarity only. Not to be too discursive, we come back to the leaves of our Stonecrop. Notice on the branches which have no flowers how crowded they are, and then look at a branch which is bearing flowers, and see how the leaves are scattered at short distances one from the other. In fact, the stem between each leaf and its neighbour has perceptibly lengthened. Moreover, if the leaves be looked at attentively they will be seen to be arranged *spirally* round the stem.

The student should take any leaf near the base of a branch, and mark it in some way, then cast his eye carefully up the branch till he finds a leaf higher up, and which stands immediately above the leaf first marked. It will now be seen, by tracing the leaves one after the other, from the marked one below to that which is immediately above it, that the leaves are arranged in a spiral coil. Now, this spiral arrangement of parts is extremely common in plants, and when the eye is once accustomed to look for it, few things are more readily discerned. A Fir cone will show this arrangement at a glance. In all plants where the leaves or other parts are *alternate* (p. 480), this spiral arrangement necessarily occurs. If the observer is of a geometrical turn of mind, he will find the study of these spirals will open up to him a new and most interesting object of research; but the subject is

FIG. 179.—SEDUM ACRE (STONECROP).

one too complex for the majority of beginners, and hence we shall not pursue it further. The inflorescence of the Stonecrop is definite, as in the St. John's Wort (p. 805). Coming now to the flower, we find it in some respects a model of symmetry; the parts are symmetrical in number, form, and, with some exceptions, in position. We have already sufficiently explained the alternate, the spiral, and the opposite arrangement of leaves and other organs. This Stonecrop flower gives us an opportunity of saying

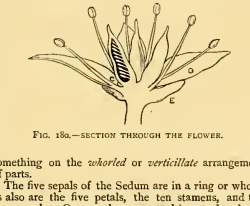

FIG. 180.—SECTION THROUGH THE FLOWER.

something on the *whorled* or *verticillate* arrangement of parts.

The five sepals of the Sedum are in a ring or whorl, as also are the five petals, the ten stamens, and the five carpels. One sepal or one petal is not placed at a different level from the rest, but all come off at the same level. In the case of *opposite leaves* already referred to, p. 480, there are but two leaves in the whorl or ring; here in the Stonecrop there are five sepals in a whorl, and so on. In this plant,

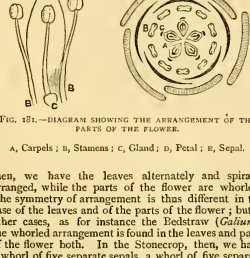

FIG. 181.—DIAGRAM SHOWING THE ARRANGEMENT OF THE PARTS OF THE FLOWER.

A, Carpels; B, Stamens; C, Gland; D, Petal; E, Sepal.

then, we have the leaves alternately and spirally arranged, while the parts of the flower are whorled. The symmetry of arrangement is thus different in the case of the leaves and of the parts of the flower; but in other cases, as for instance the Bedstraw (*Galium*), the whorled arrangement is found in the leaves and parts of the flower both. In the Stonecrop, then, we have a whorl of five separate sepals, a whorl of five separate petals, and so on. Now, notice that though there is no alternation between individual sepals or petals, yet if the whole ring of sepals be compared with the whole ring of petals that there is alternation between them, thus one petal comes between two sepals. The petals *alternate*, as it is said, with the sepals. Five stamens alternate (and these are longer than the others,) with the sepals, five other stamens alternate with the petals.

So far the alternation is perfect, but when we come to the carpels we find them, as it were, out of place; they should alternate with the petals, but they do not. In this particular then the *law of alternation*, as it is called, is not followed. The diagrams at fig. 181 will exemplify what we have been saying, but we may perhaps make this matter even simpler by the following scheme, representing arrangement of parts in a flower where all the parts alternate, and wherein S represents the sepals, P the petals, st the stamens, and C the carpels:—

S		S		S		S		S		
	P		P		P		P		P	
st		st		st		st		st		
	st		st		st		st		st	
C		C		C		C		C		

Now in the Stonecrop the arrangement is:—

S		S		S		S		S		
	P		P		P		P		P	
st		st		st		st		st		
	st		st		st		st		st	
C		C		C		C		C		

The explanation of this peculiarity, as also of certain little glands, c, fig. 181, which also deviate from the proper alternate position, is a problem for the advanced botanist to solve rather than the beginner, and hence we confine ourselves now to the mere mention of the fact.

DOUBLE HYACINTHS.

AT p. 384 I find some remarks upon the question of classifying some double Hyacinths, like Koh-i-noor, so as to separate them from *bonâ fide* double varieties, like the Lord Wellington (rose). I do not think that the term "double" is a good one to apply to such varieties as Lord Wellington, although it has been the custom for many years to call every Hyacinth which is not single, "double." It would, I think, be better to follow the example of the growers of the last century, and make a more correct distinction. In the "Treatise on the Hyacinth," by George Voorhelm, London, 1753, they are divided into classes called "single," "double," and "full," and this I consider to be the best system of classification, the terms indicating clearly the quality of the flower. Intermediate forms could be indicated as "half or semi-double," or "half or semi-full." I have already adopted these terms for years in my nursery lists.

As regards the time when double Hyacinths were first cultivated (see p. 451), I may say that I think it probable that some double varieties were obtained from seed, and grown very soon after the introduction of the Hyacinth into Europe. It is also, I think, quite certain that Peter Voorhelm (Voerhelm or Footlem), was not the first grower of them. The Marquis de St. Simon, in his work on Hyacinths (1786), states that Peter Voorhelm for some time neglected the cultivation of double sorts, and gave preference to the single, double flowers being considered as monsters unworthy of attention. These remarks can be depended upon, as St. Simon seems to have been well acquainted with George Voorhelm (grandson of Peter), the writer of the above-named treatise, at least there is in St. Simon's book a list of the Hyacinths planted in George Voorhelm's parade-bed. It is strange, however, to read in St. Simon that before the time of Peter Voorhelm there was neither cultivated nor estimated any double Hyacinth, and also that in "Swertius' Florilegium," printed at Arnheim, 1620, no double Hyacinth is figured. I have never seen this Arnheim edition of the "Florilegium," but I have before me several Amsterdam and Frankfort editions, of which the first is dated 1612, and in all of them is figured a double Hyacinth at pl. 12, described as a violet-blue and a poor thing, however, with only eight bells, but well double. Other works of that time give also figures of double Hyacinths.

In the famous "Hortus Eystettensis," of Besler (1613) there are figured three double sorts, viz., Flore cœruleo-pleno with three full bells, and candidissima flore-pleno with one very full bell at the top of the stem (ord. ii. pl. 14); both engravings are apparently taken from young plants, so that the same sorts may have produced more bells later. These two varieties seem to be described here for the first time. In the following plate (ord. ii. pl. 15) is figured Hyac. orient. flore duplici, a strongly grown bulb, with 15 true double blue flowers. This variety was then mentioned before by Clusius in "Curis Posterioribus," fol. 18 (1611). In the "Hortus Floredus" of Passæus (1614), on plate 11 of the first book containing spring flowers, is figured a Hyacinth noted as double, but nothing double is to be found in the bells, though in one instance two bells are grown partly together; and in consequence of this the epithet double may have been given to the flower. The description given of this flower in the English edition of the said work is as follows:—

"But this double oriëtall Iacinth has at his first cominge greene flowers wch afterwards appeare somewhat blewish, and being full blowne, are whyte yet somewhat greenish,

yet those stripes or veines that go through the leaves are very greene."

Popular writers of that time speak of double Hyacinths as being most esteemed by amateurs, and even preferred to singles; at least Petrus Hondius, in his treatise on gardening, &c., called "Moufeschans" (1620), and written in Dutch verses, gives them more praise than all the others. In "Laurenberg's Apparatus Plantarius" (1631), three varieties of double Hyacinths are mentioned; but in the catalogue of the Leiden garden, edited by P. Hermann (1687), seven different double full Hyacinths are described. These facts prove sufficiently that double Hyacinths were cultivated long before Peter Voorhelm, a fact to which Charles Morren, in his *historique essai* on bulbs (1842), has already drawn attention. It seems that in the middle of the 17th century bulb amateurs gave their attention by preference to the Tulip, and that it was a century later before the Hyacinth became the preferred florists' flower. A curious Dutch book at that time ("Flora's Bloem-warande in Holland") (1734), appeared in consequence of this, and for the same season the pamphlet on the Tulipomania ("Flora's Samenspraken") were printed again.

At that time double Hyacinths were grown by preference, and it may be that Peter Voorhelm was the person who brought them again into fashion after their culture had been neglected, and the singles had for some time been the most popular. The figures given at this time, for example those in "Buc'hoz Jardin d'Eden" (1781), represent double Hyacinths, chiefly of the late sorts, with very full bells. George Voorhelm, in his treatise above-named (1753), gives a list of 244 double and 107 single best sorts, and among the doubles the following are noted as surpassing all others: Full Hyacinths with white grounds:—Chandelier o' the Church, Comptroller-General, Etat-Général, Flos Solis, Gloria Florum alba, Gloria Florum suprema, Illustrious Beauty, Miroir, Mount Etna, Mount Vesuvius (extra), Spinitus.

Full Hyacinths with blue grounds:—Aspasie Panachée, Baillif d'Amstelland, Bouquet de Fleurs, Directeur-Général, Duke of Courland, Duke de Kenmerland, Flora Perfecta, François Premier, Globe Terrestre, Gloria Florum (blue), Gloria Mundi (blue), extra; Illustrious of Holland, La Belle Impératrice, La Plus Belle du Monde, L'Impératrice, Aspasie, Louis Quinze Triomphant, Merveille du Monde, Paix Douce, Passe non Plus Ultra (blue), Passe all, Rien ne me surpasse, Sanspareil Panaché, Trésorier-Général.

Full Hyacinths, with red grounds:—Coralin, Crown of Roses, Gloria Mundi rubra, Gloria Rubrorum, La Princesse Impériale, L'Assemblage des Beautés, Monarch of the World, Mount Hecla, Pontife Romain, Reviseur-Général, Riche Paix, Rose d'Hollande, Rose du Roi, Roy de Parade, Rose Sacrée, Soldat d'Or.

A few of these sorts are at present found in some collections.

In this list is also noted a Roi de la Grande Bretagne among the full Hyacinths with white grounds, but not marked with an asterisk. St. Simon, however, considers this Hyacinth to be the oldest in cultivation (it may be of the second period of double Hyacinth growing), and supposes it to have been obtained in 1668. This variety was originally preferred above many others, and sold at a high price, much surpassing 1000 guilders. This bulb, when learned very large, grows much better in warm countries than at Haarlem; it grows equally well in pots and in glasses, but perishes in cold and wet grounds.

There is still to be found in some Dutch collections of the present time a sort of the name of King of Great Britain, a late flowering variety of no merit, which answers to the description of the old renovated sort, and which may be the same. At the end of the former century double Hyacinths were much preferred to single ones in England. The treatise on Hyacinths in the "Florist's Directory," by James Maddock, begins in these terms:—

"Double Hyacinths, which are much more beautiful and estimable than those which produce single flowers, are, like the latter, known by the general distinction of reds, whites, and blues, with a few kinds of yellow, more recently obtained from seed. In many instances double Hyacinths have a peculiar advantage of a beautiful contrast of colour in the eye or centre of their bells, which the single sorts cannot possess."

We may conclude, from these remarks, that the cultivation of double Hyacinths was at that time of the introduction of this plant an object of great interest to florists. In later times (before 1700), the preference was given to singles; then, again, doubles had the preference, till, perhaps 20 years or longer after, singles again became the favourites. The reasons for these changes must be sought for in the fine novelties introduced in different periods in the double and single class, in the way of showing them, sometimes in show beds in the open ground, at another time forced in pots, and by the different system of bedding-out practised at different times, in the more or less scientific direction of horticulture, and perhaps in other circumstances. *J. H. Krelage, Haarlem, Holland.* [It is doubtless the closeness and the symmetry of the spike which has led to the modern preference for single Hyacinths as compared with double ones, which latter, however, like most double flowers, continue longer in bloom. EDS.]

Home Correspondence.

Orchid Cultivation.—I think if your correspondent "Scrutator" will read my letters again, and then his own, he will find that he is not justified in the construction he has put upon them. I did not arrogate to myself the right to advance my opinion unsupported by experience, nor did I deny him the privilege of quoting instances of success because they were not his own. There was no ambiguity about what I said, and as I repeated it a second time, there should be no excuse for perverting the sense. If you have no case abuse the plaintiff or his attorney, is an old law maxim. I am also just a little afraid that your correspondent "Ex-Cantab" is making the defence of cool treatment too personal a matter. I can assure ourselves that there are a few lookers-on, who read our letters, and that they enjoy a smart hit now and then; so far so good, I have no objection, but we should not forget that argument requires examples to the point, to convince. I have read with great interest the account of the Odontoglossum house at Fernichurst, and note that "F. W. B.," who furnishes the report, says, that the winter temperature of this house is a minimum of 40° and a maximum of 50°, or a mean of 45°. Now this is the first time that I recollect having read such a statement, and it was to bring out such an one, if anyone ever saw it, that induced me to write at p. 310: "I have never tried growing them for any length of time, say 3 or 4 months, at a temperature of 40° to 45° for a minimum; nor has any one else, in my opinion, without seriously injuring his plants." Mr. James Anderson, at p. 171, only gave us the mean of his minima as 49°.19, and "Scrutator," in his letter at p. 274, only says that the house at Fernichurst would average a minimum of temperature of from 40° to 45° during the late severe weather. I, therefore, thought I had a right to take exception to such statements being considered as proving anything, and pointed this out in my letter at p. 310. The words I used were—"We have not before us, that I am aware of, either Mr. Anderson's practice, or that followed at Fernichurst; under these circumstances nothing can be said." I am glad that Mr. Purdie has been so kind; such has not been my practice, nor that a greater heat suits O. Alexandræ was shown by one bulb furnishing 28 full-sized flowers; "F. W. B." also adds O. citrosmum as wanting a warm corner. Am I right in concluding that a gardener of even Mr. Cullingford's experience, would not allow the temperature down to 42°, without its being sheeted up?—the term used is "covered up for the night." If this surmise is correct, it is a very important element, and it should not be passed lightly over; the lower the heat the less moisture the atmosphere retain, and the greater is the danger of frost by radiation. I am glad that Purdie's experience of 40° under radiation, but it was at 10,000 feet of elevation; and as Odontoglossums do not come from that elevation, our gardeners may congratulate themselves they are not required to attend to their sashes with their teeth chattering, as I once experienced; and, as they neither came from 8000 feet, need they fear a maximum, that will burst a thermometer in a man's pocket, because it will only register 130°: see also Mr. Purdie's letters, as confirmed by M. van Volxem, at p. 584. I was much pleased to see this explanation, as it is the only one that reconciles to me the sun at high elevations in the tropics, for I mentioned Mr. Purdie's experience rather in fear, yet hoping he was right,—for the disbelief I had expressed, that Odontoglossums came from such elevations, proved dependent on his veracity. "Ex-Cantab" need not fear that I shall advise any one to follow Nature in the matter of temperatures, even in countries where such extremes are unheard of. Since writing the above I have read Mr. Anderson's letter in your journal (at p. 741), and am glad that he is about to join in the discussion; the only point he makes has certainly a chance of being heard, and as I am to be in such a minority, I must ask them to be careful that they do not make me say what I did not. "Ex-Cantab" says, I recommend a mean winter temperature of 45°. Mr. Anderson repeats it; once or twice more, and it will be considered proved. I have been very careful in advising any treatment. I have given my own practice, that I might create discussion, but I have not given a mean of 70° in winter as even my own practice, that I am aware of. Odontoglossums begins like a lawyer summing up; I am obliged for the flattering way in which he says I can write upon subjects that are not his own particular pet subjects, but he must for the present allow me to think that his advice to your readers, and such as seek instruction from your pages, is a little premature. He may be right "that I totally misunderstood the climate necessary for the cultivation of Odontoglossums," and that during the trip he speaks of he may have mastered the subject; but I hope he will be willing to give us the proof, and then I shall have some little consolation for the humble pie I must eat, in the information I have obtained. Perhaps in this I may be wrong, and it may already have appeared in your pages. As I am to have so many against me, I must mark my points, and claim what credit is due to me. Will Mr. Anderson tell me where he learned that 6500 feet is the elevation from which these plants come? Mr. B. S. Williams, in his 4th edition, p. 213, says O. Alexandræ grows at an elevation of 7000 to 8000 feet in Bogota. "Ex-Cantab" says that he advises, at p. 712 of the 3d edition, a winter temperature 45° to 50°, and in summer 50° to 60°. "F. W. B." says that the Fernichurst house has a winter temperature of 40° to 50°, in summer the natural temperature; and then quotes Mr. Warner's practice at Broadfield—a minimum of 40° in winter, and in summer as much natural heat as the summer affords. These winter temperatures will agree with Mr. Williams; but what about the summer's? Perhaps he is as far out there as he is in his altitude. "Ex-Cantab" says he thinks a minimum of 45° in winter, and a maximum of 85° in summer is cool treatment—these natural summer temperatures mean 85° at least; thus, I only differ from them in my winter temperature. I have written for Isaac F. Hutton's book, M. Jean van Volxem mentions in his letter, and will return to this subject of temperatures when it comes; but I am still of the opinion that it is a simple question of resting, and the advantage a long rest has upon an evergreen pseudobulb. I some time since referred to the three types of tropical growth embraced in Mr. Fortune's lecture, and I should put all evergreen Orchids as classing with the Mangosteen type. I at once repudiate the charge of killing an Orchid by my practice, and if Mr. Anderson says that he writes such things in "justice to your readers," I am sure that those are the last readers of them who will tell him that if he wants to retain any influence over them, he must not seek to procure such a result by false inferences. This is strong language, so I will give the quotation of which I complain:—"In reply to the first question: 'Did he find any Odontoglossum to flower?' no, of course not by "G. H.?" I did, in one or two places, but the plants, instead of being cultivated, as I understand the meaning of the word, seemed in a bad plight. A continuance in the hot, dry atmosphere in which they were confined would certainly kill them." I am one of your readers, and I hope I shall be what I read in your journal. Will Mr. Anderson, in justice to me, say where I advised "a hot, dry temperature?" My own impression is, that the point above all others that has occupied my attention is, that when we have exhausted the natural disposal, we still cannot give moisture enough. I refer you to p. 417, where, at the end of my letter, I say: "Orchids come from the wettest parts of the earth alone, and supplying them with this moisture must always be our greatest difficulty. It is a point that has occupied much more of my attention than that of high or low temperature or less." I am as willing as "Ex-Cantab" to keep the discussion to the point, which is, the relative advantages of a little heat more or less during winter, and the effect of a more complete, because longer, state of rest upon the healthy growth of Odontoglossums. *G. H.*

The Weather in Westmoreland.—We have had a most remarkable season in the lake district. Although the crops are looking healthy, and there is a fair average crop of hay, everything else has suffered more or less. Early in the morning (Whit Monday) we had on May 17 heavy rain fell up to 11 P.M., the wind being west. A sudden change then took place, the wind changing to the north; snow fell on the hills, and there was 5° of frost in the valleys. The latter wrought fearful damage upon fruit crops, Apples being completely destroyed. Pears, which were set remarkably, and nearly the size of small Beans, were left with a few scanty fruit, and the north-east winds still prevailing. The grub seems to have finished the few that were left, with the exception of some 36 trees, which I received from Thos. Laxton, Bedford. These trees were removed, to make room for seedling Roses and new Peas, on October 24—their height averaging from 8 to 15 feet, and I mention this to show that large Pear trees can be removed to a distance, and succeed admirably. Severe as the weather was—and it sat of the 20th—some of the other kinds have not been removed—there are at present 22 of the lifted trees, sent here from Stamford, that are carrying excellent crops, and are swelling their fruit in a satisfactory manner. Some of your readers may think that I have dwelt on this too long a subject, but I look upon it as a most important lesson to us gardeners in the northern counties, as to whether it might not add greatly to the securing of a crop of fruit if trees were periodically lifted, so as to retard them in the early spring. Gooseberries are a heavy crop in most of the sheltered gardens in the lake district; for although the frost of May 17 destroyed about one-third, the remainder have swelled so large that there is a bountiful crop; and the same may be said of Currants of all kinds, although they are smaller than usual, on account of the cold nights still prevailing. Strawberries suffered severely, but as there was a large quantity of unexpanded blossoms, there is a fair average crop, the fruit being fine but inferior, on account of the earth being so ungenial. Just a few words about the trees. On May 17 most of the young shoots were cut, and the trees were much browned, and at the present time can be distinctly seen—Cedrus Deodara suffering severely, while a Taxodium sempervirens some 25 feet in height is quite safe; Picea Nordmanniana having the young growth completely killed, and, in fact, in almost every case the young growth suffered the same fate. Bedding plants have

merely kept alive, some of the more tender becoming smaller than when planted out. *James Stewart, Bellsfield House, Windermere.*

The Condition of Peach and Nectarine Trees on the Open Wall.—At p. 836, the Rev. W. F. Radclyffe thus writes:—"I fear the statement made in your leading article is but too true of the above trees. Such as I have seen and heard of are in a miserable condition, some describing their trees as in a moribund state, and others as blistered, and covered with green aphis and spiders." He then proceeds to state that his trees are perfectly healthy, because, forsooth, he short-prunes, and looks after them himself; and adds, "I will not suffer severe winter or spring, red spider or aphis, to blister, curl, or afflict my trees;" all of which I should consider as wholly unworthy of notice, but for the following sentence, which is as devoid of truth as it is mischievous: "This miserable state of the Peach and Nectarine trees out-of-doors, in England, is a disgrace to science, and the result of neglect and gross ignorance." That is, the majority of the gardeners of England are grossly ignorant, and the grand remedy for it propounded by the Rev. W. F. Radclyffe in such brotherly terms is, "Come, review my trees." Under the circumstances my response, and that of hundreds more of sorely tried practicals, is, "(I thank you?)" and my advice to a writer at whose feet I have often sat with pleasure is, "Speak not evil, one of another, brethren." We often hear of the want of courtesy among practical gardeners, but do not believe there is one amongst us who, if his trees in the open had escaped injury this season, could have complacently sat down and claimed the credit of it all, and poured contumely upon his suffering brethren, who had been harder hit by the sharp shafts of the Almighty's frost. However painful to me I must request permission to protest against such statements, as the discouragement and daily bread of hundreds of gardeners are imperilled thereby. The fact is, that science and skill are powerless to save tender trees from the grip of zero, as the merest tyro in horticulture knows too well. Protect them with glass, as recommended in your leader, and the matter is easy. But I boldly assert, that the sorry state of Peaches and Nectarines in the open this year is no proof, either of a lack of science, no, nor of neglect nor ignorance; and on similar matters I claim to be as good an authority as your correspondent. I next proceed to state that the lateness of the roses this season is attributable to the lack of science among gardeners, and that the wet haysel and late harvest result from the neglect and gross ignorance of farmers. Even this would be more reasonable than the broad assertion that the skill and perseverance of any man, can make tender trees endure such hardship as we have experienced this winter, spring, and summer, with impunity. *D. T. Fish, F.R.H.S., July* 3. [We are glad to print this disclaimer, with the substance of which we quite concur. Get a *good* gardener, treat him liberally, and be sure that all that experience can suggest, or intelligence supply, will be done; and then, if failure ensue, it must not be made a reproach to him. EDS.]

Vitality of Seeds of the Shepherd's Purse.—In the autumn of last year I made a new croquet lawn from a meadow adjoining my premises, and turfed it with the turf that was growing there. This consisted of the ordinary herbage of our grass lands, and was very free from weeds. To get the level it was necessary to raise the lower part with earth dug from the same field, a fine mould, several feet in depth. To my surprise, upon the setting in of warm weather, the bank which supports the lawn below, and which was turfed over with a very clean turf, was covered with a crop of Shepherd's Purse as thickly as though it had been purposely sown over it; and the same weed is bursting up through the interstices between the turves laid on the lawn, so far as the same earth was used. There is not a plant of it to be seen on the undisturbed part of the meadow, and I can only account for its appearance by supposing that in former times there was a garden there, and that the seeds lay dormant till brought up to the influence of the air. It has been a meadow to my knowledge for 40 years, and usually fed with sheep. *R. C. A. P., Hulse, near Taunton.*

Laxton's "Alpha" Pea.—Will any of your readers (disinterested ones) who have grown this Pea please to say whether or no their experience of it differs from my own? Sown amidst a lot of other Peas, I find it to be about as early as Daniel O'Rourke, with a pod about equal in length and size. The haulm is thin, bearing about the same relation in respect thereof to Supreme, Premier, Imperial, Wonder, Prince, and others, that hay does to straw. It is also very long jointed, and produces but one pod to a stem. In productiveness I think it to be decidedly inferior to Daniel O'Rourke. My stock of it, the produce of a sealed quart, obtained from Messrs. Carter & Co., is growing where other Peas thrive luxuriantly, so I accept it as a fair trial, and am correspondingly disappointed. Alpha had been specially commended as the best of Laxton's last batch of Peas: if it is so, then I fear indifferent is the best. Comparisons may be odious, but we must occasionally put up with their objectionable character, as they are sometimes necessary; and upon that ground do I contend that, as compared with Dr. Maclean's splendid batch of dwarf Peas, Mr. Laxton's are far from being equal; even Supreme, which is truly a grand show Pea, is neither earlier nor so acceptable at table as the old Champion of England. *A. D.* [This evidence differs from that previously received from other sources. EDS.]

Ornamental Heracleums.—At this season the larger forms of Umbellifers will be coming into blossom, and now, therefore, that their value as decorative plants is more appreciated than formerly, it may be opportune

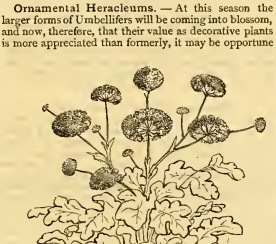

FIG. 182.—HERACLEUM EMINENS.

to introduce figures of two species of Heracleum, for which we have to thank Messrs. Haage & Schmidt, of Erfurt. One of these is Heracleum eminens (fig. 182), the other H. absinthifolium (fig. 184), or as De Candolle calls it, Zozimia absinthifolia. H. eminens, which has

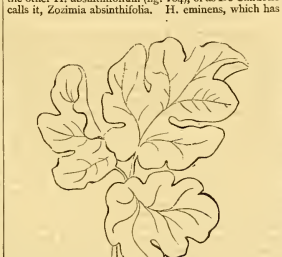

FIG. 183.—LEAF OF HERACLEUM EMINENS.

leaves of gigantic dimensions, is well marked by the blunt rounded lobes of its trifoliolate leaves (fig. 183). These leaves are stouter in texture, and consequently more durable, than those of most of the other cultivated

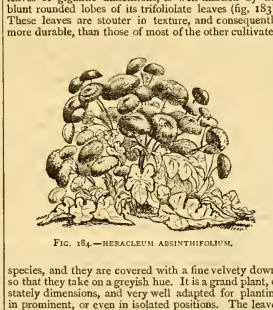

FIG. 184.—HERACLEUM ABSINTHIFOLIUM.

species, and they are covered with a fine velvety down, so that they take on a greyish hue. It is a grand plant, of stately dimensions, and very well adapted for planting in prominent, or even in isolated positions. The leaves keep, it is said, in a fresh and effective condition until the autumn. The stems support fine large umbels of flowers. Altogether, it is a highly ornamental plant. H. absinthifolium, a Caucasian and Iberian species, has much divided leaves, which are clothed with hairs, giving them a hoary appearance; the leaflets are somewhat distant, and the segments wedge-shaped subtrifid. The stems are sulcate, and grow some 2 or 3 feet high, and are almost without hairs; they bear umbels of about 20 rays, surrounded by a many-leaved involucre. As it forms a dense, close mass, a strong plant of this species would be a very picturesque object for the less refined portions of a lawn or pleasure ground. The foregoing plants are of smaller stature than H. giganteum, which latter is a grand plant for wilderness scenery or bold distant rockeries, having, however, the defects of sowing itself rather too freely and of losing its foliage before the end of summer. *M.*

Watson's Lawn Sand.—I can endorse every word of your correspondent, Mr. J. Stewart, respecting the wonderful effects of the above lawn dressing on a new lawn. I used last spring 1 cwt., at the rate of 4 oz. to the square yard, and shall, if all's well, use 10 cwt. another spring, that being considered the best time for putting it on. I used 2 oz. to the square yard, and repeated the same dose a fortnight after. I cannot describe the wonderful improvement it has made on the lawn here, but shall be glad to point out the effect to any of my brother gardeners. *Isaac Dell, Stoke Rochford.*

The Cool Treatment of Orchids.—Would "G. H." kindly inform us, through your columns, if (1) he closes the Odontoglossum house at night? and (2) if he keeps the plants wet, in addition to the damp atmosphere? *X.*

Heating by Circulation of Hot Water.—How easy it is to suggest and make improvements on almost everything that comes under one's notice, when the first principles—the most difficult steps—have been overcome; and it is almost impossible to point out any object which has not been more or less improved since it first came in vogue. Perhaps no appliance has escaped the attention of the mind of improvers more than our hot-water apparatus, particularly for horticultural purposes. If any gardener endowed with a practical mind, who has been engaged where forcing has been extensively carried on, casts a retrospective glance at the firebricks which he has burned almost needlessly into the form of coping so will he be found to be something frightful. As my desire is solely to simplify and extend horticulture, it is a pleasure to me to see the opposition elicited by the discussion of this subject, since this gives fresh life and vigour to the whole matter. How long have been enunciated that burying our heated pipes beneath the floors of our buildings, or placing them close beneath the staging, or directly over the pipes, must be wrong, both in principle and practice. I well remember Mr. Taylor, late of Shrubland Park, and formerly gardener to Mr. Cosier, read a most interesting paper at the Streatham Gardeners' Mutual Instruction Society, nearly 20 years ago, on the unnatural conditions that potted plants are subject to in the winter season, from the heat rising from the pipes, the soil at the bottom of the pots becoming powdery from the excessive and unnatural heat from below the staging; and he attributed a great deal of his success with stove and greenhouse plants at the Regent's Park shows to his placing each pot in a pan of water for so many hours every spring, to remedy this evil. I have also agreed with great interest the long discussion that has been going on now for some years on the "cool" treatment of Orchids. This has been mainly brought about by the hot pipes being placed close beneath them instead of above them, so as to emulate sun-heat. To prove the value of this theory, I fixed a 3-inch pipe just inside the angle where the rafter and top plate meet, so that the pipe is about 2 feet 6 inches above the plants, and about 5 inches from the glass. This I found to effectually prevent damp and drip from the roof; in fact it dried up the injurious moisture in the winter time, instead of creating it; and I was also satisfied, that I have been heating all my pits in the same manner, as follows:—I run the main 3 or 4-inch pipe just inside the end of the pit, a three-quarter hole with a thread is made, and a brass tap is screwed in; from this is led a common gas pipe running parallel with the main in the front of the pit, and about 8 inches from the inside of the lower frame work, and at the further end of the pit, it turns upwards for 3 feet, and then returns a little more than half way up each rafter, and the highest point, or the air pipe, is directly opposite where it first enters. I have one of these inch pipes above 150 feet in length, and all this weight of water has to be lifted, as Mr. Fish will have it, through a 3-inch tap; nevertheless the circulation is the most perfect I have ever met with. The suspending of this barrel pipe by the rafter of a quarter round cast rod, bent from each rafter, and just above the plants and a few inches from the glass, is certainly a vast improvement; it not only excludes the frost, but it effectually prevents damping, which is of vital importance in winters similar to the last. Should any of your correspondents who may doubt this statement only honour me with a visit at Woolwich, I shall expect them to satisfactorily explain how my hot water circulates contrary to their theory. Again, I have an inch pipe standing up 4 feet, with an elbow on the top, from the main supply from the boiler. This pipe is a flow, and supplies two 3-inch pipes 218 feet long, all inclining upwards, the water plunging suddenly into the boiler, to be reheated. The point at which the return leaves the house is considerably higher than the flow, and within a few inches of it. The supply of hot water is through an inch pipe, and it finds its way rapidly through the entire length, and the whole length is almost of the same temperature, and this under the most adverse

circumstances, for the small supply pipe is unquestionably much against the new system, yet the circulation is perfect. On the opposite side I have a house, which is heated on the contrary system; the water rises up about 3 feet in a 3-inch pipe, and then branches into two of equal dimensions, and just where it divides into the two pipes is the highest part in the house, so the water has to travel downwards in these 3-inch pipes round the house, a distance of 170 feet. Now if the cold water has such an effect in forcing the hot water along the lower pipes in the house, and down the bends into the boiler, how is it that I dare not put small plants (without injuring them from the intense heat) near this highest part of the piping; yet on the opposite side, when it is leaving the house, I cannot keep the plants from damping for the want of heat. If the new system is wrong, and this system right, how is it that I get a regular heat in one house and not in the other? Again, I find when my flow-valve is shut, I get no back action up the return pipe, which is very different to what happens in the house heated in the old style. If any of those who advocate the old system of circulation can explain why all these facts should occur with me, and will not do the same elsewhere, I should be exceedingly obliged. By about August 15 next I shall have one of my new boilers ready to drive the piping of six houses separately or altogether (and two of these houses heating on the new system), in all about 1200 feet of piping; and if any of your doubting correspondents will but come and elucidate the above mystery, they shall have the whole apparatus at their disposal, and I shall be only too happy to render any assistance required. *H. Cannell, F.R.H.S., Woolwich.*

Diverting a Watercourse.—I have a stream of water running through my freehold land—which passes through another field or two not mine, and then supplies a mill—have I any right to place a bay across the stream, and put a ram in my field to drive the water from the said bay into a tank erected about 14 feet above the ram, and to have pipes laid on from the tank, to water plants, &c., growing in the same field. There will be a pipe to take away the waste water from the tank when it becomes full, to carry it again in the same stream—before it gets to the mill, and of course before it goes out of my land. Or, if I have no right to lay the brook, have I a right to use the water? *J. K.* [The reply to this question seems to us to depend on local customs and private rights. Perhaps some of our correspondents can furnish a more explicit reply. EDS.]

The Horticultural Dinner at Nottingham.—Your remarks on the want of life and reality were only true of the dinner itself, and not at all applicable to the speeches that followed. There was a little unfortunate grouping at table. While many sat among friends, others found themselves among strangers, and we cannot always be lively in the society of the unknown. A little arrangement by stewards would have grouped the diners better as far as I could see; there was also no attempt at this, and hence a little restraint and dulness here and there. The same thing happens at private dinners, where the hostess fails in pairing and grouping her guests congenially. But this dinner was well arranged, and up to the last moment the number and character of the dinners remained uncertain. The fact is, we dined under difficulties; and it spoke volumes for the wisdom and tact of the chairman that most of those difficulties were conquered at the last moment, and that the Council of the Royal, scientific men, local notabilities, and practical horticulturists, all dined together happily and harmoniously. I trust that from this time the Council will take the dinner into their programme from the first, and constitute it an important part of the meeting. The managers of the Society really hesitate about dining with those who make the show, but once a year, then the Society deserves to perish. And it will. Notwithstanding the complete success achieved at Nottingham, there was imminent danger of a breach being made there between the managers and the working men who might never have dined. Horticulture has a heart as well as a head, and those who ignore that fact must suffer from it. There is also much truth in the saying that the shortest way to an Englishman's heart is through the short cut of his stomach; or, to put it in more elegant words, one of the most binding elements in social life is a good dinner. But with the dinner anything like a lack of life and reality vanished. The chairman was never more eloquent, genial, or wise; and all the speakers, from the Mayor and Council downwards, spoke with energy and force, while the audience endorsed their words with a heartiness and enthusiasm and an unanimity that is seldom seen or heard at public dinners. In one word, everything after dinner was a decided success, and there was no lack of good things at the dinner itself. All that was needed to render it lively and real was a good appetite, a grateful heart, and the belief that every one of the unknown was a brother horticulturist in disguise, and therefore, a jolly good fellow if we could broach him. *A Practical.* [Our correspondent, who we know writes from experience, substantially confirms our brief remarks on this subject. The fact is, no large assembly like this could be comfortably entertained without active stewards, and stewards there were none, so that some dined and others got—what they could. So much for the dinner, which we believe should form part of all future programmes, and we trust will go on improving. But we are sorry to find so practical a writer persisting in holding what we quite believe is a false idea that the Council objects to meet the gardeners, and the equally unpractical notion that the Council should get up the dinner. The members of Council go as strangers to the selected locality, and all arrangements of this kind belong to the local authorities. To disseminate the contrary view has been the work of officious mischief makers. The gardeners' dinner, if properly organised, and under the management of a respectable local committee, would certainly always command the sympathies and support of the Society, both Council and Fellows, as it did on this occasion. EDS.]

The Weather.—Mr. Mechi's old proverb concerning a "dripping June" has been so extensively quoted in newspaper articles, that I fancy the general public has by this time been pretty well brought to believe that "all things are in tune." Perhaps, barring a considerable fall of moist hay, things were fairly in tune up to the end of June; but how will it be if we get a wet July? Here, on the 3d, things don't look prosperous or encouraging, as we have already got this month a continued series of heavy soakings, with strong winds that are far from favourable, and which are unpleasant thoughts of the Potato disease, too much straw, laid crops, and a wet harvest. This is rather a gloomy view of things, I know, but hot dry summers have of late been so much the rule, that a wet cold one can scarcely be conceived. As a companion proverb to Mr. Mechi's I will give another, and an original one, perhaps less pleasing but none the less true, "A wet July makes all things awry." I do not want to prove a prophet of evil, neither shall I be like Jonah and quarrel should my fears not be realised. At present I think the prospect before us is far from bright, but ere this is in print we may have passed the worst. I fervently trust it may be so. *A. D.*

Foreign Correspondence.

ADELAIDE.—The following passages are extracted from the Report of Dr. Schomburgk, the Director of the Adelaide Botanic Garden, 1870:—The Guinea Grass (Panicum gigantenm), introduced last year, and which withstood so bravely the dry weather and no winds last season, has, I am glad to say, also withstood the extraordinary wet and cold winter months. In July, I lifted all the plants and divided them for distribution, the remainder I replanted. As a tropical plant this transplanting should have been done in the month of September, but in spite of it the plants have taken root again and are thriving most luxuriantly. I consider this a good test of its applicability to our climate. I mention again, that I can speak from personal observation of a five years' residence in South America, of the immense luxuriancy in which it grows there; and that I think it luxuriantly here as it does in South America, there would, through the summer months, be an end to all difficulties about green food for cattle. I must also remind all who intend to plant and secure a luxuriant growth of the Guinea Grass, that it must be planted on prepared ground, the plants 20 to 24 inches apart, and the land kept clean from weeds. I would also mention that it will not bear being fed down, nor trampled upon by cattle.

The grasses which I have already recommended in my reports, viz., Buffalo Grass, Lime Grass, Millet Grass, Meadow Fox-tail, Meadow Barley, have again stood well, and the cattle are fond of these grasses. Also the New Zealand grasses received from the Hon. A. Murray have not suffered from the last year's drought, and seem to be adapted for our dry climate. The Bulbs of the Prairie Grass and the Bromus mollis cannot be spoken of highly enough as pasture grasses and for hay.

From Dr. Hooker, Kew Gardens, I received a small packet of seed of Pentzia virgata, a much branched rigid shrub, from 2 to 4 feet high, from the mountains of Cape of Good Hope, of which Dr. Hooker remarks, that this plant is the most valuable sheep fodder for dry climates. I was so fortunate as to raise about twenty plants, which thrive remarkably well, and prove that our climate is well adapted for them. The leaves are somewhat aromatic bitterness, which, I believe as I understand, is very much liked by sheep. I hope to be able to increase this plant for distribution amongst the squatters.

The distribution of about 1700 grafts of the Sultana Grape last season, and the information I received that the greater part grew, leads me to believe that this Grape is now established in the colony. I would again direct the attention of the growers to the fact that the Sultana, like the Zante Currant, is one of the varieties of the Vine which, if short spur-pruned, will yield little or no fruit. The system of long rod-pruning must, therefore, be adopted, and at least eight or ten eyes should be left on every rod.

The encouraging news that the first sample of South Australian Flax, which has been sent home, won golden opinions in the English market, will, I hope, lead to the more extensive growth of this remunerative plant. We have to thank the energetic farmers in the south for laying the basis of this new industry; many years elapsed before an attempt was made, and, considering the unfavourable season the flaxgrowers had to contend with, the result is highly gratifying. I hope, for the well-doing of the colony, other districts will follow the example, as there is no doubt that Flax will grow in most of our districts.

From Lieut.-Colonel A. Crawford, Tasmania, I received last season a little parcel of white linseed, which this gentleman had received from East India. Colonel Crawford says in his letter:—"I am induced to forward it under the impression that it may prove a valuable crop, especially as I never before saw any like it. A very small parcel reached me from India; the gentleman who sent me this seed informed me that the Flax it yielded was exceedingly good both in staple and colour, and that he had taken the first prize for it at the Agricultural Exhibition at Jubulpore." Notwithstanding the advanced season when I received this valuable seed (the commencement of September), it turned out a splendid sample, and I gathered so much seed that I am able to distribute a little amongst flax-growers to test the quality of the plant.

For the introduction of grain into this colony we have to thank His Excellency the Governor. It has done uncommonly well at the garden, and the possibility of growing it is now beyond doubt. Notwithstanding that it was sown very late in the season, it has turned out a very good crop; the grain looked strong and healthy, and the yield is very fair. The successful cultivation of this plant would be a great good, and the attention of the farmers can be very fairly directed towards it. With the exception of Oats and Barley, very little attempt has been made by our farmers to grow other grain for cattle.

The China Grass cloth plant (Bœhmeria nivea) which has become of such mercantile value, has now satisfied me that our climate is not adapted for it, and that it cannot be grown as a payable commercial article. Mr. Hill, Director of the Botanic Garden, Brisbane, remarks in regard to this plant, "The Bœhmeria still continues to thrive exceedingly well, but though many have essayed to prepare it for manufacturing purposes, all have most signally failed. It has been experimented on by those who have spared no pains, and on every occasion with unsuccessful results."

The importance of the introduction of sericulture in South Australia is undeniable. I have advocated it for some years, and I am glad to say not unsuccessfully, as the sericulturists seem to increase.

Through the liberality of the Zoological Society in New South Wales, a stock of silkworm eggs from Japan has been received and divided among our sericulturists. I hope they will succeed in hatching and rearing the worms, and so improving our stock.

The desire which I have so long cherished to see during the summer months, instead of the dreary and death-like appearance of our lawns, changed into a more verdant one, has at length, after many trials with different kinds of grasses from all parts of the world, been realised. As I remarked in my last report, it is only the Couch Grass (Cynodon Dactylon), which will stand the severe heat of the summer months. Encouraged by last year's experiments with this grass, I have planted during the last winter about three acres; and, favoured by the genial wet season, the growth has been remarkably vigorous, and has formed a beautiful green and close lawn—not in such perfection as we used to see at home, but rarely seen in a colony, and giving the garden throughout the summer a most cheering aspect. I mention again, it requires frequent mowing—and it must not be forgotten that its dulness of colour, during the winter months, will be overlooked in the verdant freshness of the surrounding vegetation and brilliant colours of the flower parterres.

There never before was such an active interchange of plants and seeds with kindred institutions in Australia, the surrounding colonies, and Europe, as during the last year. The garden has dispatched 27 Wardian cases containing ferns, greenhouse, and other plants, and several thousands of packets of seeds, to the following Botanic Gardens:—Kew, Dublin, Berlin, St. Petersburg, Hamburg, Java, Natal, Mauritius, New Zealand, Queensland, and Sydney, and to numerous amateurs and nurserymen in Victoria, Melbourne, and Sydney for exchange; and through these means our collection has again been largely enriched by numerous valuable plants, amongst which are many of economical and commercial value.

Several cases, with purchased plants from England and the Continent arrived, I am sorry to say, in a deplorable state—often more than two-thirds of the contents having perished. The value of a newly-imported plant cannot be appreciated highly enough, as the consignments from Europe arrive so seldom in good condition.

Societies.

ROYAL HORTICULTURAL: *July 5.*—James Bateman, Esq., F.R.S., in the chair. Before proceeding with the usual business of the meeting the Chairman, on behalf of the Council, formally received the following gentlemen in their official capacity of delegates to the horticultural section of the International Exhibition of 1871:—M. Karl Koch, delegate from the Imperial Government of Germany; MM. Regel and Volkenstein, delegates from the Imperial Government of Russia; M. v. Heydet, also from Russia; M. Morren, delegate from the Belgian

Government, together with MM. Linden, Gloner, and Professor Perard, from Belgium; M. Antoloe, delegate from Austria; Dr. David Moore, who represented the Royal Dublin Society, and others.

Mr. Wilson, the Chairman of the Fruit Committee, then announced the awards made by that body, at the same time remarking that the new seedling Grape shown by Mr. Douglas was of very high promise, but not being quite ripe it was requested to be shown again; and also that a medal had been awarded by the Council on the recommendation of the committee to Messrs. Veitch and Sons for a collection and introduction of Orchids was not such a remunerative speculation as some people imagined, in consequence of the many plants which were quite dead when they arrived in this country, in proof of which assertion he showed a large bundle which had been received in that state by Mr. Bull.

Scientific Committee.—A. Murray, Esq., in the chair. His forcing-pits and grapes present at the Exhibition took their places at this meeting, having been duly introduced by the Chairman. Mr. G. F. Wilson exhibited leaves of various Lilies affected with spot, analogous to one of the diseases of spot in Orchids. The nature of the disease was not obvious, and no further light was thrown on the subject by the committee.

Mr. Berkeley read the following communication from Dr. Schomburgk, relative to a substance called in South Australia mineral gamboge, but which has no relation to gamboge:—"It is found on the margins of a sandy flat, overgrown only with Lepidosperma concavum, Br., near the River Coorang in South Australia, and is only known in one spot. It is found on bare sand in patches, and is not attached to the Lepidosperma. It encloses pieces of dead vegetable matter, but does not adhere to them, and in spirits or ether, or forms a balsam that easily absorbs water when applied as steam, becoming creamy. There is no mycelium or similar structure. Even should it be a Fungus, does the solid part form the substance of the spores, or does it take the place of mycelium? It has an ultimate composition very similar to a fined oil, and cellular tissue, and gives by destructive distillation products nearly the same as those of rape-seed oil, viz., gamboge

Messrs. E. P. Francis & Co., Hertford. The Cheshunt firm were well 1st, with, among others, excellent blooms of Marie Rady, Dupuy Jamin, Alfred Colomb, Marie Rauman, Maréchal Niel, Dr. Andry, Duke of Edinburgh, Louis Van Houtte, Triomphe de Rennes, Felix Genero, Antoine Rucher, Madame Cellier, &c. For 48, distinct, three trusses of each, the competitors were Messrs. Paul & Son and Mr. Turner, the former again coming in 1st with a grand lot, including especially good examples of Charles Lefebvre, Duc de Rohan, Alfred Colomb (wonderfully fine), Dr. Andry, Pitord, Beauty of Waltham (exquisite), Horace Vernet, Paul Verdier, Antoine Ducher, Camille Bernardin, Duchesse d'Orléans, Belle Baumann, Marquise de Castellane, and Triomphe de Rennes; Mr. Turner was 2d with admirable blooms of Climbing Devoniensis, Charles Rouillard, Baroness Rothschild, Madame C. Crapelet, Miss Ingram, Alfred Colomb, Victor Verdier, Queen Victoria, &c. Messrs. Paul & Sons were again 1st for 24 Hybrid Perpetuals, Mr. J. Fraser, Lea Bridge, being 2d. Mr. Turner and Messrs. E. P. Francis & Co. also competed, Mr. Turner surveying the whole of the collections, the most noticeable varieties were Xavier Olibo, Duchesse de Caylus, Baroness Rothschild (fine), Duke of Edinburgh, Marie Rady, Charles Lefebvre, Marie Baumann, Clémence Joigneaux, Alfred Colomb, Lælia, Baron Hausmann, &c. For 24 distinct, one truss of each, Mr. Turner was 1st, Mr. J. Walker, Thame, Oxon, 2d; and Messrs Veitch & Sons 3d; all showing remarkably fresh and good-sized flowers.

The amateurs' classes brought out a greater number of exhibitors than the preceding. The Rev. G. Arkwright, Pencombe Hall, Bromyard, was 1st for 36, with fine blooms of Baroness Rothschild, Beauty of Waltham, Madame Vidot, Moire, Nardy Frères; Mr. Chard was 2d, Mr. R. N. G. Baker 3d, and Mr. P. Stoddart, gr. to H. J. Gordon Baker, Lansdowne Park, Colchester, 4th with a very fresh group; Mr. G. W. Chard, Clarendon Park, Salisbury, being 3d; and Mr. R. N. G. Baker, Heavitree, Devon, 4th. Mr. W. Ingle, gr. to Mrs. Round, Birch Hall, Colchester, was 1st for 36, with nice blooms of Baroness Rothschild, Beauty of Waltham, Madame Vidot, Moire, Nardy Frères; Mr. Chard was 2d, Mr. R. N. G. Baker 3d, and Mr. P. Stoddart, gr. to H. J. Gordon Baker, Lansdowne Park, Colchester, 4th. The varieties were very similar to the foregoing, but there was a great want of quality amongst them. For 24, the 1st prize was won by Mr. J. Skinner, gr. to Capt. Christy, Aperfield, Tonbridge, with a very even lot, fair in quality, but wanting in freshness. The same must also be said of the other prize groups, which were shown by Mr. W. Soder, Mr. J. Wilkely, and Mr. R. B. Postans, gr. to Rose, distinct, was 1st, equally by Mr. J. C. Quennell, Brentwood, the Rev. C. C. Ellison, Bracebridge, Mr. J. Wakely, and Mr. W. Soder, who took the prizes in the order named, for the several stands of blooms. Messrs. Paul & Son were 1st for the best collection of yellow Roses, with excellent boxes of Triomphe de Rennes, and Céline Forestier, and also for the best 24 varieties of white or yellow Tea-scented being 2d in the latter class. The former had nice blooms of Paul Nèron, Mr. Gladstone, Comtesse d'Oxford, Marquise de Castellane, Louis Van Houtte, and Madlle. Eugénie Verdier, and the latter contributed Niphetos, Wm. Wood, Lord Napier, Jupiter, &c. The best 12 Tea-scented and Noisette Roses came from Mr. H. Thorneycroft, Weedon, Northampton; and Messrs. Paul & Son were 1st in the corresponding class for nurserymen. The best 12 Roses, distinct, came from Mr. Turner; and the best 12 of any Rose of 1869 or 1870 came from Messr. Paul & Son, who staged Comtesse d'Oxford, and they also took the 1st prize for the best 12 of any Rose of 1871, the group, with Louis Van Houtte, a grand Rose, velvety shaded crimson. 24 Roses in pots were staged by Mr. Turner and Messrs. Paul & Son, the former having the best of a contest in which either Rose could claim the premier position on the day. Messrs. Veitch & Sons also staged a very fine group in pots, as well as several fine boxes of cut blooms, notably one of Baroness Rothschild.

In the class for a group of nine plants suitable for dinner-table decorations, there was a strong competition, Mr. J. W. Chard, gr. to Sir F. Bathurst, Bart., Clarendon Park, Salisbury, coming in 1st with remarkably graceful and effective examples of Hypophorbe verschaffeltii and Areca aurea, the former occupying the centre. Mr. Pull was 2d with a group in which Dæmonorops plumosa occupied the centre, on either side being specimens of Deckenia nobilis and Sabal Schottii, all very graceful plants, but much too large for an ordinary table—Messrs. E. G. Henderson & Son were 3d, also contributing a group of nine plants. The same class, for groups suitable for the decoration of the dinner-table, to consist of flowers or fruit, or both combined, for which there was also a very strong competition, the 1st prize was awarded to Messrs. Phillips & Pearce, the 2d to Mr. J. W. Chard, and the 3d to Mr. Hassard, Upper Norwood, an extra prize being also awarded to Mr. W. Soder.

The miscellaneous class was greatly enriched by collections of plants from Mr. J. Linden, Brussels, and M. Alexis Dallière, Ghent. Notably in the collection from the former were Epidendrum Frederici Guilelmi, Allopiectus vittatus, Dioscorea chrysophylla, D. Eldorado and D. prismatocarpa, Maranta Mazelii and M. Wallisii discolor, Dieffenbachia imperialis and Dioscorea meleagris, which received First-class Certificates; and Aralia japonica aureo-reticula, which had one of the 2d class. M. Linden was also awarded Silver Flora Medals for the groups of Dioscoreas, Marantas, and Orchids. M. Dallière sent a magnificent collection of Marantas, which included well-grown specimens of M. splendida, M. Wagneri, M. Veitchii, M. virginalis major, M. orbifolia, M. illustris, M. majestica, M. Van den Heckii, M. vittata, and M. argyrea, for which he also was awarded a Silver Flora Medal. He also exhibited a series of Palms, &c., which received a Special Certificate. Mr. Denning, gr. to Lord Londesborough, again brought up a choice group of Orchids, including a splendid specimen of Angulloa Clowesii, Dendrobium formosum, with 6 beautiful flowers; Epidendrum nemorosum, and cut spikes of a species of Stanhopea and Cattleya Leopoldiæ. Messrs. Rollisson and Mr. Bull each staged fine groups of Palms, Orchids, &c., and from Messrs. E. G. Henderson & Son came a very effective group of Tricolor Pelargoniums and Petunias. Mr. Turner sent a splendid lot of show Pelargoniums, cut Verbenas, &c. Mr. Hooper, Bath, had some fine Carnations and Cloves, and Mr. Parker, Tooting, had a fine specimen of Ixora amabilis.

Messrs. Veitch & Sons offered for competition 6 dishes of Peas, to include Laxton's Supreme, Laxton's Quality, and Hundredfold, for which there were seven competitors, the 1st prize being awarded to Mr. Cox, gr. to Earl Beauchamp, Madresfield Court, who had very fine examples of the varieties named, two other of Mr. Laxton's new varieties, and Veitch's Perfection. Mr. C. Frisby, gr. to H. Chaplin, Esq., M.P., Blankney Hall, was 2d, Mr. J. W. Chard, Mr. Garland, Mr. Lunnden, Mr. Miles, and Mr. G. Brown also exhibited, with first-rate samples.

Floral Committee.—Dr. Denny in the chair. First-class Certificates were awarded to Mr. J. Croucher, gr. to J. F. Peacock, Esq., Sudbury House, Hammersmith, for Agave Verschaffeltii variegata, the variegation in which consists of a golden band down the centre of the leaves; to Mr. W. Bull for Alsophila Shepherdii, a very graceful miniature Tree Fern; to Mr. C. Green, gr. to W. W. Saunders, Esq., for Houlettia odoratissima anticquensis; to Messrs. Veitch & Sons, Lapageria lanata saboloides, pinkish white, and Lithospermum petræum, blue, both apparently very free bloomers; to Mr. Wiggins, gr. to J. H. Beck, Esq., for show Pelargonium Ada; to Messrs. E. G. Henderson & Son, for Pelargonium Coppa, a semi-double variety with flowers of a white ground and crimson flaked margins; and to Mr. Turner for two very large heavily laced Pinks, named Dr. Masters and Shirley Hibberd. Messrs. E. G. Henderson & Son also received a Certificate of the Second-class for a free flowering show Pelargonium named Enterprise, a very useful variety for cutting; and Mr. Bull had also one of the same order of merit for Adiantum Erinus Omen, a pretty dwarf bedding kind. From Mr. Cannell came a collection of cut blooms of Verbenas; and Mr. J. Stevens sent an exceedingly fine group of Balsams, to which a Special Certificate was awarded.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the absence of Certificates were awarded on this occasion to Mr. Gilbert, gr. to the Marquis of Exeter, Burghley Park, Stamford, for a fine-sized, highly-flavoured Melon called Selected Cashmere; to Mr. Tillery, Welbeck, for excellent dishes of Kirke's Peaches and Violette Hâtive Nectarines; to Mr. Perkins, Warren House Gardens, Stanmore, for very handsome fruit, weighing over 5 lb. each, of Queen and Ripley Queen Pines, grown from imported suckers; to Mr. Hudson, gr. to Mr. J. Douglas, gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, for a magnificent dish of Lucas Strawberry; and to Mr. Turner, for excellent dishes of Buckland Sweetwater and Black Hamburgh Grapes. Dr. Denny also exhibited a bunch of his new seedling Grape, a cross between Buckland Sweetwater and White Frontignan, which possesses the rich flavour of the latter with the larger bunch and berry of the former. It was agreed to, that the committee requested to see it again, when its very useful character will no doubt meet with due recognition. From Mr. W. Cruickshank, gr. to Lord Beiper, Kingston Hill, Dr. Denny exhibited a bunch of Cruickshank Muscadine, and Wilmot's Muscat Muscadine. Mr. Parsons, Danebury, had a very fine specimen of the Giant Puffball, Lycoperdon giganteum; and from Mr. A. Colbourne, Wellington, were seedling Potatoes of various sorts, measuring from 8 to 10 inches across. Mr. Wm. Paul sent a dish of fruit of a new Strawberry, named Waltham Seedling; and Mr. Trotman, Isleworth, again sent specimens of Strawberry Sensation. The question of the exceptional character of the season, the committee were unable to decide upon their merits. Mr. Laxton, Stamford, exhibited specimens, with the haulm, of a new dwarf Pea, named Laxton's Peerless, which reaches high, with a good crop of medium-sized, well-filled pods; also specimen pods of two other varieties, named Superlative and Achievement, which are said to grow 6 feet high. Mr. J. Walker, Thame, Oxon, sent capital specimens of Sugarloaf Brown Cos Lettuce, a good serviceable variety, which differs from the old Brown Cos in forming a close heart. Messrs. Wrench & Sons, Acton, Perry, exhibited Roiffea [?] or Reed Grass, a bast-like substance from Japan, to which, on account of its strength and softness for tying purposes, the committee voted a First-class Certificate.

THE WEST OF ENGLAND ROSE SHOW AT HEREFORD: *June* 30.—The fifth annual exhibition took place on Friday, the 30th ult., in the Shire Hall. There was a large gathering of exhibitors, and, considering the unfavourableness of the season, the show was an excellent one. Amateurs were very strong, especially the local ones. Mr. R. N. G. Baker, of Heavitree, Exeter, was there, as elsewhere this season, *facile princeps*. His blooms were magnificent. J. H. Arkwright, Esq., the Rectory, Pencombe, Bromyard; the Rev. C. B. Cotton, the Rev. E. Bulmer, the Rev. P. M. Smythe, the Rev. R. O. Carter, Mr. S. Evans, and Mr. C. J. Perry, were the chief among the amateur exhibitors. Nurserymen were numerously represented. Messrs. Paul & Son, Nurseries, Cheshunt, and Mr. J. Keynes, Salisbury, however, making up for the absence of others (and especially for the absence, as a competitor, of Mr. John Cranston, the leading Herefordshire nurseryman), who exhibited a small collection, "not for competition," the bulk of his Roses not being fully in bloom), by the great excellence of their numerous exhibits. Messrs. Paul & Son showed, as they always do, the best of Roses in the best manner. They won 1st prizes of £10 each for two collections of 72 varieties of single trusses, one open to the United Kingdom, the other limited to nurserymen nonresident in Herefordshire; 1st prize of £5 for 24 varieties of three trusses; 1st prize of £3 for 24 new Roses sent out in 1869-70-71; and equal 1st prize of £2 for 24 blooms of any one Rose, with a splendid box of Centifolia rosea. Mr. Keynes was just a shade below his usual mark, though his collections were, as is always the case, set up with excellent taste, and contained many magnificent blooms. He won 1st prizes for 24 varieties of three trusses (£3); for 12 new roses, sent out in 1869-70-71 (£2); equal 1st for 24 blooms of any one Rose, with a charming collection of La France (£2); and prizes for 24 varieties of single trusses in the same class (£6), and a similar exhibit in the limited class (£6); and a 3d prize for a collection of 24 new Roses, sent out in 1869-70-71 (£1). The varieties shown in these various stands need not be enumerated, being the same as have been shown at the other leading shows this season. The necessity for a continued repetition of the names of the best varieties gets less and less yearly; for it is a rare thing to see a bad variety shown in even the smallest collection; and as for the best sorts, are they not duly chronicled and described in the catalogues of all the leading "growers for sale," and their marked qualities known to the heart by even tyros among amateurs? The severity of the past winter and spring was so deadly in its effects on Teas, tender Noisettes, &c., that Maréchal Niel and the other delicate varieties of these favourite classes were generally absent from all the stands.

The table and floral decorations were praiseworthy, though neither so numerous nor, with one exception, so remarkable for excellence as they were last year and in 1869. On the other hand, it must in fairness be stated that they were all chaste in design, their chief characteristics being simplicity and elegance. There were no overgrowing bouquets of the proper size for holding in the hand, none being of such Brobdingnagian dimensions as they too frequently are. The cottagers made a large and admirable display, which afforded quite as much pleasure as the more aristocratic parts of the exhibition.

STAMFORD FLORAL AND HORTICULTURAL: *June* 21.—Had the weather been favourable, the first exhibition of this revived society would have proved one of the most attractive that has been witnessed in Stamford for years. The show in every department was of a superior character, notwithstanding the backwardness of the summer season. As it was the day dawned gloomily, and shortly before the time for opening rain began to fall, and continued for about two hours. Those who braved the elements, however, had a real treat, as the display in each class was excellent, and the competition very keen. The largest tents were devoted to stove and greenhouse plants and Roses; and the Floricultural Gardens, Stamford, helped to fill them met general commendation. The Ferns, Cordylines, Dracænas, and other exotics, giant Fuchsias, Caladiums, and Coleus, of every shade and colour, and an endless array of Pelargoniums, filled the three large marquee; while in that devoted to Roses were exhibited some of the choicest specimens which the best growers could produce. Messrs. Paul, of Cheshunt, were in great force, but for many of their contributions several other exhibitors, and notably Mr. Laxton, having sent trusses of the best sorts, excellent in size, colour, and form. Among the exotics and Pelargoniums in the tents in the neighbourhood were specimens from Burghley, Casewick, Holywell, Uffington, and Lilford Park. The nurseries at Cheshunt, Huntingdon, Rugby, and Stratford-upon-Avon, were also represented in the grand display of fruit from Burghley Park, which consisted of Pines, Melons, Grapes, Peaches, Nectarines, Figs, Strawberries, Cherries, and Apples, the whole so skilfully arranged as to form a perfect picture. The Grapes were remarkable for their size, the magnificent bunches were sent from the gardens of the Earl of Gainsborough and of Earl Brownlow. The vegetables also were exceedingly fine, some Cucumbers from Burghley being of immense length.

SCOTTISH PANSY SOCIETY: *June* 17.—The twenty-seventh annual competition of the Scottish Pansy Society was held on the above date in the vestibule of the Music Hall, Edinburgh, the present season being one of the worst on record for the propitious growth of Pansies and Violets, and many of the regular exhibiting members of the Society had the most of their plants destroyed, at least for all show purposes, by the severe winter; different classes were consequently not so numerous as in previous years, but what blooms were shown were of excellent quality. The competition in the nurserymen's classes was limited, but in the amateur and amateur and bedding. Messrs. Downie, Laird & Laing exhibited, but not for prizes, a long and varied stand of show Pansies—fine, as a rule, in colour, good in shape, and of excellent substance. Messrs. Dickson & Co. had a nicely arranged stand of their new bedding Violas. Mr. Duncan Kerr, Glencorse, received two Certificates of Merit; Messrs. Downie, Laird & Laing, four—three for fancy and one for bedding Pansies —and Messrs. Dicksons & Co. a First-class Certificate for a white ground Pansy, three of merit for bedding Pansies, and three for bedding Violas. Certificates of Merit were awarded to Mr. Kerr, for a white self Pansy; Mrs. Shand, and a cream self Pansy, Jessie Cunninghan; to Messrs. Downie, Laird & Laing, for three fancy Pansies, namely, William Paul, Mrs. M'Lachlan, and David Syme, and bedding Pansy Whistle Binkie. Messrs. Dicksons & Co., Waterloo Place, had a First-class Certificate for white ground Pansy, Jane Grieve; Certificate of Merit for yellow ground Pansy, A. Brodie; for a dark self Pansy, Robert Black; for bedding Violets, Stricta Alba and Butterfly; for bedding Pansy, Mauve Queen; and for Violet, Blue Beard.

June 29.—A very fine day.
" 30.—Rain fell occasionally in the morning. A generally fine day. Clouds variable.
July 1.—Cloudy till night, but fine. Cloudless after 9 P.M..
" 2.—Generally overcast. Rain fell from noon till 5 P.M.
" 3.—Generally overcast till night. Frequent heavy showers of rain fell during the day. Thunder was heard in the morning.
" 4.—A very variable day. Frequent heavy showers. Cloudless and very fine at night.
" 5.—Very variable throughout. Rain fell heavily at times, and fell also fell almost noon. Thunder and occasional flashes of lightning also showed at mid-day. A fine night.

JAMES GLAISHER.

Miscellaneous.

LOCAL NATURAL HISTORY SOCIETIES.—The yearly increasing number of these societies is a matter for congratulation, as showing a growing appreciation of science throughout the country; but, if "the child is father to the man," we have yet more reason to be hopeful for the future, when we observe the new general movement in our public and larger private schools in favour of the study of natural history. We have not yet heard of the establishment of a natural history society at Eton; but, with this exception, we believe that all our more important schools possess such an association, more or less fully carried out according to circumstances. It must not be forgotten that it is to the Society of Friends that we are indebted for the first school society. So long ago as 1834 their school at York has had its natural history class; and the establishments of the same body at Sidmonton and Croydon are similarly supplied. Harrow has long possessed a Literary and Philosophic Society; but, so far as public schools are concerned, it was at Marlborough, under the superintendence of the Rev. T. A. Preston, that a "Natural History Society" was established in 1864. Rugby was not slow to follow suit, and these two schools may be considered as fairly representing, in their respective societies, what such bodies ought to be. From the two last-issued reports before us, we learn that the study of botany is among the most popular of those undertaken by the members. The interest in this is, in a great measure, kept up by the practice of recording, year by year, the earliest date at which flowering plants are observed to blossom—a practice which tends to foster a spirit of careful observation, even if leading to no other results. In the last Marlborough report the names of more than 50 boys are given as having assisted in this work, and Mr. Preston informs us that the eagerness of some of them is quite amusing. The last Rugby report contains a paper by Mr. F. E. Kitchener, the active president of the society, on the times of flowering of plants, generalising from the observations of two or three years, and deducing certain results, which are of considerable interest. To a casual observer such matters may appear trifling, but in one who is acquainted with Quetelet's voluminous observations upon the same subject, will admit that it is one of much interest and some importance. It would be imagined, however, that such matters are the only ones attended to. Both societies have collections of plants, as of other objects, and the Marlborough herbarium is already assuming considerable importance. Mr. Preston has issued, with the last report, the first instalment of an admirable local flora, with descriptions, for the use of the members; and a third is in hand and has been granted by the Marlborough authorities for a botanic garden. We have confined ourselves to the botanical work of these societies, as more within our province; but it is only fair to add that other branches of natural science are equally well attended to. Although, in each case, one of the masters is president, it must not be supposed that this in any way interferes with the fact that the society is mainly supported by the boys—that it is, in reality, their own. While cordially wishing success to these and all similar institutions, we cannot do better than adopt a suggestion which has already appeared in a contemporary—that persons possessing a surplus stock of books cannot do better than forward them for the use of the "rising generation."

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

MANY kinds of stove and greenhouse plants will now be going out of flower; such as *Clerodendron Balfourianum*, *Pimeleas*, &c., which do not shed their old blooms freely, should have them all removed at the earliest possible moment, as the plants may not be impoverished thereby beyond what is necessary or desirable. Keep thrifty young plants of *Coccocypselum discolor* in a moderate greenhouse temperature, so as to encourage a sturdy growth, that they may the more readily be enabled to furnish an abundant crop of its remarkably brilliant ultramarine-coloured berries for early and mid-winter decoration. It should be borne in mind that though this plant is a native of Jamaica, it also inhabits the mountainous districts, hence it will thrive in a more temperate atmosphere than at first sight would appear possible. Indeed, there are many supposed exotics which might, were the altitude at which they are found better described, be far more successfully dealt with. *Epiphyllums* which have made their growths should be gradually inured to the full action of the outer air, as by these means alone can they be induced to bloom as freely as they are capable. The gorgeous *Eucharis amazonica* should be repotted about this time, by way of preliminary preparation for the Christmas blooming. Choose moderate-sized pots for this shift, as it is not advisable to give too liberal shifts at once. Peat and fibrous loam, with a fifth part of peat, and a little silver sand and thoroughly decomposed cow or sheep dung in admixture, will suit them well. As may be readily surmised, from a survey of their large, deep evergreen, ovate, glossy leaves, their delight is abundance of moisture, but when only which is fresh and sweet. They will not, in a word, thrive in a stagnant unwholesome soil, which is too frequently the cause of non-success in their culture. As is well known the fleshy bulbs increase somewhat rapidly, each older one producing annually at least a pair and often more young ones. Their doing so often causes either frequent shifts, which in the end demands somewhat large pots, or an occasional division of the increase within each pot. Now, as a rule, these plants do not like being torn asunder and divided, and hence, when they come time to re-establish themselves, hence it is not advisable to do so too frequently—not oftener, in fact, than when an increase of stock is desirable, or the stools have exceeded in size the extent of pot-room that can be afforded them. Should something further ail, it will be necessary to shade seedling *Primulas* and *Cinerarias* which have been potted off. Keep them uniformly moist at the roots, and do not omit occasionally to look over them to detect at the earliest moment any symptoms of thrip or aphis pests, which not unfrequently attack these two particular seasons. *Orchids* in bloom should now be removed into a cooler structure than an Orchid-house proper. It is often worth the outlay of time to improvise a temporary corner in a conservatory or greenhouse specially for them. One thing must, however, be borne in mind in regard to them, *i. e.*, no draughts must, under any circumstances, be permitted to reach them, or injury may be caused to the delicate young growths, which in all likelihood are now being made. Give the final shift to late blooming *Fuchsias*, and also alternate waterings of liquid manure to such as are in bloom. Give also less moisture and more air to those which are advancing to the flowering stage.

FORCING HOUSES.

Vineries, in which the Grapes are about to colour, and more especially those which have miscellaneous collections of plants growing beneath them, should have air afforded as freely as possible at this time, and it should not be necessary to add that a dry atmosphere should be uniformly maintained. To facilitate this, let all pot plants be watered in good time on the morning of each day, so that time may be allowed for the moisture to dry up before the cooler hours of night arrive, and with them the probable condensing of humidity upon fruit and on foliage. *Pines* should now enjoy an average mean temperature of from 78° to 80°, with a decrease of 10° or 12° by night. Let the heat run up to 88° or 90° during bright weather, and by sunheat alone. Should any increase in the size of the pots used for the forwardest batches of successionals be deemed necessary, it should be borne in mind that it will be advisable to use somewhat rougher compost. The "nobs" of fibrous loam may be larger, and the crocking with rather more abundance than heretofore. Attention should, in connection with all such shifts, be given to the bottom-heat, by the usual method of removing, and turning over, and moistening, &c., of the tan. Be very cautious, however, not to afford too much heat to tan at this season; else, besides plunge the pots much below half their depth, and examine frequently the state of the heat, that the roots be not scorched. Excessive humidity should be constantly maintained in connection with a free supply of fresh air.

HARDY FLOWER GARDEN.

Where, owing to the somewhat late season and the cold, wet weather, *Ranunculuses* and *Anemones* have not yet been taken up, let the operation be done somewhat by anticipation, rather than to wait longer and until any foliage, now somewhat green, ripens off fully. Attend well to the tying up of *Dahlias*, *Hollyhocks*, &c., which are so liable, through any neglect in this wise, to be broken in twain during such variable weather, the loss being irremediable when once the injury is done. *Gladioluses* should in like manner be secured before the current growths become too large. A good mulching would do these latter good now. Sow seeds of *Hollyhocks* in the open borders. Make cuttings, also, of such biennial and perennial plants as *Pentstemons*, *Phloxes*, *Silenes*, *Pansies*, of either of which a further stock is required, and desirable variety of *Antirrhinums* may now be increased by means of cuttings also. Choose hard, well developed cuttings from near the base of the old flowering shoots. Those who undertake the budding of *Roses* in their own gardens may now commence, as the stocks are sufficiently matured and the bark well run. It is perhaps as well to choose a dull day for the operation, though the buds generally take very well at any time if the above conditions are secured.

HARDY FRUIT GARDEN.

Moist as the weather is, and abundant as are snails and insects generally, the Strawberry crop is in preference the produce of Strawberry beds and Cherry trees. Hence these matters will now be forced under every gardener's notice, and the necessary kind of netting materials must be held in use. The planting of *Strawberry beds* must be brought to a close with all dispatch, so that the old forced plants be got into the ground as quickly as possible, not only to lessen the labour of watering, but that they may make some progress, in the matter of establishing themselves for the next summer's fruiting. Proceed with the summer thinning of shoots upon pyramidal fruit trees, such as *Pears*, *Apples*, *Plums*, &c. Thin out all lesser ill-placed shoots, and let those remain which are well placed, and may be used to extend the size of the trees, to be shortened to the necessary length at a later date, when the wood has become more matured than it is at present. Full attention must still be given to aphis pests and their attacks on wall fruits. The black fly is especially plentiful upon *Morello Cherries* and Peach and Nectarine trees, and can only be destroyed by the direct application of tobacco-water, Gishurst Compound, or other similar materials. Proceed with the thinning of all young shoots upon each of these latter to the walls, or fasten them by the usual secondary aids of small cross-sticks, &c.

KITCHEN GARDEN.

More *Dwarf French Beans* should now be sown on a warm and fully exposed sunny aspect. Sow also certain kinds of *Peas* for a last main supply, though a row of any quick podding kind may be sown in a sunny southern aspect later. The sorts to be recommended for this sowing are Ne Plus Ultra, Bishop's Long-pod, and any of the early and approved kinds of Sangster's No. 1—such as Carter's First Crop, Sutton's Ringleader, or Taber's Early Perfection, which, by the way, is a stronger grower, and somewhat more distinct than either. *Mazagan Broad Beans* should be sown in like manner, to secure a late crop. And with the sowing of a successional batch of *Endives*, sow also Fraser's *Batavian Endive*, or, for the matter of that, any approved kind of Batavian. If a sowing of Dutch or Early Horn *Carrots* were made now, they would come in very useful for drawing during the early winter months, and it may be, if the season is not of the

best, in the early spring months instead. Proceed with the trench-planting of *Celery* during showery weather, forming the trenches for their reception upon the ground previously occupied with Peas or other early crops. *W. E.*

TOWN GARDENING.

THE *Chrysanthemum* will now be growing fast, therefore all lateral shoots should be removed as soon as they appear; and where it is intended to produce specimen blooms, a top-dressing of rotten dung and loam will be beneficial, as liquid manure cannot be used this wet season. The management of the Pompon differs from that of the large varieties, inasmuch as that they should be pinched back up to the end of the month to produce as many laterals as possible. The *Golden Pyrethrum*, a most useful plant for town gardens, should have all flower-buds picked off as fast as they appear; they will then keep neat all the summer. Go frequently over the bedding plants, taking off all old flower-stalks and yellow leaves, at the same time stirring the soil between them with the Dutch hoe. *Carnations* should be propagated this month by layers or pipings. I prefer layering where the plants are growing in the borders. Pinks and Picotees should be layed about the 20th of this month, and when they have four leaves be potted, three in a 48-sized pot, and kept in a cold frame till spring, giving all the air possible in fine weather. *Dahlias* should now be mulched with rotten dung, and tied to stakes as they progress in growth. Most of the Cactus genus (*Cereus*) appear very showy, and do well in towns; and I should recommend, as many of them flower this month, that varieties be marked down, so that a collection can be got for another year, by planting offsets this autumn. *E. D.*

Notices to Correspondents.

CALCEOLARIA : *W. J. E.* The seedling is a showy one, and, from what you say of its habit, likely to be useful.

COTONEASTERS : *J. Morrison.* Cotoneasters are grafted on the common species, *C. vulgaris*, on the Quince, and on the Hawthorn.

EMPLOYMENT IN VINEYARDS : *Vitis* writes—"I shall be out of my apprenticeship to the gardening in a few months. Having a knowledge of the French language, and a desire to get into the wine-growing trade, would you inform me how to apply for a situation in a vineyard in the Bordeaux district. Unless our correspondent has some connection with private business in the district he mentions, we do not think he will obtain what he wishes.

GRAPES : *A. D.* The Grapes sent are fairly ripened, but not well coloured. They will, of course, be better when more thoroughly matured.

INSECTS : *Old Subscriber.* Send a specimen of the insect and a flower of the plant.

NAMES OF PLANTS : *John L.* Lotus major.—*J. Carter & Co.* Probably Sisyrinchium convolutum.—*T.* One of the varieties of Crinum capense.—*J. P. F., Chowmes.* Deutzia crenata flore-pleno. Yes.—*St. Aubyn.* We do not undertake to name florists flowers.

THE GREAT SHOW AT NOTTINGHAM.—In our report of the above show we gave Mr. F. Hope credit for showing the best single dish of Peaches, instead of Mr. Jack, gr. to the Duke of Leeds, carried off at Arundel, Sussex. We learn from Mr. R. T. Veitch, of Exeter, that he supplied the greater portion of the seed of the fine collection of vegetables exhibited by Mr. Garland, and that Messrs. Carter furnished the remainder.

WORM : *Monmouth.* Send a specimen.

CATALOGUES RECEIVED.—Osborn & Sons, Catalogue of Herbaceous, Alpine, and Bulbous Plants.—James Veitch & Sons, Catalogue of New and Beautiful Plants.—Joseph Meredith, Catalogue of Choice Stove and Greenhouse Plants, Roses, Bedding and Ornamental Plants, &c.

COMMUNICATIONS RECEIVED.—N. Y. Z.—J. M.—T. M., Philadelphia.—J. H. A.—F. L. P.—J. D. & S.—J. K.—C. S.—F. W. B.—Market Gardener.—J. W.

Markets.

COVENT GARDEN.—July 6.

The markets have fluctuated considerably during the past few days, more in consequence of the unfavourable weather than of the supply—a great quantity of many goods coming in, and realising very low prices. Bush fruit and Cherries have been much injured by the heavy rains. Hothouse fruit is amply supplied, Pines especially.

WANTED, TWO experienced ROSE BUDDERS. None but expert hands are requested to apply. A permanent situation offered to a good Rose grower. The best of reference as to ability and experience will be required.—Mr. WOODTHORPE, Munro Nursery, Bible Heddingham, Essex.

WANTED, a GARDENER, for a place in Wales.—Must understand Vegetables, and be able to keep a Flower Garden in order. No glass. Wages, 12*s.* a week and a house.—Apply by letter to W. G., Messrs. Hemmingham & Hollis, 5, Mount Street, Grosvenor Square, W.

WANTED, for St. Kitts, West Indies, as MARRIED COUPLE, a married GARDENER, who is not objected to. Must understand Ornamental Gardening, and the Management of Flowering Trees. Under unexceptionable, about 30.—Address, stating all particulars, to Messrs. A. HENDERSON AND CO., Vine-apple Place, Edgware Road, London, W.

WANTED, as GARDENER, a single young Man, to take charge of a Flower and Kitchen Garden; one who is thoroughly acquainted with the Management of Greenhouses and Hotbeds; he will also have to assist in the House. Wages, 10*l.* a-week, with board, residence in the house, and washing.—M. D., Mr. Crowder, Bakery, Church Street, Camberwell, S.E.

WANTED, a young MAN, under a Foreman, to Propagate Soft Stuff generally. None but sober, industrious, and energetic Men treated with.—RANSLEY TANTON, F.R.H.S., Epsom Nurseries.

Seed Trade.

WANTED, a YOUNG HAND; one who has been accustomed to Sowing, Samples and Writing on Parcels would be preferred.—Apply by letter to MINIER, NASH AND NASH, 60, Strand, W.C.

WANTED IMMEDIATELY, a young and active married MAN, to undertake the entire Management of a Garden, and Wife to act as Laundress to a large family, if required. A good house to live in, attached to the garden and field adjoining.—A. Z., Johnson's Library, Stamford.

WANT PLACES,—Letters to Post Paid.

Gardeners.

B. S. WILLIAMS has much pleasure in stating that the GARDENERS' REGISTER remains open, ten of the strictest integrity, thoroughly qualified to undertake the duties of HEAD GARDENER, SECOND GARDENER, and BAILIFF, or UNDER GARDENER. Ladies or Gentlemen requiring such may rely upon B. S. W. recommending only those whose conduct and abilities are worthy of their trust.

Victoria and Paradise Nurseries, Upper Holloway, London, N.W.

To Gardeners and Bailiffs (Head, Foremen, or Under) JAMES CARTER AND CO. having many applications for the above, request that those WANTING SITUATIONS will send their NAMES, and COPIES of TESTIMONIALS, for ENTRY in their FREE REGISTER. Only those who can send unquestionable references need apply.

Any Lady or Gentleman requiring GARDENERS or BAILIFFS may rely upon J. CARTER & CO. adopting the most stringent regulations in reference to their Applicants as to ability, sobriety, &c.

EXPERIENCED GARDENERS (for as GARDENER and BAILIFF), of various qualifications, recommended to Gentlemen, and further information given on application to Messrs. G. HENDERSON AND SON, Wellington Nursery, St. John's Wood, N.W.

GARDENER (Head).—Age 30, single; thoroughly understands the Culture of Early and Late Pines, Stove and Greenhouse Plants: also Fruit, Flower, and Kitchen Gardening. Good character.—W. B., 4, Alma Terrace, Thoroton Heath, Croydon.

GARDENER (Head).—Age 35, married; thoroughly understands the profession in all its branches, including Early and Late Forcing, Vines, Pines, Melons, Cucumbers, &c. Five years' good character from last employer.—L., 11, Wellington Street Leamington.

GARDENER (Head), late of Brondesbury Park.—Age 40, married, no incumbrance; thoroughly understands all branches. Used to Land, Stock, Hops and Fruit. Good character from last and previous employers.—R. B., 78, St. John's Wood Terrace, London, N.W.

GARDENER (Head).—Age 40, married; thoroughly experienced in Forcing all kinds of Fruits, Flowers, and Vegetables, the Kitchen and Flower Garden, and Greenhouses; also the Cultivation of Stove and Greenhouse Plants, and the general Management of a Gentleman's Garden. Establishment preferred. Good character.—A. B., Mr. Wood, 9, Leicester Place, Tooting, London, S.W.

GARDENER (Head), age 30.—CHARLES BUTTERS, for six years Head Gardener to the Duchess Dowager of Cleveland, at Lowhurst Manor (on her leaving the Residence of the Estate), is at liberty to engage with any Nobleman or Gentleman in want of a thoroughly Qualified Gardener. Good character from late employer.—CHARLES BUTTERS, White Hart Street, Thetford.

America.

GARDENER (Head), as FOREMAN and PROPAGATOR in a Nursery.—A pushing young Man, age 28, married, is desirous of Emigrating to America, in either of the above capacities. Has been accustomed to Growing for the Trade Principally, and the Propagation of Hard and Soft-wooded Plants. Highest Testimonials.—R. B., 3, Cambridge Terrace, Hackney, London, N.E.

GARDENER (Head, Working).—Age 30, married; thoroughly well up in all branches of the profession. Wife can Nurse Invalids or Confine. If required. First-class references.—HORTUS, Post Office, Northampton.

GARDENER (Head, Working).—Married seven years, no family; has a thorough practical knowledge of Early and Late Forcing. Good character.—G. S., Marine Park, Broadstairs, Kent.

GARDENER (Head, or Working).—Age 38, married, four children; well up in Early and Late Forcing of Pines, Grapes, Peaches, Cucumbers, Melons, &c., Stove and Greenhouse Plants, Fruit, Flower, and Kitchen Gardening. Ten years and three months character from present employer. Country preferred. —F. H. 4, Union Place, Church Street, Lee, Kent.

GARDENER, permanent or otherwise.—Age 40; a thoroughly practical Man, of good habits.—R. POST, Crawley Down, Crawley, Sussex.

GARDENER, in a Nurseryman's or Gentleman's Establishment.—Age 21; 4½ years' character.—W. H., 1, Elizabeth Cottage, King William street, Wandsworth Road, Clapham, Surrey, S.W.

GARDENER.—Age 28, single; thoroughly understands Kitchen and Flower Gardening, Greenhouses, &c. Fourteen years' experience. London or suburbs preferred. Good character.—W. PRICE, Wheatsheaf, Ewell.

GARDENER, in a single-handed place.—A young Man; understands Vines, and Flower and Kitchen Gardening. Good character.—C. D., Coley Cottage, Park Lane, Reading.

GARDENER (Single-handed, or otherwise).—Age 31, married, no family; respectable; thoroughly understands all branches of his profession. Good character.—J. A. STICKLING, Green Clavering, Newport, Essex.

FOREMAN (Indoor or Outdoor), in a Nobleman's or Gentleman's Establishment.—Understands Forcing Stove and Greenhouse Plants. Six years' character from last situation.—JOHN ALLISON, Newton Nurseries, Chester.

PROPAGATOR and GROWER of Stove and Greenhouse Plants, &c. Thoroughly experienced. Good reference.—A. B., 2, Croft Cottages, Catford, S.E.

To Nurserymen.

PROPAGATOR of Stove, Greenhouse, and Soft-wooded Plants, also Hardy Outdoor Plants.—Age 36; has had long practice in London and Provincial Nurseries. Thoroughly steady.—HENRY WEBBER, Whitington, near Lichfield.

To Nurserymen.

PROPAGATOR (Soft-wooded) or ASSISTANT GENERAL, where years' general practice. Can be well recommended.—F. S., The Nurseries, Blisworth, Northampton.

FORESTER.—Twenty years' practice in the Management of Woods and Plantations; also the Renovation of Gardens, &c. Good references.—W. K., Mr. J. Simmons, High Street, Bruton, Somerset.

MANAGER (Indoor), or MANAGER and PROPAGATOR.—Age 28; energetic and practical. Highest testimonials and references.—A. B., 38, Henry Street, St. John's Wood, N.W.

To Noblemen and Gentlemen.

STEWARD.—Land Steward of an Estate.—A Person of good education and business habits would be happy to take any position of trust, either at home or in the Colonies, and is prepared to give the highest references. He is a practical Farmer and grazier, and is a good Correspondent.—M. E. C., *Gardeners' Chronicle* Office, W.C.

WM. RUMSEY, HEAD CLERK, MANAGER of SEED and BULB DEPARTMENT, and GENERAL SALESMAN to Mr. WM. PAUL, of Waltham Cross, for the last 11 years, and for 10 years previous with the late firm of A. Paul & Son, Cheshunt, is open to an Engagement in either of the above branches of the business. —WM. RUMSEY, Waltham Cross.

BUTLER, where one or more Footmen are kept. —Age 36, married; good character, height 5 feet 9½ inches. Country preferred.—C., Utley Post Office, Dursley, Gloucester.

TO MARKET GARDENERS and FLORISTS with a Capital.—A Gentleman, having purchased above FOURTEEN ACRES of LAND, near a Railway Station, not far from Horsham and Shoreham, Sussex, and within an hour of Brighton, is wishing to have the same OCCUPIED, for a few years or permanently, either by a Market Gardener or a Florist. Assistance would be made for compensation for permanent improvements, and for Tree planting. A small Stream of Water runs through the ground.
Mr. W. H. C., 7, Phillimore Gardens, Kensington, W.

SALES BY AUCTION

Imported Orchids.
MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on FRIDAY, July 14, at half-past 12 o'clock precisely, an importation of DENDROBIUM LITTLEFORDIUM, VANDA TERES ROSEA (scarce), SACCOLABIUMS, &c., from India; a consignment of ANGRÆCUM FUNALE, &c., from Madagascar; a BRASSAVOLA CUCULLATA, &c., from Jamaica; 25 plants of ODONTOGLOSSUM BLUNTII, O. KRAMERI, and O. WELTONII, from New Grenada; and a small consignment of Established ORCHIDS, in fine condition, including Trichopilias, &c.
On view the morning of Sale, and Catalogues had.

Pine-apple Place, Maida Vale, Edgware Road.
MR. J. C. STEVENS begs to announce that he has received instructions from the Mortgagee to OFFER for SALE by AUCTION, in one Lot, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, July 20, at 12 precisely, the LEASE (38 years unexpired), STOCK, and GOODWILL of the old and well-known NURSERIES of Messrs. Arthur Henderson & Co., which have been established upwards of a century. More detailed particulars will appear in next Advertisement, and Plans will be ready 7 days prior.

Important Sale of Shorthorns
At the PRINCE CONSORT'S SHAW FARM, WINDSOR.
MR. STRAFFORD has the honour to announce that he has received instructions to SELL by AUCTION, without reserve, on WEDNESDAY, July 19 next, at the Prince Consort's Shaw Farm, Windsor Park, FIFTY-SIX HEAD of very superior PURE-BRED SHORTHORNS, the property of Her Majesty the Queen; amongst them will be found some fine specimens of the Fawsley, Booth, Crocker, and Phyllis families of the celebrated cows Aire, Cold Cream, and Furbelow. First-class Bulls from the renowned Warlaby Herd, and Heifers and Cows selected from the Barmpton, Alfrid (3,405), Birbeck Prince (14,107), Fitz Clarence (14,852), Lord Hopewell (18,210), and Grand Victory (15,881) the young Bull at the head of the latter bull. The sire now in service is Royal Benedict (17,348), from the same herd as Grand Victory.
Catalogues, with Pedigrees, may be had on application to Mr. CHARLES HOWARD, Prince Consort's Farm, Windsor; or of Mr. TAIT, at the Prince Consort's Shaw Farm, Windsor.

Winterfold, near Kidderminster.
IMPORTANT SALE OF SHORTHORNS.
MR. STRAFFORD is favoured with instructions to announce for SALE by AUCTION, without reserve, on THURSDAY, July 27, at Winterfold, near Kidderminster, a DRAFT OF SHORTHORNS, consisting of FIFTY-FIVE HEAD of BULLS, COWS, and HEIFERS, the property of Mr. Thomas Bowring, Winterfold, and Isaac Downing, Esq., of Turner's Hill, and will include several very superior animals selected from the Warlaby and Booth sires of the unrivalled Duchess family have been used, such as 3d Duke of Warlaby (21,604), 2d Duke of Wetherby (21,626), 5th Duke of Warfdale (18,603), 3d Duke of Clare (20,603), and the Bates-descended and pure-bred American 8th Duke of Geneva; the two latter are now in use.
Catalogues, with Pedigrees and other particulars, may be had on application to Mr. TAIT, at the Prince Consort's Farm, Kidderminster; or of Mr. STRAFFORD, 13, Euston Square, London.

Bulbridge Ram Sale.
MESSRS. EWER AND SON AND STANLEY beg to announce that the ANNUAL SALE and LETTING by AUCTION of the Flock Master's Stock Ram, at BULBRIDGE FARM, WILTON, on WEDNESDAY, August 2.
Mr. Lawrence has been awarded during the present year Five Prizes for his Sheep, exhibited at the Bath and West of England Society's Show, at Shrewsbury, including the Shearling Cup, Gloucestershire Agricultural Society's Show, at Cirencester, and continued success for the last 25 years renders further comment from the Auctioneers unnecessary.

Important Shorthorn Sales.
MR. JOHN THORNTON will SELL by AUCTION the HERDS of PURE-BRED SHORTHORNS, several of which are of a very first-class and choice character:—
THURSDAY, August 3, the second day of the Yorkshire Show, at Mr. Wm. Fawcett's, Wrigley, Lanarkshire, of about 100 head.
The Rev. D. Jefferson's herd.
DEVIZES, August 23.—The celebrated and first-class HERD bred by the late Thos. Barnes, Esq., at WESTLAND, Kelly, Co. Durham, which is the small Herd of Mr. Barnes, now the Rev. D. Reynell, Esq., will be SOLD at the same time and place.
FRIDAY, August 25.—The entire and valuable HERD bred by J. G. Grove, Esq., at CASTLE GROVE, Letterkenny, Ireland.
TUESDAY, September 5.—At BROUGHTON HOUSE, Eccleshall, Staffordshire, Mr. T. Bell's entire HERD.
THURSDAY, September 14.—Messrs. Dudding's entire HERD, at FARLEY, near Keighley, Lancashire, of about 200 head.
FRIDAY, September 22.—The first-class herd at CHAPEL BRAMPTON, Northamptonshire, property of Mr. Wm. Wilson.
TUESDAY, September 26.—About FORTY HEAD, belonging to Mr. Wm. Dudding, at the small Farm of Hollybrook, Doncaster.
The late Sir John Rolt's HERD will also be SOLD during the autumn, by Messrs. EWER AND PARK, Worksop, Nottinghamshire.

Agricultural Land Improvemne
DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.
THE GENERAL LAND DRAINAGE and SEWAGE COMPANY,
(Incorporated by Act of Parliament in 1849.)
DIRECTORS.
T. Chapman, Esq., F.R.S.
George Thomas Clark, Esq.
John C. Dent, Esq., M.P.
Henry William Currie, Esq.
Sir John Hutchins, Esq.
Sir William Tite, M.P., C.B.
Consulting Engineers, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works for themselves.
Tenant Farmers may also, by agreement with their Landlords, execute any of the works for which Imprest Money is granted.
The outlay, with all official expenses, may be charged upon the Estate, and repaid by Annual Rent-charge, extending, as a rule, to 25 years, or at the option of the Landowners in a shorter term.
No investigation of title is required, and no legal expenses incurred.

UTILISATION of SEWAGE.
Special Arrangements will be made with Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof will be repaid either by a Rent-charge for a term, or a definable yearly payment, discharging in a fixed period the principal amount and interest thereon.
Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 22, Whitehall Place, S.W.

THE LANDS IMPROVEMENT COMPANY.
(Incorporated by Special Acts of Parliament.)
Drainage, Reclamation, Farm Buildings, Labourers' Cottages, &c.
DIRECTORS.
John Clutton, Esq.
Thomas Eastwood, Esq.
Henry Farquhar, Esq.
Lord Granville.
John Horatio Lloyd, Esq.
Granville R. Ryder, Esq.
Granville H. Somerset, Esq., C.C.
Henry W. West, Esq., M.P.
Charles Watkin Williams Wynn, Esq., M.P. (Chairman).

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement authorised by Parliament, including Farm Buildings, to the Owners of settled and other Lettered Estates, and to Owners of Entailed Estates in Land.
Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.
UTILISATION of SEWAGE.—The Company also advances money for the purpose of Works of Sewage Irrigation.
The whole outlay and expenses are liquidated by a rent-charge upon the land, redeeming principle and interest, over 25 years.
No investigation of title is required.
For Forms of Application, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S.W.

REDFORDSHIRE AGRICULTURAL SOCIETY (embracing the adjoining Counties).—LAST DAY of ENTRY for CUTTY and PIGEON SHOW DEFERRED from JULY 12 to 18.
A SPECIAL PRIZE, consisting of a HAND SEWING MACHINE, value £2 2s., will be given by Mr. Pickering, of Bedford, for the best COLLECTION of SWEET FLOWERS, arranged in a small basket, open only to Ladies residing in Bedford or the County.
LIST of PRIZES and FORMS of ENTRY to be obtained from Mr. Jas. Sell, Corn Exchange, Bedford. THOS. LESTER, Secretary.

Price 5*d.*; post free, 5½*d.*
Published by W. RICHARDS, 41, Wellington Street, W.C.

The Agricultural Gazette.

SATURDAY, JULY 8, 1871.

MEETING FOR THE ENSUING WEEK.
ROYAL AGRICULTURAL SOCIETY'S MEETING AT WOLVERHAMPTON.

July 10	The entire Showyard open from 8 in the morning, at which hour the Judges will commence inspecting Live Stock, and making their awards. Admission, 5*s.* each person.
July 11	Admission, 2*s.* 6*d.* each person. General Meeting of
July 12	the Members in the Showyard, on Tuesday, at 2 P.M.
July 13	
July 14	Admission, 1*s.* each person.

The Showyard will be closed at 6 o'clock each Evening.
The Exhibition of Cattle in the Rings will take place at 10, and of the Horses at 12, noon, each day after Monday.

THE STEAM CULTIVATION COMPETITION at Stafford and Wolverhampton during the past week threatened at one time to be altogether a failure. A constant or frequent heavy rainfall appeared likely to beat the judges out of the field. On the one hand, the six or seven fields of light land at Barnhurst, Wolverhampton, on which rapidity and extent of work had been illustrated during the earlier trials—on which, too, exceptional tools, such as ploughs deep work, harrows, &c., had been found to have been exhibited, were inadequate as representative of the tillage difficulties of an ordinary farm; and on the other, the four fields on Mr. DARLINGTON'S farm, near Stafford, where stiffer land, uneven surfaces, and awkward fences presented some of the commoner conditions with which steam must be prepared to cope, were in the first instance too wet for work. On subsequent days, however, they were fit enough, and the report of the Society's judges will, we doubt not, be a serviceable and trustworthy account of the latest contributions to the progress of steam cultivation.

A journal of the last night or ten days, so far as these trials are concerned, is given in another page. It will suffice here to call attention to one or two of the points in which, it appears to us, this progress is exhibited. The work on light land fields have proved, in respect both of the surface of the land after steam cultivation, and that of the subsoil on which the moved soil lies, that not only can a large area be cultivated, but excellent tillage work accomplished in a very short time. Formerly speed was accomplished at the expense of unevenness and imperfection. Now, a seven-furrow plough can be depended on to turn land over with regularity of both width and depth of furrow-slice, at the rate of 4 acres an hour! Tools, moreover, for

turning land 15 inches deep can now be trusted to do their work regularly and thoroughly; harrows, rollers, drills, &c., can be worked easily and effectively by steam-power, and the mere stirring of the land or throwing it up in a tangled mass of broken furrow-slices can be done rapidly and well.

On the stiffer land near Stafford we think it has been made apparent—though the judges will hereafter speak with more authority—that that firm, having a fairly good tool at their command, who can pack the greatest quantity of power on four wheels for working it, must beat all weaker men. Messrs. Fowler & Co., with their pair of nominally 20-horse power engines, and with their balance plough or cultivator, thus still stand in the front rank of steam cultivators wherever difficult circumstances exist.

Ample opportunity has been given during the experiment for judging the quality as well as the rapidity of the work accomplished, by occasional removals of the furrow-slice, or cultivated earth, so that the character of the unmoved subsoil surface was exposed. And here, too, considerable improvement has been exhibited on all former experience. Even where the speed had been excessive, the work stood this test remarkably well. The quality of the work accomplished, apart from the mere area of it, was thus and in other ways carefully observed. The weight of earth moved per hour and per acre, as most accurately expressing the work of cultivation accomplished, was, we believe, first tested at the show of the Yorkshire Agricultural Society in 1862, where Mr. J. C. Morton was employed by the Society as their reporter. (See *Agricultural Gazette*, 1862, p. 795.) The work done was then ascertained by actual weighing of the earth moved per square yard of area, by the several competing ploughs and cultivators. It then appeared that where the speed was greatest, and the surface (left in heaps) appeared to have been most roughly knocked about, the quantity of material moved was really less than where the work had been slower and the apparent disturbance of surface had been less. At Stafford and at Wolverhampton we observed that the judges were applying the same test, but it appeared to us that they were not applying it in the right way. The object being to determine the weight of earth which had been moved, was quite within the scope of direct experiment, and ought to have been ascertained directly. It was only estimated, or determined indirectly. The weight of earth 1 foot deep per square yard was indeed determined in the several fields by actual weighing in the several fields, but the weight moved by the several competing tools was ascertained, not as it might have been, by putting a square yard of it upon the scales, but by applying the ascertained weight of 1 foot deep to the estimated depth of the work done. This, however, is incapable of accurate measurement, and the result arrived at is, therefore, after all, a mere estimate. This was plainly seen in the trials at York nine years ago, where the evil of irregularity during rapid work was illustrated by the proved superiority of the slower cultivation as regards the quantity of earth (ascertained by many weighings) which had been moved.

The report was as follows:—

"The weight was taken in so many instances because it was supposed that some mistake had been committed, the quantity of earth moved per acre by Fowler's cultivator certainly appearing to be very much greater than that moved by Howard; whereas repeated weighings proved it to be actually somewhat less. The fact was, that it was thrown about so much more roughly in the former case, that it lay looser, and appeared to be deeper than it was. And one result of these weighings is to prove the fallacy of estimates of work of this kind by mere measurement, however honestly performed."

It is of course the *quantity* of earth moved and stirred and tilled—not the acreage cultivated—which really represents the work accomplished; and it is to be regretted that this has not in every instance been ascertained by actual weighing in the several instances, instead of being left to calculation from measurements, which however carefully taken canot command the same degree of confidence.

The work done on the farm near Stafford very fairly illustrated the superiority of steam-power over that of horses on clay soils. It is here that the advantage of tillage as a fertilising agent, apart from the application of manure, is best witnessed. "Such soils are dependent on proper cultivation for their fertility, even more than upon the direct application of fertilising matter, which indeed is already abundantly present in their substance, for only plants could get at it. To this end they need to be broken up and exposed throughout their depth to the free access of air and weather. But there are comparatively few days when this can be done by horse-power, for they are generally either baked by the sun, so that horses cannot pull the plough or cultivator through them, or they are so softened by the rain that the trampling and the sliding of the team and tool will do more to close the land than open it. We want a power which shall make the full use of the short intervals when such land is in proper condition for tillage operations, and which shall at the same time avoid the evil of poaching the land above and hardening it below, which in the horse cultivation of clays is too often seen. A four-horse team and plough weigh more than 40 cwt., and all this goes trampling and sliding from end to end of the field that is being ploughed, over every 10 or 12 inches of its width; and thus, of course, a floor is formed beneath the soil, hindering drainage, which is the greatest improvement of which clay lands are capable. We want a tool weighing not more than 4 or 5 cwt. for every foot in width to be worked by it, carried on wheels, so as not to close the surface over which it travels, and driven by a power which shall not press upon the land that is being worked. All this we have in the steam-driven ploughs and cultivators that were seen at work yesterday." These words, written nine years ago, convey fairly enough the impression which this week's trials, even in the midst of heavy rain, in the steam-ploughed fields near Stafford, must have produced on the spectators. The progress visible to those who were present both there and at the trial ground near York in 1862, appeared in the greater power of the engines, the greater consequent depth, thoroughness, and speed of the work accomplished—and the much greater quantity of earth moved under each square yard of surface.

Those who may visit Barnhurst, near Wolverhampton, next week, to see the steam-ploughs at work, will be struck with the appearance, in one or two of the fields, of a poached and trampled surface, worse than was ever seen before on any horse-cultivated farm; and the effects of which we doubt not will be be visible for months and crops to come. This was the site of the "steam-horse race" described in another page. The course had been staked out, so as to include fair specimens of all the various difficulties incident to steam-traction on a farm. The engines had to traverse ploughed and unploughed land, hollows, crooked lanes, and narrow gateways. But they were for the most part ultimately beaten by the weather. Aveling's traction-engines did, indeed, overcome all the obstacles triumphantly, but the traction-engines with elastic tyres were beaten by the sloppy, slippery state of the land in the hollows.* The result, upon the whole, is, however, to make it more than ever doubtful whether the traction-engine is adapted for aiding field work—however efficient it may be, and no doubt is, on good roads.

—— On Monday, at Mark Lane, with a short supply of English Wheat and wet weather, factors asked full prices, but as little inclination to purchase was shown by millers, the sales made were at about last week's rates. On Wednesday prices favoured the purchaser—Wheat of all descriptions being purchased slowly, at drooping prices.—Trade in Beasts on Monday at the Metropolitan Cattle Market was brisk, and occasionally prices in advance on those of last week were obtained. Prices for sheep were rather lower, but those for choice lamb dearer. On Wednesday there was a short supply of beasts, and those on offer of choice quality made high prices. Sheep were rather better than on Monday—choice lambs fetching Monday's price.—Wool is advancing, and is expected to attain to a still higher figure.—In the Seed Market the belief gains ground that the growth of Clovers and Trefoil will be defective. There is little business doing excepting in Mustard and Rape seeds—which are in fair demand.

—— The following is the final account of the French Peasant-Farmers' Seed Fund, as forwarded to us for publication by the Hon. Secretaries:—The total amount subscribed to the fund up to May 24, was £41,979 18*s.* 1*d.*, including three grants amounting to £13,000 from the Lord Mayor's Mansion House Relief Fund. List 1, shows in what form the money was remitted; 2, through whose instrumentality collected; and 3, is a list of counties and countries, giving the amount received from each.

—— The very useful Food Committee of the Society of Arts have presented their annual report as follows:—

"Your committee have continued their inquiries during the past session, and have to report a great improvement in meats submitted to them, which has been preserved in tins. Both as to the quality of the meat, its appearance, and retention of nutritive qualities, there has been satisfactory progress, and your committee regard this process as furnishing a very valuable aid to other kinds of food, especially where it is desirable to have as large a quantity as possible of animal matter in a small compass.

"The trade from Australia in tinned meats has very largely increased, in the exportation both of beef and mutton; and, so far as the many specimens of this and other modes have been investigated by your committee, this one alone has not yet fulfilled the necessary conditions of bringing meat from a distance with fully-retained meat flavour, without deterioration by addition of chemical

* We extract from a report in the *Times*, July 6:—"It was quickly apparent that the elastic tyres, unassisted by spuds or other means of penetrating the ground, could not get a grip of the soft soil rendered slippery on the surface by a recent rainfall. In such circumstances, the metal tyre of the wheel rotates without advancing, the indiarubber ring of rotary motion turning round within the external chain of protecting shoes, or all three revolve, cutting down into the ground without causing the engine to advance. After attempts of ready going and sticking fast, the engine came to a standstill in a deep hollow in a Yetchstubble field, having sides sloping at inclinations of 1 in 18 and 1 in 20. Here the difficulties it was extricated from were the most laborious efforts of the Messrs. Ransome, Mr. Head, and their men in helping the wheels out of the mud by planks and posts. Not much less undaunted than Mr. Aveling would have yielded all further experimenting in such an unfavourable condition of the course, and as it was by preceding competitors, which got so soaked and washy that any heavy steam-engine would be expected to founder. Nevertheless, his 10-horse power single-cylinder engine, with coal and water, and a train of 2 cwt. (which 84 tons were upon the two 18-inch broad driving wheels), and dragging behind it two waggons constituting a load of 9 tons, made a bold, and proceeded steadily round the fields, turned admirably through all the gateways, in spite of having lost two cogs out of the driving bevel-gear, and arrived at the water-jump, or (as a wit named it) the Slough of Despond, where 'Pliable' had turned back. The round of 4 mile and three-quarters was accomplished in 61 min., with a consumption of 2 cwt. 9 lb. of coal. Mr. Aveling is to be congratulated upon the surprising capabilities and perfection of his traction-engines; but it must not be inferred from the trial narrated that the elastic tyre is a mistake, and that the fame of the road-steamer has now collapsed. Ridiculed as the first, the indiarubber cushion for the rim of a wheel is being adopted in a modified form by Mr. Aveling himself, by Messrs. Fowler, by Messrs. Ransomes, Sims & Head, and by other makers of traction-engines. Its place is upon hard roads or slushy roads, provided they have a hard bottom, or roads newly stoned, or even arable land in dry weather. These points will probably be brought out at the further trial of traction engines which is to be held on Thursday at Stafford. But a 'road-steamer' cannot become a 'farm-steamer,' unless provided with the same resources which enable ordinary traction-engines to traverse soft fields and clay lanes."

agents. No process of the latter kind which as yet has been submitted to your committee can be said to be thoroughly successful. Either the texture of the meat has been broken down or hardened, and the flavour destroyed or altered, and in many cases such a distinct saline or mineral taste added as to preclude the adoption of such specimens as articles of general consumption.

"Your committee still look with much hope to the process of preserving meat in cold temperatures, and are now engaged in a series of experiments, by which they hope to be able to determine the conditions most favourable for the practical appliance to animal and vegetable substances of this mode of preservation.

"As yet, no successful plan has been matured for bringing live animals by sea from long distances."

—— The disposal of the late Lord WALSINGHAM'S celebrated Southdown flock on Thursday of last week by Messrs. THORNTON and SLATER & SIMPSON, was attended by a large company, including many agriculturists from a distance. A gloom was cast over the latter part of the day's proceedings by the serious and sudden illness of Mr. JOHN CLAYDEN, who was struck down by a paralytic stroke in the course of the afternoon*. Eight hundred and seventy-one sheep fetched close on £5500, averaging about 6 gs. a-head. The old rams made £27 13s. each, the shearlings £22, and ram lambs, £4 10s. The 3-year-old ewes made £4 2s; the 2-year-old ewes £4 16s.; the shearling ewes realised £6 18s. apiece; the ewe lambs £2 11s.; and, on the whole, as we have stated, 871 sheep averaged £6 6s. apiece. The following is the tabulated summary :—

	£ s. d.		£ s. d.
19 old rams	27 13 2	.. ..	525 6 6
65 shearlings	22 0 6	.. ..	1431 13 6
120 ram lambs	4 10 8	.. ..	543 16 0
190 old ewes	4 0 4	.. ..	771 5 0
65 three-year ewes	4 2 4	.. ..	267 10 0

160 shearling ewes	6 18 9	.. ..	1110 2 6
160 ewe lambs	2 11 0	.. ..	407 7 6
871 averaged £6 6s.	Total	.. ..	£5489 15 0

—— The following circular has been addressed to the tenantry on the Stoneleigh Estate :—

"Estate Office, Stoneleigh Abbey, Kenilworth,
"June 20, 1871.

"Dear Sir,—I am directed by Lord LEIGH to inform you that, having gone over nearly the whole of his estates with draining, buildings, and other permanent improvements, effected at a large outlay, his lordship is of opinion (and is confirmed in that opinion by the advice of persons of experience) that a more satisfactory system for the management of his estates—both for his tenants and himself—can be arranged, the main features of which are :—

"1. That all permanent improvements shall be effected by and at the sole cost of his lordship, a settled rate of interest on the outlay being charged.

"2. That all repairs shall be done by Lord LEIGH.

"These very important changes, you will see, necessitate a re-valuation of your farm, and this his lordship has no doubt will be effected in such a manner as to give you satisfaction, and increase that confidence which has always existed between you, his lordship, and the late Lord LEIGH.

"This change will relieve you from finding and locking up in improvements that capital which will enable you more profitably to cultivate your farm, and give you more freedom to advantage yourself, by removing your capital and energies to a more beneficial occupation, without the possibility of leaving any of your money on his land.

"The subject of leases has engaged his lordship's attention, and he is not indisposed to consider any application for one. There are tenants to whom he would not grant one, and also farms so situated that he would decline to lease them, but these tenants have his engagements to value and pay for their unexhausted improvements on quitting.—Your very obedient servant,

"GEORGE JONES."

—— The *North British Agriculturist* states as a fact within the personal knowledge of the Editor, that there are several farmers in the small county of Haddington, who annually expend upon AUXILIARY MANURES and FEEDING STUFFS about £2 for each acre they possess. Some farmers in that county have estimated that the outlay on manures and cattle food nearly corresponds with the amount of rent paid.

—— Our readers will find in another page an exhaustive and practical essay on Land Drainage, lately read before the East Kent Chamber of Agriculture by Mr. WEBB, of Sittingbourne, who thus describes his own long and extensive experience as a land agent and draining engineer.

OUR LIVE STOCK.

CATTLE.

A GOOD likeness either of a man or an animal must be truthful. That truthfulness is not possible with our Shorthorn and cattle artists is most painfully evident to all who examine their productions. We almost fear that while the artists pourtray falsely, the owners of the cattle love to have it so; and this we say advisedly, from the fact that photography is not popular with breeders of high-bred stock. The conventional picture of a Shorthorn represents more properly what the breeder aims at than what he has obtained. It represents a square and well filled-up carcase, terminated by a small and pretty head, and exceedingly diminutive legs; it is the *beau ideal* of what an animal ought to be, in the estimation of the artist, but is nevertheless impossible. It would not be difficult to point out grave anatomical faults in their drawings, and they are certainly utterly worthless as representatives of the animals

FIG. 185.—REAL AND IDEAL FORequarter.

after which they are named. Photography cannot fail to give a correct outline, and to maintain the proportions between the various parts of an animal. When properly used, it places before a breeder the best

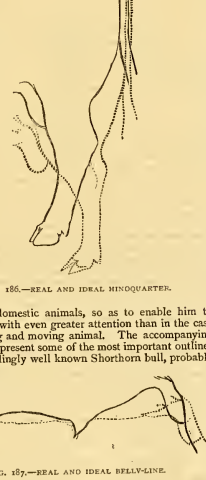

FIG. 186.—REAL AND IDEAL HINDQUARTER.

models of domestic animals, so as to enable him to study them with even greater attention than in the case of the living and moving animal. The accompanying woodcuts represent some of the most important outlines of an exceedingly well known Shorthorn bull, probably

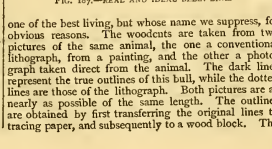

FIG. 187.—REAL AND IDEAL BELLY-LINE.

one of the best living, but whose name we suppress, for obvious reasons. The woodcuts are taken from two pictures of the same animal, the one a conventional lithograph, from a painting, and the other a photograph taken direct from the animal. The dark lines represent the true outlines of this bull, while the dotted lines are those of the lithograph. Both pictures are as nearly as possible of the same length. The outlines are obtained by first transferring the original lines to tracing paper, and subsequently to a wood block. The lines along the back of the animal in both drawings are made to coincide, and taking fig. 185, we see the result of a comparison between the conventioual and the real breast or brisket. We call attention to the increased depth of carcase, prominence of breast, and diminished size of the forelegs. Fig. 186 shows how the artist gives a more than natural squareness to the tail-head, how he confers an impossible squareness at the buttocks, and an unmasculine fineness of bone at the hocks and shanks. Fig. 187 exhibits the wonderful contrast between the real belly-line in a well-formed Shorthorn bull, and what the artist thinks it ought to be. An animal formed on the model of the Shorthorn artist would probably be incapable of "work," or even of motion, and at best is only a gross exaggeration of the fattest animals exhibited at Smithfield, and has no resemblance to a healthy animal in breeding condition. We consider it necessary to call attention to this point because pictures of animals ought to be useful not only by giving a good idea as to the original, but also in the future when faithful likenesses of well-known animals may indicate progress in symmetry, beauty, and utility of form.

TEN DAYS AT WOLVERHAMPTON.

THE trials this year embrace "steam-cultivation and Hop machinery," divided into 22 classes—18 for steam culture, besides Lord Vernon's Silver Cup, value £100, and four for Hop culture.

The trial ground consists of 17 acres on the Palmer Cross Farm, occupied by Mr. Fleming, and 103 acres on Barnhurst Farm adjoining, occupied by Mr. W. Taylor (who, by the way, is irrigating a portion of his farm with sewage from the town sewers); the adjoining lands make a total of about 120 acres, situated about 3 miles from the show-ground. The soil is light and in good working order, to the depth it has hitherto been ploughed, but in some places large stones are embedded in the subsoil, against which the implements struck, causing numerous breakages, and leaving the work not so evenly done as it otherwise would have been; and even where there were not stones the subsoil turned up very hard, and bound together. This condition of the subsoil is much to be regretted, and in selecting land for steam culture it should be avoided, unless to test special implements, as it neither did justice to the common steam-tillage implements, nor showed to those who visited the work with the view of starting steam-culture themselves, how such farms as Barnhurst and Palmer Cross should be cultivated by steam. And Palmer-mound-bottomed lands should first, "for example," be gone over with "a root or stone extractor" (class 14), and then no mishaps would take place with engines, ploughs, and cultivators afterwards. And, besides, when the bottom is unequal, the plots are also unequal, and the engines and implements do not get fair play. The Wolverhampton steam-culture trials have been looked forward to with no little expectation, and during the trials on the light land farms many farmers expressed very freely their disappointment. The heavy land consists of three large fields on New Buildings Farm, in the occupation of Mr. Darlington, situated about 3 miles from the railway station at Stafford, or about 18 miles from Wolverhampton; this distance is extremely inconvenient, and the narrow lane into the fields is awkward enough. The light land is staked out in the usual way, into small plots of about 3 acres each.

Monday, June 26.—The steam culture trials commenced this day, chiefly on the 17-acre field on Palmer Cross. Some 20 engines were in the field, with a strong force of implements and tackle, for the best combination of machinery for the cultivation of the soil by steam-power (class 1). Four firms entered as competitors, viz., Messrs. Fowler & Co., Messrs. J. & F. Howard, the Ravensthorpe Company (Fisken's system), and Messrs. Barrows & Steward. The Leeds firm were the first to get into position with their 20-horse power double winding drum set (*i. e.*, two engines on opposite headlands). This firm show other three systems of steam-culture, viz., their clip-drum system, double-drum set (*i. e.*, an 8-horse engine, carrying two drums, with a disc anchor on the opposite headland), and their detached windlass system. The Messrs. Howard exhibit three systems—two engines and one implement, two engines and two implements, and one engine with a detached windlass. Fisken's system is distinct from any of the above, so there is variety from which to choose the best. The six judges are divided into two sets :—John Hemsley, Skelton, Newark; Richard Kay, Forcett Valley, Darlington; and F. Sherborne, Bedfont, Middlesex; with W. Menelaus, C.E., Dowlais, Merthyr Tydvil, as consulting engineer, taking classes 1, 2, and 3, and also the Lord Vernon cup trial;—Major H. V. Grantham, West Keal Hall, Spilsby; John Hickeo, Dunchurch, Rugby; J. W. Kimber, Tubney Warren, Abbington; with Easton, Amos & Anderson, taking class 6 and the other implement classes. Not much was done on Monday, and at the close of the day the competitors in class 1 drew for precedence next day: Messrs. Barrows & Steward stood 1st, Messrs. J. & F. Howard 2d, Messrs. Fowler & Co. 3d, and the Ravensthorpe Company 4th.

Tuesday, June 27.—The Banbury and Bedford firms

* As we are going to press, we receive the sad intelligence that Mr. CLAYDEN is no more,—and under the circumstances it is only in our power now briefly to record the fact.

not being ready, Messrs. Fowler & Co. again took the lead, with two 20-horse engines and a 13-tined cultivator, in a field on Barnhurst Farm. Owing to the wetness of the surface, the outermost tine on each side had to be removed to prevent clogging the wheels. The 3-acre plot was finished in about 40 minutes, to the depth of from 7 to 9 inches. The 12-horse double engine set was next started on another plot, with a 9-tined cultivator, smashing up the 3 acres in rather less than an hour, about the same depth as the preceding. A 12-horse clip-drum engine next started, with a 7-tined balance cultivator, doing its 3 acres in about an hour and a half, to the depth of 7 inches. An 8-horse double winding-drum engine and disc anchor opposite, with a 7-tined turnover cultivator between, smashed up its 3 acres, 8 inches deep, in about an hour and three quarters.

The Ravensthorpe Company had in the field a 10-horse traction engine, and 10-horse portable engine, a 4-furrow balance plough, a 3-furrow balance plough, a 7-tined Howard cultivator, and a 7-tined balance cultivator; with a Howard cultivator going 5 inches deep: the 3 acres were finished in about 79 minutes.

Wednesday, June 28.—Messrs. Barrows & Steward took their turn in class 1, working a 5-tined Woolston smasher with a 12-horse portable engine, and detached windlass, with claw anchors which did not hold fast. The time occupied in doing the plot from 7 to 9 inches deep was about 2 hours 50 minutes, but out of this the stoppages, we presume, should be taken. Better things are expected of the Woolston anchors and implement in the heavy land field. This concluded the trials in class 1, Messrs. J. & F. Howard, after the breakage of their gear on Monday, having in the interim ceased to remain competitors.

The lots were then drawn for the precedence in class 2, and also in Lord Vernon's cup class. The two include seven trials, viz., 1, Howard's double drum set; 2, Edward Hayes, Stony Stratford, Bucks; 3, the Ravensthorpe Company; 4, Amies & Barford; 5, Fowler & Co.; 6, Howard's roundabout system; 7, Barrows & Steward: most of the afternoon was spent in the preliminaries.

In the lower grounds the other judges were continuing the trials of the implement classes, which commenced the previous day. Campain's anchor gave general satisfaction. The plough trials between the rival firms of Leeds and Bradford are to be resumed.

Thursday, June 29.—The trials in class 2 were continued. The three first on the list were unfortunate from breakages. In this class the weight of the engine must not exceed 12 tons, and in reference to how the weight was to be ascertained the Council lay down the rule to the judges that "the weight of the engine shall be deemed to be exclusive of coal, water, and rope, but to include the weight of the drum or windlass." The effect of this condition, which its framers ought to have seen, is so much in favour of Messrs. Fowler & Co.'s clip-drum engine as to leave a poor chance for the other sets. Messrs. Amies & Barford took their turn, with their 7-tined Woolston cultivator, going from 7 to 8 inches deep, using a pair of Campain's anchors, which is a great improvement upon the Woolston system. After working about 2 of the 3 acres in their plot, the judges were so satisfied with the quality of the work done as to allow the other acre to be ploughed, which was done with the Peterborough steam-plough. The depth of the furrow-slice was about 8 inches, and the time occupied in finishing the plot, including stoppages in coming in contact with stones, tree roots, and the paying out of the tackle, was about two and a half hours.

Messrs. Fowler & Co., the next in turn, started with their clip-drum engine and implements already described. They also use their 8-horse engine roundabout set, and made good work in the cup class, ploughing an acre in 55 minutes, cultivating another in 39 minutes, and digging the third in 36 minutes.

Messrs. J. & F. Howard and Barrows & Steward took their respective trials, the former with their cultivator, and the latter with a Woolston smasher.

Friday, June 30.—To-day the competition was in class 3, for the best combination of machinery for the cultivation of the soil by any ordinary agricultural engine, whether self-propelling or portable. The Howards used a four-furrow plough capable of being converted into a digger by removing the common breasts and putting on digging breasts, a five-tined cultivator, steam harrow and drill, and their roundabout tackle. Fowler & Co., a four-furrow plough or digger, a five-tined cultivator, harrow and drill, and roundabout tackle. Amies & Barford, their roundabout tackle, three-furrow plough or digger, seven-tined cultivator, steam harrows and roller, and Campain's anchors. Barrows & Steward, plough and cultivator, with their roundabout tackle. In this class the judges used a 12-horse Clayton & Shuttleworth engine for all the above competitors, which made the work slow.

Saturday, July 1.—The competition in class 3, and also in the implement classes, not finished, continue under both sets of judges, and in the afternoon the "traction-engine race" began, which threw the other trials in the background. A goodly number entered as competitors, but only a few came up to the starting, and fewer still reached the winning post. The race-course was measured out on the ploughed fields, headlands and lanes at Barnhurst. Aveling & Porter's 6-horse engine went the round in 22 minutes; Ransome, Sims & Head's 8-horse Thomson in 24 minutes; Burrell's 8-horse Thomson in 28; and Aveling & Porter's 10-horse engine in 29 minutes. The race is to be resumed on Monday, July 3; and the "Derby Day," from Wolverhampton to Stafford and back, comes off on Thursday, July 6.

Monday, July 3.—The great attraction of the day was the steam-horse race at Barnhurst. As stated above, a course, 3168 yards in length, was staked out. It had many sharp undulations, hills, and soft places, owing to the rain that had fallen since Saturday. On that day the judges decided that the waggons should be loaded according to the discretion of the owners, and not a few Derby Day jokes were passed as to the capabilities of the racers, and how they would show their paces here and there on the racecourse. Accordingly the waggons were loaded with "pigs,"—"legitimate pigs of the Black Country." The morning promised badly, but eventually the weather cleared up a little. Much precious time was spent in going through the routine preliminary testing of the engines, with which most of our readers are familiar. At length the judges gave the orders to start, and the racers took precedence in the order of their merit on Saturday, a safe distance being kept between competitors. The last of many heavily-laden waggons started minutes and even of seconds which the engines took to go over marked distances was carefully noted. On the order of the judges to start No. 7002 in the catalogue reached the ears of "Little Tom" (Aveling & Porter's 6-horse engine), away it started, amidst the acclamation of onlookers, and the second competitor, who had come long distances to see the race—one lady, we were told, drove from Ipswich by steam. But to the more interesting facts of the case. The engine, weighing with coals and water 5 tons 4 cwt. 2 qr., started at 2.25 P.M., drawing a load of 54 tons, including the pigs and waggon. For soft ground the engine was armed with clips and spikes, and on turning into the roads and lanes this armour was taken off. These shiftings occasioned some delay, but the winning-post was reached in 52 minutes. As soon as "Little Tom" was seen approaching, he was hailed as "Old Bachelor" (Ransome, Sims & Head's engine) started—7 minutes past 3 P.M.; weight of the engine, 10 tons 64 cwt.; load, 5 tons. Now came the test of the rubber wheels, but not long, for before the engine had gone 100 yards the indiarubber tires proved their unitness for soft wet ground, the wheels sinking almost to their different points of the compass, whilst the opposite was louder in favour of a little auxiliary assistance being all that was needed. Accordingly, planks, chains, jacks, and the thousand and one engineering appliances under such circumstances, were tried, but in vain. In spite, however, of the odds against the wheel as at present armed, the efforts the engine made getting out of one difficulty into another astonished everybody, and when the tyres got upon the hard road the engine snorted triumph in the face of its rivals. There is nothing to hinder rubber tires being made sufficiently broad, or other contrivances, so as to carry them through soft ground with as much ease as Aveling & Porter's or Burrell's. When the winning-post became hopeless to "Sutherland," Burrell's second engine started, 4 minutes past 4 P.M., with a load of 7 tons. The tyres of the wheels of this engine are armed with "spuds" or "paddles," which take a better hold of the ground than clips with spikes. The weight of Burrell's 8-horse engine is 64 tons, and with its extra load it reached the winning-post at 5.6 P.M., having thus run the course in 62 minutes. Aveling & Porter's long engine, weighing 84 tons, started at 6.35 P.M., with two waggons, the total weight of the load being 10 tons; this was found too much, but on reducing the load to 9 tons it completed its journey in 60 minutes. Both the engines of this firm called forth the loudest approbation. The spuds were taken off the wheels when they get upon a hard road.

Stafford.—The three fields at the New Buildings Farm, occupied by Mr. Darlington, were plotted out on Monday, and, according to the programme, the engines and windlasses were to be weighed on the public weighbridge at the Shropshire Union Railway and Canal Stone prior to proceeding on the same day to take up their positions on the above fields, so as to be ready to complete the competition for Lord Vernon's cup wheels or other prizes not settled. Very little progress, however, was made in this direction on Monday.

Tuesday, July 4.—The morning and evening were fine, but from 11 A.M. to well through the afternoon it rained heavily without intermission. Very few engines and implements were on the trial-ground when we left at 4 P.M., but the three fields were taken possession of, and the Messrs. Fowler & Co., who were again first in position on the more distant and hilly field—the judges having placed them on the steepest and most undulating ground of the heavy land—were finishing the turning cultivator trial, actuated by two 20-horse engines, one on the top of the hill, and the other on the farther headland below. Prior to this they had finished the ploughing with the same engines, making excellent work about 9 inches deep. The cultivator was set to the same depth. The ground is, perhaps, too wet and soft on the surface for the cultivator; but it is in fine condition for ploughing, the furrow-slice turning up beautifully. The soil is a stiff red tenacious clay, working as freely as at Christmas. In this respect the contrast between the steam-plough trials at the Wolverhampton meeting, and those at the Park, is very remarkable. In 1868 the dust at the gateways was over the shoes, and blinding with the least breeze of wind. In 1871 straw is being used in the showyard under the waggon wheels, whilst at the gateways in the field people will require to take care of their shoes, or they will leave them behind them. It is, however, to the state of the land in the fields that we wish to turn attention. How different is the resistance which the furrow-slice presents to the implement and the motive-power! At Leicester farmers complained that the land was too dry and burnt up to exemplify a fair trial of steam-culture, the same complaint cannot be raised at Wolverhampton. Go to the Stafford trials, and you will see a condition of land closely resembling that of your own land when the greater area of your farm should be cultivated by steam—say from October to March, and as often in April. It is true that the subsoil in many places, as at Barnhouse, is unsound, and that in such places it ought not to be brought to the surface, but that is only the greater reason why the unsound bottom should be subsoiled until it is thoroughly washed; and the soil in question is unusually favourable for subsoiling, breaking pan, and washing land through the instrumentality of steam-culture; and although that opinion may not yet be general, the heavy land at Stafford, as well as the light land at Barnhurst, requires subsoiling and washing, and those who are interested in steam should examine the different operations accordingly. Messrs. Fowler & Co., for example, are ploughing the land fully as deep as it can be done with profit, and when they come to try their deep ploughs, turning up other 6 inches of the unsoil, Mr. Darlington, Mr. Taylor, last week, may justly conclude "that is not a profitable lesson in steam culture." On occasions like these annual trials, losses like the present cannot easily be avoided. The practical objection is, that the two tenants who are thus loser, ought to have ploughed their land the previous year, subsoiled, washed the bottom, and adding gradually to the depth of the staple. And in all cases where subsoiling is necessary, this should be practised with greater assiduity than it now is. Practically speaking, subsoiling, extracting stones, and the like, have not been tried to this year as they ought to be tried, so as to be exemplary to farmers how the work ought to be done. Of course any omission that has taken place does not lie at the door of the Leed's firm, but the contrary, for they exhibit implements both for subsoiling and extracting stones. The practical question for Messrs. Fowler & Co. to teach, that merits special notice, and that is, how to plough and cultivate very hilly land, viz., by dividing the land at the top or ridge of the hill, ploughing and cultivating first the one side and then the other. And they further teach how a 20-horse engine can be got to the top of a hill when the land is in a soft and wet state, and also how to cultivate a steep hill-side when much undulated. The tracks of the engines going up and over the hill, and along the opposite headlands, must have struck everybody who visited the ground to-day. Indeed, the traction-ploughing still laver all natural difficulties that lie in the way. And the manner the workmen got into position, and the way they afterwards held the balance-plough and the turning cultivator under all the circumstances of the case, including the pelting rain, proved how thoroughly they had mastered all of steam-culture and all its details. Throughout the whole of the trials on the light land farms, the working staff of the Messrs. Fowler & Co. were universally admired for the ease and rapidity with which they got their engines and implements into position, and back again to the depôts when the work was finished; and also how few breakages and mishaps attended their labours. Like skilful experienced workmen, success came natural to their hands wherever they turned themselves. They have, in short, got over an apprenticeship which the other competitors would do well to study with the greatest care.

We add to our report the following clever account of the "steam-horse race," from the *Birmingham Daily Gazette* of July 4:—

"We have been assured from influential quarters for some time past, that the introduction of the Thomson road steamer, with indiarubber tyres, would entirely revolutionise the road traffic of this country; that railways need no longer be made through thickly populated districts, for that the road locomotive would be only a better and cheaper substitute; that the flexible tyre, by the enlarged area of its grip on the road, would not only effectually prevent slipping, but would enable the engine to travel over the softest land with ease and impunity; and still more, that the new invention would sweep away all other systems of steam cultivation from the face of the earth, for that any farmer would find it answer his purpose to buy a neat little engine that, at a small expense of fuel, would thresh, grind, saw, cut chaff and roots, plough and cultivate his land, to say nothing about carting his corn in harvest, and afterwards carting it to market, better and

cheaper than horses, and much more economically than the present cumbrous system of windlasses, ropes, anchors, and pulleys, which cost so much to buy, to repair, and to keep in order; in fact, that it would be cheaper and quite as effective for one of these traction-engines to be yoked to a set of ploughs or cultivators, and thus pull them directly over the land, just as horses would do.

"It is the last straw that breaks the camel's back,' and this last assertion was too much even for our credulity. We had listened with patience to the assertions about road traffic, and so on, but with the experiments of the Romain cultivator and the Bordell endless railway fresh in our recollection, we could not bring ourselves to believe in steam cultivation being efficiently and economically conducted by an engine walking over rough land, and pulling tillage implements behind it, Lord Dunmore's experience notwithstanding.

"Messrs. Robey & Co., of Lincoln, had, however, entered for trial an 8-horse road steamer, and a 6-furrow plough adapted to be worked by it, by direct traction, and so we came to Wolverhampton unbelieving, yet anxious to see with our eyes how far the assertions, which to us had sounded so extravagant, had been borne out by the facts.

"To our great disappointment, Messrs. Robey & Co. have not appeared at the trial ground to exhibit the new system of cultivation, but the road steamer, as a traction-engine, is entered in the competition for class 17, by two well-known makers.

"There is no doubt that considerable harm has been done by exaggeration of the merits of a very useful invention, for results falling short of expectations unduly raised do, perhaps, more to discredit an invention, by producing a reaction of popular feeling against it, than any amount of prejudiced hostility could produce.

"The fine weather of last week having given place to a wet Sunday and showery Monday morning, some fears were entertained that the competition of traction-engines announced for 9 o'clock would have to be postponed. The day, however, brightened up, and after many delays had taken place, a traction-engine came up the road at last, followed, with some intervals between them, by five others. Then more delay took place in fetching coals and water, putting out fires and lighting them again, and so on, so that it was more than half-past 2 o'clock before the first could be started. The rule was that every competitor had to declare the weight he wished his engine to draw, and this being weighed out to him in pig iron, the engine was expected to pull it round the course the engines had run on Saturday. A plan of the course, with gradients, had been furnished to every competitor by the Society's engineers.

"The first engine to start was Aveling & Porter's 6-horse agricultural locomotive engine, the same which ran round the mile and three-quarter course on Saturday in 22 minutes. Its price is £300. It has ordinary driving wheels, 5 feet high and 10 inches wide, to which, on soft land, are fastened angle-irons and spikes, to prevent slipping; and on this occasion, the ground being wet and slippery, their aids were very necessary. It steers by worm and wheel motion from the driver's tank. The hind wheels are driven by the ingenious 'compensating motion,' or 'Jack in the box,' as the men call it, which enables the outside wheel only to revolve in turning round a sharp corner, and checks the pace of the other in rounding a curve. The diameter of the cylinder is 7⅞, and the stroke is 10 inches. The gross weight, including driver, coals, and 105 gals. of water, was 5 tons 4 cwt. The weight declared to be drawn was 54 tons gross, including the waggon which carried the pig-iron. At 2.35 the start was made, and after a few stoppages on the bad places of the road, the little engine came in again at 3.27, having done the distance in that time.

"But before the first engine returned the next was started; this was Head & Thomson's patent farm steamer, manufactured by Ransomes, Sims & Head.

"It has a vertical boiler with globe-shaped copper pot in the fire-box, two vertical cylinders overhead, 6 inches in diameter, and the stroke of the pistons is 10 inches. It has three wheels, with indiarubber tyres, those of the two driving wheels being 5 feet diameter, 3 inches by 4½ thick. Weight, including coals, water, &c., was 10 tons 6½ cwt., and the load drawn was 5 tons. The engine started at 3.6, and it was soon seen that the rubber tyre was no remedy for the spiked or spurred iron wheel on wet slippery land. Once or twice the waggon had to be disconnected and chains used to pull the load along. Attendants with planks were frequently in requisition to prevent the smooth tyres from slipping round. At last the crucial point was reached—the engine had to descend into a sort of pit, and having done so it seemed quite impossible that it could ever get out again with its load.

"The waggon was unfastened, but the engine had to be jacked up and planks used before it could get out of the hole and on to level ground.

"To add to the miseries of the situation, a violent thunderstorm came pitilessly down, and drove most of the spectators to seek any shelter they could.

"Mr. Head, however, stuck manfully to his engine, and after some time succeeded in hauling the wagon out of its difficulty. Before, however, he had done so, and, in fact, before the rain came down, Mr. Burrell's 8-horse engine, with ordinary wheels, dragging 7 tons of load, came into the field, ran down the pit side, and after vigorously trying the impossible feat of going up the hill with the waggon, unhooked it, and having gained the level, pulled up its load with chains, and went on its way, and after having to unlimber again at a soft place in the next hedge, it got its waggon through at last, and reached the goal, having run its course in 61 minutes.

"The road steamer followed after some time, but found it quite impracticable to take its load home, so left it in the field.

"What made the misfortunes worse was that they happened under the very eyes of Lord Dunmore himself, and other influential friends of the road steamer. Mrs. Thomson, the wife of the patentee, was also present, and also a lady who had just travelled from Ipswich 170 miles with her husband in a carriage drawn by a similar engine.

"The 10-horse engine of Messrs. Aveling & Porter next went round the course. It is similar to the smaller engine, but its driving-wheels are 6 feet by 18 inches, piston, 10 inches diameter and 12 inches stroke; weight, 11 tons 4 cwt.; load, 9 tons gross, in two carriages. It ran round with hardly a stoppage, except to disconnect at the pit, and got home again in 61 minutes.

"This finished the trial, as Messrs. Tuxford & Sons withdrew; as did also Mr. Burrell, as regarded his road-steamer."

LABOURERS' COTTAGES.

THE following design for a pair of cottages is contributed by Mr. Bailey Denton, jun. It will probably be recognised by many of our observant readers as an old friend in a new dress. There is a proverb which says, that there is "nothing new under the sun;" and Mr. Denton reminds us that the original idea portrayed in this drawing was derived from the design usually called "the Leeds plan," for which Messrs. Ross & Richardson, of Darlington, most deservedly received a prize in 1861. It has, however, undergone considerable alteration; both the ground and chamber floor plans have been re-arranged, and the elevation and details of construction have been altered and modified, and, Mr. Denton hopes, improved. The agreeable appearance of the front elevation (fig. 188) has always attracted landowners, who have also appreciated the very convenient character of its internal accommodation. The living room, scullery, and pantry open into a roomy entrance or lobby, from which also springs the staircase (fig. 189). There is a capacious closet under the stairs.

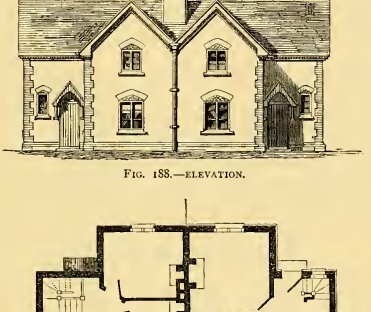

FIG. 188.—ELEVATION.

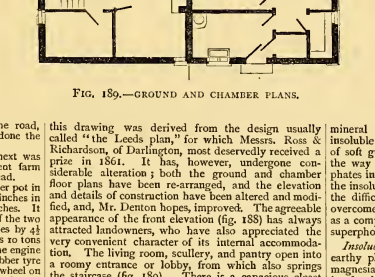

FIG. 189.—GROUND AND CHAMBER PLANS.

The cubical space contained within the cottages is as follows:—Living-room, 1200 feet; scullery, 672 feet; pantry, 196 feet; fuel store, 126 feet; lobby, staircase, closet, and landing, 982 feet; parent's bed-room, 881 feet; second bed-room, 722 feet; third bed-room, 525 feet, which together make a total of 5304 feet cube.

The cottages have varied considerably in price; in fact, from £300 in Wiltshire, to £200 in Shropshire per pair; but we may state that the average cost, without outbuildings and fencing, has been £285 the pair.

They have been erected under the superintendence of Messrs. Bailey Denton, Son & North, in many parts of England—amongst others on the Combermere Estate in Cheshire, the Cheswardine Hall Estate in Shropshire, the Walton Hall Estate in Yorkshire, the Henlow Grange Estate in Bedfordshire, and the Belmont Estate in Herefordshire.

A VALUATION OF MANURES.

[The following report, by Dr. A. Cameron, Dublin, has been published. It was addressed to the Secretary of the Queen's County Agricultural Society, which has shown the good example of protecting the interests of its members and subscribers by submitting samples of the manure they purchase to an analytical chemist.]

I HAVE altered the money values which I formerly attached to certain of the ingredients of artificial manures. These changes will be best understood by reference to the following Table:—

MONEY VALUES OF THE CONSTITUENTS OF MANURES.

	Present Values per Ton.		Values last Year per Ton.	
	£	s. d.	£	s. d.
Ammonia	80	0 0	70	0 0
Biphosphate of lime	30	0 0	36	0 0
Phosphate of lime ..	10	0 0	9	0 0
Sulphate of lime ..	2	0 0	1	10 0
Alkaline salts	1	10 0	2	10 0
Organic matter ..	0	10 0	0	10 0
Potash salts	16	0 0	20	0 0

Ammonia.—This year manufacturers have not been able to procure ammonia at less than £66 per ton, whilst some of them have paid during the present £80 per ton of this substance. As, however, any farmer can buy sulphate of ammonia at £20 per ton (*vide* "prices current"), and as that salt contains 25 per cent. of ammonia, it is evident that the chemist would not be justified in placing a higher value than £80 per ton on ammonia.

Soluble Phosphate.—Superphosphate of lime is now produced of better quality than was formerly the case; instead of containing from 20 to 25 per cent. of soluble phosphates, it now includes from 25 to 35 per cent. of soluble phosphates. As the price of this manure has been somewhat reduced, and as its composition has undergone improvement, I have decided to value biphosphate of lime at £30 per ton, instead of, as formerly, £36 per ton. I would place a higher value on it were it not that the soluble matter of lime with which it is associated is valued at 30*s.* per ton.

Soluble phosphate of lime is prepared by acting upon insoluble phosphate of lime by means of sulphuric or muriatic acid. Whether obtained from bones, or guano, or from coprolites, and similar stony substances, soluble or biphosphate of lime is equally valuable to the farmer.

It cannot, however, be produced so cheaply from guano or bones as from coprolites and other mineral phosphates; but that is a matter which concerns the producer, and not the consumer of soluble phosphates. The artificial manure manufacturer can purchase phosphate of lime at less than £5 per ton in coprolites, whereas he cannot obtain it for less than £8 10*s.* per ton in the form of bones. But why make soluble phosphates from bones? Bone soluble phosphate is precisely the same as coprolite soluble phosphate. No chemist could discover the slightest difference between them, for there is none. Therefore, even in "bone superphosphates," all the soluble phosphates should be derived from a mineral source as from bone-ash, whilst all the insoluble phosphates should be in the form of bone, or of soft guano. There may be practical difficulties in the way of producing a manure all the soluble phosphates in which would be derived from minerals, and the insoluble from animal bones; but the difficulties are not insuperable, and until they are overcome, a bone manure cannot be made as cheaply as a compound of equal value prepared from mineral superphosphate and sulphate of ammonia.

Insoluble Phosphates.—The farmer can purchase earthy phosphates (insoluble phosphates of lime and magnesia) at £10 per ton in bone-ash or bones (allowing for the amount of ammonia yielded by the latter). I, therefore, value the insoluble phosphates in manures at £10 per ton. I am aware that when farmers buy insoluble phosphates in the form of guano they pay more than £10 per ton for it, even when the dealer only makes a legitimate profit by the sale of the article. In some guanos, no doubt, the phosphates are probably in so fine a state of division that they would dissolve more readily in the soil than the phosphates in bone-ash (burnt bones); but still I am of opinion that the earthy phosphates should be sold retail at the rate of £10 per ton, and at that price farmers may procure them in bones and bone-ash.

Insoluble phosphate of lime is of but little, if any, value when it is a constituent of coprolites and dense minerals, such as phosphorite, &c. Manures which contain only from 4 per cent. to a mere trace of ammonia, and from 25 to 35 per cent. of soluble phosphates, are made from minerals or bone-ash. In the former case their insoluble phosphate is of no use;

in the latter it is valuable. Now, practically, it would be impossible to determine whether the insoluble phosphates in a manure are derived from bone-ash or minerals, and therefore I think it the better plan to value uniformly the insoluble phosphate in all kinds of manure at £10 per ton. It will, however, be found that the money value of the high-class so-called mineral superphosphates is but very little influenced by the value placed upon the amount of insoluble phosphates which they contain.

In valuing the manures analysed for the Queen's County Agricultural Society, I think it an excellent plan to value the more important ingredients separately. By this method it will be seen to what extent the amount of ammonia or soluble phosphate influences the total value of the article. By studying these figures the intending purchaser may easily determine the relative values of the different manures as sources of ammonia, &c.

I must now state that the money value which I have placed upon each manure now reported upon refers to its sale in Dublin; therefore your members cannot expect that its money value will not be increased by 8s. or 10s. per ton when it is sold in the towns in the Queen's County. You may, therefore, add, say 10s. per ton to the money value which I have affixed to each manure. Let it be clearly understood that when my value of a manure equals its selling price, the purchaser of it may rest satisfied that he is getting the maximum amount of value for his money.

The manures which I have this year examined for you are, on the whole, very good. The superphosphates are, with but very few exceptions, very rich in soluble phosphates. You have only sent me one specimen (No. 1) of nitrogenous guano, and that I find to be extremely rich in ammonia. I notice, however, that there is a large amount of volatile ammonia contained in this manure, and I would therefore recommend the purchasers of it to mix it immediately with a little oil of vitriol, or with mineral superphosphate of lime, either of which will "fix" the ammonia. One manure (No. 20) contains nearly 18 per cent. of soluble phosphate, and no insoluble phosphate, No. 28, on the contrary, contains 12.23 per cent. of soluble phosphates, and no less than 40.56 per cent. of insoluble phosphates. The addition of sulphuric acid in sufficient quantity would have rendered No. 28 a very valuable manure.

I regret to state that the specimens of Peruvian guano which I have analysed this season are, with few exceptions, very inferior to former years' importation. Indeed, this manure is now very often not worth the price demanded for it, and I would not recommend farmers to purchase it unless it is guaranteed to contain at least 11 per cent. of ammonia. I must also caution your members relative to the potash manure termed kainit, of which there are many spurious samples at present in the market.

Home Correspondence.

Mr. Morgan's Decimals.—As Mr. Morgan began this controversy in your columns, I am sure you will allow me a small space for a reply to his last. It is a fact that Mr. Morgan owes his position as secretary of the company which I created—the Metropolitan Sewage Company—as well as his connection with sewage in any and every way, to me, and to me alone. It is also a fact that in 1865, although Mr. Morgan was, as he confesses, "ignorant of everything connected with practical sewage farming," I had already made a special study of the subject for five years. These facts I never should have alluded to, because of their personality, had it not been for another fact, and that is, that of all the causes operating to retard the utilisation of sewage throughout the country, the chief cause is the obstructive inaction of the Metropolis Sewage Company; for it is a common argument in the mouth of a provincial town councillor opposing sewage irrigation, that it must have failed at Barking, otherwise the Company would have carried out the works. And, according to Mr. Morgan's figures, it has "failed at Barking"—utterly, hopelessly—for out of the 8s. a-head which the sewage is intrinsically worth, he declares, in effect, that he is obliged to waste 7s. 6d. in order to save 6d. It has, therefore, unfortunately, become a national necessity that the complete worthlessness of Mr. Morgan's statements, and the unscientific fallacy of his decimals, should be authoritatively exposed. I challenged him to submit our respective statements to the implement judges of the Royal Agricultural Society. He shirks my challenge, because his figures are purely imaginary, and he dare not face an investigation; but I pledge myself to bring the matter before the Council of the Royal Agricultural Society as a question of the greatest possible importance. Meanwhile, your readers will no doubt hesitate to accept Mr. Morgan's figures. *W. Hope, Parsloes, July* 1.

Mr. Denton's Cottages.—The fair spirit shown by Mr. Makins in his criticism of our designs may well claim acknowledgment, for it is by such means that truth will be elicited and satisfactory results obtained. In the first place, I must remark that in the design specially alluded to by Mr. Makins—as well as in all others which we may, through your kindness, present for illustration in the *Agricultural Gazette*—the regulations with regard to "space within the cottage" laid down by the judges of the cottage designs exhibited at the Royal Agricultural Society's show at Manchester in 1869 (see p. 564, vol. v., part ii., of the second series of the Society's Journal), have been as far as possible observed. They are as follows:—

Report of the Judges on Plans.

"The judges, on entering upon their duties, determined that no design afforded sufficient space unless the floor of the living-room contained an area of 150 square feet, that of the parents' bedroom 100 feet, and those of the children's rooms 80 feet each; and that the height between the floor and the ceiling of the ground floor should not be less than 8 feet, and that of the bedrooms 7 feet 6 inches, thus affording a minimum breathing space in the living-room of 1200 cubic feet, in the parents' bedroom of 750 feet, in the children's bedrooms of 500 feet each. They considered that the 'arrangement and convenience' essential for the comfort of a labourer's family should include a scullery containing at least 250 cubic feet, a pantry with shelves, having a cubical area of at least 250 feet, and a cupboard for fuel within the dwelling, as well as a copper or galvanised iron boiler, either in the dwelling or in an outhouse adjoining, together with proper privy or earth-closet; water supply, including pump; and a perfect drainage of the whole premises."

By a comparison with these rules I find that, whereas the accommodation provided in our design is generally in accordance with the figures just quoted, the cubical contents of the first bedroom in Mr. Makins' design are 28 feet less than those fixed by the judges as the least that should be adopted. Again, with respect to the pantries: although our dimensions are somewhat smaller than those taken as a standard by the judges, we are afraid it will frequently be found in actual experience that they are quite large enough for the limited supply of provisions they are intended to hold. The staircases, which Mr. Makins says are "narrow and awkwardly twisted," are of our ordinary width, and are purposely placed behind the door as being out of sight and easy to go up by, and are too easy of access from the village street. I must repeat, also, that it is not in our opinion advisable to place the pantry in direct communication with the scullery, especially when a boiler is placed in that apartment, and washing is likely to be done there and not in outbuildings. I the more readily make these remarks, Mr. Makins calls attention, with some degree of pride, to the exceeding plainness of his design. I agree with him that convenience and economy should have the first consideration, but I must also add that we have found in practice that designs of cottages may be made too ugly, and that landowners consequently are deterred from erecting them, especially on residential estates, where an agreeable elevation has a certain monetary value. I hope that each specimen we tender will be criticised, and in the same spirit as that adopted by Mr. Makins. I must now, to say, in conclusion, that I think you will do great service to the agricultural interest if you succeed in presenting the cottage question in such a way as to elicit discussion on the several features which govern the cost. By such means we may get rid of delusion and arrive at facts. *Arthur Bailey Denton (for partners and self), 22, Whitehall Place.*

Adulterated Oilcake.—The unexpected publication in your journal of my letters to Dr. Voelcker of May 20th, respecting some cake sold by him to me by Mr. Watling, of Great Yarmouth, has caused that gentleman great annoyance, and me much pain, for having unintentionally occasioned it; and I hope that, for both our sakes, you will publish this letter in your next edition. I did not receive Dr. Voelcker's oilcake referred to in my letter of April 23, but simply, at that gentleman's request, tried the effect of it upon my cattle, and afterwards sent some of it, by his desire, to Dr. Voelcker to be tested; and in my answer of the 29th to the Doctor's question of "Who was the seller of the above-mentioned cake, and the price it was sold at?" I answered that the price was £10 per ton. Unfortunately I added, "but, finding it produced disease in many cattle that were fed with it, Mr. Watling sold the rest by auction,"—which, Mr. Watling assures me, altogether devoid of fraud. Had I contemplated my letters being published, I should have sought further information before I replied. I now learn from Mr. Watling that no complaints were made of the cake up to the time of the auction; nor, indeed, until two of the purchasers at it communicated with the company after the auctioneers, consequently one by a gentleman who had purchased some prior to the auction, and, as he did not press his complaint, Mr. Watling took his to be one of the many cases which he believes frequently occur, when well-fed beasts are put on a change of cake, and this was also the opinion of an eminent chemist who tested some which was sent him to analyse. Mr. Watling further assures me that he sold only a portion of the cake in question by auction, with two other parcels, simply because his stock was in excess of his requirements, and the season near a close, as he has been accustomed to do; but he kept the remainder, and went on supplying his customers with it for nearly a fortnight after the auction, and until he learnt from the two auction purchasers the effects it had had on their cattle, and which (risking the loss of good customers) he would never have done had he known of what the cake was composed. It would seem, therefore, that the cake was bought and sold in ignorance of its deleterious composition, and I much regret that my letters should have raised a question regarding Mr. Watling's integrity in a matter which appears to have been conducted, on his part, without intention to do wrong to any one. *George Varnell, Beech House, Belton, Suffolk, June* 22.

Crops in East Lothian.—The bean land Wheat is this year very luxuriant; there are also some good fields after Turnips, particularly that portion sown in spring. However, in this neighbourhood, the larger part of the Wheat crop is after Potatos, and it is both light and thin on the ground, the straw being short, with rather under-sized heads; still, taking the crop as a whole, with good weather and a favourable harvest, it may ultimately prove an average. Barley has every appearance of being a large crop. The earliest sown fields are now in ear, and the straw is of good length. Oats have rarely looked worse, being apparently diseased at the root, and throughout the county a good field is the exception. Beans are excellent, and at present are loaded with blossom. The Potato crop, as a whole, is highly promising, though in different farms there is almost a total failure on late-planted fields. It is said, where planting was interrupted for a fortnight in April by the wet weather, the sets were lying cut, and thus became heated. Perphaps fully one-third part of the Potato crop has been already singled, at present it may be considered promising. Hay-cutting has commenced, the Rye-grass is tall, but from the deficiency of Clover plants, the weight per acre will not exceed an average. *July* 3.

Cabbages.—In a recent number of the *Agricultural Gazette*, p. 782, there is an article on the cultivation of this most valuable food for the stock of the farmer, a record of the seven years' experience of the writer. He writes—"Have any of our readers discovered a plan for keeping Cabbages?" I have had more than 20 years' experience of the value of this plant to the stock farmer, which has led to my considering it, if not the most valuable, at least of as great a value to him as any plant grown on a farm. I stated as much in my "Handy-book for Young Farmers" some 14 years ago, in which will be found, at p. 418, 2nd edition, directions for the cultivation, which I had found successful. I have tried various modes of preserving Cabbages into the winter, the following I have found to be the most successful. My Drumhead Cabbages are fully grown and ripe at Michaelmas, and are then nearly as solid and hard as a Mangel. Choose any time before frost occurs after some drying weather; cut off the stem an inch or two beyond the outer leaves with a bill-hook, and then place the Cabbage, stem upwards, on the surface between the rows (discarding any immature or inferior plants for present use), close in single line; and then cover the row with earth taken from each side side in a dry state, 3 or 4 inches in thickness, Into these trenches any rain will drain off down the outer leaves. The natural constitution of Cabbage does not admit of its preservation like other roots exposed to continuous rains after the middle of October; but mine, treated as above last year, formed most nutritious and useful food for milch cows, &c., into January last. Much of the early success in setting out Cabbage plants depends on the use of the small 3-pronged hand-fork, as I have explained elsewhere, both in taking up the plants and planting them. Thrust in the fork below the roots, and loosen the soil, when the plants come forth easily without breaking off the feeding mouths, and with some earth attached; then the planter, with a similar fork or a trowel, loosens the earth, and lays in the plant flat, without drawing upwards, as they are too apt to do. The plants so treated will hardly feel the removal, and will grow away freely. Never allow the plants to be pulled up, breaking off the material part of the root, and to be replaced with a setting-pin, the usual course, in a firm round hole. Every "setting-pin" ought to be burned. *Charles Lawrence, June* 26.

Utilisation of Sewage.—Your correspondent "F. P." is a funny fellow, and must, I presume, have been educated in the Circumlocution Office. He writes to you to ask Mr. Mechi to ask me the yearly quantity and value of the sewage of Romford, which I receive on my farm of "Breton's." I much fear he is not the simple and innocent inquirer after truth that he assumes to be. However, whether he is one or not, he is welcome to the information. "F. P." will find full details as to the town of Romford and Breton's Farm in the last Report of the British Association [London, John Murray], which contains the report of the committee appointed at the meeting at Exeter to investigate this subject; meanwhile I may assure him that the sewage of Romford does not average 100 tons per head per annum. The population is estimated (the Census return is not yet published) at from 7000 to 8000, and the average dry weather sewage at 247,000 gallons daily, equal in round numbers to 1100 tons. This is received in tanks, where it is stored, so as to admit of the whole 24 hours sewage being pumped in a day of 10 hours, and of the Sunday's sewage being pumped on the Monday. "F. P." therefore never saw any statement of mine that the pump "was worked continuously night and day." I pay £600 a year for

the sewage. But the annual value of the manurial ingredients of the sewage, or rather of the liquid and solid excreta of "man," excluding kitchen waste and wash-house and bed-room soapsuds, has been ascertained by numerous and careful researches to be about 8*s.* per head of a mixed population of men, women, and children, just as the value of the mineral ingredients of the liquid and solid excreta of sheep is about 5*s.* per head per annum. In other words, this is the market price that shrewd money-making farmers give for the same substances in other forms, although until they are reduced by rain to the same state of solution as that in which they exist in sewage they are of no use to vegetation. The value of the Romford sewage is, therefore—if the population is 6000, £2400; if the population is 7000, £2800; if the population is 8000, £3200. But although I sewage some 20 or 30 acres of my neighbour's land, and about 15 J—not 100—of my own, I still have not land enough to work up the whole of the manure contained in the sewage. I am not responsible for having chosen the term, which I consider altogether too small for the sewage of even 6000 people. I purify, but I do not really utilise, the sewage of Romford. Finally, Mr. Editor, if "F. P." is serious, and will bring a certificate from you that he is really an anxious inquirer after truth, he shall have every other information and assistance that I can give him. *W. Hope, Purslow, July* 1.

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

MONTHLY COUNCIL: *Wednesday, July* 5.—President: Lord Vernon, President, in the chair; the Duke of Devonshire, K.G.; the Earl of Powis, Viscount Bridport, Lord Chesham, Lord Kesteven, Lord Tredegar, the Hon. H. G. Liddell, M.P.; Mr. Acland, M.P.; Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Clive, Mr. Dent, M.P.; Mr. Holland, Colonel Kingscote, M.P.; Mr. Leeds, Mr. Masfen, Mr. Ridley, M.P.; Mr. Shuttleworth, Mr. Thompson, Mr. Torr, Mr. Wells, M.P.; and Professor Simonds.

The following new members were elected:—

Asterley, William Lloyd, The Pentlef, Llanymynech, Oswestry.
Bagnall, George, Draycot, Cheadle, Staffordshire.
Baily, John, Python Hill, Mansfield, Nottingham.
Baldwin, Wm. J. A., Dalton-in-Furness, Lancaster.
Barber, Richard, Harlescott, Shrewsbury.
Bate, John Wm., Astol, Shifnal, Salop.
Billington, J. S., Nethertee Hey, Madeley, Staffordshire.
Briggs, Thos., The Homestead, Richmond, Surrey.
Brown, Charles, Park Hall, Leigh, Cheadle, Staffordshire.
Brown, Richard, Ruyton Eleven Towns, Salop.
Bullock, T. F., Clewer Lodge, Windsor, Berks.
Cannon, H. R., Nagpore, India.
Carr, Wm., Dene Park, Tonbridge, Kent.
Cottle, George, West Felton, Shrewsbury, Salop.
Cope, T. Berwick, Tettenhall, Wolverhampton.
Corbett, W. A., Dumbleton, Evesham, Gloucester.
Davys, W. H. Campbell, Nenadd-fawr, Llandovery, Carmarthen.
Elwell, Paul, Evelith Manor, Shifnal, Salop.
Ford, John, Portland Lawn, Leamington.
Ford, W. H., Merridale, Wolverhampton.
Gibbon, Hy. J., Holmescales, Milnthorpe, Westmoreland.
Gosling, J. W., Little Bradley Place, Newmarket, Suffolk.
Griffin, Thos. J., Preston Vale Farm, Penkridge, Staffordshire.
Griffiths, R. C., Park Farm, Broughton, Chester.
Hollis, Edward, Steam Mills, West Felton, Salop.
Hope, Wm., Parslees, Basing, Essex.
Ironmonger, T., Wolverhampton, Staffordshire.
Jones, G. Stow, Downham Market, Norfolk.
Kempster, Wm., New Cuckett, Ellesmere, Salop.
Kelsall, Thos., Bethisfield, Whitchurch, Salop.
Langford, Wm., Cherbury Hall, Salop.
Lloyd, David, The Hayes, Oswestry, Salop.
Lyne, R. S., Compton, Winchester, Hants.
Mackenzie, J. H., Northwood, West Hoathley, Sussex.
Menzies, G., Trentham, Stoke-on-Trent, Staffordshire.
Miller, J. N., Pathingham, Wolverhampton.
Mytton, H., Garth, Welshpool, Montgomery.
Neame, Edwin, Harefield, Selling, Faversham, Kent.
Nutt, John, Filougby, Coventry.
Pearson, J. C., Newbridge, Wolverhampton.
Pooler, Hy., Calvington, Newport, Salop.
Price, Andrew, Bagley, Ellesmere, Salop.
Rigg, Joseph, Pellongley, Coventry.
Robinson, John T., Leckby Palace, Asenby, Yorkshire.
Saunders, H., Oswestry, Salop.
Smith, Henry, Harnage, Shrewsbury, Salop.
Smith, Henry Wm., Evesham.
Stanley, Hy., Yieldfields Hall, Bloxwich, Walsall, Staffordshire.
Stewart, M. J., Ardwell House, Stranraer, N.B.
Strongitharn, G., Rushall, Walsall, Staffordshire.
Taylor, Wm., Barnhurst, Tattenhall, Staffordshire.
Teanntt, James, Newstead, Nottingham.
Thomas, Edward, The Cross, Oswestry, Salop.
Thomas, Richard, The Buildings, Barchurch, Salop.
Thomas, Thos., Treprenal, Oswestry, Salop.
Thompson, Wm., Walton, Stone, Staffordshire.
Turner, E., M.P., Panton Hall, Wragby, Lincoln.
Wall, Wm. H., Pembury, Tunbridge Wells, Kent.
Wallis, Robert, Stocksfield, Northumberland.
Walters, Stanley, Blythbury, Rugeley, Staffordshire.
Wardle, Joseph, Old Fens Hall, Whitchurch, Salop.
Walker, John, Oil Mills, Leamington.
Whitfield, Edward, Oswestry, Salop.
Williams, M. Dryton, Wroxeter, Shrewsbury, Salop.
Williams, W. G., Bodulwyddan, St. Asaph.
Willis, H. R. D'A., Budgefield House, Halewood, Liverpool.
Wise, J. F., Rostellan Castle, Cloyne, Ireland.
Woodward, F. Spooner, Blake House, Great Saling, Braintree, Essex.
Wright, Lyons, 24, Worcester Street, Wolverhampton.
Yates, F. G., Iron Bridge, Salop.
Yates, James, Atchley, Shifnal, Salop.

FINANCES.—Major-General Viscount Bridport (chairman) presented the report, from which it appeared that the secretary's receipts during the past month had been duly examined by the committee, and by Messrs. Quilter, Ball & Co., the Society's accountants, and found correct. The balance in the hands of the bankers on June 30 was £2528 17*s.* 11*d.*, and £2000 remains on deposit. The quarterly statement of subscriptions and arrears to June 3, and the quarterly cash account, were laid on the table.—This report was adopted.

JOURNAL.—Mr. Thompson (chairman) reported that it was in contemplation to obtain an article for the February Journal, containing suggestions for the improvement of Irish agriculture, with a view to increasing the productive of live stock.—This report was adopted.

CONSULTING BOTANIST.—Mr. Thompson (chairman) reported that in pursuance of the power delegated to this committee by the Council at its last meeting they had appointed Mr. W. Carruthers, F.R.S., and chief of the Botanical Department of the British Museum, to be Consulting Botanist to the Society. A list of the members' privileges, with a scale of fees, will be published in the next Journal.—This report was adopted.

HOUSE.—Major-General Viscount Bridport (chairman) reported that several ceilings require whitewashing, and that a new carpet and rug is required for one of the Society's rooms, and a clock for the library. —This report was adopted.

SELECTION.—Mr. Thompson (chairman) reported that the committee recommended the election of Mr. Brandreth Gibbs as a Vice-President in the room of the late Mr. Samuel Jonas. This report having been adopted, Mr. Brandreth Gibbs was, on the motion of Mr. Thompson, seconded by Lord Bridport, unanimously elected a Vice-President of the Society.

CHEMICAL.—Mr. Wells, chairman. The committee reported that Mr. Wells and Mr. Dent, on behalf of the Chemical Committee, together with the President and Mr. Thompson, had a consultation with the counsel engaged in the case of Bradburn *v.* Royal Agricultural Society, and the result of their interview is fully reported in the report of what took place in the Court of Exchequer before Baron Bramwell. The committee regret that they did not attach sufficient weight to the explanation placed before them by Mr. Bradburn as to his connection with the sale of the manure, and recommend that the analysis of the precedent should not be published in the Journal. Professor Voelcker had reported that several cases of death have occurred amongst cattle fed on a patent cake, and a communication had been received from the Marquis of Exeter on the same subject,—a yearling bull and Shorthorn cow, fed together with linseed cake, died suddenly at Burghley, with all the symptoms of blood poisoning in their system after being fed on this cake. A heifer had also died at the Royal Veterinary College, after being fed on the same cake for 17 days. The condition of the cake appears sufficient to cause injury, but the committee having received another sample of it from the Marquis of Exeter, had requested Professor Voelcker to make a more detailed examination, and a full report of this sample, and also to procure a sample of fresh cake for the purpose of comparison. The committee wish to call the special attention of the public to the opinion of Professor Voelcker on the subject of stale and mouldy cake, as given at pp. 142, 143, vol i., 1865, and further to the caution which should be exercised in the purchase of cakes composed of several different ingredients, and which after keeping for some time in bad condition may have the effect of setting up decomposition in the other constituents of the cake, and thus produce injury to the stock using it. In reference to the case of a patent blood manure, sent by Mr. F. Minett, the committee have received an explanatory statement from the makers, Messrs. Griffin, Morris & Griffin, which they recommend shall be inserted as an appendix in the next issue of the Journal. This report having been adopted, it was moved by the Earl of Powis, seconded by Mr. Leeds, and carried unanimously, "That the Council approve of the course pursued as to the action with Mr. Bradburn by the President and gentlemen who attended the consultation with Sir John Karslake."

VETERINARY.—Major-General Viscount Bridport (chairman) reported that the committee had had an interview with the General Purposes Committee of the Royal Veterinary College, at which it was ascertained that there was considerable difference of opinion between the Veterinary Committee and the Committee of the Royal Veterinary College. A copy of the Council minute of June 5, 1861, which contains the latest arrangement in reference to veterinary privileges made between the Council of this Society and the Governors of the College, has therefore been forwarded to the Governors, with a request that they would communicate officially their views on the subject. As the August Council meeting is generally thinly attended, the committee suggested that they should defer making their report until the November Council. Professor Brown having been requested to visit Coldham Hall for the purpose of investigating a serious outbreak of splenic apoplexy amongst cattle, the committee presented his report, and recommended that it be published in the Journal and his expenses paid. The committee also recommended that Professor Simonds be allowed the travelling expenses of two veterinary assistants at the Wolverhampton meeting, and also that the remaining half for experimental purposes, viz., £25, be granted. This report having been adopted, Professor Simonds made a statement in reference to the patent cake, which had been referred to by the Chemical Committee; and Mr. Torr stated that, as a preventive of splenic apoplexy, he had successfully used weekly doses of half an ounce of saltpetre; or, in the case of very large and heavy animals, as much as an ounce.

EDUCATION.—Mr. Holland (chairman) reported that the present system of examination had been commenced in 1868, when £60 were distributed in prizes. In the following year (1869) two life memberships were gained, and £75 were given away in prizes. In 1870 no prizes were distributed. This year two life memberships have been gained, and £60 have been awarded in prizes. Thus, in the four years, four competitors have been made life members, and the sum of £195 has been awarded in prizes.

In the first year (1868) 18 candidates entered, and 12 attended the examinations, but as no one passed in book-keeping, which was a *sine qua non*, no prizes were awarded, although in other respects the results of the examinations were satisfactory.

In 1869 there were 21 entries, and 18 candidates attended; of these, two took a first-class, and eight were second-class men. In 1870 only two candidates entered; both attended, and both failed. This year there were nine entries, four attended; of the four two are first-class men, and have gained life memberships, and one has gained a second class.

The committee recommended that the usual fees be paid to the examiners for the present year, and stated their opinion that more time must elapse before the advantages arising from success at these examinations can be generally appreciated. They intended, therefore, at the August Council meeting to apply for a renewal of the grant on the same conditions, and on the same terms as those of last year.—This report was adopted.

The following noblemen and gentlemen were appointed a general Cardiff Committee:—Lord Vernon (chairman), Earl of Lichfield, Earl of Powis, Viscount Bridport, Lord Chesham, Lord Kesteven, Lord Tredegar, Sir Massey Lopes, Bart., M.P.; Sir A. K. Mitchell, Bart.; Sir Watkin W. Wynn, Bart., M.P.; C. E. Amos, C. Barnett, T. C. Booth, Edward Bowly, Charles S. Cantrell, D. R. Davies, Joseph Druce, W. J. Edmonds, B. T. Brandreth Gibbs, Richard Hornsby, C. Wren Hoskyns, M.P., Col. Kingscote, M.P., Robert Leeds, R. H. Masfen, Richard Mayor, Charles Randell, R. C. Ransome, M. W. Ridley, M.P., William Sanday, Joseph Shuttleworth, William Torr, James Webb, William Wells, M.P., Charles Whitehead, Lieut.-Col. Wilson, Jacob Wilson, the Stewards.

Mr. Thompson having moved the following resolution:—"That in future the list of questions to be answered by towns competing for the country meetings shall include one calling for a statement of the maximum cost of the land required for the trial of implements, the acreage wanted being furnished by the Society," it was seconded by Mr. Torr, and carried unanimously.

Mr. Torr then called attention to the relaxation of the restrictions on the Foreign cattle trade recently made by the Privy Council, and to the injury which may have been thereby inflicted on English herds; he regretted especially that only 12 hours' quarantine was required to be passed by animals from countries, and thought that it ought to be prolonged. He regarded the present scarcity of store stock as one of the results of the cattle plague, and he, therefore, viewed with alarm the result of allowing cattle to be imported from Hamburgh, as had recently been the case, according to his information, into Great Britain, through the port of Grimsby.

Prof. Simonds, as connected with the veterinary department of the Privy Council, wished to state that the reports which appeared in the newspapers from time to time as to cattle disease were often greatly exaggerated, and he stated that the statement quoted by Mr. Torr in reference to importation of cattle from Hamburgh was utterly untrue. No cattle are allowed to be imported into the British Islands, unless slaughtered at the port of landing, except those from Holland, Spain, and Denmark: and these countries do not allow the importation of cattle by land or sea Formerly the importation of cattle into Holland, and their transit through that country, were sources of considerable revenue to its Government; but both these branches of the cattle trade had been suppressed by Royal proclamation for the sake of preserving the export trade. The cattle were all carefully examined before being shipped, and after arriving in England two separate inspections were made at intervals of not less than 12 hours, therefore the risk was reduced to a

minimum. If, however, any case of disease were discovered, the whole cargo was immediately slaughtered, and the ship cleansed and disinfected ; and the owners of each vessel engaged in conveying cattle from Holland, Denmark, and Spain, were required to give a bond to the amount of £1000 that it had not been employed for the conveyance of cattle from the scheduled countries. In answer to a question by Mr. Dent, he added that pleuro-pneumonia was not prevalent in Holland, except in a very limited district.

Mr. J. Dent-Dent, M.P., considered that Mr. Torr had raised a very important question, and that Professor Simonds' explanation of the regulations of the Privy Council was very satisfactory. If the Council of the Society were of opinion that the importation of store stock should be prohibited, then they ought to make that representation to the Privy Council ; but if they were not prepared to recommend so serious a prohibition, he did not see that they could recommend that any additional precautions should be taken.

Mr. Thompson concurred in this view, and thought that the alarm of people on this question often arose from ignorance of the precautions that were adopted, and he also considered that any considerable extension of the period of quarantine would put a stop to the trade in foreign cattle.

Mr. Dyke Acland, M.P., also expressed his satisfaction at hearing the explanation given by Professor Simonds, and he felt that the agricultural public ought to have the statements that had been made placed before them in an official form ; he therefore moved :—

"That the Council having heard a statement from Professor Simonds, as to the present regulations of the Veterinary Department of the Privy Council, and as to the precautions adopted with regard to the importation of foreign stock, are of opinion that it would be desirable to obtain such a statement in an official form, and consequently that the Privy Council be requested to allow Professor Simonds to communicate to the Council of the Royal Agricultural Society for publication the exact regulations and restrictions under which the importation of foreign cattle is now carried on."

This resolution, having been seconded by Mr. Thompson was carried unanimously.

EAST KENT.

Land Drainage—At a meeting of the Chamber of Agriculture, held at Canterbury, Mr. WEBB, of Sittingbourne, read the followng exhaustive paper on this subject :—

He said : I think the subject of drainage, proposed for to-day's discussion, is one that may very properly follow the last we heard in this room, namely, Mr. Aveling's excellent paper on steam cultivation, because I feel certain that not only can we thoroughly develope the full advantage of that new and useful system of cultivation without first obtaining perfect drainage, for the more stiff land is pulverised the more it will retain and absorb moisture. In a national point of view our subject is a very important one, for we have, according to the best authority Mr. Read Denton, 20 million acres of undrained land throughout the kingdom, and we have many thousand acres in Kent. Now, as Mr. Baily Denton reckons that it will cost at least 100 million pounds sterling to perfect this class of land improvement, we must, I think, all regret that the surplus capital of this nation has not now to go more towards increasing the wealth and salubrity of our own island than in being drained off, as it is, in Russian, Turkish, and other foreign bonds. Although we read that the Romans well understood the art of draining 2000 years ago, yet, until the commencement of the present century, the efforts of our own countrymen appear to have been most lax in getting rid of their superabundant water, nor was much good pipe drainage done until 1846, when Parliament granted 3½ millions of public money to be advanced to landowners on the security of their estates, both capital and interest to be paid off in 22 years. The avidity with which this loan was sought and expended soon gave rise to various companies, and we have now the Lands Improvement Company and several others, all of which are willing to advance money under the Private Moneys Drainage Act, the interest charged being generally at the rate of 5 per cent., and 1½ per cent. per annum for the redemption of capital, thrown over a space of 25 years. I need hardly revert to the immense benefit which our country, but chiefly the agricultural portion, has obtained by the organisation of these public bodies. The impetus given to the improvement of estates has been immense, and a tenant for life of an estate has now the opportunity of expending money in permanent improvements without doing injury to the younger branches of his family. Although I have seen the operation of drainage in other counties, my own experience of the working part has been entirely confined to Kent, but I hope I may be allowed to say, without presumption, that I have had full opportunity of judging of the underground strata of this county, having had the superintendence of drainage works from one corner to the other. In early life I had the management of a clay farm, and I soon saw that without drainage there was an immense waste in the outlay both for labour and manure, and from the trials I made then, both by test holes and by draining parts at different depths, as well as by leaving intermediate spaces undrained, I came to the conclusion that deep drainage was the most effective ; and I can say, after having done 6000 acres, at the cost of, perhaps, £40,000, that I never had to regret (even in a single field) going too deep, or the outlay that has been made. I will not say that the work has been done as well as I could have wished, but now that we get better workmen and better pipes we shall I hope also see an improvement in the work generally. I propose to consider the subject before us under four heads :—1st. Is drainage necessary at all? 2d. What is the best method of carrying out the works? 3d. What the probable cost? 4th. The advantages obtained.

1. *Is Drainage Necessary?*—I think that all land which requires surface furrows or open drains would pay to drain, for I cannot believe that stagnant water remaining in the soil can do any good, but the reverse ; it must impoverish and deteriorate the better qualities of the earth, for after the land is drained the soil becomes a filterer, retaining the good properties which we are told both rain and snow bring down, while the roots both of plants and grass have freer action and go deeper in proportion as the soil is dry. In this we have one very good example. Upon undrained land, Wheat will frequently get root-fallen just previous to harvest, but we rarely notice heavy land, if it is drained, and at all in good heart, to be liable to rootfallen crops. I may also say the simple plan of finding whether the soil is surcharged with water is to dig a hole 4 feet deep, and to place four drain pipes upright, one on the other ; if the water rises in the hole and remains in the pipes after three or four days, it is a clear proof there is a tenacious soil underneath which prevents the water from getting away. I believe there is a good deal of land, which, although it cannot be termed clay, yet, partaking of clay and loam, would pay to drain. I allude more particularly to those fields that we find feed badly with sheep, even in wet seasons, on Turnips, they will frequently be up to their hocks in mud ; also there are many lands which, although no water is visible on the surface, require draining. For instance, I have seen several cases of marsh land where the surface has been so dry and sound that a four-horse team would hardly have turned a furrow, and I remember one in particular which some members of the Farmers' Club came to see. The surface was quite dry and hard, and, but for the purple and sickly hue of the grass, one would hardly have dreamed of water. In cutting out the first 3 feet of these drains the soil was quite dry to work, but when 4 feet deep the water spun out so fast that the pipelayer could hardly see to lay the pipes. I must mention another circumstance which came across me this year in draining under the chalk hills near Charing. The surface was quite dry at times, but as it had to be cropped with Wheat, we were obliged to begin the work early. The soil was a chalk rubble, mixed with flint stones and a stiff clay, and the men had to pickmattock the greater part ; at 3 feet deep the soil was quite dry, but at 4 feet the water ran a stream. The drains I have mentioned as having drained well, had little good effect. In speaking of draining marsh land, I feel I am treading on tender ground, for I know many excellent graziers who would not have their marshes drained if done free of cost ; but this I cannot understand, for while many disagree as to draining upland pasture, all agree as to the great benefit of draining upland pasture. Now if it is right to take away the water in one instance, surely it must be in the other. No good gardener in these days attempts to water his plants at their roots, because they thrive so much better if the moisture is supplied on the surface, and I also think it must be most injurious for grasses to lie for months with moisture at their roots. The question I think is this : Is water remaining stagnant at the root of grasses injurious to them during the winter and spring months? Is it not necessary for the sake of warmth and assistance to the plant at the time of need, namely, the summer months? My opinion is, that by relieving land of water when it is overcharged, the soil is left in a better condition ; it does not crack so much in hot weather, and the roots penetrate deeper ; great improvement is also seen in the rills and low places ; for whereas, undrained, they only produce coarse stringy grass, after draining they yield the best of herbage. Again, we have much land that rots sheep, and upon this there cannot be a doubt, for in some seasons the loss is immense. In 1860 I sent a sheep to one farm to be kept, and only one survived this disease—entirely occasioned by excessive wet.

2. *The Best Methods of Land Drainage.*—In passing on to consider the best mode of doing the work, it appears to me that in addressing the present assembly, consisting as it does of so many practical men, I shall be treating of matters which are everyday work to you, but unless I enter a little into detail I feel I shall not be doing my duty. The object of all drainage should be to make it as permanent as possible, and as the landlord has the most durable interest in the soil, he is, I think, the person that should have the work done, charging a percentage on the outlay. The system of the landlord finding tiles, and the tenant the labour, is most objectionable. I am not referring now as to whether the bargain is or is not a fair one, but, supposing that part to have been well considered, experience has taught us that under this arrangement a great deal of bad draining has been done, and money wasted, for a tenant has rarely a staff of men who understand the work, and each bottomer (as he is called) is allowed to lay his own pipes. Fortunately for us the great controversy as to deep and shallow draining is pretty well at an end ; therefore we may, I think, consider that where 4 feet can be obtained, that depth should as a rule be adopted. I am of course in this (as in all other matters) speaking generally, because we now and then find a field in which, for want of fall or some other cause, it is preferable to go 3 feet. The only land I ever doubted as to the advisability of draining 4 feet deep is the Wealden clay, which we find abounding from Ashford to Bethersden, Tenterden, and indeed nearly through all the Dene into the Weald of Sussex ; not that I am afraid as to the water getting down into a 4 feet drain, but whether the land is worth the additional expense, or, in other words, whether a 3 feet drain does not take off the water sufficiently for all farming operations. In one point there is, I think, a great difference between the yellow plastic clay of the Weald district and the blue or London clay which lies in the Beckenham, Sheppy, Hoo, and Whitstable districts ; for, although both soils are equally strong and tenacious, yet it appears to me the blue clay opens the most in dry seasons, and this much increases deep drainage. I also think (but I may be wrong) that there are more fertilising powers in the subsoil of the blue than in the yellow clays, and where the roots run the most the water is certain to follow. I hope to see the day when a Royal Canal is laid from the range of chalk hills into the Weald ; with the co-operation of the landed proprietors this might be effected at a moderate cost, and nothing would more benefit deep drainage than a good supply of chalk. On our most retentive clays it is, I think, a great mistake to put our drains too near the surface because we must put our drains deeper we should attempt to set them further apart ; 6, 7, or in some instances 8 yards is quite wide enough. Knowing that Mr. George Neve, of Sissinghurst, has had several thousand acres drained under his management in the Weald of Kent, and knowing how practical he is in all matters connected with the cultivation of land, I have asked him for the benefit of his experience, which he has kindly given me. It is as follows :—"I may say in the first place that I am convinced that no rule should be laid down as to the depth of the drains, but that nature of the soil should decide it. In no case that I am aware of has the 3 feet failed to drain the land perfectly in the stiff clays at 1 rod apart, and in the lighter soils at 1¼ rod. The 4 feet drains have been put in from 1½ to 2 rods apart, and in a few instances even further apart. Thirteen feet is the largest area I recollect. I find that even in the lighter soils the land is longer drying in the spring than with 3 feet draining." I shall also quote, with his kind permission, the opinion of another gentleman who has drained much in the same district, Mr. Rutherford, of Hothfield, who says : —"I have several experimental drainages at different depths, my most shallow drains are now always 4 feet, even upon the stiffest soils, and I very much prefer this depth to anything less. I vary the width between the drains from 18 to 33 feet, according to the subsoil." Now, before quitting the point as to depth, I must further state that hitherto we have not had the aid of so valuable an auxiliary as the steam-plough, for we shall now not only have the wet land ploughed as deep as may be required without the treading of two or four heavy horses up the furrows, but we shall have the whole of the subsoiling performed at a moderate rate, and this has hitherto been a very costly operation when done with horses ; indeed, I look upon this as the greatest boon to the occupier of wet land, for before a good subsoiling alone cost from 22*s.* to 24*s.* per acre, and now I understand ploughing and subsoiling by steam can both be done for about 25*s.* per acre. In setting out the work, the first thing is to look well to the outfall, which should be placed so that there is no possibility of roots getting into the drain ; there should also be no discharge or entry of any surface water, such as deposits to accumulate before the outfall, and it may be advisable, rather than choose a spot which will not give a depth of more than 30 inches, to carry the main across another field, which would give 4 feet. It also frequently occurs that a sufficiently good outfall cannot be obtained without getting the consent of an adjoining owner to cut through his field, and here, I may remark, that although the Land Drainage Act 1861 does provide powers for carrying a main drain or an open sewer through the estate of an adjoining owner, still it is to be regretted that in most ordinary cases of drainage, the expenses incurred in carrying out the necessary forms are too great to enable persons to avail themselves of the provisions of the Act. If the outfall is placed in a ditch where there is a hedge, it is a good plan to have 3 or 4 feet of iron pipe of the same size as the main, as that effectually prevents roots getting in, and all drains (whether mains or minors) should be placed far beyond the range of Elm or Ash roots. I have known Elm roots to travel from 40 to 50 yards from the parent stock, and I much doubt whether a drain (even 4 feet deep) is ever safe from the reach of Lucerne roots, or a 30-inch drain from

those of Mangel or Carrots, for the moisture in a drain is always attractive to roots of any kind. We have found it better to dispense with any grating before the pipe at the outfall. In the spring following the completion of the works the outfall should be headed up with brickwork and Roman cement; all minor drains should be carried into a main, and not allowed to empty themselves into a ditch, for one outfall is easier to watch and protect than so many. The main drain should be laid with a good fall and in an oblique direction to the minors, and when it is ascertained what area of land is to be carried to any one main drain, care must be taken that the size of the main pipe is all-sufficient. For instance, it will require a 3-inch pipe to carry 3 acres, a 4-inch pipe for 5 acres, a 6-inch for 12 acres, and a 9-inch for 30 acres, and so in proportion. The minor drains should be cut parallel to the rise of the hill, falling with a slight curve into the main, which is generally laid about 2 inches under the minors. I think all agree now that the drain acts much more evenly in this way than when the main is put across the slope, and anyone who has tried by test holes the two plans must have observed that the former is the best. The small pipes should be a good 2 inches in the clear, well burnt and evenly cut; but up to the present time few of our tilemakers have made the 2-inch pipes to the full size, and it is better to pay an extra 2*s.* per thousand than have them undersize. All the pipes should be laid by one foreman, or by a pipelayer pointing him, one then being made responsible for the efficiency of the work. The pipe should be turned on the hook until it fits well with the last one made, and after they are all in, the drain should have the even appearance of a length of rope. The pipe should then be covered with the stiffest soil, and no more covering necessary except in sandy or gravelly soils, where it is frequently requisite to use straw to prevent the drain from silting, especially if the work is done in wet weather. Where the soil is all sand, it must be better to use collars with the pipes, the saw answering a good work done in this way by Mr. Rutherford (whom I have quoted before). On the question of collars, he says:—"I very much prefer the pipe and collar to the old tiles and sole. First, they answer better in all soils; secondly, the water percolates as freely into the former as into the latter; thirdly, I have never had a pipe and collar drain stopped up by sand, but am always most careful not to have a sharp fall at the upper part and a less fall at the lower. The cost of the collars is 10*s.* per 1000." I hardly think it necessary to mention any other material than pipes. I have always found they have been the most efficient, and where the distance to a tilery has been very great. Although they make an imperfect conduit, they have answered well, but I much prefer pipes; there is little saving of expense, except on the score of cartage. We have also used brushwood on a small scale in woods, where we have found the Oaks getting choked and send the Ash dying. The work has been done in this way: Instead of cutting the usual 2 feet grips, we have cut them 4 feet deep, and filled up about one foot of the bottom with furze or brushwood cut on the spot, and I believe the benefits will be very great and lasting. The Oak timber is certainly wearing out fast on some soils, and if by the additional cost of 4*d.* or 6*d.* per rod the roots can be laid drier it is worth consideration. In draining marshes a sufficient fall can rarely be obtained; by carrying a drain to the common ditches. We find it necessary generally to carry the outfall to the fleets, which formerly were the main estuaries of our creeks, for nothing less than 6 or 7 feet is of much use, as marshes are so flat and the water so sluggish, that unless the minors enter the main at about 5 feet 6 inches, the men have a difficulty to keep their depth. It is better not to run the minors in flat marshes beyond the length of 120 to 180 yards. On a hill district, such as Dover and Folkestone, we often find a strong clay soil overlapping a substratum of chalk or stone, and it is not unusual in such situations to find the fields dip to the centre, where there is the possibility of getting a main except at great expense, and in such places it will be found best to sink a small well, as the water then readily gets away through the fissures of the chalk or rock. I cannot pass on without alluding to one great assistant to our drage drainage, although we do trample him under our feet—I mean the worm. We have only to examine a good piece of porous brick earth, and we find the worms have sunk fine perpendicular holes at least 8 to 10 feet deep; and as the worm is fond of clay, so it is found that they increase and assist the fertility of the soil. At present we have hardly enough in our marshes, and I think we should do right to import some from the hill pastures, where they abound. To give you an instance that they do not naturally live in either wet or salt marshes, my grandfather enclosed about 100 acres from the sea at least 80 years ago, and the old "looker," who had lived there many years, told me he had never seen a worm on the island until we sent him some Mangels for the ewes.

3. *Respecting the Cost of Land Drainage.*—I think if I give an estimate of 1 acre drained at an interval of 18 feet apart and another at 33 feet, I shall be taking the width most usually adopted for the very stiff as well as for the milder soils. The prices for cutting are those which would be paid on an average of years; but after a very dry summer, they would not be sufficient. We have had to pay as high as 10*d.* or 11*d.* per rod when the work has commenced early after harvest, and 12. 3*d.* to 12. 6*d.* per rod where there has been much gravel. In Kent I find the cost of both labour and pipes to exceed the prices paid in other counties. This I consider we may attribute to the labour market being generally higher in this county.

Cost of Draining 1 acre, 21 feet apart, 4 feet deep.

125 rods of cutting at 8*d.*	..	..	..	£4 3 9
2083 pipes at 22*s.* per 1000	..	..	..	2 10 3
Mains, labour and pipes	..	..	..	1 0 0
Heading drains ..	..	..	..	0 1 0
Laying in pipes ..	..	..	..	0 0 10
Cartage	..	..	..	0 6 0
Total	..	..	..	£8 11 0

Estimated cost, 33 feet apart.

80 rods of cutting at 8*d.*	..	..	..	£2 13 4
1452 pipes at 22*s.*	..	..	..	1 12 0
Mains, labour and pipes	..	..	..	1 0 0
Heading drains ..	..	..	..	0 1 0
Laying in pipes ..	..	..	..	0 6 8
Cartage	..	..	..	0 4 0
Total	..	..	..	£5 17 0

4. *The advantages obtained* are so clear, that I need hardly take up your time much longer. That there is a considerable increase in the crop, and especially in wet seasons, is quite certain. To speak positively of the increased value from draining on pasture land is a much more difficult task; one can keep the produce of an acre of corn separate, but to say how much more weight of grass or extra quality in the grass is not quite so easy. I can, however, give you some data that it does pay to drain and improve marshes, and I shall give these results for what they are worth, because, besides draining, there have been other improvements made. In 1849 I had the management of 400 acres of marsh land; the land was all undrained, and more or less covered with rushes and ant-hills. The produce of wool for the first seven years 1849 to 1856 (before the land was thoroughly averaged year) 25 pounds; from 1856 to 1863 (while the works were in operation) 31 pecks; from 1863 to 1870 (since they were completed), 37 pecks; being an increase of 12 pecks; and as £19 has been the average price for the last seven years, the increased value has been £228 per annum. I think the produce of wool almost a better guide than that of mutton on such an occupation, because the returns from sheep vary so much both as to prices made and the mode of grazing. I am, however, bound to say that owing to the drainage, the 1868 and 1870 returns for the last three years have been less than for any year since 1849; and although the land is improved the loss has been considerable, indeed no human power can withstand the effects of such seasons, and we must bend to the will of One who orders all for the best. From the closest observation I have made, I have not found that the drained marshes have suffered more from drought than the undrained. We have had for the last three years a less downfall of rain than for many years. I find the average has been (taken three miles from Sittingbourne) 24 inches 146 feet above the sea; not quite 22 inches, whereas for the 20 years previous to 1868 the average was 27½ inches. We have, therefore, about 15½ inches due to give us the same average for 23 years. The consequence is, our marshes and grass lands have suffered much from the want of water, and they will not recover, but the cold stiff uplands have looked better. Why is this? Because they have had no excess of wet, and are enjoying natural drainage. As we cannot very well store our superfluity of winter water, we must look forward to devising some plan for irrigating our marshes by water supplied from artesian wells; and I hope the time is not far distant before some trials will be made. The expense of getting the water does not appear to me so great an obstacle as the cost of preparing the surface for irrigation, for our marshes are very irregular. In speaking of storing water, a valuable member of this Chamber (who is not able to attend to-day) named to me yesterday the importance of some better steps being taken on the hill districts to provide reservoirs for the winter water, either in large ponds or tanks. The cost of sending water to other has been very great to many of the farmers on the hills. One other advantage is that the temperature of a wet district must be improved by a good system of deep drainage. All writers agree that the evaporation of water adds greatly to the temperature, but this is beneath the surface, and especially of a retentive soil. And as regards the importance of climate, I can give you a very good illustration. In 1859 I sowed the same sort of Wheat on two farms, one in Sheppy, the other at Frinsted. Both crops were harvested as well as the year 1860 would allow. The produce of both was sold in the same week in November, 1860; one realised about 64*s.* per qr., the other 34*s.*, and yet the distance, as a crow flies, was barely 18 miles. I do not say that you can expect to have the same climate at Frinsted as in Sheppy, but I do believe that the temperature of a large district like the Weald will be much improved by drainage. I shall conclude by saying that I do not see why draining, if done effectively, should not last from 50 to 100 years. I produce two pipes which have been taken up from two marshes, and which have been in the ground nearly 20 years. Although the bore is only 1¼ inch, you will observe there is hardly any deposit in the pipe. [The pipes produced were handed round to the members of the Chamber, and examined attentively.]

Discussion.

The Chairman said he was sure they had all heard with great satisfaction the exhaustive and valuable paper of Mr. Webb, and it was almost a pity to detract from it by reading anything more, but he had a paper by Mr. Frederick Neame, who, he was sorry to say, was unable to be present, but who would be very pleased if they would allow his paper to be read, which would further elucidate the views expressed by Mr. Webb. He would therefore call upon the Secretary to read it.

The Secretary accordingly read Mr. Neame's paper, as follows:—

"Macknade, Faversham, Juoe 23, 1871.

"Dear Sir,—I am sorry to be prevented attending the meeting of the Canterbury Chamber of Agriculture to be held to-morrow, to support our Honourable Chairman and to listen to the paper which Mr. Webb has so kindly undertaken to read on Land Draiouge. It is a subject so important, one in which those who own land, those who occupy land, and those who consume the produce of the land, are much interested, because by good drainage, followed by good cultivation, the produce of the land is much increased, and I feel that our honourable chairman and the gentlemen who have undertaken to read a paper before the Chamber are entitled to look for the support of the members; without a good attendance of members the papers lose much of their interest to those who take the trouble to prepare them, and indeed for this reason (which I feel to be a very strong one), as my absence is unavoidable, I venture to offer a few remarks on the subject for discussion.

"A few simple observations will, I think, satisfy many persons that deep draining—by which I mean drains cut 4 feet deep—and more effective than shallow drains—by which I mean drains cut 2 feet (except on very tenacious clays)—the shallow drains scarcely draining the land that is tilled, the deep drains draining the land that is tilled and the subsoil also. In the latter case plants situated with wet the roots of plants are deterred from entering it, or if they enter they perish. The evil lies generally deeper than the vegetation. The limit is not beyond our reach, at any rate we should endeavour to approach it. As the subsoil becomes drained the roots of plants perforate it more freely, and where the roots can go the water can follow, and by degrees the subsoil becomes porous; but a very dry season is very desirable after draining on very stiff land, for the purpose of opening the subsoil and rendering it porous. After wet seasons, treadiog heavy land by horses (especially in wet weather) often prevents the drains working so effectually as they otherwise would do. There is a doubt about deep draining on what we term very hard tenacious clays, which still exists among many eminent practical drainers. My own opinion is that deep draining should be done, and deep draining only, by the judicious exception. By deep draining there is no fear of the drains being stopped by deep cultivation, and less fear of their being stopped or interfered with by roots of Hops, or roots of Elm, Ash, or other trees. As the subsoil ploughs renders all stiff land more pliable, there is not that fear of the pores of the earth being stopped as there is by horse cultivation. In fact, I almost incline to think that where the steam-plough is used deep drains will become a necessity, and as steam-ploughing is most useful on the heavy lands so deep draining must be adopted on them.

"The facility of obtaining money for land draining and dividing the repayment over a number of years is worthy of consideration.

"I was in hopes I might have been present to agree with the remarks Mr. Webb may make, or to have discussed any points he may differ from.

"I trust to the kindness of the meeting to receive this from one who wishes prosperity to the Chamber of Agriculture.

"I remain, dear sir, yours faithfully,

"Frederick Neame.

"George Slater, Esq."

Mr. Murton proposed a vote of thanks to Mr. Webb for his paper. Mr. Webb had given great attention to the subject, and he thought we had got nearly done with the main points of his address. In proposing a vote of thanks, therefore, he would suggest that the paper should be printed and published, in order that members of the Chamber might have the opportunity of reading it at their leisure.

Mr. Dowker seconded, and concurred in the suggestion that the paper should be printed and circulated among the members of the Chamber. With regard to Mr. Webb's remarks, he entirely agreed with him. He could have wished Mr. Webb had said more about draining the marsh land, because in this part of the country they were highly favoured as to arable land, for they had land requiring as little drainage as any other part of Kent with the exception of gravel soils. In the Weald it was of course very different, but they had a considerable quantity of marsh land; and he was perfectly satisfied, and had been so for some years, that no land whatever in East Kent, would pay better for cultivation and drainage than marsh land. Some persons were of opinion that marsh land could not be drained without its drying up in dry summers, but he must say that his experience of marshes which had been drained was the very reverse. Where land was wet in winter time, it would be found to be all the more burnt up in summer time. Grass roots could not penetrate stiff soils; but if the land was more deeply cultivated, it would produce better grass. In many marshes he knew, before they were drained they grew nothing but coarse water-grass, which perished in the summer heat, but the same marshes when drained produced much finer and better grass. He considered they were all much indebted to Mr. Webb for his interesting and able paper.

The vote of thanks to Mr. Webb was then put and carried unanimously.

COOLE AND MARSHLAND.

Economical Management of Farmyard Manure.—At a late meeting of this Chamber of Agriculture, Mr. J. Wells in the chair, a paper was read on this subject by Mr. CONDER, of Pontefract. He said:—

This subject has an additional interest at present, when the question "How to prevent the pollution of our rivers by sewage from our large cities and towns" has become one of the great problems of the day. Every English farmer must deplore the waste occasioned by the present system of water carriage of sewage. It therefore must be a matter of some interest to us to discuss how best to conserve and how most judiciously to use the ordinary manure made on the farm. There is no doubt the system most generally pursued may be improved upon—in the fold first, by more carefully mixing the different constituents together, so as to secure greater uniformity in quality; then, by the prevention of waste occasioned by filtration or evaporation, by employing the means which chemistry has made known to fix that valuable but highly volatile substance, ammonia. To secure this end, foldyards entirely covered over are preferable to open yards; but when, on account of the money outlay necessarily involved, these cannot be had, the next best thing is to prevent the rain-water off the roofs of surrounding buildings from washing the most valuable portions of the manure out of the yard. Buildings should be carefully spouted, and the water conducted away in channels or drains under the surface. Another essential point is the application of gypsum, or some other chemical compound, in the stables, cow-bins, piggeries, &c., which will not only prevent any unpleasant smell, but will also fix the ammonia that is otherwise constantly escaping. By using gypsum or sulphate of lime (calcined, of course), this may be effected [This is very questionable. ED.]; also, by laying hold of the liquid portion of the deposits it will materially increase the value of the manure. Gypsum should therefore be liberally applied not only inside the stables, &c., but occasionally over the whole foldyard. Where this calcined gypsum is difficult to procure, the principle of Moule's earth closet may be adopted, and dry clay, finely pulverised, ashes, or charcoal of any kind may be used with a good result. Thus the health of animals kept indoors will be improved by purifying the air they breathe, and a much larger percentage of fertilising matter will be secured in the manure. Some writers on the subject recommend that foldyards should be carefully paved with bricks, and so formed that the liquid portion may be drained off into a large tank, to be afterwards pumped out and carted on the grass sward or other green crops. In some special cases perhaps this plan may be profitable, such, for instance, as where a large number of cows are kept for dairy purposes, or in any other establishment where large numbers of horses or other live stock are kept, and the most rigid economy in the use of straw has to be practised. But it may be questioned whether on farms where all the straw produced has to be consumed on the premises if liquid manure tanks are of any real value, and if the plan already described of absorbing the urinary deposits is not much preferable. The same principle should be carefully carried out when the manure is taken away from the farmstead. The system so common in some districts should be avoided.

There is still sometimes to be seen in this country a process something like the following: Manure is being carted out from the farmstead. You observe that it has the appearance of half-rotten straw; little oilcake, corn, or roots have been consumed on the steading, and the most valuable portion has been allowed to run off down the surface drains from the fold. Thus made it is carted out into some bye-lane, perhaps deposited in an open ditch, then lightly thrown out with forks to encourage fermentation. Thus the ammonia evaporates from the top as the steaming vapour arises, and at the bottom the liquid portion is being drained away as the heap decomposes, or completely through the heap, and literally wash out its most valuable constituents, its very life-blood. No wonder this treatment, when applied to the soil, fails to give the result the farmer looks for. This part of the subject has often been matter of discussion among practical agriculturists, and a variety of plans have been considered; the following has been most generally approved: Instead of the manure being thrown out of the carts as lightly as possible, the cart is driven on the top of the heap, then upturned and emptied. If near the homestead, a man is usually employed with a kind of drag to pull the lumps about, keeping the surface of the heap level, building three sides quite perpendicular, and allowing a slope at one end for the cart to ascend and return. This prevents the heap from such rapid fermentation and consequent loss of strength, and preserves its most valuable properties for the cereal crops usually following the root crops to which most manure is applied. The heap should then be covered with some soil, ditch bottom or road-scrapings being generally available, if with a coat of gypsum, so much the better. The preferable plan is to cart the dung direct from the steading, and apply it to the land previous to the winter ploughing. This plan, however, can only be adopted to a limited extent, as it necessitates the keeping of one year's stock of dung ready for the next autumn, when the state of the weather and the press of farm work might prevent it being applied. When it is considered necessary that the dung should be reduced to a shorter and more pulverised condition, this end can be attained by simply turning over the heap formed as before described two or three weeks before it is intended for use. A quantity of gypsum should again be applied to the top after being turned. It is of comparatively little importance whether the dung thus prepared is applied to the soil spread evenly over the surface, or, as it is most commonly applied, in drills or ridges, the great end having been secured, namely, the conservation of its most valuable constituents, and a large increase in the percentage of those valuable gasses that cause rapid and luxuriant vegetation. Some attention should be bestowed on the place where the dung-heap is formed. If not carted into a field, the bottom should be so formed that the liquid portion cannot be drained from the heap—this, on most soils, can easily be effected.

In further reference to the application of manure in the field, there are several principles upon which it is necessary to act. The soil must be in proper condition, and in a soft wet state, so as to be consolidated by the feet of the horse or the wheels of the dung-cart. On the lightest and most friable of soils, some injury would be done; but on heavy clays and loams it would be an act of great folly to cart manure while the soil remained in a wet condition. In the instance, whether the manure loses value by being allowed to remain on the surface after being spread, and whether it suffers by being applied when the earth is bound up with frost and covered with snow, or during intense heat and drought, by being exposed to the wind and sunshine—these topics have discussed both by practical and scientific men, and have elicited opinions diametrically opposed to each other. One is of opinion that if manure is only spread on the surface, the deodorising power of the soil is so great, it will absorb all the ammonia, nitrogen, &c., that it contains, and that nothing more is necessary. In this case, the mechanical action of the manure in preventing compression, in opening and pulverising, to use a common phrase, in mellowing the soil in which it mixes, is overlooked. Another tells us confidently that frost has no effect at all detrimental to the value of manure spread on the surface—that it lays hold only on the moisture contained in it, and extracts nothing but water. Practice has shown that manure applied while in a state of fermentation and rapid decomposition, during either of the extremes of weather mentioned, does suffer in some degree—does lose some portion of its value; a great deal depends on the state in which it is applied, and of the agencies of evaporation at work when so exposed. The point to be aimed at in all applications of manure is to bring it into immediate contact with the soil as soon as possible. It is the custom in many districts to cart out manure early in the season, to be applied to such crops as require it, in small heaps over the fields, and in this way it is sometimes left for weeks previous to being spread over the surface. There can be no objection to this mode of laying it on the land, but the practice of allowing it to remain is unwise, as in this case a very large proportion of ammonia is exposed, which, by coming into contact with the soil, as a matter of course is allowed to "waste its sweetness on the desert air." In deciding between the relative advantages of manure being applied on the surface or under the surface of the soil, it must not be forgotten that farmyard manure, while in a state of decomposing, is constantly giving off a certain amount of heat, whether in the soil or not; it follows, therefore, as a natural consequence that, unless it is in immediate contact with the earth, or some other deodoriser, it must lose value in some degree. But while strongly advocating the principle of immediate contact with the soil, to be ploughed in, or admitting manure down to the subsoil is to be recommended; on the contrary, if put on the soil and slightly covered over, so as to protect from the extremes of weather, without doubt the most judicious method is adopted. In the best farmed districts of Scotland, it is the practice to plough in manure as much as possible previous to the winter ploughing, and in that climate, and in the months of November and December, when evaporation is at its lowest point, of course the danger of waste pointed out in this paper is greatly diminished. In adopting such a system of condescending to

For heifers, I consider that the stall is always the most suitable place, but whichever of these kinds of stock or ways of disposing of them be adopted, I believe that the average returns from the cattle may be calculated on as remunerative, provided that due care and attention are bestowed on the animals. This brings us to consider what is the best way of feeding. In courts young cattle usually are given a full supply of Turnips and straw—the former, if Swedish, are cut for them by a machine before being put in the troughs, or partially cut up after being placed there. There is, doubtless, a loss of Turnips by either of those ways, as a portion of them will find their way to the dung depôt, and besides there is a certain loss of nourishment by lying in the troughs when so cut. In stalls and loose boxes this loss may be so far prevented, and the individual animals in their feeding more particularly attended to as circumstances may require. The Provost concluded by quoting details of the experience of those gentlemen who had given the subject their minute attention.

Baillie D. G. Ross thought we could scarcely have a more important subject for discussion than that of the best mode of consuming Mr. Arras' acre of Turnips. They had already been informed that the acre of Turnips was £12, and if they estimated the weight to be 24 tons, which might be taken as a fair average, it showed the crop to cost 6*d*. per cwt. Then how were they to turn this 24 tons to the best advantage? His answer was, convert them into beef or mutton. He was himself an advocate for eating the Turnips with cattle as far as possible. He would therefore confine his remarks to the manufacture of beef. He held that to feed a bullock on Turnips alone was the most expensive mode of feeding him of any, as to keep him going on anyways well it would take 2 cwt. of Turnips at a cost of 1*s*. per day, supposing, with Mr. Easdale, of 2 cwt. Turnips, which contained 90 per cent. of water, fully three-fourths more than he needed to supply his thirst, they gave him ¼ cwt. Turnips, which cost 3*d*. ; 6 lb. of cakes and meals of various kinds, costing 7*d*. ; and 6 lb. of hay, costing 4*d*., the cost was not any more than feeding with the 2 cwt. Turnips ; the beef was produced very much quicker, and by that mode he was enriching his dung even from the cattle urine alone, which was not nearly all water, as it would be from Turnips ; a by-product of the first importance to be was putting into the dung. He must now see how he was to get clear of his Turnips without a loss, and get paid for his other stuffs also, and get at his rich dung for his trouble by the mode of feeding he preferred. He would put on a well-bred 2-year-old bullock, rising three years old, 14 lb. beef per day. He was not prepared to say the weight he could put on with 1*s*. worth of Turnips alone, but he felt certain that after deducting the 90.70 water, the remaining 9.30 was not so much as his 9*d*. worth of feeding stuffs. He contented himself with leaving this point open as not costing any more than it would to keep this bullock with the 2 cwt. Turnips : of course to eat one's whole crop of Turnips in this way was impossible within the time of year that they should be consumed, for want of accommodation to do it, but he was strongly of opinion that it was the right mode to put the constitution of the farm to produce straw and corn and grass, and repair the soil that was sick of red Clover.

Mr. Fenton's experience was that the most profitable way on strong land was to give cattle half Turnip, and the rest decorticated meal. On the lighter farms, such as he possessed, he thought the best plan was to eat one half off with sheep and the other with cattle.

Mr. Ross, Keppoch, had his Turnips stored in the autumn, and took care to give them fresh to the cattle, letting them take as much as they would eat with a little cake and bruised oats. During the past two years his cattle paid uncommonly well ; his 2-year-olds, even before they reached the age of two years, were quite fit for the fleshers.

Mr. Arras found that the calculation in his former paper, as to the cost of growing an acre of Turnips, was less than the actual amount. He would take it at £14 instead of £12. Now, 240 hogs on Turnips would eat about an acre a week, and there were somewhere about 29 weeks for the wintering. At £14 this would come to £406. Suppose that the lambs in autumn were bought at £1 a-piece, that would be £240 and that £2 a-head of profit was made, which had been more than realised this year, he said £2 a-piece of profit came to £480. Put this against the cost of Turnips, £406, and a balance of £74 remains. According to that calculation, Turnips would pay even at £14 an acre ; and to that fell to be added all the manure that was left on the ground.

Mr. Walker, Mountrich, presented another calculation. He tried to go in for sheep feeding. Take an acre of Swedish Turnips, 24 tons to the acre, and get £8 10*s*. an acre ; the benefit of the sheep to the land was worth £2 an acre, which brought it up to £10 10*s*. Again, an ordinary-sized bullock, eating 2 cwt. a day, could be kept on an acre for 240 days ; at 3*d*. per cwt., or 6*d*. per day, the cost would be £6 for the Turnips. The manure for the period he calculated at 30 loads, or £4 10*s*. an acre ; total value of Turnips eaten by a bullock, £10 10*s*. But from this had to be deducted the value of straw eaten, the ordinary labour, the carrying of manure, &c., which he calculated as coming to £4 15*s*. per acre ; that only left £5 14*s*. for cattle, as against £10 10*s*. for sheep. But it might be said that the quantity of Turnips was over-estimated and the value under-estimated. Say, then, that 14 cwt. of Turnips was given daily, at a cost of 6*d*. ; that comes to £9 an acre, and the £4 10*s*., as above, brings it to £13 10*s*. ; deduct expenses, as before, £4 15*s*., and the balance was only £8 15*s*., as against 10 gs. for sheep. But really there was no use giving so much Turnips to cattle. He thought 56 lb. a day was enough, with oilcake, bruised corn, and straw. They could thus feed twice or four times the number of cattle on the same quantity of Turnips ; the cattle fed much quicker, there was better flesh, and much better manure. To carry out the plan, however, superior accomodation was required, even if they gave half the Turnips to cattle and half to sheep.

Sir Kenneth Mackenzie said it was evident that the profit of consumption lay in the return given by the following crop, as well as in the increased value of the beasts fed. He had noticed two farms near Bunchrew Station, one having beautiful grass, and the other close by with miserable bare pasture. He was told that the farmer on one side was an Aberdeenshire man, who kept nothing but cattle, and the farmer on the other kept nothing but sheep ; that the poor grass followed the sheep, and the rich grass followed the cattle. Now, it was quite possible that might be the case with grass, and yet the crop between the Turnip and the grass might be better after the sheep.

The Chairman, after some further remarks, summed up the discussion, saying first the great advantage of having good accommodation for cattle ; and second, the advantage of knowing how to buy stock, and getting them of a good kind. Looking over his accounts the other day from the time he came to Rossshire, he found that while he had increased very little comparatively in the money realised from grain, he had increased about three times in the money realised for grass and Turnips. If that was the way things were to go on, then the more Turnips they had the better, and he was very much inclined to go into that kind of thing, as people were inclined to eat a great deal of beef, and to eat it at the high price they were doing. Sheep would improve a light soil immensely ; and, in regard to heavy soils, they had not only to consider the character of the land, but the time at which the sheep were put upon the Turnips, as it made a great difference according to whether it was early or late, and there was a great difference between the effect in wet and dry weather. Put sheep on Turnips in wet weather, and they would almost certainly lose their crop. A thing on which they all seemed to be agreed was that Turnips should not be excessively used for cattle, and that artificial food was a great advantage both for the stock and the manure. He was sure they all felt exceedingly indebted to Mr. Mitchell for the pains he had taken with his paper.

Notices of Books.

Stables and Stable Fittings. St. Pancras Iron Works Company, Old St. Pancras Road, N.W.

Illustrated Catalogue. Musgrave Brothers, Belfast.

Catalogue of Patent Stable Fittings. Cottam & Co., 2, Winsley Street, Oxford Street.

List of Stable Fittings. J. Barton, 370, Oxford Street.

Let us begin with the last upon the list. Mr. James Barton, stable-fitting manufacturer, 370, Oxford Street, obtained a prize medal at the International Exhibition, 1862, and his new catalogue contains a very flattering list of patronage since then received, including various noble personages ; more recently he fitted up the stable for the Viceroy of Egypt to house 150 horses, embracing much novelty that merits special notice, because the invention of the Viceroy himself. Egypt has long been famed for the management of horses, and none of her previous rulers have been better versed in the attendance requirements of the horse than he who has succeeded them.

The Khedive's stable is fitted up with 140 loose boxes and only 10 stalls. This preference of the loose box shows that he understands how to house this noble animal, for the day is not far gone when stalls will be the exception for even farm-horses. A hard-worked farm-horse, contractor's horse, cavalry horse, or coacher has more need of a loose box in which to recruit his overtasked muscles during night than even the hunter and racehorse.

In the Viceroy's stable the enamelled iron plates extend further up the wall at the manger than is common, tinted sky-colour after the Egyptian style. The iron posts of the boxes and stalls are massy and ornamental, and surmounted each with a ball on which is figured in relief the star and crescent in front, gilded in harmony with the general design. Instead of wood-boarding, rolled iron is used of sufficient thickness to defend the heel of the horse without sustaining any harm. This gives the sill below, and cross parallel ramp, sill, and capping above, a very neat and light appearance, with greater strength and durability than when wood-boarding is used. The gutters are covered, and the whole drainage is on a much larger scale than is common in England, the gutter and drainage pipes having a greater capacity for flushing out to keep them clean.

Such is a general outline of the improvements effected by the Viceroy of Egypt in the stables at Cairo. The spring-bottomed racks, the enamelled mangers, and rotary water-troughs, although made to special order, are similar to those which Mr. Barton exhibited in the Agricultural Hall at the Christmas Show, 1870. Mr. Barton gives a great many designs for stall and box divisions, plain and ornamental, with all the other fittings required in the stable in his catalogue, and to it we must refer for further particulars.

Cottam & Company exhibited in the Agricultural Hall, during the recent horse show, their usual selection of stable fittings and at their manufactory, 2, Winsley Street, Oxford Street, W., they have fitted up a first-class stable, with stalls and boxes for horses, which merits inspection. The details are variously arranged, so as to exemplify how best to economise space, and at the same time provide for the comfort and health of the horse. Light, ventilation, and cleanliness are special objects in a stable, and these are carefully provided in the construction of the rack and manger guard fittings and twelve fittings of both stalls and boxes. As Colonel Fitzwygram justly observes in his work on "Horses and Stables :"—

"Ample light is essential to the health of the eyes. Light is, indeed, food and exercise to them. Without ample light the eyes cannot be strong. If they are altogether deprived of light, the optic nerve becomes paralysed, and blindness is the result. Again, ample light is essential to the cleanliness of the stable. A dark stable may be a dirty stable, and a dirty stable is, as a rule ; but good truth, most dark stables are dirty, and a dirty stable must be unhealthy. Both eyes and lungs are especially liable to injury from the gases produced by impurity."

Cottam's ventilating manger guard fittings provide that impurity from hay, seeds, or green forage is rapidly removed and carried before contamination with the horse's breath takes place. Their "registered ventilating sill" makes similar provision for stalls and loose boxes. This provision is more especially needed for the latter (loose boxes), for however perfect the ventilation of a stable may otherwise be, yet the air in the bottom of a loose box is liable to stagnate and become foul, unless it is allowed to escape below the sills at the sides and front.

This firm have also obtained a patent for a project embracing the replacing of broken boards without the tedious process of removing the whole, which is much experienced. This is effected by a "dove-tailed wedge" in the sill, equal to the breadth of a board, so that when a board is broken by a kicking horse, it can be removed, and as the groove of the ramp is parallel to the groove of the sill, any board or boards between the broken one and the wedge can be driven back so as to leave the opening at the wedge. The wedge can then be removed, and a new board put in ; by replacing the wedge portion of the sill, the trevice or division is thus quickly repaired. Their catalogue contains a variety of fittings, plain and ornamental, from which to select. They prefer enamelled iron tiles for linhg the wall in front of stalls and feeding boxes to wood or porcelain tile, and show patterns of different colours, as white, green, and granite.

The floor of their stable is paved with "adamantine clinkers," impervious to water, and never slippery.

Adjoining the horse stable are shown "Cottam's patent portable united cow fittings" for four cows, which consist of an enamelled manger and sliding tye for each cow, with an enamelled water-trough between two cows, so elevated as to prevent the cows dropping their food into the water.

St. Pancras Iron Works Company have published a large illustrated catalogue (May, 1871), which ought to be in the hands of every landowner or horse-owner who is about to budd a new stable or refit an old one. At the recent horse show in the Agricultural Hall, Islington, this firm exhibited loose boxes, in which the horses of H.R.H. the Prince of Wales were shown, in their manufactory, Old St. Pancras Road, London, N.W., they have fitted up a stable capable of 100 feet in length with stalls and boxes, each differing from the others, thus showing a variety of patterns from which to choose. Some of the stalls are faced with glazed tiles of various colours and shapes, against the heels of the horses, as is found so effective in such marble slab, and another with enamelled iron, and so on. The racks, mangers, and watering troughs are equally diversified, to meet the requirements of purchasers. For farm-horses low racks are useful for green forage when given alone, but when cut up into chaff along with hay or straw they should be put in the manger. Deep, narrow mangers are objectionable. There is great art in baiting a horse, and all who have any successful experience in feeding only place before him a small quantity at a time evenly spread over the bottom of the manger so as to make him feel slowly on fresh food not "blown upon," masticate and insalivate well with relish, and thus insure perfect digestion. In a narrow box the horse's breath contaminates his food—he is liable to eat too fast when he comes in hungry, bolt his food imperfectly masticated, and thus to get little benefit from it. The St. Pancras manger is shallow, with a broad flat bottom rounded at the angles, so that the horse can feed with ease without any annoyance to irritate from his mouth coming in contact with the sides ; and the lips are so narrowed and curved inwards as to prevent the food being tossed out with the nose. Some think water should always

be in the water-trough for the horse to drink when he pleases; others affirm that it is better to water at stated intervals. A clever plan is here shown to meet both views. This is done by a cock below out of the reach of the horse, for turning on and off water at pleasure, so that the horseman can fill the trough, and when his horse has done drinking he can then turn off the remainder, or he can allow the horse to drink at his leisure, cleaning out the trough once a day. The waste water from the trough flows into the gutter, washing it out clean, and keeping the stall or feeding-box free from smell. There is a considerable diversity in the trevice posts, sills, and ramps of stalls and boxes, to meet choice and style of architecture. A great many specimens of stable-paving are shown, including their own non-slippery grooved brick, small granite cubes, clinkers, red and blue Welsh and Staffordshire bricks (plain and grooved), and so on. Specimens of open and capped gutters for stalls and boxes, with trapped pots, &c., are also shown. All pots should, if practicable, be outside the stable, so as the whole of their contents can be mixed with the manure in the yard or pit. A great variety of harness-room fittings is also shown, and means for the general ventilation of the stable in summer, and warming of it during winter.

Musgrave Brothers, Belfast, have obtained several silver medals from the Royal Agricultural Society of England, one at the Leeds meeting, 1861, and a second at London, 1862, along with the International medal, and a third at Bury St. Edmund's, 1867—the latter for "continuous practical improvements," and the loose boxes and stalls which they exhibited last year and this year at the horse show in the Agricultural Hall, Islington, prove a continuance of public favour. They publish a comprehensive illustrated catalogue, to which we must refer for details. We can notice only a few of the useful novelties they have introduced into the stable and cow-house in this as in the latter country. A folding window, on the principle common in churches, is placed at the head of every stall and loose box for lighting and ventilation. In the summer time these supply an abundance of fresh air to the stable, and in winter they can be closed, and the stable ventilated and kept warm by one of their "slow combustion stoves." Their sliding-pole barrier across the gangway at night is another improvement which ought to be in every stable fitted up with stalls. We once had the hind leg of a fine mare broken by a kick from a horse that broke loose during the night, and dead low! Ap to-day the disappointment — and with such a barrier the horses would have been kept safely apart. During day, or rather when the horseman is in the stable, the pole is pushed home through the heel-post into a strong iron bracket which has a groove on the under side for the boarding, and on the upper side for any kind of ramp fittings used. By dividing the boarding with a second or third "barrier sheath," two or three sliding poles may be drawn out, so that, if desirable, the horse may be left loose in his stall over night.

Their low racks are so contrived that they answer both for hay and cut provender. When to be used for hay, the bottom of the rack is open so that seed can fall through. When filled a gridiron lid is turned over upon the hay, and as the hay is pulled through the bars, the lid slides down on vertical bars—thus keeping upon the hay, and preventing waste. When to be used for chaff, a sheet-iron covering is turned down from the back of the rack, thereby converting it into a manger or trough. The "water-pot" turns on a pivot at each side, and is so balanced that it remains steady when full of water, and is easily turned upside down when to be washed out. The foul water falls into a pipe below, and is used for washing out the gutters and drains. The front of the rack, manger, and water-trough is so rounded that the horse cannot grasp it in his mouth, or in any way injure his head and neck. Mangers are made after several patterns, to prevent the horse tossing out his food with his nose: one has the narrowed inward lip now in common use, another has a grated lid with a circular opening in the middle sufficiently large to allow the horse to feed. The open grating is for admitting air and allowing the breath to escape. A third pattern is a tumbling manger, on the principle of the water-pot, already described, the better to wash and keep it clean when the horse is fed on cooked food.

Their "harmless loose box mangers and racks" also merit special notice. An open iron hanging guard comes forward over the manger and water-pot, and is bolted flush with the edge. Boarding below descends perpendicularly to the floor. A high hay-rack is permanently fixed also flush with the boarding, so that when their spirited horse cannot injure himself in the absence of his groom. In a large stud a box or two on this plan should always be ready, to prevent harm to restless horses.

Farm Memoranda.

NORTH RIDING OF YORKSHIRE.—If there is any truth in Mr. Mechi's oft repeated adage, that "showers in June put all in tune," we ought—with our rainfall for the month of 3 inches—to have all in perfect concord. Not so, however. Our meadows are good, and give promise of abundant crops. Pastures are very much improved, and may now be described as good. Our Turnip braird is excellent, has not been so good for many years, and, thanks to the cold, sunless weather, has altogether escaped the ravages of the fly. Potatos also promise well, and so far all is in tune, but when we turn to our grain crops we strike discordant notes. Wheat generally thin, backward, and unhealthy, conveying to the mind of the experienced a distant prospect of meagre rickyards and sparse bushels. Oats, especially on the light lands, are very unpromising. Many have grubbed off, and where the main crop has had vigour enough to recover, the look of it is by no means pleasing, the plants being patchy, and of different heights, and the result at harvest we dare safely predict will be under an average. Barley, on the whole, looks tolerably well, backward, but promising fairly.

Stock of all descriptions were never before known to maintain for so long a time such high rates. Anything at all like prime beef has during the last two months readily made from 9*s.* 6*d.* to 10*s.* 6*d.* per stone of 14 lb., and mutton, out of the wool, from 8*d.* to 9*d.* per lb. Store cattle have been selling proportionately high, and there is considerable risk of many who have bought since April of having to summer graze for nothing.

Wool sells freely and well, at prices from 2*d.* to 3*d.* above last year's rates.

The stock of Wheat in the hands of the growers was scarcely ever known to be so low. *W. F. M., June* 30.

THE SPITAL IRRIGATED FARM, ABERDEEN.—Last season 11 acres were added, between King Street Road, at Spital, and the Links, belonging to Miss Knight Erskine, of Pittodrie, which has been laid out for the purpose during the previous winter, were brought under sewage cultivation with very satisfactory results as regards the crops raised. And this year, under the care of Mr. J. Cruickshank, factor on the property, a much larger extent of land has been prepared, and is now either cropped, or in process of being so, on the sewage system. The newly laid-out ground is immediately northward of the 11 acres cropped last season, and extends from Ladymill, King Street, down to the margin of the Links, and contains 36 acres, making in all a sewage farm of about 47 acres.

The additional land to which we have referred has been laid out in accordance with a plan prepared by Mr. George C. Roger, C.E. In the case of the smaller section laid out last year by the late Mr. Anderson, C.E., the work was done by day labour. This year Mr. Roger issued specifications and readily found a good contractor to work them out; and the result thus far has been a very decided pecuniary saving with no less satisfactory workmanship. The newly laid out land is intersected lengthwise by a public road leading from King Street up the Old Town Links; and five service roads have been made, dividing it into six fields of manageable size; each of which is, of course, subdivided by branch carrier drains, and waste water channels, for the purpose of flooding the several plots—the main carrier which supplies the whole passing along by the side of the public road.

In laying out the land, the first thing to be done, after having it all thoroughly furrow-drained and trenched, was to proceed with levelling and formation of the carriers. In addition to having the levels very carefully taken and marked on the ground, the work was brought gradually forward as the work progressed, and as each plot was formed and the sluices adjusted and fixed, it was turned on. This served the double purpose of testing the levels, and administering a thorough soaking to the newly-worked land. In the care taken at the outset in taking levels, no difficulty whatever occurred in irrigating the different plots, though in numerous cases the flow of sewage from the main carrier turns either to the right or left, as may be wished, at the same point. The main carriers are laid with tiles fastened with cement in the bottom, which is rendered necessary by the rapidity with which the sewage water flows through them; in the case of the branch carriers, where the descent is very little and the flow sluggish, an open trench simply is required. The whole of the sewage farm has been so arranged now that the waste water from the whole 47 acres is brought to a point in the Powis Burn at the extreme north-east corner.

In the laying out of the land, Mr. Roger has kept clearly in view—what we think is a very important element in the condition of soil and climate, and the character of the crops grown in Aberdeenshire generally; his practical knowledge of local agriculture enabling him to adjust operations accordingly. Some 6 acres have been sown down in Italian Rye-grass, the plots occupied in this way having been earliest prepared, so as to lose no advantage in having the young plants a start. Next, about 10 acres were planted in Potatos, which are just now coming into vigorous leaf. About 2 acres of Swedish Turnips have been sown, and the remaining part of the land will be laid down in common Turnips and other green crop.

The whole of the 11 acres irrigated last year have now been put in grass, of which there is a vigorous crop. A first cutting has already been taken off a small part; and we may say there is quite a ready sale for the grass when fit for cutting.

In regard to the cost of laying-out the land now being brought under irrigation, in relation to probable returns, it would be as yet premature to speak. As we have frequently said in reference to the general question of sewage utilisation, experience in each individual locality where sewage cultivation is attempted must be a main element in directing to satisfactory results, whether as regards cost in laying-out and management, or the proper crops to be cultivated. In the present case, as we have indicated, a material saving has this year been effected in the matter of laying-out. And in that respect, as well as others, the results on the Spital Farm will, we expect, by-and-by form an important contribution to the solution of the general question of sewage farming in so far as Aberdeen is concerned. *Aberdeen Free Press.*

Obituary.

WE regret to announce the decease of LORD BERNERS, at his seat, Keythorpe Hall, Leicestershire, which happened towards the close of last week, after a long illness, at the age of 74. His lordship, who was born at Kirby Cane, Norfolk, on the 23d of February, 1797, was the elder son of the late Rev. Henry Wilson, who in 1838 succeeded to the ancient Barony of Berners (to which his elder brother a few years previously had established his claim); his mother was Elizabeth, daughter of Mr. Thomas Compton, of Histon Hall, Cambridgeshire. He was educated at Eton and Emmanuel College, Cambridge, and succeeded in 1851 to the Peerage as sixth lord in actual possession of the title. He was a magistrate and deputy-lieutenant for Leicestershire, and an active member of the Royal Agricultural Society of England, over whose meetings he presided a few years ago. His lordship was twice married; firstly, in 1823, to his cousin, Mary Latitia, elder daughter and co-heiress of Colonel George Crump, of Alexton Hall, Leicestershire; and, secondly, in 1847, to the Hon. Henry Charlotte Cholmondeley, only daughter of the late Lord Delamere. But as he had no issue by either union, the title (which is descendible in the female line) devolves upon his niece, Emma Harriet Lady Tyrwhitt, as only surviving child of his deceased brother, the Rev. Robert Wilson, Rector of Ashwell-thorpe, Norfolk, by his second wife, Harriet, daughter of the above Colonel George Crump, of Alexton Hall. Her ladyship, according to "Lodge's Peerage," was born in 1835, and married in 1853 the present Sir Henry Thomas Tyrwhitt, by whom she has a family, who are heirs to both the Berners and the Tyrwhitt titles.

Miscellaneous.

THE CENSUS AND THE SEWAGE QUESTION.—Is the iconoclasm of Hunger an absolute impossibility in any country when the growth of population continues to press upon the means of subsistence, and when a reckless agriculture drains away the constituents of a people's daily food into the sea, and sterilizes while it cultivates the fields on which it lives? Natural laws are implacable. Nothing is more remarkable in these Census Returns than the evidence of what may be called the congestive tendency of an industrial civilization in the aggregations of great cities. The danger to the peace of London and other cities arising from these vast aggregations is obvious enough; but nature suggests a remedy and a compensation in the observance of that great sanitary law of a perpetually self-creating and self-supporting food supply. There is nothing transcendental in the policy of organising the circulation between town and country of the essential elements of human subsistence, and the fertilising constituents of the soil. Yet this, after all, is the problem of problems for an increasing population, unequally distributed over a limited territory, the soil of which is becoming more and more a monopoly, dependent, in a great measure, for its sustenance on foreign countries, incessantly engaged in the competition of manufacturing industry, and in the struggle for a bare existence. We trust we shall not shock any philanthropist who has been in the habit of indulging a more exalted strain of moral reflections, if we confess that these Census papers have turned our thoughts to the question how, in a country where the towns absorb the population, and wealth monopolises the fields, town and country may be made to support each other a little better, without robbing the rich or pampering the poor. It is not a political, nor a social, but a sanitary revolution that is wanted. The utilisation of town sewage is not an inviting subject for the philanthropists of the platform; but we contend it is quite as practical a question for the present age as the exhaustion of our coal-fields in a thousand years. *Daily News, June* 23.

The Week's Work

JULY 8:—*Cole Seed* or *Rape* is usually sown on land that has been pared and burned; but in exceptional seasons, when the weather is moist and growing, a crop of Turnips may be grown. Whether grown on the flat or on raised drills, the practice of manuring and seeding the land for both crops is similar. Cole is better adapted for fenny and peaty soils than Turnips. Drill in from two to four quarts of seed per acre, using the water drill in dry weather. Where Turnips have failed from the fly, or other cause, many prefer a crop

of Cole to the risk of a second sowing of Turnips. Cole may also be used for filling up blanks either by transplanting or sowing seed. When ready for cutting, it may be given to sheep in the pastures; or if the Turnips are to be eaten off by sheep, the filling up of the blanks may be timed so that both may be folded together. The crop that was sown after the middle of last month, if it has brairded well, will require a rough hoeing, and blanks, if any, may be filled by transplanting in moist weather, or after a heavy shower, or the water-cart may be yoked in dry weather. A couple of water-carts, and half-a-dozen watering pans, in active hands, soon go over a 20-acre field.

Carrots, Parsnips, Chicory, and all advanced root crops, horse and hand hoe, if the work has not already been finished. Keep the earth well up to the former three crops. It should always be borne in mind that root crops will only luxuriate in a finely pulverised and properly aërated soil, consequently frequent and deep hoeings are greatly in their favour. When a continuance of wet weather is experienced, so as to prevent the hoes being worked, and when weeds spring up abundantly, yoke the paring-plough, first ploughing the land from the one side of the plants, going as close as not to earth them up, and turning the earth close to the plants in the opposite row, so as to root up half the weeds between and cover the other half. In a day or two, as the weather and weeds direct, and thereafter quite half, thereby reversing the former and rooting up the remaining half of the weeds. In this way Wild Mustard and Charlock may be prevented from exhausting and seeding the land, and any that cannot be reached with the plough should be pulled by hand, to prevent their running to seed. A too common mistake is to let the Wild Mustard get too far a length before it is thus ploughed down. When the weather breaks up, the horse-hoe may be yoked. In dry weather, the paring-plough should, if possible, be avoided, and Wild Mustard should be like kept down by frequent and deep horse and hand hoeing.

Irrigation is a golden practice in dry weather, and July weather is seldom so wet throughout that water cannot be profitably applied to the meadows and pastures. At all events, where there is a command of river-water, the irrigation works should be ready for its application; and where river-water cannot be had, the surplus water of a rainy season should be stored for application the moment dry weather sets in. Town sewage should be applied to the hay stubbles and pastures, however rainy the weather may be. For a similar reason, where stored water or river water can be applied, it may be doctored with guano or grass manure, to fertilise poor land. And if rain is falling sufficiently plentiful to wash in the artificial fertilisers, they may be applied by broadcast distribution. Whether, therefore, the golden treasure falls from the clouds, or comes from the town sewer, the river, or the pumps, it ought to be applied the one way or the other. As for the "A. B. C." system, it is almost as hopeless in a wet summer as in a dry, even in places to which liquid sewage cannot be profitably conveyed; for in our fickle climate no dependence can be placed upon July clouds washing dry sewage into the pastures, and as there is plenty of land to consume all the sewage of our large towns in a liquid form at this season, and as it can be more profitably used in a liquid than in a dry form, even in wet weather, the practical conclusion is obvious. In winter, when the growth of grass is almost *nil*, and when water is not required by the land, the sewage of towns may be more profitably utilised in a dry state, and stored for application when vegetation commences. There is reason and hope in the future of this, for in the winter time, when the sewage is worth nothing to the farmer, and less than nothing at times, it is of most value for the dry system manufacture; and on the other hand, if farmers have not to pay for the sewage during the time it would enable them to give more for it in the summer time, when the liquid portion is for the most part of more value than the solid. The general conclusion, therefore, is obviously in favour of sewage irrigation at this season, let the weather be wet or dry. In wet weather irrigation of town and sewage grass requires to be more frequently cut, to prevent lodging and rotting at the bottom. In this way a greater weight of grass can be mown, provided the temperature is sufficiently high. In dry seasons like the last, the foliage of all sewage crops suffer from the extreme heat.

Sheep Washes include a long list of preparations poisonous to the insects which infest the skins of sheep shortly after shearing. When newly shorn the change is so great that the extremes of heat and cold produce an unhealthy state of the skin; ticks and lice follow, and to prevent or kill these insects, sheep are dipped in the various solutions termed washes. But what is poisonous to insects is too frequently poisonous to the sheep also. The better plan is to wash the sheep when newly shorn, rather than cover the animal to afford them shelter from the sun during mid-day and from cold during night and in bad weather, and feed them properly until their wool grows and forms a natural covering to defend them both from heat and cold, for were such done there would be no need of poisonous sheep washes.

Washing newly shorn sheep is done for the twofold purpose of cleanliness and to obviate catching cold, just as some shepherds wash their own heads when newly shorn. The practice has much to commend it, North and South, as it promotes the healthy action of the skin, upon which the wellbeing of the sheep so much depends, for a bright sun at noonday is as liable to injure the skin as cold at night. Hence newly shorn sheep should have shade to go under, and not be penned or turned out at mid-day exposed to the blistering action of the sun.

The Watering of Cattle with pure soft water requires more attention at this season than is paid to it, generally speaking. Pump water is often too hard; ponds and rivers are full of animal and vegetable life. The former, pump-water, should be exposed in a shallow trough for some time before cattle are allowed to drink it, and pond-water and river-water should be carefully filtered. Nothing deteriorates the quality of milk sooner than the dirty water of ponds and rivers, which milch cows drink in large quantities at this season.
W. B.

Notices to Correspondents.

ARTIFICIAL MANURES. *A Subscriber* desires to know by what method bones can best be converted into manure; the usual wholesale price of bones near towns; whether, if a pit were dug in chalk, much loss would ensue; if the fertilising material, also, how pure ammonia is best fixed and mixed for broadcast sowing? Bones must be broken or crushed, and mixed with about half their weight of sulphuric acid with dry fibres, and thereafter put in a heap to rot with sand. Ammonia can be fixed by adding acid to any liquid containing it, until the litmus-paper test shows that the liquid is no longer alkaline.

DISEASED COW: *A Correspondent, near Coventry*, writes:—"My neighbour has a cow that has been unwell for a week or ten days. She was calved about three months, very low in condition, but has done very well till about a fortnight back, when her pasture was changed from a poor to a good one. In a day or two after she gradually sunk her milk and appeared very dull, refusing to feed or drink, and at times appears to be griped and blown, almost the same as though she had been in Clover. Her bowels are very much constipated. They have given her linseed-oil and castor-oil, which passes through her, bringing very little away, and then she is the same as before. She looks as full as though she had fed as usual. She appears to me to be fardel-bound, as I have had all the same symptoms when they have been so on dry food." [The disease is probably, as you suggest, a fardel-bound, or impactment of the third stomach. Give 2 oz. of hyposulphite of soda once a day in a pint and a half of water, to arrest fermentative action. To remove the obstruction in the alimentary canal, give compound mixture of aloes 4 oz., Epsom salts 6 oz., aromatic spirit of ammonia 1 oz., water 1 pint. Four or five doses may be safely given, at intervals of eight hours, if the desired action does not follow the first dose.—*Ed.*]

NAMES OF PLANTS: *J. Rogers*. Festuca ovina.

Markets.

ENGLISH WOOL.

During the last week prices of English Wool have continued to gain strength, and are now about *3d.* to *4d.* per lb. above the rates current at this time last year. The tendency is still upwards, and we should not be surprised to see a further advance of *2d.* to *3d.* per lb. between this and Christmas.

METROPOLITAN CATTLE MARKET.

MONDAY, July 3.

The number of Beasts is very much smaller than last week, the falling off being principally in foreign. Trade is not brisk, yet in a few instances higher prices are obtained. The supply of English Sheep is about the same as last week, but of export it is larger; prices are rather lower, and it is difficult to make a clearance. There is more inquiry for Lamb, and choicest qualities are rather dearer. Trade is unaltered for Calves. Foreign.—The supply consists of 80 Beasts, 420 Sheep, 474 Calves, and 45 Pigs; from Scotland there are 50 Beasts; from Norfolk and Suffolk, 800; and 1130 from the Midland and Home Counties.

			Calves	3	8—5 0
			Pigs	3	4—5 0

Beasts, 2760; Sheep and Lambs, 25,000; Calves, 492; Pigs, 175.

THURSDAY, July 6.

We have again a short supply of Beasts, and a good demand. Choice qualities are very scarce, and the few on offer make high prices. The number of English Sheep is about the same as last week, but there are more foreign; on the average trade is rather better than on Monday. Choice Lambs are in demand, at fully Monday's quotations. The supply of Calves is large, the average quality is, however, only middling. Our foreign supply consists of 280 Beasts, 5600 Sheep, and 739 Calves.

Beasts, 750; Sheep and Lambs, 15,220; Calves, 823; Pigs, 85.

MARK LANE.

MONDAY, July 3.

There was a short small supply of English Wheat to this morning's market, and, with wet weather, factors commenced by asking full prices; millers, however, showed but little inclination to purchase, and the sales made in either English or foreign were in retail, at about last week's rates. Barley was a slow sale. Beans 1*s.* per qr. cheaper. Peas unchanged in value. The supply of Oats was large, and the sales made were at very irregular prices, generally below those of last week. Flour was quiet.

WEDNESDAY, July 5.

There was a thin attendance of millers to-day, and the trade throughout ruled dull, at prices favouring purchasers. The supplies of English grain were short, but of foreign they were liberal. Wheat of all descriptions was purchased slowly, at drooping prices. Barley was inactive, and for both grinding and malting parcels late rates were with difficulty sustained. Malt was quiet, at about late rates. Oats experienced a limited inquiry, at prices generally easier. Beans were dull, at Monday's decline. Peas were taken off cautiously on former terms. The Flour trade was inactive, and prices were very weak.

LIVERPOOL, July 4.—There was a larger attendance than usual, and a further decline from Friday's rates. A moderately fair business was done in white and red Wheat, at the reduction on the week, though rather irregular, being estimated at *2d.* to *3d.* for the former, and *3d.* to *4d.* per cental for the latter descriptions. Flour nominally lower, and hardly anything done. Beans maintain late rates. Peas 1*s.* per qr. cheaper. Oats and Oatmeal slow, and rather in buyers' favour. Indian Corn 1*s. 6d.* to 1*s. 9d.* per qr. lower on the week, and sales to a moderate extent.

SEED MARKET.

The weather has considerably improved since last week, and is now much more favourable to the maturity of seeds. Holders are, nevertheless, very firm in their demands, and the conviction gains ground that the growth of Clovers and Trefoil will be defective. There is at present scarcely any business passing in our markets, except a little in Mustard, Rape, and bird seeds, all of which are in fair demand, at unaltered rates. Offers of new Trefolium seed for delivery a few weeks hence come to hand.

DEVONSHIRE GREY STONE TURNIP (the TRUE VARIETY).
ROBERT I. PEWTON has just completed harvesting a fine pure stock of this most excellent TURNIP, the best variety for either early or late sowing. It has been selected with great care, and is very strongly recommended.
Price per bushel or cwt. on application. Quantities of half bushel or quarter cwt. and upwards forwarded to any part of the Kingdom.
54, High Street, Exeter.

FIVE HUNDRED THOUSAND PLANTS now READY, all true and fresh
BROCCOLI, Carters' Champion, Elletson's Mammoth } 5*s.* per 1000.
" Dead Early, Penzance Early }
" Purple Sprouting, Early, 4*s.* per 1000.
SCOTCH KALE, COTTAGERS' KALE, ROSETTE COLLARD, DRUMHEAD SAVOY, 3*s.*; a reduction for a large quantity.
H. J. HARDY begs respectfully to offer the above for cash, and wishes to call attention to the fact that the two first-named Broccolis stood the frost of last winter and all his other sorts failed.—All package and carriage free to London; to the amount of 40*s.*, package and carriage free to any part of England.
H. J. HARDY, Stour Valley Seed Grounds, Bures, Essex.

ROYAL BOTANIC SOCIETY'S THIRD SUMMER EXHIBITION,

JULY 12 AND 13.

AWARDS OF PRIZES.

MEDIUM GOLD MEDAL.

Mr. J. Ward, Gr. to F. G. Wilkins, Esq., Leyton, for 20 Stove and Greenhouse Plants.

GOLD MEDAL

Messrs. Jackson & Son, Kingston, for 20 Stove and Greenhouse Plants.

LARGE SILVER GILT MEDAL.

Miss Hasnard, Church Road, Upper Norwood, for Dinner-table Decorations.
Mr. John Ward, for 8 Exotic Orchids.
Mr. W. Lynn, Gr. to Lord Boston, Hedsor, Maidenhead, for a collection of Fruit.

SILVER GILT MEDAL.

Mr. W. L. Buster, St. Mary Cray, Kent, for Dinner-table Decorations.
Mr. Thos. Baines, Gr. to H. Nicholls, Esq., Southgate, for 6 Stove and Greenhouse Plants.
Mr. R. S. Williams, Holloway, for 8 Exotic Orchids.
Mr. Johnson, Gr to the Marquis of Ayesbury, Savermake, for a collection of Fruit.

SMALL SILVER GILT MEDAL.

Miss E. Harris, Clarendon Park, Salisbury, for Epergne with Cut Flowers and Fruit.
Mr. Wm. Kemp, Gr. to the Duke of Northumberland, Albury Gardens, Guildford, for 20 Stove and Greenhouse Plants.
Messrs. Jackson & Son, Kingston, for 6 Stove and Greenhouse Plants.
Mr. Thos. Baines, Gr. to H. Nicholls, Esq., Southgate, for 6 Fine Foliage Plants.
Mr. A. Wright, gr. to C. H. Roberts, Esq., Avenue Road, Regent's Park, for 8 Exotic Orchids.
Mrs. Greenhalgh, for large Fern Case.

LARGE SILVER MEDAL.

Mr. F. Perkins, Regent Street, Leamington, for Dinner-table Decoration.
Mr. John Ward, for 6 Stove and Greenhouse Plants.
Mr. E. Morse, Epsom, for 6 Stove and Greenhouse Plants.
Mr. T. Burley, Nurseryman, Bayswater, for 6 Fine Foliage Plants.
Messrs. Rollisson & Son, for 6 Exotic Orchids.
Mr. J. Carr, Gr. to F. L. Hinds, Esq., Byfleet, Weybridge, for 8 Caladiums.
Mr. T. Baines, Gr. Southgate, for 6 Exotic Ferns.
Mr. R. S. Williams, Nurseryman, for 6 Exotic Ferns.
Mr. T. Russell, Rose Cottage, Hampstead, for Pair of Window Baskets.
Mr. F. Perkins, Leamington, for Rustic Basket filled with Plants.
Messrs. Perry & Son, Dorking, for 24 British Ferns.
Mr. R. S. Williams, for Pair of Tree Ferns.
Mr. R. S. Williams, for 4 Palms.
Mr. J. Burley, Nurseryman, for 4 Palms.
Mr. J. Weston, Gr. to D. Martineau, Esq., Clapham Park, for 6 Exotic Ferns.
Mr. J. Catlin, Gr. to Mr. Lermitte, Sen., Finchley, for 6 Scarlet Pelargoniums.
Mr. C. Goddard, Gr. to H. Little, Esq., Twickenham, for 6 Tricolor Pelargoniums.
Messrs. Paul & Son, Cheshunt, for 48 varieties of Cut Roses.
Mr. W. Ingle, Gr. to Mrs. Round, Birchall, Colchester, for 24 varieties of Cut Roses.
Mr. B. R. Cant, Nurseryman, Colchester, for 24 trusses of Yellow Roses.
Mr. C. Berry, Gr. to J. Da Silva, Esq., Wandsworth Common, for 12 to Blue Grapes.
Mr. F. Feist, Gr. to R. Ashton, Esq., Staines, for 12 lb. of White Grapes.
Mr. R. S. Williams, for a collection of Plants.

SILVER MEDAL.

Miss E. Harris, Clarendon Park, Salisbury, for Dinner-table Decorations.
Miss J. Harris, for Epergne with Growing Plants.
Miss Hassard, for Epergne, with Cut Flowers and Fruit.
Mrs. Samuel M. Williams, Holloway, for Table Bouquet.
Mr. A. W. Chard, Clarendon Park, Salisbury, for Dinner-table Decoration.
Messrs. Dick Radclyffe & Co., Holborn, London, for Epergne with Plants, Flowers, and Fruit.
Mr. John Wills, Rosses Place, Brompton, for Bridal Bouquet.
Mr. F. Perkins, Leamington, for 20 Stove and Greenhouse Plants in 12-inch pots.
Mr. Joseph Wheeler, gr. to J. Philpotts, Esq., Stamford Hill, for 6 Stove and Greenhouse Plants.
Mr. W. Bull, Chelsea, for 8 Exotic Orchids.
Mr. G. Wheeler, Gr. to Sir F. H. Goldsmid, Bart., for 8 Caladiums.
Mr. J. Carr, for 6 Exotic Ferns.
Mr. J. Burley, Nurseryman, for 6 Exotic Ferns.
Mrs. Jeal, Park Street, Dorset Square, for large Fern Case.
Miss Graham, Brooksale, Haltwhistle, for small Fern Case.
Messrs. Dick Radclyffe & Co., Holborn, for Hanging Basket with Growing Plants.
Mr. C. Wood, High Street, Marylebone, for pair of Window Boxes filled with Growing Plants.
Mr. W. Cole, Gr. to F. Budgett, Esq., Ealing, for Rustic Basket filled with Plants.
Mr. J. Carr, Byfleet, for 12 British Ferns.
Mr. G. Wheeler, for a pair of Tree Ferns.
Messrs. Wyatt, Nurseryman, Kent, for 6 Fuchsias.
Mr. J. Weston, Gr. to D. Martineau, Esq., for 6 Scarlet Pelargoniums.
Mr. R. Thomas, Turner Road, Lees, Kent, for 6 Tricolor Pelargoniums.
Messrs. Carter & Co., Holborn, for 12 Tricolor Pelargoniums.
Mr. H. Cant, Colchester, for 48 varieties of Cut Roses.
Mr. W. Farren, Cambridge, for 24 varieties of Cut Roses.
Messrs. Paul & Son, for 24 trusses of Yellow Roses.
Mr. E. Cant, Gr. to J. C. Brown, Esq., Horsham, for a collection of Outdoor Fruit.
Mr. Verdier, Gr. to J. A. Rose, Esq., Wandsworth Common, for 4 Vines in pots.
Mr. A. Johnson, Savernake, for 12 lb. of Black Grapes.
Mr. G. Osborne, for 12 lb. of White Grapes.

SMALL SILVER MEDAL.

Mr. Joseph Wheeler, Stamford Hill, for 20 Stove and Greenhouse Plants, in 48-inch pots.
Mr. A. Wright, for 6 Stove and Greenhouse Plants.
Mr. Jas. Goodger, Gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, for 4 dishes of Strawberries.
Messrs. Perry & Son, for a collection of Hardy Ferns.
Messrs. E. G. Henderson & Son, for collection of New and Rare Plants.
Messrs. J. Veitch & Son for collection of New and Rare Plants.

LARGE BRONZE MEDAL.

Messrs. Pellat & Co., 25, Baker Street, for Epergne, with Plants, Flowers, and Fruit.
Mrs. Ransley Tanton, Epsom, for Bridal Bouquet.
Mr. F. Perkins, for Ball-room Bouquet.
Mr. G. Pearce, Gr. to W. S. Burton, Esq., Regent's Park, for 8 Caladiums.
Mr. A. Wright, for 6 Exotic Ferns.
Mrs. Jenkins, York Gate, Regent's Park, for large Fern Case.
Mr. Geo. Pearce, Gr., Regent's Park, for Hanging Basket, with Growing Plants.
Miss Annie Williams, Holloway, for pair of Window Boxes, filled with Growing Plants.
Mr. Ransley Tanton, for Rustic Basket, filled with Plants.
Mr. G. Wheeler, for 6 Fuchsias.
Mr. W. H. Fike, Gr. to J. Hatter, Esq., Clapham Park, for 6 Scarlet Pelargoniums.
Mr. T. Welsh, Hillingdon, Middlesex, for 6 Tricolor Pelargoniums.
Messrs. F. & A. Smith, for 3 Tricolor Pelargoniums.
Messrs. E. G. Henderson & Son, for 6 Tricolor Pelargoniums.
Mr. J. Fraser, Nurseryman, for 48 varieties Cut Roses.
Mr. J. Skinner, Gr. to Capt. Christie, Westerham, for 24 varieties Cut Roses.
Mr. W. Lynn, Gr. to Lord Boston, Hedsor, Maidenhead, for collection of outdoor Fruit.
Mr. W. Birse, Gr. to J. F. Lermitte, Esq., Finchley, for 2 dishes of Peaches.
Mr. J. Davey, Bridge Nursery, Friern, Barnet, for 2 dishes of Nectarines.
Mr. J. Smith, Gr. to the Earl of Gainsborough, Exton Park, Oakham, for 4 dishes of Strawberries.
Mr. W. Cole, for 2 Vines in pots.
Mr. C. Osman, Gr. to Capt. Hall, for dish of Figs.
Mr. J. Jaques, Gr. to J. C. Cunliffe, Esq., Croydon, for 1 Queen Pine-apple.
Mr. H. Bertram, Gr. to R. T. Crawshay, Esq., Cyfarthfa Castle, for 1 Pine-apple.
Mr. G. Osborne, Kaye's Nursery, Finchley, for 12 lb. of Black Grapes.
Mr. W. Davies, New Lodge, Friern, Barnet, for 12 lb. of White Grapes.
Mr. J. Douglas, for 1 dish of Black Hamburgh Grapes.
Mr. J. Standish, Ascot, for 1 dish of Black Grapes.
Mr. R. Ritchie, Gr. to R. H. France, Esq., Hampstead, for 1 dish of Muscat Grapes.
Mr. W. Cole, for 1 dish of White Grapes.
Messrs. Rollisson & Son, Tooting, for a collection of New and Rare Plants.
Messrs. E. J. Perkins, Leamington, for cut Geranium Blooms.
Mr. G. Pearce, Gr. for a collection of Foliage and Flowering Plants.
Mr. W. Hooper, Bath, for a collection of Picotees, Pinks, and Pansies.
Miss E. Harris, for Table Bouquet.
Miss F. Buster, St. Mary Cray, Kent, for Hand Bouquet.
Miss Hassard, for Hand Bouquet.
Mrs. Ransley Tanton, for Ball-room Bouquet.
Mr. John Cranston, King's Acres, Hereford, for Ball-room Bouquet.
Mr. G. Pearce, for 6 Exotic Ferns.
Mr. Edwin Ody, Talbot Road, Bayswater, for small Fern Case.
Mr. F. Perkins, for 6 Scarlet Pelargoniums.
Mr. T. W. Chard, for 24 varieties of Cut Roses.
Mr. A. Reid, Gr. to Louis Huth, Esq., Possingworth, Sussex, for 2 dishes of Peaches.
Mr. W. Birse, for 2 dishes of Nectarines.
Mr. W. Cole, for 2 dishes of Cherries.
Mr. F. Lovegrove, Nurseryman, Paddington, for 4 dishes of Strawberries.
Mr. H. Harvey, Gr., Wooley Park, Wantage, for a dish of Figs.
Mr. J. Jaques, Gr. to S. Copestake, Esq., Highgate, for 1 Queen Pine-apple.
Mr. G. Ward, Gr. to T. N. Miller, Esq., Bishop Stortford, for 1 Pine-apple.
Mr. M. Wilson, for 1 dish of Black Hamburgh Grapes.
Mr. F. Hicks, Gr. to C. Scholefield, Esq., for 1 dish of Black Grapes.
Mr. R. Barham, Gr. to Lord Ormathwaite, for 1 dish of Muscat Grapes.
Mr. G. Wheeler, for a collection of Achimenes.
Mr. G. Wheeler, for a collection of Foliage and Flowering Plants.
Messrs. Downie, Laird & Laing, for a collection of Hardy Annuals.
Mr. W. Bull, Chelsea, for a collection of New and Rare Plants.
Mr. W. Paul, for collection of Cut Roses.

CERTIFICATES.

Mr. G. W. Chard, for Bridal Bouquet.
Messrs. Carter & Co., Holborn, for Hanging Basket with Growing Plants.
Mr. G. Pizzey, Gr. to Sir E. Fulmer, for collection of Outdoor Fruit.
Mr. W. Bones, Gr., Havering Park, for 2 dishes of Peaches.
Mr. W. Lynn, for 2 dishes of Nectarines.
Mr. M. Walker, Gr., Gunnersbury House, Acton, for 2 dishes of Cherries.
Mr. D. Pizzey, for 4 dishes of Strawberries.
Messrs. Jaques & Son, for 2 Vines, in pots.
Mr. A. Reid, for Fruit not named in Schedule.
Mr. J. Neville, Gr. to Lord Sudeley, Weston Hall, Derbyshire, for 1 Queen Pine-apple.
Mr. R. Cockell, Gr., Page Green, Middlesex, for 1 Pine-apple.
Mr. Chas. Ross, Gr., Welford Park, Newbury, for 1 Green-fleshed Melon.
Mr. W. Lane, Gr. to J. Miles, Esq., Friern, Barnet, for 1 Scarlet-fleshed Melon.
Mr. Barham, Gr. to Lord Ormathwaite, Warfield Park, for 1 dish of Black Grapes.
Mr. W. Keeling, for 1 dish of Muscat Grapes.
Mr. D. Pizzey, for 1 dish of White Grapes.
Mr. W. Cuthbert, Gr. to Lord Petre, for a collection of Campanulas.
Mr. J. Ackhurst, for 3 Pine-apples in pots.
Mr. H. Harvey, for 4 Pine-apples.
Mr. Wyndham, for a collection of Heaths.

BOTANICAL CERTIFICATES OF MERIT.

Mr. Robert Parker, Tooting, for Ixora amabilis.
Mr. W. Bull, Chelsea, for Amorphophallus spectabilis.
Mr. W. Bull, Chelsea, for Anthurium Warshalli.
Mr. W. Bull, Chelsea, for Philodendron bipinnatum.
Mr. W. Bull, Chelsea, for Cattleyas species hybrids.
Mr. W. Bull, Chelsea, for Pteris serrulata cristata.
Mr. W. Bull, Chelsea, for Sonerila margaritacæphyllum.
Messrs. E. G. Henderson & Son, for Hydrangea japonica speciosa.
Messrs. E. G. Henderson & Son, for Verschaffeltia melanochaetes.
Mr. R. S. Williams, Holloway, for Rhopala Grandensis.
Mr. R. S. Williams, for Miltonia Warscewiczii.
Mr. Wyndham, Ingestre Park, Stafford, Gardener, for Æschmea Maria Regina.
Messrs. Jas. Ivery & Son, Dorking, for Polystichum angulare pulchrum.
Messrs. Jas. Ivery & Sons, for Polystichum angulare formiœ tridum.
Messrs. Jas. Ivery & Son, for Polypodium vulgare Whytei.
Mr. W. Bull, Chelsea, for Bighonia Roezliana.
Mr. Standish, Ascot, for Bouvardia leiantha grandiflora.
Messrs. Rollisson & Son, for Davallia clivacis.

FLORICULTURAL CERTIFICATES OF MERIT.

Messrs. E. & J. Perkins, Leamington, for Coleus Lady Leigh.
Mr. Wm. Kimberly, Coventry, for Tricolor Geranium Gem of Tricolors.

ROYAL HORTICULTURAL SOCIETY.—HORTICULTURAL DEPARTMENT of the LONDON INTERNATIONAL EXHIBITION, 1871.

The following Awards to Foreign Exhibitors have been made in this Department:—

APRIL 19, 1871.

Silver Flora Medal, M. L. Van Houtte, Ghent, for a Group of New Indian Azaleas.
First-class Certificate, M. L. Van Houtte, for Azalea Comtesse de Beaufort.
" M. L. Van Houtte, for Azalea President Ghellinck de Walle.
" M. L. Van Houtte, for Azalea George Loddiges.
" M. L. Van Houtte, for Azalea Alice.
" M. L. Van Houtte, for Azalea Marquis of Lorne.

MAY 3, 1871.

Silver Floral Medal, M. A. Dallière, Ghent, for a Group of Palms, Hollies, Azaleas, &c.
Second-class Certificate, M. A. Dallière, for Azalea La Reine.

JUNE 7, 1871.

Silver Floral Medal, M. A. Dallière, for a Group of 12 Palms.
" " " for a Pair of Pyramidal Bays.
First-class Certificate, M. J. Linden, Brussels, for Xanthosoma Lindeni.
" M. J. Linden, for Dracæna luteo-zebrina striata.
" M. J. Linden, for Acer palmatum crispum.
" M. J. Linden, for Acer palmatum roseo-discetum.
" M. L. Jacob-Makoy & Co., for Lycopodium dichotomum.
" M. L. Jacob-Makoy & Co., for Lycopodium mandioccanum.
" M. L. Jacob-Makoy & Co., for Lycopodium taxifolium.
" M. L. Jacob-Makoy & Co., for Tillandsia Morreniana.
Second-Class Certificate, M. J. Linden, for Epidendrum paniculatum.
Special Certificate, M. J. Linden, for a Group of Japanese Acers.

JUNE 21, 1871.

First-class Certificate, M. J. Linden, for Verschaffelia melanochætes.
" M. J. Linden, for Thrinax elegantissima.
" M. J. Linden, for Calamus ivoi Arenado.

JULY 5, 1871.

Silver Flora Medal, M. J. Linden, for a Group of Orchids.
" M. J. Linden, for a Group of New Dioscoreas.
" M. J. Linden, for a Group of New Maranta.
" M. A. Dallière, for a Group of Ornamental Marantas, for culture.
Special Certificate, M. A. Dallière, for Group of Greenhouse Palms, &c.
Special Certificate, M. J. Hermans, Herenthals, for Cut Roses.
First-class Certificate, M. J. Linden, for Epidendrum Frederici Guilelmi.
" M. J. Linden, for Maranta Mazellii.
" M. J. Linden, for Maranta Wallisii discolor.
" M. J. Linden, for Dieffenbachia imperialis.
" M. J. Linden, for Dioscorea melanyia.
" M. J. Linden, for Dioscorea Eldorado.
" M. J. Linden, for Dioscorea prestantica.
" M. J. Linden, for Dioscorea chrysophylla.
" M. J. Linden, for Alopecurus vittatus.
Second-class Certificate, Mr. J. Linden, for Aralia japonica aureo-reticulata.

The Gardeners' Chronicle

SATURDAY, JULY 15, 1871.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY, July 19	Royal Botanical (Fruit and Floral Committees), at S. Kensington	11 A.M.
	Ditto (Scientific Committee)	1 P.M.
	Ditto (General Meeting)	2 P.M.

IT is with surprise and regret that we have lately seen an attempt to dwell on the difference between PRACTICE and SCIENCE, as if the two were necessarily hostile instead of being complementary the one to the other. In a subject like gardening, which is at once an art and a science, neither the one nor the other can be neglected without injury to both. He who ignores the science leaves his craft as he found it – he buries his talent; he who neglects the practice injures his own interests, and has clearly no title to be called a gardener. We can only suppose that those who deem science really hostile to good idea what they mean. We fancy it is the word which is in fault here. "Science" has a Latin twang about it which raises a sort of prejudice against the thing it symbolises. Substitute the Saxon term, "knowledge," and we have a word which comes home to every man's understanding, and which at once commands his sympathies.

A gardener with knowledge is what every one wants—a gardener with science is fought shy of; but this simply means that the public, in seeking a gardener, neither wish for a philosopher nor desire a quack. They want a man who can, as Mr. FISH well expressed it, put his science into his flowers or fruit. The Pine, as we were lately reminded, that was presented to CHARLES II., and of which ceremonial the picture still remains, was but a poor affair in comparison with what the "science" of a DAVID THOMSON, or any other of our noted Pine growers, has led us to look for on our exhibition tables now-a-days.

The thousand and one illustrations of improvement in the art of gardening that might be adduced, were it not a matter of complete supererogation to do so, are, we submit, all and each as much due to science—that is, knowledge—as to practice. Without knowledge there can be no progress—with it advancement is only limited by the finite powers of individuals; and their successors, profiting by what their predecessors have done, push forward the great work and earn the gratitude of their fellows by their power of supplying human needs and human comforts.

The duty of the Royal Horticultural Society is plain, though we do not think that sufficient allowance is always made for the difficulties of its position. It must uphold the interests of all departments of gardening, scientific or practical; it must not favour either at the expense of the other; and it must get money. If it ignore science, it loses its title to influence and respect; it undoes all that SABINE, KNIGHT, LINDLEY strove so earnestly to accomplish, and descends to the level of a mere bazaar; if it neglect practice and slight practitioners the main object of its existence is annulled; while if it does not get money, naturally its own downfall must ensue.

Happily we believe none of these contingencies are likely to ensue. It is obvious enough that on the Council of the Society are some members not so useful as they might be, and who cannot be termed gardeners in any sense of the word; but as they probably aid the Society, at least indirectly, in its money-making departments, we can only wish that their aid was more freely rendered. As for other members of the Council, and these the working men—WILSON SAUNDERS, BATEMAN, WILSON, MARSHALL, CLARKE, and others—we do not see how the Society could, on the whole, be more fortunate in its councillors.

Every one of those we have named is a working horticulturist of no second rank, and they are supported by men of business and tact who have succeeded so far in steering the Society amid many difficulties, and who seem now likely to enable the Society once more to bask in the sunshine of prosperity. That the Council of a Society, with so many conflicting interests to serve, should blunder occasionally, is only to say that it is human. It could commit no graver blunder than to slight either its practical or its scientific upholders.

In conclusion, we commend the perusal of the following communication to our unscientific friends. It will probably lead them to think that if a little knowledge is a dangerous thing, no knowledge is often worse.

"Understanding that prizes are offered for hybrid plants, I should like to be acquainted with particulars, as for several years past I have quietly interested myself in the matter, and accomplished some singular crosses. I enclose a flower, the result of one Heartsease crossed with Calceolaria; it slightly shows the cross, is a first blossom; the plant is delicate, with smaller leaves than is usual with Heartsease.

"The shoots, or off-shoots, which accompany it are a more complex cross.—Heartsease crossed with common Brake Fern. Three or four plants thus crossed show most of Heartsease, but ever and anon throw up similar shoots, which vary in strength and size, and sori on back of leaves, but strangely enough they do not form fruit; the shoots sent threw out two or three blooms, and appeared likely to give seed, but, as you will perceive, did not. The parent plants are large, stems strong and coarse looking, the cross produces quite a small delicate plant, which seeds freely, and in the blossom shows the cross very plainly. I grew plants from this cross for two years; it proved only an annual. I tried repeatedly to reverse the cross, but never succeeded.

"Some years since I tried 'Borage,' or 'Bee-bread,' with Pelargonium, and the cross must have taken, for the blossoms hybridised invariably gave white seed, and they grew, but I could not see any trace of a cross in the plants. If I can, I shall repeat this cross."

Of all the HORTICULTURAL ESTABLISHMENTS of PARIS, none were more remarkable than that known as LA MUETTE. At the time of our last visit, hardly more than a twelvemonth since, one vast conservatory was filled from end to end with nothing but Azaleas, grown in the French style, and constituting, when looked on from above, a marvellously beautiful parterre of floral mosaic. The Palms and decorative plants grown in this establishment were so numerous, and the general arrangements on so large a scale, that it is no wonder that the earlier accounts received in this country were treated with incredulity as highly coloured with the exaggeration pertaining to travellers' tales. This, however, was not the case. It was soon ascertained that there was no exaggeration in the account written of La Muette. We have been naturally anxious to know what was the fate of this, in many respects, unrivalled establishment. M. ANDRÉ returns for answer that out of the 40 houses and their contents scarcely anything remains, but he attributes much of the disaster to the incompetency of the director appointed after the departure of MM. BARILLET and ERMENS. At the Luxembourg, M. RIVIÈRE has been more fortunate, and was enabled to save the greater part of his plants. Of the destruction in other public establishments, we have previously spoken on more than one occasion.

—— The last number of the "Revue Horticole," *i.e.*, the first number since the termination of the new Reign of Terror, contains a long list of persons connected with horticulture and botany who have fallen victims in some way or another to the direful calamities which have overtaken France during the last year. To some of these we have already alluded, but we have not previously announced the decease under most painful circumstances, of M. LIEBAUT, well known as a distinguished florist; M. FOURREAU, the pupil and *collaborateur* of M. JORDAN, of Lyons, well known for his extreme views as to the nature of species, and who died in battle, as also did ETIENNE DE VILMORIN, youngest son of LOUIS DE VILMORIN; and ALPHONSE MÜLLER, nurseryman, of Strasburg. Animated by noble patriotism, it is to be hoped their successors will show their love of their country by rendering the occurrence of such disasters impossible in the future.

The Earls of SHREWSBURY and of DARTMOUTH have set a good example by inviting their tenantry to visit the AGRICULTURAL SHOW at WOLVERHAMPTON, and providing luncheon for them on the occasion. This is a practice that might well be imitated by the proprietors of large garden establishments on the occasion of the provincial or other large shows of the Royal Horticultural Society.

—— CHLORIDE OF LIME is an excellent disinfectant, but it is a depilatory, and, as they have found to their cost in Brussels, some time since, a defoliator. It appears, from the "Illustration Horticole," that a quantity of the substance mentioned was stored in some warehouses close to the Botanic Garden; the result was that a large number of the plants lost their leaves in consequence of the emanations from the chloride of lime.

—— A correspondent, writing from Christchurch, has forwarded a fine specimen of SISYRINCHIUM BERMUDIANUM, L., found, as he states, in the moist part of a wood in the south of Hampshire, in a sheltered position, about half-a-mile from the coast. There is no reason to doubt the correctness of this statement, which is extremely interesting, as being the first record of this plant in Great Britain, though it was discovered some years since in County Galway, Ireland ("Phytologist" ii., 795). BENTHAM admits the plant as a native of Ireland, while WATSON, MOORE, and MORE, in the "Cybele Britannica," and "Cybele Hibernica," respectively, consider it to be an alien. If the plant has not been purposely introduced, it forms an interesting addition to the other plants of supposed American lineage, Neottia gemmipara, Naias flexilis, Eriocaulon septangulare, &c. We should be much obliged if our correspondent would favour us with another specimen.

—— The current number of that excellent periodical, the "American Agriculturist," contains a woodcut and a descriptive account of the BUFFALO GRASS, Buchloe dactyloides. This grass is widely distributed throughout the central districts of North America, from Canada to Texas, and forms a large proportion of the food of the Buffalo. The grass in question is dioicious, the male plant having so different an aspect from the female that the two sexes of the same plant have been described as separate species. Dr. ENGELMANN, of St. Louis, however, happened to meet with an obliging monstrosity, which bore flowers of both kinds, and which settled the specific nature of the plant. A grass like this, having such extensive powers of propagating itself by stolons, and one which can endure so great climatal vicissitudes, should be looked after by our Australian friends.

—— Mr. ALBERT MÜLLER has recently published, in the Transactions of the Entomological Society, an interesting paper on the DISSEMINATION OF INSECTS by means of the wind. The insects in question are such as, under ordinary circumstances, are not migratory, but are carried per force. Mr. MÜLLER cites a large number of cases which led him to the conclusion, in which we concur, that the amount of dissemination by atmospheric means is much underrated. As the dissemination of some plants, seeds, &c., occurs in precisely the same manner, we advise all readers concerned in the question relating to the dispersal of species, to peruse Mr. MÜLLER's interesting paper.

—— Those who advocate the claims of the CARPET SYSTEM of BEDDING-OUT, may be interested to know that Mr. CANNELL has one of the largest beds in flower seen at the Fuchsia Nursery, Woolwich. It is 34 feet long, and 11 feet wide, and contains over 2900 plants, estimated in value at nearly £60. As yet, owing to the ungenial nature of the weather, the plants have not made much progress in growth; but there is every reason to anticipate that, should we be favoured shortly with anything like summer weather, the bed will present many features of interest, inasmuch as nearly all the subjects available for this kind of work are represented in sufficient numbers to show the special merits of each, and grouped in such a happy manner as to make the bed a carpet picture of the most complete description. There is also another promising feature in this bed which we do not remember to have seen before, *i. e.*, the introduction of dwarf flowering plants of bright colour, to brighten up the sombre tints of the plants used for carpeting the ground.

—— The MAXIMUM TEMPERATURES in England during the week ending July 8 ranged from 77° at Leicester to 68° at Sheffield, with a mean for all stations of 71°.8; and in Scotland from 73° at Leith to 66°.9 at Aberdeen, with a mean for the several stations of 69°.5. The MINIMUM TEMPERATURES in England, as recorded at the several stations, were 47°.2 (at Salford), 47°.7 (Leicester), and 47°.9 (Nottingham); with a mean for the country of 48°.9, or about four-tenths of a degree lower than the mean for the several stations in

Scotland—where 47° (at Paisley) and 47°.5 (at Aberdeen) were the lowest temperatures. MEAN TEMPERATURES.—These values, although as a rule below their averages, were higher than during the preceding week; 60°.5 at Blackheath in England is 1°.8 above the next highest, viz., 59° at Perth in Scotland: close to which follow Portsmouth, 58°.9; Norwich, 58°.6; Leicester, 58°.4; and Manchester and Bradford, 58°.3, in England, and Leith with 58.5° in Scotland; the means for the two countries were 57°.8 for England and 57°.1 for Scotland. RAINFALL.—Some heavy falls have been recorded in England, especially at the midland stations: for instance, 2.13 inches at Nottingham, 1.76 inch at Sheffield, and 1.58 inch at Leicester; of the remainder, 1.50 inch at Hull, 1.32 inch at Liverpool, and 1.16 inch at Birmingham, were the principal. In Scotland the falls ranged in amount from 0.90 inch at Edinburgh to 0.52 inch at Leith, while at Paisley no rain fell. The mean fall for England was 1.16 inch, and for Scotland was 0.63 inch. (See Mr. GLAISHER'S Tables in our present issue.)

—— The plants composing the British Flora are now so well known, and England especially has been so thoroughly searched by careful observers, that any addition to their number, other than of critical species or evident introductions, is of great interest. More especially is this the case with the latest addition to our list—that of SILER TRILOBUM, Scop. (Laserpitium aquilegiifolium, Gouan), which has been found by Mr. J. COSMO MELVILL at Cherry Hinton, near Cambridge, close to the well-known locality for Seseli Libanotis and Bunium Bulbocastanum. The locality is given, in the "Flora of Cambridgeshire," as producing Smyrnium Olusatrum, a plant which was recorded from the same place by RAY, RELHAN, and MARTYN; and, almost incredible as it may appear, the plant seems to have escaped the notice of the many botanists who have made Cambridge the scene of their studies. Mr. MELVILL first gathered it in 1867, and we have seen in his herbarium the specimen then collected; he labelled it Smyrnium, on the faith of the Cambridgeshire Flora, recording the plant for that locality, although he had doubts even at the time as to its correctness. Having recently collected true Smyrnium, he again visited Cherry Hinton, and the result of his examination is the identification of the plant with Siler trilobum. Although in a young state (no fruit being at present matured) there can be no doubt as to the accuracy of the identification, the leaves alone, which are singularly like those of Columbine, being sufficient to show the distinctness of the plant from Smyrnium, and agreeing perfectly with authentic Continental specimens, as well as with JACQUIN'S admirable figure in "Flora Austriaca." Whether the plant is a genuine native we can scarcely pronounce at present, the Continental distribution, while not in opposition to such a conclusion, being scarcely what one would expect for a British plant: it is, however, a species which would only be introduced by a botanist, and must have retained its present position for many years. Under these circumstances we direct our readers' attention to the matter, and would advise them to examine their specimens of Smyrnium in case the same singular error may have occurred elsewhere.

—— Any one familiar with old gardening books will recall the important INFLUENCE which the MOON was supposed to exercise upon the GROWTH of PLANTS. Directions for planting trees, or gathering herbs, were almost always regulated in some manner by the state of the moon. We learn from the "Scientific American," that some of our Transatlantic cousins are still under the influence of the same belief. A correspondent of that journal writes:—"I am quite certain if Hickory timber, for instance, be cut between the full and new moon, the worms will devour it, but if cut, say, three days after full moon the worms will not touch it." Another correspondent, who had heard this point discussed for many years, tried the experiment, and, it is almost unnecessary to add, found the sticks cut at the different times mentioned in precisely the same condition, and quite free from worms. It is somewhat comforting to dwellers in the "old country" to find that even "Brother JONATHAN" has his superstitions, as his ancestors had before him.

—— Some consideration has of late years been given towards the growth of fibrous and oil-yielding plants in our colonies and foreign possessions, and amongst the latter the Sunflower, HELIANTHUS ANNUUS, has been favourably spoken of. The plant is largely grown in Russia for the sake of the oil; and it is said that, under a good system of cultivation, a bushel of seed will yield a gallon of excellent oil, which can be used for burning in lamps, for soap-making, or painting; and, if properly refined, it makes an excellent table oil. It is said to be much used for adulterating Olive oil, and is exported from St. Petersburg in large quantities, fetching about 10*s.* 6*d.* per cwt. The refuse, or marc, after the expression of the oil, is an excellent food for cattle. Horses, cows, and poultry are said to fatten rapidly after being fed with these seeds. In many places in Russia they are boiled and eaten by the people, and, when properly shelled and pulverised, they make good flour, which, being sweet, is very suitable for making cakes. The dried leaves are given to cattle instead of straw, and the stalks are said to produce a large quantity of alkali. One of the most recent applications, however, that has been advocated for the stems of the Sunflower is the manufacture of paper. Considering the ease with which these plants can be grown, and the quantity of seeds each one produces, it is time, if they are so really valuable, that they were made more generally useful.

—— The genus GAZANIA is well known both for its showy flowers, and for being peculiar in its geographical distribution to Southern Africa. None of the species, so far as we know, have, until now, been found to possess any useful properties; but one comes to us from the Bolwe River in Matabilland, Southern Africa, from the leaves of which the natives make excellent tinder. The long leaves are apparently beaten out, and the outer cuticle removed, leaving a soft, leathery substance, which is partly twisted like a rope in lengths of about 6 inches.

New Garden Plants.

SELAGINELLA RUBELLA, *Moore, n. sp.*

Stem prostrate, rooting, acquiring a brownish-red tint, branched alternately, the branches about twice dichotomously-forked; leaves dimorphous: lateral ones obliquely ovate-oblong obtuse, the anterior portion larger and dilated at the base, the margin entire, the costa prominent beneath: intermediate ones obovate, cuspidate, parallel, decurrent, auricled and slightly ciliate at the exterior base; spike ½ inch to 1 inch long, tetragonous, with ovate acuminate squarrose bracts.—*Hab.* Not known.

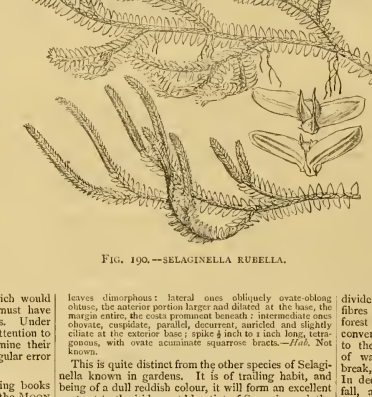

FIG. 190.—SELAGINELLA RUBELLA.

This is quite distinct from the other species of Selaginella known in gardens. It is of trailing habit, and being of a dull reddish colour, it will form an excellent contrast to the iridescent blue tint of S. cæsia, and the bright green of S. Kraussiana (denticulata of gardens). It was found by Mr. B. S. Williams, of Victoria Nursery, Holloway, on an imported Orchid, but beyond this the particulars of its history, as well as the habitat of the Orchid, have been lost sight of. Though it is thus obscure as to its origin, it will form a welcome addition to the plants of this order already in the hands of cultivators. *T. M.*

PHALÆNOPSIS MANNII, *n. sp.*

Foliis cuneato-oblongo-ligulatis acutis; racemo pluriflore deflexo; sepalis oblongo-ligulatis acutis; petalis linear-falcatis; labello trifido; lacinia lateralibus ligulatis erectis retuso emarginatis, medio bibulato callosis, isthmo a basi rotundato attenuato; lamina antica semilunata serrulata, carina papulosa in medio, papulis quibusdam per discum, plica transversa ante lacinias laterales, antepostia ligula lacuiplicata, ac carina incipiti retusa in ungue laciate media; columna apice tridentata.

Leaves nearly a span long, green, with a delicate violet border and many violet spots on the base. Flowers up to 1¾ according to a peduncle in my herbarium, with calix and petals yellow, with many cinnamon-brown dots and blotches. Lip white and purplish. Column yellow. This pretty plant was discovered in May, 1868, by Gustav Mann, Esq., who kindly sent both dried specimens and a nice faithful picture. I feel surprised that this plant emits many thin roots, quite contrary to the common Phalænopsid usance. It was a great satisfaction to name it in honour of the fortunate discoverer, who rendered the most eminent services to science, exposing himself in a very unusual and most dangerous manner. *H. G. Rchb. fil.*

ODONTOGLOSSUM HINNUS, *Rchb. fil.*

A new variety has come to hand, wanting the inner calli, and having entire wings of the column, with few toothlets, and without any tendrils. The lip reminds one of old Odontoglossum cristatum, Lindl. The sepals and petals, I may add, are undulated like those of Kennaithera Lowii, what gives it a very peculiar appearance. It is a very beautiful and decidedly very rare thing. Sent by J. Day, Esq. *H. G. Rchb. fil.*

THE NATURAL HISTORY OF A FLOWERING PLANT.

[The following is a report of Professor Thisselton Dyer's third lecture on "The Natural History of a Flowering Plant," in the Theatre of the Royal College of Science, Dublin.]

"THE stem" unites together the two great feeding systems of the plant—the leaves and the roots. The roots also serve the purpose of firmly fixing the stem to the ground, and therefore compensate partly the instability arising from the enormous surface exposed by the foliage to the wind. Great strength of material is necessarily required in a tree's framework; but it must also have elasticity, otherwise it would be shattered by every sudden blast, instead of bending before it. Timber is by no means to be regarded as having merely accidentally useful properties: these are of precisely the same advantage to the tree that they are when used for construction. There is a mechanical limit to the growth of trees—the stem increasing in a lower ratio than the strains put upon it, the weight of the upper portions would also eventually crush the lower. It should be noticed that the bulk of foliage in Palms is comparatively small—the toothold, from the want of a tap-root, being, at the same time, feeble. The unit of structure in a stem is a fibrous bundle. There are two patterns upon which stems are constructed, though, in their youngest state, both are at first similar. The substance of the young stem is cellular, and the first fibrous bundles are arranged in a circle towards the middle. The mass of cells in the interior of this circle is more or less evident in all our deciduous trees, and is called the pith. It is sometimes very large, as in the Chinese plant, where it is used in the manufacture of rice-paper. The fibrous bundles consist of an inner and an outer portion; each consists of fibres which are really cells, extremely elongated, and with their bounding membrane very much encrusted internally. Usually, except in Firs and [similar trees, there are found associated with the fibres of the inner portion of each bundle tubes whose cut ends are often visible in wood to the naked eye. Such tubes are called vessels, and they are formed from rows of cells whose partitions have been absorbed. Between the two portions of each bundle is a layer of delicate tender cells, in an actively vital state, the fibres themselves being practically lifeless and inert. These cells divide and grow, and are gradually converted into new fibres added to portions of the bundle. In a forest trees this process continues till a bundle is converted into a wedge, stretching from the centre to the circumference of the stem. In many trees of warm countries the process goes on without break, and the wood formed is quite continuous. In deciduous trees, however, it stops when the leaves fall, and this produces a line of demarcation, one corresponding to every year. In Palms the cambium, as the formative layer of cells is called, soon loses its vitality, and new circles altogether of bundles are formed; the cut ends of these can be easily detected about in a section of palm-wood. In our own trees the inner part of the wedge already described forms the wood, the outer portion the bark; the wedges are separated by often very manifest lines called pith-rays. The young one-year-old shoots bear the leaves; in these the wedges or bundles round the pith are still slender, and form, in fact, a cylinder such as may be well seen in an old cabbage stalk. It will be noticed that this is perforated with holes, through which fibrous contributions pass out from the inside of the cylinder to form the framework of the leaves; a contribution to which is also received from the bark on the outside. The outside of the stem, in its very young state, is covered with an external cellular layer—a portion, in fact, of the original cellular structure of the stem, separated from the pith by the development of the cylinder of contiguous fibrous bundles. The cellular material which fills up the framework of the leaves may be looked upon as an out-growth of this external cellular layer of the stem. In Palms, the fibrous bundles take, eventually, an outward course, and pass off bodily into the leaves; these have often a sheathing base, which, in some species, breaks up, leaving the fibrous framework projecting in stiff and rigid bristles. Under the name of Yissaba fibre (produced by a Brazilian Palm), these are used for making the common brooms with which

the streets of Dublin are swept. The sap absorbed by the roots is largely distributed through the plant by the compression and relaxation of the vessels when the branches are swayed by the wind. It is found that if a plant is constrained from swaying in a particular direction, the corresponding diameter of the trunk is shorter. Liquid is always got rid of by transpiration from the leaves, while it continues to enter the roots by absorption. When the vessels are compressed, therefore, in the bent branches the upward direction is that in which there is least resistance to motion—of the downward motion of the sap after elaboration in the leaves the cause is less obvious. Its course is mainly in the cambium within the bark; that it really takes place is proved by the swelling which is produced on a stem above a ligature. Decortication is commonly fatal to the parts of the stem above. If, however, the cambium is not destroyed, it may heal over with bark if properly protected. In this way Cinchona bark is renewed without killing the young trees. When it is necessary to prune trees, this should always be done by removing the branches without leaving a stump. This gives a chance for the wound to heal over, and so avoids further decay. Trees lose heat in the conversion of the water of their sap into vapour, but their stems at any rate absorb in the sun more than they lose, and towards the end of the day become warmer than the air.

A NEW SYNOPSIS OF ALL THE KNOWN LILIES.—V.

Subgenus 2. LILIUM PROPER.—Bulbs squamose; stigma a thick head to the style, with three blunt lobes—(*Continued*).

Group 2 : ARCHELIRION (Open-flowered Lilies).—Perianth broadly bell-shaped, horizontal, or slightly drooping, the divisions ovate or lanceolate, but widest below the middle, not unguiculate, spreading from below the middle when fully expanded. Stamens diverging on all sides.

Key to the Species.

Leaves linear sessile, verticillate in the axils of the upper ones, Stems cottony. } 9. L. TIGRINUM.

Leaves lanceolate, with a short distinct petiole, not bulbiferous in the axils. Stems glabrous.

Leaves ovate-lanceolate. Perianth segments usually banded down the centre with red. } 10. L. SPECIOSUM.

Leaves lanceolate. Perianth segments usually banded down the centre with yellow. } 11. L. AURATUM.

The three species of this section are so well known to every one that I describe them only for the sake of making my synopsis complete. To me they seem to form a distinct group, and not to range well with either the Martagons or Eulirions, but to differ appreciably from both in the shape of the entire flower and of the divisions, and to form a clearly marked group intermediate between all the other three.

9. *L. tigrinum*, Gawler in Bot. Mag. t. 1237; Red. Lil. t. 395 and 475; Ait. Hort. Kew, edit. 2, vol. ii., p. 241; Kunth, Enum. iv. 259; Spae, Mon. p. 39; Miquel, Ann. Mus. Lug. Bat. vol. iii., p. 156; *L. speciosum*, Andrews, Bot. Rep., t. 600, non Thunberg.—Stems 2—4 feet high, erect, firm, robust, purplish-black, clothed especially in the upper part with grey cottony pubescence. Leaves 20—30 at the flowering time, linear, scattered irregularly, erecto-patent or spreading, dark glossy green, stout in texture, paler on the lower side with 5—7 distinct nerves, the lower ones 4—6 inches long, 6—9 lines broad, slightly raised to a sessile base, narrowed gradually from the middle to a long point, the upper ones much shorter, linear or often lanceolate, with round nearly black bulblets in the axils of many of them. Flowers usually 2—4, but a few raised panicles, up to five in a cultivated raceme 8—9 inches broad, the lateral peduncles rigidly erecto-patent, usually furnished with a bract at or below the middle, the lower ones 3—4 inches long. Perianth 4—5 inches long, bright deep orange, and with a very large number of small distinct purplish-black spots on the face, the divisions lanceolate, the outer ones 4—6 lines, the inner 6—9 lines, broad below the middle, the lower part of a few raised papillæ, the base of the segments with a groove bordered with two pubescent ribs. Filaments 6—12 lines shorter than the segments; anthers 6—9 lines long; pollen orange-red; ovary 7—9 lines long; style 12—15 lines; stigma cup purple.

A native of Japan and China, introduced to our gardens along with L. japonicum in 1804 by Captain Kirkpatrick, but well known previously, although not named, by the figure published by Sir Joseph Banks in 1791. One of the most distinct, best known, and least variable of all the species. The principal points in which the different specimens are not uniform, are in the colour of the flowers and the extent to which they droop, which is usually but not invariably considerable.

10. *L. speciosum*, Thunb. in Linn. Trans. ii. 332; Bot. Reg. t. 2000; Zucc. in Sieb. Fl. Jap. fasc. iii. p. 31, t. 19 and 20; Kunth, Enum. iv. 259; Spae, Mon. p. 36; Bot. Mag. t. 3785; Flore des Serres, t. 276; Paxton Mag. v. t. 1, vii. t. 127; *L. superbum*, Thunb. Fl. Jap. p. 134, non Linn.; *L. lancifolium*, Faxt. Mag. v. 269, non Thunb.—Stem 1—3 feet high, rigid, erect glabrous, terete, greenish. Leaves about 50 at the flowering time, the lower ones ovate, or ovate-lanceolate, 6—9 inches long, 1½—2 inches broad below the middle, bright green above, paler, with 7—9 distinct ribs beneath, rounded at the base to a short erect petiole, narrowed gradually from the middle to an acute or acuminate point, the upper ones lanceolate, 6—9 lines broad, 3—5 nerved. Flowers usually 3—6, in a broad deltoid raceme, occasionally more numerous in cultivation, in a compound corymb; the pedunches bracteated, rigid, erecto-patent, the lowest 4—5 inches long; perianth 3—5 inches deep, the divisions spreading from near the base when fully expanded, the outer 12—18 lines, the inner 15—21 lines broad below the middle, the face in the lower half charged with copious, much raised papillæ, which reach a length of 2—3 lines, the lower third with a distinct green glabrous hollow down the keel, the colour a pure white ground in the typical form, more or less suffused, and copiously spotted with claret-red, but sometimes both the face and papillæ pure white, the bud externally greenish, the expanded flower measuring 6—8 inches across. Filaments 3—4 inches long; anthers 9—12 lines long, pollen dull red or yellowish; ovary an inch deep; style 1½—2½ inches.

A native of Japan, long known through Kæmpfer's drawing published by Sir Joseph Banks, but not introduced to Europe till 1832. As every one knows, it varies greatly in the size and colouring of the flower, but it is a most distinct plant, with no close affinity except to L. auratum, and unfortunately it was first cultivated in cultivation under a wrong name, Lilium lancifolium, which belongs to an entirely different species of the Isolirion group, which I shall have to notice presently; and a name when once put into garden circulation is very rarely entirely superseded. I very difficult to get changed. Let me beg of all my horticultural readers who have not done so already to call this commonest and best known of the Japanese Lilies, in their catalogues and on their labels, by its correct name, "*speciosum*," and probably in a few years days we shall be having the proper "lancifolium" rediscovered and introduced; but it is clearly understood that at present "lancifolium" is not known in cultivation at all. The principal named varieties are two—1, *punctatum*, with white segments, not banded, but with a few claret-red spots; and 2, "Paxton's Magazine," vol. v. t. 267, under the name of lancifolium, and there compared with speciosum as if a distinct species; and 2, *Tametano* of Zuccarini (albiflorum of Hooker, L. Broussartii, Morren, in Mem. Acad. Royal Brux., 1843), with its flowers pure white flowers. This last is sometimes called Lilium eximium in gardens, but must not be confounded with the eximium already noticed under L. longiflorum.

11. *L. auratum*, Lindl. Gard. Chron. 1862, p. 644; Hook. Bot. Mag. t. 5338; Flore des Serres, t. 1528—1531; Ill. Hort. ix., t. 338; Rev. Hort., 1867 t. 371; *L. Lexleri*, Lindl. Hort. Aug. 1862.—Stem 2—4 feet high, rigid, erect, purplish-green, terete, quite glabrous. Leaves about 30 at the flowering time, spreading or deflexed, linear-lanceolate, the lower ones 6—9 inches long, 9—15 lines broad below the middle, narrowed similar to those of speciosum in colour and texture, with five or rarely seven distinct transluscent ribs beneath, slightly narrowed at the base to a short distinct petiole, narrowed gradually from the middle to an acuminate point. Flowers usually 3—6 in a deltoid raceme, occasionally up to 20 under cultivation, the peduncles rigidly erecto-patent, bracteolate, 3—4 inches across. Filaments 3—3½ inches long; anthers 1 inch; pollen scarlet; ovary 12—14 lines long; style 3—3½ inches.

A native of Japan, and scarcely to be regarded as more than a subspecies of speciosum. Oldham writes on the label of a specimen he gathered near Yokohama in August, 1861, now in the Kew herbarium—"Left of the Japanese road, a showy plant, very pale chiefly in light rich soil amongs the shrubs and between the rocks." Introduced into this country by Messrs. Veitch, who flowered it for the first time in 1862, not 1848, as was quoted, through a misprint, in the Botanical Magazine, and in the plate in the "Botanical Magazine." There is now a pure white variety advertised, and several with the segments variously suffused or vittate with red. I have not seen the *Lilium Wittei*, described by Suringar in Koch's "Wochenschrift," 1867, p. 294, but, judging from the description, it must be a mere variety of this. *J. G. Baker.*

[Those of our readers interested in the culture and identification of Lilies will learn with pleasure that the publication of M. Duchartre's notes on these beautiful plants has been lately resumed, in the "Journal de la Société Centrale d'Horticulture de France." The Franco-German war of course put a stop to this publication, but now that the sword is once more sheathed the Lilies will bloom again, and we shall shortly continue our translation of M. Duchartre's articles. EDS.]

NEW PEARS.

AT p. 651 you give an extract, headed "Remarks on New Pears," taken from Mr. Rivers' Fruit Catalogue, where he says, "We advance but slowly in new Pears, and not more than 5 per cent. of the new varieties raised from seed on the Continent are adapted for universal cultivation." As these quoted remarks (made by Mr. Rivers about four or five years ago) may have a tendency to mislead parties with regard to Continental productions, and to have them suppose that we, as a nation, think ourselves before our neighbours in these things, I have sent you lists, which I am afraid will be too long for your columns, of Pears of English and Scotch growth, as far as I know them. The sorts enumerated have taken us many long years to produce, and are, as first-class fruits, few in number, especially when compared with the prolific productions of France and Belgium, a list of which I also send you, of kinds only produced within the last 20 years. Whilst the English and Scotch first-rate sorts produced, during 150 years or more, amount only to about 30, we have 120 new first-rate kinds produced on the Continent in 20 years. Were I to go backward 20 years more the balance against us would be great indeed. Take the productions of Van Mons alone, what can we show against them? The list I send you of new kinds, all of which, with a few exceptions, have been proved here as of excellent quality, and the greater portion of them are, in my estimation, adapted for general cultivation, where the locality does not stand at too great an elevation above the sea. The years affixed are those I received the sorts in, and these dates are generally one or two years later than the years when the respective kinds first fruited. I have by pursuit of the lists will make us cautious of giving credence to a statement which would limit the new good Pears of the Continent, suitable for general cultivation, to 5 per cent. of those sent out from the Continent. My experience is the very contrary, and I do not wish to cry up the extreme honesty of our brethren across the water, although I think that they will, as far as I am a judge, bear honourable mention beside us. My long rows of specimen Pear trees do not speak very favourably of English nurserymen, when put in contrast with our Continental neighbours. I have purchased all the sorts of Pear that I could procure in America, Great Britain, or from Continental nations, and I have kept the names of all the parties from whom I purchased, and planted their trees each according to its kind in juxtaposition with sorts under the same name, so as to enable me to judge which were the most correctly named, the Americans, the Continentals, or Britons. Although I am ashamed, I am constrained to say that I have found the nomenclature of fruit in England very much behind either America (from which I have no sorts of Pear) or the Continental nations, from which I have imported nearly 1200 kinds, very few of which belie their names. In my specimen rows there stand against my English brethren a very sombre array of false kinds and false names, and these are exceedingly vexing, as, unintentionally, I send them all over the country, before the error of name and kind is found out, which to do takes years of patient attention. Alas! it is the labour of a long life to do it. Uncorrectness of nomenclature is now almost as bad as it was before Thompson tried his hand at Pears upwards of 30 years ago, and would, indeed, take a Hercules now to gather together our golden Apples and Pears and to send them forth into the world each under its proper character and name; then how am I, a poor mortal, to grapple with the hydra of such nomenclature? My collection of Apples contains about 1000 sorts, gathered from under the four winds of Heaven. When I look at it, it makes me stand aghast, and I exclaim to myself, Alas! what can I do! I feel myself helpless amidst the confusion. I had in my fruit room last winter over 600 kinds, according to the names received with them, and I intended sending 300 sorts to the Fruit Committee of the Royal Horticultural Society; but when I came to arrange and test them I found only 250 sorts that I could send with anything like correct names. Many of the others were fine fruit, but I was doubtful of them, and kept them back, until I could examine them further. In concluding, I must in justice give the prize to the American and Continental collections.

A LIST OF ALL THE PEARS RAISED IN ENGLAND, THAT I KNOW.

Aston Town, 1st quality.
Beadsell's Seedling, 1st to 2d quality.
Bergamotte, Cassell's, 1st rate.
" " late, worthless.
" Hadley Pears, 2d rate.
" Seaside, 2d rate.
" St. Leonard's, 2d rate.
" Tadbeck, 2d rate.
" Wormsley, 2d rate.
" Hampden's, 2d rate.
Beurré d'Amalenburg, early, 2d rate.
" Winter, Rivers', 3d rate.
Bon Chrétien, Williams', 2d rate.
Black Worcester, 3d rate.
Brockworth Park, said to be 1st rate.
Brougham, 1st rate.
Broom Park, 1st rate.
British Queen, 1st to 2d rate.
Bishop's Thumb, 1st to 2d rate.
Bringewood, 1st rate.
Bury Hill, 2d rate.
Crassane, Althorpe, 2d rate.
" Stroud House, brown, 1st rate.
" Stroud House, green, 2d rate.
Doctor (The), or Benedictine, 2d rate.
Duchesse d'Angoulême, Pitmaston, 1st rate.
Dumore, 1st to 2d rate.
Downton, 2d rate.
Elton, 1st rate.
Eastnor Castle, 2d rate.
Eyewood, 1st rate.
Golden Russet, 2d rate.
Hampton Court, 2d rate.
Incomparable, Hacon's, 1st rate.
Josephine, Autumn, said to be 1st rate.
King Pear, or Caillot Rosat, 2d rate.
King Edward, 3d rate.
Monarch, 1st rate.
Maud Hegg, said to be 1st rate.
Moccas, 1st rate.
Nelis, Chatsham's Autumn, 1st rate.
Prince Consort, 1st rate.
" of Wales, 1st rate.
Princess of Wales, 1st rate.
" Royal, Groom's, 1st to 2d rate.
Shobden Court, 1st rate.
Stevenstone, 1st rate.
Suffolk Thorn, 1st rate.
Swan's Egg, 2d rate.
Sir Gerrard Noel Noble's, 3d rate.
Tillington, 1st rate
Victoria, Huyshe's, 1st rate.
52 sorts, 29 of which are 1st rate.
18 " " 2d rate.
5 " " 3d rate.

The above are all the sorts of English Pears that I know, or that I have been able to procure, and the list shows that we are far behind our Continental neighbours in Pear raising. I have not taken into account the Perry sorts, nor some third-rate kinds that have only

a local standing. I dare say some of your correspondents could eke out this list very much.

A List of all the Scotch Pears I know, or that I have been able to procure. Quality in England.

Achan, 2d rate.	Green Pinckey, 2d rate.
Bervie, 2d rate.	Grey Goodwife, 3d rate.
Briar Bush, 3d rate.	,, Honey, 1st rate.
Busked Lady, 2d rate.	Golden Knap, 3d rate.

Gamon's, 2d rate.	Sauch, a beautiful Pear, 3d rate.
Green Yair, 2d rate.	Unicorn, 3d rate.

Of the above there are two or three that may be called first-rate, but as a rule few of the Scotch Pears are found to be of first-rate quality so far south as Somerset.

A List of New Continental Pears introduced since 1850. All of first-rate Quality.

Besides the above I have imported about 50 other new kinds, said to be all of first-rate quality, since 1869; so that during the last decade, above 100 new kinds have been added to our collection. All the above quoted, up to 1869, I have fruited here, and so proved their claim to the first rank. *J. Scott, Merriott.*

KARL THEODOR HARTWEG.

We have already (p. 313) chronicled the loss of another of that energetic band of botanical collectors who travelled under the auspices of the Horticultural Society of London, and to whom we are indebted for many of the choicest plants in cultivation. We glean most of the following particulars of his career from a more detailed sketch which appeared in the "Wochenschrift."

The subject of our memoir, a native of Karlsruhe, was born June 18, 1812, and descended from a long line of distinguished gardeners. Besides the advantages of his father's experience, he enjoyed the benefits of a far better education than usually falls to the lot of a gardener. Unfortunately, his father died before he, Karl, had completed his nineteenth year, and consequently he determined to visit France and England, where the state of horticulture was in advance of that of Germany.

He went first to Paris, and succeeded in obtaining a situation in the Jardin des Plantes, and whilst there he laboured most assiduously to make the most of the opportunities offered by that establishment to improve himself. After gaining a tolerable knowledge of French, he came over to England haphazard, but falling ill before he obtained employment, he became very needy. At length, when his health became better, he entered the Horticultural Society's garden as a common labourer, where his superior intelligence and education soon became evident to the authorities, and he was advanced to the higher and more lucrative post of garden clerk. About that time the lamented Douglas met with his death, and it was resolved by the Society to seek another person to explore the highlands of Mexico, chiefly with a view to the possible discovery of new plants which would bear the climate of this country.

Hartweg having been selected for this expedition, left England October 8, 1836, for Vera Cruz, and from thence went to Santa Fé. He did not, however, remain long in the unhealthy lowlands, but ascended the first terrace, Taupapan, on the east side of the lofty Orizaba. And here he found the first batch of the many splendid epiphytal Orchids with which he enriched our gardens. Agave saponaria was another interesting discovery of his in this region. After a brief stay he pushed on by way of Xalapa to Mexico, there to present his credentials and obtain permission to proceed to Guanxuato. But the vegetation of the mountain plains and declivities not answering his expectations, he longed for the tropical vegetation of the lower zones. Still poorer was the vegetation of Leon, where he stayed two months —during the dry season, it is true—without finding anything to interest him. Its only charming Latin majalis. But in Aguas Calientes there was more luxuriance, though not sufficient to detain him, and he decided to explore the lower terraces and valleys, and for this purpose he went to Bolanos. Bromeliaceæ, Cactese, and Acacias in great variety formed the most striking features in the first district upon the town of Zacatecas, which is situated upon one of the highest and most barren terraces of northern Mexico. Evergreen Oaks and various species of Pinus were plentiful, but he was too late to get seeds. Having little else to do, he now arranged his collections, and forwarded them to England, thus completing the first year of his travels.

In February, 1838, Hartweg started for San Luis Potosi and Rancos de los Gallitos, where also he found immense tracts of evergreen Oaks, richly adorned with Epidendra, Tillandsias, Orchideæ, and introduced to the State of Mechoacanaha, where, amongst other things, he found Pinus oocarpa, P. leiophylla, and P. pseudostrobus. Here, too, grew the majestic sacred Fir, Abies religiosa, rising to a height of 150 feet. The next year was to Reall del Monte, the home of the "Old Man" Cactus, Cereus senilis, and thence to Queretaro, where greater variety rewarded our traveller. The dwarf Pine, Pinus Llaveana, which only grows about 15 feet high; P. apulcensis and P. patula, in company of Cupressus thurifera, a tree of 150 feet; Juglans mollis Garegnii.

At the close of 1839 Hartweg was instructed to go to Guatemala, and on his way he visited Oaxaca, the seat of Cochineal culture. He remained a few days, and discovered Pinus Russelliana, P. Devoniana, P. Teocota, and Tilia mexicana, &c.

He now went again to Tuxtelenango to collect Orchids, ascending the mountains to the highest terrace, where Oaks, Pinus Hartwegii, P. oocarpoides, P. filifolia, and Alnus mexicana abound. An important excursion from this point to the lower plains, bordering the Pacific, resulted in a rich booty of Orchids, many of which flowered in London in the course of the following year.

His next trip was to the highlands of Ecuador, where he visited Riobamba, Acobamba, &c., but was less successful. Towards the end of May, 1841, he set out upon his journey to the Cordilleras, but of the 70 species of Orchids collected few were alive when they arrived in England. Before leaving he ascended the Pichincha, to investigate the alpine flora. He returned to England in 1843, and in a report of his travels it is stated that the cost of the journey was covered by the sale of seeds and living Coniferæ alone.

The exertions of the Horticultural Society at this period to introduce new and beautiful plants, will be understood when we remember that the sum of £3837 was expended for this purpose between 1840 and 1846. If Hartweg was sent out again in 1845, and this time to California. Our space will not admit of a detailed account of his second journey, but it is very well known that an immense number of our hardy annuals and herbaceous plants from that region were introduced by him and Douglas.

We must not omit to mention the valuable collections of dried plants he brought home, and which Mr. Bentham described and published, under the title of "Plantæ Hartwegianæ."

Altogether, Hartweg was absent about nine and a-half years. He did not remain long in England, but soon returned to his native country.

The late Grand Duke Leopold having taken great interest in him, appointed him Inspector of the Ducal Gardens at Schwetzingen, which post he held till his death. Of a modest, retiring disposition, he seldom took part in public meetings, believing that little came of them; but he was induced to take part with others interested in the improvements of fruit culture.

Some six or eight years ago, his hitherto strong constitution began to fail, and he suffered from everincreasing attacks of palpitation of the heart; this, coupled with an affection of the brain, gradually brought him to his grave, and he died on February 3 last.

LUMINOUS PLANTS.

"'Tis said in summer's evening hour,
Flashes the golden-coloured flower,
A fair electric flame." Coleridge.

There are some of the phenomena of life which are so startling in their character that they cannot fail to attract attention, even amongst the unlearned. Of such is the emission of light by insects and plants; especially in countries where fire and light are held to be more or less divine, and the object of adoration, we may anticipate that such phenomena are regarded with peculiar interest. It is so in India, where the idea that some plants, under favourable conditions, evolve light, has firm possession of the minds of the inhabitants. That nothing of the kind has been observed, even by the most sceptical would doubt, but it is equally probable that exaggeration has lent something to the reports. The prevalence of this idea in India long since was noticed by Major Madden in one of the Indian horticultural journals, when he stated that "vague ideas of the existence of luminous plants in India and the neighbouring countries, still float about, as in the days of the old Hindoos and Greeks." The major gave instances, of which some probably had their foundation in fact. It is not that we place implicit reliance on all that we read on this subject, that we are induced to allude to some recorded instances, but rather with the view of collecting together some of the gossip on the subject.

If we refer to No. 153 of the "Journal of the Asiatic Society of Bengal," we find it there recorded that in Affghanistan, to the west of Nahoug, is a mountain called Sufed Koh, in which the natives believe gold and silver to exist, and in which they say, in the spring, is a bush which at night, from a distance, appears on fire, but on approaching it the delusion vanishes." It is very probable, in this instance, that the belief is based on vague report.

Baron Hugel's name is well known in connection with Kashmere, and, as a naturalist, his evidence, if positive, would be accepted with respect. But, again, only report is cited, for the Baron says that he was told that there was a plant found on the hills, which, brought down from Thibet pieces of timber which "shine in the dark as long as they continue moist." The phosphorescence of decaying wood is nothing new, and it is probable that this is attributable to the same cause. Schoolboys did believe in the phosphorescence of "touchwood" many years ago and probably do so now. In those days we have recollections of carrying such treasures in our pocket for practical illustration in the dormitory at night.

Of a somewhat different characters are the substance exhibited on April, 1845, at a meeting of the Royal Asiatic Society. It was the rootstock of a plant from the Ooraghum jungles, at the foot of the Madura Hills, near Tuchoor, and was supposed to belong to some species of Orchis or Marica. It was said of it that it possessed the peculiar property of regaining its phosphorescent appearance when a dried fragment of it was subjected to moisture, "gleaming in the dark with all the vividness of the glow-worm, or the electric Scolopendra, after having been moistened with a wet cloth applied to its surface for an hour or two; and it did not seem to lose the property by use, becoming lustreless when dry, and lighting up again when moistened." The *Gardeners' Chronicle* stated at the time, that "a small slice of the dried root being wrapped in a wet cloth, and allowed to remain about an hour, shines in the dark like a piece of phosphorus, or perhaps somewhat paler, more like dead fish, or rotten wood."

Accompanying this account in an Indian journal is the statement that this plant has long been familiar to the Brahmins under the name of Jyotismati, and "is occasionally referred to a species of Cardiospermum, perhaps a variety of the white-seeded, on the black seed of that plant." The discovery of the Coromandel plant was made, it is said, by a "tuhseeldar, compelled by rain to take shelter at night under a mass of rock, where he was astonished to see a blaze of phosphoric light over the grass in the neighbourhood."

Sanscrit authorities refer the Jyotismati to the Himalayas, and Major Madden found, upon inquiry at Almora, that there was a luminous plant well known there by that name and the Jwalla-mat, implying the possession of light or fire. This plant proved to be the Antilisia Asiatica, of which perhaps a single pod a hundred is said to be luminous at night during the rainy season. Other grasses, species of Andropogon, are reported to possess the same property, and both Hindoos and Moslems are persuaded of the existence of a plant called Sunee, extolled for its power of revealing the wonders of fairyland; and eagerly sought by fakeers and serpents.

In 1845 the natives of Simla were filled with a rumour that the mountains near Syree were illuminated nightly by some magical herb.

It has been supposed that some of these reports may be traced to a species of Dictamnus, as there is one which is very closely allied to the European form (the Dictamnus himalayensis of Royle), which abounds near Gungotree and Jumnotree. If the Indian species really possesses the power of exhibiting itself in the manner of its European relative, it is not at all surprising that the natives should spread its fame as that of a bush ever burning but never consumed.

Apropos of the European Dittany (Dictamnus Fraxinella), the late Professor Henslow explained the inflammable atmosphere generated about it, on a calm still evening, as the evaporation of a volatile oil, and adds that "if a candle be brought near it, this plant is enveloped by a transient flame, without sustaining injury."

Fire is said to be latent in the "Summee," which is supposed to be Prosopis spicigera, the Jhund of Northern India. It may be that only such latent fire is alluded to as may be obtained by friction.

The English translation of the Ulfaz Udwiyeh gives Siraj-ul-kootrub as "the fairy's lamp—a plant which shines at night like the glow-worm."

Another plant which has obtained the reputation of being luminous is the Tuberose (Polianthes tuberosa). It has been observed, so it is said, of a sultry evening after thunder, to dart small sparks in great abundance from such of its flowers as were fading. The rare occasion when fading flowers, a thunderstorm, and an observer, meet together for such an exhibition, must be some apology for the doubt which may be entertained as to the speedy verification of the facts.

It should be remembered that Josephus, in his "Wars of the Jews" (book vii., chap. vi.), writing of Macherus, says:—"There is a certain place called Baaras, which produces a root of the same name with itself; its colour is like that of a flame, and towards evening it sends out a certain ray like lightning; it is not easily taken by such as would do it, but recedes from their hands." The only virtue this root possesses is its supposed power in the expulsion of demons.

As to the incident recorded in connection with the Fraxinella, Dr. Hahn has offered explanations in the "Journal of Botany" for 1863. "When the daughter of Linnæus one evening approached the flowers of Dictamnus albus with a light, a little flame was kindled without in any way injuring them. The experiment was afterwards frequently repeated, but it never succeeded; and the most eminent scientific men regarded the whole as a faulty observation or simply a delusion, others endeavoured to explain it by various hypotheses. One of them especially, which tried to account for the phenomenon by assuming that the plant developed hydrogen, found much favour. At present, when this hypothesis has become untenable, the inflammability of the plant is mentioned more as a curiosity, and accounted for by the presence of etheric oil in the flowers. Being in the habit of visiting a garden in which strong healthy plants of Dictamnus albus were cultivated, I often made the experiment, but always without success, and I already began to doubt the correctness of the observation made by the daughter of Linnæus, when during the dry and hot summer of 1857 I repeated the experiment once more, fancying that the warm weather might possibly have exercised a more than ordinary effect upon the plant. And in a lighted match close to an open flower, but again without result; in bringing, however, the match close to some other blossoms, it approached a nearly faded one, and suddenly was seen a reddish, crackling, strongly shooting flame, which with powerful action was small, and did not injure the peduncle. Since then I have repeated the experiment during several seasons, and even during wet, cold summers, it has always succeeded; thus clearly proving that it is not influenced by the state of the weather. In doing so I observed the following results, which fully explain the phenomenon. On the pedicels and peduncles are a number of minute reddish-brown glands, secreting etheric oil. These glands are but little developed when the flowers begin to open, and they are fully grown shortly after the blossoms begin to fade, shrivelling up when the fruit begins to form. For this reason the experiment can succeed only at that limited period when the flowers are fading. Best adapted for the purpose are those panicles which have done flowering at the base, and still have a few blossoms at the top, as the entire panicle cannot be lighted twice. The rachis is uninjured by the experiment, being too green to take fire, and because the flame runs along almost as quick as lightning, becoming extinguished at the top, and diffusing a powerful incense-like smell."

In 1843, the luminosity of plants was recorded in the Proceedings of the British Association. Mr. R. Dowden is said to have made mention of a luminous appearance on the double variety of the common Marigold. This circumstance was noticed on August 4, 1842, at 8 o'clock P.M., after a week of very dry weather. Four days after the phenomenon was observed shutting off the declining daylight, a gold-coloured lambent light appeared to play from petal to petal of the flowers, so as to make a more or less interrupted corona round its disk. It seemed as if this emanation grew less vivid as the light declined; it was not examined in darkness. When this subject was discussed, Dr. Allman expressed his opinion that the phenomenon was not at all due to phosphorescence, but was referable to the state of the visual organ, that is, an optical illusion. This led Mr. Babington to mention that he had seen, in the south of England, a peculiar bright appearance produced by the presence of the Schistostega pennata, a little moss, which inhabited caverns and dark places; but this, too, was objected to by a member present, who stated that Professor Lloyd had examined the Schistostega, and had found that the peculiar luminous appearance of that moss arose from the presence of small crystals in its structure, which reflected the smallest portion of the rays of light.

These remarks having been published in the *Gardeners' Chronicle*,* Dr. Edwin Lankester, in a succeeding number communicated some observations on the subject of luminosity, in plants more especially,† in which he referred to many of the facts of luminosity which had been recorded.

"The light from the moss," he says, "mentioned by Mr. Babington has also been observed in Germany on another species (Schistostega osmundacea). It has been observed by Funk, Brandenberg, Nees von Esenbeck, Hornschuh, and Struve. Bridel-Brideri and Agardh attributed this light to a small Alga, which the former called Catoptridium smaragdinum, and the latter Protococcus smaragdinus, which they supposed occupied the moss. Unger, however, has examined the moss accurately, and finds that at certain seasons the peculiar utricles of this moss assume a globular form, and being partially transparent, the light is refracted and reflected in such a way as to present a luminosity on the surface of the vesicles. Meyen says he has confirmed Unger's observations."

With regard to the light given out from flowers, the doctor cites Christina Linné, Linnæus, the younger Linnæus, Haggren, Crome, Zawadski, Hagen, Johnson, and the Duke of Buckingham as those of the observers whose experiences have been recorded. The plants enumerated by him are the Nasturtium (Tropæolum majus), the Sunflower (Helianthus annuus), the Marigold (Calendula officinalis), African and French Marigolds (Tagetes erecta and Tagetes patula), Martagon Lily (Lilium chalcedonicum and Lilium bulbiferum), the Tuberose (Polyanthes tuberosa), Poppy (Papaver orientale) Chrysanthemum (Chrysanthemum inodorum), Evening Primrose (Œnothera macrocarpa), and Gentian (Gentiana).

In addition to the observations on the light of flowers, there are some on the phosphorescence and luminosity of sap. Mornay describes a tree in South America, called Cipo de Cunaman, with a milky juice, which gives out in the dark a bright light. Martius, also, in a plant which he named Euphorbia phosphorea, says that, when wounded, the sap gave out a light. To these instances is added a reference to Senebier, who observed in his experiments on Arums, on one occasion, when confining an Arum in oxygen gas, that it gave out light and heat.

On the same page of the *Gardeners' Chronicle* on which Dr. Lankester's observations are printed, another correspondent expresses surprise that any doubt should be thrown on the luminosity of plants. "For," he says, "I have observed it frequently, and have looked for it on each succeeding summer, on the Hairy Marigold, and more especially the Hairy Red Poppy (Papaver pilosum), in my garden at Moseley, in Worcestershire. In the evening, after a hot, dry day, the flashes of light afforded much amusement to myself and others."

Fifteen years later, and the subject was again revived in the pages of the *Gardeners' Chronicle*, by the record of certain experiences tending to corroborate those of others which had previously been made, and to which we have already directed the attention of our readers.

This observer, quoting from his diary, states:—"We witnessed (June 10, 1858) this evening, a little before nine o'clock, a very curious phenomenon. There are three scarlet Verbenas, each about nine inches high, and about a foot apart, planted in the border in front of the greenhouse. I was standing a few yards from them, and looking at them, my attention was arrested by faint flashes of light passing backwards and forwards from one plant to the other. I immediately called the gardener and several members of my family, who all witnessed the extraordinary sight, which lasted for about a quarter of an hour, gradually becoming fainter, till at last it ceased altogether. There was a smoky appearance after each flash, which we all particularly remarked. The ground under the plants was very dry; the air was sultry, and seemed charged with electricity. The flashes had the exact appearance of summer lightning in miniature. This was the first time I had seen anything of the kind, and having never heard of such appearances, I could hardly believe my eyes. Afterwards, however, when the day had been wet, and the ground was dry, the same phenomenon was constantly observed at about sunset, and equally on the scarlet Geraniums and Verbenas. In 1859 it was again seen. On Sunday evening, July 10 of that year, my children came running in to say that the "lightning" was again playing on the flowers. We all went, and observed, July 11. I thought that the flashes of light were brighter than I had ever seen them before. The weather was very sultry."‡

These instances of luminosity in flowering plants, and those about to be alluded to amongst Fungi, are referable to two very distinct causes. Those of Fungi being entirely exhibitions of phosphorescence, causes which are inadequate to explain the phenomena in the other cases. Two or three paragraphs have already appeared in recent numbers of this journal, illustrative of this phase of the subject, and the following are given as more detailed accounts of the instances alluded to by Mr. W. G. Smith.

The Rev. M. J. Berkeley § alludes to the luminosity of Fungi, in his excellent "Introduction," when he says, "This luminosity has been observed in various parts of the world; and where the species has been fully developed, it has been generally a species of Agaricus which has yielded the phenomena. Agaricus Olearius of the South of Europe is one of the best known, but other species have been observed, as Agaricus Gardneri in Brazil, Agaricus lampas, and some others in Australia; in Amboyna, by Rumphius, &c. Mr. Babington has observed imperfect myosita extremely luminous near Cambridge; and Dr. Hooker speaks of the phenomenon as common in Sikkim, though he was never able to detect the species to which it was due. Tulasne, ‖ who has specially examined the luminosity of the Agaric of the Olive, has observed dead leaves in the south of France to be endowed with the same property, without, however, being able to detect the cause. Fabre, in a paper in the "Annales des Sciences Naturelles," ascribes it to a temporary increase of oxydation.

Beautiful, however, as the effect may be in these instances, it is far excelled by the phosphorescent appearance presented by Rhizomorphæ in mines, the splendour of which is described by Humboldt in the most glowing colours. Such Rhizomorphæ are, I believe, always the subterranean mycelium of common Fungi, as is the case with Rhizomorpha subcorticalis. De Candolle long since explained their real nature; but it is very curious, if this be the case, that our common Polypori and Xylaria, which give rise notoriously to such productions, are not themselves luminous when perfectly developed.

Mr. Gardner gives the following account of the Brazilian species first discovered by himself: "One dark night, about the beginning of the present month (December, 1839), while passing along the streets of the Villa de Natividade, Goyaz, Brazil, I observed some boys amusing themselves with some luminous object, which I at first supposed to be a kind of large fire-fly; but on making inquiry I found it to be a beautiful phosphorescent species of Agaricus, and was told that it grew abundantly in the neighbourhood on the decaying fronds of a dwarf Palm."

The whole plant gives out at night a bright phosphorescent light, somewhat similar to that emitted by the larger fire-flies, having a pale greenish hue. From this circumstance, and from growing on a Palm, it is called by the boys "Fire-fly do Coco."‡

It has been stated that the mycelium of truffles is luminous; but this seems to rest upon the authority of one observer, and, as far as we can learn, has never been verified.

Mr. James Drummond, in a letter published in "Hooker's Journal" for April, 1842, and dated Swan River, 1841, gives some account of luminous Fungi of that region:—"As respects Fungi I would chiefly like to give you some account of two species of Agaricus, belonging to the division which has the stem at one side of the pileus. They grow parasitically on the stumps of trees, and possess nothing remarkable in their appearance by day; but by night they emit a most curious light, such as I never saw described in any book. The first species in which I observed this property was about two inches high, and was growing in clusters on the stump of a Banksia tree, near the jetty at Perth, Western Australia. The stump was at the time surrounded with water, when I happened to be passing on a dark night, and was much surprised to see what appeared to be a light in such a spot. On examination, I found it to proceed from this Fungus. It is six or seven years since this circumstance occurred. The late Dr. Collie, then our colonial surgeon, possessed a good collection of botanical books, which he and I consulted, but without finding anything which bore on the subject. When this Fungus was laid on a newspaper, it emitted by night a phosphorescent light, enabling us to read the words round it; and it continued to do so for several nights, with gradually decreasing intensity as the plant dried up. A few weeks ago, and not till then, I discovered another instance of the same kind. I was collecting plants on an ironstone hill in the Toodjay district, when I was struck with the beauty of a large Fungus, of the same character as the former, measuring six inches across, and about a foot from the root to the extremity of the pileus. The specimen which I carried home weighed about 5 lb., was very smooth, yellowish-brown above, and dirty white upon the gills; it gradually became thinner towards the outer edge of the pileus, where it was waved and sinuated. As I had collected specimens which induced me to gather it, for as to making a full collection of the Swan River Fungi, such a task would require an entire season, and the skill of a person who could make drawings or models of them. The specimen in question was hung up inside the chimney of our sitting-room to dry, and on passing through the apartment in the dark, I observed the Fungus giving out a most remarkable light, similar to what I have described above. No light is so white as this, at least, none that I have ever seen. The luminous property continued, though gradually diminishing, for four or five nights, when it ceased, on the plant becoming dry. We called some of the natives, and showed them this Fungus

when emitting light; the room was dark, for the fire was very low, and the candles extinguished, and the poor creatures cried out 'Chinga!' their name for a spirit, and seemed much afraid of it; and I certainly must own it is a very extraordinary 'Will-o'-the-Wisp.'"

This, then, is a summary of the facts which we have been able hastily to collect together concerning the luminosity of plants. There may be other recorded cases which have passed from our memory, or with which we have never become acquainted, and to these it is not at all improbable that some of our correspondents will be able to add others. The subject has now been fairly opened, it is a very interesting one, and it must be confessed still not wholly without mystery, especially in so far as regards the light emitted from the flowers, &c., of the higher orders of plants. *Hardwicke's Science-Gossip.*

SOBRALIA MACRANTHA ALBIDA.

THIS is a very elegant variety of the well-known but too little grown Sobralia macrantha. It was exhibited at South Kensington a few weeks since by Mr. B. S. Williams, of the Victoria and Paradise Nurseries, Upper Holloway, but it is not known from what locality the plant had been received. The reed-like stems attain to some 3 or 4 feet in height, and produce from the apex numerous large flowers, which are upwards of 6 inches across; and although the individual flowers are short-lived, yet the numbers which are produced in succession amply compensate for it, and render this novelty a very showy and attractive ornament to an Orchid-house or ordinary stove.

The sepals and petals are of a soft creamy white, large and spreading, whilst the lip is very large and nicely expanded, the colour being a rich soft purple, rendering the contrast between it and the creamy-white sepals and petals really charming.

In potting Sobralias, it should be borne in mind that they are terrestrial plants, and do not require elevating above the rim of the pots, in the manner practised for the epiphytal kinds; they should be potted in good peat and leaf-mould, to which may be added a little loam and sand, and the pots should be well drained. During the summer season they enjoy a liberal supply of water, and should be placed at the cool end of the Cattleya-house. In winter less water will suffice, but at no season should they be allowed to become thoroughly dry, or it will cause the leaves to turn yellow and fall off, to the great detriment and disfigurement of the plant.

FIG. 191.—SOBRALIA MACRANTHA ALBIDA.

NOTES ON CONIFERS.

As one who, I doubt not, is not singular among your readers in taking an unceasing interest in coniferous plants, especially those suited to our climate, I saw with much pleasure Mr. Rolson's paper on the subject, and ask your leave to make a few remarks and statements. Cupressus funebris: I add my testimony to his report as to this tree. As far as I know or can learn, it has never shown in this country the weeping habit for which it has credit on the faith of Mr. Fortune's original description. I have always suspected that there must have been some confusion in his notes, and that the weeping tree of China is really the Cryptomeria, which, when well grown, much better corresponds with both description and plate in his book. It is here about 12 feet high. Pinus insignis here is hardy as regards its vitality, but the foliage gets in severe winters so browned as in a great degree to destroy its beauty. Pinus austriaca is a noble tree, of rapid growth, and suitable for planting on a large scale. Is it anything but a very vigorous variety of Pinus sylvestris? Pinus cephalonica appears not to suffer from spring frosts when it has got to a good height, and is then a very handsome tree. When young and low its early shoots suffer every year. Pinus Sabiniana is quite hardy, grows with considerable rapidity, and is very striking in appearance. Pinus halepensis is here quite hardy. It is but of moderate height, and has a very neat and pleasing appearance. Picea Pinsapo deserves all the praise given to it, as being perfectly hardy, and truly symmetrical. Picea Nordmanniana is entitled to the same praise, and grows with much rapidity. Cupressus Goveniana is here fully 20 feet high, and covers a space down to the ground of the same diameter. It is a very striking object, being always covered with cones in all sizes and stages, which are at first a yellowish-green, and appear never to fall off. It is not injured by any severity of weather. Cupressus Uhdeana: This plant, after having attained nearly the same size as the above, was this winter killed to the ground. Cupressus Lambertiana (or macrocarpa), when fully developed, makes a noble tree. Libocedrus chilensis is quite hardy, and has now attained a height and form that give promise of much future ornament. Sequoia sempervirens deserves all that can be said in its favour. It covers the whole of the ground on which it stands. It grows with great rapidity; soon repairs any casual injury, and is a much handsomer tree than Wellingtonia, which is very stiff and formal. Cunninghamia sinensis is so far hardy that it stands our winter, though the foliage is much browned. The new growth, however, is of bright grass-green, and the upright stem about 8 feet high. *G., Bath.*

Home Correspondence.

Orchid Cultivation.—I have neither time nor inclination to go into a controversy which, at least, so far as "G. H." is concerned, is to have little effect in changing what looks very like the foregone conclusions of that gentleman. All the evidence that has been published in your columns for the last 18 months, were it summarised, is directly against that treatment which "G. H." insists upon. As a matter of courtesy, I reply to his queries, in the hope that I may neither be misinterpreted nor misunderstood. "G. H." asks, first, "Will Mr. Anderson tell me where he learned that 6500 feet is the elevation from which these plants come?" I learned it from "G. H." himself (see p. 615), who, again, took his information from M. J. Van Volxem, who found Odontoglossum Alexandræ and O. triumphans, the one at so low an elevation as 5500 feet, and the other about from 6000 to 7500. I may state further that in a private letter from Mr. Blunt which I had access to, it was stated that he found the bulk of those sent home—O. Alexandræ, Lindleyanum, hystrix, &c.—a little lower than the high range of Bogota. I need scarcely defend myself from the strictures of "G. H." as to my not being up in "my altitudes," for I had written long since that Bogota was fully 8000 feet above sea-level. My observations as to the summer temperature necessary for the plants found in these regions at the heights spoken of were from my "home" experiences, and it would be a point of importance to know whether those on the low natural line are in as good a condition as those on the high natural line. The difference, however, in mean temperature, does not appear to be so great between a 6000 and a 7000 feet elevation, as some suppose. I am glad to hear that "G. H." has not killed an Orchid at the high temperature he recommends; it appears from a very lengthened practice that a continuance of such, even with copious moisture, "will certainly kill them." The next question that your correspondent asks me, and which he is specially concerned about, is, "Will Mr. Anderson in justice to me say where I advised "a hot, dry temperature?" I had not been sufficiently explicit in replying to the question of "Ex-Cantab" on that matter, and the inference may be drawn that "G. H." had something to do with the recommendation of dryness along with heat. But any one reading his numerous letters will hear him out as one that has all along prescribed extreme humidity in the growing season, and by no means a dry climate, even in the quiet season, where young growths were moving onward; so that if his disciples, or rather the disciples of the school in which he allied himself, took his temperatures without his wet atmospheric climate, they would be applying his teachings falsely. "G. H." may console himself, therefore, that his was not one of the places where the plants "were in a bad plight." Indeed, at the time of my "tour throughout many Orchid-growing establishments" (see p. 712), "G. H.'s" collection of cool Orchids, and, in truth, his collection of Orchids in general, was only in its infancy. Your readers may ask me how I know "G. H.'s" establishment, and what object I have, even supposing I knew it, of exposing his hand? In the first place, "G. H." (see p. 76) intimates to your readers that he is sending you a photograph of a plant of Odontoglossum Bluntii, with a flower-spike bearing 28 flowers, and that "it is our intention to send it up to the next Floral Committee of the Royal Horticultural Society." Turning over to p. 78, I find that Messrs. Brooke & Co., Fairfield Nurseries, Manchester, exhibited a splendid cut spike of Odontoglossum Bluntii, or Alexandræ (see p. 76), which also received a special award. "G. H.," speaking for that firm at that same period, asks a question as to cool temperature, and then answers it in the following words:—"I do not consider that mine is cool treatment; say a mean of 70°, the highest 80°, the lowest 60°." He still persists in these figures in the *Gardeners' Chronicle*, which I and others of your correspondents challenge as not the figures for the treatment of the majority of Odontoglossums. However, he cannot be in earnest, he is surely writing for controversey sake. Let your readers or yourself turn to James Brooke & Co.'s catalogue of select Orchids for 1871, which you have already noticed in rather a prominent way, and you will find, at p. 6, under "Remarks on Cultivation," the following paragraph:—"Cold temperature, or from 50° to 60°, with plenty of moisture, when growing; 40° to 50°, and dry, when at rest." In case, however, your indefatigable correspondent should wriggle out of that by stating that the cold temperature was for something else than what we discuss, namely, Odontoglossums, I refer him to p. 20, and thereader will find, under the head of "Odontoglossum," that the plant succeeded well in a house from 40° to 50°. Pray what meaneth all the discrepancy? Your correspondent must disclaim all knowledge of the catalogue, else he will be sure to say that I misled. Captain Auchterlonie's Tables of Temperature, reprinted in Mr. McPherson's note (see p. 775), is as near as possible what I have all along aimed at for the five winter months, from October onwards. Our summer temperatures are necessarily much higher, sometimes higher than they ought to be, especially when the sun in June and July particularly, and that is why I have recommended a north house for such Odontoglossums as I have named above, and for Masdevallias and for Oncidium cucullatum nubigenum—all plants requiring the coolest summer temperature at command. O. grande, O. citrosmum, O. Insleayi, O. Reichenheimii, and some others, require a much warmer climate, and so do, in my opinion, a good many more of those published in "Ex-Cantab's" list. *James Anderson.*

—— The last communication of "G. H." (p. 874) induces me to think that every detail of accurate information regarding the native climate of the Odontoglossa may be found valuable. Some notes, made by Professor Lindley, "Upon a collection of Orchids formed in Columbia and Cuba by Mr. J. Linden," have been thrown into a pamphlet, published by

Bradbury, Evans & Co. for 2*s. 6d.*, which deserves to be better known by cultivators than it is. Nearly 150 species of Orchids are there enumerated, and arranged in tables, according to their native elevation; and the mean temperature of each level is added, from data furnished by Humboldt. I will here give only the Odontoglossa mentioned:—

Elevation, 10,000 to 11,000 feet: Mean temp., 49°: min., 32°.—Odont. densiflorum.

9000 to 10,000 feet: Mean, 52°.—Odont. dipterum; Odont. divaricatum.

8000 to 9000 feet: Max., 69°; mean, 56°: min., 36°.—Odont. Hallii, Odont. epidendroides; Odont. luteo-purpureum.

7000 to 8000 feet: Mean, 59°.—Odont. megalophium.

6000 to 7000 feet: Mean, 62°.—Odont. crispum; Odont. angustatum.

2000 to 3000 feet: Max., 80°; mean, 75°; min., 55°.—Odont. hastilabium.

In the notes which follow the technical Latin diagnosis (what Linnæus called the *nomen specificum*) of each species, we learn one or two other points of interest, such as that most of the species named grow in forests, and that some of these forests are expressly designated "thick," "damp," "damp and gloomy," epithets which appeal to other points of treatment besides temperature, viz., humidity and light. On the charming genus Masdevallia, which is just now beginning to occupy our stages, there is a good deal of very useful information contained in the pamphlet from which I quote. May I request, I think, Mr. Editor, that if you would just refer to it, you would perhaps judge the preface, which is of no great length, worthy of being extracted *in extenso*, to your own columns; although, to be sure, the date in the title-page is MDCCCXLVI. *P. H. Gosse, F.R.S., Torquay*. It will comply with our correspondent's suggestion in a future number. EDS.]

—— "G. H.," in a recent number, writes thus: "'Ex-Cantab' says, I recommend a mean winter temperature of 70°, and Mr. Anderson repeats it, but I have not given a mean of 70° in winter that I am aware of." Now will he be surprised to find that at p. 76 he has written this—"I will consider 60° quite a cool treatment—say a mean of 70°—the highest 80°, the lowest 60°"? As I brought this sentence to his notice at p. 380—and there was no correction in his reply thereto—he exceeds the boundary of fair discussion in accusing as of misrepresenting him upon that point. Again, a little further on he says, at p. 876, "these natural summer temperatures mean 85° at least." This, too, is a mistake. I meant 85° at the most—a maximum of 85°, let the day be as bright and hot as it may (see p. 380). The minimum temperature in the house must depend in a great measure upon the temperature of our summer nights; it will be 70° very often without fire-heat, but is seldom lower than 60°, which is quite sufficient. But the most remarkable sentence at p. 874 runs thus: "But we should not forget that arguments require examples to the point to convince." Has your correspondent seen the *Gardeners' Chronicle* lately? Allow me to bring to his notice a few examples given at p. 712, 741, and 837. *Ex-Cantab*.

Box Edging.—Can any of your readers oblige me with any suggestion as to the probable reason of the failure of Box edging, which I cannot make to grow? I remember mine well, but, after the lapse of a few weeks, it looks as shabby as before, nearly half the Box being dead. My garden is on a poor gravel, but I can hardly think that the subsoil has anything to do with the failure. *F. C.*

The Royal Horticultural Society and the Horticultural Dinner.—Perhaps no better time than the present could be chosen for coming to a final decision upon this question, that is, whether another year will elapse before another provincial show, and, therefore, the matter may be talked over quietly, and definitely settled to the satisfaction of all parties. Most of the ills of life arise from misunderstandings; these unexplained grow into dislikes, hard words, hatreds, and all such unkindness. Their removal is like oil on the gearing of machinery—making all to run smooth, without strain or waste of power. That misunderstandings still exist your Editorial note to my last proves. Long and, I may add, intimately as you have known me you could not have caught the drift of my remarks. You say that I am so unpractical as to wish the Council to get up the dinner. What I did say was, that they ought to take it into their programme; and to this I adhere. There ought to be no divided authority at these meetings; all that is done should be under the official sanction of the Council. I advocate this course less in the interest of gardeners than of the Royal Horticultural Society. Let the dinner and the Congress slip from its grasp, and it loses its hold on its practical supporters, in the exact ratio of the success of these two features of its provincial shows. By separation there is also a great danger of a clashing of authority. Is it not a fact that something of this sort did actually occur at Nottingham? Was not the dinner first accepted by the Council, then relegated to the local committee, then officially announced, then reannounced by the Council of the Royal, the first bills withdrawn, and subsequently reannounced unofficially? And yet after this warning of the evils of divided authority we are asked to leave such matters to local management, and reproved for entertaining the false idea that the Council object to meet the gardeners; if not, what was all the fuss about, and why have the Council not dined with the exhibitors before? [Because there has not before been a properly organised dinner. EDS.] The Royal, as far as I am aware, is the only horticultural society that has ventured into the provinces without dining with its constituents; all the agricultural societies do so. The dinner is just as prominently announced on the official bills as the show of implements and bullocks, and for my own part I cannot yet see any just cause or impediment why the Royal Horticultural Society should not do likewise. [It is beyond the limits of etiquette for a public body to go as visitors to any place and then to get up or even to instigate a public dinner, which, if it means anything, must be supposed to be held in its own honour. EDS.] No one asks the Society for a free dinner, nor to make themselves in any way responsible beyond announcing it and appointing a dinner committee, or requesting the local authorities to do so: official sanction is all that is asked for. I know nothing of mischief-makers, but this I know, that many of the best gardeners in British do believe, and grieve over the fact, that the Council seems unwilling to meet them at the festive board or in the intellectual arena; and when pried with assurances to the contrary, the pertinently retort has baffled them, Why, then, did the Society not secure the dinner at Nottingham the last moment? why has it not dined with gardeners before? and why was there no congress at Nottingham? I should be grateful to have these questions solved without blame to the Society. I love the old ship for her own sake, personally have the highest respect for the Council; in fact, it is chiefly my love for the Society, and my desire for its prosperity, that prompts me to the thankless duty of criticising its conduct. It has done good work in improving the material of horticulture, but the time has come for it to win the love of horticulturists. That it can do so is easy, by little social courtesies that cost it nothing. But if it refuses, horticulturists are becoming strong enough to take care of themselves. Gardeners are proverbially grateful for small favours, and it surely is a small matter that their employers should meet them at the annual gatherings of these provincial shows, and that a Congress be held for their pleasure and instruction. This is, however, probably the last time the Society will be asked to undertake such matters; I am assured, on good authority, that both a dinner and Congress will certainly take place at those great gatherings, whether the Society patronises either or not; and, further, that probably one of the first matters discussed at such independent Congress, will be the relation of the Royal Horticultural Society to practical gardeners; and then, perhaps, we shall find Our Journal, *The Practical*, *July* 8. [It will be well worth the time and space occupied if the discussion of this subject should lead to the removal of the misunderstanding alluded to. As to the dinner, we have already pointed out how it ought to be managed. As to the Congress, it was all along understood that there was to be one, or something equivalent to it, at Nottingham, but why it was not carried out, we have never learned. Had we been aware that nothing would have been done, we should ourselves, certainly, as before, have taken some active steps to promote one. EDS.]

Diverting a Watercourse.—As you justly say, "J. K.'s" inquiry is much dependent upon local customs. A precisely similar case existed not far from my abode, and since then the water passing through other property ere it reached the mill below. In this instance, however, the water was only dammed back to form a waterfall. This was contested unexpectedly by the owner of a mill above, from the fact that it flooded his "mill-tail" unduly, to his injury, in regard to the working of the mill. The miller from "J. K." has not only a right to be recouped for the loss of the water maintained and kept from him during process of filling the newly made vacant bay, but also for the fact that the bay will for all future time stay the impetus of the stream, which will act very detrimentally in the case of cases of a scarcity of water—independently of the fact that the increased area increases likewise by the absorption of the soil, the loss of the water: to say nothing of the fact as to whether your correspondent has a lien on what water he requires from the stream for his use. *William Earley*.

—— "Sic utere tuo, ut non lædas alienum" is a good, sound old legal maxim, and one that seems to me quite applicable to your correspondent, who makes inquiries about "diverting a watercourse." It seems to me impossible for such a thing to be done without injury to his neighbour, or those below him on the stream, even though "there should be a pipe to take away the waste water from the tank when it becomes full, to carry it again in the same stream." I should think the miller below could be free to bring an action against the diverter, and in all questions arising in courts of law, none are so strongly contested as those arising out of the rights to waterrcourses, and, I may add, none so uncertain in their results. *E. C.*

The Gardeners' Dinner at Nottingham.—In your comments upon the letter of "A Practical," there is a statement which is not correct. You say that "The gardeners' dinner, if properly organised, and under the management of a respectable local committee, would certainly always command the sympathies and support of the Society, both Council and Fellows, as it did on this occasion." The facts are, that at an early meeting of our local committee, the secretary, Mr. Lowe, was requested to ask the Council of the Royal Horticultural Society to assure us that a gardeners' dinner would have that support and sympathy; and the answer which he brought was this, "the Council do not seem to take an interest in the dinner, and they leave it to Mr. Hole." *Not, Mr. Ardern reported to.* [No discrepancy here: they would not, because, as they think, they could not, take up the subject, as promoters. EDS.]

A Caution.—Would you let me look at your Lawn Mower, Sir?—Makers of these useful machines would do well to look after a set of cunning fellows who go about the country under pretence of being skilled in repairing, setting, and making old machines cut like new ones. Unless they produce more substantial evidence than that of their ready tongue about re-friction, &c., gardeners should be aware of them. Of course there are some who will produce their card, and give satisfactory references. *Caution*.

Flower Show Appeals.—The Chelmsford and Essex Horticultural Society offers a prize at its annual exhibition for "6 plants for beauty of foliage (distinct species)," and last year one of the exhibitors showed in the class two Coleus, viz., *C. Verschaffeltii* and *C. angustifolium*; but as these were both varieties of the same species, he was very properly disqualified. This year, however, one exhibitor showed two Alocasias in the class, viz., A. Lowii and A. macrorhiza variegata, and, contrary to precedent, and to the expectations of the majority of the exhibitors there present, he was awarded the 1st prize. This is all the more to be wondered at, seeing that it was awarded by the same judges as last year. If it be nothing more, this is surely a little piece of inconsistency; for why should one collection containing two Crotons be disqualified, and another with two Alocasias be honoured with the 1st prize? Surely a little explanation is required, and as both the judges and the exhibitor of the two Alocasias in question are readers of the *Gardeners' Chronicle*, I trust they will use that medium of conveying such explanation. I write this with no ill feeling, but in order that a definite and proper understanding may be arrived at to guide us in future years. *Thomas Simpson, Broomfield, Chelmsford*. [The Alocasias mentioned are a distinct species, and therefore comply with the terms. EDS.]

The Last Trail of the Winter of 1870-71.—So at least we may venture to hope was the terrific hailstorm that swept across a great portion of East Anglia, from the coast to 30 or more miles inland, on July 5. A few very loud peals of thunder soon after noon, from a huge black cloud which was rent asunder, and the rain and hail poured down pell-mell in buckets-full, tearing, rending, shattering everything in its hurried course, converting, roads and walks into rivers of floating ice, and leaving on the level ground in many places a deposit an inch deep of blunt, conical hailstones, the form of a boy's spinning-top, and of the same dimensions. Though the day was extremely hot, and much rain fell with the hail, it was quite two hours before it disappeared from the shady side of walls or trees, and almost any number of cartloads might have been collected on our lawn. I have never seen anything like it in summer. For the time, it chilled the air, it stopped the cricket, the mouth, and the noise and confusion while it lasted were indescribable. From what I can learn, we got the tail of it here, as it did not proceed above a mile beyond us in any direction, except towards the east; but it seems as if the strength and fulness of the cloud has been in its tail, for I do not gather that more hail fell anywhere than over here; and, singularly enough, considerably more fell in the kitchen-garden than in the flower garden, though the two are within a quarter of a mile of each other. But the kitchen garden is probably 40 feet lower; and I have observed this difference in quantity of fall, both of rain and snow, before. It was a pitiable sight to see the Coleus, Iresine, Perilla, Pelargonium, subtropicals, &c., shivering amid the large pieces of ice, which glistened like plump drops of crystallised sugar, such as delight baby eyes, and satisfy and fill their mouths with sweets. So late as the mornings of Jane 25 and 26 frosts had bitten into many of our Coleus and other tender plants, and it seems doubtful if they will get over this pelting with ice balls. And you suppose the fruits and vegetables to show you how hardly they have been hit. I confess I was somewhat proud of our crops of Apples and Pears. We had a better crop than most this year. I very much fear that the hail will ruin them. The indentations are so deep, that it seems as if the bruised portions must decay. It strikes me that the form of the hail had something to do with the depth of these bruises. Most of the hailstones, I suppose, would fall with their narrow points downwards; but the mere weight of the hail may have been sufficient to cause the injury. The fruit on walls is also greatly bruised, that on cordons, perhaps, most of all. I mark the samples sent—cordons, wall, open. The Pear perhaps, reveals the severity of the storm more than aught else. You will see that they are bruised almost right through. I also send some

Onion plants, which have suffered much. Before the hail they were a model crop—without speck or bruise, now the whole is battered and wounded. Lettuce plants are torn to shreds. Some Broccoli plants, just pricked out, strong and healthy, are, I fear, utterly ruined. In fact, it seems as if this last trail of winter in July was to prove more disastrous than all that had gone before it. Would that we, in East Anglia, could have taken a leaf out of your correspondent's book, and said to this storm-cloud, We do not suffer hail in July to wreck and ruin our crops. But though all ministering priests, serving before the great altar of Nature, we have no such power to close the windows of heaven, even when they discharge such huge morsels of ice—to our utter discomfiture and heart-breaking—at mid-summer. We can but say, "Even so, Father, for so it seemeth good in thy sight;" and reverently, hopefully, and mercifully set to work to restore what the storm has well nigh ruined. *D. T. Fish, July 6.* [The samples sent were very much injured, some of them beyond recovery. EDS.]

Vitality of Seeds of Foxglove.—Upon two or three roods of ground I had trenched deeply in the new works here last winter, a dense mass of seedling Foxgloves has sprung up, where no symptom of such existed before. *William Earley, Valentines.*

Laxton's Alpha Pea.—Your correspondent "A. D.," commenting on the character of the above Pea, gives it a widely different description to what I should have expected from my own experience, excepting in one point, viz., its earliness, which I consider to be on an equality with Daniel O'Rourke, but with pods double the size, and much longer, and Peas more resembling the Broad Bean in size than a Daniel O'Rourke Pea, and far surpassing it in flavour. The haulm is strong-growing, as is the case in all Laxton's Peas, and abundantly prolific, hanging more like Hops in the county of Kent. *E. Morgan, Harrow-on-the Hill.*

The Trade Yard at Nottingham.—"The true Epic of our time is, not Arms and the Man, but Tools and the Man—an infinitely wider kind of Epic" (T. Carlyle.)—The great success which has attended the Royal Horticultural show at Nottingham induces me to ask, through your valuable journal, whether the Council would adopt on the next occasion some better method in the arrangement of goods in that portion of the ground set apart for trade. It is scarcely in keeping with the high purposes for which the Royal Horticultural show is held that the visitor on entering finds himself in the midst of a fancy bazaar, and that the principal approaches to the grand marquee are lined with booths similar to those we see on fair day in market towns. None but the most persevering of sightseers would be likely to see anything beyond this in the trade ground. The manufacturers of implements, tools, and apparatus used in horticulture ought to be recognised by the Council as having a claim to a constant and prominent place at the show. There is no need to exclude other trades, but it is by no means necessary that dealers and manufacturers of goods having no special interest to the horticultural world should monopolise the best places. Next in point of attraction to the show of plants and fruit, come the implements and apparatus used in the garden. They have contributed some share, however humble, to the great triumphs of the horticulturist. It would but be in agreement with the proper fitness of things, if the principal avenue to the marquee were set apart for the use of manufacturers and their representatives. Then let the sellers of agricultural implements and miscellaneous goods take the second and third places. Of course if it is absolutely necessary to the prosperity of the Royal Horticultural Society that the vendors of toys and the retailers of beer should have the most prominent positions in the trade ground, by all means let them have it. No one, however, who saw the thousands that poured into the Park on each day of the show would suppose that they stood in need of any such support. A manufacturer does not attend the show merely to take orders. That branch of trade is now permanently established, and there is always ample stock in the hands of agents to meet the wants of the public. It is the only time during the year, and for that district in several years, that he has the opportunity of meeting both professional gardeners and amateurs, who have always some inquiries to make, or wish to test the merits of some novelty in garden requisites. By the present arrangements that opportunity is not given them. Therefore let the Council institute a new organisation of the trade yard, which will give the visitors convenience of access to the manufacturers of implements and apparatus, concentrate their attention on the special purposes for which the show is held, and add to its completeness. *George Baines.*

Orchard-house Culture made Easy.—One of the lions of Nottingham in the shape of fruit tree culture is a long ladder and plank shed or general store of stock-in-trade of the well-known horticultural builder, Mr. Foster. This shed is 200 feet long, more or less, supported on pillars, the roof sufficiently high to admit of carts, &c., being safely sheltered from the weather. The roof is simply a common span, but instead of being slated or tiled it is glazed with strong glass, which enables Mr. Foster to make the best of this shed for two purposes, viz., general store and orchard-house. The shed is open on one side and weather-boarded on the other up to the eaves, and appears to answer all the purposes of an orchard-house so far as securing plenty of fruit. After a scramble over planks, casks, and other sundries, I found that the trees in this house are all planted out, and are fruiting in a state worthy of a different situation. I did not go the whole length of the shed, but the sorts of trees which I observed were Apricots, Nectarines, Plums, and Peaches; and had they been put up for exhibition for quantity of fruit, they would have taken prizes in the order named. So far as I could see, the trees were all trained standards, or what are termed riders; they are planted inside the house and close to the boards, and their straight stems reach to the eaves, the branches being afterwards trained in the fan shape to a wide trellis underneath the roof, where they are luxuriating in the greatest health and vigour. A good deal of Mr. Foster's success lay in the large amount of ventilation, and in the shoots being close to the glass. Upon the outside of the house, and on the weather-boards, are the finer sorts of Pear trees, trained horizontal fashion, and they seemed equally thriving situation. The above shows what can be done with a little ingenuity and forethought in turning such lumber sheds to a useful account. Had Mr. Foster known that his model orchard-house was going to be taken by storm, and inspected by a host of dukes and duchesses and others, he would no doubt have taken a leaf out of his neighbour Mr. Pearson's book, and had the trees duly pinched and stopped. *J. Miller.* [A most successful experiment, as we ourselves can testify. EDS.]

Caterpillars and the Fruit Crops.—It is a general complaint amongst fruit cultivators this season that there has been not only a great destruction of fruit trees, but also of the fruit crops, by blight and caterpillars. Many of the mums are quite alarming; therefore, any suggestions tending towards the mitigation of the ravages of these pests cannot be otherwise than acceptable to gardeners. I think the nature of the species of caterpillar that has worked so much mischief among our fruit trees is not generally known. In their habits, I may say, they are so propetuates its species by forming a ring of a hard substance round the small wood of the tree, in the months of July and August, where it remains until the ensuing spring. There is a most simple and effectual method by which this pest can be destroyed, viz., that of pruning away the rings during the autumn and winter months. It is only by close observation that these rings can be discovered, because of the resemblance they bear to the bark of the tree on which they are placed. A sharp look-out should be kept in the spring of the year for any caterpillars that may, in spite of any caterpillars, the product of any rings that may have escaped the eye of the pruner, and were not destroyed in the dormant form. As a matter of course the appearance of the caterpillars will depend very much upon the forwardness or otherness of the season, and will generally be detected by the appearance of a web, or nest, on the tree, encasing the progeny in a cluster, when they can readily be destroyed. A remarkable circumstance of the partial manner in which blight will attack fruit trees of the same kind, recently came under my own observation. In a case of two market gardens, the one separated from the other by means of a quick hedge. Both were planted with an upper and an under crop. In the one case the whole under crop, consisting of Red and Black Currants, was destroyed; the upper crop being only slightly touched. In the other case the under crop of Currants was uninjured, but the upper crop, consisting principally of Apple trees, is almost leafless, through the attacks of caterpillars. The following circumstance will probably account for the partial and slight destruction worked in the Apple trees forming the upper crop in the first instance. The unprotected state of the under crop during the past winter, adopted a system of close pruning from the base to the top of all the main branches of the trees, and so unconsciously removed the rings in which reposed the embryo caterpillar. *J. T.*

The Setting of Grapes.—In your paper of July 1, appears a communication from Mr. Josiah Elcombe, of Exeter Nursery, Southampton, quoting the following opinion of another gardener, with whom a house of grapes under his care :—"These I gave a good syringing to, at a certain stage of blooming, as is usual with me to do, and thus save the trouble of thinning." I would feel obliged to Mr. Elcombe (or to any other experienced person) if he would tell me at what stage of blooming this should be done to effect the purpose intended, as if it does do that, it would confer a great boon on those who have ground vineries, in which the "trouble of thinning" is fivefold what it is in ordinary ones. *A. Boyle, South Wales.*

Horticultural Boilers.—At last a ray of broad common-sense light has dawned upon this vexed question, and as we are just entering into a sort of boilerphobia, Mr. Stevens is to be thanked for having struck the key-note in a correct and proper spirit. Waste in the stokehole is no good to any one, and it may be fairly asserted that in proportion as the chimney above the boiler is heated, so is waste going on. I never yet felt the chimney above a vertical boiler that it was not more heated than was consistent with economical heating. When the Polmaise advocates, nearly 30 years ago, tried to enlist the late Mr. John Wilmott, of Isleworth, into their ranks, he said : "No, I cannot afford to boil the kettle at the top of the chimney," and whoever tries to extract a maximum effect from a minimum cause, must necessarily do so by a great waste of power. When you see on a dark night white light escaping from the chimney-top, rest assured fuel is being wasted, and yet with the vertical boilers it is not an unusual thing, in very severe weather, not only to see light, but frequently flame also escaping from the chimney top. The vertical boiler may be said emphatically to be wrong in principle, and whatever is defective in principle must be bad in practice. In a place near Coitonopolis, where the one-boiler principle is being carried out on a large scale, but where three boilers are needed to do the work of one, all goes tolerably well until the greenhouses want assistance to repel the frost, and then down falls the bed in the stoves, so much that during the past winter I had reason to know, from an eye-witness, that with the three full-sized boilers fired to their utmost, and the vitals red hot, several degrees of frost were registered in one, if not more, of the cold houses, while, at the same time, there must have been a great waste of fuel up the chimney. Mr. Steve ns was, therefore, quite right in selecting the Cornish horizontal boiler, as that form which allows the products of combustion to come with the least velocity from the surface of the boiler must be the most effective. For a boiler to be thoroughly effective and economical, it must not only be equal to its work in the coldest weather, but, as Mr. Stevens remarks, in proportion to its size, equal to several hundred, or may be thousand, feet more of pipe, and there will be no need for forcing the heat up the chimney, as is constantly the case with small and inferior boilers. It may be laid down as a truism, that every pound saved in the fixing of an inferior boiler will involve the waste of pounds in fuel every year afterwards ; for though dealers may tell us of the economy of their special crotchet, that "a shovelful of cinders" will be sufficient for this, or a bushel of coal for that, the fact is, the boilers can absorb no more heat than the fuel generates : and hence that form which, by a series of flues and slow combustion, allows the heat to be absorbed before it reaches the chimney stack, must be the best. Then, again, the setting of a boiler is a material point. With the old saddle, for one properly set you may find a dozen that are not doing their work in a proper manner ; and so it is with almost every form of boiler, therefore by fixing one out which requires no skill in setting will be a great point gained. I am not one of those who think that the heat which may enter the brickwork is so much lost ; on the contrary, as the fire lowers the heat will enter the boiler ; yet at the same time I am convinced a jacketed and insulated boiler is the correct thing, and that such a one, surrounded by a stratum of confined air, must be the least wasteful of any. Chimney dampers are, in my opinion, an abomination ; and if a boiler is properly set, and furnished with accurately fitting feeding and ashpit doors, there is no slightest need for a damper. We do not want fresh air down the chimney, nor at all except to regulate the combustion of the fuel, and every molecule admitted beyond that need must be the parent of waste. Of this there can be no question. The best furnace fittings are unquestionably those made according to Sylvester's patent, as they fit with perfect accuracy, and, acting upon the slide principle, may be adjusted with the greatest nicety, and cannot with fair usage get out of order. Here, too, expense may be complained of, but the first cost which leads to an annual saving is not a waste of means. The material of a boiler cannot matter much ; I have had good and bad of both materials, but, fractures apart, cast-iron is the most durable. Any one passing St. Paul's, in London, may prove this to demonstration, for while the wrought-iron spikes of the palisading are all in a state of decay, the cast-iron standards are as sound as the day they were put up. I believe, however, for horticultural purposes more boilers rust out than wear out, and that in cold houses the few months the boilers are out of use in the summer causes more injury than months and months of firing. With wrought-iron boilers I think this especially the case. Next to the good boiler, the good stoker is the essential point. The clean, thinking, intelligent fireman will, as Mr. Stevens observes, burn the fuel to clinkers, and get sufficient heat with little fuel, while the slovenly stoker will waste a large quantity of fuel and generate comparatively little heat. This is indeed the young gardener the how and why of this stoking operation is one of the most important duties of the employer. I heard a year or more ago, from my friend JMr. Speed, of the power and economy of Mr. Stevens' boiler, and recently Mr. Tillery Welbeck sent me the figures which Mr. S. has reproduced. These are most important, and may be studied with profit. The horizontal action is however the true principle of economy in boiler construction, and in no other way can they be made to work without waste. For four years I have been working one of Messenger's triangular tubular boilers, and at the first nothing could be more satisfactory. Eighteen months ago it went wrong, and though the sweep and bricklayer were called in, nothing like effective action could be restored. At last, in a fit of desperation, for we were sitting up with it until midnight regularly, I put on an

old suit, and took a turn at it myself. Clearing the fire away, I found the only escape for the flame was by the side of the tubes, instead of at their ends, and examining it more closely I found the throat of the fire-place as completely stopped as if filled in with cement, so firmly as to require a crowbar to break it out. Removing this the action of the fire was perfect, so much so that we can now leave the fire on the coldest nights 12 or 14 hours with perfect safety, though both Grapes, stove plants and Orchids, are depending upon it. I mention this to show the imperative necessity of young gardeners being made acquainted with the setting and action of a boiler, and how much trouble a little care and forethought may save. My test for a boiler is not the heating of the pipes. I take stock of its action some feet up the chimney, and in an inverse ratio to the heating of the brickwork so do I pronounce it good, bad, or indifferent. The new boilers recently introduced are all horizontal. Mr. Cannell's is before the public, and Mr. Westland's, which I have seen, is not materially different. In however, is in action, with results not less gratifying in an economical point of view than those claimed by Mr. Stevens. If not in for a "mania" we are certainly verging upon a revolution in the manufacture of horticultural boilers, and if we are right in doing it work properly, sends the least heat up the chimney, will certainly be the best and most economical. "The boiler of the future," remarks Mr. Tillery, "must not require attention more than twice in 24 hours," and where even high or low temperatures are required in a series of houses, that may be accomplished by a mean of 70° is required in some houses, and not more than 40° in others, then attention to the valves must involve almost as much trouble as attention to the fire. Let the principles which Mr. Stevens enunciated have set forth the ground out, and then should the 2 past mystery about boilers will be dissolved into thin air. *W. P. Ayres.*

—— Two cracked boilers and a severe winter are about as unpleasant things to deal with as a gardener possibly can have; and this was my case last winter. Talk about Pharaoh's lean kine, nothing is nothing compared to nightmare brought on by the cracking of boilers. Cracked, yes; and the fires put out—like disaffected soldiers, at a time when their services were most required. Such treachery was certainly too bad. So I always upheld the tubular boilers, notwithstanding the fact of their consuming an enormous quantity of coal, making an enormous quantity of ashes, added to their being as awkward boilers to build stokeholes for, or to keep clean, either outside or in, or to stoke, as possibly could have been invented. And upon the top of all my misfortune has been guilty of the crime of laughing at his neighbour's calamities, and he is in possession of one of these boilers, it will assuredly bide its time, and mete out to him such measure of retributive justice as the fulness of the cup deserves. If I have been guilty of the above crime, I certainly have suffered enough at the hands of the vindictive tubulars last winter, and should not wish my worst enemy to have to go through any similar ordeal. The tubular boilers have served their day and generation, and no material progress can be made in the improvement of such boilers until lately, through the columns of the *Gardeners' Chronicle*, we have hailed with joy the advent of some improved forms of horticultural boilers. All of them have been launched forth with more or less force of argument, and some of them it would appear were launched before they were built—notably, by-the-by, that builders of such big ships as the Great Eastern might well copy. Whilst in a dilemma whose boiler to choose, a happy incident introduced me to the acquaintance of Mr. Stevens' modified Cornish boiler. I went to it, was accompanied by Mr. Tillyard, of Coventry, a gentleman having considerable experience of boilers, a horticultural builder and lover of gardening generally, and an ardent admirer of the late Sir Joseph Paxton. Arrived at Trentham, we were shown by Mr. Stevens several of his boilers —some at work, and more in process of being put down. We were of course told all about their power, how their introduction reduced their enormous coal bill to a trifle, how they were so easy to fix, so easy to stoke, so easy to keep clean both outside and in, and altogether, in short, all the good qualities were good ones, for bad ones they have none. The boiler carries common sense on the face of it, and recommends itself irrespective of anything requiring to be said in its favour. Let a boiler be ever so much written up, or, on the other hand, written down, if it really is a good one, it will recommend itself; and this boiler of Mr. Stevens, even supposing a single line had never been written about it, would have made its own way. Moreover, I believe that the inventor or improver of a boiler is never in more danger of making wreck of his cause than when he feels it is necessary to follow it with such support as that "it is the most powerful and most efficient boiler ever offered to the public." In the modest simplicity of the manner in which Mr. Stevens introduces his boiler there is much to admire. Given to us without a trammel of any sort, the horticultural world has much cause to thank Mr. Stevens, and also the North Staffordshire Engineering Company, for sending out so very substantial and well-made an article, one of which we have here doing the work of two tubulars. My employer encouraged me to go to greater expense in fixing it than I could have done on my own responsibility. To be out of sight and out of everyone's way, we found it necessary to fix the new boiler at a point 80 yards distant from a good deal of its work. Instead of sending the smoke through 80 yards of an underground flue, as we formerly had to do, we now send the hot water, and have also got rid of the nuisance of drawing coals and ashes to and from the awful hungry maws of the displaced tubulars. Altogether, we have done nothing lately of which we are more proud than the re-arranging of our heating, and it will afford me very great pleasure indeed to show Mr. Stevens' boiler and our system of heating to any one who may choose to come. "A Practical Hand" at p. 646 asks what proportion of heat passes into the lower flue. As regards this, he need have no misgivings, for when the fire is at work the flame can easily be seen (through a crevice) passing from the upper to the lower flue, thence up the chimney with a tremendous draught, especially if the damper is three parts or fully open. From the top of our chimney to the ground line is 28 feet, and from this point to flue under the boiler is 14 feet more, or 42 feet in all. The chimney is the same which had previously been used for the displaced tubulars. I saw a very elaborate chimney, and very satisfactorily one of the same boilers in the vineyard of Mr. Sage, at Atherstone, but I think it was the intention of Mr. Sage to further economise the heat by constructing an underground flue, having a house built over it. To my boiler there is at present attached 4000 feet of 4-inch piping, and judging from the heat we raise in those pipes, it appears quite likely enough to do as many more. Allow me, in conclusion, to remark that I should not like to have the water of the return-pipe enter the boiler at, or even near the same temperature as that enjoyed by the water in the boiler itself, and with so powerful a boiler as I find Mr. Stevens' one, I should calculate soon to have an explosion. *Wm. Miller, Combe Abbey Gardens.*

Ventilating Plant Structures.—In your paper of June 24, under the above heading, Mr. C. B. Saunders gives an account of ventilating plant-houses, but as my man does not understand the account, would Mr. Saunders kindly give some further details, so that a country carpenter will understand it? *A. W.*

Societies.

ROYAL BOTANIC: *July 12 and* 13.—The last, and, possibly, the most successful exhibition of the season drew, was held on Wednesday and Thursday, despite the most unfavourable circumstances as regards the weather, which, as on all former occasions of the kind this season, has been about as ungenial as it well could be, tending in no little measure to make these exhibitions, which have been much better than the average of the last few years—thanks to the indefatigable exertions of the courteous superintendent, Mr. Don—anything like so successful in a financial point of view as they ought to be. On this occasion the display was a bright and cheerful one, as, in addition to the fine collections of flowering plants, judiciously interspersed with foliaged plants, such as Palms, Ferns, and the showy-leaved Caladiums, Crotons, &c., there was a very large assortment of all that pertains to the decoration of the dinner-table and the following is a list of competitions that were the most prominent part; and foremost amongst these was Miss E. Harris, a niece, we believe, of a well known and much respected exhibitor at the metropolitan shows—Mr. J. W. Chard, gr. to Sir F. Bathurst, Bart., Clarendon Park, Salisbury. This lady took two small silver-gilt medals for two epergnes, one as a centre table decoration, with growing plants, and the other with cut flowers and fruits, besides being first in the competitions for a miscellaneous assortment illustrative of dinner-table decoration, and for table bouquet (not tied). In the former class, Miss Hassard, St. Ronan's Road, Norwood, was 1st and 2d with epergnes, Mrs. Andrew Anderson, Dalkeith, was best table bouquet (not tied), and Miss P. Buster and Miss Hassard took equal 2d honours in the class for hand bouquets. In the open class for a bridal bouquet, the best was contributed by Mrs. Thompson, Sussex Place, Brompton; Mr. Ransley Tanton, Epsom, coming in 2d; and Mr. J. W. Chard 3d. Mr. F. Perkins, Coventry, had the best ball-room bouquet, Mr. Cranston and Mr. Ransley Tanton being placed 2d and 3d. In the class for dinner-table decoration with plants, flowers, &c., Mr. W. S. Buster, St. Mary Cray, Kent, was 1st; Messrs. Perkins, 2d; and Mr. J. W. Chard 3d; and Messrs. Dick Radclyffe & Co. had the best epergne, or centre table decoration with growing plants.

Stove and greenhouse flowering plants were well represented, considering the lateness of the season, the principal competitors being Mr. Bull, Messrs. Veitch, J. Wheeler, Mr. Carr, and Mr. A. Wright, amongst amateurs; and Messrs. Jackson & Son, Mr. Morse, Mr. R. Tanton, and Messrs. Perkins, amongst nurserymen. In Mr. Bull's group of 6 were fine effective arrangements of Dipladenia amabilis, Allamanda Aubletii, remarkably good; Erica obbata, and E. Parmentieri rosea, &c., both varieties fine and effective. The 2d prize group, contributed by Mr. J. Ward, were a beautifully grown and exquisitely flowered plant of Plerona elegans, the deep blue flowers of which gave a cheerful relief to all around; a capital specimen of Allamanda grandiflora, and the same of Erica Parmentieriana rosea, &c. In the corresponding class for nurserymen, excellent groups of the usual plants were staged by Messrs. Jackson and Mr. E. Morse. The class for 20 in 12-inch pots brought out a better lot than usual; and with it was exhibited in this section came also some fresh subjects, fresh in the sense that metropolitan growers but very seldom show them—we allude to the group shown by Mr. F. Perkins, of Leamington, who had very neat specimens of Begonia Sedeni, Pancratium speciosum, Cassia corymbosa, Clerodendron fallax, Diplacus californicus grandiflorus, Eranthemum Andersoni (elegans), Crassula Francis Dubois, and Sebrala macrantha, &c. Excellent collections were also contributed by Mr. J. Wheeler, Mr. J. Ward (including two very beautiful examples of Kalosanthes), Messrs. Jackson & Son, and Mr. W. Kemp, gr. to the Duke of Northumberland, Alluwy Park, Guildford, &c.

In fine-foliaged plants Mr. Baines also took the lead, with a capital group of Palms, Crotons, Sarracenias, &c.; Mr. J. Burley coming in a good 2d with handsome Palms, Cycads, &c. Beautiful collections of Palms, for which a class was as usual made, were contributed by Mr. B. S. Williams and Mr. Burley, and the former had also a pair of handsome Tree Ferns. Well grown Caladiums were contributed by Mr. J. Carr, Mr. G. Wheeler, and Mr. G. Pearce, gr. to W. S. Burton, Esq.; and from Mr. R. Ritchie, Mr. G. Wheeler, Mr. Baines, Mr. A. Wright, Mr. B. S. Williams, and Mr. Burley, came capital groups of exotic Ferns, the British section being exceedingly well represented by Messrs. Ivery & Son, Dorking. Of Orchids the show was but poor, the principal exhibitors being Mr. B. S. Williams, Mr. Bull, Messrs. Rollisson, Mr. J. Ward, Mr. J. Wheeler, &c. There was a nice display of Scarlet or Zonal and Tricolor Pelargoniums, the best groups coming from Mr. J. Catlin, gr. to Mrs. Lawrence Hanley; Mr. Stevens, Ealing; and Mr. J. Goddard, Twickenham.

Of cut Roses there were some grand examples, taking the state of the weather into consideration; Mr. W. Paul, who does not generally compete, sent some fine boxes of rare excellence, the blooms being fine, both in size, colour, and form. Messrs. Paul & Son contributed collections which fully maintained their reputation, and the same may also be said of Mr. Cranstoun and Mr. Cant. The amateur contingent were well represented by Mr. J. Skinner, Mr. Chard, Mr. Ingle, &c.

In the miscellaneous class were a very fine group of new plants, contributed by Messrs. Veitch, Palms, and flowering subjects, from Mr. B. S. Williams; smaller collections from Mr. Bull and Messrs. Veitch & Son, including from the latter some admirable cut Roses; a large and effective group of hardy flowers from Messrs. Ivery & Son; a large collection of decorative plants from Messrs. E. G. Henderson & Son, and the same from Mr. G. Pearce; six exceedingly good specimens of Lilium auratum, from Mr. W. Wells; and a dozen very well grown and much admired Phloxes in pots, and a group of new Bronze Zonal Pelargoniums, from Messrs. Downie, Laird & Laing; from Mr. Mann, Brentwood, a group of new Zonals; and from Mr. Cannell, Swanley, a group of cut blooms of the same class, including several bunches of that gem of the scarlet-flowered section, Jean Sisley; a large and very attractive collection of Zonal Pelargoniums from Mr. W. Paul; six very fine Heaths from Mr. A. Wright, &c.

Botanical Certificates of Merit were awarded to Mr. R. Parker, Tooting, for Ixora amabilis; to Mr. Bull, for Amorphophallus spectabilis, x Alocasia Marshallii, Philodendron hybridum, Dioscorea spectabilis, Pteris serrulata cristata, and Goniophlebium glaucophyllum; to Messrs. E. G. Henderson & Son for Hydrangea paniculata; and to Mr. B. S. Williams for an elegant Rhopala; to Mr. H. Wendland, inspector of the Royal Gardens, Herrenhausen, Hanover, for Æchmea Maria Regina; to Messrs. James Ivery & Son for a pretty Impatiens roseo-picta; Pelargonium Belairsise, P. angulare proliferum Marshallii, and P. vulgare cornubiense (Whytce); to Mr. W. Bull for Bignonia Kœcaliana; to Messrs. Standish & Co., for Bouvardia leiantha grandiflora; and to Messrs. Jackson & Son, for Davallia elevata. Floral Certificates of Merit were voted to Messrs. E. & J. Perkins, for Coleus Lady Leigh; and to Mr. Charles Kimberley, Coventry, for Tricolor Pelargonium Golden Queen.

The show of fruit was the largest of the season, though in none of the classes were there any especially remarkable productions. Two collections of fruit, 8 dishes were shown, the best coming from Mr. Lane, gr. to Lord Boston, Hedsor; Mr. A. Johnson, Savernake Forest, coming in 2d. Mr. Lynn had in his collection a very fine Queen Pine, excellent dishes of Black Hamburgh and General of Grapes, and a good Victory of Bath Melon, capital Grosse Mignonne Peaches and Elruge Nectarines, Sir Joseph Paxton Strawberries and Bigarreau Napoléon Cherries. Mr. Johnson had very nice Queens, capital Black Hamburgh and Tottenham Muscat Grapes, Peaches, Nectarines, Melons, Strawberries, &c. In the class for a basket of Black Grapes, not less than 12 lb., there were seven competitors: Mr. C. Noble, gr. to J. Da Silva, Esq., Burntwood House, Wandsworth Common, coming in 1st, with a very well-finished sample, though many of the berries were not equal in size. Mr. A. Johnson was 2d, and Mr. G. Osborn, Sayes's Nursery, Frimley, 3d. Mr. E. Sage, Atherstone, sent the best coloured lot, and Mr. Bones, gr. to D. McIntosh, Esq., Havering Park, had the largest berries: these would undoubtedly have secured first had they been better in colour. The other exhibitors were Mr. G. Wallis, gr. to J. Dixon, Esq., Aston Park, Congleton, and Mr. Walker, gr. to H. J. Atkinson, Esq., Acton. In the corresponding class for White Grapes, the best were a well-grown and nicely-coloured basket of Muscat of Alexandria, shown by Mr. P. Feist, gr. to R. Ashton, Esq., Bishopsgate House, Staines, Mr. G. Osborne coming in 2d, his berries being fine in size, but not quite ripe; the same remarks also apply to the 3d prize lot, which came from Mr. Davies, Friern, Barnet. The best single dish of Black Grapes was contributed by Mr. J. Douglas, gr. to F. Whitbourne, Esq., Loxford Hall, Ilford, a nicely-finished lot of Black Hamburgh; Mr. M. Walker coming in 2d, and Mr. W. Lane, gr. to J. Miles, Esq., Barnet, all showing very creditable examples. Messrs. Standish & Co. exhibited a fair-sized dish of Madresfield Court Grapes, and took the 1st prize in the class for any other black variety; Mr. F. Hicks, gr. to C. Scholefield, Esq.,

being 2d with Black Prince; and Mr. Barham, gr. to Lord Ormathwaite, 3d, with Muscat Hamburgh. In the corresponding class for a dish of Muscats, there were nine competitors, the 1st prize being taken by Mr. R. Ritchie, gr. to R. H. Prance, Esq., Frognal, Hampstead, with perfectly finished examples of Bowood Muscat; Mr. Barham coming in 2d with capital bunches of Muscat of Alexandria, a trifle green in colour; and Mr. Kemp, gr. to the Duke of Northumberland, Albury Park, Guildford, 3d, with smaller bunches of the same variety. Mr. W. Davies, Barnet, sent three bunches of Muscat of Alexandria weighing 13 lb., very fine, but unripe. Mr. J. Douglas, Mr. W. Lane, Mr. E. Sage, and Mr. A. Wright, all staged the last-named variety. The best single dish of any other white variety was a very nice one of Buckland Sweetwater, shown by Mr. M. Cole, gr. to F. S. Bullard, Esq., Ealing Park; Messrs. Standish & Co. being 2d with Ascot Citronelle, a new Grape of excellent merit, combining the flavour of the Citron and the luscious Muscat: it does not crack, and will carry well for two months after ripening; and Mr. D. Pizzey 3d, with White Muscadine. Of Queen Pines, 8 were shown—the best, a specimen weighing 6 lb., coming from Mr. J. Jaques, gr. to J. C. F. Cunliffe, Esq., Hooley House, Croydon; Mr. J. Akehurst, gr. to S. Copestake, Esq., being 2d, and Mr. J. Deaville, gr. to Lady Edwards, Wooton Hall, Ashbourne, 3d. The best dish of any other variety was a Providence, weighing 9 lb. 4 oz., from Mr. H. Balham, gr. to R. T. Crawshay, Esq., Cyfarthfa Castle; Mr. G. Ward being 2d with a smooth-leaved Cayenne, weighing 7 lb.; and Mr. A. Rochford, Page Green, 3d, with a nice fruit of the same variety. There were six other competitors. For the best three of Peaches there were 13 competitors, goodsized, well-coloured fruit being the rule. Mr. W. Birse, gr. to J. F. Lermitte, Esq., Finchley, was 1st with handsome examples of Violette Hâtive and Royal George; Mr. A. Reed, gr. to L. Hath, Esq., Passingworth, being 2d with Barrington and Grosse Mignonne; and Mr. W. Lane, 3d, with Violette Hâtive and Royal George. In the class for Nectarines the display was not so numerous. Mr. W. Birse had very well-coloured dishes of Balgowan and Violette Hâtive; and next Mr. A. Rochford, Dr. Belliers and Elruge; capital specimens of Newington from Mr. J. Davey, and Hunt's Tawny from Mr. Kemp. The best scarlet-fleshed Melon, in a collection of 7, was a small Scarlet-fleshed, shown by Mr. W. Lane; Messrs. Wright, Lee, Kent, had also a nice fruit of the same variety. Mr. T. Crane, gr. to the Rev. L. Deedes, Bramfield Rectory, Herts, had Improved Scarlet Gem. In the green-fleshed class there were 6 examples shown, including a nicely ripened fruit of Triomphe de Nice, from Mr. T. Crane; a nice flavoured example of Conqueror of Europe, from Mr. W. Lane; Golden Gem was shown by Mr. W. Cole; Bedfordshire Court, and Bailey's Green-flesh came from Mr. C. Ross. In the class for 2 Vines in pots, any kind, there were three exhibitors, Mr. Cole, Ealing Park; Mr. Wesker, gr. to A. Pearson, Esq., Fenside, Wandsworth Common; and Messrs. Lane & Son. The former sent very well-done specimens grown on the system described by Mr. William Thomson for table decoration, and from both of the latter came plants grown in the usual way. Mr. Wesker was placed 1st, Mr. Cole 2d, and Messrs. Lane & Son 3d. Collections of 6 dishes of outdoor fruits of the usual description were shown by Mr. W. Lane, Mr. W. Bones, Mr. Kemp, Mr. Pizzey, and Mr. A. Clarke. Capital dishes of Bigarreau Napoléon and Black Tartarian Cherries were shown by Mr. W. Cole; and Mr. M. Wallace, Mr. J. Smith, gr. to the Earl of Gainsborough, had nice dishes of Elton and Downton. Of Strawberries, Mr. J. Douglas had very fine dishes of Lucas, Frogmore Late Pine, British Queen, and Admiral Dundas. Of Black Currants, Mr. Wesker, Mr. Napier, and Lucas, &c. Mr. Johnson, Mr. Kemp, Mr. Pizzey, Mr. C. Kimberly had also very good examples. In the miscellaneous class, Mr. Harvey, gr. to P. Wroughton, Esq., Wooley Park, Wantage, had a Queen Pine, grown on the Hamiltonian system. Figs were shown by Mr. A. Reid, Mr. H. Harvey, Mr. C. Osman, and Mr. C. Ross; and Apples were shown by Mr. T. Crane, Mr. E. Clarke, Mr. Johnson, Mr. G. Osman, &c. Mr. W. Cox had 4 Golden Gem Melons, and Mr. Harvey sent 2 fruits and flowers of Stephanotis floribunda.

EDINBURGH BOTANICAL: *April* 13. — Alexander Buchan, Esq., the President, in the chair. The following communications were read :—

I. *Notes on the recent Progress of Botany in Denmark*; by Dr. Robert Brown.

Dr. Brown gave a review of some of the more important researches made by Danish botanists during the last few years, and published chiefly in the Danish language, in the Transactions of the Natural History Society, the Botanical Society, the Academy of Sciences, or as separate works. In noticing the proposed removal of the Botanic Garden from the centre of the city of Copenhagen, where it has long been, he called attention to the foundation of the Botanisk Forening, or Botanical Society, which now numbers between one and two hundred honorary, resident, non-residents, and foreign members, and publishes a yearly "Tidsskrift," or fasciculus of transactions, containing many papers of merit. The last part is occupied by Rosenvinge and Kostrup's "Icheines Danicæ." It is under the presidency of Professor Lange, and is mainly increasing in importance and numbers. The publication of the 47th livraison of the "Flora Danica," under the editorship of Professor Lange, marks an era in Danish botany, and keeps up the high reputation this work has attained. The present part contains, like its predecessors, 60 plates, representing 75 plants (14 of these being varieties already partially described in the "Flora Danica," and two hybrids), of which 24 have not been figured previously in any iconographic work. These 75 plants comprise 35 Phanerogamia (25 dicotyledons, 9 monocotyledons, and 1 gymnosperm), and 40 Cryptogamia (1 Fungus, 7 Characeæ, 12 mosses, 10 Hepaticæ, and 10 Lichens). The plates are executed by Mr. Thornman, and very faithfully and beautifully pourtray the objects they are intended to illustrate. Perhaps next to the "Flora Danica," the most important botanical work produced in Denmark of late is "L'Amérique Central," of Professor A. S. Œrsted, the result of a journey in Costa Rica and Nicaragua, in 1846-48. As yet only the first part is issued, partly at the expense of the Danish Academy of Sciences. It contains 16 folio pages descriptive of the physical features of the country, a map, two physiognomical views, and 18 magnificent plates, on copper, representing new species of plants. Œrsted has also published elaborate researches on the classification of the Oaks, founded on the form of the pistil, venation of leaves, &c., which differs materially from that of De Candolle and other preceding writers, and is a valuable contribution to the history of the Cupuliferæ. In the Proceedings of the Academy of Sciences, the same author has also contributed a paper on the "Silphion" of the ancients, which, from a study of the classical writers, Greek coins, and vases, he considers is a species of plant allied to Narthex Asafœtida, and which he proposes to call Narthex Silphium. Professor Œrsted's numerous papers on the Development of Fungi, his splendidly illustrated Introductory to the Study of Coniferous Plants, and his Memoir on the Morphology of the Coniferæ, were also noticed. Of late years Dr. Eugène Warming has visited Brazil, and made a collection of plants in the neighbourhood of Lagoa Santa, which he is now in course of description by himself and other botanists, chiefly Augustus Progel, J. A. Schmidt, Johannes Müller (Argoviensis), Otto Eickeler, C. F. Philippi, Lange, Dr. Th. Decker, Dr. Kampe, Dr. George de Martens, and Otto Nordstedt. The memoirs of these botanists are published chiefly in the Natural History Society's Transactions, are written in Latin, and illustrated by numerous plates. Dr. Warming has published notes on, many new or little known species. Warming has published, in the same place, remarks on the Development of Heat in Philodendron Lundii (*n. sp.*) from Brazil. The development of heat during the flowering period embraces two calorific undulations. The first day the greatest temperature is towards 6 to 7.30 P.M. It then abates and falls to the normal heat during the night. The next day the second undulation commences at the minimum point, 8.10 A.M.—and ceases towards noon. These observations are made on a plant which flowered from November 16 to 17, 1864. The culminating point of the first undulation does not coincide with the highest temperature of the air is at its maximum—viz., 2.30 P.M. However, there has been observed a certain dependence between them, that when the temperature of the spadix rises above that of the air, it sinks considerably below the air. The first period of heat presented the greatest intensity. Not only did the temperature last a much longer time, but was more elevated than in the second period. The greatest heat found during the flowering embraces two calorific undulations. The first day the temperature of the air is at its maximum—viz., 2.30 P.M. However, there has been observed a certain dependence between them, that when the temperature of the spadix rises above that of the air, it sinks considerably below the air. The first period of heat presented the greatest intensity. Not only did the temperature last a much longer time, but was more elevated than in the second period. The greatest heat found during the flowering was observed was 39½° Centigrade, the temperature of the air being then 25¾°, showing a difference of 13¾°. The difference in the part occupied by the stamens and pistils was 14½°. Dr. Warming's paper on Bidens's Platycephala; Warming on the Spiral Arrangement of the leaves of the Cucurbitaceæ, and on Scopolia atropoides and other Solanaceæ; Lange's addition to his "Handbook of the Danish Flora;" Didrichsen's "History of Danish Botany;" and Warming's "Inaugural Thesis on the Inflorescence and Development of Euphorbia."

II. *On the Phyllotaxis of Lepidodendron*; by Professor Alexander Dickson.

Dr. Dickson exhibited, and made some remarks on, specimens of Lepidodendron from the coal measures, which, in the arrangement of their scales, or leaf scars, illustrated the same spirals as found in plants at the present day.

III. *Note on Lilium canadense, L., var. puberulum, Torr.*; by Mr. Robert Brown.

In the enumeration of Dr. Bigelow's Californian collection, in the fourth volume of the "Pacific Railroad Surveys," Professor Torrey notes a variety of Lilium canadense, distinguished by the leaves being narrower, being minutely pubescent, the leaves broadly lanceolate, with the margin and nerves puberulous, the flowers few (2—7), largely pedunculated, the sepals markedly reflexed and pointed, and the capsule very short. He considers it doubtful his own and the late Mr. Jeffrey's collection, Dr. Brown had found specimens which corresponded to Torrey's description, but the characters are by no means constant, nor are all found on one plant. In specimens of Lilium canadense gathered in Canada, the leaves were found quite as broad as any from North-West America; and in numerous specimens of Lilium canadense from Oregon, California, and British Columbia, the leaves were always linear lanceolate. The pubescence is not a constant character, for while it was found on young plants, it was absent from old, nor was constant on either. Most probably it is cultivation that is the result of this; but in all likelihood, there is only one form of Lilium canadense found over the whole American continent, from the Atlantic to the Pacific, and that any varieties (such as those mentioned by Torrey [*Cat. pl. Wood in "Proc. Acad. Nat. Sciences of Philadelphia," 1868, p. 166*) are merely local, and the result of habitat, age, or other circumstances, which do not give the character derived therefrom any kind of specific value. Specimens, and a coloured drawing of the plant from life in North-West America, were exhibited.

IV. *Report on the Open Air Vegetation at the Royal Botanic Garden*; by Mr. M'Nab.

After the meeting of the Botanical Society (March 9) and until April 3, the weather was excessively dry, accompanied with north-easterly winds. On 15 mornings the thermometer was at and below the freezing point, the lowest markings being on March 25, 17, and 29, and on April 7, 8, and 11, falling respectively to 22, 28, 26, 28, 25, and 24 deg. It is remarkable that those plants fixed on for the purpose of recording the dates of their flowering, this year came within a range of rather less than two months—viz., from February 13 and April 19. The plants enumerated generally extend over a part of four months. The short period this year was caused by the unusually long winter, which prevented the Snowdrop and Winter Aconite (two of the earliest flowering flowers) opening their blossoms before February 13. Some of the latest recorded during April are fully 18 days earlier than last year. During 1870, the same plants ranged between January 9 and April 30; and during 1869 between January 9 and April 3, showing a considerable range in the periods of flowering of the same plants during different years :—

BIRMINGHAM ROSE SHOW AND EXHIBITION OF GARDEN TOOLS, &c.—We have to record a thoroughly successful exhibition, which was held in the Town Hall, Birmingham, on Thursday and Friday, July 6 and 7, being the tenth held in that noble building. As a Rose show it may be pronounced nearly if not quite, the best of the season, and the collections of horticultural tools and appliances were both large and interesting. Mr. John Keynes, Salisbury, was 1st with a fine stand of 72 varieties, single trusses; with 48 varieties, 3 trusses; with 24 varieties, 3 trusses; with collection of 24 new Roses sent out by English nurserymen in the spring of 1869, 1870, or 1871; with 12 trusses yellow or sulphur Roses, all of one variety, and with 12 trusses dark crimson or rose-coloured Roses all of one variety. Mr. John Cranston, Hereford, was 2d, with 72 varieties, single trusses, and with 24 varieties, 3 trusses; and 1st with collection of 12 blooms, 3 trusses, of one variety, for which he showed a magnificent box of Baroness Rothschild. Of amateur exhibitors, the following won the principal prizes :—Mr. R. Draycott, gr., Hallsford Bridge; Mr. Joseph Bagnall, gr., Mrs. King, Wilton, Salisbury; Mr. C. J. Perry, Castle Bromwich; Thomas Lloyd, Esq., The Priory, Warwick (gr., Mr. J. Moore); the Rev. F. M. Smythe, Solihull; Mr. S. Evans, gr., to C. N. Newdegate, Esq., M.P., Arbury, Nuneaton; J. H. Arkwright, Esq., Hampton Court, Leominster; Mr. J. E. Cavell, Walton Manor, near Oxford; and Captain W. G. Webb, Elford House, near Tamworth. There were many local prize-winners not enumerated above. The general excellence of the amateurs' stands was most marked. In some of the divisions there were as many as 25 entries. The following varieties were shown uniformly well by nurserymen and amateurs :—Hybrid Perpetuals: Abbe Giraudier, Alfred Colomb, Charles Lefebvre, Clemence Raoux, Charles Turner, Duke of Wellington, Duke of Edinburgh, Empress Eugenie, Elie Morel, Emilie Hausburg, Exposition de Brie, Ferdinand de Lesseps, Fisher Holmes, Général Jacqueminot, Hippolyte Plandrin, Horace Vernet, La France, La Reine, Louis Van Houtte, Madame Charles Wood, Madame Llabaud, Madame Victor Verdier, Mdlle. Eugène Verdier, Marie Baumann, Miss Ingram, Marquise de Castellane, Marquise de Mortemart, Paul Verdier, Princess Mary of Cambridge, Reine Blanche, Sénateur Vaisse, Thyra Hammerich, and Victor Verdier. Tea-scented varieties: Devoniensis, Gloire de Dijon, Madame Sertot, Souvenir d'un Ami, and Madame Willermoz. Noisettes: Maréchal Niel and Triomphe de Rennes.

A very decided and beautiful feature in the show was the display of dinner-table decorations and bouquets, which were exceedingly tasteful and full of great merit. The principal exhibitors and prize-winners in these departments were Mr. F. Perkins, Leamington; Miss Cole, Birchfields; Mr. H. Pope, King's Norton; Mr. C. H. Harrison, Edgbaston.

Collections of Roses not for competition came from Mr. C. Turner, Slough, who showed a magnificent collection; Messrs. Francis & Arthur Dickson, Chester; and Mr. R. H. Vertegans, Malvern and Edgbaston.

Garden tools and appliances were shown in great variety by Messrs. Mappleback & Lowe, Birmingham, whose collection, which was a very large one, included almost every kind known in the trade, and attracted much attention, especially on the part of the nurserymen and professional gardeners, for whom of course they had a

special interest. They exhibited handsome iron vases, garden seats in great variety with and without movable awnings, garden engines, lawn-mowers, chairs and tables for the garden or greenhouse, a Fern stand of new design, flower-stands, and an exhaustive collection of garden tools, garden cutlery, &c. They likewise exhibited a recently patented invention of Messrs. J. & A. Pumphrey "The Paxton watering-can and garden engine," which, as its name indicates, may be used as an ordinary watering-pot, or as a garden engine or syringe. It is a cheap and effective apparatus, well made, likely to have a large sale chiefly among amateurs. It is by no means cumbersome, and is made of various sizes, the smallest being especially adapted for ladies. The small garden engine with which it is fitted is light and portable, with an air vessel, and extremely useful for greenhouse and other purposes. where the diffusion of dew-like spray is desirable. Mr. G. H. Harris, Birmingham, exhibited a "garden or let-down garden lounge," or an awning raised or lowered with much ease, which was much admired; water-barrows, hose-reels, garden-rollers, lawn-mowers, garden seats, &c. Messrs. Griffiths & Browett had an extensive exhibit of hydropults, watering-pots, a sulphurator, &c.

The annual dinner of the Society was held on Thursday afternoon, at the Acorn Hotel, Mr. Councillor Lowe in the chair, there being also present a number of exhibitors, subscribers, and members of the committee.

Wolverhampton Horticultural: *July* 11.—This show was held for three days in connection with the meeting of the Royal Agricultural Society, but the success on the first day seems to have been marred by bad weather. The flowers, fruits, and vegetables were displayed in five large tents, and the centre of the field was occupied with archery, artistically arranged by Mr. R. Lowe, of the firm of Lowe & Co. The rocks were interspersed with Ferns, whilst a fountain, manufactured by Mr. J. Matthews, of Weston-super-Mare, played in the middle of the circle. For some distance around the fountain, the field was dotted with greenhouse plants, together with flowers and shrubs, which gave a pleasing appearance to the grounds. In a tent on the right-hand side of the entrance the collection of stove and greenhouse plants was arranged, and as this class was open to all comers, some very fine specimens of ornamental, fine foliage, and variegated plants were exhibited, and greatly admired. The next class contained plants shown by the nurserymen of gentlemen in the counties of Salop, Worcester, Warwick, Hereford, and Cheshire, and in this class there was a fine display of greenhouse plants in bloom, which attracted considerable attention. There was a good show of fruit, and the 1st prize for a collection of six varieties was awarded to Mr. Bannerman, gr. to Lord Bagot. In the open competition for cut Roses, Messrs. Paul & Son, of Cheshunt, succeeded in carrying away two of the first prizes, while one first prize was awarded to Mr. R. B. Cant, of Colchester. In the gentlemen's gardeners' class for cut flowers, gardeners of Messrs. G. F. Perry, of Castle Bromwich, and Mr. J. Forsyth were amongst the most successful in carrying off first-class prizes; whilst second-class prizes were awarded to the gardeners of Lord Hatherton, Mr. A. Walker, and Mr. J. Lee. In the gentlemen's gardeners' classes for stove and greenhouse plants, Messrs. R. S. Walker and G. H. Perry were awarded the largest number of prizes. Mr. John Matthews, of Weston-super-Mare, exhibited a large number of well-executed statuary fountains, vases, Italian Fern and other baskets, as well as many other descriptions of pottery goods for the nursery and garden, manufactured in Worcestershire; and some of the articles—which contained specimens of Ferns and other choice plants—belonging to Messrs. Lowe & Co., looked exceedingly pretty. We may also mention that Messrs. Lowe & Co. exhibited, but not for competition, a fine assortment of greenhouse and other plants in a separate tent. Lady Dartmouth's prize for wild flowers brought forth numerous competitors, and some of the designs were exceedingly pretty and well executed. The prize was awarded to Mrs. H. Underhill, who exhibited an ornamental display of wild flowers.

Manchester Horticultural (Rose and Fruit Show): *July* 12.—The attempt made by the Manchester Botanical Horticultural Society to establish a July Rose and fruit show at Old Trafford may be pronounced successful. As a spectacle, a Rose show cannot compare, either in magnificence or variety, with exhibitions of plays of greenhouse plants and Orchids; but whatever differences of opinion may exist as to the special excellences of other gardening products, every lover of the art is more or less a rosarian. And if such a show, however well stocked, can never be supposed to equal in effect the luxuriance and grandeur of tropical plants, yet in minute beauties—in perfection of form, and in delicacy of colour and fragrance—they afford sufficient matter of study and contemplation to justify a special exhibition. In the first three classes of nurserymen's prizes, Messrs. Paul & Son were easily the winners, for although the famous Sussex growers, Mr. Mitchell, of Piltdown, challenged their claim to premier honours, the general excellence of Messrs. Paul's collection was certainly unrivalled. The Cheshunt firm sent several extra magnificent stands of cut Roses, the most noteworthy being the Baroness Rothschild, a finely-developed flower, of a delicate pink colour; the Comtesse d'Oxford, a very distinct red; and the Duke of Edinburgh, a very dark-red flower. In the amateurs' class the competition was keen and representative, the premier honours being pretty fairly divided between the Rev. G. Arkwright and the Rev. S. Reynolds Hole. In the competitions which were open to all classes, the most successful exhibition was of Tea-scented and Noisette Roses, in which Messrs. Paul & Son were again the winners. Mr. R. S. Yates also exhibited in this class a magnificent collection, yielding delicious fragrance. A valuable prize was offered for the best collection of new Roses, but the result was a walk-over for Messrs. Paul & Son, whose fine display was unchallenged. The special prizes offered for dinner-table decorations, and for bridal and ball-room bouquets, brought out a competition which, on the whole, was satisfactory. The fruit show was in all points excellent. The exhibition owed its most attractive garnishing to a number of old contributors, who, though not competitors on this occasion, sent choice specimens of plants and flowers by the way of betokening interest in this new effort of the Society, which will probably be the forerunner of many excellent shows.

Notices of Books.

How to See Norway. By J. R. Campbell. Longmans. 8vo. Pp. 84; tab. 5.

A little book of unpretending character, but of a degree of merit amply sufficient to justify its reprint from the pages of the "Alpine Journal."

The author gives a quantity of useful information in a short compass. Amongst other things he alludes to the comparative infrequency of crime in Norway, and the general absence of the "rough" element, and attributes much of this immunity from the worst features of more southern countries to the excellent education afforded to every child. "Every child learns to read and write. Valleys where neither church nor road are found have each a schoolmaster during several months in the year. Where the valley is too long for all the children to attend one school, it is partitioned out into two or more districts, and the teacher devotes a certain number of weeks to each in succession. * * Most peasant children are taught a little history and everyday science (in addition to reading, writing, ciphering, and religious knowledge). The schools have the most admirable books on general knowledge I ever saw—far better than those used in English parish schools." This statement is confirmed by the admirable books and materials for instruction exhibited in the Swedish schoolhouse at the International Exhibition, and to which we have already referred.

Transactions of the Woolhope Club, 1870. *Hereford Times* Office. 8vo, pp. 321.

This volume worthily maintains the reputation of the Club—a club which not only attends to the amenities of quasi-scientific picnics, but earns a right to enjoy itself in that or any other way by the sterling value of the information which its energetic members get together. Edible Fungi, notable trees, Mistleto-Oaks, as usual, come in for a large share of attention; but we have, in addition, capital geological papers, gossiping archæological memoirs, besides notes on entomological and meteorological subjects. Mr. R. Bligh contributes a good paper on the growth of the Mistleto, in which he asserts that the parasite has the power of penetrating the hard wood, and not merely of becoming imbedded therein by the formation of new wood over it. The photographs of remarkable trees of the district are creditable, and several other illustrations are added. As there may possibly be some difficulty in securing more finished lithographs, we would suggest that the legend relating to them be confided to the printer, as the lettering of the plates greatly disfigures them.

An interesting feature of the present volume consists in the reproduction from Fries' "Monographia Hymenomycetum Suecie" of the autobiographical memoir of the veteran Swedish mycologist, accompanied by a photographic portrait.

We may conclude our notice of this interesting volume, by extracting from its pages certain details as to the growth of the Wellingtonia:—

"The Sequoia Wellingtonia in Holm Lacey Park is the finest tree (of its kind) in the county. * * It was planted in November, 1853, when it was 8 inches high. In 1866 it was 18 feet high; at 1 foot from the ground the circumference of the bole was 3 feet 1 inch, and at 5 feet, 1 foot 8 inches. At the present time, 1871, the tree is 36 years old, and 27 feet high. It girths at 1 foot from the ground 5 feet 3 inches, and at 5 feet from the ground it is 3 feet 6 inches in circumference. Its rate of growth, therefore, is about 1 foot 9 inches a year."

Introductory Text-Book of Meteorology. By Alex. Buchan, M.A., &c. Blackwood & Sons. 8vo. Pp. 218; 8 plates.

We have already had occasion to speak in the most favourable terms of the "Handy Book of Meteorology," by the same author, and we can as conscientiously recommend the present condensed treatise to the notice of our readers. Possible purchasers, however, should have been informed as to the relative status of the two books. Those who have the "Handy Book" will hardly require the "Introductory Text Book," while for very many, perhaps the majority of readers, the latter volume will answer the purpose as well as the larger volume.

—— Two numbers of the *Illustrated Gardeners' Guide* are before us, and demand some notice at our hands. The publication in question is published in the German, French, and English languages, in three parallel columns, and is devoted to horticulture in all its ramifications. It is edited by the directors of the Pomological Institute at Ringelheim (Hanover), with the assistance of M. Emile Rodigas, of Ghent. The publication is an ambitious one, well got up, illustrated with excellent cuts, and also with chromo-lithographs, while the general character of the articles is good and practical. The "Guide" is of a large 4to size, and may be had from Messrs. Silberrad, Harp Lane, Great Tower Street, E.C.

—— The first part of a new edition of *Varrell's British Birds* (Van Voorst), revised by Professor Alfred Newton, is before us. The original work has been so highly esteemed by naturalists, that it has passed through three editions, the latest of which was issued in 1856. Since that time very great additions have been made to our knowledge—not that the absolute number of species observed has been very greatly extended, but the knowledge of their habits has been greatly enlarged. It is needless to say that the typography and engraving are equal to those of former editions, while the reputation of the present editor offers a guarantee for the value of this new edition.

—— *Knife and Fork* is the suggestive title of a new journal, "devoted to the science of gastronomy," and edited by Fin Bec. The specimen before us contains a variety of savoury articles, not the least curious of which is an article devoted to the Knife and Fork Fund, and soliciting subscriptions in order to place the Journal on a thoroughly sound and lasting basis, and to institute various reforms in the culinary art. To attain the latter object, it is proposed to establish courses of lectures on domestic economy, cookery schools, competitive examinations for domestic servants, prizes for the cheapest and most nutritious dishes, economical cooking apparatus, and for methods of producing food abundantly and cheaply. All this we may look on as a prospective arrangement, contingent on circumstances—a *mênu* for what may possibly be a Barmecide's feast. To deal merely with the spread before us, we can conscientiously recommend the *pièces de resistance* and *relèves* as well served and substantial, the *entrées* and *entremets* as light, varied, and toothsome.

—— Not content with the boon offered to botanists by the publication of his "Refugium Botanicum," Mr. Wilson Saunders has laid naturalists under a further obligation by issuing a series of *Mycological Illustrations* (Van Voorst), consisting of figures and descriptions of new and rare Hymenomycetous Fungi. Mr. Saunders has associated with him as co-operators Mr. Worthington Smith and Mr. A. W. Bennett. In the part before us some 30 species are illustrated on 24 plates. Not only are characteristic portraits given, but also sections, together with figures and measurements of the spores. We venture to suggest the desirability, in all cases where it is possible to do so, of adding yet further microscopical details relating to the basidia, cystidia, &c.

—— Having noticed from month to month the periodical issues of the *People's Magazine*, we need only now refer to the fact that the half-yearly volume is complete, and would, from the variety and quality of its articles, form a suitable present for young persons as also to those of larger growth.

—— *How to Live on a Sixpence a Day* (Longmans), is the title of a sixpenny pamphlet, written by T. L. Nichols, M.D., and contains a series of small income crotchets. The writer disregards too much the individual peculiarities of digestion. He overlooks the fact that "what is one man's meat is another man's poison," and hence his assertions are often too sweeping. Tea and tobacco could be of much service as food, in the sense intended by Dr. Nichols, but it is idle, in the face of such enormous experience as we have, to deny their value. Dr. Nichol's idea is that the best diet for man is one composed of bread (including all grains, Potatoes, Yams), and fruit, while the dearest, and most doubtful, and most expensive form of food is flesh. Dr. Nichols prefers cheese to meat, and, weight for weight, no doubt it is more nutritive; but what about the relative digestibility of the two? Some of the dietaries are well chosen on the score of economy, and labourers and others with small incomes might do worse than adopt some of Dr. Nichols' hints. Here is one, well suited for healthy children, at any rate:—"the best Scotch oatmeal costs twopence a pound. You could hardly eat more than half a pound a day, which, with sugar, milk, and fruit might come to threepence, and, with the addition of cheese, fourpence a day."

—— Referring once more to the *Nederlandsche Boomgaard*, noticed by us at p. 276, we may state that there is an edition of this publication published in the French and German languages under the title "Le Jardin Fruitier Neerlandais." It is known to us by the Correspondence of the Pomological Society of Boskoop, and not by Dr. Van Hall, as we had erroneously stated. The preface alone is the work of that gentleman. The preface to the French edition is from the pen of Dr. Karl Koch, of Berlin.

—— The *Belgique Horticole*, the regularity of whose publication has been interfered with by the Franco-German war, has appeared in an improved type, and with sundry other ameliorations. It is, however, somewhat odd to read in the number for January and February, 1871, the account of the opening of our own International Exhibition of May 1.

—— A German edition of *How Crops Grow*, already noticed in our columns, has been published under the superintendence of Baron Liebig, and may be had of

Messrs. Williams & Norgate. The German title is "Wie die Feldfrüchte Wachsen."

—— Mr. Robinson, whose literary activity is worthy of comment, has just published a *Catalogue of Hardy Perennials, Bulbs, Alpine Plants, Annuals, Biennials, &c.*, including a complete list of British flowering plants and Ferns. (Murray, 12.) It is a mere enumeration without any descriptive detail, or even attempt to adjust synonyms; hence the same plant sometimes gets entered under more than one name. The catalogue will be serviceable for making lists, marking *desiderata* for exchange, &c.

—— Any one with a taste for debating can hardly do better than purchase the *British Controversialist* (Houlston). For ourselves, there are many controversies in which we are naturally obliged to take some practical part, that but little leisure remains for the mere discussion of such subjects as are handled in the magazine before us.

Garden Memoranda.

ORTON HALL, NEAR PETERBOROUGH, THE SEAT OF THE DOWAGER MARCHIONESS OF HUNTLY.—The house is about 2¼ miles from Peterborough, and the place is distinguished for a choice collection of fine Conifers and a splendid avenue of Wellingtonia gigantea. These were raised from seed about 15 years ago; grown and planted, I believe, by Mr. Reid, now gardener at Haigh Hall, Wigan. Their healthy condition and rapid growth bear witness to his careful management and skilful planting. There seem to be Wellingtonias everywhere about the grounds; so plentiful are they, that the public road is lined with them for some distance from the entrance gate, and a farmhouse by the road-side has its avenue of Wellingtonia gigantea. Here and there, too, we drop upon fine specimens, ranging from 30 to 40 feet in height and broad in proportion, in secluded nooks and warm sheltered corners, or nursed round with other trees. But the grand muster of these arboreal giants is on each side of the carriage drive. The latter describes something like the circular line of a quadrant, leaving one road, and sweeping round to join another that leaves the first road at nearly right angles. The mansion is placed on the side of the carriage road, which extends for nearly a mile. The drive is lined throughout its whole length with Wellingtonias, planted in lines 36 feet apart and 27 feet from each other. Some of the trees stand on the grass, others among sheltering shrubs or underwood, others on the bare earth which will have the trees and shrubs mixed with mixed borders of bedding plants. The trees are very much alike in all portions of the avenue, though the flowers seem scarcely in harmony with the grandeur of these monarchs of the forest. Possibly as they advance, the whole space on each side of the road will be laid down in grass, and the entire ground line made uniform in character. The trees all seem remarkably healthy. None seem to have suffered in the least by the severity of the winter, neither do any manifest a tendency to lose portions, large or small, of their branches, though many to be a natural failing of the Wellingtonia. It ought to be observed, however, that these trees are mostly much sheltered. The demesne is well wooded, and the avenue at most points is backed up at one or both sides by the shelter of the house, shrubberies, or established woods. This I believe to be one great cause of the healthy condition of the Wellingtonias. Trees are naturally sheltered; each shelters its neighbour. And in large forests, or even on the more exposed hill-side, one part of the tree shelters the other, and the whole afford protection to each. This is too often forgotten in our dotted styles of planting. A tree is set down on an open lawn or field, with its 30, 60, 100, or more feet of space, all bleak and bare; and then we greatly wonder why it does not run up quickly and continue green and healthy. I know several avenues and many single specimens of Wellingtonia in exposed, open places, but none equal in vigour and robust health to these; and I believe one chief cause of their pre-eminence is the large amount of shelter they enjoy. All the Fir tribe are most impatient of being overtaxed, but side shelter is quite a different thing, and an important help to rapid growth.

At first sight it seems as if these two lines of trees were far too close together; but possibly they are well placed for ultimate effect. To form a covered road, the boughs have to be pruned up from 20 to 30 feet high, and then to drive or walk beneath the interlacing boughs of the giant Wellingtonias would be a new sensation of rare novelty and great pleasure. The close proximity of the colossal trunks would add to the magnificence of the scene, and many centuries must come and go ere the holes meet, as meet they will, as they ever arrive at anything like Californian dimensions in Britain. Some very fine specimens of choice Conifers are found in other portions of the ground. These are all equally well or better sheltered than the the Wellingtonias.

The following are some of the finest specimens seen in a small pinetum or arboretum, belted round at all points nearly, with masses of deciduous, evergreen or other trees and shrubs:—Many fine specimens of Thuja Lobbii, gigantea, and chinensis; Cupressus Lawsoniana, and macrocarpa; Picea bracteata, very fine; P. Nordmanniana, good; P. Pinsapo, very fine; P. cephalonica, good; P. Jasiocarpa, fine healthy plant; Abies Douglasii, good, but lealier lost; A. Smithiana, good, more strong and dense in habit than generally seen; Cedrus africana, very fine, and glaucous; Pinus excelsa, Sabiniana, and macrocarpa, were especially large and good. I also observed some very large Tulip trees, huge masses of Euonymus, of sorts; Libocedrus, Cedrus Libani, and Thujopsis borealis, while the Taxodium or Sequoia sempervirens was everywhere. The Araucarias were almost the only Conifers that did not seem quite at home. Even the trees and shrubs overflowed, as it were, into the fernery, or rather a good part of the latter is found under Yews and Cedrus Deodara, &c.; and the background and highest points are mostly filled in with Conifers and such shrubs or plants as Honeysuckles, Hypericums, Yuccas, Sedums, Pamarias, Spiræas, common Roses, Silenes, Foxgloves, Nepetas, and last, but by no means least, a coarse sort of Euphorbia. A considerable extent of uneven ground is provided here in a small space by the formation of an undulated base, the piling up of rocks, and a multiplicity of walks at different levels—now descending, now at right of steps, and again crossing a rustic bridge; now a mound, and again a pool of water; here a jutting corner of sandy soil studded with rare alpine plants, such as the Gentiana verna; and anon a receding shady vale in miniature, where Ferns live in a fresh green paradise. Altogether, for a small fernery, it is very prettily and nicely furnished. The present dowager marchioness is constantly adding something collected by herself from the Alps and other alpine regions.

The kitchen garden is large, and well furnished with crops. A herbaceous border of flowering plants is carried round it in the old style. There is one great advantage in having choice gems within the walls—they are safe from the ravenous mouths of hares and rabbits.

On one part of the wall we noticed a huge plant of that grand old Noisette Rose Lamarque. On the conservatory roof was a fine plant of Maréchal Niel, which had been literally covered with its burden of golden treasure. In the same house were some very fine plants on the roof of Rhynchospermum jasminoides, so seldom seen in such a position. Fine as a pot plant, this sweet climber is much better on a conservatory rafter.

Finally, two houses of Grapes, one chiefly of Hamburghs, and the other wholly of Muscats, proved by the regularity of the crop and size of bunch and berry that the present gardener, Mr. Collie, is a fruit as well as a tree grower. Altogether this quiet and comparatively small place is well worth a visit from the lover of trees, as well as the maker of ferneries. In regard to the latter, a middle course has been chosen, between the stiffness of formal art and the bold freedom of Nature. *F.*

Miscellaneous.

THE HARDER PART.

Ho, ye who at the anvil toil,
And strike the sturdy blow;
Who feel the blood within you boil
Before its furnace glow—
Ne'er envy him whose life is passed
As one long holiday,
For know it is the harder part
To idle life away.

Ho, ye who on the rugged farm
Contend with hardy soil,
To wrest from out earth's bosom warm
The fruits of honest toil,
Ne'er envy him whose life is passed
In indolence and play,
For know it is the harder task
To idle life away.

Ho, ye who rack the weary brain
In study hard and long,
That ye perhaps at last may gain
The honour of a song—
Though wearily the time is passed
As work ye day by day,
Yet his is still the harder task
Who idles life away.

And so, whatever be your work,
Perform it with a will,
And never from its duties shirk,
Nor soul with envy fill;
For that which makes the happy heart
Is work, not foolish play,
And freedom from that harder part
Of idling life away.

S. A. M., in "Kentish Gazette."

THE SECRET OF GROWTH.—A discussion took place some years ago in the *Builder* on the influence of coloured glass on conservatories, and experiments were afterwards made which seem to have since assumed an exaggerated shape in America, where it is gravely announced that "the germ of all growth and life lies in blue glass." The "discoverer" learnedly sets forth to the public, in a pamphlet, that "he covered a grapery with glass of a blue or violet hue. In five months 2-inch Vines had grown 45 feet; in a year they bore Grapes in startling abundance. He covered a piggery with it: the three sows, under the violet glass, increased 12 lb. in an incredibly short time, and a barrow pig increased even more rapidly than this," owing to the "abnormal development of greed and viciousness enabling him to seize on more than his share of animal food." After these successes, he next put up an Alderney bull-calf just born, and apparently dying, under glass of this mysterious colour. In a few hours it got up and ate with great vivacity: it began to grow next day," and was "full-grown in four months." The author recommends that architects be directed to roof our houses with the life-producing violet hue; and if this practice be observed he promises that "we can produce in the temperate regions the early maturity of the tropics, and develope in the young a generation, physically and intellectually, which will become a marvel to mankind." A commentator remarks that when the members of the human race look blue, they are supposed to be just then in a very flourishing condition. *Builder.*

MONSTERA DELICIOSA.—Some readers may remember this under the old name of Philodendron Pertusum. We have grown the plant for its fruit for a great many years, and, as was remarked at the Fruit Committee on the 6th ult., when a ripe fruit was exhibited, no plant could be more easy to cultivate. We have been in the habit of planting a lot out every summer in sheltered situations, with many other choice plants, and few prove to be more interesting than this, more particularly if a lot of the leaves and shoots are pinched in before planting. This gives the plant more vigour, and tends to assist in developing its magnificent and singular-looking leaves. These, like those of many Endogens, spring as it were from the bottom of the previous leaf-stalk, and push out the top of the next leaf, while the leaf itself bent down agrainst the side of the stalk, or something like a flag rolled up. This, under favourable circumstances, lifts itself gradually, and developes into a leaf 3 feet 6 inches by 2 feet 6 inches. Curious as is its manner of unfolding, it is rendered even still more curious by the small threads that connect the outer segments of the leaf, giving it an entire and perfect shape. These are soon broken by wind or movement. We have generally grown the Monstera planted out in small bricked-up corners of cool houses, where we could, by an alteration of the plants, make the most use of the sun-heat in summer. It will succeed perfectly, I have no doubt, in a common greenhouse where Vines are grown, and where in the summer months I have no doubt that a little extra heat would ripen the fruit sooner. With us, it takes 12 months from the time of blooming. Of course, there is mostly a succession of fruit on each plant. The report published states that this fruit is very delicious. In my opinion, it is one of the most delicious fruits grown; and, if allowed to grow freely, instead of being hampered in a pot, the fruit loses the little asperities or raphides that cause a peculiar tickling sensation in the throat in some cases. I considered at the time that there were two varieties, but I am now convinced that the difference is simply due to the conditions of growth. Some of our first fruits this year were from 14 inches to 18 inches long, with a good depth of the eatable part. One ripe to-day is scenting the air round the house, more so than a room at a house of Pine-apples would do. The habit of the plant is creeping, or, if it were consistent, we might say stalking, as the rootlets come from the stem, at a foot or 18 inches from the ground, and form fine strong spongelets as thick as one's finger. These on finding the soil either penetrate it or go along to the wall, where they spread out into numerous tufts of roots. Any sort of soil appears to suit its growth. We have always used good loam and a bottom of brick rubbish. *J. F., in "Florist and Pomologist."*

A NEW INDUSTRY IN THE SUGAR-CANE has been successfully introduced into the French colonies. The fact is interesting to our sugar planters, because the time has come when the yield of the cane must be increased, and it is well known that certain species are more susceptible of improvement than others. This law holds throughout the vegetable kingdom, and people who cultivate vegetables for manufacturing purposes always, therefore, not only look for what grows best, but for what will yield most readily to cultivation. The Beetroot growers, by acting according to good judgment on this point, have devoted so much attention to the selection of the richest varieties of their plant, that they have raised its saccharine strength from barely 4 per cent. to 8 and even 12 and 15 per cent., and this within less than 50 years. On the other hand, it is undeniable that the cane-growers of the tropics contented with the gifts of Nature, and have done very little towards raising the quality and productiveness of their plant. The humble root which rivals the cane has been doubled and trebled in richness, whilst the cane has remained comparatively stationary. It is asserted by many able to judge in the question, that Beetroot has now reached its maximum of sugar-producing quality, and we ought to be encouraged in our efforts to improve the cane by the knowledge that our plant has not yet passed its maximum. The plant is called the Salangore Cane. The results were mainly obtained from the trial of the new cane at a plantation called Grand Pare, situated near Basse Terre. The results are specially noteworthy. Planted at the full distance apart (2 metres by 2 metres), which is an essential con-

dition, and manured at the right times, the Salangore Cane grows with such vigour, and in such thick tufts, that in five or six months it forms so thick a green covering that weeds cease to grow about it. The weedings are thus notably reduced. The cane goes through the period of flowering without injury. The tufts yield from 25 to 40 canes. In consequence of the enormous quantity of canes produced by each tuft, the weight to the hectare is much above that of an ordinary hectare of canes. In one case 16 tufts of canes, which were far from being the best in the field, were cut in a square space of 38 metres 45, and they weighed 367 kilogrammes nett, from which, in proportion, we should find, in round numbers, 100, 600 kilogrammes to the hectare. To ascertain the weight produced from a hectare of ordinary canes, the members of an assembly of the Sugar Society of Point-a-Pitre, of December, 1869, were consulted, and an authoritative declaration was made as follows:—In Guadaloupe, an average of 40,000 kilogrammes of cane to the hectare is obtained, whilst at Grande Terre 30,000 only are obtained. The average at Beauport has been only 27,000 kilogrammes to the hectare. The bragasse of the Salangore canes gives so much fuel that only a small addition of straw is required, and this quantity leaves as much upon the ground for the use of the plantation as the other kinds of canes. The juice of the Salangore cane is abundant. The sugar is easily made, without any other ingredients than those used in the manufacture of sugar from other kinds of cane. The sugar is of the best quality, and of a hard and brilliant grain. The yield per hectare is considerably superior to that of other cane. *Colonial Standard.*

July 6.—Cloudy till the afternoon, and again after 8 P.M. Variable between 3 and 8 P.M. A little rain fell occasionally.
— 7.—A very fine day. Light clouds prevalent.
— 8.—Very fine throughout. Breezy.
— 9.—Clouds varied rapidly in amount throughout the day. Fine.
— 10.—Cloudy throughout. Rain commenced falling at 8 P.M., and continued steadily till midnight.
— 11.—Generally overcast. Rain fell more or less heavily from midnight till 5 P.M.
— 12.—Cloudy, but variable in amount from time to time. Showers of rain fell in the afternoon and evening.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

Those *Camellias* which have already finished their growth, and upon which the young wood is moderately firm, should be placed at once in a position where air to the fullest extent can be afforded them. Do not expose them too freely to the more powerful rays of the sun at this early season, especially as the wood and young leaves are but moderately ripened or hardened. These remarks also apply to *Indian Azaleas* in a like stage of growth. Continue the shifting on of *Cinerarias* and *Herbaceous Calceolarias*, as regularly as they fill the fresh pots and soil with roots, and require such attention. Encourage now by every possible means the growth of all plants specially grown for winter decoration, because the utmost amount of growth that can be made between now and the long cold nights of autumn will not be any too much, if, indeed, enough. Pinch back all strong young shoots as frequently as this becomes necessary, so as to secure size and beauty of form in each plant, as well as to increase their bloom-ing capacity. Amongst the many subjects to be thus treated, which are familiar to all, I may mention the old and greatly neglected *Rondeletia speciosa*, and what is equally as badly treated, but if possible more beautiful, *Mitraria coccinia*, *Justicia speciosa*, *Torenias*, *Fuchsias*, *Lantanas*, *Geraneum*, *Begonias*, *Aphelandras*, *Achimenes picta*, *Eranthemums*, &c. Give to many a moderate shift as often as required, and when the fresh pots are moderately filled with roots, afford alternate waterings, with properly prepared and wholesome liquid manure. Use the syringe freely amongst them night and morning, and so endeavour to afford suitable conditions for the full development of their growth. Even at this season, however, I suggest that every means be employed to maintain, even around these fast-growing subjects, a cool night temperature—cool, be it observed, in a comparative point of view. The external air will afford sufficient warmth for all their requirements at such times, then permit its invigorative properties to pervade the structure freely. In short, always give air freely at the apex of each stove when the thermometer out-of-doors registers 60°, and there is no sign of a change. Should, however, the thermometer, as it will do occasionally, maintain anything like a temperature of from 67° to 70° in the late evening, give air back and from it, without any hesitation. One whole night of this free buoyant air, will do all the inmates of such structures more good than a week's growth in a closed and confined, some atmosphere. In show-houses and conservatories there will now be a great variety of plants in bloom, many of which, especially of the soft-wooded sections, will have become pot-bound, and, if they have been in bloom long, much exhausted in their energies. It is advisable, therefore, to have manure-water handy, so that a little can be given to such as require it, at each watering. I refer to *Fuchsias*, *Brugmansias* growing freely and beginning to bloom, *Tuberous Begonias*, root-bound, *Bouvardias*, *Salvias*, &c., to which manure-water may be applied with far less risk than to many kinds of hard-wooded subjects. Do not fail to afford to such "miffy" subjects as *Boronia serrulata* a little artificial warmth, whilst engaged in making growth. A nice gentle humid warmth, such as pervades an early vinery, suits it well, just at the heighth of its growing season. The free-flowering *Acacia Drummondii*, and such like subjects, will also be much benefited by having a little of such assistance.

FORCING HOUSES.

In many instances *Muscat Grapes* will now be in their last stage of ripening, and with the acquiring of their richly vinous flavour, should also be "putting on colour,"—that golden tint so much sought after. Gently raise the heat, therefore, until in the course of a week or two, from 90° to 95° may be permitted with perfect immunity from injury by-and-by. In the event of dull, cold weather, give a little artificial heat; at the same time be it remembered that air must also be afforded with no niggard hand. Ofttimes, between the stoning and the final swelling process, the Vines will make a growth from the points of sublaterals. Do not permit these to exceed two or three joints in length, excepting it be a few shoots at the back or front, or any position where they will not unduly interfere with the more matured foliage that does the work. *Early Vineries*, from which the whole crop has been taken, should still have abundant air thus afforded to them. I do not advise a resort to too free exposure until the foliage has become properly developed. Keep *Pines* growing as much as possible, having a due regard to the proper maturation of the growth made. I was much surprised at the last meeting of the Fruit and Floral Committee, on the part of Mr. Perkins, a very expert Pine grower, of two beautifully grown "Queens," which had been grown from a rootless sucker in a few days only over 12 months. Even such grand results as these, I find, are attained under the most rational system of culture. As I have frequently urged, a mean minimum temperature only should be determined upon, the maximum being at all times suggested by the external elements. By slow but constant gradation get the trees in Peach and Nectarine houses inured to the full outer air, afterwards removing the lights altogether. Subsequently give all necessary attention to such cleaning, mending, and painting as may be required in connection with the several structures. Occasionally syringe all trees in this state during dry hot weather, should such favourable weather visit us.

HARDY FLOWER GARDEN.

Sweet Peas, properly selected, should never be dispensed with. They are so bright and so fragrant, affording besides one of the sweetest subjects for associating with the colourless *Mignonette* as cut flowers for the use of the boudoir, &c. Moreover, by sowing seeds successionally, their period of blooming may be made to last many months; little outlayin labour being requisite. They also make excellent "shift-seasons," to afford variety to the annual arrangements of all "by-ways" in garden enclosures, which sometimes possess unseemly back-grounds. Where *Dahlias* have not been mulched, as previously suggested, this should now be done, as by these means many more surface roots are encouraged, which otherwise would not exist to support the plants. Make up all deficiencies in beds of every kind of summer bedding plants. Hoe well the surface of each, subsequently raking them neatly, and make some progress in the pegging down of *Antirrhinums*, *Verbenas*, and other similar semi-trailing plants. Tie in the Picotees and Carnations of the better sort, placing card-boards to the blooms where the kinds are worthy the attention, and high-class culture is aimed at.

HARDY FRUIT GARDEN.

Tie up the points of the growing shoots upon *Espalier trees* by the usual means of stakes. Spur back the shoots formed during the current spring to two or three eyes from the base. Continue the removal of all *Strawberry runners* as they form, when not wanted for the increase of stock. Give some kind of artificial support to *Filberts* in all instances where such a crop exists as to demand it, as is the case in some neighbourhoods this season.

KITCHEN GARDEN.

Trench up where practicable every piece of ground now becoming vacant, if not done within the last two years. Use the hoe freely, and where practicable a fork, to loosen the soil well between growing crops, which is one of the most powerful of all incentives to growth. Sow more *Lettuce*, *Spinach*, *Endive* and *Carrots* on deep warm type, where not done last week. "Drain" the crop of autumn Onions, and by full exposure to the sun, and by occasionally turning them over, encourage them to ripen oft quickly. Make now a sowing for the main crop of autumn *Cabbages*. Keep all recently planted *Celery* well watered, should hot weather ensue. Do not let any early-running a seedy appearance remain one hour more than is needful; they impoverish the ground beyond what many unacquainted with the matter would surmise. *W. E.*

Notices to Correspondents.

Anthurium Scherzerianum: *E. B. C.* Sow the seeds at once in a pan of nice, light, peaty soil, in a warm, moist stove or pit.

Coleus: *Subscriber, Ajax* is a bronzy-crimson, with golden margin. Bausei is nearly of the same colour, with green margin, or sometimes, when at its best, almost wholly of the deeper colour.

Cupressus macrocarpa: *C. C. H. G.* The ground on which this plant grows in California is said to be rather wet, but not heavy. The destruction caused in these islands by the frosts of a few years since, prevent us from recommending if as a desirable tree to cultivate for timber.

Diseased Peaches: *R. G.* The little protuberances on the Peaches noticed by you are caused through gumming and unhealthy action of the roots of the tree.

Floral Devices: *Subscriber.* We do not understand your question, and therefore cannot advise you.

Grapes Decaying: *J. D. & S.* We have never seen berries go off in the manner yours seem to have done. Is it general or partial? We should like to know a few more particulars.

Grapes Injured: *T. H. B.* Your Grapes are injured through a settlement of damp upon them, and the neglect to give air early enough in the morning. Lady Downes is very liable to this.

Insects about Strawberries: *A Constant Reader.* These, no doubt, are encouraged by the mulching materials used; but this season Strawberries are a prey to innumerable vermin, through the excessive wet.

Names of Plants: *W. C. Trevelyan.* Pteris aquilina, in the young or seedling state.—*J. C.* 1, Scandix pecten veneris; 2, Tragopogon pratensis var. minor; 3, Ranunculus arvensis.—*C. J. C.* 1, Asperula Cynanchica.—*H. M.* Specularia hybrida, if, as we understand, it is found wild.—*K. & S.* Apparently a particularly good form of Athyrium Filix-femina lacinitum.—*Subscriber, Leamington.*—*J. S.* Pyrethrum sonchifolia.—*C. W. H.* Sisyrinchium bermudianum: a great rarity. The first record of the occurrence of this plant in Great Britain. Was discovered some years ago in County Galway, where it is now thoroughly established; but has never previously been met with beyond that county.—*H. Titley.* The two Lilies of which flowers are sent are both the same, botanically, Japanese forms of bulbiferum coming in about half-way between the type and Thunbergianum, as Lindley figures it. The finer flower has broader perianth-segments, not so distinct a claw, and more distinct papillæ

than in the other. The colour of both is pretty much that of European Croceum. There are numerous garden names for the forms of this species, but different people apply them quite differently, and they are nowhere drawn or described in any botanical work. *J. G. B.*

NORTH BORDER : *G. S.* A north border, where scarcely any sun is seen for nine months of the year, would suit hardy Ferns better than any other class of plants we can recommend ; and those are so numerous that if adopted G. S. had better select them at some of the nurseries where Ferns are made a specialty. If patches of peat soil were introduced, such plants as the hardy Cypripediums, the Trilliums, the Goodyeras, some of the choice Primulas, &c., ought to succeed.

PEACH TREES NOT FRUITING : *J. A.* Your failure may be attributable to various causes. Perhaps owing to the excessive vigour of the trees, which makes them cast their fruit, as we have experienced often ; perhaps dryness at the root about the time the fruit stones ; the trees attain age, if you treat them properly, you will get plenty of fruit most likely.

PELARGONIUM STALKS : *F. L.* The white spots on the Pelargonium stalks are very curious. We have never seen them before. The tissue beneath the spots looks unhealthy, having a brownish tinge. We will inquire further in the matter. *M. T. B.*

RHODODENDRON : *A. F.* The tuberiform bodies on the Rhododendron ferrugineum are caused by an undescribed species of Ascomyces, one species of which causes blister in Peach leaves. We have seen nothing like it before. *M. C. C.*

SMUT : *Earl of Essex.* It is the common smut, Ustilago segetum. The spores are blown off by the wind and do not vegetate till the new crop is sown, so that there is no remedy in the case of hunt. *M. T. B.*

VINE ROOTS : *J. B.* After a very careful examination of your Vine roots, we can find no trace of the new insect pest, nor do we see any place where the eggs could have been nestled. The larger roots have been dead for some time, and merely exhibit the usual condition of dead Vine roots. *M. T. B.*

CATALOGUES RECEIVED.—Louis Van Houtte, Catalogue of Bulbs, New Perennials, Stove and Greenhouse Plants, and Hardy Shrubs.

Markets.

COVENT GARDEN.—July 6.

We have still to report a very uncertain supply, in consequence of the unsettled weather, which has much injured the berries and hush fruit. Hothouse fruit is amply supplied, and we notice an unusually large supply of English Pines among the dealers. Those from the West Indies are also now in their prime, the quantity varying at sale from 20,000 to 25,000 weekly. In the Potato market we have no alteration to report.

PRIZE LISTS, CERTIFICATES of ENTRY, and every information may be obtained from the Secretary.

The ENTRIES CLOSE on SATURDAY, October 28.
JOHN B. LYTHALL, Secretary.
Offices, 39, New Street, Birmingham.

The Agricultural Gazette.

SATURDAY, JULY 15, 1871.

WOLVERHAMPTON, which divides with curious exactness the iron and manufacturing industry in its neighbourhood from the agricultural—the "black country" stretching directly southwards from it, and a green and fertile country coming up to its very suburbs on the north—has during the past week been the common centre of attraction for both the commercial and agricultural classes. Farmers from every county have been drawn together by the annual exhibition of the Royal Agricultural Society in its showyard, and crowds of spectators from its grimy southern neighbourhood have enjoyed the sight of whatever is foremost in the live stock and the implements of agriculture, not only as furnishing them with their home supplies of food, but as taking from them no small portion of the products of their industry. This Wolverhampton show has been thus a wholesome mutual introduction of two sets of workers, who are now more nearly related than they may have thought; and each is the stronger and the better for being brought to feel its dependence on and interest in the other.

The showyard in which they have met has been more than usually good. Classes of Shorthorns, several of them unrivalled in the past history of English exhibitions, 161 entries in all, contributed by 42 breeders in 31 English and many Scottish and Irish counties — excellent classes of Herefords, and a good show of Devons, 87 and 47 entries respectively, shown, the one by 28 breeders, and the other by 12 breeders, in 11 and 6 English counties, and a few Scotch and Irish counties respectively—and a capital show of Channel Island stock, besides other less definite classes, make up a very good exhibition of our cattle. Noble classes of Leicester and Southdown sheep—fair classes of Cotswolds and Lincolns and Oxford and West County Downs—a very remarkable exhibition of the Shropshire breed—besides small classes of Ryeland, Dorset, Cheviot, and mountain sheep, make up a very perfect representation of the sheep stock of the country. The pig classes include most perfect illustrations of the white breeds, a fair display of the black breeds, and a good show of Berkshires. The horses, which have proved the greatest attraction in the yard—the ring in which they are paraded having been continually surrounded by a dense throng—are a stronger and better collection of their several classes than has been witnessed at any previous show of the Society.

If this be a fair account of the live stock yard,

what shall be said of the implement department? It is more useful and substantial, less disfigured by petty and bazaar-like stands, than we have seen—characterised by an appearance of business-like utility, with, however, but little novelty to attract the attention of those whom we hear described as "the miscellaneous judges," who award the silver medals at the disposal of the Society. It is impossible to walk round the 40 or 50 sheds here gathered full of implements and tools of every kind, adapted for every scale of farming—from steam-ploughs that will cultivate a "land" in a single bout, to spades and forks and drills for hand use—without being impressed by the immense magnitude of the growth which the agricultural machine manufacture of this country has experienced during the career of the Society. This, then, has been the spectacle offered at Wolverhampton, and enjoyed, so far as weather would permit, by the crowds who have thronged the showyard.

If we may now venture upon a criticism intended more for professional than for general readers, we would direct attention to the sources whence the show proceeds. The Shorthorns exhibited by 42 breeders in 31 English counties are a remarkable illustration of the ubiquity of the dominant breed of the country; nevertheless, considering that ubiquity and the hundreds of our pure-bred herds, they display less energy and public spirit on the part of breeders, than do the Herefords with their 28 breeders, or even the Devons with their 12 herds represented. In these last it is plain that a larger proportion of those who are interested in the fortunes of the several breeds have exerted themselves. In the sheep classes the difference thus exhibited amounts indeed to contrast. The whole of the Leicesters are shown by only five breeders—the whole of the Cotswolds by six, the whole of the Southdowns by nine. And the numbers of sheep in these three classes are 67, 56, and 80 respectively. Look now at the Shropshires. There are 39 flocks here represented, and with fewer than 538 sheep shown, the whole of the other sheep classes together numbering only 401. Surely there is a lesson here of energy and public spirit—resolution to carry public opinion — determination to show what the live stock of a single English county can accomplish—that may be taken to heart by those who undertake to illustrate the merits of our other breeds, whether of sheep or cattle. Let us in particular call the attention of the Gloucestershire cultivators of the Cotswold breed of sheep. They have the very grandest of the Flock in their hands, but it is never adequately represented, and most of the exhibitors this year are from other counties, much the larger proportion of the prizes going to Norfolk!

In the implement yard the great feature is the success of Messrs. FOWLER & Co. in the steam cultivation competition. They carry off both the 1st and 2d prizes (£100 and £50) for "the best combination of machinery for the cultivation of the soil by steam-power;" the 1st prize (£50) for "the best combination of machinery for the cultivation of the soil by steam-power, the weight of the steam-engine not to exceed 10 tons;" the 1st prize (£50) for the best combination of machinery for the cultivation of the soil by an ordinary agricultural engine, whether self-propelling or portable; and Lord VERNON'S cup (£100) for "the best combination of machinery for the cultivation of the soil by steam-power, the cost of which shall not exceed £700." They also win the special prizes for plough, subsoiler, digger, cultivator, scarifier, and root-extractor. On the other hand, the FISKEN system of steam cultivation receives a second prize in its class; and Messrs. HOWARD, who may be named as the great rival steam-cultivating house, receive the second prize in the class for cultivation by ordinary agricultural engines, and the prizes for the best harrow, and the best drill, and the best combined subsoiler and ridger.

We confess that we are glad to find the judges in the first of the above decisions doing what in them lies to check that growth towards the gigantesque, which in steam cultivation has threatened to become monstrous. It is FOWLER'S 12-horse power double engine set that is placed first—the 20-horse power engines are placed second. It may be quite true that he who can pack the greatest number of horse-power on four wheels will beat his weaker neighbour at the pinch, yet it is well not to ignore the ordinary and average circumstances of English farms and English farming; and the judges have done right to let the manufacturer know that these are what, in the opinion of the Society, should guide him in catering for his customers.

The novelties of the showyard are not numerous. There is a thatch-making machine, and a simple pulley slide in the thatcher's ladder for supplying him with material; a simple and very workman-like potato-riddle, for use in the field at digging time; a potato-planter, which ribs the land, sows rather than "sets" the tubers, and covers them up; a clever feeding-house arrangement, by which Turnips are sliced or cake broken and fed into the manger as the machine carrying both is pushed along the feeding gangway. We must refer our readers to the report in other pages for these and other particulars. This general reference to the yard must not, however, conclude without mention of the very admirable stands of plants and seeds contributed by Messrs. SUTTON, Messrs. CARTER, Messrs. GIBBS, Messrs. WHEELER, and others, to which further reference is made elsewhere.

WE have again to report the triumph of THE FOUR-COURSE CROP ROTATION—this year pure and simple. The prize farm in the Royal Agricultural Society's Wolverhampton district has been cultivated by its present tenant for more than 20 years upon this principle; and no variation from it, for the safety of the Clover crop, has been permitted. There has been no such device as an eighth in Peas or Beans in order to create a double interval of time between successive Clovers—hardly anything in the way of a catch crop, such as the early management of last year's prize farm sanctioned, in order to vary the rapidly recurring monotony of cultivation under the four-field course of cropping. Wheat, Turnips, Barley, and Clover, have been the almost invariable succession; and the land at Sherlowe, the farm which has been this year decorated, looks as if it liked it. The Wheat, indeed, is only fair; but the winter had destroyed so much that a great deal had to be re-sown, and it is very creditable to the management that it looks so well. The Mangel Wurzels, Swedes, and common Turnips are all first-rate. The Barley is magnificent. The second growth of Clover, with Rye-grass among it, is giving a good bite to lambs and yearlings—though the crop of hay from it has not been very good, and a good deal of the second year's growth had been kept on, owing to a difficult seed-time and consequent loss of plant last year. "You will see nothing very remarkable in the cropping," we were told, "but the live stock is undeniably first-rate." The country generally thereabouts is well cropped, and that may account for the judgment given us of this year's produce—for, as regards the half occupied by the Barley and the green crops, the land was covered as one rarely sees it on the best of soils at this season of the year; and the quality of the land at Sherlowe is not by any means of the best, although the soil is such as presents no difficulty to the cultivator.

We were not fortunate enough to find Mr. FORRESTER at home (Sherlowe, High Ercall, near Wellington), during the short visit paid to his farm immediately after the announcement of its success in the prize farm competition; but a very intelligent bailiff, who had been on the land as long as his master, accompanied us through the fields.

The decision of the judges this year, unlike that of last year, has no doubt been materially influenced by the quality and management of the live stock of the farm. A better herd of Herefords, a better flock of Shropshires, one rarely sees. So far as derived from them—the annual meat produce of the land (rather more than 400 acres, of which less than 300 are arable) may be put at 25 to 30 2½ to 3-year-old Herefords, sold at from £30 upwards each, derived from about as many cows, which, with their produce up to this age, make up the Sherlowe herd; and some 200 fat shearlings, fed up to 15 months, and then fetching 50s. and upwards as mutton—the produce of 150 to 160 capital Shropshire ewes, which with their lambs make up the Sherlowe flock—as compact, tidy, and symmetrical a lot of sheep as if they were pure-bred Southdowns. We do not see that these are equal to the consumption of 70 acres of such a green crop as is this year awaiting them—but of any further purchase of stock for winter keeping we have no information. Besides these there is a varying quantity of pork and bacon fed, not bred, upon the farm.

The grain produce may be put at 4 to 4½ qr., or sometimes more, of Wheat, over some 70 or 75 acres, and from 44 to 50 bushels—this year certainly much more—of Barley over a similar extent. This, it must be remembered, is the produce of only second-rate, and for the most part light and easily worked, red land. It is a produce due not merely to natural fertility and good tillage, but to the large purchases of oilcake and manures which are annually made.

Four pairs of horses, with an odd one, accomplish all the work at Sherlowe Farm—easily accomplish it, for everything is already done, and the horses are all at grass. The Mangels and earlier Swedes already nearly cover the land; the later Swedes are being singled; Kohl Rabi is a capital plant, all singled; the common Turnips are ready for the hoe. Seventy-two acres are all thus covered with a most promising plant. All the farm is as clean as possible; we saw no Couch nor any other weed that we remember, unless the Plantain among a somewhat imperfect Clover plant be considered one. Some 20 tons of BOGTOR & GRIFFIN'S, and 1 ton of GRIFFIN'S Turnip manures, and 2 tons of nitrate of soda are applied every year; and a large quantity of farm-yard dung from cake-fed beasts is made in stalls and yards.

The landlord has done his part as effectually as the tenant. The farmhouse is a mansion, and the buildings are as well equipped and complete a homestead as any one would wish to see. The roads are good, the land is drained, the fences are well kept, the lines of Thorn as clean, and tilled each year as carefully, as any other crop upon the farm. Credit is due, we understand, to Mr. FORRESTER for much of the present arrangement of the land. It was formerly subdivided with great irregularity—and the larger fields and straighter fences are his handiwork. A large field of rough and marshy pasture-land has been lately drained, and is being gradually got into better cultivation, partly by paring and burning, partly by ordinary arable tillage, partly by laying it down again. A large extent of a most promising crop of Oats standing on this temporarily broken up land is one of the features of this year's cropping.

Sherlowe may be taken, on the whole, as a sample of clean and business-like, comparatively small farm management, where no great difficulties exist, but where by liberal treatment the soil has been made to yield much beyond the produce of its natural fertility. We are glad to see, from the extra prizes which they have been able to award, that the judges have had their eye upon the profitable character of the management as the main test of its merit. Mrs. SANKEY, who receives one of these extra prizes, farms not far from Sherlowe. We can congratulate her upon magnificent crops of Wheat and Beans, a flock of useful large-framed Shropshire sheep, and well-kept fences, all of which we have upon every side. We cannot congratulate Mr. FORRESTER upon a success achieved apparently by long continuance in well doing according to the ordinary rules of management proper for light soil cultivation, upon a moderately sized farm of mixed arable and pasture-land.

A hamlet, with the parish church, lies at some little distance, on the northern or north-western side of the farm; large and open fields, with occasional woodland, slope southwards from it; and Sherlowe itself, so liberally and handsomely equipped, looks out upon a smiling English landscape, the morning shadow of the Wrekin stretching over it, and the distant Welsh Hills bounding it upon the west. It is the very ideal of a gentleman farmer's home.

—— TRADE has been dull during the past week in Mark Lane, in spite of small supplies, with a fall of 1s. in English Wheat.—In the Metropolitan Cattle Markets on Monday trade was active at late rates. On Thursday the tendency continued upward.

—— The show just terminated at Wolverhampton has, we hope, turned out a financial success in spite of untoward weather during the greater part of the time. On Monday, a fine day, 2654 persons paid 5s. each for admittance; on Tuesday, a damp and doubtful morning, after a heavy rainfall during the night, 7064 persons paid 2s. 6d. each. The yard was in a very wet and miserable plight, but the authorities did what was possible to make dry footpaths here and there where it was wetted, by means of planks and straw. On Wednesday, 11,514 paid half-a-crown—weather still cold and dull and showery, land still soft and marshy. On Thursday, up to 2 P.M., 42,994 had paid a shilling each to see the show—weather fine, and footing firmer! These are better than the Oxford figures. The visitors on that occasion through-

out the week were about 78,000 in number. Here we have a total of 64,000 already at 2 P.M. on Thursday, and a fair probability, therefore, that the total of the week may reach 100,000.

NOTEWORTHY AGRICULTURISTS.

Mr. John Bennett Lawes.

A Memoir of Mr. Lawes is a history of successful agricultural investigation during the past quarter of a century—such as no other time or country offers. We can, however, give but a scanty outline of his life and labours here.

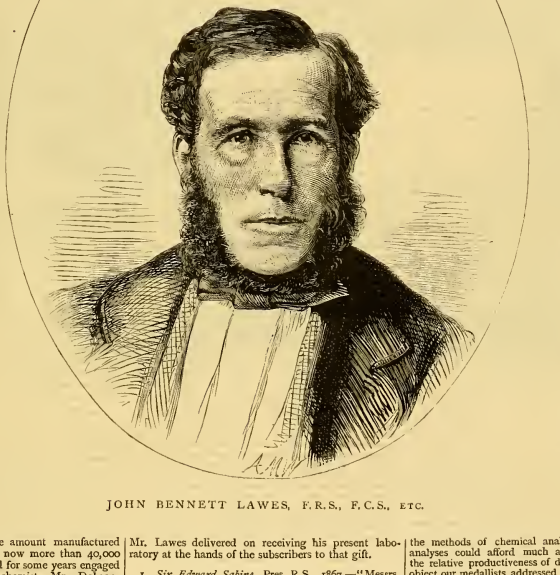
Mr. J. B. Lawes was born in 1814, and on the death of his father, in 1822, succeeded to the estate of Rothamsted, in Hertfordshire. He was educated at Eton, and at Brasenose College, Oxford, where he remained from 1832 to 1835; and he afterwards spent some time in London for the purpose of the further study of chemistry. He took possession of his property at Rothamsted in October, 1834, and at once instituted experiments in agricultural chemistry. He studied with great interest the researches of De Saussure on vegetation, and sought to apply his scientific knowledge to the solution of questions affecting practical agriculture. Among other subjects, his friend and neighbour, the then Lord Dacre, particularly directed his attention to the fact that bones, which proved so valuable as manure on some lands, were quite or almost useless on others. Several hundred experiments were made, some upon various crops in the field, and others with plants grown in pots, in which the constituents found in the ashes of plants, as well as others, were supplied in various states of combination.

Of all the experiments so made, those in which the neutral phosphate of lime in bones, hone-ash, and apatite, was rendered soluble by means of sulphuric acid, and the mixture applied for root crops, gave the most striking results. The results obtained on a small scale in 1837-8-9, were such as to lead to more extensive trials in the field in 1840 and 1841, and to the taking out of a patent early in 1842.

In 1843 Mr. Lawes established large works in the neighbourhood of London for the manufacture of the manure now generally known under the name of superphosphate of lime; and it is understood that after a period of nearly 30 years, the amount manufactured at Mr. Lawes' works alone is now more than 40,000 tons annually. Mr. Lawes had for some years engaged the assistance of a young chemist, Mr. Dobson, who, on leaving Rothamsted in 1843, was succeeded by Dr. Gilbert, in conjunction with whom a systematic series of agricultural investigations in the field, the feeding shed, and the laboratory, was undertaken.

An old barn was fitted up as a laboratory, but this in time proved insufficient for the requirements of the investigations that were carried on. About the year 1854 a considerable sum of money was subscribed as a testimonial to Mr. Lawes for the services he had rendered to British Agriculture; and it was proposed to him by the committee to expend the amount in plate, when he at once expressed a wish that, instead of this, it might be devoted to providing a new laboratory, which would enable him the better to prosecute and extend inquiries, the publication of the results of which would be the best return he could make for the honour that had been conferred upon him. The results of the Rothamsted investigations, from 1843 upto the present time, 1871, will be found in the Journal of the Royal Agricultural Society of England, the Reports of the British Association for the Advancement of Science, the Journal of the Chemical Society of London, the Proceedings and Transactions of the Royal Society of London, the Journal of the Society of Arts, the Journal of the Horticultural Society of London, the *Edinburgh Veterinary Review*, the Reports of the Royal Dublin Society, the *Philosophical Magazine*, the *Agricultural Gazette*, the *Chemical News*, some official reports, and elsewhere. Mr. Lawes was elected a Fellow of the Royal Society in 1854, and in 1867 the Royal Medal was awarded to him, conjointly with Dr. Gilbert, by the Council of the Society. Mr. Lawes has also received a gold medal from the Imperial Agricultural Society of Russia, and a medal from the Society of Arts.

We append to this short notice two passages, one the address of the President of the Royal Society on the presentation of a Royal Medal to Mr. Lawes and Dr. Gilbert; the other a portion of the speech which



JOHN BENNETT LAWES, F.R.S., F.C.S., etc.

Mr. Lawes delivered on receiving his present laboratory at the hands of the subscribers to that gift.

1. *Sir Edward Sabine*, Pres. R.S., 1867.—"Messrs. Lawes and Gilbert have been engaged for the last twenty-four years in a systematic series of researches upon agricultural chemistry, with a view of determining, by exact experiments, the principles, chemical and physiological, which are involved in the general and fundamental processes of successful agriculture.

"These investigations have embraced:—

"1. Researches into the exhaustion of soils, including experiments on Wheat, on Barley, on Turnips, on Clover, and leguminous crops.

"2. Researches on the principles of rotation and fallow.

"3. On the mixed herbage of grassland.

"4. On the process of vegetation generally, including researches upon the action of manures.

"5. On the origin of nitrogen in plants (Phil. Trans. 1861).

"6. Researches on the feeding and fattening of animals (Phil. Trans. 1859).

"It is difficult to give in a short compass the practical conclusions arrived at from a series of investigations upon a number of subjects each so complicated in its nature, so important in its object, and continued systematically over so protracted a period. At the time your medallists commenced their experiments it was generally supposed that certain saline bodies, or so-called mineral constituents, were essential to the growth and development of the plant, and that such substances must be furnished to it by the soil. The necessity of a certain quantity of nitrogen was also recognised; but it was imagined, since wild plants could thrive without any artificial supply of nitrogen, that a sufficient amount of this element existed in the atmosphere (in the form chiefly of salts of ammonia) to render it unnecessary to take any steps for increasing this supply; and it was supposed that the fertility of a soil might be maintained for an indefinite period if the different mineral constituents carried off by the crop were annually returned in due quantity as mineral manure to the soil.

"This mineral-ash theory, as it was termed, was proposed by Liebig; but it likewise was adopted by Messrs. Lawes and Gilbert to be erroneous, as it embraces a part only of the truth.

"The field experiments upon which this conclusion rests were commenced in 1843. Fourteen acres, divided into about twenty plots, were devoted to experiments upon Wheat, and seven acres, divided into about 24 plots, to experiments upon Turnips. Subsequently similar experiments were made upon Beans, Clover, Barley, and the mixed herbage of permanent meadow land. The general plan of the field experiments consisted in selecting fields in a condition of agricultural exhaustion, that is, in a state in which a fresh supply of manure was needed to fit the soil for the growth of another crop. Upon this exhausted soil each of the most important crops in the rotation were grown, year after year, upon the same spot, both without manure and with many different descriptions of manure, each of which was, as a rule, applied year after year to the same plot. By this means it was possible to determine the point of relative exhaustion or excessive supply of any of the constituents of the manure.

"Wheat, for example, was grown year after year upon the same land for 24 years; Turnips (with an interval of three years) for 25 years; and in the experiments on rotation (which comprised the 'four-course' of Turnips, Barley, leguminous crop [or fallow], and Wheat) the last of the fifth 'four-course' rotation was completed, comprising 20 years in all.

"Parallel with the field experiments, records relating to the fall of rain, atmospheric pressure, temperature of the air, and of the dew-point, were kept or collated, so as to enable the observers to ascertain the effects of the varying season upon the quantity and quality of the field produce.

"It soon became evident that much remained to be done in perfecting the methods of chemical analysis before comparative analyses could afford much assistance in determining the relative productiveness of different soils; and to this object our medallists addressed themselves both with skill and success.

"The practical value of these experiments may be seen from the fact that, taking the results of twenty years, the annual average produce in bushels of Wheat per acre without manure was 16½, with farmyard manure nearly double, and with artificial manures 35¾ bush., the latter being considerably more than the average produce of Great Britain when Wheat is grown in the ordinary course.

"The produce of Wheat grown successively on the same plot without manure scarcely altered from year to year, whilst that of the Turnips became reduced to nothing; the effect of a manure of superphosphate being most marked upon the Turnips, whilst the employment of salts of ammonia mixed with alkaline salts and phosphates was most suitable for Wheat, although these are not the manures indicated by a simple analysis of the ashes of the two crops. The authors remark, 'Indeed the whole tendency of agricultural investigation seems to show the fallacy of alone relying upon the knowledge of the composition of a crop, as directing to the constituents probably more especially required to be provided for it by manures; and rather that the elucidation of agricultural

principles must be looked for from a due consideration of vegetable physiology as well as chemistry, of the special functional peculiarities and resources of different plants, as well as their actual percentage composition.

"The investigation into the feeding of animals was even more laborious; but it was a necessary complement to the experiments upon the growth of crops. It was directed to the solution of the following among other important problems :—

"1. The amount of food consumed, and its several constituents, in relation to the production of a given live weight, for different animals.

"2. The comparative development of the different organs in the fattening of animals, and their composition.

"3. The relation of the manure produced, both in quantity and quality, to the food consumed.

"4. The expenditure of heat, by respiration and exhalation of the animal, considered as a meat-producing and manure-making machine.

"It is impossible to go into detail into this portion of the inquiry, the principal results of which are given in a paper published in the Philosophical Transactions for the year 1859.

"It may be sufficient to sum up these remarks by stating that the various inquiries, to which a brief reference has been made, have been conducted with a skill, perseverance, and success which have placed their authors, by general consent, at the head of those who have pursued this important branch of experimental inquiry."

2. Extract from speech delivered July, 1855 (Earl of Chichester in the chair). Mr. Lawes said :—

"Gentlemen, I will now explain to you to what purpose we intend to devote your building, and to show you in what manner science is most likely to be beneficial to agriculture. The great chemists of old had an opinion that science could do but little in aid of agriculture. Sir H. Davy, one of the most eminent of that class, wrote a book on agricultural chemistry, but I am not aware that any improvement resulted from it. If you consult works on agriculture previous to 1840, you will find no mention of the terms commonly used now. The French and Germans took the first to apply the science, and they made progress in the chemistry of agriculture. Little attention was paid to the subject till Baron Liebeg's works were published in 1840, and this aroused the agriculturists of this country. Allow me to say that some writers on chemistry have exaggerated its importance, which has been the means of retarding rather than advancing the matter. On looking at the great advantage which chemistry has conferred on manufactures, some have gone so far as to say that the same result would arise to agriculture; but we must not be dazzled by such predictions. There is an essential difference between manufactures and agriculture, which it is necessary for us to bear in mind. The success of our manufactures arises from a combination of skill and capital with an abundance of such things as iron and coal. I am not prepared to deny that our agriculturists possess equal skill and equal capital; but where is the abundance of their raw material? Where are guano beds in Great Britain? We have large deposits of phosphate of lime; but we are deficient in that very important article—ammonia. If science would give us such abundance of necessary manures at very low prices, it would create as great a revolution in agriculture as it has done in manufactures. But even then there would still remain a great distinction in favour of manufactures, for the manufacturer a great and continued demand for his goods, and there is no limit to his productive powers. He can erect fresh buildings : he can construct new steam-engines ; he can obtain the assistance of more factory girls. But even if we had an abundance of excellent manures at a cheap rate, our productive powers would still be limited by climate. The sun is our steam-engine, the showers are our factory children. These are not at our command—they will not do our bidding ; and therefore, with all the advantages that science can give us, we must not expect the productive powers of agriculture to increase in the same ratio, and with the same certainty as the productive powers of manufactures. Agriculture, as practised in Great Britain in the present day, is a very different process, requiring more skill and capital, than agriculture as practised in other nations. In those countries where land is cheap and abundant, and where a man has merely to cast his seed into the earth, without any previous preparation, and pay no more attention to it till the harvest time, when it goes and reaps a certain quantity as the produce of Indian Corn per acre, it would be a mockery to offer the assistance of science to agriculture. But in a country like this, where land is scarce and fetches high rents, where the land requires a great deal of preparation, and where labour is dear, the application of science is absolutely necessary. The process of corn crops drawing the land, and the properties of various manures, are involved in the science of agricultural chemistry ; and the knowledge of these subjects which is to be obtained from that science should enable us to conduct our operations with certainty and success. I have often received visits from practical agriculturists, some of whom have come from a great distance, and very glad I have been to see them. One question, however, they invariably put, but which I would they should not put. It generally comes out where the finest crop is found ; the question is, 'Does it pay?' Of course, I cannot very well say 'yes,' but if I give a negative, then my friend, whoever he may be, is apt to think, 'Ah, it's all very well for you who have got a little money to spare for such pursuits ; but it is nothing to me.' But I must explain to you, gentlemen, that the object of these investigations is not exactly to put money into your pocket, but to give you the knowledge by which you may be able to put money into yours. Science is not to do away with a rotation of crops ; but to enable you to judge of the properties of all your several crops in rotation ; and whether it would be better under certain circumstances to grow a second, third, or even fourth crop on the same land, or to follow your usual course. Science will not enable you to grow two grain crops in one year, but it may give you such information respecting the principle of manures as will enable you to turn over your capital in a much smaller space of time than you do at present. A great deal of your capital is placed in the land, where it lies dormant for a long time ; but science may correct that evil by enabling you to put the right manure in the right place. It is sometimes said the farmyard manure possesses an advantage over artificial manures, in its great lasting qualities ; but this is a fallacy. The lasting qualities of farmyard manure are not an advantage ; for it is getting back your money by instalments, instead of getting it all at once. What is your farmyard manure, but so many tons of oilcake and barrips ? If a man owed you £1000 would you prefer having it all at once, or in ten instalments of £100 a year? The artificial manure pays ready money ; but the farmyard manure pays by instalments. The application of science to feeding is only another phrase of the same principle. We give you that knowledge which will enable you to pursue that course which would be most profitable to you. Gentlemen, it is not the object of science to interfere with your management of your estates, but will impart to the landlord a good knowledge of the qualities of his own land, and it will enable the tenant to turn to the best account the floating capital which he has embarked in the soil. Gentlemen, when investigations such as these have occupied our attention many years, we are led to regard them in some way as our children, and are unwilling to desert them or leave them destitute at the time of our death. This infant of ours, for which you have built this magnificent abode, combines with the helplessness of the babe the appetite of a giant ! The consumption is only limited by the supply. When, some few years ago, I delivered it into the care of my present nurse, Dr. Gilbert, it was struggling for an existence. Under his tender management it has arrived at its present thriving condition. The interest in its welfare is not confined to this immediate neighbourhood, for I receive every week letters from foreign countries, for it was only the other day, in a work published in Germany, that my child was pronounced to be dead, and it was stated that Dr. Gilbert had been called in to attend it. Gentlemen, when you have had opportunities of seeing that this rumour is without foundation, and that the infant is in a thriving condition. I hope the only corpse we shall have to bury is that old building which is the cause of the publicity of investigations confined to this new building ; and I hope feelings of gratitude to you for your kindness this day, will cause such an electric current to run through its veins as to stimulate it to more active growth and improvement. Gentlemen, you had, although a very important element in the conduct of these investigations, is not the only one. There must be a taste for scientific pursuits, which alone can give them vitality. If our tastes and habits were hereditary, and descended to our children in the same way that our property does, I should have no anxiety on this subject with regard to the future. But I cannot conceal from myself the fact that the pursuits of the father are very rarely the pursuits of the son ; and glad should I be if my son should prove an exception to this rule. So great is the amount of accumulated matter which I have not hitherto published, that I consider it would take at least five years to place it all before the public. I have, therefore, although the subject is surrounded by many difficulties, provided that in the event of my death these investigations shall be still carried on, and I intend to-day of what we have already done placed before the public, for a term of at least 5 or 7 years. A variety of circumstances prevented me doing more than this ; but I cannot conceive that the agriculturists of this country, who have shown so great a sympathy with the experiments I have carried on, will ever allow the building to fall into disuse. Gentlemen, I should be most ungrateful were I to omit this opportunity of publicly and gratefully acknowledging the gentlemen whose lives are devoted to the conduct and management of my experiments. To Dr. Gilbert more especially I consider a debt of gratitude is due from myself and from every agriculturist in Great Britain, for the every gentlemen of his attainments who would subject himself to the caprice of an individual, or risk his reputation by following the pursuits of a science which has hardly a single attraction. For 21 years his assistance has existed, and I hope 12 years more will find it continuing. Gentlemen, to you who have left your several important occupations to assemble here to-day, as well as to those who have subscribed to the experiments, and were unable to be present, I return my most sincere thanks. The scientific investigations which I have carried on will henceforth assume an importance in my eyes not hitherto belonging to them. Whether they are eventually to become the guiding star to agriculturists or to sink into insignificance before others more grand and comprehensive, my gratitude to you will be the same ; and a remembrance of your kindness to me to-day will be engraven in my heart until my eyes shall become dim, and my memory shall cease to serve." *Herts Guardian, July 28*, 1855.

[We hope in a few weeks to place in our columns a portrait of Dr. Gilbert.]

OUR LIVE STOCK.

CATTLE.

The Wateringbury sale on the 5th inst. was undoubtedly a great success. There was not a large company, but those who were present meant buying, and the prices were very high, especially when the age of the stock is taken into account. After the first two lots (see below) had been disposed of at fair prices, *Specimen 2d* by 15TH GRAND DUKE, and of the "Charmer" tribe, a thick, deep heifer, appeared, and was knocked down at 120 gs. to Mr. W. Angerstein. *Baroness* (lot 6) by 15TH GRAND DUKE, and of the *Cathleen* by Caliph tribe, was bought by Mr. W. Lancaster at 150 gs. *Charming Duchess*, by the same bull, and of the "Charmer" family, was purchased by Mr. J. W. Larking for 70 gs. ; but we have not space to mention prices below the 100 gs. in this remarkable sale, and must rest content by referring our readers to the complete list given below. *Duchess of Brailes* by DUKE OF BRAILES (23,724), and of the *Aline* by SNOWBALL sort, made 105 gs., and went into Mr. Angerstein's hands ; and Mr. J. W. Larking gave the same sum for *Specimen 2d* by 15TH GRAND DUKE. A "Sweetheart" heifer, *Twin Duchess 5th*, by 15TH GRAND DUKE, brought 185 gs. from Mr. Angerstein ; and finally *Oxford Fawsley 3d* by GRAND DUKE OF KENT (26,289), a very fat and not by any means faultless heifer, not more than six months old, brought the astounding sum of 310 gs. from Mr. W. Lancaster. *Lady Bates* by 15TH GRAND DUKE, was purchased by Colonel Kingscote at 160 gs. ; *Baroness Fawsley*, by the same bull, was bought by Mr. Sartoris for 125 gs. ; *Charming Lady*, by the same bull, for 215 gs., by Mr. H. Brassey ; and *Charming Duchess 2d*, by the same bull, for 190 gs., by Mr. H. J. Sheldon. Such were some of the highest prices given at this remarkable sale, the total proceeds of which amounted to £3264 9*s*. The average over the 44 animals sold was £74 3*s*. 10*d*. ; the average over 32 females being £90 10*s*., and over 12 bulls £30 14*s*. 3*d*.

GENERAL	May, 1871	25	Mr. F. Wythes.

— The Smeeth sale of 38 Shorthorns, comprising Mr. F. Marton's entire herd, was conducted by Mr. Strafford, the day after the Wateringbury sale. The result was a general average of £25 15*s*. 7*d*. Twenty-nine cows made £26 6*s*. 6*d*., and nine bulls averaged £18 10*s*. each. No high prices were given, none of the animals fetching as much as 50 gs.

— We have received a catalogue of some well bred Shorthorns, which will be sold by Mr. Strafford, at Winterfold, on the 20th inst. These cattle are the joint property of Mr. Harward and Mr. Downing, of Turner's Hill, and comprise many specimens of well-known and much esteemed families. Lot 1 is the dam and oldest of eight representatives of the well-known "Bates Blanches," tracing back to *Blanche* by BELVEDERE. There are also five Kirklevingtons, three members of the "Surmise" tribe, six Keturahs, of Didmarton notoriety, a *Lady Waterloo*, by 3RD DUKE OF CLEVELAND, and from *Waterloo Cherry*, by CHERRY DUKE 4TH. *Joan of Arc* and *Clara Novello*, both by CUPID (14,359), head a somewhat numerous group, and there are other well-bred animals. The bulls recently used have been of the most excellent sort, namely 3RD DUKE OF CLARE (23,720), 5TH DUKE OF WHARFDALE, and 8TH DUKE OF GENEVA.

— On the 19th inst. Mr. Strafford will sell, without reserve, 56 animals from the Queen's herd at Windsor, 15 being bulls. The cows are said to be extraordinary breeders and good milkers.

SHEEP.

Last week our notice of the dispersion of the Merton flock was scarcely complete. We append a list of some of the most important prices given. The yearling ewes were put up in pens of five, and were purchased as follows :—One pen of 5, Duke of Richmond, 10 gs. each ; 1 do., Sir G. Musgrave, £5 10*s*. ; 1 do., J. White (for Australia), £5 ; 1 do., Mr. Banks, for the Pacific Steam Navigation Company, and Peru, £14 each ; 1 do., Mr. E. Wilson, £8 each ; 1 do., H. Gorringe, £8 ; 1 do., the Prince of Wales, £10 ; 1 do., Hon. E. Kenyon, £9 ; 1 do., E. Wilson,

£9 10s.; 1 do., H. Stone, £10; 1 do., Lord Sondes, £7 10s.; 1 do., £10 10s., H. Gorringe; 1 do., £8, the Prince of Wales. In the ram sale Lord Sondes bought a 3-shear, commended at Oxford, for 25 gs. 1 3-shear was sold for 65 gs. to Mr. J. J. Coleman, M.P.; 1 do., at 25 gs., Hon. E. Kenyon; 1 2-year-old, 40 gs., Mr. Wachter; 1 do., 50 gs. (1st prize yearling at Oxford), Prince of Wales; 1 do., 84 gs. (2d prize yearling at Oxford), Lord Portsmouth; 1 do., 60 gs., Sir W. Throckmorton. In the shearling class, 1 sheep was sold at 180 gs. to Mr. H. Chappel; 1 do., at 35 gs., J. White; 1 do., 41 gs., Mr. Turner; 1 do., 30 gs., Mr. E. Wilson; 1 do., 100 gs., Prince of Wales; 1 do., 45 gs., Mr. G. W. Homer; 1 do., 35 gs., Duke of Portland; 1 do., 34 gs., Duke of Portland. Such were some of the highest prices in a ram sale which averaged £27 13s. 2d. upon 19 old rams and £22 upon 65 shearlings. Two-year-old ewes fetched from 70s. to 175s. per head, the highest figure being given by Lord Portsmouth, who also secured another pen of ten at 145s. each. Three-year-old ewes made from 60s. to 125s. each, the last named price being given by Mr. J. J. Coleman, M.P., and 100s. by Lord Sondes. Mr. W. Taylor gave 120s. each for a pen of five full-mouthed ewes; Mr. G. Smith gave 160s. each for a second pen, and a third was secured at 140s. by the Prince of Wales. Even broken-mouthed ewes went at from 55s. to 75s. each. The highest prices for ram lambs were as follows:—17 gs., Mr. Delome; 20 gs., Mr. Foljambe; 20 gs., Mr. Majoribanks; £20, Mr. N. Grenville; £20, Mr. Seaward. Most of the lambs made from 4 to 6 and 8 gs. each, while others were sold as low as 45s. Ewe lambs commenced with the sale of lot 1, a pen of 5, at 77s. 6d. each, to Mr. Haar; three pens were sold at 80s. each, and others brought from 45s. to 60s. each.

PIGS.

Mr. Swanwick, of the College Farm, Cirencester, has, among other good sales, just disposed of his 2-year-old prize boar at Wolverhampton to Mr. Craig, of Edmundton, Ontario, Canada, for 65 gs.; also the 1st prize boar in the young class for £30, to Mr. Cochrane, of Canada; and the 2d prize in the same class for 30 gs., to Mr. Snell, of Edmundton, Canada.

TELEMACHUS.

Telemachus (27,603), the Shorthorn bull whose portrait is given above (fig. 193), is the property of the Marquis of Exeter, and was calved on April 13, 1868. He is by Nestor (24,648) of the Gwynne tribe, and from *Louisa 9th* by the pure Bates bull Prince Albert (18,579). His grand-dam was by Baron Farnley (14,129), and his great-grand-dam by 3d Duke of York (10,166). Telemachus is of a pleasing and gay roan colour. His head is not strongly masculine in character, and has even been accused of being cow-like, but we are informed that he has recently lost hair from his head, which it is hoped he will regain. He is of excellent symmetry, is very well made over the shoulders, is good in the girth and middle, but loses a little at the loin, which might have been better covered. He has just crowned a long series of honours, which we append, by taking the 2d place at Wolverhampton in a remarkably good class, in which the celebrated Edgar, bred by Mr. Saunders, of Nunwick, took the lead. Mr. Walton, of Burghley Park, thus writes to us:—

"I bought his dam at Peterboro', at a sale held in the market there by Mr. Carr during the cattle plague restrictions; and she was bred by Mr. Emmerson, Over Dinsdale, Darlington. We put her to our Gwynne bull Nestor, a first-rate sire, as all his stock prove. Nestor is by Mentor, who on his dam's side is of the old Burghley blood (known here nearly 60 years); Mentor was by the celebrated bull 4th Duke of Thorndale (17,750), who was bought by the late Marquis of Exeter, when three years old, for 410 gs.; and after five years' service here was sold at the sale in March, 1867, after the late Marquis' death, for 440 gs. (when eight years old),—a thing unparalleled in the history of Shorthorns.

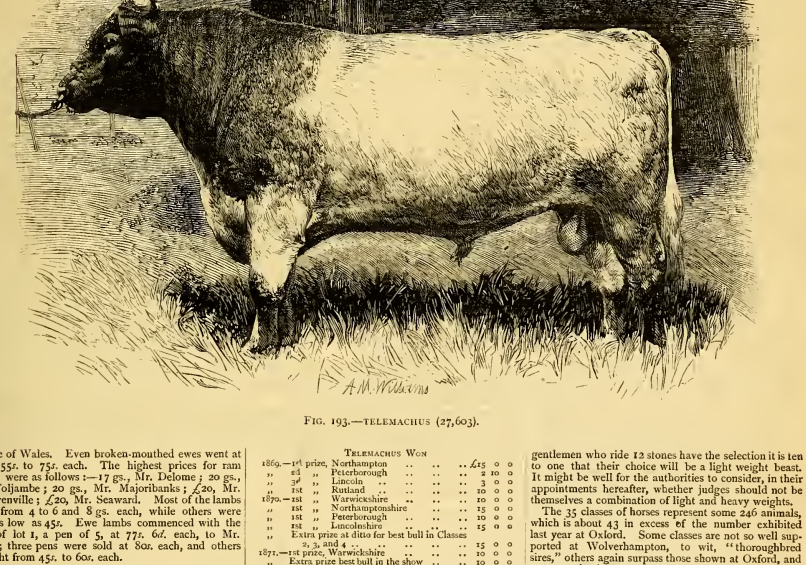

Fig. 193.—Telemachus (27,603).

THE WOLVERHAMPTON MEETING
OF THE
ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

We refer to a leading article for general remarks on a meeting which has been held with great success, despite considerable difficulties of weather; and we proceed here at once to describe the several sections which have made up the very remarkable show just closed.

HORSES.

The exhibition of horses at the Royal show at Wolverhampton forms not the least interesting feature of the meeting, and probably receives closer attention from the majority of visitors than all other classes united. Around the ring on Monday last, gazing with all their eyes, hung a crowd of all classes, young and handsome women, their elders and protectors, besides hosts of men—from the bishop of the diocese downwards—all of whom watched with the liveliest interest the various animals as they came before the judges. Whilst the latter were patiently discharging their laborious task, the public earnestly scrutinised, and formed silent opinions upon the animals. When the verdict went forth, and the distinctive badges were affixed to the victorious competitors, occasional murmurs might be heard in the crowd, as individuals assented or differed with the fiat of the judges. With but few exceptions, their selections met with approval, and these gentlemen are fairly entitled to praise for the care and excellent judgment which marked their decisions. In cases where exhibitors met with disappointment, exclamations against the choice of the judges might be heard, and accusations, too, of their *penchant* for breed or quality when an animal lacking these points was passed over.

There is no question that men's judgments are influenced by their tastes, needs, and requirements, and if gentlemen who ride 12 stones have the selection it is ten to one that their choice will be a light weight beast. It might be well for the authorities to consider, in their appointments hereafter, whether judges should not be themselves a combination of light and heavy weights.

The 35 classes of horses represent some 246 animals, which is about 43 in excess of the number exhibited last year at Oxford. Some classes are not so well supported at Wolverhampton, to wit, "thoroughbred sires," others again surpass those shown at Oxford, and we may justly pronounce the exhibition of 1871 a greater success, as far as horses are concerned, than the show on the banks of the Isis.

The class list opens with agricultural stallions, foaled before January 1, 1869 (not qualified to compete as Clydesdales or Suffolks).

Mr. N. Welcher takes 1st prize with "Honest Tom," an animal of great strength and bone, with wonderful arms, back, and loin. You wonder how a horse with his characteristics has found his way to Westtoft, Norfolk, a locality celebrated for beasts of a far different stamp. The 2d prize falls to Mr. J. Manning for a chestnut, "Young Champion,"—not badly named, for it will take a good one to beat him. There is a weighty grey named "A 1," and a thick cobby iron-grey, No. 1, named "Lion," which bear inspection, besides one or two others that go to make up a very decent class. Class 2—stallions, under the same rule, but only two years old,—and some very nice ones there are amongst them. No. 16, "Captain,"

owner Mr. Geo. Street, of Mauldon, Beds, is a cobby, fine-coloured beast; and the 2d prize horse also deserves praise, but we thought some of the animals small.

Clydesdale stallions next claim attention. Class 3 gives us five animals foaled before 1869. The next class, for 2-year-olds of this breed, has no entries. Her Majesty the Queen sends a grand horse, "Sandy," with wonderful back and loins and great arms, but he fails to attract the attention of the judges, who leave the 1st houron on Mr. Henry Tomlinson's "Young Lofty," and right well we agree with them, but not so in the award of 2d favours to Colonel Lloyd Lindsay's "Prince Albert," a sour-headed beast we had no fancy for.

In Class 5, six Suffolk stallions, foaled before 1869, enter the arena, and exceedingly fine fellows they are. But there is the same old fault—too much top-weight for the legs which carry it. The 1st prize, "Cupbearer," owned by Mr. R. Garrett, of Saxmundham, is a huge beast, with indifferent hocks, anything but good forelegs, and not so deserving merit as "Hercules," exhibited by Mr. Badham, who receives 2d honours for an animal of better proportions and plenty of bone. The 3d prize goes to Baytham Hall, Suffolk, for "Bismarck," a lofty colt, with good body and clean legs. The Ipswich Corn Colliery Company show a grand beast, light in colour, with a finely-turned neck, and good lines generally, in character not unlike a sculptured outline of ancient days.

The next class, No. 6, for Suffolk stallions, foaled since 1869, presents three capital animals, and the judges had no little difficulty in awarding the most worthy. The choice at last fell on Lieut.-Colonel Maitland's "Heir Apparent," a beast with an extraordinary back and loin, but otherwise somewhat cumbersome, and to our mind not so good or deserving as No. 30, a horse with great bone and liberty and good feet; and though named "Patriot," numerous barred hairs, not pure, nor did he appear quite the type of a Suffolk Punch,—a character thoroughly well supported by the 2d prize horse "Emperor," the property of Mr. Badham, of Sudbury. The thorough-bred stallions in Class 7 are both fewer and inferior to those shown at Oxford in 1870. We miss the contributions of Lords Craven and Norreys, and several others, and wonder why a spot so central as Wolverhampton has failed to attract a larger number of thoroughbred sires. The 1st prize goes to Mr. J. Casson, of Carlisle, for "Sincerity," an old stager of some 15 years, with many good points; and Mr. John Watson, of Kidderminster, takes 2d, with a spanking bay with black legs, "Blinkhoolie." We were glad to see our old friend "Laughing Stock," and congratulate my Lord Coventry on possessing a nice little animal like "Umpire;" we have, however, no regard for "Protection," which Mr. Stewart sent from Saint Bridge. Class 8, for stallions not exceeding 15 hands, formed a most creditable collection, and caused no little trouble to the judges, many of the animals being so evenly matched it was no easy task to define which was most worthy. Shropshire reclaims the 1st prize, Mr. J. Lockhart, of Bromfield, most properly getting it for his clever breedy little beast "Dick Turpin," a capital mover and pretty well grown. The 2d prize goes into Norfolk, to Mr. B. Mitchell's "Fireaway," also a fine mover, pins somewhat coarse in his hocks, but this colt has yet to furnish, and will come out well, or we are mistaken; which cannot be said of the 3d prize horse "Cleartheway," with his straight shoulders and bad forelegs. Mr. Beart's "Ambition," which received only commendation, we should have preferred for 3d honours, as possessing really better points. No. 44, "Young Cheesikiver," a cobby horse, moved well, but we did not like his shoulders; "Enterprise" is a particularly square beast, but is too long in his fetlocks; and his stable companion "Alonzo" lacks quality. The leaning of the judges being evidently towards breed and quality, animals devoid of these qualifications stood not the slightest chance, and bitter disappointment was both expressed and felt at some of the awards; our tendency being in favour of breed, we did not object to the decisions in this class on the whole.

Pony stallions not exceeding 14 hands, in Class 9, produced three competitors. Had there been ten times that number, Mr. Roundell's beautiful brown "Sir George," four years old, must have held the position assigned to him at Wolverhampton; anything more perfect in the shape and going of this little horse you could not see, and loud were the praises he received. His quick clever going raised him to the same position amongst the horses as Messrs. Aveling & Porter's little busy engine obtained in the lists for traction-engines. Of course the 1st prize is in Mr. Roundell's possession, the 2d being held by Mr. C. Groucock, of Wymondham, Norfolk, for a breedy chestnut, named "King Arthur," with a capital middle piece, and good head and neck.

Fifteen agricultural mares, with foals at foot or in foal, competed in Class 10, and a lot of powerful, useful animals they were. Few had foals at their sides, which is to be regretted, as the intention of the Society is clearly for the encouragement of brood mares, and for this reason we object to the honours going to aged mares without colts, unless the prize be withheld until the foal is dropped, a rule which applies to other stock. The 1st prize goes to Mr. Henry Overman for a stylish, active, black 10-year-old, named "Diamond" (in foal), and no doubt she is an attractive, good beast, but we very much prefer the 2d prize mare, "Smart," the property of Mr. Crowe, of Downham Market, Norfolk, with her grand walk and well-turned quarters, although she is nine years old (and in foal to Honest Tom). No. 62 "Beauty," the property of Mr. Lamb, of Granthom, is a fine animal, with good points, somewhat of the Cleveland bay type, but she is a gummy goer. Norfolk gets 3d honours with a mare, also named "Beauty," owner Mr. Welcher, of Tofts, near Brandon, who deserves it for such a compact, well-grown beast. 66, "Diamond," owner Mr. Salt, of Kirby Frith, Leicester, is a quick, active animal, with a good colt at foot, and ought to as a mare not unlikely to prove to be a coacher. Many mares in this class were clumsy and loose, their only redeeming point being a useful foal by their side.

Class 11, Clydesdale mares, under same conditions as last, produces four competitors; although a nice lot, they do not approach animals which we still recollect with so much satisfaction at the Manchester show in 1869. Mr. Thomas Statter's "Princess" worthily receives 1st honours, a compact mare with good limbs; and G. H. Head gets the 2d place with a coarse, bold-looking mare, whilst Col. Lloyd Lindsay is nowhere with his "Polly," notwithstanding her excellent feet.

Suffolk mares, under same rules as these Clydesdales, find five entries in Class 12, and we heard them pronounced excellent, and indorse the statement. The county which gives them the title in this instance, Norfolk, is represented. The Executor of Mr. Capon, of Wickham Market, is 1st with "Matchit," all over a good mare, and a grand mover. Col. Maitland gets 2d with a mare of great quality and length, with good bone and feet; Woodbridge receives a prize in Mr. H. Wolton's "Diamond," a lumpy, rolling beast, with great walk and limbs, but short legs. Salop sends one specimen from Oswestry, a compact mare, with first-rate legs.

We observed with much pleasure that all the specimens of the Suffolk Punch, at Wolverhampton, had much better feet than heretofore has been the case; a still further improvement will be made when both legs and body, and in such case the animal must become more popular in counties which now do not care for it. An interesting class follows next in succession, and we wish that we could speak of the animals entered in it with satisfaction. No. 13, for mares suitable for breeding hunters, in foal, or with foal at foot, has 10 competitors; the mares were not only weedy, but the few colts alongside them were the most miserable lot one ever saw. The 1st prize mare, "Lady Emily," the property of Mr. Miller, of Lancashire, however, would not have attained the honour but for her creditable colt; the 2d prize animal, "Lady Byron," from Leeds, though 18 years old, possessed a deal of character, and, despite her small bone, was rightly placed; the 3d prize animal, "Jasy," from Salop, had no pretensions to a prize, with low straight shoulders and small girth; whilst 95, a long roomy mare of the old school, with a fine colt at foot, left the ring, to our regret, without distinction of any kind.

The next class, 14, for mares above 14 hands, scarcely commends itself to notice. Mr. Henry Overman's 1st prize mare takes the prize a very successful but rather under-bred, and the 2d prize, "Judy," the property of Mr. Thomas Jones, does not attract one, with her straight action and upright shoulders; whilst 98, "Miss Dodson," the property of T. Latham, of Wittenham, Berks, is a breedy animal, of good shape and make, for which she receives commendation.

Six mares compete in class 15, and they possess rather more merit than the animals in the two classes immediately preceding them. "Kitty," the property of Mr. Coates, of Wenchcombe, with her wall eye, gets 1st, and "Bright Eyes," evidently considers herself entitled to 2d, notwithstanding a plain head and bad loin. Mr. G. Stokes gets commended for his "Polly," an active, light-carcased mare, that looks like a hunter.

Hunter geldings find seven competitors in Class 16. They are not an unuseful lot, and we agree in the selection which placed Mr. W. Armstrong's sweet-topped horse, "Banker," 1st. There is a deal of character in 120, a fine-coloured brown, standing over a lot of ground, an animal that can move; and "Roman," the 3d prize horse, though small, has many merits; not so his neighbour, "Young Dragobert;" and No. 109, "The Emperor," will be more correctly placed in the army than by the cover side.

Class 17, hunter fillies, exhibits six animals. "Luna," the property of Mr. J. Moffat, of Cumberland, receives 1st honours, and well she deserves them, with her fine hock action. Mr. E. Philimore, of Prestbury Park Farm, Cheltenham, gets the 2d prize with a pretty beast, with good shoulders, but with a tail put on too low, and bad forelegs. The 3d prize is bestowed on Mr. Booth's "Duckling," a lady all over, with plenty of substance and good legs. The remainder, we thought, had few merits.

Hunter gelding or filly, four years old, Class 18.—13 out of 16 entries compete. Great interest is evinced by those around the ring in these animals, and the judges find it no easy matter to draft the favoured ones from those left without a prize. Captain Barlow, of world-wide celebrity, is here with some of the right sort, and we were glad to see him mounted on one of the competitors, although we do not understand why the Captain preferred "Beckford" to "Tregothnan;" the latter animal most deservedly secured 1st honours, and "Beckford," not so properly, obtained the 2d; Gloucestershire gets the 3d place, and Staffordshire takes a commendation in "Blankney," a well-bred, clever gelding, with good middle. Several in this class looked to advantage as they were extended. "Magic," No. 135, and "Scale," 128, galloped well.

As the next class entered the ring, the interest of the public seemed to have attained the utmost height. On one entire side the railings were thronged three deep; in the front rank sat many ladies. Class 19—hunters, mare or gelding, up to not less than 12 stones. Eleven competitors, but few with great claims. We specially made our selection, as, indeed, we did in most of the classes, and we did not find that our view differed materially from the authorities. Mr. J. Booth, of Killerby, Catterick, Yorkshire, sustains his character by conveying off the 1st prize with "Banner Bearer," a strong hunter all over; whilst Nottinghamshire receives 2d honours with "Borderer," a good-looking chestnut, with great back and loin; and Mr. G. van Wart, of Birmingham, obtains the 3d distinction with "Loxley," a gentlemanly mover. We did not care for "Cymbeline's" shoulders, nor for the substance of the Coleshill gelding, and far less for the puddling going of "Ace of Clubs."

Class 20. Hunter, mare or gelding, up to not less than 12 stones.—Of the eight competing we cared but for four, and the judges took the same opinion. My Lord Coventry got a 1st for a hot-headed black, named "Bird-on-the-Wing," breeder unknown, whilst the 2d prize went to "Loiterer," a real specimen of the old school, not an everyday beast, and from the right source, 100—Mr. S. J. Welfitt, a name well known. A nice, quiet, workmanlike mare "Witch" (No. 160), that gallops in good form, got 3d prize.

Class 21 contained but one entry—a pair of prettylooking roans.

Roadsters, mare or gelding, Class 23, produced some 18 very meritorious animals, which taxed the efforts of the judges to no small extent. After a preliminary trial of the whole, eight were soon shelved, and then the business became anything but easy. The preference which these gentlemen possessed for quality and breed again evinced itself as they dwelt over Mr. Moffat's breeding mare "Covet," and "Cook's Tart," not omitting Mr. Cook's "Lizzie," a pretty goer, as quick as a cat; and more especially evident in their selection of Mr. Fell's black gelding, which looked more like winning a plate than hacking on the road. Encouragement of this character will never forward the idea of good roadsters, for which England was once so justly celebrated. The before-named animals of Mr. Moffat's received honours—"Covet" obtaining 1st prize, and "Land Agent" 3d, whilst the 2d prize went to Mr. Fell's gelding. 176, a black mare from Droitwich, was very attractive from her power and make, but she performed badly, although rumour said that such was not her habit. "Quicksilver," a strawberry roan, was striking, from his well turned neck and throat and short strong back, but both these animals lacked quality, hence their fate. For roadsters, mare or gelding, above 15 hands, seven competed in Class 24, and they were very commendable animals too. The 1st prize went to "The General," the property of Mr. North, Cambridgeshire; Mr. Badham, of Sudbury, took 2d; and Lancashire had 3d, in a nice grey gelding of Mr. Horrocks Miller's.

Class 24, which next occupied the attention of the judges, would, but for the rain which had commenced steadily falling, have attracted the attention of many. It presented a very good selection of cobs, mares, or geldings, but there was a deficiency of bone and substance about these animals. A remarkably stout active animal, with hogg mane, a fine goer, was passed over for 1st place because his head was somewhat large, but then he carried it well, and what matters? 198, a cream, with white mane and tail, had no right to the 1st prize, so all maintained; and Mr. G. Smith may congratulate himself on his 2d prize, for Mr. Wiley must bear the defeat of his "Bob" as he can. A breedy gelding, "Camperdown," from Southwell, Notts, received commendation, and nothing else deserved it.

Class 26, for ponies, produced nine specimens, which may be pronounced excellent. The 1st prize (212), "Jumney," a grey, seven years old, a perfect model. He held himself as though he knew it, and all his movements were equally correct. The 2d prize, "Billy," is a smart little pony, with a good back and loin. Mimma, a dark chestnut from Cardiff, failed to attract the judges, although she possessed lots of quality; and great was her owner's disappointment.

Returning to the classes for agricultural horses, we find in 27 eight 2-year-old fillies competing. With but two exceptions, these animals are small, and it was Lombard Street to a China Orange that Mr. J. Linton took 1st honours with his "Princess." Mr. Davis' roan, "Darling," is a nice-topped animal.

Clydesdale fillies in Class 28 brought four competitors; of these Her Majesty the Queen exhibited two. The 1st prize must deservedly fell to Mr. Parker, his animal having all the merits, whilst the remaining

honours went to the Throne for beasts without any sufficient merit.

The last class that we need refer to is 30, for agricultural pair of geldings or mares. Six enter, and that number compete. Without any exception, they are the best lot perhaps that ever came together so far as weight, action, and matching qualities go; but that the animals are such as an agriculturist would use is utterly improbable. With but two exceptions, they are perfect specimens of the dray-horse, and as such they should be disqualified to compete in this class. The judges were evidently of this opinion, as they conferred the ribbons on those pairs which exhibited the qualities we look for in horses for farm work. A grey mare, "Sensation," six years old, shown by Mr. Brierley, of Rhodes House, Middleton, Manchester, is as fine a specimen of a huge, active van-horse as could be seen; she moved like a pony, and when standing attracted the attention of every one.

The show of horses we have written upon must be pronounced exceedingly useful; and if it does not come up to the Manchester collection of 1869, it is, nevertheless, a great exhibition, and must have given both profit and satisfaction to the visitors of the Wolverhampton meeting. It is unfortunate that the site on which it was held lay so low: the soil being boggy; the weather wet, nothing could be worse for an exhibition of live stock and steam machinery than the racecourse of Wolverhampton.

The following is the list of judges and their awards:—

JUDGES.—The Hon. G. F. Lascelles, Sion Hill, Thirsk: N. G. Barthropp, Wisbech Market: Joseph Cope, Oulton: Bosworth Grange, Rugby: A. L. Maynard, Skimmingrove, Saltburn-by-the-Sea: J. H. Wood, Humberstone, Grimsby: D. Wright, Beal, Selby, Yorkshire.

Agricultural Stallion, foaled before January 1, 1869 (not qualified to compete as Clydesdale or Suffolk)—1st, £25; 2d, £15; 3d, £5—Richard Welcher, of Mouse Hall, West Ilsley, Berkshire, Captain Brown. Highly Commended: James Parkin, of Thorpe Arch, Wetherby, Young Prince.

Agricultural Stallion, foaled before January 1, 1869—1st, £25; 2d, £15; 3d, £5—1st, Henry Tomlinson, Bickford, Rugeley, Young Cadet—2d, Colonel R. Loyd Lindsay, M.P., of Lockinge Park, Wantage, Prince Albert. Highly Commended: Matthew Read, of Beamish Barn, Chester-le-Street, Wellington.

Suffolk Stallion, foaled before January 1, 1869—1st, £25; 2d, £15; 3d, £5—1st, Richard Garrett, of Leiston Hall, Saxmundham, Crown—2d, George David Badham, of The Lawn, Bulmer, Sudbury, Hercules; 3d, William Wilson, of Beythan Hall, Ipswich, Duke.

Suffolk Stallion, foaled in the year 1869—1st, £20; 2d, £10; 3d, £5—1st, Lieut.-Colonel Fuller Maitland Wilson, of Stowlangtoft Hall, Bury St. Edmunds, Apparent—2d, George David Badham, of the Lawn, Bulmer, Emperor. Highly Commended: James Algerman Pigot, of Peckingham Hall, Witham.

Thoroughbred Stallion, suitable for getting Hunters—1st, £30: 2d, £25; 3d, £10.—1st, Joseph Casson, Burgh-by-Sands, Carlisle, Bonny Boy—2d, William Watson, Wetherby, Kidderminster, Blinkhoolie: 3d, W. Taylor Sharp, of Banmber Park, Horncastle, Suffolk. Commended: the Earl of Coventry, of Croome Court, Severn Stoke, Worcestershire, Umpire.

Stallion, above 14 hands but not exceeding 15 hands 2 inches, suitable for getting Hackneys—1st, £20; 2d, £10; 3d, £5—1st, James Lockhart, of Culmington, Bromfield, Salop, Dick Turpin; 2d, Benjamin Mitchell, sen., of Crome Hall, Sowbrook Green, Feeaway: 3d, Henry Bulstrid, of Bedwellhay Grange, Ely, Cambridge, Clear-the-Way.

Pony Stallion, not exceeding 14 hands—1st, £15; 2d, £10; 3d, £5.—1st, Henry Roundell, of Otley, Yorkshire, Sir George: 2d, Charles Grocock, of Stanfield Hall, Wymondham, King Arthur: 3d, William Dew, of Wellfield House, Bangor, Llewelyn.

Agricultural Mare, in foal, or with foal at foot, suitable to compete in the classes for Clydesdale or Suffolk—1st, £20; 2d, £10; 3d, £5—1st, Thomas Statter, jun., of Stand Hall, Whitefield, Manchester, Lady—2d, George Hall Dudding, of Dalston, Carlisle, Deborah.

Suffolk Mare, in foal, or with foal at foot—1st, £20; 2d, £10: 3d, £5—1st, the Executors of the late Thomas Capon, of Donnington, Wickham Market, Suffolk, *Matchit*; 2d, Lieut.-Colonel Fuller Maitland Wilson, of Stowlangtoft Hall, Bury St. Edmund's, Suffolk, *Bury Empress*; 3d, Horace Wolton, of Newbourn Hall, Woodbridge, *Diamond*.

Mare in foal, or with foal at foot, suitable for breeding Hunters—1st, £25; 2d, £15; 3d, £5.—1st, Thomas Horrocks Miller, of Singleton, Poulton-le-Fylde, *Lady Emily*; 2d, Joseph Clarke, of Ivegill, Carlisle, *Lady Byron*; 3d, Joseph Heywood, of High Downs, Bridgnorth, *Fanny*.

Mare, above 14 hands, but not exceeding 15 hands 2 inch, in foal, or with foal at foot, suitable for breeding Hackneys—1st, £20; 2d, £10.—1st, Henry Overman, of Wesenham, *Jenny Lind*; 2d, Benjamin Mitchell, of Cross Lane Head, Brighnorth, *Judy*. Commended: Thomas Latham, of Littleham, Abingdon.

Pony Mare, not exceeding 14 hands—1st, £10; 2d, £5.—1st, William Coates, of Scarborough Farm, Winchcombe, *Kitty*; 2d, Richard Milward, of Thurgarton Priory, *Brighteyes*. Highly Commended: George Stokes, of Camp Farm, Kingsbury.

Hunter Gelding, three years old—1st, £20, offered by A. Bass, Esq., M.P., William Armstrong, of Kendal, Westmoreland, *Banker*—2d, £10, offered by the Staffordshire Agricultural Society, Lawson, Bart., M.P., of Brayton, Carlisle; 3d, £10, by the Wolverhampton Local Committee, Frederick Barlow, of Hasketon, Woodbridge, Suffolk; 4th, Charles Cook, of Taddington, Wincomb, Gloucestershire.

Hunter Filly, three years old—1st, £20, offered by the Wolverhampton Local Committee, James Moffatt, of Hartington Park, Carlisle, *Luna*; 2d, £15, by the Wolverhampton Local Committee, Edward Phillimore, of Prestbury Park Farm: 3d, £10, by the Wolverhampton Local Committee, John B. Booth, of Killerby Hall, Catterick. Highly Commended: Charles Boyd, of Littywood, Staffordshire.

Hunter, Gelding or Filly, four years old.—1st, £30, offered by H. Meynell-Ingram, Esq., M.P., Frederick Barlow, of Hasketon, Woodbridge, Suffolk; 2d, £20, offered by H. Meynell-Ingram, Esq., M.P., Frederick Barlow, of Hasketon, Woodbridge, Beckford; 3d, £20, offered by H. Meynell-Ingram, Esq., M.P., Charles Cook, of Taddington, Winchcomb: 4th, £5, offered by H. Meynell-Ingram, Esq., M.P., George John Mitchell, of Newton Mount, Burton-upon-Trent, Blankney.

Hunter, Mare or Gelding, up to not less than 15 stones.—1st, £30, offered by Major Thornecyroft, Captain Boughey, and Members of the Albrighton Hunt; John B. Booth, of Killerby Hall, Catterick: 2d, £20, offered by Major Thornecyroft, Captain Boughey, and Members of the Albrighton Hunt, T. Harvey, Esq., of Edenhall House, Cumberland: 3d, £10, offered by Major Thornecyroft, Captain Boughey, and Members of the Albrighton Hunt, George Van Wart, of The Shrubbery, Birmingham: 4th, £5, offered by Major Thornecyroft, Captain Boughey, and Members of the Albrighton Hunt, Richard Basnett Dowell, of Shelvock, Penkridge, Sibby.

Hunter, Mare or Gelding, up to not less than 12 stones.—1st, £25, offered by T. M. Weguelin, Esq., M.P., the Earl of Coventry, of Croome Court, Severn Stoke, Worcestershire, Lady Coventry: by H. Ward, Esq., Samuel James Wellfit, of Tathwell Hall, Louth; 3d, £10, offered by S. Loveridge, Esq., William Armstrong, of Kendal, Westmoreland, *Lady*: 4th, £5, by Hall-Clarke, Esq., George Smith, of Alston, Stratford-on-Avon.

Carriage Horses or Mares, in pairs, under six years old.—1st, £25, offered by the Earl of Dartmouth, John Thomas Robinson, of Leckby Palace, Thirsk.

Roadster, Mare or Gelding, above 14 hands 1 inch, and not exceeding 15 hands 1 inch.—1st, £20, offered by C. W. Lyon, Esq., James Moffat, of Kirklington Park, Carlisle, Cumberland: 2d, £10, offered by the Wolverhampton Local Committee, William Fell, of The Close, Lichfield: 3d, £5, offered by H. Rogers, jun., Esq., James Moffat, of Kirklington Park, Carlisle, Cumberland: 4th, £5, by Richard Milward, of Thurgarton Priory.

Roadster, Mare or Gelding, above 15 hands 1 inch—1st, £20: 2d, £10: 3d, £5, offered by M. A. Bass, Esq., M.P., Edward Barth, Sutton, Ely, Cambridgeshire: 2d, George David Badham, The Lawn, Bulmer; 3d, Thomas Horrocks Miller, Singleton, Poulton-le-Fylde, Commended: Thomas Statter, jun., Stand Hall, Whitefield, Manchester.

Cob, Mare or Gelding, above 13 hands, and not exceeding 14 hands 2 inches.—1st, £20, offered by Wm. Esq., of Ashley, by Frank James, Esq.: 3d, £5, by the Wolverhampton Local Committee.—1st, George Smith, Alston, Stratford-on-Avon, Warwickshire: 2d, William Bradley, Bosworth End, Market Bosworth, Nuneaton: 3d, John G. Boraston, Kidderminster.

Pony, not exceeding 14 hands.—1st, £15, offered by Wm. Perry, Esq.: 2d, £5, by R. J. Moore, Esq.—1st, Frederick Bower, 29, Albion Street, Birmingham: 2d, William Tyler, Friday Bridge, Wisbeach. Highly Commended: Thomas Statter, jun., Stand Hall.

Agricultural Filly, two years old, not qualified to compete for Clydesdale or Suffolk.—1st, £15, offered by Lord Berwick, Hall, Cambridge: 2d, £10, James Hawksworth, of Barton Fields, Barton Bount: 3d, £5, Stephen Davis, of Woolashill, Pershore.

Clydesdale Filly, two years old.—1st, £15, Thomas Townley Parker, of Charnock Hall, Chorley: 2d, £10, Thomas Boon, Winsor Castle. Highly Commended: Her Majesty the Queen. Commended: Thomas Statter, jun., of Stand Hall.

Suffolk Filly, two years old.—1st, £15, William Thompson, jun., of Thorpe, Colchester.

Agricultural Pair of Geldings or Mares, of any age.—1st, £50, offered by Lord Berwick, Hall, Cambridge: 2d, £30, offered by Mr. P. Herrick, Esq., Thomas Statter, jun., of Stand Hall: 3d, £20, offered by the Staffordshire Agricultural Society, Charles William Brierley, of Rhodes House, Middleton. Highly Commended: the Earl of Dartmouth.

Agricultural Pair of Geldings or Mares, four years old.—1st, £30, offered by W. T. C. Giffard, Esq., Thomas Statter, jun., of Stand Hall.

Agricultural Pair of Geldiddes or Mares, three years old.—1st, £20, offered by C. B. Wright, Esq., Thomas Statter, jun., of Stand Hall: 2d, £10, offered by the Staffordshire Agricultural Society, Charles William Brierley, of Rhodes House, Middleton.

Agricultural Gelding, three years old.—1st, £10, offered by the Earl of Bradford, Edward Tongue, of Manor House, Aldridge, Walsall, Staffordshire.

Agricultural Gelding, two years old.—1st, £10, offered by the Staffordshire Agricultural Society, James Perry, of Salter's Hall, Claverley, Bridgnorth: 2d, £5, offered by the Staffordshire Agricultural Society, Thomas W. D. Harris, of Wootton, Northamptonshire.

Agricultural Gelding, yearlings.—1st, £10, offered by the Staffordshire Agricultural Society, Thomas Statter, jun.

CATTLE.

Shorthorns.—The number of entries in this class was 161 against 159 exhibited at Oxford last year. The quality of the animals was considered by the many thousands of people surrounding the rings to be exceedingly good, and this remark especially applied to the bulls above two and not exceeding three years, the yearling bulls, and the heifer classes.

Bulls above three years old formed a grand class, in which Mr. H. Thompson's Edgar, formerly the property of Mr. Stephenson Clark, of Ketton Hall, Darlington, whom he was purchased by his present owner last autumn, took the 1st place. Edgar is one of the best bulls of his day, and, from whatever point he is viewed, he is alike good. He is well known as a prize winner, having taken 2d last year at Oxford, when Bolivar took the 1st place. Any one who wishes to study a perfect form, will do well to spend a short time in examining this bull. His fine masculine head is succeeded by a finely formed neck, upon which the hair forms a definite mane. Age has told upon him, although not to any great extent, where he is a little bare, but in every other point he is level as a die. A stick laid across from shoulder point to hook bone touches the animal during its whole length—a crucial test of merit. His girth is 9 feet 2 inches; he is thoroughly packed on the ribs, and can be decklet down at both flank and fore-flank. He is very nearly pure Bates in his breeding, being by Prince Patrick (18,633), and from *Young Emma*, of Mr. Crofton's "Emma" tribe, by Mac-Turk (14,872), g.d. *Countess Emma* by Heir-at-Law, g.g.g.d. *Baroness Emma*, by Baron of Ravensworth (7811).—Telemachus, the 2d prize bull, is of undoubted merit, but a little slack on the loin, which is compensated for by magnificent shoulders. We refer to this bull, which is figured in the present number elsewhere. The 3d prize was awarded to the Rev. Walter Sneyd, for his Ironmaster, a very level, well-fleshed bull, especially forwards, but rather small and complained of by some as not quite let down near enough to the ground. Neither must we omit to mention Charlie by 1st Fiddle, and therefore half-brother to Bolivar, a very good bull, and a prize winner at Manchester. This bull had many friends, and was considered to be a better bull than the 4th prize, Mans Estate, owned by Mr. John Wright. This 4th prize bull is a good animal, of taking appearance, and a son of Edgar's. We also spent some time over Mr. Willis' Windsor-Fitz-Windsor, a gaily-coloured bull, with famous loins, great length of carcase, very thick through the heart, straight below, muscular in the forearm, and short from flank to inside of hock. He is a little weak over the crops, which may account for his not having been placed by the judges.

In the class of bulls above two and under exceeding three years old, Mr. William Linton, of Sheriff Hutton, York, took the 1st prize with Lord Irwin, a son of British Hope (21,324), and *Hand Maid* by May Day (20,323). This is a white bull, of large size for his age, with a famous girth and remarkably good shoulders, but paunchy withal, not very level on the top, and low in the loins. It is of good quality, and well deserves his place. The second prize bull is the property of Mr. John Outhwaite, of Bainesse, Catterick, Yorkshire, a well known and veteran agriculturist. This animal, Royal Windsor, is white in colour, and was bred by Mr. Willis, of Conock. He is by Windsor-Fitz-Windsor (25,458), and out of *Royal Lily* by Fitz Clarence (14,552). He is a very good animal, with famous hind-quarters, albeit a little low in the chine and a trifle hard to the touch. Sir David Baird, of New Blythe, Preston Tower, Haddington, comes out with Baron Lawrie 3D, bred by Mr. G. R. Barclay, Keavil, and by the grand old bull Heir of Englishman (24,122). Lady Pigot's Bythis could only obtain a 4th place, although decorated last year at Oxford, as a yearling, with the highest honours. It must be remembered that this year, at Oxford, there was some little dissatisfaction when Bythis was crowned, while Lord Irwin was placed 2d, and Lord Braybrooke's Haydon Duke only 3d. The last 12 months have reversed the decision, and now Lord Irwin takes the 1st. Messrs. Dudding, of Panton House, showed a good bull, Standard Bearer, of good Booth origin, which was highly commended, and would have been worthy of a better place but for his being somewhat patchy.

The yearling bulls formed a remarkably good class, comprising 20 entries. A finer lot of young bulls were never brought together, and pitching upon the best was apparently no easy task to the judges. After much consideration, the choice was restricted to eight first-rate animals, including Mr. Richard Stratton's very good bull, Master Glanville; Lord Sudeley's very good Seraphina bull Cherub, by Baron Booth, which eventually came out 2d; Mr. G. Garne's Earl of Warwickshire, bred by Mr. Sheldon, of Brailes, and uniting the best Booth and Duchess strains; Mr. Linton's Royal Bull Ignoramus; Mr. J. Meadows' Prince Charles, and Colonel Towneley's Baron Hubback 2d. Further sorting resulted in the red rosette being given to the last-named bull. He is by Baron Oxford (23,375), and out of *Duchess 7th*, by Duke of Lancaster (10,883). Any more may be described as a level, red bull, a little deficient in loin, and rather spoilt in appearance by his drooping horns. Lord Sudeley's red bull, Cherub, is a good animal, especially in front, is level, but not very weighty. He was 1st at Guildford in the recent show, and was much admired at Wolverhampton as he passed round the ring. The 3d prize bull, Ignoramus, is small, but young, and on the whole of good quality; and the same remark applies to Mr. Meadows' Prince Charlie, which, after having been "sent back" by the judges, was afterwards recalled, and placed 4th. We should have liked a higher place for Mr. Garne's Earl of Warwickshire 3D, a decidedly useful, well-grown bull, which, however, must rest content with high commendation only. Although undoctored by the judges, we must mention as a very pretty but small, and at the same time very young bull, Mr. James Beattie's Baron Tore, of Alesby origin, and the winner of a 1st place at the Highland and Agricultural Society's show at Dumfries last summer.

Bull calves were also a good class, 12 in all, of which Messrs. William & Henry Dudding's British Flag, by the Panton bull Robin, was very properly placed the 1st. He is a good toucher, has a level top, a good middle, and stands well on his legs; he is also a good-haired bull for his age. Mr. William Linton's Leeman, of Booth extraction, was placed 2d, a not large bull, but of excellent quality and well haired. Messrs. Thomas Garne & Son, of Broadmoor, Gloucestershire, also showed a bull of good quality, which was placed 3d, and there were other excellent animals.

Shorthorn cows were fairly represented, and the judges for long hesitated before deciding as to which was best. The struggle was principally between Mr. Beattie's *Warrior's Plume* and Mr. Dugdale's *Kent Cherry 2d*. The former was bred by Mr. Torr, and is

by BREASTPLATE (19,337), and from *Warrior's Pride* by DR. MCHALE (15,887). She has an immense but badly placed udder, and is exceedingly plain behind, being low in the rumps, and moving along in anything but good style. In spite of these defects she has many excellent points, especially about the loins and ribs. On comparing *Warrior's Plume* with Mr. Dugdale's *Kent Cherry* 2d, we find in her a large and handsome rival, having no glaring defect, splendid hind-quarters, and very good over the shoulder, a point in which *Warrior's Plume* is somewhat deficient. The 3d place was awarded to Mr. James How's *Windsor Butterfly*, a thick, level, good, but rather low cow. Mr. William Bradburne, of Wednesfield, Wolverhampton, showed a very good cow, *Miss Chesterfield* by FITZ TURK (19,763), and out of a cow by DUKE OF MANCHESTER (15,934).

The class for heifers in milk or in calf was a remarkably good one. Lady Pigot's *Dame Swift* by PRINCE OF BUCKINGHAM, dam by VALASCO, g.d. by BRITISH PRINCE (14,197), a handsome white heifer, but with a light neck, was placed 1st. Mr. How's *Vesper Queen*, of really good Booth origin, came 2d, and thus gained a step upon the 3d place she took last year at Oxford, when in competition with Mr. Mackintosh's *Lady Knightley*, now Mr. Dudding's *Countess of Yarborough*. The 3d place was awarded to Mr. F. J. S. Foljambe's *Concert* by LORD LYONS (26,677), and descended from *Seraph* by LORD OF BRAWITH (10,465). Messrs. W. Hosken & Son received a high commendation for their strikingly handsome heifer *Queen of Oxford* by 2D EARL OF OXFORD, a large heifer for her age, and the 2d prize taker at Guildford. Mr. W. H. Hewett also showed two very good heifers.

In the class for yearling heifers, Mr. John Outhwaite, of Bainese, Yorkshire, took the 1st place with a good, thick, wide heifer. His decision was generally satisfaction. Mr. Foljambe, of Osberton Hall, came 2d with his *Fleur de Lis* by LORD LYONS, a well topped heifer, which, if she had a fault, stood too far off the ground. Colonel Towneley took the 3d place with *Baron Oxford's Duchess*, a level, neat heifer, with scarcely the substance of the two first.

Heifer calves were represented by a large and good class, in which a very good calf, now the property of Mr. Arthur Garfit, a young gentleman who has recently commenced farming and Shorthorn breeding at Scothern, Lincolnshire, was placed first. His calf, named *Brilliant Rose* 2d, was purchased at Mr. Cheney's sale, and is by GENERAL NAPIER. She is a lengthy, pretty animal, good in most points, but scarcely nice at the shoulders. The second place was awarded to Lady Pigot's *Victoria Regina*, a well-haired calf, good behind but rather lower, but deficient in the beef-bed, *i.e.*, between rump and hooks. The third place was given to the Messrs. Dudding's *Lady Grace*, a nice heifer, with beautiful touch, good shoulders, and better between "hooks" and rump than the 2d prize heifer.

Herefords.—The show of Herefords was considered a very satisfactory feature of the meeting there being 87 entries, which, at least, shows an undiminished interest when contrasted with the 86 entries of last year. In the class for bull calves, Mr. Thomas Evans' MONAUGHTY 3D, "red, white face," which, by the way, seems now to be almost unnecessary in describing a Hereford, was placed 1st. He was in somewhat low condition last year, when, in the 2-year-old class, he made a good 2d to Her Majesty's PRINCE ALBERT EDWARD. This year he has been more successful, and has been placed 1st at Guildford and again at Wolverhampton. He is a large, good bull, with wonderfully developed buttocks, grand loins, and great depth. Mr. Philip Turner's BACHELOR, the 2d prize bull, is eight months junior of his rival, and, not yet in any sense large, and lacks the character which forms one of the points of MONAUGHTY 3D. The 3d prize bull, exhibited by Mr. Nathaniel Benjafield, is an extremely level animal, with scarcely the necessary quality as indicated by touch, but is wonderfully improved since he gained his first honours at Southampton two years ago. Passing on to the next class, that that of bulls above two and not exceeding three years, we find Mr. John Williams the winner of the 1st prize, with ROYAL HEAD, a small bull of very excellent quality, and of level and good form. Mr. Philip Turner's (3295). the 1st prize calf at Manchester, from whence he went into Scotland, and has now returned to England. Mr. Philip Turner's PROVOST, son of the prize bull BACHELOR above mentioned, is a nice level animal, who makes a good 3d. Among the yearling bulls, Mr. Richard Hill's PEARL, a bull of good all extraordinary quality, makes a good 1st, and Mr. Child's STAR OF THE WEST, also a bull of good quality and pleasing appearance, comes 2d. Both of these bulls are sold for Sidney. The 1st prize bull calf, belonging to Mr. H. N. Edwards, is a very good one; and the 2d prize, bred and exhibited by Mr. Taylor, of Showle Court, is nice, but showed to disadvantage owing to want of the necessary condition.

The queen of Hereford cows this year is *Ivington Rose*, the property of Mr. W. P. Peren, a grand heavy-fleshed cow, standing on low legs, but full of substance. Glancing at her pedigree, we find she is by the celebrated sire SIR THOMAS (2228), dam by MASTER BUTTERFLY (1313). The 2d prize cow *Livia* belongs to Mr. P. Turner, of The Leen. Last year she was, as a 2-year old, 2d to *Silver Star*, since gone to Australia; but despite this relief, she still remains only 2d. The year previously, at Manchester, she was also 2d; but although she seems destined to rise no higher, she is a good cow, and requires a particularly good one to beat her. The 3d prize in this class was awarded to Mr. R. Tanner's *Queen*, which occupied a similar position last year in the same class at Oxford. She is a large cow, but wants the level of her rivals. Passing on to the heifers in calf or in milk, Mr. P. Turner again leads with a heifer by BACHELOR—*Rarity*, a very nice young animal, only three weeks over two years old, and therefore competing most creditably with animals months older than herself. Mr. J. Harding's *Dahlia* received the 2d prize, and Mr. Fenn's heifer, *Duchess of Bedford* 6th, the 3d place. This was rather a change from Guildford, when *Dahlia* made a 2d to *Duchess of Bedford*; but this is accounted for by the last-named heifer being out of form from having calved in the show-ground. In the yearling heifer class, Mr. Harding's *Lissie Jeffreys*, a heifer not previously known as a prize-taker, took the 1st place, and Mr. P. Turner secured the 2d prize with *Plum*, another prize animal by the prize-taker BACHELOR. The 3d prize calf at Oxford, Mr. Thomas Mackintosh's *Swiftness*, became a 3d as a yearling. Lastly, in the calf class, Mr. Thomas Fenn's *Lady of the Tene* is a perfect gem; and Mr. Morris' *Madeline* by the Royal prize-taker STOWE (3478), makes a good 2d.

Devons are pronounced to be a very excellent show, said by many to be one of the best ever held, but numerically inferior to Oxford by a dozen entries. The prize-takers will be seen by reference to the list; but in giving a very passing notice of this beautiful breed, we will remark that the well-established breeders still continue to remove the Society's prizes. Mr. J. Howard Buller's red, unnamed, and unpedigreed bull, takes the 1st place over Lord Falmouth's well-known NARCISSUS; and Mr. Davy, of Flitton, is placed 3d with DUKE OF FLITTON 4TH. The 2-year-old bull class was represented by three animals, each of which is decorated with a prize. Yearling bulls are a good class, and so are the calves, in both of which Viscount Falmouth, Mr. Walter Farthing, and Mr. Davy take off the prizes. In the cow class Mr. William Taylor, of Ottery, takes 1st and 2d prizes with a pair of level, fine cows in milk or in calf, Mr. Smith, of Hoopern, stands 1st, and Mr. William Taylor 2d. We have not space to speak at length of the merits of these animals, and their names and owners appear in the prize lists below.

There was a fair show of *Jersey* cattle. In the bull class, Mr. Walter Gilbey, of Hargrave Park, Essex, took the 1st prize with BANBOY, and Mr. George Simpson, of Wray Park, Reigate, came 2d, with his old bull PRINCE. In the class for cows and heifers in milk or in calf, Mr. Gilbey took the 1st place with an imported cow, and Mr. George Digby Wingfield-Digby came 2d with a nice 4-year-old cow, *Julia*. Mr. Wingfield-Digby also took the 1st prize in the heifer class with *Miss Edith*, daughter to *Julia*; and Mr. Wingfield-Digby and Mr. Cunningham, of Winslow, Bucks, showed the 2d prize heifer. *Guernsey* cattle appeared in considerable force, there being eight entries of bulls, and 17 of cows and heifers. The Rev. Joshua R. Watson carried off the 1st prize for bulls and cows, and Mr. Charles Le Page, of Guernsey, took the 2d prize for bulls, and the 1st for heifers in milk, Mr. Blondel Le Page coming in 2d.

Norfolk and *Suffolk* cattle were not numerously represented. Mr. Benjamin Brown, of Thursford, Thetford, Norfolk, succeeded in obtaining all three 1st prizes, namely, for bulls, cows, and heifers in milk. For further particulars regarding the honours in this class, we refer our readers to the prize list.

There were some fine specimens of *Longhorns* exhibited in the class for other established breeds. The Duke of Buckingham and Chandos' bull YOUNG CONQUEROR was well worthy of his 1st prize, and Mr. Godfrey SAMSON 2D, the 2d prize bull, is also a magnificent animal. This breed took four out of the six prizes offered for "other established breeds," the other two being taken by Angus cattle, both the property of Mr. Statter, jun., of Stand Hall, near Manchester. In the two classes for the best pair of heifers and cows in milk, also, Mr. Statter was unrivalled, and carried off all four prizes with three pairs of Ayrshires, and a pair of cross-breds.

The following is the prize list of the cattle classes :—

JUDGES.—Shorthorns : G. Bland, Coleby Hall, Lincoln; W. Parker, Carleton Hill, Penrith; J. Robinson, Clifton Pastures, Newport Pagnell. Herefords and other Established Breeds : H. Margetts, Stretton, Hereford; W. Taylor, Haughton Court, Hereford. Devons and Norfolk and Suffolk Polled : S. P. Newbury, 4, Boringdon Villas, Plympton; and Thomas Pope, Whitestaunton, Wellington. Jersey, Guernsey, and Dairy Cattle : C. P. Le Corne, Trinity Manor, Jersey : Henry Tait, Shaw Farm, Windsor.

SHORTHORNS.

Bull, above three years old—1st, £30; 2d, £20 : 3d, £15; 4th, £10.—1st. Mr. Henry Thompson, of Maiden Hill, Penrith, Cumberland, EGGAR; 2nd, the Marquis of Exeter, of Burghley Park, Stamford, TELEMACHUS (27,603) : 3d, the Rev. Walter Sneyd, of Keele Hall, Newcastle-under-Lyne, Staffordshire, IRONMASTER, red; 4th, Mr. John Wright, of Green Hill Head, Penrith, Cumberland, MAN'S ESTATE (26,806). Highly Commended : Mr. Richard Forster, Soffe, of Hams, Easleigh, Southampton, LORD MORPETH.

Bull above two and not exceeding three years old—1st, £25; 2d, £15; 3d, £10; 4th, £5.—1st, Mr. William Lintoco, of Sheriff Hutton, York, LORD IRWIN, white : 2d, Mr. John Outhwaite, of Bainesse, Catterick, Yorkshire, GENERAL WYNDHAM, roan : 3d, Sir David Baird, Bart., of New Blythe, Preston Kirk, Haddingtonshire, BARON LAWRIE 3D, red : 4th, Emily Lady Pigot, of Branches Park, Bythus, red and white. Highly Commended : Messrs. W. & H. Dudding, of Panton House, Wragby, Lincolnshire, STANDARD BEARER, red.

Yearling Bull—1st, £25; 2d, £15; 3d, £10; 4th, £5.—1st, Colonel Charles Towneley, of Towneley, Burnley, Lancashire, BARON OF KENDAL, red, 2d, Lord Middleton, of Teddington, Winchcombe, Gloucestershire, CHERUB, red : 3d, Mr. John Lamb, of Burrell Green Penrith, Cumberland, IGNORAMUS, roan : 4th, Richard Townley, of Townville, Dublin, Ireland, PRINCE CHARLIE, roan. Highly Commended : Mr. George Garne, of Churchhill Heath, Chipping Norton, Oxfordshire, EARL OF WARWICK, red and white : 2d, Mr. Richard Stratton, of Burderop, Swindon. MASTER GLANVILLE, rich roan : Mr. John Reeve, of Leadenham House, Grantham, Lincolnshire, GRANDSON OF THE KING, roan : Mr. George Mann, of Scamby Hall, Doncaster, ROBY OF THE HILLS, roan.

Bull calf, either sex and not exceeding twelve months old—1st, £15; 2d, £10; 3d, £5.—1st, Messrs. William & Henry Dudding, of Panton House, Wragby, Lincolnshire, BRITISH FLAG, red and white : 2d, Mr. William Linton, of Sheriff Hutton, York, LEEMAN, red and white : 3d, Messrs. Thomas Garne & Son, of Broadmoor, Northleach, RED PRINCE, red.

Cow above three years old—1st, £20; 2d, £15; 3d, £5.—1st, Mr. James Beattie, of Newbie House, Annan, *Warrior's Plume*, roan : 2d, Mr. Adam Dagdale, of Rose Hill, Burnley, Lancashire, *Kent Cherry* 2d, roan : 3d, Mr. James How, of Eaton Constantine, Huntingdon, *Windsor Butterfly*, red and white. Highly Commended : Mr. Richard Forster, Soffe, of Hams, York, *Countess*, roan. Commended : Mr. W. J. Whitsted, of Abbey Farm, Wroxall, Warwick, *Magnolia*, red roan : Mr. William Bradburn, of Wednesfield, Wolverhampton, *Miss Rose*, red and white.

Heifer, in milk or in calf, not exceeding three years old—1st, £15; 2d, £10; 3d, £5.—1st, Emily Lady Pigot, of Branches Park, Newmarket, *Dame Swift*, white : 2d, Mr. James How, of Broughton, Huntingdon, *Vesper Queen*, red; 3d, Mr. F. J. Saville Foljambe, M.P., of Osberton Hall, Worksop, Notts, *Concert*, red. Highly Commended : the Rev. Arthur Bruce Kennard, of Marnhull Rectory, Blandford, *Oxford Duchess*, roan : Mr. W. Hewett, of Norton Court, Sittingbourne, *Queen*, white : Messrs. William Hosken & Son, of Loggan's Mill, Hayle, Cornwall, *Countess of Oxford*, roan. Commended : Mr. William Linton, of Sheriff Hutton, York, LEEMAN, Hunts; Mr. James Beattie, of Newbie House, Annan, *Sonsie*.

Yearling Heifer—1st, £15; 2d, £10; 3d, £5.—1st, Mr. John Outhwaite, of Bainesse, Catterick, Yorkshire, GENERAL WYNDHAM, roan : 2d, Mr. F. J. Savile Foljambe, M.P., of Osberton Hall, Worksop, Notts, *Fleur de Lis*, roan; 3d, Colonel Charles Towneley, of Towneley, *Baron Oxford's Duchess*, red. Highly Commended : Colonel Charles Towneley, of Towneley, *Butterfly's Memento*.

Heifer calf, above six and under twelve months—1st, £10; 2d, £5.—1st, Mr. Arthur Garfit, of Scothern, Lincoln, *Brilliant Rose* 2d, white : 2d, Emily Lady Pigot, of Branches Park, Newmarket, *Victoria Victrix*, roan. Highly Commended : Richard Stratton, of Burderop, *Mabel*, rich roan : Messrs. W. & H. Dudding, of Panton House, Wragby, Lincolnshire, *Lady Grace*, roan. Commended : Charles Towneley, Burnley, Lancashire, *Butterfly's Memento* 3d, red and white.

HEREFORDS.

Bull above three years old—1st, £25; 2d, £15; 3d, £5.—1st Mr. Warren Evans, of Llandowlais, Usk, MONAUGHTY 3D; 2d, Mr. Philip Turner, of The Leen, Pembridge, Herefordshire, BACHELOR (9941); 3d, Mr. Nathaniel Benjafield, of Short's Green Farm, Motcombe, Shaftesbury, Dorset, THEODORE. Commended : Mr. H. N. Edwards, of Broadward, Leominster, Sir John.

Bull above two and not exceeding three years old—1st, £25; 2d, £15; 3d, £10.—1st, Mr. John Williams, of St. Mary's, Kingsland, Herefordshire, ROYAL HEAD : 2d, the Earl of Coventry, of Croome Court, Worcestershire, CROOME HERMUS (3995) : 3d, Mr. Philip Turner, of The Leen, Pembridge, Leominster, PROVOST. Commended : Mr. John Harding, of Hampton, Shrewsbury, SOLDIERS.

Yearling Bull—1st, £25; 2d, £15; 3d, £5.—1st, Mr. Richard Hill, of Orleton Court, Ludlow, PEARL DIVER : 2d, Mr. George Child of Wessington, Derbyshire, STAR OF THE WEST : 3d, Mr. John Crane, of Benthall Ford, Shrewsbury, PRINCE GEORGE. Highly Commended : Her Majesty the Queen, PRINCE GEORGE FEREDOS.

Bull Calf, above six and not exceeding twelve months old—1st, £10; 2d, £5.—1st, Mr. H. N. Edwards, of Broadward, Leominster, Herefordshire, ALEXANDER. 2d, Mr. William Taylor, of Showle Court, Ledbury, THE WOLVERHAMPTON BOY. Highly Commended : Mr. Nathaniel Benjafield, of Motcombe, Ludlow, THE COLONEL : Mr. John Morris, of Town House, Madley, VENEGOSE. Commended : Mr. W. B. Pereo, of Compton House, South Petherton, Somerset, PRINCE.

Cow above three years old—1st, £20; 2d, £10; 3d, £5.—1st, Mr. William B. Pereo, of Compton House, South Petherton, *Ivington Rose*, red : 2d, Mr. Philip Turner, of The Leen, Pembridge, Leominster, *Livia*; 3d, Mr. Richard Tanner, of Frodesley, Dorrington, Queen. Highly Commended : Her Majesty the Queen, *Princess Amelia*; Mr. John Baldwin, of Luddington, Stratford-on-Avon, *Princess 7th*; Mr. Richard Forster, Soffe, of Hams, Dorrington, *Lady Milton*; Mr. John Morris, of Town House, Madley, *Chignon*.

Yearling Heifer—1st, £15; 2d, £10; 3d, £5.—1st, Mr. John Hardiman, of Ivington, Shrewsbury, *Lissie Jeffreys*; 2d, Mr. P. Turner, of The Leen, Pembridge, *Plum*; 3d, Mr. T. Thomas, of St. Hilary, Cowbridge, Glamorganshire, *Lady Hughly*. Highly Commended : Mr. Peter Davis, of Bickmarsh Hall, Alcester, Warwickshire : Mr. J. Hungerford Arkwright, of Hampton Court, Leominster, *Rose of Normandy*, 2d; Richard Pritchard : Mr. Henry Rawlins Evans, jun., of Swanstone Court, Dilwyn.

Heifer Calf, above six and under twelve months—1st, £10; 2d, £5.—1st, Mr. Thomas Mackintosh, of Stonebrook House, Ludlow, *Lady of the Tene*; 2d, Mr. John Morris, of Town House, Madley. Highly Commended : Mr. T. Thomas, of St. Hilary, Cowbridge : Mr. Henry N. Edwards, of Broadward, Leominster : Mr. Thomas Fenn, of Stonebrook House, Ludlow (2) : Mr. William Tudge, of Ashforn, Leintwardine : Mr. J. H. Arkwright, of Hampton Court, Leominster. Commended : Mr. Tudge, of Coston Hall, Aston-on-Clun.

DEVONS.

Bull above three years old—1st, £25; 2d, £15; 3d, £5.—1st, Mr. J. H. Buller, of Downes, Crediton, Devon; 2d, Viscount Falmouth, of Tregothnan, Probus, Cornwall, NARCISSUS; 3d, Mr. James Davy, of Flitton Barton, North Molton, DUKE OF FLITTON 4TH. Highly Commended : Her Majesty the Queen; Mr. John Pinfield, of Symondsbury, Bridport. Commended : Mr. John Peake, of Mullaghmore, Monaghan : Mr. Walter Farthing, Stowey Court, Bridgwater.

Bull above two and not exceeding three years old—1st, £25; 2d, £15; 3d, £5.—1st, Mr. James Davy, of Flitton Barton,

DUKE OF FLITTON STH; 2d, Viscount Falmouth, of Tregothnan, Probus, Cornwall, JONQUIL; 3d, Mr. William Smith, of Hoopern, Exeter, Devon, PENNSYLVANIA.

Yearling Bull—1st, £25; 2d, £15; 3d, £5.—1st, Viscount Falmouth, of Tregothnan, Probus, CINNAMON: 2d, Mr. Walter Farthing, of Stowey Court, Bridgwater, MASTER HARRY: 3d, Mr. James Davy, of Flitton Barton, North Molton, DUKE OF FLITTON 6TH. Highly Commended: Viscount Falmouth.

Bull Calf, above six and not exceeding twelve months old—1st, £10; 2d, £5.—1st, Mr. Walter Farthing, of Stowey Court, MARQUIS OF HARTINGTON: 2d, James Davy, of Flitton Barton, North Molton, CONQUEROR. Reserved Number: Her Majesty the Queen.

Cow, above three years old—1st, £20: 2d, £10; 3d, £5.—1st, Mr. William Taylor, of Glynley, Westham, *Profit's Duchess*; 2d, Mr. William Taylor, of Glynley, Westham, *Prudence*; 3d, not awarded. Highly Commended: Mr. James Davy, of Flitton Barton, *Lovely Queen.*

Heifer, in milk or in calf, not exceeding three years old—1st, £15; 2d, £5.—1st, Mr. William Smith, of Hoopern, Exeter, *Duchess*: 2d, Mr. William Taylor, of Glynley, Westham, Eastbourne, *Princess 4th*; 3d, Mr. Trevor Lee Senior, of Broughton House, Aylesbury, Bucks, *Young Daisy.*

Yearling Heifer—1st, £15; 2d, £10; 3d, £5.—1st, Mr. James Davy, of Flitton Barton, North Molton, MISS *Gipsies*: 2d, Mr. James Howard Buller, of Downes, Crediton, Devon; 3d, Mr. Walter Farthing, of Stowey Court, Bridgewater. Highly Commended: Mr. George Turner, of Broadclyst House, Exeter.

Heifer Calf, above six and under twelve months old—1st, £10; 2d, £5.—1st, Mr. James Davy, of Flitton Barton, North Molton, MISS *Gipsies 2d*; 2d, Mr. Walter Farthing, of Stowey Court, Bridgewater. Highly Commended: Her Majesty the Queen; Mr. Walter Farthing, of Stowey Court.

MISCELLANEOUS BREEDS.

JERSEY.

Bull above one year old—1st, £10: 2d, £5.—1st, Mr. Walter Gilbey, of Hargrave Park, Stanstead, ESSEX, BARBOY: 2d, Mr. George Simpson, of Wray Park, Reigate, Surrey. Reserved Number: H. Frederick Simpson, of Soft House, Belbroughton, near Stourbridge.

Cow, above three years old—1st, £10; 2d, £5.—1st, Mr. Walter Gilbey, of Hargrave Park, Stanstead; 2d, Mr. George Digby Wingfield-Digby, of Sherborne Castle, Dorsetchire. Highly Commended: Mr. Walter Gilbey, of Hargrave Park, Stanstead. Commended: Mr. P. Gaudin, of Spring Farm, St. Martin's, Jersey: Mr. John Gellibrand Hubbard, of Addington Manor, Winslow, Bucks.

Heifer, in milk or in calf, not exceeding three years old—1st, £10; 2d, £5.—1st, Mr. G. Digby Wingfield-Digby, of Sherborne Castle, Dorsetchire; 2d, Mr. J. G. Hubbard, of Addington Manor, Winslow, Bucks. Highly Commended: Mr. George Simpson, of Wray Park, Reigate, Commended: Mr. Philip Gaudin, of Spring Farm, St. Martin's; Mr. J. G. Hubbard, of Addington Manor, Winslow: Lord Chesham, of Latimer.

GUERNSEY.

Bull, above one year old—1st, £10: 2d, £5.—1st, the Rev. J. R. Watson, of Le Bocage, Guernsey: 2d, Mr. Charles Le Page, of Les Nuftiaux, Guernsey. Reserved Number: Mr. E. A. Sanders, of Stoke Canon, Exeter, Devon.

Cow above three years old—1st, £10; 2d, £5.—1st, the Rev. Joshua Rundle Watson, of Le Bocage; 2d, Mr. T. Blondel Le Page, of Maison de Bas, St. Andrew's. Guernsey. Highly Commended: Mr. Thomas Statter, jun., of Stand Hall, Whitefield.

Heifers, in milk or in calf, not exceeding three years old—1st, £10; 2d, £5.—1st, Mr. Charles Le Page, of Les Nuftiaux, Guernsey; 2d, Mr. Thomas Blondel Le Page, of Maison de Bas, St. Andrew's. Highly Commended: Mr. Thomas Blondel Le Page.

NORFOLK AND SUFFOLK POLLED.

Bull above one year old—1st, £10: 2d, £5.—1st, Mr. Benjamin Brown, of Thursford, Thetford; 2d, Mr. J. J. Coleman, M.P., of Carrow House, Norwich. Highly Commended: Mr. Thos. Hind, of Marham Hall Farm, Downham.

Cow above three years old—1st, £10; 2d, £5.—1st, Mr. Benjamin Brown, of Thursford, Thetford; 2d, not awarded. Commended: J. J. Coleman, M.P., of Carrow House, Norwich.

Heifer, in milk or in calf, not exceeding three years old—1st, £10; 2d, £5.—1st, Mr. Benjamin Brown, of Thursford, Thetford; 2d, not awarded. Highly Commended: Mr. Thomas Statter, jun., of Sale, Thetford. Commended: Lord Sondes, of Elmham Hall, red (Norfolk).

OTHER ESTABLISHED BREEDS

(Not including the Shorthorn, Hereford, Devon, Jersey, Guernsey or Norfolk and Suffolk polled breeds).

Bull above one year old—1st, £10; 2d, £5.—1st, the Duke of Buckingham and Chandos, of Stowe, Buckingham (Longhorn): 2d, Mr. John Godfrey, of Wigston Parva, Hinckley, Leicestershire (Lincoln). Highly Commended: Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester, black (Angus).

Cow above three years old—1st, £10; 2d, £5.—1st, Mr. John Godfrey, of Wigston Parva, Hinckley, Leicestershire (Lincoln): 2d, Mr. Thomas Statter, jun., of Stand Hall, Whitfield, Manchester, black (Angus). Highly Commended: the Earl of Fowis, of Fowis Castle, Welshpool (Ayrshire); Mr. Adam Duglide, of Rose Hill, Burnley, Lancashire, (West Highland); Mr. William Thomas Lucas, of Derby (Longhorn); Mr. Richard Hemming Chapman, of Upton, Nuneaton (Longhorn). Commended: the Earl of Harrington, of Elvaston Castle, Derby (Ayrshire).

Heifer, in milk or in calf, not exceeding three years old—1st, £10; 2d, £5.—1st, Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester; 2d, the Duke of Buckingham and Chandos, of Stowe, Bucks (Longhorn).

DAIRY CATTLE.

Pair of Heifers in milk, under three years and eight months old.—Prizes offered: 1st prize, £10 (offered by Mr. J. W. Phillips); 2d, £5 (offered by C. Twentyman).—1st, Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester, *Rose* and *Beauty* (Ayrshires); just over three years old, breeders unknown; 2d, Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester, *Buttercup* and *Dairymaid* (Ayrshires), about three years old, breeders unknown; 3d, Mr. John Jervis Sharp, of Broughton, near Northampton, *Julia* and *Rosa* (Shorthorn), three years and five months old, bred by exhibitor.

Pair of Cows, over three years and eight months old, in milk—1st, £10 (offered by the Staffordshire Agricultural Society); 2d, £10; 3d, £5.—1st, Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester, *Rose* and *Beauty* (Ayrshires); just over three years old, breeders unknown; 2d, Mr. Thomas Statter, jun., of Stand Hall, Whitefield, Manchester (crossed); 3d, Mr. Henry Crossley, of Watkinson Hall Farm, Halifax (Yorkshire cross). Commended: Mr. Thomas Nash, of Featherstone (Shorthorn); Mr. Josiah T. Poyser, of Stapenhill, Burton-on-Trent (Shorthorn): Mr. Charles William Brierley, of Rhodes House, Middleton, Manchester (crossbred).

SHEEP.

Leicesters.—There was a good show of these rams, and a meagre one of ewes. The older class of rams was indeed considered to be the best that had been shown for years. The names of exhibitors in this class still continue the same, with the exception of the substitution of the Rev. George Inge for that of the late Col. Inge, who was an exhibitor for so many years. Mr. F. H. Hutchinson, of Manor House, Catterick, Mr. R. W. Creswell, of Ravenstone, Ashby de la Zouch, Mr. Turner, of Alexton Hall, Mr. George Sunday, of Holme Fierrepont, and Mr. John Borton, of Barton House, Malton, Yorkshire, all appeared in their usual places. The honours were not, however, completely divided, for Mr. Creswell, although exhibiting some very admirable sheep, was left out in the cold. Taking a more minute look at the Leicester classes, we may mention the 2d prize shearling, the property of the Rev. George Inge, as a very good animal, while the 3d prize, also from Thorpe Constantine, although a good carcased and well-topped sheep, was a little wanting in fleece. The highest honours were taken by Mr. George Turner, of Alexton Hall, with a sheep very good along the top, but a rather loose handler; this sheep stands well on his legs, is of large size, and is covered with a good fleece. Mr. George Sandays' No. 664, in the catalogue was a good sheep, and received a high commendation. Mr. John Borton also showed a sheep which for neatness of form was surpassed by none, but he was deficient in wool underneath. The rams of any other age were a remarkably good class. The animal noticed was the property of Mr. Hutchinson, No. 278 in the catalogue, a remarkable sheep, with good shoulders and grand breast, capital rumps and back, and of good Leicester character, the winner of 15 first prizes, 2d at Oxford, 2d at Manchester, and yet on the present occasion not able to look after the 3d best sheep, also Mr. Hutchinson's, might be described as a splendid animal, well covered with firm flesh, very thick, covered with good wool, and possessing a good head. Mr. Creswell's old rams were also large and excellent. No. 281 in the catalogue was a grand sheep; No. 682 was altogether good, large, wide, and well woolled. Next to him was another beauty, succeeded by a wonderful sheep (684) for width at shoulders and at rumps, of very excellent form, and well woolled. The 1st prize, bred by and the property of Mr. Turner, is a good sheep "all round, I mean," firm handler. He was 1st at Guildford. Mr Sanday's 2d prize is a large, good sheep, well covered with firm flesh; and Mr. Borton's 3d prize is also a good sheep, but looser in the flesh. The ewe class was not very full, and only contained three pens, all of which took prizes. The 1st place was awarded to a pen exhibited by Mr. Hutchinson, the 2d was awarded to Mr. Borton, and the 3d to the Rev. Mr. Inge. Mr. Borton has let two sheep at high prices to Mr. Hutchinson, and also sold him a pen of gimmers at £10 each.

Cotswolds.—The competition in the Cotswold classes was as usual carried on principally by breeders from Oxfordshire and Norfolk. The Cotteswold mean appear Hatsfield, and Mr. Hobbs's sheep were the finest in wonderful sheep excepting at their own annual ram sales. The two pens of theaves exhibited by Mr. Russell Swanwick, of the College Farm, Cirencester, formed a pleasing exception to this rule, and Mr. Swanwick also appeared with a capital pen of rams for rams. The 1st prize for rams was taken by a lengthy large sheep, which however had lost most of his top-knot, if he ever had more, the property of Mr. Thomas Brown, of Marham Hall Farm, Downham Market, Norfolk. Both 2d and 3d prizes and the reserve number went consecutively into the same hands. The 1st prize for rams of any other age was taken by a sheep belonging to the executors of the late Mr. T. Gillett, Kilkenny, Faringdon, Oxon, and both 2d and 3d prizes were awarded to Mr. Brown, of Marham Hall, Norfolk, for the class for shearlings. The ewes there were only five entries, and both 1st and 2d prizes were awarded to Mr. Swanwick, of the College Farm, Cirencester, for two capital pens of up-standing, large and lengthy sheep—both, we understand, sold on the ground, at good prices, to American purchasers.

Lincolns formed a very excellent show. In the shearling ram class, Mr. William F. Marshall, of Branston, won the 1st prize, and Mr. Thomas Cartwright, of Dunston Pillar, the 2d; while Messrs. Dudding, of Panton, came 3d. Probably the firm touch and characteristic wool of the 1st prize sheep outweighed form in the estimation of the judges. Be this as it may, the Messrs. Dudding's sheep is larger, heavier, and better carried out both before and behind, than those of his successful rivals, but we confess him to be somewhat loose in the top, and to have possibly too fine a character of wool for Lincoln. Still, in the succeeding class, wool of the same character as that of this shearling has not prevented the judges from awarding a first place to a very firm and good sheep, the property of the Messrs. Dudding. The 2d prize is awarded to a ram, bred and owned by Mr. Algernon Hack, of Buckminster, Grantham. Mr. Gunnell's five ewes, shown in Class 82, are good in every way, and uniform both in character and fleece. In this class Mr. Cartwright is 2d, Mr. John Pears, of Mere, Lincoln, 3d.

Oxfords formed a good show, well represented in all the classes, with the exception of the shearling ewes, which only contained three pens of good sheep. In the shearling class, Mr. Treadwell, of Winchenden, carried off the prize with a very true sheep, the first at Guildford, and Mr. Longland is 1st prize winner in the class for older rams. The 2d prize is taken by Mr. Wallace, of Old Stafford, who also holds the reserve number. In the class for older rams, Mr. Longlands leads the way with what was the reserve number in the same class at Oxford last year. He is in every way a typical sheep, having a uniformly rich brown face, free from grey or white, a good top-knot, plenty of wool between the ears, a firmly fleshed and well-covered back, plenty of substance and weight, and in fact, a good sheep all round. The 2d prize is taken by a ram belonging to Mr. Milton Druce, of Burghfield, a truly grown and firm sheep, like the last, but a year younger, and not quite so good at the neck. This sheep was 3d at Oxford last year. We may mention as an instance of the changes wrought by time, and a change of judges, that Mr. Wallis' 1st prize at Oxford was only commended at Wolverhampton, and that his 1st prize shearling at Oxford was only 3d at the recent Royal meeting. There were some good Oxfordshire ewes shown, but rather few of them. Mr. M. Druce's 1st prize pen of five were remarkably good, and Mr. Howard's 2d prize were well headed, and in other respects excellent.

Southdowns.—There was a fair show of rams and a good show of ewes in these classes, although the former were most numerously represented. The 1st prize for shearling rams was secured by Sir William Throckmorton, of Coughland, Faringdon, Berkshire, with a sheep which, although weak in size, has the 2d prize sheep, which was also one of Sir William's exhibits, was of more perfect form and better quality. Mr. Rigden's 3d prize sheep was also very excellent in his points. The Duke of Richmond's reserve number and highly commended sheep, although good in many respects, had a light neck, and was not quite true grown at the rumps. The same remark applies to Mr. Heasman's commended sheep, No. 840. In class 89, for rams of any other age, H.R.H. the Prince of Wales obtained a high commendation for the reserve number. Sir William Throckmorton is again placed 1st, with a good, straight, well headed and well woolled animal.

Shropshire sheep formed, as might have been expected, a great feature at Wolverhampton. Instead of the 111 entries made in these classes at Oxford, there were 186 entries, and this increase was no doubt partially due to the special cup offered by Mr. R. H. Masfen and other breeders of Shropshires for the greatest number of prizes which should be taken by any exhibitor of these sheep in all classes. We may mention at this point that the cup was won by Mrs. Beach, of The Hattons, a lady who has so long been associated with the improvement of this now well-known breed. The shearling rams were the largest class ever shown, containing 85 entries, the major part of which possess a uniform character and colour, and the few exceptions come from the flocks of younger breeders. The prize animals are of a bold type and of well developed masculine character, dark in colour, with bold heads, with well developed bodies covered with heavy fleeces, free from black or grey, mounted on short legs. This is satisfactory, since such is the type of Shropshire which ought to be cultivated; and it is by giving prizes to such sheep that breeders will be stimulated to endeavour to produce similar ones. The 1st prize shearling, bred by and the property of Mr. Charles Byrd, of Littywood, is such an animal as has been already described, with a lively countenance and perfect carcase, rectangular, and wonderfully symmetrical. He is of the same family as the 2d prize shearling at Oxford last year, which was let to Lord Chesham for 116 gs. Mr. Mansell, the breeder of the sire of the 1st prize sheep, takes the second place with a shearling of precisely similar type and character, with more weight about him, but somewhat wanting in symmetry. Mrs. Stubbs' 3d prize sheep is similar in colour, seems to have led the judges in their decision, but is less stylish, has not so well covered a back, and shorter wool. In the class for rams of any other age, Mr. Mansell takes the head with a remarkably noble sheep, with extraordinary masculine character and fore-end. He has a long, heavy well-developed body, capable of making the heaviest sheep of his class, and is covered with a splendid pile of wool, free from grey or black. His features are somewhat bolder even than Mr. Mansell's type, and there is in this sheep a tendency to grey on the nose, which is not a characteristic of the flock from which he springs, but we are informed that this is traceable through a ewe to a remote progenitor, "Old Marquis." The Shropshire ewes were not so good as the rams—very numerous, but not a very excellent show.

There was a large entry of Shropshire shearling ewes. The 1st prize was well won by a pen of five, exhibited by Mrs. Beach, of The Hattons. These sheep were of the best Shropshire type, having dark brown faces and legs. It is possible to imagine heads better wooled, but the general style of the animals, and the thickness and weight of carcase, fairly entitled them to their position. Lord Chesham, who took both 2d and 3d prizes in this class, showed sheep of the same uniform good type, and Mr. H. Smith, of Sutton Maddock, received a high commendation for some good sheep, with scarcely frame enough to stand against the prize pens.

The best ten Shropshire ewes made another class, where Mr. William Baker, of Moor Barns, took the lead with an excellent pen which, if we must criticise, had a trifle too much grey on their faces. Mrs. Beach's pen, placed 2d, was free from this fault, but had not the weight of carcase of the 1st prize sheep. Mr. Thomas Nock's 3d prize ewes were also a grand lot of sheep, which scarcely the faces to please judges in a class of so much excellence. The class for ten ewe lambs was well filled, and the 1st prize was awarded to Mr. John Hanbury Bradburne, of Pipe Place, Lichfield, for some grandly carcased lambs, with scarcely wool enough between their ears, and the 2d place was taken by Mrs. Beach for a stylish, good pen. Lord Chesham's 3d prize pen might have been a little better matched, but were good lambs. We were particularly struck with the wonderful character and quality of Mrs. Beach's ten ram lambs, which took off the 1st prize in their class. They were all "as like as peas," and the wool between the ears and on the forehead was developed in a remarkable degree. The 2d prize pen, in the same class, also contained some very excellent lambs, which, although scarcely so grand in their fleece as in the first pen, reflect credit on their breeder, Mr. Thomas Nock, of Sutton Maddock. Mr. Henry Smith's lambs were 3d, and scarcely possessed size and condition to rival the first two pens.

Such is a slight sketch of a remarkable show of Shropshires. The whole breed is distinctly rising in quality and *muiformity*, and the judges certainly appear to have had a model before them to which they adhered, throughout all the classes, with praiseworthy tenacity.

The following were the judges and their awards :—

Judges.—Leicester : R. Fisher, Leconfield, Beverley : T. Potter, Yellowford, Thorverton : T. H. Simpkin, Hoby, Leicester. Cotswolds and Oxfordshire Downs : R. Garne, Sidwarth, Northleach : R. J. Weston, Campsfield, Woodstock. Lincolns, and Rylands and other Long-woolled Breeds : C. Clarke, Scopwick, Sleaford : J. Wortham, Blankfield, Whaley, South Downs, Hampshire, Dorset, and other Short Wools : H. Fookes, Whitechurch, Blandford : J. S. Turner, Seaford, Sussex. Shropshires : B. Bond, Hayley Green, Haywood, Stafford : W. Keay Bourne, Fisherwick, Lichfield : R. H. Masfen, Pendeford, Wolverhampton. Cheviots and Mountain Sheep : J. Irving, Shap Abbey, Westmorland : J. Robson, Shortwood, Jedburgh. N.B. Inspectors of Shearing : W. B. Canning, Elston Hill, Devizes : W. Jobson, Buteland, Hexham ; J. E. Workman, Kidon, near Pershore.

Leicesters.

Shearling Ram.—1st, £20, George Turner, jun., of Alexton Hall, Uppingham ; 2d, £10, the Rev. George Inge, of Thorpe Constantine, Tamworth, Staffordshire ; 3d, £5, the Rev. George Inge. Highly Commended : George Henry Sanday, of Holme Pierrepont.

Ram of any other age.—1st, £20, G. Turner, jun., Alexton Hall ; 2d, £10, Henry Sanday, of Holme Pierrepont ; 3d, £5, John Borton, of Barton House. Highly Commended : the Rev. George Inge. Class generally Commended.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, Teasdale Hilton Hutchinson, of Manor House, Catterick ; 2d, £10, John Borton, of Barton House ; 3d, £5, the Rev. George Inge, of Thorpe Constantine.

Cotswolds.

Shearling Ram.—1st, £20, Thomas Brown, of Marham Hall Farm, Downham Market, Norfolk ; 2d, £10, Thomas Brown ; 3d, £5, Thomas Brown.

Ram of any other age.—1st, £20 (reserved), the Executors of the late Thomas Gillott, of Kilkenny ; 2d, £10, Thomas Brown, of Marham Hall Farm ; 3d, £5, Thomas Brown.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, Russell Swanwick, of the Royal Agricultural College Farm, Cirencester, Gloucestershire ; 2d, £10, Russell Swanwick.

Lincolns.

Shearling Ram.—1st, £20, William F. Marshall, Branston, Lincoln ; 2d, £10, Thomas Cartwright, Dunston Pillar, Dunston ; 3d, £5, William & Henry Dudding, Panton House, Wragby. Highly Commended : Robert Johnson, Kirkleton, Wirksworth.

Ram of any other age.—1st, £20, William & Henry Dudding ; 2d, £10, Algernon Hack, of Buckminster, Grantham ; 3d, £5, John Fowler, of Melton, Lincoln. Highly Commended : William & Henry Dudding.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, Thomas Gunnell, of Willow House ; 2d, £10, Thomas Cartwright, of Dunston Pillar ; 3d, £5, John Pears, of Mere. Highly Commended : Richard Newcombe Morley, of Leadenham, Grantham.

Oxfordshire Downs.

Shearling Ram.—1st, £20, John Treadwell, of Upper Winchendon ; 2d, £10, George Wallis, of Old Shifford, Bampton, Faringdon ; 3d, £5, George Wallis, of Old Shifford, Bampton.

Ram of any other age.—1st, £20, James Congdon, of Kemdon, Northampton ; 2d, £10, A. F. Milton Druce, of Burghfield, Reading ; 3d, £5, George Wallis, of Old Shifford.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, A. F. Milton Druce, of Burghfield, Reading ; 2d, £10, Charles Howard, of Biddenham, Bedford.

Ryland and other Long-wools,

Not qualified to compete as Leicesters, Cotswolds, or Lincolns.

Shearling Ram.—1st, £15, John Lynn, of Church Farm, Stronton ; 2d, £5, John Lynn.

Pen of 5 Shearling Ewes of the same flock.—1st, £10, Thomas William Daniel Harris, of Wooton, Northamptonshire.

Southdowns.

Shearling Ram—1st, £20, Sir William Throckmorton, Bart., of Buckland, Faringdon ; 2d, £10, Sir William Throckmorton ; 3d, £5, William Rigden, of Hove.

Ram of any other age—1st, £20, Sir William Throckmorton, Bart. ; 2d, £10, William Rigden, of Hove ; 3d, £5, William Rigden, of Hove. Highly Commended : H.R.H. the Prince of Wales, K.G.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, the Duke of Richmond, K.G. ; 2d, £10, Lord Walsingham, of Merton Hall, Thetford, Norfolk ; 3d, £5, Colonel R. N. F. Kingscote, M.P., Kingscote Park, Wooton-under-Edge. Highly Commended : Sir William Throckmorton, Bart.

Shropshires.

Shearling Rams.—1st, £20, Charles Byrd, Littywood ; 2d, £10, Thomas Mansell, Adcote Hall ; 3d, £5, John Stubbs, Burston, Stone, Staffordshire. Highly Commended : Sarah Beach, The Hattons, Brewood, Staffordshire.

Ram of any other age.—1st, £20, Thomas Mansell, Adcott Hall ; 2d, £10, John Evans, Uffington, Shrewsbury ; 3d, £5, John Coxon, Freeford Farm, Lichfield. Highly Commended : William Baker, Moor Barns, Atherstone ; Sarah Beach, of The Hattons, Brewood ; Thomas Nock, Sutton Maddock, Shiffnall ; Charles Reynolds Keeling, Yew Tree Farm : Richard Edwards, Udlington, Shrewsbury : Lord Chesham, Latimer, Chesham, Bucks.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, Sarah Beach, of the Hattons, Brewood, Staffordshire ; 2d, £10, Lord Chesham, of Latimer, Chesham, Bucks ; 3d, £5, Lord Chesham. Highly Commended : William Baker, of Moor Barns, Atherstone ; William Yates, of Grindle House, Shifnal : W. O. Forster, of Apley Hall, Shiffnal.

Ten Shropshire Ewes having had lambs in 1871.—1st, £20, William Baker, of Moor Barns, Atherstone ; 2d, £10, Sarah Beach, of The Hattons, Brewood : 3d, £5, Thomas Nock, of Sutton Maddock, Shiffnal.

Ten Shropshire Ewe Lambs.—1st, £15, John Hanbury Bradburne, of Pipe Place, Lichfield ; 2d, £10, Sarah Beach, of The Hattons, Brewood : 3d, £5, Lord Chesham. Highly Commended : William Baker, of Moor Barns, Atherstone.

Five Shropshire Ram Lambs.—1st, £15, Sarah Beach, The Hattons, Brewood ; 2d, £10, Thomas Nock, Sutton Maddock, Shiffnal ; 3d, £5, Henry Smith, New House, Sutton Maddock, Shiffnal.

Hampshire and Other Short-wools.

Not qualified to compete as Southdowns or Shropshires.

Shearling Rams.—1st, James Rawlence, of Bulbridge, Wilton ; 2d, Alfred Morrison, of Fonthill House, Tisbury, Wilts ; 3d, Alfred Morrison. Highly Commended : Robert and John Russell, of Horton Kirby. Commended : Robert and John Russell, James Rawlence, of Bulbridge, Wilton.

Ram of any other age.—1st, £20, James Rawlence, of Bulbridge.

Pen of 5 Shearling Ewes of the same flock.—1st, £15, James Rawlence ; 2d, £10, James Rawlence.

Dorsets.

Shearling Ram.—1st, £15, Henry Mayo, of Cockers Frome, Dorchester ; 2d, £5, Henry Mayo.

Cheviots.

Ram of any age.—1st, £15, John Robson, of Bymess, Rochester ; 2d, £5, John Robson. Highly Commended : John Robson.

Pen of 5 Ewes of any age.—1st, £10, John Robson ; 2d, £5, Alexander Roxburg, of Caerllo. Highly Commended : Alexander Roxburg, of Caerllo.

Mountain Sheep,

Not qualified to compete as Cheviots.

Ram of any age. —Three entries, disqualified by the Inspectors of Shearing.

Pen of 5 Ewes of any age.—1st, £10, Jonathan Peel, Knowlemere Manor, Clitheroe. The other two entries disqualified by the Inspectors of Shearing.

PIGS.

The Pig classes are remarkable for the excellence of the white breeds exhibited. The black classes were not by any means so good, and the Berkshires as a whole are far from up to the standard of merit. In the large good class of white boars over twelve months old, Mr. Eden, of Saltord, takes the 1st prize with a large well-made pig, showing perhaps a little more quality than the 2d prize boar of Messrs. Duckering. The younger class of boars are also a fair class, varying, however, in size. Mr. Deverell, of Thetford, takes the 1st prize with a long and rather slim specimen, Mr. Wheeler, of Shipston-on-Stour, being 2d. The sows of this breed are a wonderfully fine class. Messrs. Eden and Duckering are again 1st and 2d respectively—the former showing a sow with eight large and handsome pigs, the latter showing one with six, much younger and less prosperous looking. In the class of three breeding sows of the same litter the same order obtains—Eden 1st, Duckering 2d ; the latter showing two pens. These three pens were remarkably even, and the reward in the same class showed a pen considerably smaller, being three months younger. The boars of the small white breed are shown in two very good classes. Mr. Eden, again 1st in the older class—a very even and capital lot—but unsuccessful in the younger class, where Mr. Palmer, of Marston, and Mr. Wheeler, of Shipston, are respectively 1st and 2d. There are capital classes also of breeding sows and sow pigs—Mr. Duckering, 1st in the former class, Mr. Eden 1st in the latter, which certainly was a remarkably fine class.

The older class of boars of a small black breed were a middling lot. Mr. Mortimer Ware, from Helstone all the way, was 1st, with a very good boar ; and Mr. H. Crossley, of Halifax, 2d. In the younger boars Mr. Ware was again 1st, and Mr. Sexton 2d.

The sow classes of this breed were better than the boar ones. Mr. Ware 1st, Mr. Hope, of Parsloes, Barking, 2d, with a very handsome specimen of the breed, showing both quality and constitution, and Mr. Sexton is 1st and 2d in the class of young sow pigs.

The Berkshire classes are tolerably good, Mr. Swanwick, of the Royal Agricultural College, who has for some years been exhibiting, at length succeeding in taking all the chief honours, *i. e.*, 1st in the older class of boars, 1st and 2d in the younger class of boars, and 1st and highly commended in the sow class, a very large and good collection.

The white breeds of classes "not eligible to compete in any of the preceding classes," and here we have the same names again succeeding—Mr. Peter Eden, who has had unrivalled success as pig breeder, at this meeting taking the 1st prize for both boars and sows.

The following were the judges and their awards :—

Judges —J. Angus, Whitefield, Morpeth ; H. Aylmer, West Dereham Abbey, Stoke Ferry ; J. Smith, Henley-in-Arden.

Large White Breed.

Boar above 12 months old.—1st, £10, Peter Eden, of Cross Lane, Salford ; 2d, £5, Richard E. Duckering, Northorpe, Kirton Lindsey. Highly Commended : Henry Goodall, Arcted, Sandbach.

Boar above 6 months and not exceeding 12 months old.—1st, £10, Francis H. Everett, Bridgham, Thetford ; 2d, £5, John Wheeler, Long Compton, Shipston-on-Stour. Highly Commended : Francis H. Everett, Bridgham.

Breeding Sow.—1st, £10, Peter Eden ; 2d, £5, Richard E. Duckering. Highly Commended : Edward Davis, 9, Old Mill Street, Wolverhampton ; James and Frederick Howard, Britannia Farm ; Peter Eden.

Pen of 3 Breeding Sow Pigs of the same litter, above 4 and under 8 months old.—1st, £10, Peter Eden ; 2d, £5, Richard E. Duckering. Highly Commended : Richard E. Duckering.

Small White Breed.

Boar above 12 months old.—1st, £10, Peter Eden : 2d, £5, John Sagar, of Lister Hills, Bradford. Highly Commended : Thomas Comber, of Redcliffe, Newton-de-Willows ; Lord Chesham.

Boar above 6 months and not exceeding 12 months old.—1st, £10, Matthew Wood, of Stockley Park, Anslow, Burton-on-Trent ; 2d, £5, John Edward Fox, of Mansion House, Great Horton, Bradford. Highly Commended : Richard E. Duckering.

Breeding Sow.—1st, £10, R. E. Duckering ; 2d, £5, Charles Roberts, of Wakefield, Yorkshire. Highly Commended : Clement N. Beswick-Royds, of Fyke House, Littleborough.

Pen of 3 Breeding Sow pigs of the same litter, above 4 and under 8 months old.—1st, £10, Peter Eden ; 2d, £5, Richard E. Duckering. Highly Commended : John Clark Andrew, of Crewkerne, Somerset.

Small Black Breed.

Boar above 12 months.—1st, £10, William Mortimer Ware, Newham House, Helstone ; 2d, £5, Henry Crossley, Broomfield, Halifax. Highly Commended : Henry Crossley.

Boar above 6 months and not exceeding 12 months old.—1st, £10, W. Mortimer Ware ; 2d, £5, George Mumford Sexton. Highly Commended : George Mumford Sexton, of Wherstead Hall, Ipswich.

Breeding Sow—1st, £10, George Mumford Sexton ; 2d, £5, William Hope, of Parsloes, Barking, Essex. Highly Commended : George Turner, jun., of Alexton Hall.

Pen of 3 Breeding Sow Pigs of the same litter, above 4 and under 8 months old.—1st, £10, George Mumford Sexton, of Wherstead Hall, Ipswich ; 2d, £5, Samuel Geater Steam, of Brandeston. Highly Commended : Thomas Comber, of Redcliffe, Newton-le-Willows.

Berkshire Breed.

Boar above 12 months old.—1st, £10, Russell Swanwick, of Royal Agricultural College Farm, Cirencester, Gloucestershire ; 2d, £5, Arthur Stewart, of St. Bridge, Dumfries. Highly Commended : John Gilbert, of Half-way Farm, Perry Barr ; Heber Hilton Parry, Kingston Farm, Shrivenham.

Boar above 6 months and not exceeding 12 months old.—1st, £10, Russell Swanwick, of Royal Agricultural College Farm, Cirencester ; 2d, £5, Russell Swanwick, of Royal Agricultural College Farm.

Breeding Sow.—1st, £10, Russell Swanwick, of Royal Agricultural College Farm ; 2d, £5, Arthur Stewart, of Sir Bridge, Dumfries, of Yilliers Hill, Keolworth, Warwickshire ; Russell Swanwick, of Royal Agricultural College Farm : Arthur Stewart, of St. Bridge.

Pen of 3 Breeding Sow Pigs of the same litter, above 4 and under 8 months old.—1st, £10, the Rev. Henry G. Baily, of Swanbourne, Winslow ; 2d, £5, John Gilbert, of Half-way Farm, Perry Barr. Highly Commended : Henry Stanley, of Upton, Shiffnal ; Russell Swanwick, of Royal Agricultural College Farm.

Breed not eligible to compete in any of the preceding Classes.

Boar.—1st, £10, John Edward Fox, of Mansion House, Great Horton : 2d, £5, Peter Eden.

Breeding Sow.—1st, £10, Peter Eden : 2d, £5, William Parker, Bradford. Commended : Richard E. Duckering.

Pen of 3 breeding Sow Pigs of the same litter, above 4 and under 8 months old.—1st, £10, Clement N. Beswick-Royds, of Fyke House, Littleborough, Lancashire ; 2d, £5, Thomas Bantock, of Merridale House, Wolverhampton.

We append, for the sake of completeness, the names of the judges in the undernoted divisions :—

Wool.—Jason Gurney, Hoanslow, Middlesex.

Butter and Cheese.—W. Clark, of Manly, Tyneside, Street, Bristol ; J. Robinson, Town Hall Buildings, Newcastle-on-Tyne : J. Watson, Carr's Lane, Birmingham.

THE IMPLEMENT YARD.

The implement catalogue is a more bulky volume than last year by some 500 entries, the total being 7650, numerous entries containing several articles. There are 363 stands, of which 232, containing 6535 entries, are in the main area, divided as usual by a central avenue. In the machinery in motion department there are 79 stands—42 on the east side, and 37 on the west, containing 481 entries. In the seeds, roots, and manure, &c., department, there are 40 stands and 534 entries, and in the open space, comprising greenhouses and other articles, 17 stands and 100 entries. In the left of the main entrance there are two long sheds for wool and dairy produce, not included in the implement catalogue.

Of the special entries for the Wolverhampton meeting, there are 105 "for trial," under steam culture, traction engines having thirty-four entries, under field implements there are 20 entries "for trial," besides several doubles not thus entered, and two or three hoppresses for brewers, catalogued along with hop-presses for hop-growers. Some 19 entries claim novelty sufficient to merit the 10 silver medals, and are accordingly entered for "for trial," 144.

In our report we shall first notice steam-culture implements ; 2d, hop-culture implements ; 3d, the miscellaneous articles entered for the 10 silver medals ; 4th, a few articles of special merit, and then, as we can, run over the other articles as we have hitherto done at the meetings of the Royal Agricultural Society.

Steam Cultivation, &c.—Premising that we must postpone till next Saturday a further account of the steam cultivation trials, we now report that there is a larger exhibition of implements and machinery under this head than has been seen at any previous meeting of the Royal Agricultural Society. There may be a few forced entries, where the articles shown have but a slender connection with steam-culture or engines employed in agriculture, but exceptions of this kind are unworthy of notice. We are unable to take the articles in the order they stand in the catalogue, and must be satisfied with mentioning only a few of the leading stands.

Messrs. J. & F. Howard, Bedford, have a splendid

show under 17 entries. (1). They show for the first time a pair of their tubular safety-boiler traction-engines adapted for the double engine and single implement system, or for the double engine and double implement system, which latter permits of each engine continuously working one implement, thus performing double work as compared with the single implement systems. The engines are each fitted with two winding drums, so that they may be worked conjunctly or separately on the right across or roundabout plan; (2), a pair of their common patent traction engines with boiler across the framing, fitted each with a single winding drum for the double engine and single implement system; (3), a set of steam tillage implements with detached windlass and tackle, including snatch-blocks, rope and anchors, adapted for being worked by a common portable engine; (4), a new improved patent detached windlass with tackle, &c., as entry 3; (5), a pair of steam traction waggons made entirely of wrought iron, except the axles, which are of steel; (6), a 3-furrow semi-balance plough with three sets of bodies mounted on strong flanged steel beams, one set for ploughing, the second for digging, and the third scarifying or smashing; (7), a 4-furrow semi-balance plough similar in respects except the last in (8), a 6-furrow semi-balance plough, similar in other respects to the two preceding, for either ploughing, digging, or scarifying, according to the kind of breast fixed on the frame; (9), a 2-furrow deep tillage implement, also similar in principle of construction to the preceding, but adapted for ploughing, digging, or smashing to the depth of from 12 to 18 inches deep; (10), a 4-furrow or double stetch ridging steam-plough, with framing as entry 7, and which can be used as a 4-furrow plough, digger, or scarifier—and by changing the breasts, the implement makes two drills or set the same at a time. This is an invaluable implement on all farms where root crops are grown; (11), a one-way double-pointed rocking tine cultivator for 1, 2, 3, 4, or 5 tines, as the nature of the ground requires. Each tine rocks in the frame, so that the point in action is depressed, and the one behind so raised as not only to avoid sole friction, but to aid in the work of cultivating the land; (12), a cultivator similar in construction to the last, with steel beams, fitted for seven rocking double-pointed tines; (13), a steam cultivator for light and medium soils, working 9 feet in breadth and 12 inches in depth, with simple, efficient steerage, and an improved method of carrying the slack rope; (14), an improved steam corn-drill; (15), a steam clod-crusher, similar to a horse clod-crusher, but fitted with steerage, so as to adapt it to steam-power by means of rope haulage; (16), a set of patent zig-zag steam harrows; (17), a heavy drag steam-harrow. Very great progress is manifested in the exhibits of this firm, that of the tillage implements being based on the principles of construction of their horse implement, with which they have been for a long time more than successful. Their safety-boiler traction-engine is one of the greatest advances in the implement-yard, and is based upon their safety fixed boilers, which are gradually obtaining adoption. No doubt the greater power of generating steam, as compared with the common boiler, will require a corresponding degree of caution during the excitement of trials to avoid breakage, but this is only a question of experience and calculation in the construction of gearing to secure safety in this respect, as in obviating harm otherwise by the premature wearing out of the parts. A great many steam implements shown by the Bedford firm are not entered for trial.

Messrs. Ransomes, Sims & Head exhibit an 8-horse (nominal) power traction-engine with elastic tyres, invented by R. W. Thomson, of Edinburgh, and John Head, of Ipswich. It carries its own driving, so that its power may be transmitted to all sorts of farm machinery and implements when not applied to hauling waggons, &c., by direct traction. This firm also exhibit an 8-horse (nominal) power locomotive-engine, invented by R. W. Thomson and John Head, similar in construction to the preceding, but fitted with cast-iron road wheels of such a form that angle-iron spuds can be attached to the rims. Both these engines are adapted for driving a detached windlass for hauling implements, with an anchor on the opposite headland, or on the roundabout plan, with a set of snatch-blocks and snatchblocks, and also for working Fisken's light rope system. This firm also exhibit one of the East Indian Government engines with a single carriage, already alluded to under the traction-engine race.

Amos, Barford, & Co., of Peterborough, have 13 entries for trial, viz., (1), a steam-culture set, consisting of a 10-horse power traction-engine, a detached windlass, 7-tine improved Woolston cultivator, a 3-furrow balance-plough and digger, a pair of Campain's patent anchors, an illustration of which was given in the *Agricultural Gazette* at the Oxford meeting last year; (2), a windlass driven by friction brakes, which enables the engine to run continuously without stopping to make the return journey; (3), cultivating windlass, invented by Brown & May, of Devizes, driven either by a "tumbling shaft or strap," and furnished with improved clutch gearing. The drums have coiling apparatus, and are mounted on a four-wheel frame; (4), an improved 7-tined Woolston smasher; (5), an improved 5-tined Woolston smasher for heavy work; (6), a combined cultivator and scarifier, similar to 4, but provided with a set of steel shears for skimming, paring, or scarifying; (7), press wheel-roller, or clod-crusher, for working on the roundabout system, with improved steerage for turning at the headlands; (8), press wheel-roller for not turning at the headlands; (9), patent drag-harrows, invented by J. Ostler, of Walrond Park; (10), a combined cultivator and seed and manure drill, on the principle of a modern Suffolk drill, with Chambers' patent manure-distributor; (11), Campain's right-hand anchor; (12), a 10-horse traction-engine, manufactured by Tuxford & Sons, Boston; (13), a portable wire-rope tarring machine. Campain's left-hand anchor is exhibited, but not entered for trial in the catalogue. Campain's anchors were deservedly the most popular articles in the trial grounds. Their high merit, both for anchorage and the economising of manual labour, is fast recommending them to general use.

John Allen Williams, of Bayden, Wiltshire, one of the earliest improvers and users of steam-culture implements, exhibits for trial a steam-roller, consisting of three cylinders, each 3 feet in diameter, on a common axis in an iron frame, with steerage-wheel 10 front; also a combined roller, cultivator, and set of three harrows. The roller is the same as described above. The cultivator is in front of the roller, the set of harrows is behind. By means of a lever, the cultivator is raised at the land's-end, so as to permit of the combined implement being readily turned.

Charles Burrell, Thetford, Norfolk, exhibits an 8-horse power traction-engine, with springs mounted on springs, with a driving-chain on each side. It has a single steam-cylinder, with change of speed for double power when such is required; also an 8-horse (nominal) power road-steamer under Thomson's patent, with double cylinder and fast and slow gear, adapted for road traffic, heavy culture, and other agricultural purposes. He also shows a 12-horse (nominal) power double-cylinder engine under Thomson's patent, with fast and slow gear, and an arrangement for raising and lowering the boiler, so as to keep it level in hilly roads and ground.

The Ravensthorpe Engineering Company, Mirfield, Yorkshire, exhibit for trial (1) a complete set of steam-ploughing tackle, invented by the Messrs. Fisken, consisting of two patent windlasses, six corner anchors, one tension-anchor, two claw-anchors, 30 light rope-carriers, 1,200 yards of Manilla rope; 1,000 yards of wire-rope, a 4-furrow balance-plough; (2), a complete Fisken set, consisting of a 10-horse traction engine, two patent windlasses, six corner anchors, a driving-rope tension-anchor, two claw-anchors, 25 rope-porters, a 7-tined fulward cultivator, 800 yards of Manilla rope, 800 yards steel wire rope; (3), a 16-horse Clayton & Shuttleworth portable engine; (4), a 7-tined Fisken balance-cultivator; (5), a 4-furrow Fisken balance-plough; and (6), an improved Fisken harrow.

Messrs. Fowler & Co., Leeds, have no fewer than 40 entries for trial, of which four are complete sets—two on the double-engine system, and two single-engine sets—viz. (1), a 20-horse power double set of steam-ploughing and cultivating machinery. The set includes two 20-horse power double-cylinder traction engines fitted with winding drums, steerage, and all the more recent improved appliances necessary for steam-culture and tractive purposes; also 800 yards of best steel wire rope. The spokes of the fly-wheel are of wrought iron, the shafts and gear of steel. The extended use of steel in this manufacture is their answer to how thoroughly this firm study the requirements of field practice, thereby profiting by their extensive experience. (2). A 12-horse power double set of steam-ploughing and cultivating machinery, the latter including balance-diggers and cultivators, also turning cultivators. With the exception of the horse-power and the single-cylinder engine, the set is similar to the preceding. (3). A 12-horse power single set of steam-ploughing and cultivating machinery and apparatus. This is their clip-drum set, about which so much has been said during the Bedford trials. It includes a 12-horse power single-cylinder engine, fitted with clip-drum, a 6-disc anchor opposite, 800 yards of steel wire rope, and 20 rope-porters, with balance-plough, convertible into a digger or cultivator by change of breast, or a turning-cultivator, and all the necessary appliances for steam-cultivation by traction. The spokes, axles, and gear are made of steel. Total weight under 10 tons. The introduction of steel boiler plate increases strength and reduces weight, a most important improvement in traction-engines for farm and road work. (4), An 8-horse power double-engine set, consisting of 8-horse power single-cylinder engine, fitted with two winding-drums, a 6-disc anchor, 1200 yards of common steel rope, 16 rope-porters, a balance-plough, digger or cultivator, &c.; (5), Fowler's winding-windlass and tackle; (6), 8-furrow balance-plough; (7), 6-furrow balance-plough; (8, 9, 10), three 6-furrow balance ploughs; (11), 5-furrow balance-plough; (12), 4-furrow balance-plough; (13), 4-furrow balance-digger; (14), 4-furrow balance-plough; (15), 4-furrow balance-plough fitted with slack gear; (16 and 17), two 13-tined turning cultivators, extra strong, for 20-horse engines; (18, 19), two 11-tined turning-cultivators; (20, 21), two 9-tined turning-cultivators; (22, 23), two 5-tined light land turning-cultivators; (24, 25), two turning-harrows with steerage frame, so constructed as to take different weights of harrows. The frame can also be fitted with ridging breasts. The harrows can be lifted, to clear them of weeds, &c. (26), 7-tined balance-cultivator; (27), 7-tined balance-cultivator, with slack gear; (28), a patent Coultas seed-drill, fitted with the exhibitor's steerage harrows before and behind, which are raised at the headlands, to permit turning. The frame is entirely of iron, and the drill finishes the work at once. (29). General purpose seed and manure drill by Coultas and the exhibitors, fitted with steerage, turning apparatus, &c.; (30), subsoil - plough, for turning over the furrow-slice and loosening the subsoil below to the depth of from 18 to 24 inches; (31), trenching plough, for turning down the staple to the bottom and bringing up the subsoil to the surface; (32), patent mole-draining plough; (33), plough for cutting or cleaning open ditches, 20 inches wide by 18 inches deep; (34), a root or stone extractor; (35), 3-tined knifer; (36), 2-tined knifer; (37), two water carts, with hose for feeding boilers; (38), 12-feet roller, with patent steerage apparatus; (39, 40), two sleeping vans for the labourers of hirers-out, fitted with vice for small repairs and boxes for carrying duplicates.

Robey & Co., Lincoln, exhibit an 8-horse power traction-engine, under Thomson's patent, for road work or steam-culture by direct or rope traction. Also a 6-furrow plough, adapted to their Thomson engine, for steam-culture by direct traction.

Tuxford & Sons, Boston, enter for trial a 10-horse traction-engine or farm locomotive for drawing, cultivating, and farmyard purposes. The engine is of extra strength, so that it can with safety work considerably above its nominal power. They also enter an improved cultivating windlass, with adjustable expanding friction-couplings and automatic friction-brakes, so that the drums can be thrown into and out of gear without shock or jar, and the brakes prevent slack in the rope and the injury so often experienced therefrom by windlasses without such improvements.

Aveling & Porter, Rochester, Kent, enter for trial (1), a 12-horse (nominal) power traction engine, fitted with a single winding-drum for the double-engine system of working; (2), a 6-horse (nominal) power traction-engine for road work, steam-cultivation by a detached windlass, threshing and other farm purposes. (3), a 6-horse (nominal) power traction-engine, for road and other farm purposes as the last; (4), a 6-horse (nominal) power agricultural locomotive engine, with improved wheels; (5), a low-sided wagon-trolley, capable of carrying 5 tons; (6), a waggon, also capable of carrying 5 tons of agricultural or other produce.

Hop Cultivation.—Messrs. Coleman & Morton, Chelmsford, enter a hop-cultivator, fitted with wheels in front, having crank-axles for regulating the depth of working by the action of a lever; also another hop-cultivator, or nidget, similar to the last, but lighter. They also enter for trial a hop syringing-engine, for washing the Hop plant when infested with aphis blight. It consists of a double barrel of copper, mounted on wheels, fitted with a force-pump and two jets, with 16 feet of delivery hose to each. The pump has an air vessel attached to the suction pipe, a strainer inside, so that two continuous jets of washing liquid can be delivered for washing two sides or hills at once. The general form may be gathered from fig. 194, which shows the same general apparatus adapted as a road-watering machine. This machine has gained the first prize of £10.

William Weeks & Son, of the Perseverance Iron Works, Maidstone, Kent, have a very excellent exhibit of Hop cultivating implements, machinery, and apparatus, well worthy the attention of Hop-growers. Twelve articles are entered for trial, viz. (1), a Hop-washing machine, capable of holding 28 gallons. The pump is fitted with double hose, each having 25 feet of 3-ply hose, with jet and jet; the interior is furnished with a filtering or straining bag, similar to a coffee-pot, so that in washing off the aphis blight the leaves of the bine are not injured with thick matter, such being strained out by the strainer; (2), a hop-sulphuring machine, for destroying mould in Hops. It consists of a small fan mounted on wheels, from which motion is given to the fan; the exit blast is divided into two currents, so that when wheeled forward between two rows of poles, or bines otherwise trained, both sides are dusted over with the sulphur blown from the machine. The sulphur is fed regularly and measured from a hopper. This machine has gained the 1st prize of £10. (3). An improved hop-presser with case and weighing apparatus, which has gained the 1st prize of £10; (4), a hop-presser, with or without case, to which the jury were unable to award the Canterbury meeting of the Royal Agricultural Society in 1860; (5), a hop-bine cutting machine on travelling wheels, for cutting hop-bines into short lengths for manure or other purpose. In principle of construction it is that of a portable chaff-cutter, the bine being drawn between fluted rollers, &c. (6). A hop-alley deal-crusher, invented and manufactured by the exhibitors; (7), a heavy iron hop-skim or cultivator, invented and manufactured by the exhibitors; (8), a light iron hop-skim or cultivator; (9), an iron hop-nidget fitted with steel shares for heavy work; (10), an iron hop-nidget fitted with steel shares for light land; (11), a portable dipping-tank for dipping hop-poles in creosote; (12), a fire-basket for drying Hops in kilns.

Richard Read, of 35, Regent Circus, Piccadilly, London, enters for trial a hop-washing machine with double hose and jet for washing two hills or rows of

Hop plants at a time. It has a copper wire-gauze strainer, through which the washing liquid is drawn to the pump, and a safety-valve may be had to order similar to another hop-washing machine exhibited but not entered for trial. Mr. Read also exhibits for trial a small pail-washing machine for small Hop gardens, which, it is stated, can be worked by one person.

Mellard's Trent Foundry, Rugeley, Staffordshire (Alfred Giles, manager), enter three of Godfry's American revolving mouldboard-ploughs for trial. An illustrated notice of this implement was given in the *Agricultural Gazette* at the Guildford meeting of the Bath and West of England Society last month, and to it we refer. The judges awarded a silver medal to one of these ploughs, viz., entry 3012 in the catalogue. In a field not far from the trial grounds at Stafford a farmer was working one of the American single ploughs, and making excellent deep ploughing. The work was better done downhill than up-hill. The implement was hauled by three horses, all going in the furrow—old style.

GENERAL REPORT OF IMPLEMENTS.

There is a fine show of horse-ploughs on the stands of Messrs. J. & F. Howard, Ransome, Sims & Head, and Hornsby & Sons. Double-furrow ploughs have increased tenfold since the Oxford meeting. Very great improvements have been introduced by the Ipswich firm during the current year. We figure in particular the simplest and lightest of the existing double-furrow ploughs, lying on its side for turning at the land's-end (fig. 195), and a one-way double-furrow plough—fig. 198 in the position in which it is at work, fig. 199 in the position half-way towards reversal, at the land's-end, in which it can be shifted from place to place. Cultivators are equally numerous; broad-shares and scarifiers are plentiful; harrows and drags, including chain-harrows, are well represented by the Howards, Hunt & Pickering, Larkworthy, Underhill, Ball, Cambridge, Corbett & Chipchase, Page & Co., Denton, &c.; horse-hoes by Garrett & Sons, Clay, Hill & Smith, Page & Co., Priest & Woolnough, and others. Rollers are exhibited on 25 stands, corn and seed drills on upwards of 60, turnip-drills on 15 stands.

There is an extensive exhibit of mowing and reaping machines, horse-rakes, &c. Burgess & Key have greatly improved their conical reel-raker, which they recently introduced. Instead of wood tubular iron arms have been introduced. The leverage is so arranged that the driver, riding on one of his horses, has, by means of a vertical lever rising up to his hand, as complete control over the whole machine as if seated on the machine in the ordinary way. Wood has a fine show of American machines; he has introduced a self reel-raker, in which the arms are each hinged some 6 inches from the end next the standard, and by means of a three-lobed cam the arms rise vertically as they come round to the seat of the driver, and fall into the cam as they come round. The main carriage wheel rotates on three small friction wheels, working in the interior of its rim; this permits the connecting rod to work through the wheel, and the crank to have a direct thrust in a line with the bearing of the wheel. Hornsby & Son exhibit their best machines; so do the Howards, Samuelson & Co., Picksley, Sims & Co., Bamlett, the Reading Iron Works, Kearsley, &c. Hayes & Son exhibit excellent waggons; so do Ball & Son, Milford & Sons, the Bristol Waggon Works Company, Crosskill & Sons, and the Beverley Iron and Waggon Co. Single-horse carts are shown on 13 stands; two-horse carts on 8 stands, cattle carts on 3, drays on 3, general purpose carts on 3, harvest carts on 6, market carts on 3, pony carts on 2, sanitary carts on 5 stands, watering carts on 4 stands, dog carts on 14, horse-rakes on 27 stands.

Horse pitchforks and straw and hay elevators are exhibited on upwards of a dozen stands; one of the latter we shall hereafter notice, viz., Tasker & Son's folding balance-elevator. Steam-engines, threshing and dressing machines are above an average show. Clayton, Shuttleworth & Co., Marshal & Sons, Tuxford & Sons, Ruston, Procter & Co., Robey & Co., the Lincolnshire firms, appear as if arrayed in competition, and no donbt so they are. In short, threshing machines are shown on no fewer than 32 stands. Horse-gears, powers, and intermediate motions are shown on 32 stands. The other articles of the barn are immaterable. Riches & Watts, of Duke's Palace Iron Works, Norwich, Norfolk, exhibit in motion Child's Patent "Aspirator," for dressing all kinds of grain and rice by the combination of riddles, elevators, and exhaust. The machine attracted much attention during the show, and merits a more detailed notice than our present limits will permit us to give it.

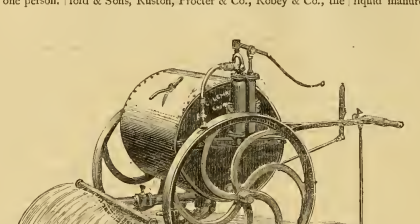

FIG. 194.—COLEMAN'S WATERING-MACHINE.

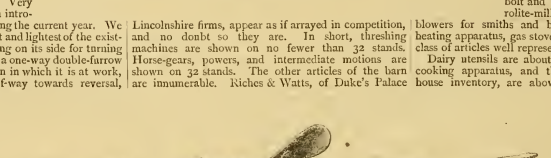

FIG. 195—.RANSOME'S LIGHTER DOUBLE-FURROW PLOUGH.

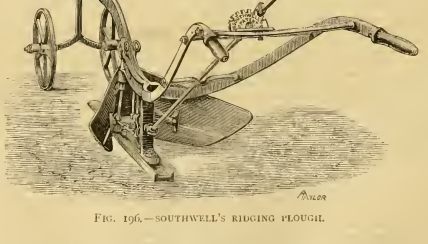

FIG. 196.—SOUTHWELL'S RIDGING PLOUGH.

Of flour-mills and grinding-mills for man and beast, the number for hand, horse, and steam power exceeds that of previous years, when they were included in the special trials. The same may be said of chaff-cutters, root-cutters, pulpers, and cake-breakers. Chaff-cutters, for example, are shown on no fewer than 50 stands; turnip-cutters, slicers, pulpers, &c., on 26; cake-breakers on 27 stands.

Stable and cattle-house fittings are unusually well represented by Musgrave Brothers, Belfast; the St. Pancras Company, London; Cottam & Co., London; R. Willacy, and others.

Pumps and pumping apparatus for irrigation and liquid manuring, sewage distribution pipes, water and liquid manure carts, are unusually numerous. Liquid manure pumps, and pumps generally, are shown on some 40 stands; liquid manure carts and distributors, on 15 stands: such facts speak more than volumes for the progress of liquid manuring.

The three firms who competed at Leicester—Whitehead, Pinfold, and Page & Co.—exhibit brick and tile machines; Stoner & Co., and Wade & Cherry also exhibit. Draining tools are exhibited by several firms, so that this branch is fairly represented.

Saw-tables, band-saws, circular-saws, turning-lathes, mortising machines, &c., are very much as last year. Great progress has been made in this department of machinery in motion, which is annually becoming more and more attractive.

Fencing of various kinds for large animals and small, from bullocks down to rabbits; gates and gate-posts, are abundant if not more numerous than usual. Stone-breakers, steam-hammers, wheel-moulding apparatus, anvils, annealing oven for iron and steel, bolt and nail forging machine, coprolite-mills, bone-mills, and blowers for smiths and blast furnaces; fire-engines, heating apparatus, gas stoves and boilers, form another class of articles well represented.

Dairy utensils are about an average; kitchen and cooking apparatus, and the various articles on the house inventory, are above an average. Wm. Hill & Co., 15, Pavement, York, exhibit on stand 261 a very ingenious mode of cooking by steam. "Its economy," says the exhibitor, "is proved by the fact, that if 20 lb. of meat be roasted the loss is 6lb.; if boiled the loss is 4 lb.; but if steamed in this apparatus the loss is only 1 lb." Mr. A. Mills Dix, Shelton Brewery, Potteries, Staffordshire, exhibits a novel refrigerator for cooling worts, of considerable promise to brewers, large and small, and which is available for brewing family ale where a moderate quantity is consumed.

The garden is superabundantly well represented on something like a hundred stands. Some large stands are exclusively devoted to supplying garden requirements.

To the following articles we give a special notice, taking them in the order they stand in the catalogue. Further instances will be given next week:—

Reynolds' Patent Thatching Apparatus (entry 171) is exhibited by Woods, Sclatter & Warner, Suffolk Iron Works, Stowmarket, sole licencees and manufactnrers. This thatch-manufacturing apparatus is extremely simple. By means of a winch on an axis, with a forked termination, each with an eye, through which a wire passes from a coil similar in principle to what is used in rope-making, a handful of straw or other thatch, as reed or flax, is twisted in at every revolution of the winch-handle. A web may be thus made the whole length of the stack, or of any convenient length. At one end of the web two or three turns are made to fix the wires, which are then cut off. It is found from experience that webs or mats from 2 to 3 feet in length are the most convenient, as they can be made at some slack time prior to harvest, folded up, tied in bundles, and stacked until required for thatching. The thatch they form differs little in outward appearance from thatch put on in the usual way in the southern and midland counties of England, where the thatch is wetted, "yarmed," as it is termed in Hants, carried up by the attendant, and put on, "yarm" after "yarm," by the thatcher, the wetness of the straw and the manner it is yarmed helping to bind it together. By the new machine the

thatch is put on dry, and at a fraction of the expense of the old plan, whilst it stands the weather and defends stacks better.

According to the new plan, the thatcher places each mat on the roof, and pegs it down with a patent "broach" or thatch-peg, composed of a sharpened stick of the ordinary kind now in use, but having a hole in its head, through which a twisted thong of wire is attached, having a loop in the opposite end—the length of the thong being equal to the breadth of the mat. Thatch-pegs and thongs being in readiness for use, when one mat is laid, the thatcher takes the thong of the previous peg, stretches it firm over the mat, puts a peg through the loop which holds the mat fast. Another mat is laid and pegged down in the same way, and thus the work proceeds. Mr. Reynolds has also patented ladders for the use of the thatcher, and for hoisting the mats and pegs. With straw of an average length, he says, 20 mats, 2 feet in width, will cover a square. These can be made in as many minutes—half a pound of wire for the same will cost 4*d*. Twenty mats will require 20 thatch-pegs, and a man and boy will lay from four to seven squares per day—so that the total expense does not exceed 7*d*. per square. The thatch is adapted both for round and long stacks, and good straw may last more than one year.

The Oxford Patent Ridging Plough, exhibited by Southwell & Co., of Rugeley, has a very ingenious device for expanding or contracting the mouldboards, by the ploughman standing between the stilts, either at the headland or whilst the plough is going. This is done by simply turning a crank-lever, with a ratchet-catch, to the right or left; the one way to contract the breasts, and the other to expand them. From this crank-lever a shaft extends to the body of the plough; upon the lower end of this shaft are fixed two cam levers, the one on the up-side, the other on the down-side; from these two hinged link-levers extend, one to each breast, so that when the crank-lever is turned to the right the breasts are expanded, and when it is turned to the left they are contracted. This implement was highly commended at the Oxford meeting, and is favourably noticed by the judges in their report in this journal, p. 528. (See fig. 196.)

Willacy's Patent Cattle Feeding Machinery (fig. 197).—At the Aylesbury and Oxford meetings it was our duty to report favourably on the successful endeavours of Mr. Robert Willacy, of Pentwortham Priory, Preston, Lancaster, to expedite and economise labour in the feeding of cattle, more especially when large numbers are housed together. It is a well-known fact, that when the cattleman feeds the first ox all the others in the building become restless, and not unfrequently play mischief. This Mr. Willacy obviates by placing a combined chaff-cutting, root-pulping, and cake-breaking machine on a railway in front of the feeding troughs, which will supply a mixture of cut chaff, pulped Turnips, or other roots, and broken oilcake to 100 head of cattle in ten minutes, or as fast as the machine can be wheeled along the rails. At Oxford the machine only sliced the Turnips and broke the cake, and the judges, in their report gave a very favourable notice of the machine. Since then the machine has been improved by substituting a root-pulper for a turnip-slicer, and by the additional mechanism for supplying cut chaff along with the pulped food. This is a most important improvement. Pulped roots and chaff have of late been strongly advocated, and it affords us great pleasure to report the advance thus made by Mr. Willacy, which proves that he continues to lead on his brother farmers in the march of progress.

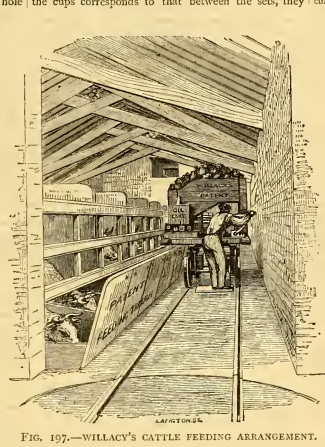

FIG. 197.—WILLACY'S CATTLE FEEDING ARRANGEMENT.

Self-ridging Potato and Manure Drill.—Lewis Wright, of Hannah Alford, Lincolnshire, exhibits a new machine for planting and manuring Potatos at one operation, in drills or rows on the flat. There are two hoppers, the upper or large one for the Potato sets, the lesser one below for the artificial manure. Two traveller bands with cups bring the Potatos out of the hopper, one in each cup, and empty them into two spouts placed at the desired distance between. Two coulters or small ridging-ploughs open two furrows into which the Potatos drop, and as the distance between the cups corresponds to that between the sets, they drop regularly in their places at the proper distance asunder. In the bottom of the Potato hopper a stilted frame moves to and fro by a cam movement, which prevents the sets falling through, thereby supplying the cups with a regular feed. If more than one set is brought up by a cup, the odd ones fall down a spout into a box behind, and are put back into the hopper. The manure is delivered into two spouts for each Potato-drill in the usual way, and falls on each side of the open furrow. Two closing breasts behind follow, covering in the earth and manure mixed together over the Potatos; motion is taken from the wheels, and the horse yoked in shafts in the usual way. The machine has not yet been tried sufficiently to warrant our opinion on its practical merits, but its mechanism is not without promise.

The following is the prize-list in the implement department:—

SECTION I.—STEAM CULTIVATION.

CLASS 1. For the best combination of machinery for the cultivation of the soil by steam-power, 1st, £100, Messrs. Fowler & Co., 12-horse power, double engine set, price £1280; 2d, £50, Messrs. Fowler & Co., 20-horse power, double engine set, price £1880.

CLASS 2. For the best combination of machinery for the cultivation of the soil by steam-power, the weight of the steam engine not to exceed 10 tons, 1st, £50, Messrs. Fowler & Co., 12-horse power clip-drum engine and disc anchor, price £740; 2d, £30, the Ravensthorpe Engineering Company, 10-horse portable engine and set, price £690.

CLASS 3. For the best combination of machinery for the cultivation of the soil by an ordinary agricultural engine, whether self-propelling or portable, 1st prize, £50, Messrs. Fowler & Co., stationary winding set, with 4-furrow combined plough, digger, and cultivator, price £280, with combined drill and two sets of harrows, and combined drill and harrow, £416 19*s*. 2*d*., £25, Messrs. Howard & Co., stationary windlass set, with five-tine reversible cultivator, price £250, with 4-furrow combined plough and diggers, one set of harrows, and combined drill and harrows, £416 19*s*. 2*d*.

A Silver Cup, value £100, offered by the Right Hon. Lord Vernon, president, given for the best combination of machinery for the cultivation of the soil by steam-power, the cost of which shall not exceed £700, the engine to be locomotive, and adapted for threshing and other farm purposes, Messrs. Fowler & Co., 8-horse power double-drum engine and disc anchor, price £696.

CLASS 4. For the best Windlass, detached, £20, Tuxford & Son.

CLASS 5. For the best Snatchblock, or substitute thereof, £10, Amies, Barford & Co.

CLASS 6. For the best Plough, suitable for steam cultivation, £25, Fowler & Co.

CLASS 7. For the best Subsoiler, suitable for steam cultivation, £20, Fowler & Co.

CLASS 8. For the best Digger, suitable for steam cultivation, £25, Fowler & Co.

CLASS 9. For the best Cultivator, suitable for steam cultivation, £25, Fowler & Co.

CLASS 10. For the best Skim-Plough or Scarifier, suitable for steam cultivation, £20, Fowler & Co.

CLASS 11. For the best Roller, suitable for steam cultivation, £10, Amies, Barford & Co.

CLASS 12. For the best Harrow, suitable for steam cultivation, £10, J. & F. Howard.

CLASS 13. For the best Drill, suitable for steam cultivation, £20, J. & F. Howard; £10, J. Coultas.

CLASS 14. For the best Root or Stone Extractor, suitable for steam cultivation, £10, Fowler & Co.

CLASS 15. For the best combination of any of the above implements not qualified to compete in classes 1, 2, or 3, £60. (Not subscribed.)

CLASS 16. For the best implement, or part of tackle, suitable for steam cultivation, of any other description, not qualified to compete in the preceding classes, £5, £10, J. & F. Howard, subsoiler and ridger; 2d, £10, Fowler & Co., harrow-frame fitted with ridging bodies.

CLASS 17. For the best Agricultural Locomotive Engine, applicable to the ordinary requirements of farming, £50, Aveling & Porter. Highly Commended: Aveling & Porter. Commended: C. Burrell.

CLASS 18. For the best Waggon for agricultural purposes, to be drawn by an agricultural locomotive engine, £20, Aveling & Porter. Commended: Hayes & Son.

SECTION II.—HOP MACHINERY.

CLASS 1. For the best Machine for the Cultivation of Hop gardens, to supersede manual labour, £20. Prize withheld.

CLASS 2. For the best machine for washing the Hop plant to remove the aphis blight, £10, Messrs. Coleman & Morton, Chelmsford, Hop syringing engines, with branch pipe and delivery hose.

CLASS 3. For the best Hop presser, £10, Messrs. Weeks & Son, Maidstone, Hop presser.

CLASS 4. For any other improved implement or implements used in the cultivation or management of Hops, £10, William Weeks & Son, Hop sulphurator.

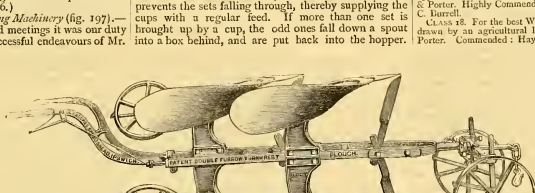

FIG. 198.—RANSOME'S ONE-WAY DOUBLE-FURROW PLOUGH (AS AT WORK).

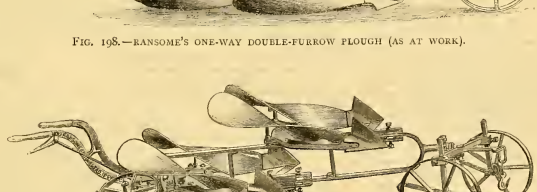

FIG. 199.—RANSOMES' ONE-WAY DOUBLE-FURROW PLOUGH
(Half-turned for change of Furrow).

MISCELLANEOUS AWARDS—SILVER MEDALS.

(To Agricultural Articles and Essential Improvements therein.)

Silver medal for the adaptation of the principle of the rotating disc, mould plough, entered among the Hop-cultivating implements, Messrs. Mellard's Trent Foundry (Limited), Rugeley.

J. Fowler & Co., ditching plough.

Ransome, Sims & Head, 8-horse power agricultural locomotive engine, with indiarubber tyres.

Aveling & Porter, 6-horse power agricultural locomotive engine, with internal indiarubber tyres.

SEEDS, ROOTS, MODELS, AND MANURES.

Artificial Manures are well represented by samples on the stands of Griffin, Morris & Griffin, Wolverhampton; Webb & Co., Worcester; W. & H. M. Goulding, of Dublin and Cork; Gibbons, Mills & Gibbons, of Wolverhampton (Henry Gibbons was manufacturing superphosphate in 1833, and therefore may be considered the father of this new branch of industry, so important to modern agriculture); Bradburn & Co., Wolverhampton; E. Packard & Co., Ipswich; the Agricultural and Horticultural Co-operative Association, London. On all these stands samples

of the raw materials are shown, and also samples of the manufactured articles for the different kinds of crops.

Seed and root stands we shall take in the order of the catalogue, giving each stand a separate notice.

James Dickson & Sons, Chester, have a large collection of dried specimens of grasses, principally of those grown in this country for stock ; samples of grass and Clover seeds in bags for permanent meadows, pasture and alternate husbandry ; also in bags, seed of their prize Purple-top Swede Giant Long Red Mangel, Defiance Yellow Mangel, &c. ; likewise the different cereals and pulse crops in bags, numerous specimens of evergreens, forest trees, &c., in pots, from their nurseries ; the whole being set off with a very pleasing variety of horticultural decorations for the table, as Palms, &c.

John Kemp King, of Coggeshall, Essex, has an unusually fine show of roots and seeds. He was the first to show roots at the summer meetings of the Royal, and the movement thus started was a good one, as it tests their keeping quality. Those shown on his stand are as clean in the skin and as fresh as they were at the Christmas show in the Agricultural Hall ; and he has done well to leave the fresh growth untouched, as it shows the health and freshness of the root. This applies to the different varieties of Mangels, Kohl Rabi, and Swede, whose quality is unsurpassed. The secret lies in the care with which the roots are selected for seeding, the harvesting of the seed-crop, the cleaning and preservation of the seed. We have on many previous occasions drawn attention to this, but we never saw his roots so fresh and full of life at this season. He has also a fine display of growing roots and grasses in pots, looking very promising for next year ; likewise of the different seeds.

Edward Webb & Sons, of Wordsley, Stourbridge, Staffordshire, show a small but fine collection of seeds, roots, grasses, linseed and cotton cakes, manures, &c.

Richard Sankey & Co., Wolverhampton, exhibit very fine samples of farm and garden seeds ; also a fine show of shrubs and forest trees. The stand is skilfully arranged, and tastefully decorated with bouquets of flowers.

J. C. Wheeler & Son, Gloucester, exhibit, as they usually do at the summer meeting of the Royal, a first-rate collection of agricultural seeds, also particularly the British grasses, both dried and growing in pots, scientifically arranged with the view of laying down land for permanent meadow or pasture, and also for alternate husbandry, according to climate and the geological nature of the soil. This firm also shows samples of the different varieties of their celebrated Potatos.

Thomas Gibbs & Co., seedsmen to the Royal Agricultural Society of England, corner of Half Moon Street, Piccadilly, London, have a most splendid and extensive selection of seeds, roots, and dried specimens, their stand being laid out with the greatest possible taste and skill. Their roots include Mr. Brandreth Gibb's celebrated Yellow Globe Mangel Wurzel, with various other kinds ; agricultural seeds of every kind of the best quality ; a general collection of nearly 300 specimens of grasses, flower, and other cultivated crops, growing in pots, illustrative of the soundness and vitality of the seed thus sown ; collection of dried specimens of selected natural grasses, English and foreign Wheats, Barleys, Oats, &c., ornamentally and instructively arranged for profitable inspection. This stand always forms an inviting study among farmers, and this year the arrangement exceeds any previous exhibition.

James Carter & Co., London, have a magnificent stand. Of late years they have been annually improving in the artistic and decorative arrangement of their fine exhibits, and this year we have to report Wolverhampton in advance of Oxford and Manchester. The wonderful specimens of Mangel Wurzel which they exhibited at the Christmas meeting of the Smithfield Club in the Agricultural Hall are here as fresh as they were then, and the graceful manner they are panelled out with specimens of grasses, &c., growing luxuriantly in pots, shows off the whole to the best advantage. The samples of the different kinds of seed-corn, &c., are of the best quality. They also show Mangels, Kohl Rabi of the present year's growth, which, taking into account the lateness of the season, are very promising.

Harrison & Sons, of the Royal Midland Seed Warehouse, Leicester, have a choice selection of roots and seeds. Their new Normanton Globe and Giant Long red Mangel Wurzels maintain the high position they have long held at the summer meetings of the Royal Agricultural Society of England—the best guarantee of the standard quality of the seed.

Sutton & Sons, of the Royal Berks Seed Establishment, Reading, Berks, have a magnificent exhibit. Some 200 dried specimens of the natural grasses, gathered on their own experimental farm, adorn the back of their stand. The superb specimens of their different varieties of Mangel Wurzel, Kohl Rabi, and Swede, are as fresh as they were at the Christmas cattle show in the Agricultural Hall, Islington, thus proving their superior keeping qualities. The Mangels are skilfully laid out, the specimens of growing grasses, &c., being very artfully intermixed, giving to the whole stand a very attractive appearance. The Italian Rye-grass, and other grasses, the growth of the current season, are something wonderful, and but for the fact that they speak for themselves, such luxuriance of growth would hardly be credited. They also show specimens of Kohl Rabi of the current year, of the best quality, and of good size, considering the lateness of the season. The canvas bags, upwards of 200 in number, containing their own home-grown seeds, carefully harvested, and all of the very best quality, are a splendid show of themselves. A large selection of seed is also shown in glass-cases or behind glass, which has a fine effect. They also show their splendid Purple-top Swede and Globe, an immense head of Cabbage of this year's crop, and the largest selection of new Peas which we ever saw shown at the summer meeting of the Royal Agricultural Society, quality and variety super-excellent.

Wool, Butter, and Cheese.—There is a better exhibition in this department than there has been for many years. The wool is confined to Shropshire fleeces, and although some entries are rather coarse, there are some good fleeces shown.—If the cool season is not the best for the production of butter, it is favourable for its exhibition. At the last show the weather was so hot that the butter appeared in a semi-fluid state ; but the rolls, prints, &c., are as shapely and rich in colour as they were when they left the dairies of the exhibitors. Lord Chesham, of Latimers, Chesham, Bucks, who was 1st for wool, is here again 1st for Butter, and the quality is first-rate. The show of Irish butter from Limerick is also fine.—Cheeses are divided into four classes : (1), coloured, over 6 inches thick ; (2), coloured, under 6 inches thick ; (3), uncoloured, over 6 inches thick ; (4), uncoloured, under 6 inches thick ; and, with a few exceptions, the samples in each class are very creditable favourable. It is interesting to examine the diversity on the stands, and to ascertain where this and the other is made. Upon the whole, it is to be hoped we are making progress everywhere in the making of cheese.

THE ANNUAL MEETING.

The Annual Meeting was held in the Show-yard, on Tuesday afternoon, under the presidency of Lord Vernon. There was a good attendance.

The Secretary read over the list of farm prizes, and also stated that the cup given by Mr. Masfen and other breeders of Shropshire sheep to the exhibitor taking the greatest number of prizes in all the Shropshire classes had been awarded to Mrs. Beach, The Hattons, Brewood, Staffordshire.

The following is the list of prizes for the best managed farms :—

Farm Judges.—G. Jackson, Tattenhall Hall, Chester ; W. Sanday, Radcliffe-on-Trent, Nottingham ; J. Wheatley, Neswick, Driffield.

For the best managed Arable Farm.—1st, £100, given by various landowners in Staffordshire and Shropshire, Mr. G. T. Forrester, Sherlowe, High Ercall, Wellington, Salop ; 2d, £50, given by the Society, Mr. T. Winterton, Alrewas Hayes, Lichfield. Highly Commended, and a special prize of £25, given by the subscribers for his successful management of good land, Mr. W. Bremner, Baddeley Hall, Biddle, Wem, Salop. Highly Commended, and a special prize of £25, in recognition of her profitable management, Mrs. E. Sankey, Bratton Farm, Wellington, Shropshire. Commended, Mr. C. B. Spalding, Tythe Farm, Penkridge ; and Mr. G. A. May, Elford Park, Tamworth.

For the best managed Dairy Farm.—1st, £100, given by the same landowners, Mr. Lyon Lamaide, Oswestry, Salop ; 2d, £50, Matthew Walker, Stockley Park, Anslow, Burton-on-Trent.

Thanks were voted to the Mayor and Corporation of Wolverhampton, and, amidst a good many dissentient voices (owing to the lack of accommodation to Birmingham) to the railway companies for their arrangements.

Sir John Morris then moved, and Mr. Aveling seconded, a vote of thanks to the President, for whom three cheers were given.

Lord Vernon in reply, spoke of the Royal Agricultural Society as the greatest educational engine in the country. One of its principal advantages was its exclusion, as much as possible, of everything sensational, and its devotion to practical business. The great advantage of the Society visiting a town like Wolverhampton was the bringing of the enlightened workman into contact with those who produced him food, while the latter, on the other hand, had the benefit of seeing the centres of industry where the forces of Nature were employed in making the machinery for the cultivation of the soil. The great feature of the show was the exhibition of steam cultivators and traction engines. It would be impossible for any local society to undertake the exhibition and trial of those particular implements, which required not only a vast area of ground, but the highest possible engineering skill in testing. If the presentation of a cup, which he had been allowed to offer during his presidency, produced what so many members of the Council were desirous of seeing, viz., the bringing of the means of cultivating by steam within the reach of the smallest farmer, he was sure that they would consider that they had performed one of the greatest services they could. He congratulated Mr. Fowler on winning the cup. To the skill and organisation which he exhibited on the field, as well as to the discipline of his men, much of his success was due. He expressed his high sense of the assistance given to the society by the local committee, who had had unusual difficulties to contend with.

The proceedings concluded with cheers for Sir Watkin Wynn, the president elect.

Farm Memoranda.

Wester Ross : *July 6.*—After the thorough pulverisation of the soil by the unusually intense and long-continued frost, the crops braireded and came away regularly and very promisingly, with the exception of some of the Wheat on light and exposed fields, which was very much thinned out by the late frost, but which, although doing its best by tillering, has failed in occupying fully the ground. The Wheat, which is now generally coming into ear, is well strawed, but the fields that are sufficiently planted are the exception, not the rule, so that our crop of Wheat will be rather under than up to the average. Should we have a good blooming and ripening season the yield might be more abundant than we anticipate. For Oats the season has once again been too dry, and, like the three previous years, they generally are very short in straw. Last year they yielded very badly, as the crop was not only light but many of the ears were black and useless, and this year they appear pretty largely affected in the same way. The abundant showers we are now having will do something in lengthening the straw, but a heavy crop they cannot now be. Barley is the heaviest cereal crop we have, but it is not so largely sown as Wheat or Oats. It is thickly planted, and many fields are abundantly strawed. The earlier fields of Barley are also getting into ear. The harvest will be later than it has been for the last few years. Unless the weather be forcing little will be cut in August. Part of our Turnips brairded irregularly from scarcity of rain, and part of the seed had to be sown a-blowing, having been destroyed by fly. On the whole, however, our Turnips are coming away promisingly. The Swedes have been singled, and the common Turnips are now coming to the hoe. There is now abundance of rain everywhere in the North, and in some places a little too much. On a few adjoining farms the burning waterspout seemed to fall. Every Turnip-drill had a current, carrying along with it the soil, in some places to a great depth ; and, at the bottom of a brae-set field, the water gathered together and ran through a gate in such volume as to carry along with it, for a short distance, a Turnip sowing machine which stood in its way. Afterwards it ran down the steep part of another field of Turnips, leaving bare the very rock, and burying some 2 acres of Turnips and Potatos with the drifted soil. Potatos, perhaps, never looked better than they do now. Some of the earlier fields, after being drilled up, are covering the ground. The cutting of hay has commenced, and the crop, if any, is not much short of an average. The price of hay is now low, and bids fair to be so for some time. Our pastures are better supplied with grass than stock. The high price and keen demand for cattle has drawn away to the South more than the usual number, so that, with fine weather, the prices cannot be low for some time to come.

Lancashire.—The long-continued spell of unsettled weather which has prevailed here has materially damaged the hay crop, which, if favoured by fine and dry weather, would have been unusually heavy. Scarcely any hay has been stacked, and a great quantity is lying damaged in the fields. Yesterday and to-day (July 4 and 5) very heavy rain has fallen, and there are no signs of improvement. Mr. Gibbs' drying-machine would be useful if it were able to turn out a reasonable quantity per diem, but people here fancy the process, besides being costly, is so slow as to be practically useless. It would be well if agricultural journals would afford some information as to this apparatus, and state its capabilities and cost. *W. H. B., July 5.*

Obituary.

The death of Mr. John Clayden, of Littlebury, will be learned with sincere and general regret. We abridge the following short memoir of his useful life from the columns of the *Mark Lane Express* :—

As had been feared, Mr. Clayden never rallied from the fit of paralysis with which he was attacked on the station at Watton after attending the Merton sale, but gradually sank and died in the village on the morning of Tuesday last. He thus survived but a few weeks the death of his brother-in-law, Mr. Samuel Jonas—a prominent man like himself, not only about home, but as an eminent English agriculturist.

Mr. John Clayden was born, where he continued to farm, at Littlebury, in July, 1805. He was the eldest of seven children, the family of Mr. William Clayden, a well-to-do yeoman and practical farmer, far in advance of his own times. As such, he was a frequent attendant at the famous Holkham sheep shearings, and personally well known to Mr. Coke, afterwards Lord Leicester, who once called at Littlebury, on his way to London. The son, John, began life at a good school in his native village. Mr. Clayden, senior, died in 1828, and at the age of 23 his eldest son came into the control of a business which included the farming of 800 acres at home, and of another large occupation, about ten miles off, which his father had been superintending for an aged relative. In the first instance, the brothers, John and William Clayden, took their own farm conjointly; but in 1832 the younger brother removed to Linton, in Cambridgeshire, leaving

to John the undisputed possession of Littlebury. The active, business-like habits of Mr. Clayden soon gave him a standing and repute among his neighbours, conspicuous amongst whom was the late Mr. Jonas Webb; and the two became fast friends. Beyond frequent visits to each other's houses, they were almost invariably to be seen together at the agricultural shows just then springing up, and amongst which, previous to the formation of the Royal Agricultural Society, the Saffron Walden gathering held a good place. The tastes of the two friends, moreover, "hit" very much as to the best kinds of stock, so that they were often associated together as judges. And there were few better "all-round" judges than John Clayden. Whether it were over cart-horses, cattle, sheep, or pigs, he was never out of his element; and, as a consequence, no one was so continually called in as referee—that is, from the particular class over which he might be acting. As an exhibitor, his chief successes were with his Southdown sheep, his Suffolk horses, and his Shorthorn cattle. On the death of Mr. Jonas Webb, Mr. Clayden was appointed Chairman of the Agricultural Hall Company, but his public duties were by no means confined to this office. He was a member of the Council of the Royal Agricultural Society of England; a member of the Council of the Smithfield Club; a member of the Committee of the Farmers' Club; one of the Directors of the Agricultural Hotel Company; the Chairman of the Walden Agricultural Manure Company; one of the Honorary Secretaries of the Royal Agricultural Benevolent Institution. Then, he had been Mayor of Saffron Walden as often as Whittington was of London; but he found time to farm in the very best style 1000 acres of land which he held under Lord Braybrooke, about 100 acres belonging to other proprietors, and 800 acres more of his own. Mr. Clayden was a man of very active, business-like habits, while he united with these a special charm in his cheerful, genial manner, that, backed again by his high character, had served to culminate the success he so deservedly achieved in the annals of modern agriculture; and in the beginning of the year 1870 a testimonial was presented to him at a dinner at Saffron Walden. Mr. Clayden, who had been twice married, eaves a family of two sons and five daughters.

To this may be added, that Mr. Clayden was Chairman of the Cattle Defence Association, and took a warm interest in its proceedings. Only just before his death, in a letter to the Secretary, he had expressed a very decided opinion as to the necessity of beginning their work afresh, in consequence of the recent Orders in Council.

The Week's Work.

JULY 17.—*Summer Meetings* during the month are numerous, and that of the Royal Agricultural Society of England at Wolverhampton will serve the twofold purpose of holiday amusement and practical education. Of the former nothing requires to be said, but it is otherwise with the latter, for the agricultural public not only learn in the exhibition of implements and live stock the progress made since Oxford last year, but along the various lines of railway leading to Wolverhampton they obtain from what they see on either side an amount of practical education relative to the crops, pastures and grazing stock, the value of which it were difficult to estimate. Such education, including the "railway return" and the showyards, is the best farmers' sons and daughters can receive, and to this the families of landlords and agricultural labourers may honestly be added; for besides what they see and hear at the time, the mind, on their return home, is turned out of the antiquated path of the past into a new channel, thus giving greater force to the current of thought—just as the straightening of a river gives greater velocity and force to the stream.

Labourers' Holidays involve one of the most important movements of the day, not only in social science, but in agricultural practice. No industrial class stands more in need of this practical education taught by a visit to county shows and the meetings of the Royal Agricultural Societies of England, Scotland, and Ireland than agricultural labourers, for when confined at home for life they are apt naturally to treat the introduction of new labour-abridging machinery, or even improved machinery and implements of any kind, by their employers, as an innovation of their rights, and to carry into effect their use with an unwilling hand and unfriendly spirit; whereas, when they see the competition at these meetings, they appreciate their practical value often better than their employers, consequently they return home elated with a spirit of enterprise, anxious for an opportunity to exemplify what they themselves can do, and by such means not unfrequently induce their employers to go a-head when otherwise they would lag behind. The practice of sending out servants to learn the catchpenny extravagance too common in our large towns, is not to be approved of, and were extravagance the worst that is learnt the evil would be less than it is, but a farmer cannot invest his capital better than by giving his labourers a holiday at Wolverhampton and other local shows and ploughing matches of the district.

Cabbages horse and hand hoe as soon as the plants are firmly rooted. Hoe deep, and draw the loosened earth up to the plants. This is all the more needful if the surface has been crusted by heavy storms of pelting rain, or by the liberal use of the watering-pan at the time of planting. Some object to the use of the watering-pan, but in dry weather we have used it as successfully in the field as in the garden; and, if the water is near, the work of watering is not such a heavy one as some imagine. Water in the progress of things will be more liberally applied to all cultivated crops than it has hitherto been, and what is chiefly wanted just now is more courage to go a-head.

Lupins, Lucerne, and *Sainfoin*, when grown as forage crops, go over after every cutting and remove all weeds. Grass or weeds of any kind are said to be more obnoxious to these crops naturally than any other; but be this as it may, their successful growth depends upon their being kept clean.

Turnip Seed is harvested during this month in the South, and the earlier part of August in the North, and at the time we write there is nothing to indicate an exception. The crop should always be cut with a sharp stem-cleaved reaping hook, and leave it abroad in small parcels until ready for the threshing floor, others tie up the crop in small sheaves as fast as cut, and stack immediately. There is no little art in stacking this crop. If the stack is of any considerable size there should be a tripod of three poles in the centre, to prevent it settling down, so as to obviate mouldiness and insects. In building the stack, the bottom sheaves are placed erect upon their butts, as in stacking Flax; the courses above are laid slanting, with their butts outwards, and as loose and open as possible, and the stack should be thatched down to the bottom immediately. If properly stacked, the seed keeps better in the stack than in the granary, and the crop is threshed when the seed is to be used. When the seed is threshed out at the time of harvesting it is very liable to become mouldy and to be eaten by insects, and therefore it should be frequently examined. Some fumigate with weak fumes of sulphur or pyrolignic acid; others mix a small quantity of soot, to prevent animal and vegetable growth. Some farmers hang up in bags what seed they require in the kitchen chimney, and when sufficiently dried to prevent insects and the spores of Fungi doing any harm, the seed-bags are hung up in a dry place until seed time. In both these plans of preserving the seed very great care is necessary not to injure its vitality, otherwise the seed will braird weakly, and so on.

Corn Harvest last year (1870) was general by this time in the southern counties of England. This year it is later. *W. B.*

Markets.

ENGLISH WOOL.

The demand during the last week has been unabated, at gradually hardening prices, and our views in this respect appear to have been fully carried out. American buyers have been operating lately, and we believe everything points to still higher prices.

HOPS.

BOROUGH MARKET, July 13.

Messrs. Pattenden & Smith report that the prospects of the coming crop are still more unfavourable than a week ago. The cold ungenial weather causes the bine to look very weak and unhealthy, and there is still a large quantity of lice throughout the plantations in general. The market is consequently very firm, and prices have an upward tendency. Holders of choice samples stand out for a considerable advance.

METROPOLITAN CATTLE MARKET.

MONDAY, July 10.

We have a very short supply of Beasts, especially of choice English; trade is active, at fully late rates; in some instances our top quotations have been rather exceeded. There are very few more Sheep than last week; trade is not quite so brisk throughout, and prices are scarcely altered. Choice Lambs are in demand, although not quite so dear as on Thursday. Calves are on the average lower. Our foreign supply consists of 750 Beasts, 10,300 Sheep, 450 Calves, and 65 Pigs; from Scotland there are 80 Beasts; from Norfolk and Suffolk, 500; and 1140 from the Midland and Home Counties.

Beasts, 1090; Sheep and Lambs, 13,500; Calves, 737; Pigs, 35.

MARK LANE.

MONDAY, July 10.

There was again a very short supply of English Wheat to this morning's market, but the trade was dull, and it could only be disposed of at a decline of fully 2s. per qr. The attendance was good, but the few sales made in foreign were in retail, at a similar reduction. Barley, Beans, and Peas were unchanged in value. The Oat trade was dull, as about last week's prices. Flour was slow, and rather cheaper.

WEDNESDAY, July 12.

A dull feeling pervaded the Corn Exchange to-day, and prices exhibited much weakness. The supplies of English Wheat were short, but from abroad they were larger. Transactions in all descriptions were restricted, at prices tending downwards. Barley dull; sold on former terms. Malt was dull, at about late rates. There were good supplies of Oats, which changed hands to a limited extent, at drooping prices. Beans and Peas were in slow demand, at recent values. Flour was depressed, and prices in some instances were further reduced.

SEED MARKET.

Inactivity continues to characterise the seed trade. For the moment there is no speculation whatever in any single article. Rape and Mustard move off in retail, at unaltered currencies. The large quantity of Trifolium seed which will be saved causes cheap offers to come to hand from the country. Hemp and Canary meet with a quiet demand.

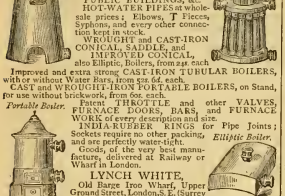
Patent THROTTLE and other VALVES, FURNACE DOORS, BARS, and FURNACE WORK of every description and size.

INDIA-RUBBER RINGS for Pipe Joints; Sockets require no other packing, and are perfectly water-tight.

Goods, of the very best manufacture, delivered at Railway or Wharf in London.

LYNCH WHITE,
Old Barge Iron Wharf, Upper Ground Street, London, S. E. (Surrey side Blackfriars Bridge). Price List on application.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.



These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "Patent Double L Saddle Boiler" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and, being made of wrought iron, are not liable to crack. They are made of the following sizes :—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	5 0 0

GRAY'S OVAL TUBULAR BOILER.

INTERNATIONAL EXHIBITION, CLASS IX., NO. 2119.

MR. GRAY begs to call the attention of the Nobility, Gentry, Nurserymen, Gardeners, &c., to his

NEW OVAL TUBULAR BOILER.

Acknowledged by practical judges to be a great improvement on every form of Tubular Boiler yet introduced. It has proved itself superior to all other Boilers for quickness of action and economy of Fuel, doing its work with one-third less the amount required by any other.

Extract from Report in GARDENERS' CHRONICLE *of International Exhibition, May 24, 1862, page 476.*

"The upright form of Boiler is usually made on a circular plan, but the oval form given to Mr. GRAY'S variety of it is, said to be preferable in consequence of its bringing the tubes in closer contact with the fire. The usual form of a furnace being a parallelogram rather than a square, it seems feasible that the Boilers on the oval plan should bring the tubes more completely within range of the burning fuel; and this being so, the change, though a slight one, is no doubt an improvement."

☞ *They are made of all sizes, which, with prices, may be had on application.*

JAMES GRAY, HORTICULTURAL WORKS,
DANVER'S STREET, PAULTON'S SQUARE, KING'S ROAD, CHELSEA, S.W.

J. C. & J. S. ELLIS,
HORTICULTURAL ENGINEERS,

NORFOLK FOUNDRY, SHEFFIELD,

MANUFACTURERS and ERECTORS of HOT-WATER APPARATUS

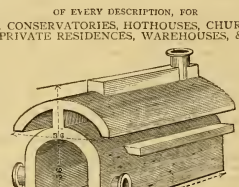
OF EVERY DESCRIPTION, FOR

HEATING GREENHOUSES, CONSERVATORIES, HOTHOUSES, CHURCHES, PUBLIC BUILDINGS, PRIVATE RESIDENCES, WAREHOUSES, &c.

The great advantages of these Boilers are :—

The fire acting directly under the flow pipe, the water begins to circulate immediately.

The Flues all being formed by a continuous water-way, the fire and all the hot gases are brought in direct contact with the heat-absorbing surface of the Boiler, thereby giving a greatly increased amount of power, and by which an immense saving of fuel is effected.



PATENT DOUBLE-ARCH BOILER.

These Boilers offer great facilities for banking-up the fire, and will burn easily from 12 to 14 hours without attention.

The arrangement of Soot-doors in the brickwork is such that all the flues can be cleaned in a few minutes.

TESTIMONIALS.

"The Gardens, Chatsworth, January 19, 1871.

"DEAR SIR,—After using your Patent Double-Arch Boiler for the past 12 months, enables me to speak with a practical knowledge of its merits; and I have no hesitation in saying, out of many Boilers, of all sorts of construction, we have in use, it is the most efficient, and I believe it to be the best Boiler extant; neither do I think there is another that exposes so much surface to the direct action of the fire. Its efficiency, economy in fuel, and the minimum of attention, renders this Boiler a valuable improvement in Horticulture, and it reflects great credit on your good sense in designing it. I shall be glad to show the one I have in use to any person calling at Chatsworth.

I remain, dear Sir, yours truly, THOMAS SPEED.

"Mr. Ellis."

"Westbourne Gardens, Sheffield, October 27, 1870.

"DEAR SIR,—Your Patent Double-Arch Boiler, that you have put down for us lately, to heat the whole of our houses, answers admirably. Its heating surface exceeds all others which I am acquainted with. The small amount of fuel required, the way it is set, and the arrangement of soot-doors, renders it the most complete and economical Boiler I have had to do with.—Believe me, Sir, yours truly,

"W. H. BIRD.

"Mr. Ellis, Norfolk Foundry, Sheffield."

THE LANDS IMPROVEMENT COMPANY.
(Incorporated by Special Acts of Parliament.)
Drainage, Reclamation, Farm Buildings, Labourers' Cottages, &c.

DIRECTORS.

John Clutton, Esq.	Granville R. Ryder, Esq.
Frederick L. Dashwood, Esq.	Granville E. H. Somerset, Esq., Q.C.
Henry Farquhar, Esq.	Henry W. West, Esq., M.P.
Lord Garlies, M.P.	Charles Wetton Williams Wynn, Esq., M.P. (Chairman).
John Horatio Lloyd, Esq.	

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy in respect of their Glebe Lands.

Tenants may, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.

UTILISATION of SEWAGE—The Company also advances money for the purpose of Works of Sewage Irrigation.

The whole outlay and expenses are liquidated by a rent-charge upon the land, redeemable at the option of the tenant, over 25 years.

No investigation of title is required.

For Forms and further information, apply to GRANVILLE R. RYDER, Esq., Managing Director, No. 1, Great George Street, Storey's Gate, Westminster, S.W.

Agricultural Land Improvements.

DRAINAGE, SEWAGE IRRIGATION, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY
(Incorporated by Act of Parliament in 1849.)

DIRECTORS.

T. Chapman, Esq., F.R.S.	The Right Hon. Viscount Combermere.
George Thomas Clark, Esq.	Edward John Hutchins, Esq.
John C. Colcbrd, Esq.	Sir William Tite, M.P., C.B.
Henry William Currie, Esq.	

Principal Engineer, Mr. J. BAILEY DENTON.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works by their own agents.

Tenant Farmers may also, by agreement with their Landlords, promote the execution of such Improvements.

The outlay, with all official expenses, may be charged upon the Estate, and paid off by a Rent-charge of 5 per cent., for a term of years, at 3½ per cent., at the option of the Landowners in a shorter term.

No investigation of title necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.

Special arrangements will be made with Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, discharging in a fixed period the principal amount with interest thereon.

Application to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 22, Whitehall Place, S.W.

ZOOLOGICAL RECORD ASSOCIATION.—This Association has been formed for the purpose of continuing the publication of the RECORD of ZOOLOGICAL LITERATURE, commenced six years ago by Dr. GÜNTHER, F.R.S., who has resigned his Editorship to Professor Newton.

The RECORD consists of an Annual Volume, containing a very complete Abstract of and Index to the Zoological Literature of the preceding year; and its use has been so generally recognised, that for the last four years the British Association has voted (on the unanimous recommendation of the Committee of the Biological Section) a liberal grant in its aid.

The Contributors to the forthcomoig Volume are—

Mammalia, Reptilia, and Pisces	Dr. Günther, F.R.S.
Aves	H. E. Dresser, F.Z.S., and R. B. Sharpe, F.L.S.
Mollusca, Molluscoides, and Crustacea	Dr. E. von Martens, F.M.Z.S.
Arachnida and Myriopoda	Rev. O. Pickard-Cambridge, C.M.Z.S.
Cleoptera and Hymenoptera	E. C. Rye.
Lepidoptera	W. F. Kirby.
Diptera	O. H. Verrall.
Neuroptera and Orthoptera	R. M'Lachlan, F.L.S.
Rhynchota	John Scott.
Vermes	E. Ray Lankester.
Echinodermata, Coelenterata, and Protozoa	Professor Traquair, M.D.

This Association consists of Members and Subscribers. The Members are liable to the extent of £5, in the event of the Funds from all other sources proving insufficient to meet the liabilities of the Association.

Subscribers pay annually, on July 1, 20s., but incur no other liability.

Gentlemen wishing to join the Association as Members or as Subscribers, are requested to communicate with the Secretary, H. T. STAINTON, F.R.S., Mountsfield, Lewisham, near London, S.E.

Upwards of Eighty of the leading Zoologists of the country have joined the Association as Members.

THE EDINBURGH REVIEW, No. CCLXXIII., JULY, is just published.

Seed Warehouse: 44, English St., & Blackfriars St. NURSERIES & SEED FARM: KNOWFIELD, near CARLISLE.

THE SUBSCRIBERS having entered upon possession of the Old-established SEED and NURSERY BUSINESS so long carried on by Messrs. LITTLE AND BALLANTYNE, of this city, respectfully request a continuance of the support so liberally accorded to the Old Firm. They shall continue to conduct the business as already carried on under the Firm of LITTLE AND BALLANTYNE, and they will endeavour to merit the confidence of the Trade by close personal superintendence in every department of their Business.

LITTLE AND BALLANTYNE.
WM. BALLANTYNE SMITH, } Sole

July 1, 1871.

WILLIAM MOORE, Deceased.—All PERSONS INDEBTED TO, or having any CLAIMS against the Estate of WILLIAM MOORE, late of East Dereham, Norfolk, Nurseryman, deceased, are requested to PAY THEIR DEBTS, and send particulars of their CLAIMS to me, the undersigned, JAMES ELVIN, Executor, before October 11 next; after which day the said Executor will not be answerable or liable for any claims or demands he shall not then have had notice of.

(Signed) JAMES ELVIN.

East Dereham, July 18, 1871.

The Cheapest and Best Insecticide.

POOLEY'S TOBACCO POWDER.

Of all Nurserymen and Seedsmen.

Weeds Eradicated from Lawns.

WATSON'S LAWN SAND both Destroys Dandelions, Daisies, Plantains, Ribbed Grass, &c., and invigorates the Grass, keeping it green during hot or dry weather. Cleanly and inodorous. 30s. per cwt.; 56-lb. tins, 10s. Directions and testimonials on application.

Principal Agent —W. D. BARBOUR, 3, Park Row, Leeds.

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS are made in materials of great durability. The planer vors are especially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.

F. AND G. ROSHER, Manufacturers, Upper Ground Street, Blackfriars, S.E.; Queen's Road West, Chelsea, S.W.; Kingsland Road, E. Agents for LOOKER'S PATENT ACME FRAMES, PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., from 3r. per square yard upwards. Pattern Sheets of plain or more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Rangers, Baths, &c. Grooved and other Stable Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds, Roofing Tiles in great variety, Slates, Cements, &c.

F. AND G. ROSHER, Brick and Tile Merchants.—See addresses above.

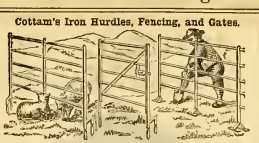
SILVER SAND, fine or coarse grain as desired. Fine 14s., Coarse 17s. per Ton. In Truck Loads 1s. per Ton less. Delivery by Cart within three miles, or to any London Railway or Wharf, as per Ton extra. Samples of Sand free by post.

FLINTS and BRICK BURRS for Rockeries or Pemeries. KENT PEAT or LOAM supplied on lowest rates in any quantities.

F. AND G. ROSHER.—Addresses see above.

N.B. Orders promptly executed by Rail or to Wharves. A liberal discount to the Trade.

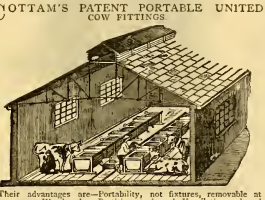
Cottam's Iron Hurdles, Fencing, and Gates.



COTTAM'S HURDLES are made in the best manner, of superior Wrought Iron, by an improved method.

Illustrated Price Lists on application to COTTAM AND CO., Iron Works, 2, Winsley Street, Oxford Street, London, W.

COTTAM'S PATENT PORTABLE UNITED COW FITTINGS



Their advantages are—Portability, not fixtures, removable at pleasure; no Woodwork or Partitions to impede Ventilation or breed Vermin; Hay Rick dispensed with as unnecessary; increased width and depth of Feeding Troughs, Water Cistern, and Patent Drop Cover to prevent over-gorging. Cleanly, durable, and impervious to infection, being all of Iron. Price of Fittings per Cow, 55s.

Prospectuses free of COTTAM AND CO., Iron Works, 2, Winsley Street (opposite the Pantheon), Oxford Street, London, W., where the above are exhibited, together with several important Improvements in Stable Fittings just secured by Patent.

By Appointment to H.R.H. The Prince of Wales.

BARTON'S PATENT STABLE and HARNESS ROOM FITTINGS, BRACKETS, &c.

Patronised by H.I.H. the Viceroy of Egypt, the King of the Belgians, the King of Italy, the King of Holland, by the principal Nobility of the Kingdom, and adopted by the first Architects and Builders of England and the Continent. Illustrated Catalogues sent on receipt of 1s. stamps.

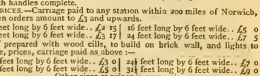
For ALTERATION of STABLES a competent person can be sent to any part, to inspect and give Estimates.

JAMES BARTON, Iron Works, 370, Oxford Street, W.

W. S. BOULTON AND CO., Norwich, HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MANUFACTURERS.

New labour-saving machinery enables us to supply first-class CONSERVATORIES, VINERIES, ORCHARD HOUSES, FORCING PITS, &c., at very low prices. Designs and Estimates furnished. Carriage paid to any station in the kingdom.

MELON and CUCUMBER LIGHTS ready for delivery.



These are strong and well-made Sliding Lights, glazed, and painted three coats. Height of frame, 14 inches in front, 25 inches at back. With handles complete.

PRICES.—Carriage paid to any station within 200 miles of Norwich, when orders amount to £3 and upwards.

6 feet long by 6 feet wide.. £2 15 | 16 feet long by 6 feet wide.. £5 0
12 feet long by 6 feet wide.. £3 17 | 24 feet long by 6 feet wide.. £7 5

If prepared with wood cills, to build on brick wall, and lights to slide, prices, carriage paid as above :—

10½ feet long by 6 feet wide.. £3 0 | 24½ feet long by 6 feet wide.. £7 0
17½ feet long by 6 feet wide.. £5 2 | 31½ feet long by 6 feet wide.. £9 0

Other sizes at prices in proportion.

PLANT PRESERVERS.

Illustrated Catalogues free on application.

Rose Lane Works, Norwich.

The Gardeners' Chronicle
SATURDAY, JULY 22, 1871.

FARMERS long held the notion that the presence of the Barberry (Berberis vulgaris) in their hedges was prejudicial to the Wheat crops in the adjacent fields. As there seemed on the surface no good reason for this, botanists and scientific men scouted the notion. That the Fungus so common on the Berberis (Æcidium berberidis) should have anything to do with the Uredo rubigo of the Wheat, or with the Puccinia, seemed too absurd a notion to be at all credible. Nevertheless, changes as strange do occur in other cases, and the forms and stages through which some of the Fungi pass should at least lead us to give a fair hearing even to the enunciation of the most startling notions, provided they are made by persons whose attainments are such as to warrant us in placing some confidence in their judgment.

Few things in Nature, for instance, can be more unlike than the fleshy orange-coloured Fungus so often found on the Savin (Podisoma Juniperi Sabinæ), and the small crisp flask-like Fungus which appears on the leaves of Pears (Roestelia cancellata), yet it was shown by Prof. Oersted, of Copenhagen, that the one is but a form of the other. The Danish Professor, as we have previously recorded, proved this by inoculating the Pear with the Fungus of the Savin. Naturally the statement was received with incredulity, and requires the concurrent testimony of many witnesses before it can be definitely accepted. One such witness is M. Roze, who repeated Oersted's experiments with success. Last May we had an opportunity of seeing in Paris another case of the same nature, in which the French botanist just named had succeeded in inducing the presence on the Hawthorn of Roestelia (Æcidium) lacerata, by placing on the young shoots the minute spores of another fleshy Fungus commonly found on the Juniper, viz., Podisoma clavariæforme.

The method or procedure adopted by M. Roze was to detach from the Juniper some of the fleshy tongue-like masses of the Podisoma. These were just moistened with water, and placed in watch glasses, under a bell glass. After twenty-four hours the Fungus had swollen greatly, from the imbibition of water, the sporangia or sporecases became erect, and from several of them proceeded fine threads, bearing the sporidia or seeds. Some of the latter were removed by a camel's-hair brush, and transferred to the leaves and young shoots of the Hawthorn. The sporidia so sown immediately germinate, emit a filament which penetrates the epidermis of the young branches. Eight days afterwards yellowish spots were observable on the Hawthorn, and in a month's time the leaves of the Hawthorn were more or less thickly covered with the Roestelia lacerata. Similar experiments made with Podisoma fuscum, an allied form, had only negative results.

These experiments require to be repeated with the greatest caution by other observers; but we think enough has already been done to show that the ridicule excited at the onset by the statements of the Danish botanist was ill-timed and out of place.

When informing us of the entire success of the first or experimental Rose show at Manchester, alluded to last week at p. 911, Mr. Findlay threw out an excellent suggestion as to a Conference for fixing Dates, which the different societies would do well to take into consideration. The success realised on this occasion leaves, he thinks, little room to doubt that Manchester will see an annual show of the same kind; and he goes on to make the following apposite remarks:—"There are so many Rose shows held in the country just now, that I think the time has arrived when there should be a kind of conference of the representatives of the leading societies throughout the country, in order to arrange dates, with a view to avoid clashing. The week before last, for instance, three important Rose shows were held—Kensington on the 5th, Birmingham on the 6th and 7th, and Manchester on the 7th and 8th. The dates should be arranged not later than Christmas." It would be a manifest advantage if some arrangement of this kind could be adopted; and the suggestion need by no means be confined to Rose shows, but might well be extended to all great floral gatherings, and to none with more reason than to the Metropolitan exhibitions, which are becoming much too numerous, and which we believe would be brought far more of by the public if each Society would confine itself to one show a year, and endeavour to make that as perfect and attractive as possible. We are not now alluding to the bi-monthly meetings at Kensington, which are mainly held for the sake of exhibiting novelties; and which have latterly been somewhat simplified, in consequence of the proximity of the International Exhibition; but we refer to what the Societies themselves designate and advertise as their Great Summer Shows. In any case it would seem that the amenity of conferring together, as to dates, could have no other than a salutary effect.

—— Monster Mushrooms seem to be unusually abundant this year. At the meeting of the Royal Horticultural Society on the 5th inst., Mr. Cole, of Woolhampton, showed a boxful of very large and succulent specimens, measuring from 8 to 10 inches across; but these seem to have been eclipsed by others gathered in different parts of the country, as recorded in the local papers. Here are some of these modern instances:—"A large Mushroom, lately gathered in the parish of Fenton-by-Newark, Lincolnshire, was 54 inches in circumference, the stem was 9 inches round, and the weight was 4½ lb. (*sic*). It was a fine and perfect specimen, and of a beautiful red colour." Again: "Two monster Mushrooms were gathered in a meadow at Old Hays, Ratby, Leicestershire; they were perfect in shape, without a blemish of any kind, and of the following dimensions:—No. 1, circumference, 2 feet 9 inches, diameter, 9½ inches, weight, 14¼ oz.; No. 2, circumference, 2 feet 5¼ inches, diameter, 9 inches, weight, 14 oz." Again: "At Bromsgrove a specimen 10¼ inches in diameter, and 5 inches high, weighed 1 lb. 2 oz." Again: "At Enstone, Oxfordshire, a specimen was gathered which measured 2 feet 10 inches in circumference, and was perfectly round and flat." These, no doubt, are good examples of Agaricus arvensis. The gigantic Gooseberries must look to it, or they will be quite superseded.

—— One of the most remarkable productions at the South Kensington meeting on Tuesday last was the fine group of Lily of the Valley, in full bloom, from Messrs. Standish & Co. The flowers were as large and perfect as usual in spring. We understand from Mr. Standish that they are part of a considerable quantity obtained last autumn for forcing purposes, but that it was found they would not force, the usual stimulating influences being quite ineffectual in their case, but that when planted outdoors in shady places they have done thus late into bloom. They must be of a distinct variety, the leaves being unusually short and broad, and marked with darker green veins, and the investing sheaths at the base of their stems being of a deep red colour. As extending the season of the Lily of the Valley, this variety will be invaluable.

—— One of the most remarkable productions at the Royal Botanic Gardens Plantes last year was the Zamioculcas, an Aroideous plant, having pinnate or bipinnate leaves, like those of some Aralia, and thus affording, it is believed, a solitary instance of the existence of compound leaves among eudogenous plants. We know not whether the plant has escaped the destruction from frost or fire which befel so many of its companions. The genus was founded on the Caladium zamiæfolium, of Loddiges' "Botanical Cabinet," a plant of south-east tropical Africa, very imperfectly known till last year, when it produced its flowers, and was examined by M. Decaisne. This plant has pinnate leaves, but a second species, also from Zanzibar, has bipinnate leaves, the leaflets of which are deciduous, and the common stalk swollen as in Anthurium. Loddiges' plant was supposed to have been derived from Brazil, but this is now shown to be an error. The name, Zamioculcas, given by Schott, and which signifies Zamia-like Colocasia, affords, says M. Decaisne, an illustration of the inconvenience that accrues from founding a generic name upon the aspect of a species, since the name is only significant of the first species, Z. Loddigesii, with impari-pinnate Zamia-like foliage, and not to the new species, Z. Boivinii, which has bipinnate leaves like an Aralia. The technical description of the genus, and other matters above referred to, will be found at p. 321 of the "Bulletin de la Société Botanique de France," vol. 17 (1870).

—— The following letter from a correspondent in reference to The Horticultural Provincial Dinner (see p. 907), deserves consideration:—"If the dinner is looked upon as an honour to the Council chiefly, your view is the right one. Common modesty, as well as etiquette, forbid them to move in the matter; but I hold that the dinner should be held for the *good of horticulture*, and, looked at thus, there is no more egotism in eating a dinner with one's friends than in gathering them together to see a show. Horticulture has a social as well as a cultural side to it, and while the one has been stimulated to the utmost, the other has been neglected. Is it, therefore, any wonder that it sometimes runs to seed? I know of no greater service that the Royal Horticultural Society could render to horticulture at the present time than the binding of its practical supporters more closely to itself by social intercourse, such as an occasional dinner, *soirée, conversazione*, or congress. I will not say we want the patronage of any, but many of us yearn for sympathy. We are accustomed to manifestations of respect and kindly feeling from the highest and the best in the land, and have a right to expect something different than hurried impatience and cold shoulder from the representatives of a Society which exists for the advancement of horticulture: and, as one great means to this end, the elevation of horticulturists."

—— At last something is to be done with the Alexandra Palace, at Muswell Hill. The principle of a prospectus now before us is the Tontine one, by which every subscriber is to have what are termed Right Certificates, to which are attached certain privileges in proportion to the price paid. These include admission to the Palace and grounds, and competition in art unions, giving a chance to each 21*s.* subscriber of securing five prizes of £500 each. In 1886 the whole property will be sold, and the proceeds divided amongst the Tontineers. To provide against loss in the event of death, an insurance office has agreed, in consideration of the payment of 1*s.* on every 21*s.* right, to refund 20*s.* of every such guinea upon the death of the life so insured should it occur before the close of the Tontine. As all the profits on this undertaking are to go towards the improvement of the property, the value of which (with the building fund surrounding the grounds) stands at present very high in the market, it is probable that on the sale in 1886 the return to the Tontineers will be such as to have made the investment of a lucrative character. For the details of the scheme we must refer to the prospectus, but we may remark that as the promoters incur no any liability, as it is a trust matter. It will be remembered that Captain Fowkes' domes for the Exhibition of 1862 were removed to Muswell Hill, where they form a landmark for miles around. The garden arrangements are, we believe, entrusted to Mr. McKenzie.

—— We are informed that a Supplemental Rose Show will be held at the Crystal Palace on August 5 next.

—— With reference to the Sisyrinchium bermudianum, alluded to in our last number as having been found in Hampshire, we have this further information from the finder:—"The plant grows in one part of a wood, within a radius of 10 or 15 yards, where it is pretty abundant. It grows amongst low, thick Oak underwood, and the rank grass, the place being a moist one, and near a small running stream, which comes from the direction of the New Forest. There is a small cottage and garden near the edge of the wood, about 100 yards from the place where the Sisyrinchium is found, to the south-west, the prevailing wind being W.S.W. No other garden is near, and the wood is a private one." It is possible the plant is an escape from the garden aforesaid, or from some other; but in any case, it is singular it should have hitherto escaped notice.

—— The extreme Maximum Temperatures recorded at each of the stations in England during the week ending July 15, ranged from 80° to 81° at Blackheath to 69° at Newcastle, with a mean for the different stations of 74°, or about 2° above the mean for the several stations in Scotland—where 75° at Perth and 69° at Aberdeen were the highest and lowest. The extreme Minimum Temperature registered at any station was 45°.9 at Salford, whilst at Newcastle the lowest recorded was 54°. The means for the two countries were very nearly of the same value, viz., for England 48°.4, and Scotland, 48°.6. The Mean Temperature of England, as deduced from the observations taken at the different stations, exceeds that of Scotland by 1°.7. In the former country 61°.7 at Blackheath and 61°.3 at Norwich were the highest, and 57°.6 at Salford the lowest, mean temperatures, and in the latter country the extremes are represented by 59°.5 at Perth, and 56°.6 at Paisley.

RAINFALL.—The principal falls of rain appear to have taken place south of latitude 53°, the mean fall for the stations below that parallel being 1.17 inch, and for the English stations above, 0.57 inch,—the Scotch stations having a mean of 0.33 inch only. The principal falls in the two countries were, at Portsmouth 1.92 inch; Blackheath, 1.51 inch; and Nottingham, 1.26 inch. (See Mr. GLAISHER'S Tables in our present issue.)

—— In the last volume of the "Transactions of the Botanical Society of Edinburgh" mention is made of a Brazilian plant, the scientific name of which is not given, the leaves of which are eaten by a large lizard during or after its combat with venomous snakes. The people of the country say that it is an ANTIDOTE to the SERPENT POISON. It is interesting to notice here the similar superstition which in former times attached in Europe to the Michaelmas Daisy, Aster Tripolium, of which we are told that "when a spider stings a toad, and the toad is becoming vanquished, and cannot defend itself, it bursts asunder. But such a burst toad is near this plant, it chews it, and becomes sound again." The same belief occurs in another form in more than one German fairy-tale. Hares are similarly defended from all disease by eating of the Sowthistle, which used to be called on this account "Hare's Palace;" and must have been to the Ieporine race as invaluable as Parr's Life Pills and similar specifics are said to be to human beings.

—— Amongst ECONOMIC PLANTS the TOBACCO is undoubtedly the most widely used. Volumes of matter have been written on the subject in its various phases, which are about as numerous as the range of its applications is wide. The "weed" is an important article in the commerce both of civilised and uncivilised countries, and some ingenuity is frequently shown, and much trouble gone through, in preparing the leaves, and afterwards enjoying their narcotic effects. In some parts of the East Indies, for instance, the natives use a black, disagreeable-looking and heavy smelling compound of dried and pounded tobacco leaves, palm-sugar from Borassus flabelliformis, the pulp of the Banana, and Rose water; these are all well mixed together, and constitute hookah tobacco. To keep this damp, clammy stuff alight in the hookahs they use fire-balls, which are somewhat larger than a walnut, and are made of fine charcoal of teak-wood, mixed with rice paste and a little sandal-wood to give it a perfume. In different parts of Africa various plans prevail in the curing of and trading in tobacco, On the Zambesi River, and on the Mangwe River in Matabililand, the leaves after being cured are pressed into wooden moulds of a bowl shape, a stick with a knob at the bottom being first placed upright in the centre of the bowl, and the tobacco pressed tightly around it; this stick is afterwards used to withdraw the compressed mass from the bowl, and the hole left by the stick after it has itself been withdrawn is used to pass a string through for convenience in carrying. A very tightly rolled kind, something like Cavendish, is manufactured by the Kaffirs in very large quantities, which they use not only for smoking, but also for making snuff. At certain periods of the year the bushmen—a wandering race, who neither sow nor plant, but live entirely upon game, wild roots, and plunder—come down from the mountains they inhabit to purchase this commodity from the Kaffirs, for which they make payment in horses and mares they have stolen, either from the European settlers, or other Kaffir tribes, hundreds of miles distant from the place of exchange.

—— Botanists are frequently taxed with the want of euphony and of poetry in the PLANT NAMES which they bestow; and it must be admitted that many fearful "jawbreakers" might be cited in support of the charge. Occasionally, however, we find names bestowed in a more romantic spirit; and such is the case with the Andromeda, a title which Linnæus first bestowed upon another Kaffir example of the genus, A. polifolia. In his "Tour in Lapland" he tells us of the connection between the flower and the heroine of mythology which led to his selection of the name :—

"As I contemplated it, I could not help thinking of Andromeda, as described by the poets; and the more I meditated upon their descriptions, the more applicable they seemed to the little plant before me; so that had these writers designed it, they could scarcely have contrived a more apposite fable. Andromeda is represented by them as a virgin of most exquisite and unrivalled charms; but these charms remain only so long as she retains her virginal purity, which is also applicable to the plant now preparing to celebrate its nuptials. This plant is always fixed on some little turfy hillock in the midst of the swamps, as Andromeda herself was chained to a rock in the sea, which bathed her feet, as the fresh water does the roots of this plant. Dragons and monstrous serpents surrounded her, as toads and other reptiles frequent the abode of her vegetable resembler, and when they pair in the spring, throw mud and water over its leaves and branches. As the distressed virgin could not relieve herself by using force through excessive affliction, so does this rosy coloured flower hang its head, growing paler and paler till it withers away. . . . At length comes Perseus, in the shape of summer, dries up the surrounding water, and drives away the monsters, rendering the damsel a fruitful mother, who then carries her head (the capsule) erect."

—— We gave at p. 771, a figure of Mr. DRECHSLER'S Carrot-boarding machine, and now add a representation of his WINNOWING MACHINE, which being made of various sizes will be useful to all those who grow seeds, whether for private use or commercially. The following description will, with the aid of the woodcut (fig. 200), make it clearly understood :—A is the passage for the dirt; B, handle inside the hopper, by which to carry the machine; C, lever to regulate the fall of the seed from the hopper at D; E shows where the second quality of seed falls down, the best quality falling down the inclined plane A, and coming out in the middle of the machine near F. A box must be placed under the machine, reaching from 1 to 2, to receive the clean seeds, and another much smaller under E to take the second quality of seeds. The lever-guide is saw-like underneath, and the lever has a wedge-like point falling or rather pressing into those notches; the lever is made of spring steel for this purpose, and made to press from the machine, which is considered an improvement on all previous arrangements. This winnowing machine affords a medium between the slow and imperfect fan, and the cumbrous, unwieldy, and complicated winnowing machines, which are not at all suited for small quantities of flower or vegetable seeds, especially when they are light. The blast may be regulated by turning slower or faster, and is powerful enough for any kind of seeds. The machine may be used on a counter, or table, or on the floor. It is also intended to send it out packed in a close

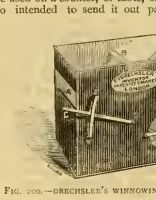

FIG. 200.—DRECHSLER'S WINNOWING MACHINE.

substantial case, made so as to be readily converted into a stand. This stand, while admitting of working the machine without stooping, will also guide the seeds into any shallow box which it may be convenient to use. The different sizes will respectively hold 1 to 2 pecks, 3 to 4 pecks, and 5 to 6 pecks. Mr. DRECHSLER'S address is 63, Arlington Street, N.W.

—— At one of the recent meetings of the Scientific Committee, Mr. BERKELEY exhibited ROOTS of ADIANTUM SETULOSUM studded with small tubercles, like those found on the roots of many leguminous plants. We are now, thanks to Mr. BERKELEY, able

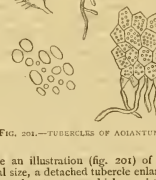

FIG. 201.—TUBERCLES OF ADIANTUM SETULOSUM.

to give an illustration (fig. 201) of the roots, of the natural size, a detached tubercle enlarged, and a section showing the structure, which consists of an epidermis with long hairs, enclosing a mass of hexagonal cells filled with ovoid starch grains of very unequal size.

New Garden Plants.

SACCOLABIUM BUCCOSUM, *n. sp.*

Foliis ligulatis, apice oblique obtuseque bilobis; racemo pauciflore, subdensiflore; floribus erectis, parvis; bracteis triangulis ovariis pedicellatis multo brevioribus; sepalis oblongis acutis; petalis ovatis bene brevioribus; labelli lamina libera trifida lacinis lateralibus ovatis acutis, lacinia media lanceolata acuta carinulis geminis per discum, calcari cylindraceo depresso apice dilatato obtuse emarginato angulo prominulo in pariete superiori intus; columna brevi, triloba, fovea stigmatis tegmine cincta, ad latera bucris prominulis obtusangulis; anthera rhombea rostrata: pollinis triangulis inferne sulcatis; caudicula lineari bene incurva, glandula minuta.

A plant in the way of Saccolabium micranthum (Lindl.), but with yellowish flowers, with a few dark purplish-brown dots on the side lacinie of the lip, and the spur, and a very peculiar, queer column, that would perhaps be sufficient to establish a new genus, if we knew in all cases the structure of the columns of the Saccolabia which have been only seen in a dried state. I am indebted for this very interesting botanical novelty to my invaluable correspondent, J. Day, Esq., who imported it from India. *H. G. Rchb. fil.*

CALANTHE PLEIOCHROMA, *n. sp.*

Foliis petiolatis oblongis acuminatis; pedunculo elongato minute velutino; bracteis oblongis acutis; ovariis pedicellatis velutinis plus triple brevioribus; sepalis petalisque oblongis acutis; labelli adnati laciniis posticis semiovato-falcatis albescentibus anticeps; lacinia media ab ungue late flabellato biloba; calli seriebus tribus a basi in basin unguis, multipapulosis; calcari gracili filiformi; ovario pedicellato bene breviore.

Very near Calanthe versicolor and sylvatica, but these have a much wider, usually straight spur, a much shorter-stalked ovary, and a nearly sessile middle part of the lip. The flowers are as large as those of the species just named, whitish, with a light purplish hue in front, then they become yellowish, the lip darker ochre colour, with reddish-orange calli at the base. This very unexpected novelty came from Japan to the Veitchian Royal Exotic Nursery, flowering in May. *H. G. Rchb. fil.*

ODONTOGLOSSUM TRIPUDIANS, *Rchb. fil., Warsw.; Seemann's Bonplandia*, ii., *Walp. Ann.* vi. 830; *Hamb. Gtz.* 1857, 212.

Sepalis cuneato oblongis acutis; petalis subaequalibus, labello ab angue brevioribus, unidentatis obtuse emarginato toto limbo serrulato, ima basi cordato; carinis supinis in dactylos liberos acuminatos excentibus, radiantibus, a basi in discum, genuis illa maxima uncinatis, nunc interjecto pari minori secundo; columna supra unguem angulata, alis circa foveam serratis.

A very nice Odontoglossum, in the way of Odontoglossum cristatum, but with a blunt lip. The sepals and petals are brown, with yellowish-green edges, and dots few in number. The lip has a white basilar disk. The region around the calli is of a beautiful purplish-violet, and there are some brown bars and blotches around the basilar part of it. The column is whitish, with purplish-brown wings, and a similar limb to the angull. The species was originally figured by Von Warscewicz in Costa Grenada. Then it appeared in 1857, in the Lindenian establishment; and Christmas, 1870, once more in the celebrated Dayan collection. J. Day, Esq., kindly informs me it came from Mr. Low's great sale in February, 1870. *H. G. Rchb. fil.*

THE AMATEUR GARDENER.

Culture of Hyacinth Bulbs in England.—The conclusion appears to be generally arrived at that Hyacinths must be imported from abroad year by year if good, healthy bulbs are to be secured, unless after flowering in pots or glasses, they are put into the borders of the garden, with no great expectation of their doing much good. We believe that, in most instances, these bulbs, which have done their work for a season, are generally neglected, perhaps left in a tool-house, or thrown aside in some corner of the garden to rot. There is no wonderful if anything more were seen of them in a growing condition, or, at the most, they reappear in some small imperfect growths in the borders. There can be no doubt that the soil and climate of Holland are specially favourable to the successful growth of these beautiful flowers, and there is no valid reason why its culture should not be successfully carried on in England. The soil should be sandy, and it can be artificially made so; and the substratum should be moist to feed the deeply descending roots—a condition which may, partly at least, be secured by art; for instance, by placing a thick layer of well-rotted cow-dung 3 or 4 inches below the crown of the bulb. By observing these important requisites there is no doubt that Hyacinths may be grown from offsets till they acquire a fair size, and become available for pot or glass culture.

For the last three years we have turned out our Hyacinth bulbs from the pots and glasses as soon as the beauty of the flower was over, planting them in a warm border, in light sandy soil. This spring, there being a large accumulation of these old servants, some of them with fine healthy trusses of flowers, we took the whole of them and were agreeably surprised to find bulbs fully developed, and as round and compact as any foreign ones we have ever seen. A more healthy set of bulbs we do not desire to have, and we have set aside the best for pot and glass culture, intending not to purchase any in the coming season, as we have always done before. On former occasions we have found the bulbs get mouldy and become injured, by storing them away in boxes or drawers, but last year we avoided these evils entirely by keeping them in the open air from the time of taking up till that of planting. We place them singly, in semicircular drain tiles, and put one over them, so that a circulation of air is secured. We then stand the tiles one at the top of another, looking at them occasionally. They keep quite healthy in such a position, and we shall plant our present full-grown stock about the middle of September, putting some in glasses at the same time. We have separated all the offsets, planting them at once, as they are apt to wither when kept too long out of the ground. We hope in two or three years to find these fully grown, and, if so, we shall become nearly independent of the florist for a stock as good as we can wish for, only purchasing for the purpose of adding new sorts to our collection.

Besides the saving of expense, there is more interest in growing one's own Hyacinths from season to season, but it is only the careful amateur who can expect to succeed in the process we have described. This year, as we hinted above, the Hyacinths put out into the nursery border had flowers of the finest size and character, and that led us to take up the whole for

examination. In future we shall make home culture an express part of our garden work, and we hope our readers will follow our example, and record the result of their experiments. *H. B.*

ORCHID CULTIVATION.

[In compliance with a suggestion made by a valued correspondent, we reprint from the Preface to Dr. Lindley's "Orchidaceæ Lindenianæ" such portions as are relevant to the discussion going on in our columns on the subject of cool treatment of Orchids. We may here state that the disastrous events which have happened in Paris have hitherto prevented M. Triana from fulfilling the promise made some time since of communicating some notes on the climate of New Grenada. Eds.]

It was not without reason that Humboldt thus characterised the Orchids of Equatorial America. "Although," says that illustrious philosopher, "such plants are scattered through every part of the torrid zone, from the level of the sea to the height of 10,000 to 11,000 feet, yet it must be admitted that in the number of species, the colouring of their flowers, delicious fragrance, rich foliage and brilliant colours, none can be compared with those which inhabit the Andes of Mexico, New Grenada, Quito and Peru, where the shade is moist, and the breezes mild, the mean temperature of the year at an elevation of between 4800 and 6600 feet, being from 64° to 69°." Mr. Linden's collection shows that of 129 species nearly half are found in such localities.

If, however, any general conclusions are to be drawn from Mr. Linden's useful notes, it is necessary to examine the species in detail, and for that purpose they are classified in the following lists according to their elevation above the sea; the temperature of each group being computed from the data furnished by Humboldt:—

12,000 to 13,000 feet. Epidendrum frigidum.	*(Mean Temp. 40°.)*
11,000 to 12,000 feet.	*(Mean Temp. 46°.)*
Restrepia parvifolia.	Masdevallia affinis.
,, maculata.	,, polystacha.
Epidendrum chioneum.	
10,000 to 11,000 feet.	*(Mean Temp. 49°; Min. Temp. 32°.)*
Pleurothallis aurea.	Epidendrum tolimense.
,, lucida.	,, fimbriatum.
,, intricata.	,, refractum.
Diadesia rhodella.	Odontoglossum densiflorum.
Masdevallia tubulosa.	Pachyphyllum crystallinum.
,, caudata.	Telipogon latifolius.
,, affinis.	
9,000 to 10,000 feet.	*(Mean Temp. 52°.)*
Pleurothallis aurea.	Epidendrum flavidum.
,, intricata.	Evelyna furfuracea.
,, roseopunctata.	,, bracteosa.
Stelis? triura.	,, lupulina.
,, sesquipedalis.	Odontoglossum dipterum.
Masdevallia caudata.	,, divaricatum.
,, affinis.	Pachyphyllum crystallinum.
,, coccinea.	Telipogon latifolius.
Epidendrum tolimense.	Acraea multiflora.
,, carneum.	Cranichis parvilabris.
8000 to 9000 feet. *(Mean Temp. 56°; Max. Temp. 69°; Min. Temp. 36°.)*	
Pleurothallis chloroleuca.	Evelyna furfuracea.
,, bivalvis.	,, capitata.
Epidendrum fimbriatum.	Oncidium cucullatum.
,, torquatum.	Solenidium racemosum.
,, leucochilum.	Odontoglossum Hallii.
,, tigrinum.	,, epidendroides.
Evelyna bractescens.	,, luteo-purpureum.
,, kermesina.	Maxillaria ubata.
,, colliquorris	Uropedium Lindeni.
,, ensata.	
7000 to 8000 feet.	*(Mean Temp. 59°.)*
Pleurothallis bogotensis.	Epidendrum fallax.
,, semiscabra.	Evelyna flavescens.
Restrepia maculata.	,, furfuracea.
Masdevallia coriacea.	Oncidium cucullatum.
,, cuspidata.	,, baltcatum.
,, Schlimii.	Odontoglossum megalophium
Epidendrum brachychilum.	Maxillaria nigrescens.
,, tigrinum.	Sobralia violacea.
6000 to 7000 feet.	*(Mean Temp. 62°.)*
Pleurothallis ruberrima.	Odontoglossum angustatum.
,, undulata.	Nasonia sanguinea.
Stelis Lindeni.	Maxillaria meridensis.
Epidendrum recurvatum.	,, longissima.
,, xylostachyum.	,, tigrescens.
,, maxillachyum.	,, pentura.
,, sceptrum.	Ornithidium aveum.
,, tigrinum.	Rodriguezia amoebilis.
,, fallax.	Sobralia violacea.
Evelyna furfuracea.	Ponthieva maculata.
Oncidium macrolobium.	Altensteinia fimbriata.
Odontoglossum odoratum.	Cranichis monophylla.
5000 to 6000 feet.	*(Mean Temp. 65°.)*
Pleurothallis chamensis.	Cyrtopera Woodfordii.
Stelis spicata.	Maxillaria undulinguis.
Epidendrum dichotomum.	,, grandiflora.
,, cerutistes.	,, melina.
,, Lindleyi.	,, nigrescens.
,, carneum.	,, luteo-alba.
,, tigrinum.	Lycaste gigantea.
Schomburgkia rosea.	Angulua Clowesia.
Chondrorhyncha rosea.	Scaphyglottis rubcrrima.
Pilumna fragrans.	Camaridium luteo-rubrum.
Fernandezia longifolia.	,, purpureum.
Oncidium falcipetalum.	Ornithidium sanguinolentum.
,, lingulforme.	Cyrtopodium bractcatum.
Brassia glumacea.	Comparettia falcata.
Govenia fasciata.	Sarcoglottis picta.
Zygopetalum gramineum.	Physurus rostratus.
4000 to 5000 feet.	*(Mean Temp. 68°.)*
Masdevallia triangularis.	Cleistes rosea.
Warrea bidentata.	Sobralia dichotoma.
Mormodes Carroni.	Epistephium sessiliflorum.
Trichocentrum maculatum.	Physurus Presleii.
3000 to 4000 feet.	*(Mean Temp. 72°.)*
Epidendrum stenopetalum.	Habenaria maculosa.
Cattleya Mossiæ.	,, Lindeni.
Ghiesbreghia calanthoides.	
2000 to 3000 feet.	*(Mean Temp. 75°; Max. Temp. 80°; Min. Temp. 55°).*
Schomburgkia undulata.	Burlingtonia granadensis.
Odontoglossum hastilabium.	Ionopsis pulchella.

From this we learn that a species of Epidendrum is found where the mean temperature of the year is about 40°, where trees are wanting, pastures only being found, and where it occasionally snows. This would be incredible upon worse testimony than Mr. Linden's, if we did not know from Professor Jameson that one Oncidium (subigenum) is found in Peru at the height of 14,000 feet, and rarely below it. Mr. Linden tells us that his plant, which grows at only a short distance from eternal snow, is covered all over, flowers included, with a varnish, which is perhaps intended for a safeguard. It is remarkable that all the Epidendrums, with one exception, occur above 5000 feet, and that they form a continued chain of species up to the ground of E. frigidum.

It is, however, the Pleurothals that principally occur in such elevated regions; Masdevallia, Restrepia, Stelis, and Pleurothallis itself, constituting the most striking feature of the Orchideous flora until the mean temperature rises to 56°, where they begin to disappear.

The genus Odontoglossum appears to be more important of heat than its nearly allied genus Oncidium, for a species is found where the mean temperature is only 49°, and where it sometimes even freezes; the others are scattered over the mountain slopes till they reach the lowest limits of their order, where the mean temperature rises to 75°, where it is never cooler than 55° nor hotter than 80°: in such a climate not one of the race is found except a Schomburgkia, a Burlingtonia, an Odontoglossum, and an Ionopsis. In the hot lands on a level with the sea the Orchids do not seem to be able to exist.

It is evident indeed that these Colombian species have no affection for a high temperature, and that many prefer a low one. No fewer than 13 occur between 10,000 and 11,000 feet, where Humboldt tells us it is as cold as the mean of the month of March near Paris; 19 where the mean is that of May in the same city; while the mean temperature of those between 5000 and 6000 feet, where the largest proportion exists, is only that of Paris in August, according to the same authority.

These, and many more interesting facts of a similar kind, will strike every intelligent observer; they seem on the one hand to show to the gardener the great importance of studying well the climate of the plants he cultivates, and on the other they ought to teach the collector the incompleteness of any memoranda in which the details of climate are not fully given. General observations are not sufficient; particulars are indispensable. Suppose, for example, on the assertion of some generalising traveller, we were led to believe that the Masdevallias all require a cool climate, because the mass of them disappears below 9000 feet, how erroneous would be that conclusion when we find a species peculiar to a zone 5000 feet lower, and possessing a mean temperature of 16° higher.

It must not, however, be supposed that temperature is the only influence to be considered in the cultivation of these plants; it should in all cases be regarded in its relation to humidity, light, and atmospheric pressure; but unfortunately we have little information concerning the first, and the two last are beyond our control.

ROYAL GARDENS, KEW.

[The following are extracts from the report of the Director on the progress and condition of the Royal Gardens at Kew, during the year 1870.]

THE total number of visitors in the year 1870 has been 586,835, as against 630,594 in 1869, and 502,369 in 1868.

Total number on Sundays	265,585
Total number on week-days	321,250
	586,835
Greatest monthly attendance (June)	145,099
Smallest monthly attendance (December) ..	9,871
Greatest week-day attendance (Whit Monday, June 6)	41,527
Smallest week-day attendance (December 9) ..	211
Greatest Sunday attendance (June 5)	19,365
Smallest Sunday attendance (February 13) ..	70

Number of Visitors in each month of the year 1870.

January	4,071
February	14,241
March	20,487
April	88,557
May	68,207
June	145,099
July	103,878
August	74,831
September	58,119
October	21,700
November	6,585
December	2,671
Total	586,835

1. *Botanic Gardens.*—The improvements in the laying out of the grounds of this department, which have been in progress for the last five years, are now nearly brought to a close, by the remodelling, during the past year, of the herbaceous ground; by the construction of the Rose walk, 215 yards long, along the wall bounding the herbaceous ground on the west, which has been heightened by the addition of 3 feet of pierced brickwork; by the fencing off of the reserve ground; by the completion of the terrace on which the new range of stoves, &c., stands (which is, however, only partially planted); and by the formation of the paths leading to this. Many Pines and other evergreen trees have been transplanted, chiefly by the transplanting machine, and placed as screens to shut out the view of the backs of the houses on Kew Green, and the fronts of those along the Richmond Road; and many deciduous trees have been introduced along the walks; large beds of Rhododendrons, Laurels, and other shrubs, have also been planted along the principal paths.

An attempt has been made to utilise the Deodars, with which some parts of the garden were too much crowded, by placing a number of them at equal distances along a line concentric with the New fence which encloses the Palm-house area, leaving a broad grass walk between the fence and the Deodars. Similarly, many of the scattered Atlas Cedars have been transplanted, and now form an avenue along the curved walk leading to the back of the old Victoria-house. Other Conifers, together with the scattered Wellingtonias, have been planted along the vists which leads from the west door of the Palm-house to the great Cedar in the pleasure-grounds.

Large beds of mixed flowering, evergreen and deciduous shrubs have been planted on both sides of all the gates leading through the wire-fence into the pleasure-grounds, and in other exposed places, with the view of mitigating the effects of the hot summer winds and cold winter ones, which since the denudation of the ground by the loss of timber and shrubberies, every now and then devastate the gardens. The terrace on which the Palm-house stands has been relevelled for the first time since its construction in 1846; its angles have been filled with large beds of Laurels and Rhododendrons, and the whole terrace bordered with Ivy.

A great deal remains to be done in bringing the many young trees that have from time to time been planted in old shrubberies and on the lawns, into picturesque groups, and many more have still to be introduced. Most of the old shrubberies want renewal or clearing away, and the American garden behind the Palm-stove, which has suffered severely from the summer drought, requires replanting throughout.

The banks of the ornamental water are constantly being washed away by the ripple, owing to the depth of water due to them; they should be wattled, and planted with clumps of Osier, Sedge, &c.

The heating apparatus throughout the hothouses and conservatories has worked well, and notwithstanding the severity of the weather no accident has occured.

2. *Pleasure Grounds.*—The effects of the long and severe summer's drought on the old trees in this department have been disastrous; they have perished by hundreds—Elms, Ashes, Beeches, and Sycamores especially; many, no doubt, from having approached the limits of life to which such trees attain on so excessively poor a soil as that of Kew, but more, perhaps, through having been drawn up in thick plantations, and thus starved from the first.

In pursuance of the Board's directions, active steps have been taken to clear large areas of dying and dead trees, to level the ground, and close it of old roots, and plant closely a mixture of young trees of all sorts, which will be thinned out as they grow. This operation has enabled me to arrive at an approximate estimate of the ages of some of the more common trees in the grounds, and of the average duration which the several sorts have attained.

The oldest trees in the grounds are undoubtedly Oaks, English Elms, and perhaps Hawthorns; of which some of the first and last may be relics of the aboriginal forests that covered this part of England; whilst the Elms were undoubtedly all planted. No data have been obtained for ascertaining the age of the Oaks, but probably none exceed 300 years, and the majority date from the reign of George II. The only large ones that remain are several near the Brentford Gate, one near the margin of the lake, and several near the Queen's Cottage grounds.

The largest English Elms of which the rings have been counted are about 250 years old, but there are a few near the palace gates which have probably attained 300 years. Of these the top of that nearest the gates was blown off in this winter, and the stump removed; but the butt was too far decayed for its rings to be counted. All the old Elms in the grounds and their outskirts are in rows, and were either planted along former walks, or came up in hedge-rows, and were spared when the domain was enclosed and the hedges removed. Of Elms under 200 years old there were innumerable examples throughout the grounds; these were for the most part suckers from the roots of older Elms, which, coming up amongst the other and better trees, have done irreparable damage to them; the English Elm being of all plants the most impoverishing of light soils.

Of the old Hawthorns, the last fine one perished during the summer's drought; they abounded at one time on the gravelly parts, and appeared to be of the same age as the old Richmond Park Hawthorns.

Beech, Oak, and Maple are the only other trees that have sprung up spontaneously in the grounds, and all

from originally planted trees. The oldest Beeches were planted in George II.'s reign, and are about 150 years old; but of these there are very few indeed; the largest of them is a magnificent tree near the Brentford Gate, with a trunk 10½ feet in girth at 5 feet above the ground; its branches, which sweep and root in the ground, form a circle 116 paces in circumference. It is showing signs of decay.

The majority of the Beeches, which formed eight-tenths of the arborcous vegetation at Kew, are part of an extensive and dense plantation, made about 1750, but which, having been wholly neglected during the succeeding hundred years, have impoverished one another to such an extent that the majority are already diseased and fungused. It is upon this Beech forest that the winter gales and last summer's drought have told most heavily; the majority, having no root-hold, could not resist the blasts, and the loss of one is immediately followed by that of its neighbours, both from the admission of the wind, and from the sun's rays drying and heating the surface of the previously shaded soil over their roots.

Of other trees there are several good Limes, ever-green Oaks, Spanish and Horse Chestnuts, all from 150 to 200 years old; these trees have thriven well, and last long in the soil of Kew. The Ashes, Poplars, Acacias, and Willows average only from 100 to 150 years, and the Birches to 80 years.

The only good Coniferous trees of any age at Kew are Cedars of Lebanon and Larches; many of the former were planted about 1750, but of these not a dozen remain; the largest have attained a girth of 11 feet at 5 above the ground. The Spruces, Scotch, Firs, Pinasters, and Weymouth Pines, have all been ruined by being crowded amongst forest trees. The Hemlock Spruces, with which the path by the Richmond Road was ornamented 20 years ago, are every one dead; the last, which stood near the Pagoda, having succumbed to the drought of the past summer. Of Pines there never were many; a few fine orientals, planted in 1740-50, remain in the King of Hanover's grounds, one near the old palace, and one near the Temple of the Sun.

The above enumeration comprises all the trees of which there were any quantity in the grounds previous to their being made over to the public in 1845; since which time four-fifths have either died or have been removed to make way for buildings, avenues, paths, &c.

Between 1840 and 1865 many efforts were made by my predecessor to keep up the sylvan scenery of the pleasure grounds, by planting Conifers amongst the old trees, in every available open space, especially Deodars, Cedars, Scotch, Douglas, Austrian, Corsican, and Weymouth Pines, Pinus longifolia, Smithiana, and Spruces of various sorts, besides forest trees innumerable; but as permission could not be obtained, either to make sufficient clearances, or to disturb the roots of the old trees by trenching the ground, these plantations have utterly failed. On the other hand, he covered many acres of unoccupied land, by the river and elsewhere, and in the Queen's Cottage grounds, with plantations, which have all done well, and are now being thinned, by transplanting young trees from them to fill the clearances which are being made elsewhere.

Eight hundred yards of "blind paths" for carts, &c., have been made through the woods, with gravel from the lake-bed.

The lake in the pleasure-grounds, which was half finished in 1869, has since been completed, and the whole of the ground on the south side of it cleared, covered with good soil, and prepared for the formation of the new Pinetum, the planting of which will be begun forthwith. In reference to this Pinetum I have to state that, as no complete public arranged and named collections of hardy Conifers exists in England, the establishment of such an one at Kew is looked forward to with much interest by both collectors and nurserymen. Of the latter, two of the principal, Messrs. Lawson, of Edinburgh, and Dickson & Turnbull, of Perth, have presented to the Royal Gardens specimens of every species and variety that was to be found in duplicate in their extensive collections. Mr. McNab, of the Edinburgh Botanic Gardens, has also sent many valuable plants for this establishment. Many thousand loads of good loam from the lake-bed have been carted to those parts of the grounds, especially on the east side, where the soil is excessively poor, preparatory to forming new plantations; and the rest of the soil has been put round the roots of the trees wherever it was thought advisable.

3. *Interchange of Living Plants and Seeds.*—The demands upon this establishment, especially from India and the Colonies, for tropical and temperate plants and seeds; and from planters, forest and garden superintendents, for information of all sorts, increase annually; and these demands are of so miscellaneous a nature that it is often difficult to keep up with them.

Six more active and intelligent young gardeners have been sent to the Cotton, &c., plantations in India, in which country there are upwards of 30 former Kew *employés* engaged in various departments of horticulture and arboriculture. A skilful gardener has been sent to the botanic gardens in Jamaica, which are being revived under the energetic government of his Excellency Sir J. P. Grant; and another to take charge of the Agri-Horticultural Society's Garden at Madras.

The success of the Cinchona experiment is now fully established in the Sikkim-Himalaya, the Nielgherries, Khasia Mountains (East Bengal), Ceylon, and Jamaica. The bark from the first-named localities has commanded a price equal to the Peruvian in the English market, 19 cases of red bark from Darjeeling having been bought by Messrs. Howard & Sons for 1s. 9d. per lb., which these gentlemen inform me is what South American bark of the same age would have fetched. No less than a ton of prepared bark has been sent to London from Ceylon, the produce of seeds sent to Dr. Thwaites from Kew in 1861.

I was assured by the late Dr. Anderson, Superintendent of the Calcutta Botanic Garden, and the successful introducer of the plant into Sikkim, that it will in a very few years be produced there in any quantity at the rate of 3d. per lb.

I continue to have demands for Cinchona seed from many quarters, which I am enabled to supply from seeds ripened in the Ceylon plantations under Dr. Thwaites' superintendence.

Great exertions are being made by the Indian Government to introduce the Ipecacuanha plant into India; in which operation this establishment has been called upon to take an active part. This is due partly to the limited and uncertain supply of the drug received from Brazil, and partly to the revival of the old practice of administering it in large doses in cases of dysentery, upon which it acts as a specific. It is a singular fact that the introducers of the Ipecacuanha into European practice, the Brazilian traveller Marcgrav and the physician Piso (in 1648), explicitly stated that the powder was a specific cure for dysentery, in doses of a drachm and upwards; but that this information appears never to have been acted upon till 1813, when Surgeon G. Playfair, of the East Indian Company's service, wrote testifying to its use in these doses. Again, in 1831, a number of reports of medical officers were published by the Madras Medical Board, showing its great effects in hourly doses of five grains, till frequently 100 grains were given in a short period; testimony which, notwithstanding its weight, was doomed to be similarly overlooked, till quite recently, when it has been again brought directly under the notice of the Indian Government, which is making very vigorous efforts to introduce the culture of the plant into suitable districts of India.*

The number of plants, seeds, &c., sent out, is as follows:—

Hardy trees and shrubs..	1494
Stove and greenhouse plants	5186
Herbaceous plants	1317
Packets of seeds	4911
Ward's cases	24
Recipients	150

The receipts have been:—

Hardy trees and shrubs	971
Stove and greenhouse plants	1409
Herbaceous plants	1219
	* 3599
Seed packets	2630
Ward's cases	30
Donors	152

The greater proportion of plants sent out has been to Jamaica, Ceylon, India, Australia, Algeria, the United States, and botanical gardens; of seeds to all the Colonies, and the United States; and of Ward's cases to the West Indies, Australia, and Natal.

A very extensive correspondence was commenced last year with H. Capron, Esq., the active Commissioner of the Department of Agriculture of the United States of America, by which means a vast number of American seeds, and especially of Californian and Rocky Mountain trees, have been procured, and distributed to the Colonies.

Messrs. Booth, of Hamburgh, have presented a second selection of the rarer European and American forest trees in their nurseries, to the Arboretum, including many kinds that are not to be found in English collections. It is a curious fact that the rage for introducing Coniferous trees into English parks and gardens has almost extinguished the culture of all but a few deciduous trees; and I have now to apply to foreign nurseries for the rare Maples, Oaks, Ashes, Limes, Poplars, &c., which were so extensively planted in English parks in the early part of this century, and which, when the Kew Arboretum was made, in 1840-50, were to be procured at the suburban nurseries. Messrs. Lee, of Hammersmith, have promised a full set of their hardy deciduous trees, &c.; and Mr. W. Paul, of Waltham Cross, and others, have most liberally supplied many deficiencies.

Besides the above, the following contributions are of special value or interest:—

Mr. C. P. Ansteenius, H.B.M. V.-Consul, Mogador; the true Euphorbium of commerce, the drug of which has been imported into Europe for upwards of 2000 years, whereas the plant producing it was never previously known to Europeans. Seeds of the Argan tree.

M. Kuffmann, Botanic Gardens, Moscow; live plants of the drug Sumbul, from central Asia, another important medicine, whose origin was previously unknown.

A third hitherto unknown plant, yielding a drug of the greatest value, has been for the first time introduced into Europe during the past year, namely, the true medicinal Rhubarb, from Western China, of which a healthy live plant has been received from the Jardin d'Acclimatation of Paris.

HOTHOUSE BOILERS.

IT has been said that in the multitude of counsellors there is wisdom, and it is to be hoped that amid the multiplicity of boilers, economy in heating may ultimately be attained. Considering, however, the number in use, and the suggested improvements which almost every experienced horticulturist is prepared to offer offhand concerning the best of them, perhaps the marvel after all is, not that we have so many boilers, but so few. The greater number, too, are made after a few well known types. Starting almost with bells hung over the fire, we have advanced to saddles, single and double, backed, topped, arched, and convoluted astride of it. We have also filled tubes and cylinders, vertical and horizontal, with fire inside, and wrapped them round with fire jackets outside, and cast or built up stacks of tubes of all heights or styles into boilers, with fire playing round and among them in all directions. The size of boilers has fluctuated more than their shape has varied; the best size for a given amount of pipe is still, I believe, a moot point. If I remember rightly, Hood laid down certain rules upon the subject; whatever these rules were they have not been adhered to by horticultural engineers. We have rushed to considerable extremes in the matter of size, at one time using boilers about the size of cash boxes, and actually heating them to such a degree that the water could neither get out nor come in. From this extreme we passed on many rushes to boilers into the one-boiler mania. Now I find a good many seem to be returning to their first love of small boilers. Mr. Grix, as I understand him, is decidedly of opinion that more heat is got out of two or more small boilers than one of the same capacity as the series of small ones. I confess I cannot see it myself, but doubtless there is a considerable loss of heat in working a large boiler for a small result. The one-boiler system I consider the best when worked up to its full power; but supposing it capable of heating 10,000 feet of piping, and only 500 feet are wanted at a time, there must be a tremendous loss of heat upon the boiler, and the great volume of water that it contains. It is something like filling a dry dock to float a child's boat. Of course this is putting it in a very extreme way, as no one could scarcely require to use such a small proportion of heating power at any one time who needed so much at any other. But nevertheless large boilers require large furnaces, and there is a marvellous waste of fuel on both when not worked up to their full capacity. Attempts have been made to remedy this evil by dividing the boiler itself. Mr. Baines, I think, showed how this was done with his fluted saddle boiler; and I think the boilers of Messrs. Weeks, Ormson, and others, are made in duplicate when desired, not only to guard against accident, but likewise to enable part of them to be employed at pleasure. The Messrs. Dennis, of Chelmsford, also offer a boiler formed of a series of horizontal pipes, which can readily be stacked higher or lower, thus increasing or diminishing the volume of water heated as occasion requires. All these are steps in the right direction. By such arrangement the boiler power is no longer a constant quantity. When little is required from it, it is readily made smaller, or enlarged. This flexibility of capacity and power of boiler results in a great saving of fuel. The chief difficulty hitherto in working adaptable boilers has been the danger arising from the escape of water, or the action of the fire on joints or unions. It takes exact workmen to keep such in a better still, perhaps, to withstand the scathing action of glowing flame. Hence such boilers have not been very popular. But keep the connections wholly from the fire, and the chief objections to adaptable boilers vanish at once. This is what Mr. Cannell, of Woolwich Nursery, proposes to do with his Registered Hot-water Circulator. I have not the pleasure of knowing this gentleman, but as my letter to the *Gardeners' Chronicle* (p. 274) brought me plans and a model of this invention, I venture to bring it before your readers. The inventor claims fourteen or more special merits for his new fuel economiser. But with these I will not trouble your readers. By his courtesy I have been enabled to form an independent judgment as far as models and diagrams will help one to do so; and I wish rather to describe the new boiler than to dogmatise upon its merits. The mode of enlarging or reducing the area of the circulator is new, and the whole thing is novel in form. It is not unlike a railway carriage without wheels or windows, with a door in the end, and two guards to protect it on each side. These projecting guards are the pipes that connect all the parts of the boiler together, and convert it into one whole. The boiler is complete in itself, forming

* I am indebted for most of these facts to my friend, Dr. Christison, F.R.S., who informs me that he has habitually referred to them in his courses of University lectures, and has long wondered how it was that medical men should have so long and so obstinately shut their eyes to this troth.

The merit of proposing the introduction of the Ipecacuanha plant into India, is, I believe, due to Dr. Murray, Director of the Medical Staff of the Indian Army, and the operation was being energetically conducted by Dr. Anderson, late Superintendent of the Calcutta Botanic Gardens, who at the period of his untimely death (in October last) had procured a large quantity of plants for transport to India.

its own furnace and flues. It only requires a few bricks at each corner to raise it sufficiently to form the ash-pit and admit the air. The fire-bars and plate at the far end are parts of the boiler. There is no dead-plate at the mouth of the furnace, but a movable section of the boiler fits on, to contract the end, and throw the furnace-door further back, so that less heat can be wasted through it. The sides and top of the boiler are slightly convoluted, after the manner of Mr. Ormson's, but nothing like to the same extent. The furnace is of the same area throughout, and the entire centre of the boiler is filled with a square compact mass of fire; the back is cast in a separate piece, and, like the front section, attached to the other at the corners with patent universal-headed bolts and joints. So far this circulator differs little from other boilers, excepting in its square slightly bent sides and three curved crown. Also in the fact that there is no contraction of the fire, nor forcing of it through narrow flues, so apt to be choked up by careless stoking at the far end; on the contrary, the fuel may fill the furnace throughout without fear of a block anywhere.

The boiler might have finished here, and proved a complete, simple, and useful one; but its chief characteristics begin at this point. It would never do to allow all the caloric generated in that roomy square furnace to make its exit at the end into the open air. The usual course is to divide the fire at the far end and make it branch back in two or more divisions along the outside of the boiler, and return by skirting its top. Doubtless there is a marvellous loss of heat involved in this arrangement. The flame hits the boiler sideways, or from above, and the direction is unfavourable to the full development of force in both cases. Heat is ever struggling upwards. Eagle-like, it is ever soaring towards its grand source, the sun. It is only on this tack that its full energy and force can be brought out, and hence the chief merit, I believe, of Mr. Cannell's hot-water circulator. The caloric is carried along the best line for heating the water, and none of it is expended in brick flues. Above the boiler proper other and fleeter ones are arranged, like a series of gas retorts, one above the other, and these are not only waterways but fire-flues as well; the flame and smoke are carried backwards and forwards in these till their heat is exhausted. Each of these additions is complete in itself, and is merely laid on the top of the boiler or each other. They are united together by the side pipes only, so that where the fire goes all is solid iron without joint or union, or any such thing.

There is no doubt that more heat will be absorbed from flame travelling thus than in side flues, or flues above the boiler. Besides, in this arrangement the fire is wrapped all round with iron and water only. Hitherto, the heat has not touched brick, excepting at the four corners. Those of us who have burned out fire-brick furnaces with the fierceness of our fires this winter can estimate to some extent the amount of caloric wasted on such destructive work. It seems as if Mr. Cannell's Circulator might have utilised nearly the whole of this wasted heat in driving the water through the pipes to heat our houses. If so, the saving of coal must have been immense. Mr. Cannell promises ocular demonstration of this at his nursery very soon. He certainly deserves credit for originality of construction and a simple mode of doubling or trebling the fire-power.

If the joints can be warranted leakless, and can be so readily put together as Mr. Cannell asserts, and the flues can be warranted not to choke at the ends, or rather the far end from the furnace-door, the Circulator is likely to have a future that will more than satisfy its inventor. Then, again, if the side pipes with their union-joints can be made to bear fire, the flame could be carried round the sides as well as over the top, until the smoke vanished into the air—cold, almost delicately blue, and sootless, that is, without unburnt coal. Possibly, if such arrangements were would be no danger of the spaces between the lids blocking up. But it is needless to pursue the matter further, for I observe the inventor claims it among the advantages of the hot-water circulator that it can easily be cleaned out of either sediment from the inside or soot from the flues, when required, both being the work of a few minutes only. I can see how the first can readily be done, as a tap is shown in front at the bottom of the boiler. But how the flues are to be cleaned without detaching the far end of the boiler itself is not so obvious, as, of course, every addition to the bottom boiler abuts at one point against the end; otherwise, the flame would stream up there in a vertical current, instead of moving backwards and forwards in horizontal lines, to the warming of every portion. The end of the boiler would also have to grow with the addition of every part; or rather, several ends would, I presume, be provided to fit each size of the boiler, while detached from brickwork. Such points in its working are simple enough, as it would remain accessible at all points, and the inventor asserts that it can be built up or taken down with the utmost despatch; besides which, though these regulations of size, heating force, and, consequently, of consumption of fuel, are important characteristics of this Circulator, they are by no means essential to its working. A certain size, with so many retorts mounted on its back as shall exhaust the heat of the fire, may be fitted up at once, and worked as any other permanent boiler. The heat from the Circulator itself might likewise be economised for the warming of Mushroom-houses, back sheds for forcing Seakale, Asparagus, Rhubarb, &c., or it might be sent into the houses with proper precaution. The whole surface could also be wrapped round with rough sacking, felt, or other non-conductors, so as to retain the heat in the iron and the water, instead of allowing it to escape from its sides.

But all these are matters of detail—mere trifles some will say. Quite so. But successful heating consists in attention to such trifles, as an inch more or less air, a shovelful more or less fuel, ashes or clinkers in the right or wrong place, or a single turn of a stopcock here or there. The fact is, there are no trifles in our business. The greatest results arise from the smallest things. The art of heating, like that of gardening itself, can only be mastered a trifle at a time. It is upon the sure and solid foundation of numberless trifling facts—the grasping, collating, interpreting and applying an endless series of minute details—that all sound theory and good practice are based. Even genius itself may not be inaptly defined as trifles utilised, quickened, glorified, if you will, by the touch of a master mind. To the gardener, I suspect, no fact is trifling. These trifles are the rounds in the ladder by which, if at all, he must reach to fame and fortune. As to this hot-water circulator, experience will soon determine whether it is to become one more useless trifle to be added to the long list of abortive inventions—or is really the coming boiler, that is to cut our coal bills in twain, and save the largest half of them. *D. T. Fish, F.R.H.S.* [We ought to state that the publication of this paper has been unavoidably delayed, and further, that we have others in hand from Mr. Fish totally disposing of the reversal of the circulation. Eds.]

FIG. 202.—REID'S TRANSPLANTING MACHINE.

TRANSPLANTING MACHINES.

WITH the accompanying illustration (fig. 202) of an implement I have in use, it may perhaps be unnecessary to give minute details of its formation, as I presume it will be perfectly clear to any one having a small measure of constructive genius, and understanding the nature of a lever, that it is adapted to raise and remove a mass of earth in proportion to the strength of its make and size. Under this impression, it may be briefly termed a combination of a huge shovel and fork mounted on an axle, with two wheels. The axle, it will be observed, is bolstered with timber, by which it is raised to the top of the wheels; this timber is cased at back and stays, &c., to which it is firmly riveted, and fastened to the axle in lines likely to afford strength; the wheels are 2 feet in diameter, and the length of the plate 3 feet 10 inches, by 3 feet 4 inches in breadth, these dimensions allowing the prongs to project 6 inches beyond the plate. The plate is flanged at both sides, and at the front.

The preparation for lifting is done after the usual manner, but I prefer a square to a round ball in general; and perhaps the best way is to cut down at both sides at a proper distance from the stem, undermining it a little at back and front. The machine is then brought forward and the prongs jerked under, the lever is then applied, raising the block of earth to an angle of 45°, at which it is easily balanced, when another jerk brings the plate and the bottom of the ball to an equal angle; the ball is then pressed forward, the lever being at the same time pulled down, which elevates the back part of the ball in turn to a similar angle, and is now moved off to its destination. The pit being ready, a track is cut for the wheels; the ball is then gently slid into its place, and nothing else is required but watering to complete the work, and the usual careful adjustment of the soil. A weight of 10 cwt. is conveyed and planted with surprising facility with this machine. *John Reid, Haigh Hall Gardens.*

Home Correspondence.

The Cultivation of Loranthaceæ.—I have read Dr. Welwitsch's interesting account of the African Loranths at p. 835, and as I can fully endorse all he says as to the great beauty of many of the species, permit me to supplement his remarks with some further particulars regarding them. My observations will be confined to such representatives of the order as are found in southern India, at various elevations. I have seen Loranths growing only too luxuriantly from the level of the sea up to elevations of 7500 feet and upwards; some of these have gorgeous red and yellow flowers, others have beautiful berries, and most of them have foliage charmingly contrasting with that of the trees they live upon. One very common species has a very striking silvery pubescence on the under side of the leaves; the flowers are much the same colour as Mignonette, and the berries are also of a dull greenish white; but as it grows principally upon dark-foliaged trees, such as the Acacia robusta, or on the dull evergreen trees, such as the Tea, the Citron, &c., the contrast is very striking. Another species, which would certainly be a great acquisition to our greenhouses, has most beautiful flowers, reminding one somewhat of the Trumpet Honeysuckle. It grows very commonly on the Peach trees about Coonoor and Ootacamund, on the Nielgherries, although I have not seen it flower on the Peach. On many of the indigenous forest trees, however, it is often so covered with bloom as to entirely colour up the tree upon which it grows, and to lend it a glory which ought to compensate it somewhat for the loss inflicted upon it by the beautiful but ravenous parasite. The leaves of this species are of a dark shining green when young, and are as large as those of the Portugal Laurel. In the dry season, however, they often have a reddish hue, particularly on worn-out trees. There are other species too numerous to describe in a brief note, even if I could recollect their peculiarities: indeed Loranths are so numerous that when I told Mr. Black, the late talented curator of the Botanic Gardens at Bangalore (and formerly of the Kew herbarium), that I had brought with me berries of the Mistleto, with a view to attempt their cultivation on the hills, he assured me that no one would thank me if I succeeded, as there were too many representatives of that order already in India for the well-being of arboriculture. I, however, duly inserted all my berries on either Apple or Pear trees, but although I had carefully packed them in sand, not one of them grew; possibly the failure resulted from the tin box being too close, so that the berries were parboiled in their passage through the tropics. Some of the seeds were inserted in Coorg when comparatively fresh, the bulk were, however, quite dry and shrivelled, having been three months in the sand. I believe, however, that fresh berries could be had, and at Kew, the Crystal Palace, and other large conservatories, there are plenty of large trees of the kinds that the Loranths would be likely to grow upon. The Ficus, of species, is a great favourite of the tropical Loranthaceæ. *James McPherson.*

The Condition of Peach and Nectarine Trees.—I have read the Rev. W. F. Radclyffe's sweeping assertions on this subject, but I have no intention of adding to the disclaimer made by Mr. D. T. Fish, as that gentleman is quite a host in himself, in defence of the British gardener. I confess myself much indebted to the reverend gentleman as a writer on many subjects, but I must assert that his last is not one of them. Still we should not criticise too severely. These assertions, made in an unguarded moment, while being

elated with his great success in the midst of what appeared to him universal failure, seem to me foreign to his usual liberal heart. That this failure is universal, however, I most positively deny, and also demur from his statement that the cause of his success is owing to short pruning. I have under my charge about a dozen and a half Peach and Nectarine trees, all pruned on the long-shoot system, that occupy the usual space on a wall nearly 20 feet high, and which have now in them present an enormous crop of fruit. They are also perfect specimens of good health—scarcely a blister, an aphis, or a red spider to be seen. These trees I have thinned at different times, and have taken bushels of fruit off them; indeed, I have just lately finished that operation entirely (but don't think I should be sorry if some one else were to go over them again). Although the crops on walls are not so bad in this neighbourhood as your correspondent asserts, yet from various sources I understand they are not up to an average. I do not know how it is that I am so favoured, as my treatment differs nothing in this from former years, nor, so far as I know, from that of my neighbours. Were I to offer an opinion, I should say that it is owing to soil and situation. The latter is slightly elevated; the former is light and rich, of deep tilth, and well drained—such soil as is well adapted for producing early vegetables. When the fruit is swelling, I several times give the soil about the trees (with a water-hose) a good soaking of sewage water; this ensures a good growth of wood, while the nature of the soil is favourable to its early ripening, and of the wood well ripened I do not think that an English winter, however severe, will affect them in their dormant state. I am of opinion that the hard winter had nothing at all to do with the present unsatisfactory state of Peach trees. If we look for it anywhere, we must look to last year's unusually heavy crop. From my own recollection, I cannot remember such a crop of Peaches as we had last year. The northern markets were so glutted that I actually saw beautiful Peaches sold at 9*d.* per score. Last summer was very favourable to the growing and ripening of the fruit; but not for the formation of wood, hence I think the advantage of my sewage application. Of course this must be applied with some discretion—such a summer as this, when it is raining (in this neighbourhood at least) every day, I would never dream of applying it, nor yet when the crop is scanty. I wish I could report as well of the Plums as I can of the Peaches on the same wall—the fact, between the Peach trees. I thought at one time they would succumb altogether during that week of cold, north-easterly winds, which all gardeners must remember. Every leaf curled up, being as full of aphis as it could be. For a time they presented a sorry wrecks, as it were, hanging between life and death; they have now, however, grown out of it, and look better than I expected to see them this year. *A. Yorkey.*

Odontoglossum Bluntii.—I send you by this post two flowers from separate plants of Odontoglossum Bluntii in the large collection here. I find one of the flowers to be 4 inches across, with ten flowers on the spike: bulb 6¼ inches round; the other flower 4¾ inches across, nine flowers on the spike: bulb 5¾ inches round. *E. Culley, Gr., Fernehurst.*

The Thinning of Grapes by the Syringe.—This is no new fancy, it has cropped up at different times for years past, and this is by no means the first time that I have pointed out what is a fancy and nothing more. No amount of syringing will remove any berries after they are properly set, without an amount of force being used that would seriously bruise and injure the berries left. But a great many Grapes, and notably Muscats, never set one-half of their berries, often not a fourth part, and some people use the syringe to the bunches before thinning, which, of course, drives off all these unset berries, and this they call the thinning of Grapes by such means. It is mere nonsense, a mere tap or shake does the same thing, that is, brings off all the berries which are not set. *A Practical Hand, July 15.*

The Implement Yard at the Provincial Shows of the Royal Horticultural Society.—I wish to endorse and add force to—if that be possible—all that Mr. Baines says upon this subject at p. 908. I believe the local secretary was solely responsible for stuffing the yard full of baby's perambulators, and all sorts of fancy-fair things, which certainly do not comport with the dignity of a Royal show. But apart from things of this sort, which ought not to be admitted, surely some attempt might be made to offer prizes for, and test the merits of, horticultural implements or inventions. I would suggest that prizes should be offered for the best specimens of hothouse building, also for new modes of ventilating hothouses and arranging them internally for the different purposes of gardening. Something might also be done to break up the monotony of colour in glass houses by offering a prize for the most effective or chaste coloured house, or sample or model of the same. In this age of new boilers, also, prizes should be given for the best, and some means of testing devised. These are mere suggestions, and others will readily occur to your readers. Under the present arrangements, the implement makers and house builders seem rather hardly dealt by. They have to pay pretty high for space; at times they are badly located, and better places are taken up with refreshment tents or fancy-fair goods that have no possible connection with horticulture. I heartily endorse Mr. Baines' view, that the trade-yard ought to be revised and improved. *Quercus.*

Laxton's "Alpha" Pea.—In reply to your correspondent at p. 875, as one of your "disinterested" readers, I would beg to say that my trial differs somewhat from his. The stock was obtained from the same source, and was sown on a well-manured piece of ground, in the same row with Daniel O'Rourke. I counted the number of pods on both, and certainly the Daniel O'Rourke had a slight advantage in that respect, in productiveness, but the Alpha is rather earlier, and the Pea of a sweet juicy consistency, possessing the merit of its own (wrinkled) class, which will secure for it a precedency over the other. It is rather earlier than Maclean's Nonpareil, and follows Carter's First Crop so closely, that I would prefer it for my earliest pulling. It must be remembered, however, that for earliest crops the wrinkled varieties are not quite so certain in every soil and climate as the round or smooth kinds, as these are apt to burst and rot in unfavourable circumstances than the other. This season, however, in many respects a very trying one, Alpha was fully as healthy as Carter's First Crop. Dr. Maclean's Peas are certainly worthy of high commendation, but that is no reason why Laxton's should be depreciated. In all fairness, while Laxton's Supreme is not a wrinkled variety, it is not only "a grand show Pea," but a splendid second early of good quality, deserving of general culture. I will only add that it was ready for use in my trial three or four days before the Champion of England. *W. F. C., Stirling.*

——I have seen this variety in several places this year, but for one instance, in reply to your correspondent "A. D.'s" inquiry, I will name that of Messrs. Standish & Co., as doubtless many other gardeners besides myself can speak as well of it. On Latter I saw this fine Pea there in really good condition, being only a few days later than Sutton's Ringleader; its only drawback appears to be its inability to withstand severe winter frost. Mr. Standish considers it ought not to be sown till the end of February or beginning of March, and sown at that time it only four or five days later than Ringleader sown in November, is a much heavier cropper, and of first-class flavour. If sown on turves or in trough-like boxes, and planted out early in March, I believe it would be quite as early, and a long way in advance in other qualities. Mr. Standish has so good an opinion of it, that he is crossing it with various sorts, to improve them, and to all appearance will some day give us some fine Peas. *John May, The Gardens, Westfield, Havant.*

——I forward you herewith a small box of Laxton's Alpha Pea for your opinion. Your correspondent "A. D." is quite in error in saying that they bear only single pods, for the majority have pairs, as you will see; and I can with truth say that Laxton's Alpha is the best early Pea that I know. *G. R.*

Odontoglossum Culture.—In a collection of New Grenada Odontoglots everything is doing well but O. coronarium. Can any of your readers tell me if any special treatment is necessary for this species? Imported plants appear as though they had been exposed to the sun. *J. Day.*

Flower Show Appeals.—In your last issue, at p. 907, in answer to Mr. Simpson, you state that Alocasia Lowii and A. macrorhiza variegata are distinct species. Now, if they are distinct species, by what rule are exhibitors allowed to show them with Caladiums? At the last show of the Royal Botanic Society at Regent's Park there were in the 1st prize lot Alocasia Lowii and A. Veitchii, and in the 2d, Alocasia metallica and A. macrorhiza variegata. My question is—What rule do the judges act upon when the schedule says Caladiums, and they see Alocasias instead, and award them the prizes? *A Young Exhibitor.*—There was a misprint in our note on Alocasias at p. 907. It should read:—They are "distinct species," not "a distinct species." As regards the present inquiry, Alocasias should not be shown as Caladiums, if the schedule is to be strictly interpreted. As, however, they form a desirable variety, it would be well if the schedules were made to include both. Eds.]

Grape Judging at the Royal Botanic.—In principle I think it unwise to complain of the decision of judges, but when they depart from the established rules of making awards, as they did in my case at the Royal Botanic, July 13, I think I should be wrong not only to myself, but to the general interest of Grape growing, if I refrained so. And in this opinion I am supported by most, if not all the exhibitors of Grapes at the show that day. Mr. Johnston and Mr. Osborne, who competed against me for the basket of not less than 12 lb., and who won the 2d and 3d prizes, assured me that they disclaim the right to have been placed before me, and think it most unfair I was not awarded the 1st prize; and yet no award whatever was made to my Grapes, though for colour and finish, I shall be bold enough to say, they were the most perfect Hamburgh Grapes in the show, while the winners of the 1st prize in this class fell far below perfection of colour and bloom, and that, too, as your reporter observes, with an irregular-sized berry. *Emanuel Sage, The Grapery, Atherstone.*

Ivy Against Buildings.—I am at present threatened with a lawsuit by a neighbour for growing Ivy against a gable-end of his house, which forms the boundary of my garden, and which was a sad eyesore before I did so. Although I have had the opinion of an experienced architect and also of a practical builder, that the Ivy is a positive benefit to the wall in question, the proprietor stubbornly insists that some damp, really caused by salt bricks, is owing to the Ivy. I have no fear for the result of a trial, but it is no joke to be run to great expense and anxiety by a pig-headed opponent ignorant of natural history. I shall be glad if any of your readers can tell me of any legal decision on the point, or otherwise aid one who likes an Ivy-covered wall rather than a horrid mixture of bricks and plaster. *L.L.D.* [We believe if a wall be in good condition that no harm, but rather good, results from the Ivy. Eds.]

Fruit Growing at Okeford Fitzpaine.—No one who knows the kind and genial nature of my friend Mr. Radclyffe will suppose for a moment, I think, that he meant in his observations to brand gardeners, as a class, with ignorance; his idea was, I believe, simply to assert that very often that is put down to the freaks and caprices of the season, or to the climate, which is owing to culpable neglect or gross ignorance. I do not think that he meant more than this. Whether my opinion on this fact is of any value or not, at any rate my statement of what I have seen of the condition of his fruit trees may be worth something, as showing that he is not one of those who profess what they do not practise. Let it be distinctly borne in mind that he possesses no advantages in either soil or situation; that his garden stands right in the wind's eye of the south-westerly gales which prevail so much in this part of England; that his soil is a tenacious sort of loam, and not peculiarly suited for any of his fruit trees, cultures; and that, therefore, his success is to be attributed not to any special opportunities that he possesses. And what in this very trying season is the condition of his trees? I have been in many gardens, large and small, this summer. I have seen blight, and canker, and red spider, and all sorts of things on the wall trees, but here I saw none. There is not a blighted leaf or a sign of disease of any kind from beginning to end. His Peach and Nectarine trees, let it be remembered, are small, but there is an excellent crop on them—more than I have seen this year at three times their size elsewhere. Indeed the whole appearance of the trees such as any man might be proud of. I attribute this result, 1st, to a thorough good practical knowledge of the physiology of plants; and, 2d, to unceasing vigilance in supplying their meat at the proper time—giving them such food as they require, when they require it, when in bloom, stopping at the right time, watering and syringing when required. I might dilate on his wonderful crops of Strawberries, &c., but have thought that this testimony ought to be borne to the success of one who is so well qualified to teach as my friend is. *D., Deal.*

Caterpillars and the Fruit Crops.—I have just been reading "J. T.'s" article, entitled "Caterpillars and Fruit Crops." He has got hold of the "right pig by the ear" in one instance, but has missed more for him to catch yet. When he speaks of the hard rings round the twigs of Apple, Plum, and other fruit trees, I presume he alludes to the circular clusters of eggs of the Lackey Moth (Cisiocampa neustria), which are laid in August, and in early spring produce a number of small yellowish-coloured caterpillars, striped white, orange, blue, and black, living till nearly full growth in colonies in silken nests, which they construct among the branches, and stripping all the twigs in the vicinity of the nest completely bare of leaves. This very conspicuous species of caterpillar is, however, very easily got rid of by simply cutting off the twig at night, when the inmates, which feed only in the day-time, have retired to rest. The great enemies of our fruit trees are the larva of the two winter moths, Cheimatobia brumata and Hybernia rupicapraria, especially the latter. These larva, which are of various shades of green more or less marked with white, are the produce of moths which emerge from the chrysalis and deposit their eggs from November till the beginning of March. The larvæ live when not feeding between two or more leaves spun together; they are so common, and appear in such numbers, that I consider it a hopeless task to attempt to get rid of them: probably every twig of a fruit tree has eggs deposited upon it in the winter months. Sparrows, hedge-sparrows, robins, and numerous other birds destroy these larvæ by wholesale, choosing the breeding season for the purpose of feeding their young. These larvæ do but little damage to our Gooseberry and Currant bushes; the mischief here is done by a caterpillar, which does not produce a moth at all, but a saw-fly, Nematus grossularia, which deposits its eggs along the ribs at the back of the leaves, and of which there are several generations in the course of the year. I am told that Hellebore powder sprinkled over the bushes with a flour duster will destroy these larvæ, but I have not tried it, and know of no other cure. But few

birds (of whom the cuckoo is one) will eat this caterpillar. The larva of the Currant Moth and the V moth, Abraxas grossulariata and Halia wavaria, the former black, white, and yellow, and the latter green, yellow, and black, occasionally do a little damage to our Currant trees by eating the leaves; and that of the little Clear-wing, Trochilium tipuliforme, by feeding internally on the pith of the branches; but they never occur in sufficient numbers to excite any alarm. *H. Harpur-Crewe, the Rectory, Drayton-Beauchamp, Tring, July* 17.

Sudden Rise of Temperature.—After an unwonted long cold period, the thermometer here registered at 4 P.M., July 16, 110° in the sun—the day having been uniformly hot and fine throughout. *Wm. Earley.*

Luminous Plants.—In your late article on this subject (pp. 904-906), you anticipate additional information from correspondents. Allow me to submit a first fruit of such addenda. In the year 1838 I was pursuing the study of natural history in the State of Alabama. About the middle of September I was traversing, together with a friend, in the early hours of night, one of the gloomy swamps that border the river in the neighbourhood of Cahawba. The timber, at the part of which I speak, was almost wholly of one kind, the Beech, Fagus americana, a noble tree, with the same smooth, blue, pillar-like trunk as its European congener, but attaining a loftier elevation. In the deep, rich soil of these swamps, it frequently exceeds 100 feet in height, with a magnificent head of foliage. The roots spread a great distance, and form a sort of network on the surface of the ground, in some measure impeding the progress, or at least making it more tortuous than the trunks seem to require. As we plunged into the deep swamp, the scene every moment grew grander and more gloomy. The ground was damp and muddy, but not wet; so that, in this respect, we could walk with ease. The trees were, as I have said, large, set far apart, with little underbrush. On one of these hoary Beeches, I saw an object that interested me much. A spot of bluish light attracted my notice, resembling that of a glow-worm; which, on my coming to it, I found to proceed from a foliaceous Lichen or Fungus, growing on the bark within reach, in the form of a rosette or cockade, about as large as a shilling. The substance of this was somewhat fleshy, or rather cartilaginous; and was luminous throughout, as if penetrated with light, which was feeble, and of a pale blue tint, like that which proceeds from wood decomposing under certain circumstances, popularly known as touchwood. The above particulars are already published in my little work "Letters from Alabama," p. 257; and though the incident is vividly painted on my memory, I regret that I cannot add anything to their precision. My acquaintance with botany was not at that time sufficient to determine the exact character of the luminous plant; the appearance was rather that of a Lichen than that of an ordinary fungoid; but more than this I am unable to say. I am sorry that I did not preserve the specimen. *P. H. Gosse, F.R.S., Torquay, July* 17.

Hardiness of the Araucaria.—As an observation has been made in your columns that planters are discouraged from cultivating the Araucaria, owing to the many instances in which these trees have suffered severely from our winters, I have thought that an instance of their extreme hardiness in a most unpromising situation, which has come under my notice, is worthy of record. Mr. Hill is known to be the highest land in the south of England (more than 900 feet above the sea), yet on the very summit are now growing a number of Araucarias, which were planted without the least shelter, apparently six or eight years ago. These trees are growing in a soil which these trees flourish; their foliage remains quite green, as if never at all browned by past winters, and they maintain their uprightness in this bleakest of all situations, where one should suppose even a Scotch Fir would with difficulty raise its head. *P. P. C.*

The Palmete (Prionium Palmita), mentioned in your journal as likely to "be found of use in the fabrication of ropes and paper," is a plant whose utilisation has been many times attempted in this country, but hitherto without success. Some of the uses for which it has been recommended and tried are as a substitute for bristles in brush-making, as a substitute for horse hair for stuffing cushions, and also, as you state, for ropes and paper. Though it has been well known and recommended for these purposes for many years, the prospect of its general application seems as far off as ever. *John R. Jackson, Kew.*

The Potato Murrain.—I am not an alarmist, but "for a' that" I am sorry to state the fact, that although our Potato prospects have been very first-rate, there are unmistakable symptoms of a determined attack from the disease from which we have enjoyed some slight immunity for a year or two. Around here, in Essex, in fields of great extent, in which may be seen the finest descriptions of Potato growth, the dire pest is but too plainly observable in patches here and there of acres in extent. Early Shaws seem to succumb to its influence first, for these plainly discerned patches are principally of that variety. Other early sorts, such as varieties of Regents, have also been smitten by the unrelenting enemy. Already I hear young Potatos have fallen by 20s. per ton in the metropolitan markets, owing to the influx caused by growers hurrying in the produce of their palpably smitten crops. *W. Earley, Valentines.* [We hear also of wholesale destruction by the disease in Leicestershire and in Kent. Eds.]

Horizontal Sash Bars.—At the late show of the Royal Horticultural Society at Nottingham, Mr. Bickley, of Smallbrook Street, Birmingham, exhibited an ingenious mode of glazing, which we noticed at p. 842. We are now enabled to supplement the remarks there made by the following illustrations (figs. 203, 204) and description, furnished by the patentee:—"A, zinc plate; B, wood bar; C, portion of rafter; D, groove or rebate in wood bar to receive upper edge of glass; E, clips, formed in zinc to receive lower edge. At certain distances, they are turned the reverse way, and a nut fixed on them (see H); at these spaces the glass is inserted and slid along the groove to its place. The projecting portions of metal, F, serve two important purposes,

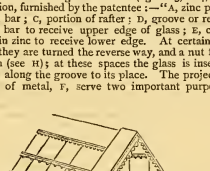

FIG. 203.—BICKLEY'S MODE OF GLAZING.

viz., to carry the water far down on to the next lower row of panes, and also to hold them firmly down, acting as a spring. I find one or two of them ample for this purpose to each pane, it should be slightly bent downwards, just before the glass is slid under it. The sloping part, G, carries all condensed moisture safely away from the inside of the glass on to the top of the next row of panes, thus preventing drip, which exists in all other methods of glazing. The bars may be either screwed or nailed on the rafters with zinc or iron nails, and the roof will be much firmer if they are let into the rafters a quarter of an inch. They may be painted ornamentally blue, with turned up part white, &c. They may be used for a variety of purposes, viz.:—Double glazing greenhouses, over an existing roof,

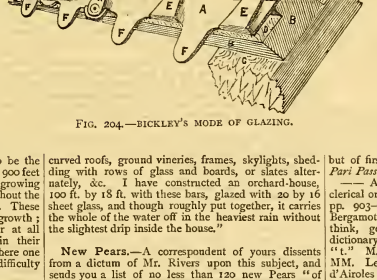

FIG. 204.—BICKLEY'S MODE OF GLAZING.

curved roofs, ground vineries, frames, skylights, shedding with rows of glass and boards, or slates alternately, &c. I have constructed an orchard-house, 100 ft. by 18 ft. with these bars, glazed with 20 by 16 sheet glass, and though roughly put together, it carries the whole of the water off in the heaviest rain without the slightest drip inside the house."

New Pears.—A correspondent of yours dissents from a dictum of Mr. Rivers upon this subject, and sends you a list of no less than 120 new Pears "of first-rate quality," sent to him from the Continent during the last 20 years. I have fruited about a sixth part of these, of which only two (or 10 per cent.) have proved up to and over the second-rate; one of those two, viz., Doyenné du Comice, is perhaps the very best Pear known; at any rate there is no better. The other, viz., Marie Louise d'Uccle, is decidedly a good second-rate, and a fine handsome fruit. Of the rest I would speak as follows:—B. Bachelier is large and fertile, but miserably tasteless; B. Durand (if identical—which I only suppose—with a Pear received from the Continent as "Durandeau") is very handsome, but never loses its coarse acridity; Beurré Six is quite worthless; Calabasse Delvigne the same; Désiré Cornelis is large and a fine grower, a juicy and sweet Pear, but with very little flavour; Dr. Nelis and Dr. Trousseau are worthless; and so is Duchesse Hélène d'Orléans; General Todtleben is worse, if that be possible; which Leopold I. quite proves. Madame Elise is very poor, Marie Louise never ripens, neither does Napoléon Savinleu. Passe Crassanne (in spite of even Mr. Rivers' good word) is a wretched thing; and Poire Pêche is quite contemptible. If "Poiteau" be the same as Nouveau Poiteau, it is never fit to eat. These Pears have turned out as above, not in a cold ungenial situation, but in Middlesex, in a garden where we gathered Peaches from the open wall on July 14 of the present backward season. I do not charge your correspondent with any desire to mislead anybody, for I hold it to be one of the very worst features of horticultural discussion, that it seems to beget personalities, even more than religious dissension. He may have a soil and climate of extreme optimising power as regards foreign fruit, while it sympathises more judiciously with our native products. But one thing he seems to pay small heed to, which is of first-rate importance, I mean the effect of season—an influence of undeniable force upon all fruit, but of paramount import as regards the Pear, which is the most sensitive and capricious of all English fruit. There is no Pear as yet in our knowledge which can be relied upon for first-rate excellence every year; *e.g.*, D. du Comice was first-rate when for three years in succession, the fourth year it was second-rate upon trees of all ages, and it might well be proud of premiership for three years out of four. Knight's Monarch has twice been A 1; but no Pear can be insured as "A 1 for seven years." Hence I venture to submit that we cannot draw so precise a line as your correspondent would establish. We must allow for stock, soil, and normal climate, and the effect of these three as diversified by perpetually mutable seasons. Only one thing seems reasonable, to wit, that a Pear which is not good in one year out of three, or a Pear which rarely ripens here, should accept the Chiltern Hundreds. I have piled and over-piled my list, having at one time 400 sorts, and being perhaps as enthusiastic as your agreeable correspondent; but long experience has convinced me that five-and-twenty kinds of Pear are ample for any garden, or even for a nurseryman who wishes to please his customers. Even the *furor* of young people is worn out at length with a tale which is "all sound and fury." I cannot but doubt whether your correspondent is correct in his ethnology, *e. g.*, in d'Aremberg and Uvedale's St. Germain being believed to be seedlings, and so is Gansel's Bergamot, according to the well-known story; and why does he omit from the English list Huyshe's Bergamot, and Thompson's [Thompson's is not English], both first-rate sometimes? Moreover, there is at least a tradition, which I have heard confirmed in this neighbourhood, that Marie Louise was gained in England, and by Mr. Braddick; neither do I think that your correspondent, so charitable to foreign stuff, is justified in banishing B. d'Aremberg (whatever be its origin) to the second class. It is not always, but surely it often is first-rate. Beurré Paris, on the other hand, has been good once here, neither has Dunmore, but Gansel's Late Bergamot has. Hacon's Incomparable, on the other hand, never was worth eating here. In short, the moral of the tale is this—We cannot dogmatise upon Pears, and there are very few sorts indeed which can be generally, much less universally, recommended; and no amateur who cannot afford to put up with loss of time and money should place any faith in foreign catalogues, nor even in an English one, unless it be that of Mr. Rivers, nearly all of which is true, according to my experience. Through that great veteran's enterprise, the autumn supply of peaches is extended a good month either way. His Early Louise ripened, on my walls, before the earliest Apricot, and his Princess of Wales prolongs the season, not of Turnips, like Late Admirable, but of first-rate Peaches, to the battle of Trafalgar. *Pari Passu.*

—— Allow me to call your attention to a few clerical or typographical errors in the lists of Pears at pp. 903-904. In the first place, should we write Bergamotte, or Bergamot? The former, I think, generally spell it with one "t," and the dictionary of the French Academy has it with one "t." M. Decaisne writes it with one also, as does MM. Leroy, Van Houtte, &c.; but M. Lirou d'Airoles has the double "tt," as have several of the older writers. I follow the dictionary of the Academy. There is also the word Arenberg, often written "Aremberg." Nearly all the French and Belgian writers write it with an "n." I think the Germans write it with an "m." I suppose that they should know best. The following names require correcting:—Elshan Hoft to "Haft"; Bergamote Flou to "B. Flon"; B. Jolais to "Jalais"; B. Luiget to "B. Luizet"; Doyenné Flou Aîné to "D. Flon Aîné"; Général Davevier to "G. Duvivier"; Jacques Hamoret to "Hamaret"; Vazille Jumelle to "Mme. Vazille." I am sorry that I did not take greater pains in forming my letters, which no doubt caused the misprints. *J. Scott, Merriott.*

Diverting a Watercourse.—Your correspondent "J. K." (p. 876), asks for information respecting water-rights, but does not give the name of the stream he is situated upon. My opinion is that he can place a bay or dam across the stream, provided it does not

obstruct the watercourse to the injury of any land or property above or below, and he can erect any machinery, and use the water as a motive-power, if no injury can be proved to the flow; if so, he will be liable to an action for damages. He certainly cannot divert or abstract any water from the stream or river, even with a pail, unless he can prove a right to do so. No person has a right to take water from any stream above the intake of any mill, unless such a right was gained before the erection of the mill, or by purchase since. Every landed proprietor has a right to use the water (if not polluted by him) flowing through or over his land by a natural stream, but he cannot deprive or injure the rights of other proprietors over whose land the stream runs, unless he has a title or prescriptive right to otherwise use it. *Thomas Garratt, Sole House, Hertford.*

Societies.

ROYAL HORTICULTURAL: *July* 19.—James Bateman, Esq., F.R.S., in the chair. At the conclusion of the preliminary business, which included the election of one new Fellow—Mr. J. T. Peacock—Mr. Berkeley remarked, in regard to the show of Picotees and Carnations, in another place, that these flowers had not been shown in such good condition as on this occasion for several years, and directed attention to Messrs. Veitch's cut flowers of Spiræas, which included S. sorbifolia, one of the most charming of the series, and S. Lindleyana, of which specimens could be more beautiful for planting in shrubbery borders. Mr. Berkeley then commented upon some coloured plates of Melastomaceous plants, from M. Linden, and upon some leaves of trees and shrubs, sent by MM. Ottolander, of Boskoop, of which further particulars will be found below; and then directed attention to a remarkable new variety of Lily of the Valley, shown by Messrs. Standish & Co., to whom a new large bottle was forwarded by mistake from the Continent some months ago. Mr. Standish bought them to force early in the spring, but do what he would, a start into growth they would not make. At last he turned the lot into a cold frame, and the result was that, though not in flower, fully six weeks later than those out-of-doors. It was quite distinct from the common variety, having shorter, blunter, and more rigid leaves, and the flowers were very large-bells, which makes it a valuable acquisition. Alluding to the small group of plants from Mr. W. W. Saunders, attention was directed to a Rush-like plant, the flowers of which resembled those of the Stanfieldia, which on examination were found to have the three stamens and inferior ovary of the Iridaceæ; and to a white-flowered species of Rochea, which he had not seen before. Coming next to the subject of stoneless Grapes, Mr. Berkeley remarked that the probable origin of a stoneless variety of Black Hamburgh had long been the object of hybridisers. To obtain this, the above-named variety was crossed with the Black Monukka, an exceedingly good fleshed, stoneless Grape, which it was very difficult to catch just in the proper condition for crossing. This had, however, been done by Mr. Barron, of Chiswick, at great inconvenience to himself, and he (Mr. Berkeley) was glad to say that the cross had taken place, as in plants raised from the crossed seed this year the distinct foliage was plainly discernible, and he hoped that the fruit which these canes would produce next year would prove stoneless.

Concerning the Potato disease, Mr. Berkeley observed that, in his own garden, the Potatos were attacked by it in a more virulent form than he had ever seen. The disease in question was due to a species of mould, and the reason why it was more prevalent in wet seasons than dry ones was owing to the fact that this mould was capable of producing another form, resembling animals, or, as they were called, *Zoospores*, and these are unable to move without wet.

Mr. Bateman then made some observations on Orchids, and the meeting was adjourned.

Scientific Committee.—A. Murray, Esq., in the chair. Rev. M. J. Berkeley exhibited fragments of Rhododendron ferrugineum with a large fleshy gall-like body on the leaves, and which he considered to be the result of a Fungus mould, a species of Ascomyces, similar to that which produces blister in Peach trees.

Professor Karl Koch, of Berlin, made some comments on the large and interesting collection of leaves of trees and shrubs, sent to the last meeting by MM. Ottolander, of Boskoop. The following is the substance of M. Koch's remarks:—

"The Scientific Committee has honoured me by referring to me a collection of branches of trees and shrubs to report on. I know the establishment where they are grown very well. The nursery of Messrs. Ottolander, of Boskoop, is perhaps the largest establishment for the culture of trees in Holland. Boskoop is a village near Gouda, where nurserymen alone reside. The collection contains 83 species and varieties of ligneous plants, especially Salix (43) and Populus (11). Most of them are interesting, and not much diffused in the gardens, also some quite new. Time does not permit me to speak about all the species and varieties which Messrs. Ottolander have sent, but I may allude to some of the most interesting. Among the 43 Oaks are worthy to be mentioned the varieties with red and yellow leaves. The best are nigra and Concordia. I have seen in Belgium trees already large and wonderfully beautiful. All the 11 varieties of Q. pedunculata. Another section of that species are very remarkable for their small and incised leaves. Some of these have long been known, the others are new.

"Among the species I recommend especially the Caucasian Oaks, Quercus castaneæfolia and macranthera (not macrantha), because the trees grow quickly and make a very good appearance. Quercus alba Rousseau is not the American species, but the true Quercus pubescens of the mountains of middle Europe. Quercus dentata is a Chinese species, much resembling Quercus coccifera of the Levant. Quercus glabra longifolia is the finest Oak with evergreen leaves, and merits recommendation. I do not know 'Quercus Fan,' but I believe it is a variety of Quercus pedunculata, with almost black petioles and branches.

"Among the Maples, all the varieties of Acer polymorphum, Sieb. (not Spach), merit the greatest recommendation; but I believe that the trees suffer in England in the winter time. An interesting variety of Acer platanoides is that which received the name palmatum long ago. I saw this variety in my youth in the park of Weimar, but since that time it has disappeared.

"Cornus sibirica is the true C. alba, L., and a fine decorative plant in the winter time, because the branches have a red colour. The branches of Salix are so flexible, that they afford excellent material for binding.

"Finally, I have the honour to call attention to the variety heterophylla of Fagus sylvatica. It is much used for decoration by reason of its beautiful appearance. This tree is the Oak-leaved Beech of Goethe and other German poets."

A yet larger collection, containing, *inter alia*, a great number of Hollies, including many new seedlings raised at Boskoop, was exhibited. Messrs. Ottolander also sent Pterocarya caucasica and levigata, two species which are often confounded in gardens, like the former one, which was referred to M. Koch to report on at a future time.

Major Clarke exhibited an interesting case of herbaceous grafting in a variety of Cotton, in which a young seedling, some ten inches old, had been grafted with a piece of a plant of Gossypium herbaceum, and had made rapid growth.

The Chairman showed portions of a Pinus attacked by an insect, Tortrix histrionella, which seems increasing.

Professor Asa Gray exhibited a Viola pedatifida Prosperor dubium deformed and enlarged by some insect larva.

Dr. Masters exhibited, on the part of M. Linden, of Brussels, some coloured drawing of the flowers of Melastomaceous plants, and a Dracæna allied to Sanderiana the provisional names of Amaraboya princeps, splendida and amabilis. These are plants with all the habit of Melastomaceæ, but the flowers differ in their size and texture. *D. amabilis* has pink flowers, magnificent flowers of a pale pink colour; *A. splendida* has smaller flowers of a bright carmine, while *A. amabilis* has small flowers of a pink colour. The petals in all cases are six in number, and connected as being like those in coriaceous in texture. In all three species the stamens are represented as partially united at the base, and forming an incomplete ring. These stamens are stated to be of a waxy or livid colour. The plants are from Guatemala. The plants were found in Choco, New Grenada, by Mr. Wallis, but the drawings, though serving to give a general idea if the plants, are not sufficient, from a botanical point of view, to enable a definite opinion to be formed as to the genus. Dr. Hooker suggested a relationship to Bellucia, but were it not for the capsular not baccate fruit, the plants would appear to be nearer to Blakea. In any case the plants are grand additions to gardens, and it is to be hoped that M. Linden will soon flower them, and enable their botanical *status* to be ascertained.

Dr. Masters also exhibited, on the part of Mr. Earley, some double flowers of Sweet Pea. Major Clarke stated he had occasionally met with similar flowers.

From Mr. Grote came specimens of Maize, in which the female inflorescence had the branched form of the male flowers. It is said that this variety occurs in some parts of India, and that it occasionally occurs in this country.

Dr. Masters, alluding to the four styles of Eschscholtzia californica, and two of which were described by Payer as processes from the placenta, stated that an examination of the course of the development had led him to the conclusion that the supernumerary styles were really the rudimentary stamens, the short calyx splitting and at right angles to the first pair. This second pair of carpels remained in the rudimentary condition.

Dr. Masters then read the following communication from Mr. Fowler, relative to the possibility of inducing variegation in the leaves of a stock by engrafting on it a variegated scion. The result of Mr. Grieve's experiments, like those of Mr. Laxton, alluded to at the last meeting, are of a negative character. Mr. Grieve's paper is subjoined:—

"I have been recently reminded of some experiments made by me during the spring of 1869, with a view to ascertain if something of the influence which the stock exercises upon the scion, &c.

"The experiments referred to were described by me in a paper which I had the honour of reading before the Horticultural Congress held at Manchester on July 21 and 22 of that year; and this paper was subsequently published, with others, in the *Gardeners' Chronicle* and other horticultural journals. I there recommended that, with a view of ascertaining the possibility of producing the condition of variegation in the scion on the stock by their influence upon each other, I stated that I had engrafted variegated stocks with green and plain or green-leaved varieties upon variegated stalks, &c.; and in most instances allowing the stock to develope itself as well as the scions. But in no instance during the time the present time the result is of a strictly negative character, and can now point to green-leaved varieties of plants, which have been growing for upwards of two years upon variegated stocks, without having in any instance shown the slightest indication of becoming variegated. Also to variegated varieties growing upon green stocks, which have never in any instance reverted to the green or normal condition.

"The results which these experiments have been tried are principally Pelargoniums, but I also endeavoured to transmit or reproduce the quality of scent by grafting many of the highly-perfumed Cape varieties, such as "tomentosum," upon green-leaved zonal sorts, &c., but all with a like negative result.

"I also at the same time, viz., early in the spring of 1869, grafted or inarched many varieties of leguminous plants, such as dwarf French Beans upon Scarlet Runners, and Scarlet Runners upon dwarf varieties, Green Windsor Beans upon Early White Mazagan, and White Mazagans upon Green Windsor, Green Marrow Peas upon early white sorts, and early white sorts upon green marrows, &c. I carefully saved the seeds from all the grafted plants, and during the spring of the following year, viz., 1870, sowed them at the same time, place, and under precisely similar conditions, with ordinary seeds of each respective variety, and carefully watched for the development of any peculiarity which might be ascribed to the influence of the stocks upon which the plants which had produced the seed had been. As regards the dwarf French Beans which had been produced upon Scarlet Runners, I could perceive no difference whatever, while the Scarlet Runners which had been produced upon dwarf French Beans exceedingly productive, but did not grow so luxuriantly at any time during the season as the plants produced by the ordinary seeds. But this season up to the present time I cannot perceive any difference.

"With regard to the Mazagan and Green Windsor Beans the operation of grafting had no visible effect, and the birds having made free with the produce of the grafted Peas, I only succeeded in saving a very few seeds of the variety known as Yorkshire Hero, which had been grafted on Sutton's Ringleader, one of the earliest sorts in cultivation. These few seeds I saved by themselves during the spring of 1870, and managed to secure about half a pint of seed from them, and this I sowed as far as it went in a long row or line in the kitchen garden—on February 23 finishing the line with ordinary seed of the variety Yorkshire Hero, also the produce of last year; and they are fully in flower at the time of writing the descendant of the grafted plant, although the tallest by quite a foot, will not be ready for at least a week from the present time, so that earliness has by no means been obtained by the operation of grafting. The pods of the latter have also the appearance of being considerably longer than the former, and contain morePeas. Altogether the line has at present the appearance of being composed of two very distinct varieties of Peas. But, notwithstanding all this, the conclusion I feel forced to come to respecting the results of the experiments I have endeavoured to describe are, in the first place, that variegation cannot be produced artificially, and secondly that neither any authenticated instances of its having followed that operation this fact will not by any means prove that it was the result of such operation, as variegation is found in so many instances to produce itself naturally.

"I am also inclined to doubt the existence of a 'graft hybrid,' for although, as in the case of the Pea alluded to—where a variety appears to have been produced distinct from both stock and scion, I still apprehend that, as in the case of the Scarlet Runner, this divergence will in the course of another year or two entirely disappear. Still this divergence, produced to all appearance by the influence of the stock, may prove to be more permanent or otherwise, appears to be interesting, and may be considered as not unworthy of further investigation." *P. Grieve, Culford, July* 15.

Floral Committee.—J. Fraser, Esq., in the chair. The most interesting feature of this meeting was perhaps the exhibition of a group of fine new Agaves and other plants, from the nursery of M. Jean Verschaffelt, of Ghent. Of Agaves there were a dozen, and the following were selected by the International Committee for First-class Certificates:—*A. Ingentissima*, sp. nov., *A. Regeli macrodonta*, and *A. Mescal folia stristis*. We hear that this fine lot will not return to the Continent, having passed into the hands of Mr. J. T. Peacock, Shirley House, Croydon, a gentleman who makes this class of plants a speciality, and whose collection is already a rich one, gathered together within the last few years, from every available source. M. Verschaffelt also received certificates for Dracæna Chrysophlebia, a very beautiful form; for a new species of Zamia from New Caledonia; and for a new form of Dicksonia (? Sellowiana) from St. Catherine's, Brazil. Continental exhibitors also were represented by Messrs. Makoy & Co., Liege, who had a First-class Certificate for a new dwarf Tillandsia (Platystachys) complanata, which bears beautiful blue flowers; and by M. Wendland, of the Royal Gardens, Herrenhausen, Hanover, who had a like award for Æschmea Maria Regina, a very attractive plant, with clear, deep, rosy-pink bracts. Messrs. E. G. Henderson & Son exhibited several beautiful varieties of Nasturtium, which, from the compactness of their habit and the density and bright colours of their flowers, give much promise. The most noticeable were Sunset, a medium variety, with very flat petals, of a rich orange colour, shaded with red; and Celestial Blue, one of the pumila section, very dwarf and free-flowering; and Brilliant, rich deep blue, belonging to the Erinus section, and having large flat flowers. The two last named had First-class Certificates. A very free-flowering white variety of the speciosa type was also shown by Messrs. J. & C. Lee, under the name of White Perfection, and a similar award was made to it. Messrs. Carter, Holborn, exhibited a beautiful several new seedling Picotees, and received the highest honours for two varieties, named respectively Mrs. Brown and Morning Star. Certificates were awarded to Mr. Sheen, Trentham, for a fine cut spike of Odontoglossum hastilabium, and a nice plant of Barkeria spectabilis; to Messrs. Veitch, for a box containing cut flowers of 8 distinct sorts of Lilies; to G. F. Wilson, Esq., for a beautiful group of Lilies, including one of the canadense type, brought by Mr. Robinson from the Rocky Mountains; to Mr. Lawrence, gr. to Bishop Sumner, Farnham Castle, for a wonderfully fine specimen of Dendrochilum filiforme, on which were 150 spikes of flowers; and for a nice plant of the beautiful white Maxillaria venusta; to Mr. Denning, for a group of Orchids, alluded to elsewhere; to Mr. Mackintosh, Hammersmith, for a well-grown specimen of the Ivy-leaved Pelargonium; and to Mr. Cranston for some very fine cut Roses, of which several good boxes

also came from Messrs. Veitch. Messrs. Paul & Son had First-class Certificates for Roses Comtesse d'Oxford, and Louis Van Houtte, and the same award was made to Mr. T. Milner, Bradford, for Fuchsia (tricolor) Sunray. Messrs. Paul & Son sent 9 boxes of cut Roses, Mr. B. S. Williams had an interesting group of new plants, and the same may be said of a small collection from the gardens of W. W. Saunders, Esq. Mr. Croucher, *gr.* to J. F. Peacock, Esq., exhibited a new Agave, under the provisional name of Shawiana, which the Committee thought might be shown again when further developed. Mr. Hepper, Acton, sent a group of very dwarf Cockscombs, and from Mr. Cunningham, Moor Park, Rickmansworth, came flowers of a pure white Verbena named White King, of which the Committee requested to see a plant. If it has the well known habit of the old Purple King it will be a grand acquisition as a bedder.

In addition to the above, a medium-sized tent was erected near by, and was made exceedingly attractive with large collections of very choice plants from Mr. B. S. Williams, Messrs. Veitch, Messrs. E. G. Henderson & Son, Mr. Denning, gr. to Lord Londesborough, Mr. Parker, Messrs. Downie, Laird & Laing, and Mr. J. Mann, Brentwood, &c. In Mr. Williams' excellent group were a specimen of Cochlostema Jacobianum, with four spikes of flowers, a very healthy example of Thunia alba, with 13 beautiful spikes, capital pots of Miltonia spectabilis, Cypripedium superbiens, and Cattleya Warneri; some handsome specimen Palms, as Areca sapeana, Heaths, Yuccas, Pandanads, &c., and a glorious plant of Adiantum farleyense. Messrs. Veitch had beautifully grown plants of Dracœnas Mooreana, regina, Youngii, Guilfoylei, porphyrocardia, and Lindenii, Orchids; example of Oncidium macranthum with a spike about 10 feet long, on which were 29 flowers, splendid in size and more highly coloured than it has been seen before, a very healthy specimen of Sacanthus Celsii, with a dozen beautiful spikes; and nice plants of Angulos. Ruckeri, Miltonia Regnellii purpurea, Cattleya Mossiæ, Stenia fimbriata, &c. Messrs. Downie, Laird & Laing sent a capital collection of Phloxes, including 6 in 8-inch pots), which took a 1st prize. The remainder were in much larger pots, and from their compact habit, fine foliage, and large trusses of flowers, it is evident that the size above mentioned is much too small. Mr. Mann sent a dozen nice baskets of Zonal and Tricolor Pelargoniums, and from Mr. Parker came a miscellaneous group of ornamental plants in pots, which took the 1st prize. The plants were about 18 inches through, and under 2 feet in height, clothed with foliage to the pots, and covered with flowers, especially Campanulata carpatica, Coreopsis lanceolata, Œnothera venusta, Betonica hirsuta, Tradescantia virginica rubra, &c. Prizes were offered by the Metropolitan Florist Society, for 12 Picotees and 12 Carnations, Mr. N. Norman, Cresswell, near Plumstead, being 1st, and Mr. Pizzey, gr. to Sir E. Perry, Fulmer, Slough, 2d in the class for Picotees, the awards being reversed in the class for Carnations. Similar classes were also made by the Society, Mr. Norman being 1st for Picotees, and Mr. Turner for Carnations. Mr. Hooper, Bath, had an extra prize for capital boxes of bloom, and of the above-named flowers, and some fair Pansies, Pinks, &c., came from Mr. Hepper, and Messrs. E. Shenton & Co. M. Verschaffelt, Ghent, sent over a dozen excellent standard Orange trees, nice bushy heads on clean stems, about 4 feet high.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Mr. Hoes, gr. to Lord Carrington, Wycombe Abbey, Bucks, sent very fine specimens of four varieties of Pine-apples cut from plants 16 months old; their weights were as follows:—Enville, 11 lb. 4 oz.; Queen Cayenne, 8 lb. 8 oz.; Charlotte Rothschild, 6 lb. 8 oz.; and Queen, 5 lb. 12 oz. A Special Certificate was awarded. Messrs. Rivers & Son, Sawbridgeworth, sent fruit of a new large deep black Cherry, named Belle de Noir de Schaerbeek, to which a First-class Certificate was voted. The same award was also made to Mr. Bradley, Littledale, Southwell, for a large fine flavoured Strawberry, named The Amateur; and to Mr. Standish & Son, for their excellent new Grape the Ascot Citronelle, a variety having a very high flavour, and the excellent character of hanging well and not cracking. Special Certificates were voted to Mr. Ivery, Welwyn, for a collection of fruit, consisting of Cherries, Nectarines, and three varieties of Strawberries; and to Mr. Bland, gr. to Earl Kilmorey, Gordon House, Isleworth, for a dozen finely-ripened and coloured Pine-apple Nectarine Peaches. Mr. Hepper, gr. to P. S. Millard, Esq., Acton, sent capital specimens of Veitch's Autumn Giant Cauliflower, and Mr. Smith, gr. to the Earl of Gainsborough, Exton Park, sent a brace of Cucumbers, a hybrid between Worcester Prize and Carter's Champion. Messrs. Carter & Co. offered two prizes for a collection of vegetables, the 1st of which was taken by Mr. Miles, gr. to Lord Carrington, he being the only exhibitor. His collection was a large one, and comprised first-rate examples of Asparagus, Carrots, Turnips, Parsnips, Salsafy, Scorzonera, Peas, Globe Artichokes; Carter's Daredevil, Laxton's Supreme, and Carter's Imperial Wonder, Runner, capital Broad and Kidney Beans, Cabbage, Celery, Lettuce, &c. Mr. James, gr. to W. F. Watson, Esq., sent a seedling Pea of considerable merit, named "James' Prolific," which grows to the height of about 5 feet, carrying a first-rate crop of well-filled straight pods, about 3—4 inches long.

THE CHANNEL ISLANDS EXHIBITION.—This exhibition, in its scope and object, the variety and excellence of its details, and its successful financial results, by far the most remarkable in the annals of the Channel Islands, has just closed after a three weeks' career. It was held in the building and grounds belonging to Victoria College, Jersey, a site which, by its natural beauty, materially contributed to the success of the show, in which were comprised agricultural, horticultural, and native art and industry departments, with such rare objects as the islands possessed added, and lent for the occasion.

Though our remarks in these columns are necessarily confined to the horticultural section, it is obvious that the most distinctive and interesting feature was the display of native cattle in numbers nearly equalling the great English shows, and exhibiting an amount of beauty unprecedented, and worthy of foreign admiration. Since Oxford, of last year, the cattle of Guernsey and Jersey have been classed separately, an arrangement which has obviated future disputes, and which any observer would here acknowledge as just, and long delayed. To the English mind these breeds, so distinct, were long known as Alderney—an island which contributed no specimen to the show. It is sufficient here to say that the characteristic features of Jersey and Guernsey cattle, while assimilating as opposed to the larger English breeds, have each their sturdy partisans in the islands, and are now generally recognised as best when kept from intermingling. But to our task.

The horticultural section, though deficient in some parts, owing to the late and backward spring, and lately to the incessant rains—this is one fabulous spring and glowing summer!—presented, as a whole, great excellence. The florist accustomed to London, Manchester, or Leeds, would find no gorgeous foliaged plants whirled by their facility of grouping diversify the monotony of staged specimens.

There is not a stove-house, worthy of such designation, in either island, and those private ones, the pride and glory of the mother country, would not find scope here. The work seen is, therefore, mainly amateur, and very good as such.

The display may be said of fruit culture, and especially in Grapes, which are largely exported, and generally grown to suit the market, and do not exhibit that standard of merit which scientific training produces. The best grower in either island is Mr. Pond, the sole gardener at the St. Lawrence Nurseries. The Grapes exhibited by this veteran were of an excellence and perfection in staging seldom seen in our best metropolitan shows.

The Strawberries, Peaches, Nectarines, and flowers was designed by the secretary, Major Howell, and a great advance—resisting bravely there easterly gale which raged round the exhibition buildings, and had previously unguardedly injured its fury on the tender fruit—and raised the hair on many an official head during the momentous instant devoted to photographic skill. *Ehen! fugaces.*

The blooms of Roses were generally good, though the lateness of the season and the cold rain had been most adverse. In these Mr. De Faye was 1st. The Roses from Guernsey had besides a rough sea voyage to endure, which sustained the competition without disadvantage. Much of the show consisted of Zonal Pelargoniums, Captain Saumarez taking the silver medal, Mr. Le Sueur was 2d, and Mr. Mauger received very good Ivy Pelargoniums. In Ferns the competition was keen, Mr. Cutlin taking the silver medal. Mr. Saunders, nurseryman, showed the rarest Ferns in the sixes. Probably the most interesting feature in the show was Mr. Pond's seedling Pelargoniums, Silver Tricolors, in which were Mrs. Rousby (which Mr. Turner lately exhibited, and was 1st as the best new variety of its class), a beautiful plant, of good habit, and Mrs. Pond, which is so strong as to require support, and richer in colour, though not so flat in the leaf as Mrs. Rousby. These two will prove decided acquisitions.

Among the fruit were dishes of Peaches and Nectarines, Mr. Pond obtaining the silver medal for his collection of Grapes, comprising noble Canon Hall, Black Hamburgh, Muscat of Alexandria, Golden Champion, and Muscat Hamburgh.

Vegetables were few in number, but very good; the American Potatos as usual fine, but, Early Rose specially, too apt to degenerate in these climates to make them profitable.

Silver Medal was awarded to Bréhaut's new lawn conservatory and fruit case (Rendle's patent), and another to Messrs. Haynes & Son, of London, for their syringing apparatus.

In other departments of the exhibition were well filled, and the whole matter has proved a great success, originating, as it did, with the energetic President, Mr. C. P. Le Cornu, and patronised by as many as 10,000 visitors in a single day.

WOODBRIDGE HORTICULTURAL: *July* 13.—This Society held its annual summer show in the grounds of W. F. T. Phillips, The Grange, a situation admirably adapted for such a display; indeed, a more beautiful spot it is scarcely possible to imagine. The marquee was placed upon rising ground in a well-wooded park, in which may be seen many fine examples of Cedars, Oaks, and Beeches; it also commanded many entrancing views of the surrounding country, with the pleasant waters of the river Debden in the distance. The visitors were further permitted to feast their eyes upon the beauties of a very nicely laid-out flower garden, which extended from the mansion to their enjoyment. Not only did Mr. Phillips assist the Society by thus throwing open his beautiful grounds to the visitors, but he also rendered material assistance to the show with the splendid display of his fine collection, making it the finest and largest exhibition ever yet held in the town of Woodbridge. One plant in particular, from Mr. Phillips' garden, deserves special notice, a remarkably handsome and well grown pyramidal Puchsia, called Julius André, which measured 8 feet in height and nearly 6 feet in diameter; it was, indeed, a perfect model, from which many of our London exhibitors of this graceful plant might take a lesson with advantage.

Stove and greenhouse plants, both those with beautiful flowers and those with ornamental leaves, were well and creditably represented, so also were hardy and exotic Ferns, the best collection of fine-foliaged plants coming from Mr. Mill, gr. to Lord Rendlesham, and the best collection of Ferns from Mr. G. Berry, Ipswich. Heaths, Geraniums, and quantities of soft-wooded plants, were also shown in excellent condition, proving how valuable they are for decoration at this particular season of the year, for, without them, our greenhouses and conservatories would almost be without flowers; amongst them may be named Achimenes and Balsams, which were shown in excellent condition by Mr. Goldsmith and Mr. King. Cut Roses were another conspicuous feature in the show, Mr. Cant, of Colchester, carrying off the silver cup for the best 24; whilst Mrs. Kent, gr. to J. G. Barnard, Esq., was 2d with a very fine set, and Mr. W. Nicholl, 1st in the class for 6. Carnations and Picotees are extensively grown in the neighbourhood, and the flowers exhibited on Thursday were amongst the finest we have ever seen. We were also very pleased to see prizes offered for herbaceous plants, which brought several very creditable collections, that of Mr. J. Gilbert & Son, of Ipswich, being 1st, and Mr. J. Buxton 2d. This is undoubtedly a step in the right direction, for we have certainly been losers by banishing so many of our fine hardy plants from the flower-borders. The table decorations produced a splendid excellent taste, the prize offered by Lord Mahon for the best going to Mrs. Wrinch for an exquisitely-arranged epergne; Mr. Goldsmith, gr. to Mrs. Day, also carried off 1st honours for basket table plants. Hand bouquets were shown in quantities, and were very tastefully arranged, Mrs. Keen carrying off the 1st prize in this class. The Woodbridge show has always been famous for its excellent display of fruit, and this season has been no exception to the rule. The Grapes, in particular, were very fine, both as regards size of bunch and berry, as well as general finish and colour. Indeed, we have not seen their equals at any exhibition during the present season. The principal contributors were Mr. Blair, Shrublands Gardens; Mr. Wright, of Whitton; Mr. Wallace, of Wacton; and Mr. Cousins, of Beeches. Pine-apples, Cherries, and Strawberries were also very good. For the best basket of fruit, artistically arranged, not less than 8 varieties, Mr. Blair, of Shrublands, was 1st with a choice lot, and Mr. Wright 2d.

The cottagers' classes were admirably sustained, and the fine collections of fruit and vegetables contributed gave ample proof that great attention must have been given to the garden after the usual toil of the day was over, especially when we consider the many difficulties with which every one has had to contend during this changeable and fickle season. There was a large attendance of visitors, to whose enjoyment the band of the 2d Queen's Dragoons, the leadership of Mr. Cousins, added considerably, continuing to enliven the company with exquisite music up to 10 o'clock in the evening, when the gathering was brought to a close by a grand display of fireworks, thus ending the most successful meeting the Society has yet held.

SOUTH NOTTS HORTICULTURAL.—The 20th annual exhibition of this flourishing society was held on the Scores Hills, Newark, and was by far the best ever held (with the exception of Nottingham) in the county. The floral and horticultural exhibition took place in several large tents, and immediately adjoining these was a tent devoted to a show of poultry by the Newark Society. All the tents were well stocked with an excellent display. The stove and greenhouse plants were a manifest advance upon previous years, while the fruit quality was very good, the Roses fine, and the vegetables even superior to the late show at Nottingham. The great prize of the day was a silver cup, value ten guineas, for a stove and greenhouse group, filling a large opening, the other foliage. For this prize three competitors put in an appearance — Mr. Cooper, nurseryman, of Derby; the Rev. S. R. Hole, of Caunton; and Mr. Nevile, Esq., of Holme Pierrepont, the latter gentleman especially the foliage, but several of them had seen their best day, while some of the flowering plants were not A 1. The specimen of Stephanotis floribunda was first-rate, but the Allamanda cathartica, though bloomed and coloured, rather spare in foliage. Allamanda cathartica and Hendersonii wanted finish, while Erica Parmentieriana rosea, though a nice plant, was not in bloom. The specimen of Eucharis amazonica was extremely superb, but the same must be said of Croton angustifolium, finely coloured, with its golden tresses sweeping almost to the ground. The other Crotons were not good, but there was a fine plant, up to 1st rate, of Dracæna terminalis, and fine Fan and Sago Palms. Mr. Hole's plants were smaller, but more rare, most of them in fine health. Anthurium Scherzerianum, with a dozen or more of its brilliant spathes; Dendrobium chrysanthum, in nice condition; Dipladenia amabilis rather pale; Ixora coccinea, with a dozen or more nice heads of bloom; Erica Parmentieriana rosea, in good condition. The foliage plants comprised nice examples of Alocasia Jenningsii and Lowii, both fine plants; A. metallica; the Thief Palm, Phœnicophorium sechellarum, with its broad, handsome foliage; Thrinax radiata, another elegant Palm, and nice specimens of Maranta Veitchii, Sanchezia nobilis, and a very promising young specimen of Croton angustifolium. The plants matched well, and formed an admirable group. In the collection sent by E. Nevile, Esq., the plants were Croton angustifolium, Alocasia Lowii, very fine, in fact superb; Croton variegatum, a pyramid, 6 feet high; Rhynchospermum jasminoides, nicely bloomed; Dipladenia amabilis. In the collections of 6 plants Mr. Cooper also obtained 1st honours, with a finely bloomed Allamanda grandiflora, Erica Atoniana, E. Turnbullii, in fine condition, E. Irbyana, E. Spenceri, not good; Dipladenia amabilis, fine in colour; and a passable D. crassinoda. The 2d prize went deservedly to Mrs. G. Gilstrap, who had a superbly bloomed Pleroma elegans, the bright purple flowers producing quite a glow; Stephanotis floribunda, finely bloomed, but rather formal; Rhynchospermum jasminoides,

good; Erica depressa, an upright growing and very remarkable variety, nearly 3 feet high.

For foliage plants Mr. Hole obtained the 1st position with some nice healthy plants—Caryota urens, Elechnum cocrowadense, Marrants wittata, Gymnostachyum Pierrei, and Fittonia argyroneura. Mr. Cooper sent Dicksonia antarctica, the Fan Palm, two Crotons, Gymnogramma Martensii, and Dasylirion gracile. A 3d prize was awarded to Mr. Moore, gr. to Earl Brownlow, who had the most perfectly powdered silver Ferns, Gymnogramma peruviana argyrophylla, we ever saw. In the Ferns Mr. Moore took the 1st position, with really fine plants of Woodwardia radicans, Cyathea medullaris, Adiantum tarentinum, and the singular Lomaria cycadifolia. Mr. Cooper was 2d, and W. Newton, Esq., and Mrs. Bradley took equal 3d prizes.

In Lycopods Mr. Hole was again 1st with some clean well-grown specimens, the best being Selaginella Poulterii, inæquifolia, Martensii, formosa, apoda, and cæsia. Mr. Moore sent smaller plants of S. flabellata, lævigata, Willdenovii, Wallichii, and Kraussiana. Mr. Newton had also some nicely-grown small plants, among which we saw the rather scarce S. involvens. In the class for 6 foliage plants, Mr. Hole was again 1st, and Mr. Moore sent the most elegant of all Palms, Cocos Weddelliana. Cut flowers were abundant, but most of them clumsily arranged, while the judging of them was in several cases anything but satisfactory.

Roses were grand, far superior to those at the Nottingham show, and the competition close and spirited. In the nurserymen's class, for 48 blooms, Mr. Frettingham, of Beeston, obtained the 1st place, with the following flowers, most of them superbly grown, though a little bruised from the storms of the last few days:—Abel Grand, Alfred Colomb, Beauty of Waltham, Centifolia rosea, Charles Lefebvre, Charles Margottin, Charles Verdier, Comte de Nanteuil, Comtesse d'Oxford, Dr. Andry, Duchesse de Caylus, Duchesse de Morny, Duc de Wellington, Duke of Edinburgh, Elie Morel, Exposition de Brie, François Lacharme, Henry Ledechaux, Horace Vernet, John Keynes, John Hopper, Jules Calcot, La France, Leopold Hausburg, Lord Macaulay, Mademoiselle Annie Wood, Madame Boll, Mademoiselle Bonnaire, Madame Clémence Joigneaux, Madame Charles Wood, Madame Charles Verdier

July 13.—Overcast throughout. A little thin rain fell occasionally.

— 14.—Large amounts of cloud were generally prevalent. A little rain fell. Distant thunder heard at 9 A.M.

— 15.—Rain fell between 1 A.M. and 4 A.M. Cloudless about 9 A.M., and again at night. Cloudy between those times.

— 16.—Generally cloudy. Hazy and misty, but fine.

— 17.—The amount of cloud gradually decreased as the day advanced. Fine throughout.

— 18.—Nearly cloudless till 3 P.M., afterwards variable.

— 19.—Cloudy till night, and a few drops of rain fell between 6 and 7.30 A.M. Generally cloudless after 9 P.M.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING WEEK.)

PLANT HOUSES.

THE *Victoria regia* will now be making rapid growth. Be particular at this junction to keep the water within the tank as clean as possible, by means of a constant flow of pure fresh water. It does not matter much how small is the quantity, [as the antidote to slimy formations consists in the fact that the water does not become absolutely stagnant. Sometimes when these unwholesome substances are permitted to form, they collect freely on the undersides of the leaves, and especially upon the younger ones. In an instance where the tank was of sufficient dimensions, I used to turn the more moderate-sized leaves upside down, and then removed all such particles as were attached. Some care, however, must be taken not to damage the leaves in any way, and the operator must look after his bare arms if the leaves have attained to anything like maturity, if he does not wish them lacerated by the sharp prickles to be found on their undersides. Let the surfaces of the latter be syringed occasionally, and thus assist the blooms to push by every possible means. These remarks apply in general terms to smaller *Aquariums*, whether these consist of tanks for *Nymphæas* or the more simple forms employed indoors. The more frequently the water is changed the better, and the oftener the sides of the glass, or slate, &c., are washed, the easier will all be kept clean and wholesome. Now that we have something like warm weather, it will be possible to dispense with fires in ordinary stoves for a short period. If, however, the weather suddenly turns cold again, the fire should be "lit up" daily, between 3 and 4 P.M., and be damped down finally by 5 o'clock, or after burning for about two hours. Be very particular not to cause too high a night temperature by artificial means, as few things are more injurious. Keep together the *Cape Pelargoniums*, which gradually come in from flowering, in a properly cindered corner, until a sufficient number are obtained to operate upon, in the matter of cutting back, &c., after the wood has been better ripened by exposure to the air and sun. Give to *Oranges* and *Citrons* a good mulching with thoroughly decomposed cow-dung and yellow loam, pressing it down firmly after first removing a fair portion of the old surface soil. Where the above were mulched earlier in the spring, as was then suggested, it will aid them materially to afford all thrifty growing specimens an occasional watering with rather strong liquid manure. By the term strong, I do not mean such crude stuff as is generally to be met with in farmyards and the like, but rather such as has been properly prepared in the usual manner. Use the liquid in a day or so after making it, and when it has become moderately clear.

FORCING HOUSES.

I fear in many instances, where the borders of old *Vineries* are out-of-doors, and have had to undergo the rigours of the past inclement period with its excessive rains, the roots will not now be in a very happy condition, consequently that most distressing malady shanking, will in all probability be somewhat prevalent. The only remedy is to follow the most rational course, as by these means we can meet its onslaught hand to hand, and contend with it somewhat successfully. By a rational course, I mean affording an abundance of fresh air both by day and by night. This we shall be better able to do if the fine weather continues. As I take it, shanking is but the effect of a want of health, a languid supply of nutriment, and, owing to a want of greater vigour, the non-capacity to turn the crude sap to a good account. I look upon the shanking of the fruit-stalk in precisely the same light as I view the ill effects of immatured wood. If the young wood of the current season's formation shows a blotchy state of ripening, is over succulent, and not possessed of that hardened yellow hue which gardeners so much admire, then they will not have to look for a proper state of maturity; and if even no shanking exhibit itself, bad colouring will ensue, the primary causes of the latter defect springing from a like foundation. Those who possess small vineries in which it is necessary to maintain a miscellaneous collection of plants should act freely on this suggestion, and by doing their utmost to insure the young wood upon the Vines being speedily ripened, insure the proper finishing-off of the fruit at the same time.

HARDY FLOWER GARDEN.

That good old favourite flower, the *Auricula*, which has certainly become much more popular amongst us of late, may now be fresh potted with much hope of finishing off a goodly summer's growth. Good rich, fibrous, yellow loam, which has been well exposed to the air, and which is now moderately dry, should be used in a rough state with a moderate quantity of thoroughly decayed cow-dung, adding just sufficient sand to resist any too great binding tendency which the soil might possess. Following the possession of a properly prepared compost, clean pots are of the next importance. Do not make shift with pots simply wiped out, but thoroughly scrub and rinse them, so that the original porosity of each be assured as much as possible. In instances where new pots are employed, let them be well soaked in water for six or eight hours, and then moderately dried in a warm situation before their use. When taking the old plants out of the pots they have been growing in, remove as much of the old soil as possible, and shorten with a sharp-edged knife all the longer roots, severing a piece off the main root also, if of undue length. In potting them judge nicely so as to have the collar of the plant properly exposed. Too deep potting is one of the chief errors made through a want of practice. Lay each root out separately upon a bed of soil properly pressed into the pot, and then finish off by distributing the soil evenly and firmly amongst them. When in place they turn into a moderately shaded cold frame for a week or so. Let the surface of the soil become just dry, and should rain follow, take the lights off and permit it freely to fall on to them. If no rain ensues at the proper time, give them a nice soaking with a fine-rosed watering-pot, and with soft water if procurable. When the surface soil again becomes moderately dry, just pass the fingers over it to freshen up the surface, following with the watering, and so continue to keep them uniformly moist. In about 12 or 14 days they may be placed out-of-doors in their permanent summer quarters. One point I find I have omitted to notice, *i. e.*, that thorough good drainage must be afforded. Let it be a moderate one in regard to the quantity of crocks used, but most efficient in connection with the free egress of all water which reaches the ball. Younger plants or offsets should also be potted on. These, however, simply need a shift, and it is not desirable to remove the soil from around the roots this time.

HARDY FRUIT GARDEN.

Persist in keeping the runners removed from all *Strawberry Plants* intended for another season's crop, if these are not wanted for forming further stock. *Figs* should have some of the grosser shoots thinned out, where these are too redundant and fruitless. *Outdoor Vines* should also be gone over, and tacked to the walls. It is very questionable whether these can carry any crops this season. The Vines need not, however, be neglected on that account. It is a commendable practice to pinch off the points of any very free-growing shoots upon red and white *Currants* at this season; and in instances where the many young shoots which form have not been previously thinned out, do so now, the better to ripen off the wood intended to bear the next season's fruit crop.

KITCHEN GARDEN.

Transplant summer *Cauliflowers* from seed-beds, to induce further growth, in preparation for planting them out upon ground which may shortly come in, following a crop of Potatos, &c. These will then afford a crop, it may be, for drawing and placing in a frame or so when the early frosts arrive. Persist in filling up every vacant space, as it occurs, with the various kinds of *Winter Greens*, *Broccoli*, &c. Give fresh plantations of *Celery* copious waterings, using during bright hot weather clear water only, unless of long continuance, when manure-water will become a desideratum. It should, however, only be applied as in the day as possible, so that its burning tendencies may not be increased by the heat of the sun. Those who require *Sorrel* for use in the early autumn, should now cut a portion down, that young growth may be formed in readiness. Make a final sowing of *Dwarf Kidney Beans* on a sheltered sunny aspect. These may afford a supply which, owing to the late quantities required in most establishments during the long months of winter, should always be sought after. Thin out the Carrots sown last, and finish transplanting *Leeks* into prepared and well-manured shallow trenches. Cut away all Cabbages not required from the main bed, and allow the sprouts to form; this will afford a good permanent supply of greens away into the winter months. For the rest keep the hoe going freely amongst all crops, not alone for the purpose of destroying weeds, but also as an incentive of more rapid growth. Partially hoe the soil amongst *Asparagus* beds at this time, and before the young growth has become so dense as that weeds are not readily destroyed should damp weather supervene, and they have been permitted to get too far ahead. *W. E.*

Notices to Correspondents.

BOILERS: *E. F.* According to all the principles of heating by hot-water pipes, you seem to have them well placed. Still you say the return-pipe vigorously heats. Is there no stoppage? Is the boiler properly set, and does the fire burn well? We think the error must be there somewhere. The boiler is quite large enough to heat all the piping. The flow-pipe should, if possible, always rise from the boiler to the extreme end, and the return-pipe to follow in the same line, entering the boiler at the bottom.—*W. B.* A saddle boiler of the second or third size, or the Cornish boiler, as modified by Mr. Stevens, if properly set, would do all you require. It is not economical to have too small a boiler.

BOOKS: *G. C. B.* You do not say whether you want a work on British Botany or what. Lindley's "Vegetable Kingdom," the "Treasury of Botany," Hooker's "Students' Flora (British)," will probably suit you.

CLIPPING BOX EDGING: *Alex. Bee.* Box edgings should be clipped annually in the middle of June, in the first place, to economise labour, of which a considerable amount is required for this work in some places; and, secondly, because by permitting a part of the spring growth to be made before being cut back, the edgings so treated will "break" more densely, and yet afford time to make a neat growth before winter sets in. If you clip twice there is just the danger that many parts so cut back will remain bare and unsightly during the winter. Hence the suggestion referred to. If your position is exceptional, your edging vigorous, and you can fairly expect a further growth, clip it now without delay, but not otherwise. *W. E.*

FERNS: *E. A.* If a prize is offered for Ferns, these only being specified, you certainly cannot show Selaginellas, which belong to a totally different natural order. F.R.H.S. signifies a Fellow of the Royal Horticultural Society, and the initials may be used by all who are elected in this position. Apply to the Assistant-Secretary, South Kensington, for particulars.

FLOWER POTS: *S. K.* writes: "Please inform me whether the idea that plants grow best in porous pots is exploded or not?" Certainly not. "Will they flourish in zinc or cast-iron jars or pots? Or in glazed earthenware?" No. "Would not oil-paint on the pots exercise a deleterious influence on plants?" Yes.

FUCHSIAS: *W. H.* The specimen plant in question was undoubtedly grown from a cutting less than 12 months old. We suppose its resemblance to a pot of cuttings, 12 or 14 in the pot, is attributable for the style of training adopted.

GARDENERS AND THE TRADE: *Somerset*. We quite agree with you that no transaction of the kind should take place without the express permission of the employer. It is the tradesman who is most to blame here.

GARDENERS' APRONS: *A Gardener*. Blue serge is the more commonly used material now, but the real thing is blue shalloon, a kind of worsted stuff, imported from Châlons, in France, where it was first made. Gardeners of the old school would have repudiated the idea of using anything but the last-named article.

GRAPES FROM ONE-YEAR-OLD VINES: *W. W.* The fruit sent were in every way commendable; bunches of a good serviceable kind, berries large and well coloured, and thoroughly ripe. We submitted them for inspection to several of the London delegates to the Conference, who also expressed their admiration of the fine quality.

INDIAN FORESTS: *R. M.* Apply to the Secretary, India Office, London.

INSECTS: *I. H. A.* Your Melon plants are infested with a species of Aphis. Fumigation, properly applied, will certainly destroy them. Washing the leaves over alternately with lime-water mixed with soft soap and clear water, will also be efficacious. *J. O. W.*

LAWN SAND.—We have no experience of this, but it is well spoken of by several of our correspondents. It is to be had of Mr. W. D. Barbour, 3, Park Row, Leeds.

MUSHROOMS: *J. C. N.* If you will send a specimen, we will endeavour to name it for you. It is impossible to do so from your description.

NAMES OF PLANTS: *Mansfield*. We cannot undertake to name plants without flowers.—*W. K.* We cannot name your succulent kind of plant from the scrap sent us.—*W. Davidia elegans*.—*F. M. Shoberden*. The plant sent is not Specularia hybrida but S. Speculum, the Venus' Looking-glass, which, if gathered wild, must be an escape from some garden.—*Rob.* Potentilla reptans.—*W. Pea*. The common Marjoram.—*Mr. Mackerwain*. The grasses you have sent are Agrostis vulgaris, variety pumila, a denizen of poor dry soil, generally, and some Luzula, probably L. campestris.—*F. P. C.* Alcheritilla vulgaris.—*J. Fire Fly*. *Subscriber*. 1, Diplacus glutinosus; 2, Metrosideros floribunda; 3, apparently Neja gracilis; 4, Cystopteris fragilis; 5, Polypodium Dryopteris.—*Y. H. F.* No. 2 is Goniolipidebium appendiculatum, we certainly: the other next week.—*W. D.* 1, Nephrolepis tuberosa; 2, Cystomium Fortunei; 3, Asplenium flaccidum; 4, Cystomium caryotoides. Williams' Book on Fern Culture.

NECTARINE TREE: *X. Y. Your* Nectarine tree is attacked with some peculiar disease, which shall be inquired into, meanwhile we would recommend you to destroy the tree altogether. The sort is at best but a poor one.

PELARGONIUM: *Bell & Thorpe*. The truss of your double-flowered variety, Miss Evelyn, is one of the finest we have seen, round as a cricket-ball, and quite densely filled out with full double flowers of a vivid carmine-rose.

PHYSOSTIGMA: *G. W.* Physoiphon Loddigesii, a native of Mexico, is a curious small-growing, small-flowered Orchid, allied to Stelis and Pleurothallis. It should be grown on a block.

REMOVING TREES AND SHRUBS: *Old Subscriber*. No: unless by consent.

VERONICAS: *Devonian*. Very pretty for home growth, but not so good as some of the Continental varieties. Several of the shrubby Veronicas are almost hardy, even in the climate of London: we are, therefore, by no means surprised to hear that they often survive in Devonshire.

YELLOW BEDDING PANSY: *Oldroyd & Son*. The specimens sent are good, both in form and colour, and must, on account of its neat habit, hardy constitution, and free flowering capabilities, be a desirable acquisition.

ERRATA.—At p. 907, col. *a*, five lines from the bottom, for "re-announced," read "renounced." Same page, col. *c*, four lines from bottom, for "Pear," read "Pea."

Markets.

COVENT GARDEN.—July 20.

The markets generally during the past week have been much more active, and a steady demand has ruled for most of the articles in general consumption. Bush fruit is now at its best. Strawberries still hold out good. Hothouse and West Indian Pines are also very plentiful and good; prices low. The Potato market is thoroughly glutted, inferior samples being the rule.

THURSDAY, September 21.—The entire Herd, Scholding's entire HERD, at BOOTHAM, Stray, York, about FORTY HEAD, from the Sprayfoot Manor Estate.

WEDNESDAY, August 23.—The celebrated and first-class HERD bred by the late Mr. Thomas Bates, at KIRKLEVINGTON, Yarm, Co. Meath, Ireland. The small select HERD, the property of R. W. Reseley, Esq., will be SOLD at the same time and place.

FRIDAY, August 25.—The entire and valuable HERD bred by J. G. Grove, Esq., at CASTLE GROVE, Letterkenny, Ireland.

TUESDAY, September 5.—At the OAK HOUSE, Beckishall, Staffordshire, Mr. T. Bell's entire HERD.

THURSDAY, September 7.—Messrs. Scholding's entire HERD, at PANTON HOUSE, Wragby, Lincolnshire, of about 100 head.

TUESDAY, September 12.—The late Sir Henry Boynton's first FLOCK of COTSWOLD SHEEP, RAMS, &c., at OZLE-WORTH PARK, Northallerton, Yorkshire.

FRIDAY, September 22.—The first-class herd at CHAPEL BRAMPTON, Northampton, the property of T. Reasley, Esq.

FRIDAY, August 25.—The entire and valuable HERD belonging to Mr. Ashburner, at NETHERHOUSES, Diverstone.

The entire HERD, the property of the late Mr. ROBERT ALLILING-STONE DAYRELL, Buckingham, consisting almost entirely of Cruickshank blood, will be SOLD on the premises, by order of JOHN THORNTON, 135, Langham Place, Regent Street, W.—July 1.

Biddenham Annual Sale.

MR. STRATFORD is instructed by Mr. Charles Howard, of Biddenham, near Bedford, to announce that the ANNUAL SALE by AUCTION will take place on FRIDAY, July 28, when FIFTY OXFORDSHIRE DOWN RAMS and SHEARLING RAMS and a few OLDER SHEEP; also Two young Bulls, will be SOLD by AUCTION.

Luncheon at 1 o'Clock; the Sale immediately afterwards.

Biddenham is 1½ mile from Midland Station at Bedford, where Conveyances will meet the Trains.

Parnley Hall, near Otley.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions from the Executors of the late Francis Hawkesworth Fawkes, Esq., to announce that they will SELL by AUCTION the far-famed FARNLEY HERD of PURE-BRED SHORTHORNS (as taken place on TUESDAY, August 1 next), being the day previous to the Yorkshire Agricultural Society's Meeting at Otley, when a grand DOWN SHEARLING RAMS and a few OLDER SHEEP; also Two young Bulls, will be SOLD by AUCTION.

Luncheon at 1 o'Clock; the Sale immediately afterwards.

Conveyances will be in attendance at the Midland Station at Bedford, where Conveyances will meet the Trains.

Parnley Hall, near Otley.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has been honoured with instructions to SELL by AUCTION, without reserve, the entire and valuable HERD of PURE-BRED SHORTHORNS (as taken place on THURSDAY, August 10, next, some very superior SHORTHORN BULLS, and a choice selection of COWS and HEIFFERS, the property of the Right Hon. the Earl of Feversham, which have been long and carefully bred from the best and most fashionable blood. Full particulars of which pedigrees have been used, principally of the Kirklevington blood.

Catalogues will be issued shortly be issued, and further particulars given in future Advertisements.

Brailes House, Shipston-on-Stour.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD begs to announce that he has received instructions from Henry J. Sheldon, Esq., of Brailes House, Warwickshire, to fix the FOURTH BIENNIAL SALE of PURE-BRED SHORTHORNS for WEDNESDAY, September 20, which will consist of about 45 Bulls, Cows, and Heifers, chiefly of Kirklevington and Fawsley blood. The Sire now in service is the 18th Duke of Oxford (25,056), bred at Holker from this justly renowned tribe of Shorthorns.

Catalogues, with Pedigrees and other particulars, will be issued in due time, and announced in future Advertisements.

London : 13, Euston Square, N.W.—July 18.

HIGHLAND and AGRICULTURAL SOCIETY of SCOTLAND. EDINBURGH SHOW, 1871.

WEDNESDAY, July 26.—Showyard open at 9 A.M.—Members and Exhibitors of Stock admitted during the Judging at 5s.; Non-Members, 10s. After 2 P.M. Members and Exhibitors free; Non-Members, 2s. 6d. Horse Parade at 4 P.M.—Admission to Gallery, 1s. Dinner in County Hall at 6.45.—Tickets, 10s.; application for which to be made to the Secretary before July 26, or Mr. Richardson, 1, George Street, Perth.

THURSDAY, July 27.—Showyard open at 8 A.M.—Admission, 2s. 6d. till 2 P.M.; after 2, 1s.; Members and Exhibitors, free. Horse Parade at 1 and 4 P.M.—Admission to Gallery, 1s. Ball in the County Hall.—Application for Tickets (Gentlemen, 15s.; Ladies, 10s.), to be made to J. G. Richardson, 1, George Street, Perth.

FRIDAY, July 28.—Showyard open from 8 A.M. till 5 P.M.—Admission 1s. till 12 noon; after 12, 6d.; Members and Exhibitors, free. Horse Parade at 12 and 3 P.M.—Admission to Gallery, 1s.

J. R. Dudgeon, W.S., Secretary.

3, George IV. Bridge, Edinburgh. P. N. MENZIES, Secretary.

BIRMINGHAM HORSE SHOW, 1871.—The SIXTH GREAT EXHIBITION of HORSES, PONIES, CARRIAGES, HARNESS, &c., will be held in Bingley Hall, Birmingham, on TUESDAY, WEDNESDAY, THURSDAY, and FRIDAY, August 15, 16, 17, and 18.

ENTRIES CLOSE on SATURDAY, July 29.

For PRIZE LISTS and all other particulars, apply to the Secretary, 39, New Street, Birmingham. J. B. LOCKETT, Secretary.

MANCHESTER and LIVERPOOL AGRICULTURAL SOCIETY.—Prize Lists for the Show at Liverpool in SEPTEMBER NEXT may be had on application to the Secretary. Upwards of THREE HUNDRED POUNDS are offered in PRIZES, including £100 for the best Hunter, £80 for the best Shorthorned Bull, upwards of £200 for Dairy Cows, for Poultry, upwards of £225 for Pigs, and £300 for Sheep. ENTRIES CLOSE AUGUST 1.

Winsford, Cheshire. THOMAS RIGBY, Secretary.

SATURDAY, JULY 22, 1871.

MEETINGS FOR THE ENSUING WEEK.

July 26	Annual Meeting of the Highland and Agricultural	
to	Society, at Perth.	
July 28		
July 26	Annual Meeting of the Royal North Lancashire Agri-	
— 27	cultural Society, at Blackburn.	

WE have received some samples of injured Wheat from Lincolnshire, and as a field on our own farm threatens a loss of as much as 10 per cent. of the crop from a similar injury, we direct attention to the matter, in the hope that our friends may furnish us with their experience upon so important a subject. The following was the letter which the occupancies of Wheat from Lincolnshire were accompanied :—

"My object in sending you a few roots of diseased Wheat, which I have now growing, is to ascertain whether the injury was done by horse-hoeing, or by an insect or worm at the root. I have a field of 37 acres, and a portion of the crop is found to be dying, and on examination I find a weak off at the root, when pulled, it is now growing up again. The previous crop was Flax, afterwards steam-cultivated, and then well manured. The land is worm-proof, was ploughed and reclaimed from the sea upwards of 20 years ago; it grows good Flax, but the Wheat crop afterwards is not nearly so good as when following Clover, Peas, Beans, &c."

Our own affected crop, of 12 acres, was sown upon a clover-lea, and we distinctly call to mind a crop of 32 acres in 1864 upon clover-lea that was similarly affected, for then, as now, we recollect the first sight so much as it grew appeared to be scrawled on the ground as to lead to the belief that sheep had found their way into the crop and trodden it down.

This was the appearance of our 12-acre field on July 3, and what made our first thought seem the more reasonable was, that sheep were hurdled on an adjoining plot of Italian Rye-grass. Moreover, the fallen ears, all in full flower, presented a green appearance, as though the filling, from whatever cause, had taken place suddenly. The truth is, the Wheat had suffered from the recent heavy rains and high gales; but we ascertained before quitting the field that another cause had rendered much corn too weak to stand against the weather, so that, as before stated, about one-tenth was spread upon the ground in all directions.

On taking up some of the scrawled specimens we found them to break off in the hand, which induced us the more carefully to lift the roots out of the soil, and we think the following will be best explained by the accompanying illustration (fig. 205). This represents the appearances observed in our own crop, but we failed to find any insect specimens in the examples received from our correspondent. The partially eaten stems, however, and the whole appearance of the sample, point to insects as the cause of the mischief to his Wheat as to our own.

In both cases we observe the effects of an effort of Nature to repair the mischief done by voracious larvæ, the early attack of which, it would appear, was between the two lower nodes of the stem; and while these creatures were severing the straw, new roots were not unfrequently sent out from the upper node, and it was by means of these that the injured straws were kept in position until the ears began to get heavy, and

then the wind and rain soon sent them to the ground.

From many of the straws being thus half cut through (see *a*, fig. 205), our correspondent was impressed with the notion that the injury was done by the hoe. In our own case the crop had been hoed, but, even if carelessly done, this operation could not have made mischief in the regular manner we have witnessed.

The Wheat had fallen before any injury had been detected; and this will account for our not having seen the insect in the larva state; but the pupæ are of a rich brown colour, and in some cases as many as five of these have been observed together, wrapped close to the stem by the leaf-sheath.

We have collected some of these, in order to make out the fly—for we doubt not it is a two-winged fly—by which the injury to our crop has been brought about. It seems, too, to be highly probable that it is some member of the genus Chlorops, but the nature of the creature itself,

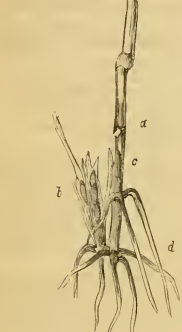

FIG. 205.—A ROOT OF INJURED WHEAT.

a, Stem, nearly eaten through by the larva of a fly; *b*, Pupæ of fly attached to a portion of the straw, the sheath of the leaf thrown back to expose them; *c*, An indentation from whence a pupa has been removed; *d*, Roots of Wheat.

and other effects of its life and labours upon the Wheat crop in our own and other fields, we hope soon to determine, as we have no doubt further information will arrive upon this interesting matter, and we shall then have the pleasure of reviewing the subject.

—— WHEAT fell 1*s.* to 2*s.* per qr. at Mark Lane on Monday, and could obtain a sale on Wednesday only at Monday's lowest rates.—In the Metropolitan Cattle Market on Monday trade was dull; on Thursday, however, it was brisk, with an upward tendency in price for everything.——Wool is advancing in price. ——Hops are dear, the accounts from the plantations being still very unfavourable.

—— After a week of unwonted summer sun one is the more willing to give circulation to the impressions of an optimist and enthusiast on the current FOOD PRODUCE of the COUNTRY. The following is Mr. MECHI's last letter on this subject, written on July 16:—

"Another week of heavy rains caused alarm, but an unprejudiced examination of my own and other crops has convinced me that the rains have done quite as much good as harm, especially on well-drained and highly-farmed lands, on which there is a promise of abundance, provided that we get seasonable weather. The change of colour in the cereals indicates that rapid ripening which frequently follows abundant summer rainfalls. Potatos and all roots and vegetables promise to be large crops, and although I have heard of Potato disease, we have none at present in our immediate neighbourhood. Barley, Peas, and Beans are all over average. Oats have been greatly improved by the late rain. There are fine crops of Wheat on well-drained and well-farmed lands, but there are a great many instances of thin plant on ordinary soils, and opinions vary between average and near average. I am sorry to see cases of root-falling, which always diminishes the crop. Hay-getting has been anxious, tedious, and expensive; a few fine dry days are sadly wanted. Those who persist in thick sowing with high farming have their Barleys sadly laid. I am confirmed in the opinion I recently expressed in your columns, that, including meat, butter, cheese, milk, and vegetables, there is much more food for the people than there was last year."

So far to the *Times*. We have since received the following note to ourselves:—"I am sorry to find some of the Wheat root-fallen. So far as I can judge, and also gather opinions, Beans, Peas, and Barley are likely to be over average. Wheat average, or somewhat less. Oats much improved. Potatos, roots, green crops, and grass over full average. There are some cases of Potato disease, but not in my immediate neighbourhood."

—— The following was the ATTENDANCE in the SHOWYARD at WOLVERHAMPTON last week:—

On Monday, 2654 paid 5*s.* each	.. ..	£663 10 0
,, Tuesday, 706 paid 2*s.* 6*d.* each	.. ..	883 0 0
,, Wednesday, 11,514 paid 2*s.* 6*d.* each	..	1439 5 0
,, Thursday, 5300 paid 1*s.* each	.. ..	2650 0 0
,, Friday, 33,624 paid 1*s.* each	.. ..	1681 4 0
Total, 108,456	.. ..	£7316 19 0

These figures compare favourably with those of the last few years, being 36,000 more visitors and £2000 more money than collected at Oxford, and 10,000 more visitors and £700 more money than obtained at Leicester. At Manchester, however, midway of these two last-named shows, the number of visitors was not less than 104,733, while the money collected was £15,629. Wolverhampton must, nevertheless, be reckoned amongst the largest and most productive of the Society's meetings.

——Several of our leading agricultural machine-makers have addressed a memorial to Lord DUNMORE, who presides over the Lords' Committee on the ROAD LOCOMOTIVES BILL, proposing the following conditions as proper for enactment:—

(1). That the speed of engines travelling on the high-road shall not exceed 5 miles per hour in the country, and 3 miles per hour in the towns, power being given to the Board of Trade to grant permission for increased speed under special rules and regulations.

(2). That in all cases an extra man accompany each train, whose duty it shall be to lead horses and assist carriage traffic in passing.

(3). In order to insure as far as possible the public safety, any new or more stringent rules for the conduct of locomotive engines on highways which the committee may think it advisable to issue, in order that the responsibility of the owners of these engines may be clearly set forth and definitely settled, it being understood that, if the laws and regulations in the Act be strictly adhered to, to the satisfaction of the Board of Trade, the liability of the owner of the engine, in case of accident, should cease.

(4). That a notice be fixed to every bridge, signed by the county surveyor or other responsible person, stating the load which such bridge will bear, and should any accident or damage occur after such notice, no responsibility shall fall upon the owner of the engine, provided such load shall not have been exceeded; and, in case of any difference of opinion respecting the safe working load of any bridge, the Board of Trade shall send a surveyor to report on the said bridge, whose decision shall be final.

—— We learn from the Journal of the Society of Arts that the Paris Academy of Sciences is occupying itself seriously with the question of the CATTLE DISEASE, which has proved so fearfully in Paris since the war. M. BOULEY, who is specially engaged on the subject, declares the disease to be endemic in all that part of Europe comprised between the Ural and Carpathian mountains; that it is permanent, and consequently not contagious. In Paris the mortality caused by it has been terrible, not more than 1 per cent. of the animals attacked having survived. In reply to those who have asserted that the disease in question arises in western countries from climacteric causes, or want of care, M. BOULEY cites the following striking fact:—The 4000 bullocks and cows sheep enclosed in Paris during the siege were placed in peculiarly unfavourable circumstances; all suffered, but not a single animal was attacked by the epidemic during the whole period of the siege. When the armistice opened the circle around the city, cattle were purchased from Prussian sources, and the disease immediately made its appearance, the stock was affected, and the animals died at the rate of 200 per day. M. BOULEY declares the flesh of animals attacked by the disease to be perfectly innocuous. He protests against the system which prevailed in the departments of the Nord, where even animals suspected of being attacked were killed and buried. He protests in like manner against what has been done in Brittany, where 800 diseased animals a-day had been placed on board old ships, and sunk by cannon-shot in the Atlantic. Not surprisingly, M. BOULEY condemns the present direction in the treatment of the disease with phenic acid, and Dr. DÉCLAT is pursuing other experiments with an analogous substance. M. BOULEY expresses great hopes of the success of these modes of treatment, the results of which will be reported shortly. M. DUMAS, the perpetual secretary of the Academy, communicated another mode which had been suggested, namely, to surround the animal with an antiputrid atmosphere by means of a considerable dose of napthaline in the litter, to wash it with water containing phenic acid, and to administer daily from 10 to 12 litres of water containing a one-thousandth part of phenic acid—this by way of preventative. In cases of positively diseased animals, a like course is recommended, but with an increase in the quantity of the acid to 25 grammes (nearly an ounce) a-day. In case the remedy should fail to save the animal, the flesh, it was observed, would be impregnated with the antiseptic, and cease to be an element for propagating the disease.

—— Mr. ODAMS, of Fenchurch Street, thus writes to the *Times*:—

"The supply of beasts is limited.' Such is the heading of your Market Report this morning. It may be asked,—Why this great irregularity of supply and consequent fluctuation in price? Simply from the fact that our own producers dare not risk their cattle within the cordon which surrounds our Metropolitan Market. On the 12th ult. your reporter writes, 'Meat, 4*d.* to 6*d.* per stone lower.' I would ask consumers whether their butchers' bills have undergone any change within these dates, or into whose pocket does the difference go? Surely it is high time these restrictions upon our food supply should be got rid of? We are importing animals weekly from countries where disease exists, and sending them broadcast over our own. Why, then, should the transit of our own stock be prevented? It is now five years since cattle plague made its appearance. Legislation on the subject has become a dead letter, and the Corporation, who were to complete a waterside market by 1872, have not yet commenced. No wonder, then, that when to these restrictions on home cattle we add the severe drought and loss by disease, consumers suffer from the high price of meat."

—— The *Inverness Courier* announces that last week's WOOL MARKET was a brisk one; and, in estimating the result, it must be remembered that last year there was an advance in the price of sheep of from 4*s.* to 7*s.* on Cheviot stock, and on blackfaced of from 2*s.* to 6*s.* each. This year the advance on the prices of last July is as follows:—Cheviot wedders, £4 to £6 per clad score; Cheviot ewes, £4 to £7 do.; Cheviot lambs, £2 10*s.* to £2 15*s.* do.; half-bred lambs, 3*s.* 6*d.* to 4*s.* 6*d.* each; blackfaced wedders, £6 per clad score; blackfaced ewes, £4 to £6 do.; blackfaced lambs, £1 10*s.* to £2 10*s.* A great deal of wool changed hands, and the rise may be quoted at 5*s.* to 6*s.* per stone for good-laid Cheviot wool, and 3*s.* to 5*s.* for laid Highland; in white Highland the rise has been extraordinary—from 7*s.* to 9*s.* a stone.

OUR LIVE STOCK.

CATTLE.

ON Wednesday a draught from HER MAJESTY'S Shorthorn herd was sold by Mr. STRAFFORD, at the Shaw Farm, Windsor Park. The herd was founded by the late PRINCE CONSORT, with the object of breeding animals of real utility for the dairy and the butcher. Several of the pedigrees were traced back to *Alix*, *Cold Cream*, and *Florimell*, bought at the celebrated Fawsley sale, in 1856; others were descended from the herds of the Marquis of EXETER, Lord SHERBORNE, and other breeders. From the animals sold we select the following:—*Honesty*, a handsome cow, calved in 1864, sold to Mr. LANGHAM for 50 gs.; *Alix 2d*, a cow calved in 1867, by RAJAH, sold to Mr. G. GARNE for 49 gs.; *Princess Louise*, a cow calved in 1863, sold to Mr. BANYARD, of Poplar Hall, near Cambridge, for 33 gs.; *Princess Mary*, a heifer, 29 gs.; *Princess Christian*, calved in 1870, sold to Mr. BLANDY JENKINS for 50 gs.; *Princess Beatrice*, calved 1871, sold to Mr. WOODWARD for 42 gs. Of the bulls, PRINCE LEOPOLD, a roan, calved in 1869, was sold to Mr. SYERGEON for 45 gs.; PRINCE ALBERT VICTOR, calved in 1869, was sold to Mr. BANYARD for 43 gs.; EARL RUSSELL, calved in 1870, sold to Mr. THORNTON for 63 gs.; MARQUIS OF LORNE, calved Jan. 10, 1871, sold to Mr. THORNTON for 46 gs. Other animals fetched rather lower prices.

—— Lord Dunmore has concluded an important purchase of two heifer calves. They are from *Duchesse 35th*, calved in 1034, by Mr. Booth's renowned, were sold to Mr. Cochrane by Captain (now Major) Gunter for 1000 gs. and 1500 gs. respectively, last summer. The calves of these two cows have been purchased from Mr. Cochrane by Lord Dunmore at precisely similar prices, or 2500 gs. for the two, and will be shipped for this country in September.

—— Some important "Hereford" sales were effected on the Wolverhampton show-ground. The 1st and 2d prize yearling bulls were sold, the 1st to Mr. Nowlan, and the 2d to Mr. Taylor, both of Sydney, Australia; also *Lizzie Jefferys*, the property of Mr. Harding, and the 1st prize heifer in the yearling class, was bought by Major Fenning, also of Sydney. The 1st prize yearling bull was the property of Mr. Hill, of Orleton Court, and is a son of TRIUMPH (2837) and *Gift* by UMPIRE (2764), and the 2d was exhibited by Mr. G. Child, of Westonbury, Pembridge, and is by NORTH STAR (2138), and out of *Pigeon* by YOUNG TREASURER (1473).

—— We learn that the sale of Mr. J. P. Foster's Shorthorns at Killhow, is fixed for Friday, Sept. 8, when about 80 head will sell about 50 head of carefully bred cattle. 17TH DUKE OF OXFORD (25,994), the sire of most of the young stock, is still in service.

—— The following important Shorthorn sales are at present advertised by Mr. Thornton. On August 3, 40 head from the herd of the Rev. J. D. Jefferson, of Thicket Priory, will be sold at York. These cattle are principally of the Waterloo, J. Daisy, Emma, and Flourish tribes. The sale of the late Mr. Barnes

stock at Westland, County Meath, takes place on August 23, when a large number of famous Booth cattle will be disposed of. On August 25 the entire Castle Grove herd, comprising 50 head, will be dispersed. On Sept. 12 the Brocton House herd, bred by Mr. Thomas Bell, will be disposed of; September 14 will witness the dispersion of the Panton House herd, numbering 100 head, belonging to the Messrs. Dudding; on Tuesday, September 19, the sale of the late Sir John Rolt's Shorthorns and other stock takes place; and afterwards sales are advertised as late as September 26, at Chapel Brampton, Northampton, and Netherhouses, Ulverston.

— We understand that there has been a delay in the publication of Mr. Bell's "History of the Improved Shorthorns," owing to the prints not being ready, but it will appear in about 14 days. It promises to be not only a complete history of the Shorthorns, but very interesting to all agriculturists. It will contain copious accounts of the scientific education of Mr. Bates, and his intercourse and correspondence with all the leading agriculturists and noblemen of his time. The alloy and cross-breeding are very fully discussed, and the very delicate question of course, and a full account of George Coates and the origin of the "Herd Book," and his private remarks on the animals, extracted from his manuscripts. The work will be very interesting and instructive to the American breeders, and will do appreciation of their character and exertions in Shorthorn matters.

— At Havering Park Farm, on June 12, *Grand Duchess 21st* gave birth to a roan bull calf, got by 3D DUKE OF GENEVA (23,753). The calf is a fine strong one, and has done exceedingly well since his birth. As far as one can judge at present, he promises to do credit to his distinguished lineage; shows already good loins, quarters and girth, fine shoulders, and altogether a good back, with plenty of nice soft hair. Mr. M'Intosh's small, though select herd, is also otherwise doing remarkably well.

SHEEP.

THE season for ram sales has again come round. Mr. W. G. Preece informs us of his numerous engagements to sell Shropshires, beginning on August 2 with 45 ewes and 150 rams, bred by Mr. Mansell, of Adcott Hall. Messrs. Lythall & Clarke will sell Shropshire rams at the 12th great central sale at Bingley Hall, so early as the 27th inst. Messrs. Lyne & Acock again advertise their Cotswold sales, in which the names of Lane and Garne are conspicuous. All the breeds are well represented, and it would be a vain task to enumerate the coming sales of Hampshires and Southdowns, of Lincolns and Leicesters, which occupy the advertising columns of our agricultural papers. We hope, however, as these interesting events occur to place the results before our readers.

PIGS.

A CONTEMPORARY asks why Berkshire pigs should be favoured with a separate class at the Royal Agricultural meeting at Leeds, is, of course, room for two opinions in such a matter, but we submit that the Berkshire is a very characteristic and widely-distributed breed of pigs, that it is purely bred, and much thought of in America as well as at home. While it is somewhat difficult to discriminate between many white and black races, there is never any doubt as to the Berkshire. His short head, turned-up nose, and white points, mark him as a pig of unmistakeable personal character; his quick growth and fitness for both pork and bacon, render him desirable as a profitable animal, and his docility and activity mark him in his younger days to range stubbles and ransack fold-yards. Surely, when a breed has definite and recognised points, a large number of promoters (breeders), and commands a ready market at home and abroad, it is much better to class. How indeed could a judge decide between an Essex and a Berkshire competing together? The heads alone would make the task a very difficult one; and although this might be got over in a small county show, it would be insurmountable in the case of such a meeting as that just held at Wolverhampton.

PRESENT APPEARANCE OF THE CROPS.

EAST NORFOLK.—As far as I can at present judge, the Wheat in this district will be an average crop. It presents generally a bulky appearance, and has shot a good ear, but it is rather wide set, and not likely to be so well filled as it was last season. Much depends on the weather during the next two or three weeks. Barley is long in the straw; the early-sown promises to be good in quality, but I do not anticipate anything beyond an average yield. On our best lands I think the crop is rather light. Peas and Beans not much grown here—the latter are blighted. Hay is various; some very heavy crops, others indifferent—secured without any material damage. Turnips promising; but in many cases have come in too fast, and could not be singled in due season. Harvest in about five weeks time: with forcing weather, like the present, may be a little earlier. Stocks of old Wheat never more exhausted. *W. Cubitt, Bacton Abbey, July* 18.

KENT.—Our Wheat crops will, I think, be under an average, there is so much injured by the recent high winds. Barley I call an average crop, and Oats, on the whole, are very good. The early crops of hay and fodder came down very short, but the later ones are a good growth. Mangold Wurzel came up pretty well, but has been till now growing very slowly. The last few fine warm days appear to have done it much good. Turnips are an extraordinarily good plant, and grown away well; there is a first-rate look on for winter feed. This makes store and fat stock very dear. *M. Sandford, Martins, Dover, July* 18.

MERSE OF BERWICKSHIRE.—A most favourable season for Turnip sowing was brought to a close (with one or two exceptions) about the middle of June; and since that time we have had nearly 3 inches of rain, but no growing weather until the close of the month. To our neighbours on the west it has come with a vengeance; Turnips washed away, corn buried, hail in blocks, and inches of snow lying for hours. We were permitted to hear the thunder at a safe distance. Turnips are certainly taking advantage of the situation, and thinning engages all hands—which we may term a novel and pleasing experience. The fleas were exceedingly active for a few days, but soon made off, never settling to their work, except where fresh salad was provided by repeated sowings. Again, be it noted, the first time of sowing is the best, if but a plant here and there be left uneaten. Mixed grasses for hay are much twisted and laid, and what is cut is in bad case. Pastures were very growthy for some time, and scoured stock remarkably, but the surplus is less than it was. Many of us have had Potatoes lying cut during three weeks of wet in April, and these sets are almost a failure; while fresh-cut sets look well. Corn looks middling, and harvest will be two or three weeks later than last year. Frost and drought have "slain" and "legged" a deal of Oats. Wheat plants may recover, but they look ill now. Barley is light and thinly planted. Beans seem to be the crop of the season, but the acres are few. *J. T., July* 8.

NORTH LINCOLNSHIRE.—Our crops of Wheat have very much improved this last week, and have come out with a good ear. I hope, with fine weather, we may have an average crop; it very much depends upon the next month. Spring corn looks well, and will be a full average. Roots of all descriptions are a full plant, and look remarkably well. Hay a good crop, and pastures most abundant. So that altogether farming prospects look favourable: and if it please God to give us favourable weather for the next two months the farmers have no occasion to fear. *F. A. Sowerby, Aylesbury, July* 18.

NORTHUMBERLAND.—Corn crops have improved much during the past month, but still, with the exception of Barley, will be below average. Wheat below average, Barley full average, Oats most miserable. I have not seen a full crop of Wheat anywhere this season, and even a decent Oat field is unknown. Turnips and Potatos look now like being full crops. Seed's light. Meadows good, but very bad weather for winning. *Thos. P. Dods, Anick Grainge, Hexham, July* 15.

SHROPSHIRE.—The crops in this neighbourhood are very variable. With very few exceptions, Wheat will be below an average, the crops being thin on the ground, and the ears generally small. It is, moreover, in many places considerably damaged by maggot, and some crops we have seen are nearly smothered with Poppies and other weeds. A large breadth was either cross-sown or was ploughed-up early, and replanted with Spring Wheat or Barley, with variable results. Barley presents generally a promising appearance, and will prove an average crop if we have fine weather, but in many places it is lodged with the heavy rain. Oats will be also an average, but are little forward since April. Winter Beans in general are a decided failure, in consequence of the severity of the winter, but spring-sown ones and Peas will turn out well. The hay crop is generally not a heavy one, except in low-lying situations. Seeds are especially thin, the Clover being almost universally killed by the frost, &c. The weather has been wretched for securing this crop, which is, consequently, much damaged. Turnips are generally very promising, not having been damaged by fly, but late-sown ones have suffered from the cold, wet weather we have experienced during the last month. Mangels are partially good in some places; they are injured by grub. Potatos are looking well, and, if the weather is suitable, will turn out a good crop. *W. D. P., West Felton, July* 18.

SUFFOLK: *Bury St. Edmund's.*—Business engagements gave me a run from the east into the midland counties last time, and going over the Midland Railway, and returning by the Great Northern and Great Eastern, and halting at several points, and keeping an eye on the crops all the while, a pretty true estimate could be formed of their state and condition. In the eastern counties great corn crops of Wheat and Barley still look well. There will be lots of straw, but the ears are of good size, and if the weather, even now, takes up, the yield promises to be heavy. These continuous rains, however, will soon tell injuriously upon the Wheat, and it is looking too pale for robust strength. Many crops must likewise be considerably damaged by the hailstorm that crossed a large portion of Suffolk last Wednesday. The Barley still looks well, and the few Oats that one sees here and there are very strong indeed. Beans are a large crop of straw; but we hear of scant podding here and there. Those I have examined are fairly heavy. But an excess of straw on strong land is generally inimical to a good harvest of Beans. Moderate growth and height of straw is the most favourable to fertility. Peas are a wonderful crop generally—quantities of straw, well podded, and free from lice. Peas set more freely in wet weather than Beans, though some of the later want sun to ensure maturity in reasonable time. Cattle crops are mostly a good plant, but there are exceptions. The cold, frosty nights, and an excess of wet on cold lands seem to have killed the seed in some cases, and Turnips and Swedes grow but slowly; whereas, Mangel and Sugar-Beet make scarcely any progress at all. It is too wet for them. Water is constantly passing by the roots, either upwards or downwards, and either way it chills the earth, and consequently checks growth. On clear nights the evaporation is so rapid as to cause instant frosts at the ground-line, and this renders growth impossible. Even when the days are warm, the rains have sodden the ground into such puddly softness, that Beet and Mangels push out fibres there instead of enlarging their roots, the tops make little progress, and upon the whole the prospect of a large crop of Mangel or Beet is not encouraging at present. Late Turnips are a good plant, and are growing faster. Potatos, where they have escaped the frequent frosts, which have continued at intervals up to July, produce well, and the early crops in East Anglia are remarkably good. I saw, however, a great many fields of Potatos in Peterborough shrivelled and stunted, looking as if they had been frozen through. Cabbages everywhere are a wonderful crop, they suffered much during the winter, but have grown in an extraordinary manner ever since. Parsnips seem also at home in the wet, Carrots do not look so well, Onions are fine as yet, and promise a heavy crop. The Wheat in the Fens when I passed through about a week ago, was still standing, but the ears were small in proportion to the strength of the straw, and in many places the plant was thin. I also observed a large proportion of Bearded or Bird's-eye Wheat, and on making inquiry found that a good many of the fields had been sown on Wheat that had failed. Clover and Sainfoin were heavy crops, but a good deal had been lost in the Fens through bad weather. I saw one field between Cambridge and Huntingdon nearly wholly under water, with the Clover lying in the swathe, and the young plants springing up through it. Some farmers in the train assured me that a good many crops had found their way into the muck-yard. It certainly has been a most ticklish haysel. Grass everywhere is a prodigious yield. All that is needed is weather to make and cut it. Much hay was carted in this neighbourhood yesterday; but it began to rain in the night, and has poured all day, and still rains. Everywhere the grass is getting past its best. A good deal has been cut, and some as it were from the rain; but thousands of anxious farmers are waiting till a change comes. It is to be hoped it will come soon, for notwithstanding the Mechian proverb about rain in June—which, however, as I take, does not mean rain all the time—things will soon be sadly out of tune, after this kind of haysel, if the rain does not stop now June is over. There is another old saw, which seems more likely to be verified this season: "Wet barking, wet haysel, and a wet harvest." We had a wet barking time, though the bark was never better than this season. It is needful to fill in the haysel, or let alone the harvest; but should this saying come to pass, I fear it may be added to thus—a cold and a hungry winter. For famine, or scarcity in England, never yet did come by drought but by water. But let us hope that the weather may soon change, and settle down fine, so that the moderate abundance of food for man, the superabounding store for beast, with which the earth is covered, may be garnered in safety. *D. T. Fish, July* 11.

WORCESTER.—It really is too soon to say what the Wheat and other crops of this neighbourhood will be. A continuance of the wet weather we have had for the last five weeks would be most disastrous, whereas three weeks of sunshine might do wonders. The present position of the Wheat crop of this district is this:—A large portion of the early-sown, on clay land especially, was much killed by frost and part replanted. All this must be a deficient crop. The later sown stood the winter, is a very bulky crop; much of it laid and twisted by heavy rains and wind, which have prevailed during the whole blossoming season, and must be prejudicial. I have no faith in the probability of a good crop. If mildew be the consequence of the saturated state of the clays, it will be a very bad one. A late harvest is inevitable. Barley is a great crop, but much of it is laid; the quality of such must be inferior. Beans: An immense crop of straw; too bulky, and much blighted; not likely to be an average crop. Hay: Our first fodder crops, Trifolium, entirely spoiled; only fit for litter; the first part of the hay very much damaged; the remainder, in process of cutting, we hope

to be more fortunate with. Roots are likely to be the greatest crop grown for many years; they want dry weather. *C. Randell, Chadbury, near Evesham, July* 17.

THE IMPLEMENT YARD AT WOLVERHAMPTON.

We continue our notes of the Implement Yard. The following are some of the entries of cultivating tools to be worked by steam power :—

Ashby, Jeffery & Luke, Stamford, exhibit an 8-horse traction engine, which they recommend as suitable for every description of agricultural work, and specially adapted for working Fisken's steam-culture tackle.

John Sainty, Barnard Sainty & John Sainty, Wisbech, exhibit a corn-drill adapted for either steam or horse power.

Barrows & Steward, of Cherwell Works, Banbury, Oxon, exhibit a steam-cultivating set on the Woolston principle, consisting of an ordinary 12-horse portable engine, detached windlass, rope-porters of several kinds, tackle, snatchblocks, cultivators with 3 and 7 tines, iron clam, and "dead anchors," which were tried both at Barnhurst and New Buildings Farm, and met with considerable approbation.

John Hensman, of Ampthill, Beds, exhibits a 13-row drill, fitted with patent steerage behind, which gives greater facility for steering than the old front steerage, and at the same time saves the labour of the person in front. It has a self-acting balance-box for corn and seeds, and is adapted for either horse or steam power. A drill with any number of rows may be constructed which the steam-power employed may require.

Priest, Woolnough & Michell, Kingston-on-Thames, exhibit a new patent combined corn-drill for steam-power, fitted with improved turntables, chain, and fore-steerage. It is 12 feet wide, and can be converted into two horse-drills each 6 feet wide.

Mellard's Trent Foundry (Limited), Rugeley, Staffordshire, exhibit Godfrey's American revolving mould-board two-furrow plough, and single-furrow plough for deep culture.

Cambridge & Parham, Bristol, exhibit a Cambridge roller and clod-crusher, 8 feet wide by 30 inches in diameter.

Edward Hayes, of Stoney Stratford, Bucks, exhibits, under steam culture, eight entries for trial, viz. :—(1), a complete set of steam cultivating machinery and apparatus, consisting of a 12-horse power portable engine; a self-acting windlass, also entered singly; self-acting anchors, also entered separately; a 5-tined cultivator, auxiliary claw-anchor, snatchblocks and rope-porters; (2), a 12-horse portable engine; (3), patent self-acting windlass, which prevents stopping at the headland; (4), a 5-tined cultivator; (5), an improved snatchblock; (6), an improved claw-anchor; (7), an improved rope-porter; (8), a pair of patent self-moving anchors, for roundabout work. The clip-chain movement, taken from the rotating pulley, over which the wire rope passes by means of a worm working in a spur wheel, is very simple, effective, and ingenious, as it enables the anchor to move forward the breadth of the implement, so as to permit of fresh ground being taken on. There is a similar anchor at the opposite headland. On the direction of the rope being reversed, one of the anchors is stopped by a ratchet catch, and remains at rest whilst the other anchor is moving a breadth forward. There are several changes of gear wheels to suit different lengths of land.

John Fenwick, engineer, Grantham, Lincolnshire, has three entries for trial, viz. (1), a snatchblock; (2), an anchor; and (3), winch barrel with chain, and spring anchor and pulley, all manufactured by Picksley, Sims & Co., Leigh, Lancashire.

William Ashton, of Horncastle, Lincolnshire, exhibits, his "chisel-toothed harrow, on wheels," improved by Henry John Seels, for horse or steam culture,—can be lowered into and taken out of the ground at pleasure without stopping.

The following is a list of articles claiming novelty entered for trial for the 10 Silver Medals :—

John Freer & Co., Rothley, Leicestershire, show a corn-planting machine having six dibbling wheels.

James Coultas, Grantham, shows a 14-row corn and seed drill, with Fowler & Co.'s patent steerage.

G. W. Murray & Co., Banff, show a double-drill plough, which can be hauled by two horses, which promises to economise horse-labour in getting in Turnips and other drilled crops.

Matthews, Son & Co., Driffield, enter a new substitute for linseed cake, made chiefly from home produce.

Benjamin Perowne, of Great Snoring, Norfolk, has invented an attachment to turnip-cutters, to prevent the last piece of root escaping uncut.

William Walker & Son, Tithley, Notts, enter for trial a 12-row corn-drill, with canisters for turning two rows down one conductor if necessary. It has wrought-iron sides, screw gearing, and waterproof box with patent lid prop, and the conductors are proof against wind, dirt, or rain; also a 12-row drill, with newly-invented barrel for rough and uneven surfaces.

Henry Pooley & Son, Liverpool and Manchester, enter a new patent automatic grain scale, self-acting, and registering the quantity weighed.

Hayward, Tyler & Co., London, enter the universal steam-pump, one of which was selected by the Bath and West of England Society for supplying their showyard with water; also their patent upright feed-

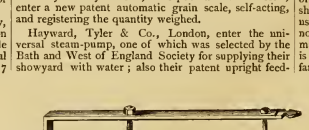

Fig. 206.—Top gate-hinge.

Fig. 207.—Bottom gate-hinge.

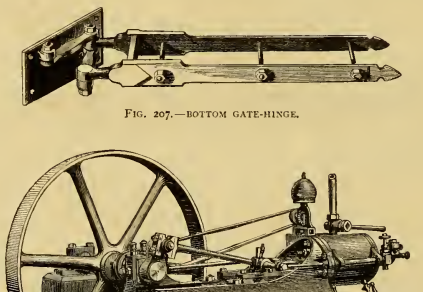

Fig. 208.—The reading company's 2-horse fixed engine.

boilers, by which water can be supplied to the boiler at any required temperature.

Schiffer & Budenberg, of Manchester, enter a new hand fire-engine and double-action pump, the valves of which are so arranged in the cylinders that they can be easily removed for cleaning.

H. K. Marsden & Co. enter an improved stone-breaker with vertical engine combined.

John Robertson Mackenzie, Birmingham, enters three patent pneumatic fire-extinguishers and garden-irrigators; also two fire and garden engines.

Milburn & Co., London, enter a patent cylindrical steam-heated drying-machine, adapted for desiccating brewers' grains; also a patent combined portable engine and drying-machine for corn and roots.

It will be seen from the prize list (p. 927) that none of the above entries for medals have been successful; but the justice of this may be called in question, for only three out of the 10 medals have been awarded, whereas, in our opinion, there is ample merit in the yard for the whole.

We add a few paragraphs relating to three or four items in the catalogue which seem to deserve further notice :—

The Reading Iron Works Company exhibited their very neat, well-packed, and compact little 2-horse power horizontal fixed engine, of which we present their block (fig. 208). It is provided with high-speed governors, feed-pump, &c., complete on metal plate.

Two-row Turnip and Mangel Seed-drill, exhibited by Mellard's Trent Foundry, Rugeley, Staffordshire, is decidedly the best machine of the kind we have seen. The seed boxes, hoppers, and conductors have a balance motion, which adapts them for hill-side work. The front rollers have not only a projection at each end to keep them on the drill, but a central V-ring, projecting the depth at which the seed should be placed; along the rut made by this ring the coulter passes, depositing the seed at the proper depth. The two small rollers behind follow up on even ground, thus running better, and are more easily kept clean, whilst they at the same time cover the seed more evenly. The result of all this is a more uniform braird and healthier plants, which is everything in the growth of root crops. The drill is made entirely of iron, the shafts being of tubular wrought-iron. The loss in using bad machines which require to be lifted every now and then to keep them clean, and which thus make blanks and place the seed at irregular depths, is incredible; and we venture to say that on a large farm Mellard's machine will pay for itself in a single season.

Patent Adjustable Gate-hinges for Pork, Field, or other Gates.—James Braggins, of 8 and 9, Fish Street, Banbury, Oxfordshire, has fitted up on his stand an ornamental gate and side gate of very high merit. The posts, framing, and stay-bars are made of English Oak, filled up with horizontal bars and vertical standards of twisted wrought iron; the top rail or bar is ornamented with cast-iron scroll. The parts are well proportioned, and the style of the whole agreeably antique. What gives the gates their real value is the patent adjustable swing hinges, of which fig. 206 is the top hinge and fig. 207 the bottom hinge. It is necessary to understand that the hinge is fixed to a bed-plate, which is bolted to the post by four bolts; besides the two principal fastenings, one for each side of the hinge, each side of the hinge is double-jointed, the two being connected by a short bar-lever, the farther side bar-joints being above the near side bar-joints. In both cases the bed-plate on the post is the fulcrum upon which the gate turns. In the engraving the lower hinge is shown opening outwards, the upper jointed bar resting against the bed-plate, the near-side lower joint receding from the bed-plate, so as to give the gate swing. The moment the hand is removed from the gate the receded joint comes up to the bed-plate, rests against it, both the short bars being close to the plate, the one above the other. Were the gate drawn inwards the upper and further joint would recede from the bed-plate, the same as the engraving shows the near joint. The mechanism is complete, simple, and effective, for no bullock or force of any kind applied can throw the gate off its swing-centres without breaking the gate itself. It is otherwise with the common swing-gates, for they are continually being thrown off their pins. Should the posts or gate be thrown off centre, provision is made for adjusting the gate by undoing the bed-plate and placing a piece of wood or iron behind to bring the centres right. The top hinge (fig. 206) is also adjustable, by means of the nut and screw. Thus, should the gate drop at the opening, or latch and drag when shutting, the hinge wearing, then by turning the nut the gate can be adjusted and always kept right. Practically speaking, to keep the gate-hinges right is to increase its durability, so to speak, for it is when gate-hinges go wrong that the gate goes to the dogs. We also have any experience in keeping a number of gates right are familiar both with the expense and bother they give, and Mr. Braggins' hinges will do much to obviate this botheration and expense.

Bearc's Manure Distributor.—This is another valuable addition to our implement list. The principle of delivery is a rotating barrel with flat-threaded zig-zag screws kept clean and of uniform working order by means of a number of scrapers driven by a cam-wheel on the axle of the barrel, which corresponds with the zig-zag groove and small portion of the screw that brings up and delivers the manure. A second bar, furnished with a number of stirrers, works backwards and forwards in the manure-box by a cam movement, breaking the manure fine, thereby supplying the delivery-barrel uniformly without clogging. The speed of delivery is regulated by a slide actuated by rack and pinion. The machine can be made to sow, either

broadcast or in drills, all kinds of artificial manure without any other mixture, at the rate of from 2 to 10 cwt. and upwards per acre, with a seed-box attached for sowing Turnips and Mangel Wurzel any distance apart. A number of these machines are now in use, and those who use them write favourably of their performance.

Patent Folding Balance-Elevator.—Wm. Tasker & Sons, of the Waterloo Iron Works, Andover, Hants, have effected two important purposes. First, the elevator, when the stack is built, can be folded up, removed with ease, and stowed away in an ordinary cart-shed. Second, it can be made almost to any height by adding joint after joint, without increasing its length when folded up. Practically, the highest elevator required for stacking either hay, straw, or corn in the sheaf, can be folded up so as to go into a shed. Thus, fig. 209 shows Tasker's balance-elevator and ricker, open for work; and fig. 210, the same folded for travelling and housing. In this position it is balanced over the large wheels, hence it is termed a "balance-elevator." When exposed to the weather, elevators soon get out of truthful working order, and are expensive to keep in repair, and soon become worn out. The housing of them will save much expense of repairs, and otherwise increase durability and efficiency of working. When pitching straw it can be worked by the engine used in threshing, and when used in pitching hay or corn it can be worked by horse-gear and a small pony, or by a small engine and gear strap. Those in use are giving great satisfaction. Mr. C. Read, of South Charford Farm, says his one "will deliver the hay on the rick from four pitchers in the field, and it is very easily worked with a small pony."

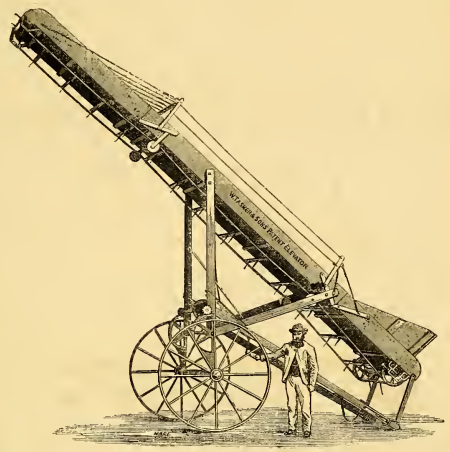

FIG. 209.—TASKER'S BALANCE ELEVATOR.

The *Department for Seeds, Roots, Models, Manures, &c.*, is better arranged than usual, articles of a kind being exhibited in close proximity.

Mr. Goss, of Plymouth, exhibits stencil-plate letters cut in zinc for marking sacks and the like, branding-irons, &c.; Davis & Co., London, thermometers, barometers, &c.

Alfred Welsh, of Southall, Middlesex, exhibits two models, the one a railway horse-van, and the other a cattle-yard, with arrangements for supplying food and water.

Passing over cattle foods, medicines, horse harness, mowing-machines, &c., we come to a series of stands of sewing-machines, which may be termed the "Ladies' Corner," and which form an excellent exhibit. Mr. Jones, of Gloucester, also shows as usual his waterproofing for boots and shoes, which is much needed in the showyard.

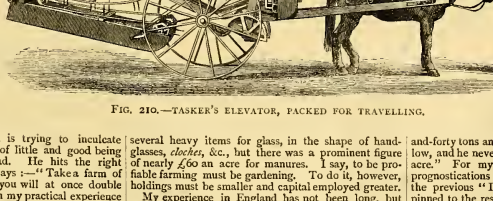

FIG. 210.—TASKER'S ELEVATOR, PACKED FOR TRAVELLING.

GARDENING AND FARMING.

MR. MECHI, who for more than a quarter of a century has been pounding away at the agricultural head, and trying to knock common sense into it, has, in a recent issue, under the head of "Gardening and Farming," again returned to the attack, and is trying to inculcate the common sense principle of little and good being preferable to much and bad. He hits the right nail on the head when he says:—"Take a farm of 300 instead of 600 acres, and you will at once double your areable capital, and from my practical experience I can assure you that you will thus considerably increase your percentage of profit." The principle involved in that sentence ought to be written in letters of gold. Did the farmer, as a rule, instead of taking his chance of a favourable season for getting his livelihood from a large acreage, simply act as any manufacturer would, and confine himself to an acreage proportional to his capital, he would, as a matter of course, rent and rates being constant quantities, find it more for his advantage to make 30*s.* an acre profit from 300 acres than to make 10*s.* an acre from 600. Now, as far as I can see, he is not so sure of making even 10*s.* an acre nett profit from a holding of 600 acres with a farming capital of £10 an acre as he would be of making 30*s.* with an outlay of £20 per acre, after debiting his farm with 5 per cent. on capital employed. The land, as a matter of course, will do nothing for you, if you do nothing for it. The only question that arises is this, Has the maximum amount of capital that can be laid out on land to advantage been laid out? I should scarcely think it has, if one may look on the amount laid out on the 100 acres of a market garden as compared with what is laid out on 100 acres farmed in the highest manner. The quantity of vegetable matter produced on an acre of market garden ground is manyfold that of an acre farmed in farmers' style. I was reading a little book I purchased in the Rue Jacob in Paris, being a brochure on market gardening near Paris, when to my surprise I found that a capital of not less than 26,000 *f.* was required to work a market garden of a surface not exceeding 5 acres. True it is, there were several heavy items for glass, in the shape of hand-glasses, *cloches*, &c., but there was a prominent figure of nearly £60 an acre for manures. I say, to be profitable farming must be gardening. To do it, however, holdings must be smaller and capital employed greater.

My experience in England has not been long, but sufficiently long to tell me that the only chance of the farmer is a heavy expenditure judiciously laid out. I profess myself a true follower of Mechi. I have read his book, enlarged from time to time, over and over again; among the many forcible remarks made by him was the one in which he asks a neighbour why he trenched his garden. I would simply ask, Why does not the farmer trench his land, or give it a stirring up equal to a trenching? I have in my time cultivated a considerable amount of land in the tropics, I have always found that where I dug my ground to the depth of 12 or 13 inches for crops like Jute, Hemp, Tobacco, Chilies, Indigo, or other tropical crops, I got my outlay back with a considerable addition over and above what I got from ordinary ploughing. On my return to England in 1869 I was determined to try the same plan, but I could not get labour for digging, except at a price absurdly high. So I took the best substitute I could find, a plough drawn by four horses, followed by a subsoiler drawn by three others. I moved the ground from 16 to 20 inches, having previously drained it with 2-inch pipes 4 feet deep, 30 feet apart. Previous to this, about 4 inches below the surface, there was a pan as hard as slate. My neighbours looked on me with a sort of contempt mixed with pity. My ploughing and subsoiling brought an *emeute* into my establishment. Ploughman No. 1 led the way. He did not understand these new-fangled ways; he did not like to see the country ruined, &c.; that Major Monsoon, who had College Farm, on the other side of the road, nearly ruined *himself* with deep ploughing, and if he had not died would soon have ruined the country; with a lot of like rubbish. By dint of keeping my bailiff close on the ploughman's heels I got my work done, say 16 to 20 inches deep, and left as much of the ground as I could get finished to mellow through the winter. On a portion of the ground so treated I made up my mind to try what luck I should have with Mangel. I did this because I was told my land would not grow roots. As soon as ever I could get on the land in the spring, I had it broken up, rolled, and ploughed, and in due season applied 15 to 20 large cartloads of muck, made and kept under a covered yard by about 45 horned animals, fed on cake and corn; 3 cwt. of guano, and 3 of bone superphates. My farmyard manure I valued at 8*s.* 6*d.* the load. The total cost of ploughing, subsoiling, horse-hoeing, hand-hoeing, earthing up, pulling, drawing, and pitting, I put at £14 8*s.* an acre, exclusive of rent, &c.

My sowing took place about April 29. May passed—not a sign of a single plant. My neighbours, who had throughout ridiculed the notion of my growing roots on such land, seeing nothing coming up, gave me the usual "Did I not tell you so?" and laughed at my disappointment. I attributed the failure to the seed, not to the cultivation. I telegraphed on the last Wednesday of May to the seedsman, requesting the instant despatch of fresh seed by passenger train. By a singular stroke of good luck, either the telegrah miscarried, or the seedsmen were too busy to attend to the order, or they had sent the seed by goods-train, and it had miscarried. Up to the Saturday night no seeds came. On Saturday night, June 1, a strong shower came, and on Monday morning the old seed came forth in shoots without a single gap—at the same time came the usual cry of my neighbours, "Who would have thought it? Why, you are going to have five-and-forty tons an acre? Why yours beats Mr. D. hollow, and he never grows less than five-and-forty tons an acre." For my part, I had as little faith in their prognostications as to quantity of produce as I had in the previous "Did I not tell you so?" My faith was pinned to the result in the scales. When pulled in the latter end of October, I had an acre measured across each field; this acre was weighed to an ounce on one of Fairbank's weighing machines, which will turn with sixpence, and the roots put into pit, and the cubic dimensions taken. From these cubic dimensions the result of the whole cultivation came to 27 tons 19 cwt. 2 qr. per acre. Now, my whole and sole object in going into all this detail, is, having shown the cost and the produce and its market value, to show that, as far

as that crop went, my outlay was profitable, and that but for deep and expensive cultivation, I should, like my neighbours, have had no Mangel. I could have sold the whole of it. I did sell a great portion; as I fell short of straw for fodder, and as my beasts were in first-rate condition, I sold beasts and sheep except lambing ewes. I sold more than 100 tons at the pit at 22s. per ton as they stood, without topping or trimming. I realised at the rate of £30 16s. an acre, at a cost, including 50s. for rent and taxes, of £16 18s., thus realising a profit [at the rate] of £13 18s. per acre. As a matter of course, 22s. a ton was an exceptional price, it could not be got every year, but even taking the selling value of Mangel at 15s. per ton, there would have been a nett profit of £4 2s. I must not, however, charge all the amendment to the Mangel crop; on a portion, viz., 5 acres, I have as fine a crop of Canada Oats as are to be seen. I reckon on getting from 8 to 10 qr. of grain and 50 cwt. of straw. As an illustration of the benefit of deep cultivation, I may state that, notwithstanding the very dry season, I observed my plants grew very vigorously (more so than those of my neighbours). In the latter end of July I took a small garden hand-fork, and took away the earth from around the root of a plant, and traced root and rootlets without beaking to their extremities. The tap-root went straight down, say 16 to 18 inches, to the full depth of the subsoiling; as it could get no further down, it struck off at right angles, and I traced it about a foot further, until it got so fine I could not trace it further.

On another piece of land treated in the same way, I had 7 acres of the finest Cabbages to be seen, part of which I drew for the bullocks, and the remainder I solled with sheep. On that land I have as fine a crop of Barley and seeds as any one could wish. The value of my Cabbages I cannot estimate, as they all went back into the land through animals' stomachs. I need not weary your readers with further detail as to the doings on the remainder of my farm. Suffice it to say, independently of the cost of drainage, my tenant-capital has been more than £20 an acre, and could I rely on steady labour I could employ advantageously considerably more. Although I have only 96 acres, I keep fully employed eight horses, each of which I give from 12 to 14 lb. of grain a-day throughout the year, without which they could not stand the work they have. As I am building largely with concrete I am forced to hire for all my leading in the building line; the expenditure is great, but I am beginning to see my way ahead. It may be asked by some of your readers, Why write all this? Others have done the same on a far larger scale than myself, why should you teach us to suck eggs? My simple answer would be: The food question is rapidly becoming a serious question in Great Britain; what it is and has been for a long time in China it shortly will be here. In China every available inch of ground is made the most of. Until Great Britain this is not the case. The present production is subsidised by a payment for imported cereals of not less than 20 millions yearly. This is paid for by the produce of the loom, the forge, and the workshop. All our best customers are rapidly becoming manufacturers for themselves. We cannot always expect to get a large portion of our food through the loom and the forge. The manufacturing class, sooner or later, will be thrown back on the land: as at present cultivated it cannot support them. If it cannot support them some curious questions will arise as to the rights of property. As these rights are simply founded on an idea, a future idea may probably come to the conclusion that property held by the few in large extent might be held more advantageously by the many in smaller allotments. Having property, I trust this will not happen in my day. The small speck, however, can be seen on the horizon. To prevent the rising higher we must grow more food. To do this farming must be gardening, or something next akin to it. To make farming gardening more capital must be put into the land. Holdings must be smaller. Landowners will have to make the roads required for drainage and homesteads, and tenant-farmers must be prepared to take smaller holdings, or somehow find a working capital of not less, if not more, than £20 per acre. *Khoda Bux.*

JOURNAL OF THE STEAM CULTURE TRIALS AT WOLVERHAMPTON.

[We conclude our short journal from p. 884.]

Wednesday, July 5.—From the heavy storm of rain yesterday, the trials were suspended for a time, but the weather having cleared up to-day, the work continues without interruption. The four fields of old grass selected for operation are divided into 14 plots, and these are appropriated to competitors as follows:—The first field is divided into two large plots for the trial of the extensive assortment of implements entered by the Messrs. Fowler & Co. in class 1. Their ditching plough is also tried here. The second field adjoining on the left is divided into four plots, viz., 3, 4, 5, and 6. Plot 3 is occupied by the Messrs. J. & F. Howard, who here compete for the prize, class 3. Plot 4 is in the possession of Barrows & Steward, who enter for classes 1, 2, and 3. Plot 5 falls to Fowler & Co., who enter for the prize, class 3. Plot 6, if it belongs to Fowler, has not been broken. The third field, on the left of the second, is divided into four plots, plot 7 falling to the Ravensthorpe Company (Fisken), who enter for class 1, class 3, and Lord Vernon's cup. Plot 8 is occupied by Amies, Barford & Co., who enter for class 3 and Lord Vernon's cup. Plot 9 is the Bedford firm's, who enter exclusively for the cup, and plot 10 is the Leeds firm's, who enter for class 1 and the cup. This field was technically termed throughout the day "the cup field." The fourth field is divided into four plots. Plot 11 falls to the Messrs. Howard, who enter for class 1. Plot 12 is Fowler & Co.'s, who compete for class 1 and class 2. Plot 13 is occupied by the Bedford firm, who enter for class 2. And the last plot, No. 14, falls to the Ravensthorpe Company, who enter for classes 1 and 2. The four fields are far from being of a uniform quality of soil or, we may add, evenness of surface. Field No. 1 is very undulating, the inclination in some places measuring 1 foot in 2 feet in plot 1, where Fowler & Co. started yesterday with their 20-horse double set, ploughing, digging, and cultivating. In some parts there is much drift mixed with the Stafford clay, giving it the character of a light gravelly clay. The upper portion of this field of 20 has a considerable slope, and the soil is also more uniform. In this plot, Fowler's 12-horse double set was tried in ploughing, digging, and cultivating, making rather rough work in ploughing, owing to the great speed and softness of the land from the heavy rain on Saturday. The digging and cultivating were excellent in the lower portion of the field, plot 1. Some excellent work was also done by the 20-horse double set with a 4-furrow balance-plough, about 12 inches deep, and also with a 3-tined knife, going from 20 to 24 inches deep.

During the day, the rope of one of Fowler's 20-horse engines was yoked to Mellard's double-furrow American rotating mouldboard-plough, which made very good work. In field 2 the Messrs. J. & F. Howard got their 3-furrow balance-plough and detached windlass tackle into position, and started, making good work, from 7 to 8 inches deep. Their 3-tined cultivator followed. The Messrs. Barrows & Steward also commenced in this field, the surface of which is very undulating, with a 3-tined cultivator. This was followed by a 4-furrow balance-plough, which made more satisfactory work. The 3-tined cultivator, the shares of which were too narrow for the plasticity of the soil, *i.e.*, they "stripped."

The Messrs. Fowler also commenced in this field with their roundabout tackle, and a 4-furrow balance-digger. They also got on with their 10-h. 3, with their 8-horse double drum system—first, with a 4-furrow balance-digger; second, with a 4-furrow balance-plough; and third, with a 7-tined cultivator. Amies & Barford also did some fair work with a 3-furrow plough in field No 3. The Bedford firm also got into position. In field No. 4 Messrs. Fowler & Co. worked their 20-drum set, making good work with a 7-tined balance-cultivator from 8 to 9 inches deep. This was followed by a 4-furrow digger, going 7 to 8 inches deep. The Ravensthorpe Company also did some good work on their plot in this field, first with a 4-furrow balance-plough 8 inches deep, second with a 7-tined cultivator, or rather with a 7-tined cultivator, two of the tines being removed to obviate choking. The soil in this field is a very tenacious clay.

Thursday, July 6.—In field No. 1, the Messrs. Fowler & Co. continued their trials with their 12-horse double set, and in the afternoon after the trials were over they made better work in ploughing and digging than they did before. The plough had disc coulters before the common ones, which appeared well adapted for the great tenacity of the subsoil. On Saturday, from the heavy rain of Tuesday, as the furrow-slice was turned over less broken and more evenly laid. No doubt the slower pace at which the implement was moving partly conduced to this result, a rapid pace having a tendency to break the furrow-slice and lay it unevenly. In this field the Leeds firm did some work with their ditching plough. This implement, we were informed, is intended for the Sugar-cane and Cotton plantations, Louisiana, where it will be of more use in keeping the open ditches or rather irrigation water carriers and gutters clean than in cutting new ones. The plough is somewhat similar to those made by the late Mr. Smith, of Deanston, the writer, and others, who attempted to open drains by means of draining ploughs hauled by horses. In field 2, the Messrs. Howard, Barrows & Steward, and Fowler & Co., did some ploughing, digging, and cultivating with their respective roundabout tackle, finishing what they began the previous day. In field 3, the Ravensthorpe Company got their light rope into position, so as to exemplify one of the peculiar features of their system. At the further end of their plot, and at the further corner of the adjoining field, there was a supply of water, and instead of carting this water to the engine, the engine was taken to the water, and the light manilla rope laid out through the entrance to this field and around their plot. This done, they commenced ploughing, making very good but rather broken work. Amies & Barford finished their work in this field, and the Messrs. Howard made, if not the best, some excellent ploughing on their plot for the cup. After the judges were through, most of the competitors did some excellent work to the Council and a larger number of visitors than were present on any previous day.

There was a good deal of complaint amongst practical farmers relative to the quality of the work done, which they considered below the standard of the everyday practice of those who use steam-culture implements. They had come to see something better than what they saw at home, but were disappointed. At Barnhurst, too, better things were promised at New Buildings Farm, whilst something worse has been realised. Of course the comparison of Barnhurst and New Buildings Farm goes for nothing, but the prior argument has material weight, for at the national steam-ploughing match farmers have a right to expect something better than they see and do at home.

"There are reasons for everything," it is said, and there are two reasons for the complaints in question which ought not to be passed over unnoticed. First, the exceptional character of the season and land, and the question, How far provision was made for such in the construction of the implements and the racing speed at which they were driven? Second, the surface of the ground was not only undulating longitudinally but transversely. The former did not materially deteriorate the quality of the work even in the worst place, but to the latter much of the objection of unequal depth, unequal flatness in laying of the furrow-slice was due. Thus the old outcastings of the ridges are in many cases deep while in the crowns they are shallow, owing both for the inequality of the depth and the flatness of the furrow-slice in places, seeing that the plots were laid out angularly across these. A moment's reflection will suffice to satisfy any intelligent mind practically versed in the matter, that it is impossible to make a 4-furrow plough set an equal depth and breadth over such a surface. In short, land thus laid down to grass ought not to have been selected for the trials. But the fact that it has been selected, and the results that follow, ought not to prejudice any observant farmer against steam-culture.

On Thursday the five road-steamers which competed at Barnhurst on Saturday and Monday last started from Wolverhampton at an early hour for Stafford, each attended by a judge or engineer to report its performance, consumption of coal, water, &c. The distance going and returning is nearly 20 miles, and to those that went up to the trial fields at New Buildings Farm it exceeded this, so that the test was rather a severe one. They started separately, each with a load of some kind or other of a known weight, but sufficiently near each other to enable Mr. Bramwell, who was to weigh by weigh-bridge, to note is some discrepancy in the weight of the loads and engines themselves as communicated to us, and as marked upon the engines and waggons with chalk, and until differences are reconciled, we forbear giving either. "Sutherland," the engine of the Messrs. Ransome, Sims & Head, was the best to start, and has quite effaced all misfortunes at Barnhurst; Aveling & Porter's 6-horse and 10-horse roadsters followed, and Burrell's two engines of 8-horse each came last. The Government road-steamer "Chenab" and carriage, known as "the Indian train," also made by Ransome, Sims & Head, started from Wolverhampton some half-hour later, *i. e.*, about 7.30, the carriage or steamomnibus being well filled with officials, &c., but running at 11 miles per hour it soon passed the others, stopping to allow their inspection. The journey going and returning is highly creditable to all the engines, proving road-traction an accomplished fact.

Friday and Saturday, July 7 *and* 8.—The judges return to Barnhurst to test the draught of special implements, which was not concluded on Monday last, July 3, the engine of Mr. Hayes, Stoney Stratford, was specially selected and engaged to remain at Barnhurst during the Stafford trials to finish the work. According to the official programme of proceedings, the testing should have been continued on Tuesday the 4th, but the heavy rains of that day were unfavourable; and besides this, it was as well to see what took place at New Buildings Farm. There were also a number of drills, rollers, clod-crushers, and ridging-ploughs, that had to be tried. On Friday forenoon, owing to the showers which occasionally fell, the season for drilling and rolling was unfavourable, but in the afternoon the weather cleared up, and the several operations were proceeded with, and finally brought to a close on Saturday by the trial of the ridging-ploughs and subsoiling-ploughs of the Bedford and Leeds firms.

Home Correspondence.

Utilisation of Sewage.—My letter to you of June 20, inserted in your journal of July 1, has failed to procure from Mr. Mechi the information it sought. I am, however, obliged to Mr. Hope for the information which his letter of July 8 contains, notwithstanding that it fails to make clear to a "simple inquirer" what the practical results upon the Romford farm have been. Mr. Hope had previously announced the population of Romford to be 6000, by his declaration that he paid a rental of £600 a year at 2*l.* a head of the population. He does not absolutely contradict the figures given by Mr. Mechi in his communication to the *Times* of June 26 last, but speaking of the quantity

of sewage he receives, he says that "the average dry weather sewage" is estimated, in round numbers, at 1100 tons daily. Mr. Mechi's figures may, therefore, still be quite right, as he of course endeavoured to inform the public, not what the estimated dry weather flow of sewage was, but what quantity of sewage was sent on to the farm from Romford; and what I desired to learn was, what number of acres received this supply? Although Mr. Hope, writing during a very wet season, assures us that the sewage of Romford does not average 100 tons per head per annum, as I gathered from Mr. Mechi's letter, he argues upon the average dry weather sewage as "estimated," and which, by the way, gives an annual quantity of 67 tons per head for the population on which he pays. This quantity can hardly be a fair sample of what is delivered on to the farm. I regret that I fell into the error which Mr. Hope corrects, but I was led to believe that the pumps were worked night and day, by a statement of his having utilised the sewage of Romford "night and day continuously;" and when I alluded to the subject I was not aware that he could so use the sewage without pumping it for distribution. I am not at all disposed to discuss the question of the intrinsic value of town sewage, and it may be Sr. a head, as Mr. Hope states it is; but it is very essential to obtain facts—what quantity of sewage is used, how much land it is applied to, the condition of it as it is received and as it leaves the farm, and the results in an agricultural point of view. If the sewage of Romford is purified, as Mr. Hope states that it is, nothing but good will result; and if 115 acres of land, the solution of the question is here satisfactorily arrived at, for the land receives and passes to the crops the manure which the town supplies, and 60 persons annually provide something between 67 and 100 tons of sewage apiece to very little more than 115 acres of land, and obtain, as Mr. Mechi tells us, excellent crops of all kinds. Mr. Hope, it is true, complains that the farm is too small for the quantity of sewage he receives, but if he can purify between 4000 and 6000 tons an acre, on the average, in preference to 1000 tons, nothing in the way of extended experience will show that the same quantity of sewage can be more advantageously distributed over a larger area. *F. P., July* 11.

Labourers' Cottage.—It appears to me that Mr. Makins' (p. 851) criticism of Mr. Denton's cottage plans, published by you on May 15, is rather harsh; the plans were intended for the country. Mr. Makins' plans are admirably adapted for towns, where land is expensive and a narrow frontage desirable, but I, as a land-agent, should generally prefer Mr. Denton's. On June 24 you published another of Mr. Denton's plans, in which the bed-room accommodation must be pronounced deficient. Accompanying is a copy of a plan of mine that has given satisfaction (fig. 211). Its outer form is similar to Mr. Denton's, but it has better bed-room accommodation, and a good dairy (the smallest bed-room has an area of 80 feet). It has only one outer door. Any style of elevation may be adopted. *W. G. Gibson, St. Clement's Terrace, York, July* 6.

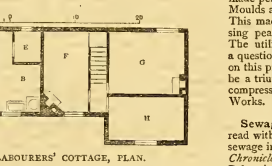

FIG. 211.—LABOURERS' COTTAGE, PLAN.

A, Kitchen; B, Scullery; C, Porch; D, Fuel; E, Dairy; F, G, H, Bedrooms.

Co-operative Societies.—I certainly thought, as well as hoped, that the controversy respecting the Co-operative Supply Association had come to an end—that the arguments on both sides, having been clearly stated by myself and my antagonists, our readers might have fairly been left to form their own conclusions, but it appears this is not to be the case. Mr. Greening, in a communication in your columns (which reads uncommonly like an advertisement), while he does not object to my allegation that it is the craving after cheapness which is the indirect cause of a great deal of the adulteration in manures and oilcakes which exists, is yet very indignant that I should also state that it is by the attraction of cheapness that these societies seek to attract their customers. Well, I cannot withdraw the charge, but am quite content to leave the matter to public opinion. He wishes to enlist my evidence that the existence of a high percentage of soluble phosphate is a proof that the superphosphate in consideration was made from the highest class of phosphates; but this is not the case, for low class materials, such as English coprolites, by skilful treatment will yield the percentages mentioned, whilst bone-ash, which is really a high-class material, and which costs about double the price, viz., about £6 per ton by the cargo, is far too costly to be employed in the manufacture of these cheap superphosphates. It is a great mistake to ignore the value of what is called insoluble phosphates, even when not derived from bones. I have proved their value in the open field by unmistakable experiments, and by avoiding the errors which had led other experimenters to wrong conclusions. I have, however, no wish that this discussion should wander into other fields, but in concluding it I must remind our readers that, without impugning the motives of members of co-operative societies, or the right of private individuals to avail themselves of their real or supposed advantages, I have contended that, inasmuch as they destroy trade, interfere with commerce, are injurious to the public revenue, and opposed to local interests and that sympathy which ought to exist between one class and another, the existence of which is one of the strongest sources of our national strength—that inasmuch as they tend to centralism, which, in a neighbouring country has led, more than anything else, to the evils of Communism, and the destruction of property—and that for these several reasons the existence of these co-operative supply associations is opposed to public policy, and ought not to be supported by public men. *W. C. Spooner.*

The Sheep Tick.—Many sheep in this neighbourhood having been attacked by what are called here "grass ticks," soon after being driven to pasture this year, and in many cases have died from the effects produced by those creatures, I have been led to inquire into the matter, and as to what these "ticks" differ from the ordinary sheep ticks, but in what way I cannot ascertain; also that certain lands are more subject to them than others. I should feel much obliged if you could give me any information about these creatures, and if there is any means of exterminating them. Many flockmasters (some friends of mine included) have been obliged to have all their sheep looked over singly, and these ticks picked out by hand, and the losses in some instances, especially in the case of lambs and tegs, have been serious. *A Subscriber, Cuckfield Grange, near Canterbury.* From this we append a letter of explanation by our correspondent, Mr. Wilson, of Edington Mains, which appeared at p. 906 in our last year's volume, wherein he refers to the two different insects to which the name tick is applied. "O. F." had commented on a previous letter by Mr. Wilson (p. 600, 1870), wherein he had expressed his belief that the so-called "loupingill"—a convulsive attack—to which sheep are liable, is owing to these true ticks (Ixodes Ricinus).

"'O. F.' says of my letter:—'There must be some error in your writer's idea of certain lands in certain districts being infested with sheep tick.' This sentence makes it evident that when 'O. F.' and I write about ticks we respectively apply this name to two entirely different insects. His remarks apply to the fag or kaid (Melophagus Ovinus), which breeds upon the sheep, and is, I suppose, to be found in every flock, probably on every sheep, in Great Britain. My remarks had reference to the true tick (Ixodes Ricinus), which breeds in the ground, is found only in certain districts, and fastens itself on sheep and other animals during a part only of its existence. Instead of moving about amongst the wool like the kaid, the tick at once inserts its head deeply into the skin of its victim, and remains fixed in the same spot—so firmly fixed that it is difficult to pull it out—until it has completed its course, when it drops off into the ground. It makes its appearance among the herbage in spring in its active stage, gets upon any animal that comes in its way, and fastens upon it in the manner already mentioned. There are some grazings in the South of Scotland so infested by these ticks that the occupiers dare not put sheep upon them until midsummer or even later. Cows and Shorthorn yearlings also suffer severely from them; the only stock that sustain their attacks with impunity being West Highland and Irish cattle. A great deal of misunderstanding has arisen from the name tick being applied indiscriminately to these two distinct parasites, which differ so entirely in their habits, and in the effects which they produce on the animals upon which they are found. On consulting such books as I happen to have by me, including Youatt, Spooner, 'The Book of the Farm,' and 'Morton's Cyclopædia,' I find more or less of this vague use of the name, tick; some of the statements made applying to the one parasite, some to the other. In the *North British Agriculturist* of the 2nd inst., there is an article on the dipping of sheep, all through which the name tick is used, although the context makes it evident that it is the Melophagus kaid that is meant. The same thing constantly occurs in advertisements by the manufacturers and vendors of sheep-dipping stuffs. My object in now writing to you is to try to clear up this confusion; and in particular to call your correspondent, 'O. F.,' who appears to be an experienced flockmaster, that my former letter had exclusive reference to the true tick (Ixodes Ricinus), from which his part of the country seems, happily, to be exempt." *John Wilson.*

See also the following veterinary report, taken from p. 509, 1870:—

"Some other novel cases occurred in lambs, in which death resulted from parasites existing on the skin. The parasites in question were those commonly known as ticks (Ixodes Ricinus). These parasites abound in most countries, and are met with both on wild and domesticated animals, firmly attached to the skin, from which they draw blood as their food. Until now they have not been found on animals in Great Britain to an extent injurious to health, much less as causing death. In hot countries, however, and particularly in many parts of South America, these parasites attack animals in such vast numbers, that even oxen succumb to the irritating and exhaustive effects of their attacks. Specimens of the skin of lambs, thickly covered with these ephizoa, were sent from Kent by a veterinary surgeon consulted on the case. In his communication he writes that 'they had attacked the sheep and lambs, both on uplands and marshes, and that one farmer found a large quantity of them on some colts which were at pasture near to the sheep.' There are few parasites more tenacious of life than ticks, but experiments have shown that they can easily be destroyed by carbolic acid, it was recommended that a trial should be given to dipping the sheep and lambs in a diluted mixture of the acid. This proved most effective in the destruction of the ticks, and thereby prevented a further loss of lambs."]

Large's Brick-Machine.—This brick-machine, shown in the International Exhibition, invented by Henry Large, and manufactured by H. Clayton, Son & Hewlett, is chiefly for concrete bricks that do not require burning. The moulds are filled with semi-dry material and compressed by the central plunger, actuated by an eccentric on the axis of the large spur-wheel. A second plunger, on the right, is worked by a rocking lever, and when the mould with the compressed brick comes under it, its downward stroke presses it through on to a receiving table, which elevates it to the side of the shed where the brick being removed by hand. This done, the receiving-table rises to its former position by a weighted lever, ready to receive another brick, and the empty mould is taken off and refilled. On the left-hand side a bent iron is furnished with a long handle, and a small roller, against the side of a newly filled mould, which it forces in below the central plunger, and in doing so pushes the compressed brick out from below forwards, and also the second compressed brick on to the receiving-table under the second plunger. When the bent lever is drawn back, a newly filled mould is again placed before it. About 500 bricks are made per hour, or 5000 per day of 10 hours. Moulds are made of any size or shape ordered. This machine may also be used for compressing peat or small coals into bricks for fuel. The utilisation of our peat bogs is just now a question of national interest, and if machines on this principle can be profitably used, it will be a triumph. Some promising specimens of compressed peat are shown at the Atlas Works. *W. E.*

Sewage Irrigation at Rugby.—I have read with interest the article by Mr. Palmer on sewage irrigation at Rugby, in the *Gardeners' Chronicle* of July 8. On one point Mr. Palmer's statements appear contradictory, but a word of explanation from him would probably clear up the apparent inconsistency. Mr. Palmer states, "Nothing in the shape of storage is possible. The sewage must be distributed at the earliest possible moment to prevent decomposition and consequent nuisance, as well as to secure its full value to the land." But a little further on, in stating the mode of application, Mr. Palmer recommends that the land should be well irrigated before the crop is sown, and slight irrigation should be given after the crop is up, another dressing in the spring, and a copious dressing after each cutting of the crop. Now, in order to act upon these suggestions, there must surely be a storage of the sewage. If not, in what manner is it to be dealt with? Another point in which Mr. Palmer could add to the value of his communication, would be to state what amount of sewage per acre he considers most valuable to the land. Of course the answer to this question must depend on the strength of the sewage. *J. M.*

Fisken's Steam-plough.—At p. 854 you give an extract from the Highland Society's Proceedings, which contains a very interesting account of Fisken's steam-plough, as worked upon Hall Farm, Penshaw, near Sunderland, by Mr. M'Laren. There is, however, one extraordinary statement in this account which it is very hard to understand. Messrs. Swinton and Wilson, who were deputed by the Society to inspect the working of this plough, report that the engine was a Clayton & Shuttleworth 24-horse power traction engine, with two 8½-inch cylinders and 12-inch stroke, and they say it was working at 180 to 200 revolutions per minute, with a pressure on the boiler of 60 lb. to 75 lb. They then say "from these data it will be seen that at 70 lb. pressure the engine was giving off a power equal to about 20 horses." Surely this is a mistake! We are not told that the engine was working "expansively," and if we suppose it was working with full steam, shutting off, say, at three-quarter stroke and 70 lb. steam, the gross theoretical power would be upwards of 73-horse power, so that we must suppose 53-horse power to be absorbed in friction, cooling, waste, and back-pressure, to bring down the effective power to 20 horses. Here is the calculation, taking the lowest rate of speed named, 180 revolutions, or 360 feet per minute in the piston. The two cylinders have an area of rather more than 100 square inches,

and 70 lb. steam cut off at ⅔ of the stroke will give an average pressure of 67 lb.; therefore $67 \times 100 \times 360 = 2,412,000$ lb. raised 1 foot per minute, or "foot-pounds," as they were called. Now, a horse-power is 33,000 foot-pounds, therefore $\frac{2,412,000}{33,000} = 73.09$, or 73-horse power. According to Tredgold a non-condensing engine wastes four-tenths of its whole original power by friction, cooling, waste, and back-pressure, leaving six-tenths as the effective power, but $73.09 \times 0.6 = 43.85$, or nearly 44-horse power "effective." Modern inquirers do not allow so much as four-tenths for waste and friction, some call it three-tenths, others 1, or others, again, as little as two-tenths. If we allow three-tenths, which I believe to be a very fair allowance, then seven-tenths are effective, and seven-tenths of 73.09 would be 51.16, or upwards of 51-horse power effective. How, then, do Messrs. Swinton and Wilson make out only 20-horse power? But Clayton & Shuttleworth's traction engines are furnished with link-motion for reversing, and by means of this the engine can be made to work expansively to a certain extent. And if we suppose the steam cut off at one-third of the stroke, it would give an average pressure of 42 lb. on the piston, and a gross theoretical power of $42 \times 100 \times 360 = 1,512,000$ foot-pounds, or $\frac{1,512,000}{33,000} = 45.82$ horse power; and if (as there is considerable back-pressure in working expansively with only link-motion gear) we allow four-tenths of this to be wasted, and only six-tenths effective, it would still give 27½-horse power effective. I cannot therefore conceive how Messrs. Swinton and Wilson arrive at their estimate of 20-horse power. But there is another element in their paper which is also curious; it required 8 lb. pressure on the boiler to keep the engine going at 160 revolutions a minute, and to keep both the engine and the flying rope going required 20 lb. on the boiler, although no other work was done except keeping the machinery moving round. If we suppose the same pressure, 20 lb., would keep the whole moving at 180 revolutions (360 feet) per minute, then the power absorbed by friction, waste, &c., assuming the engine to be cutting off at three-fourths of the stroke, 20 lb. as follows:—20 lb. steam would give about 19 lb. average pressure, therefore $19 \times 100 \times 360 = 684,000$ foot-pounds is the power absorbed in keeping the machinery in motion at that speed without doing work. Now, when it was moving the implement, it was said to use 70 lb. steam, which, as mentioned before, will give an average pressure of 67 lb., and the whole power developed would be $67 \times 100 \times 360 = 2,412,000$ foot-pounds; and if we deduct from this the power required to overcome friction, 684,000 as above, we get 1,728,000 foot-pounds as the power absorbed in merely moving the implement and the windlass-wheels; but $\frac{1,728,000}{33,000} = 52.36$ horse-power, or more than 52 actual horse-power, after deducting friction and waste! It certainly seems to me that there must be some error in the figures that are given in Messrs. Swinton and Wilson's report. *G. A. H.*

Foreign Correspondence.

BERLIN: *July* 20.—*Liernur's Pneumatic Sewerage* (see p. 755, June 10).—In my last communication upon this subject, I have been asked in an editorial parenthesis what I mean by irrigation having come to grief. Well, I am not going to be aggravating; however, I can't help stating that it has. I know very well that Mr. Mechi himself has given up irrigating his own fields, and has again begun to cart his dung in a sober manner—everybody nearly in Germany knows as much as the Tiptree Hall proceedings; it has gone the round of the fifty agricultural journals in Germany. But I will not dwell upon this. England, I suppose, cannot do without irrigation, as she has not been able to do without sewerage, which without would be blurred and unfinished; and, mayhap, irrigation will suit England as a very comfortable and cleanly labour, it certainly will not suit Germany, where it is regarded as a squandering, dear, unpractical, and out-of-the-way institution altogether, *i.e.*, sewerage and irrigation as an unit.

They have tried it in the south of Berlin, on the Tempelhofer-Feld, and have found out that the German winter, with an average of 15° R., will not permit of the irrigation going on for at least two months at all—in some years this period would even last four months. During all this time the sewage would have to go down the river, do away with the fish, create nasty sediments in the little Spree, which is the name of the Berlin rivulet, and poison the watercourse also of the Elbe. Besides, about 25 per cent. of the whole town manure would be lost in the course of the year; and, worse still, a certain smell which an impartial nose could not fail to discover in the very winter on the fields, would become insupportable in summer,—a rather hot time in the interior of the Continent. The glorious waves that surround England make the winter warm and the summer cool, the rivers short and broad and full, the air pure and ever-changing, and make the people of that country rich and generous, so as to enable them to afford squandering money and manure in sewers, water-carriage, irrigation, and irrigation dinners, all for the sake of the comfort of their national economists. The Germans are a stingy nation—they cannot help being it, as they are rather out of the way of the money-courses, and the world's great storehouse, the ocean. This stinginess is the more prominent the more you get into the interior, and although money here is dearer than anywhere else, the stinginess of the people drives up the prices of everything in proportion, and you live no cheaper in Saxony than in Hamburg. This stinginess makes people slow about taking up new ideas practically, and makes them rather sharp about the costs; so, they have found out the water-carriage system to be the dearest in getting up and on, and the least likely to pay; which, indeed, cannot be denied to be true. The Germans, and the Saxons most so, have Chinese ideas upon comfort, their highest comfort being saving money, storing knowledge, and utilising every available thing except rats' tails. They will utilise Englishmen, I can tell you, and they will utilise English institutions, if so be that they are anything like paying for any amount of trouble; but they will not, and do not care for comfort, if it be too dear a piece of furniture.

In this turn of mind they have calculated that every conveyance above ground is cheaper than below; that a railway without a locomotive will carry any amount of non-diluted town-manure 600 times as far as a sewer and a pumping machine for the same money; that the undiluted town-manure is more useful and more easily utilised than the best sewage can be by irrigation; that the farmers will take to the undiluted manure very readily, and that they abhor the sewage; that they will pay for the former, but not for the latter (if they are not paid for paying), and thus that a contractor for the scavengering business can be found, but not for the sewerage and irrigation (as there is no land-letting system). Thus again the townspeople see their way to a considerable saving by the introduction of contractor-scavengering-man pay for the things he carries off to the country, whilst there is no doubt that sewerage aggravates the local expenses. Now Mr. Liernur steps forward and tells them that he will procure for the townsmen all the comforts of the water-closet and water-carriage system by his pneumatic works, pay the whole hundred of scavengering-men, keep the houses from abomination by his machine, give the farmers what they are in need of for a cheap price, if he be allowed to have the proceeds, or, as I understand, if he is paid for his patent.

Now, this is not going or agoing like a gas or water company, to the works of which Liernur's have the greatest resemblance possible, although, indeed, they are not in the least as ponderous. Nevertheless, the three systems correspond and are of the same importance. The gasworks have done away with darkness, with oily-smelling candles, with the fire-pitch, and the like medi:eval comforts; the waterworks have done away with dirt, open wells to fall into, street-pumps to run your head against in a starless night, dearth, oriental water-managing, and the like; and Liernur's works, which are the inverted gasworks, only a deal more simple, will in their turn do away with those beastly apartments that make German towns at present nearly uninhabitable for Englishmen, and, what is not much less, will do away with those retorts for miasmatic exhalations, those sources of impregnation of soil, air, and water, which we delight in calling sewers.

There is no denying that all infectious diseases have been on the increase ever since sewers have begun to brew underground; mortality has risen in London for diseases, such as bronchitis, typhus, consumption, in the most fearful ratio—during the period between 1849-1866, from 4333 to exactly 8666 in the million. Sewers are the cause of the subsoil-water lowering its level, and of the infective germs finding their hothouse enlarged underground. However, this subject has been ventilated all the more, as the thing itself is unventilatable; as, indeed, with the loose Berlin soil, the slowness of the river, and the absence of all fresh sea-breezes, with the impossibility of all irrigation proceedings, on account of both heat and cold, there is hardly a less comfortable thought, and a thing so much to shrink from, than the sewerage of the town. Eating and the living, walking, eating, drinking, and sleeping upon sewers, with the Pettenkofer hypothesis distrubing our dreams.

Thus I find every reason to be rather enthusiastic when speaking of Liernur's invention, which, of course, has its adversaries—not so much the people of brick-makers and contractors, who naturally prefer building sewers to anything else, as amongst the people themselves; for Germans, on the whole, are the most conservative people in Europe, and fearful of any invention that has not been in practice during the period for a score of years at least. I will drop my enthusiasm for once, just for the sake of convenience, and proceed to Prague where the system has been in use during three winters.

Professor Ranke, a delegate of the Munich magistrates, went to Prague to study the subject, and did it slily too, for he never discovered his mission to anyone there. He had read about the systems being a swindle, and was fearful of being swindled himself. On the night of March 23, 1870, he arrived, quite in the way of a Carbonari, and took a dose of sound sleep, to be all awake in the morning. Well, we cannot be so circumlocutive though as he is himself about all his precautions, and must simply state what he saw and heard upon the subject in hand.

There were great barracks, with 2200 soldiers in, and there was Major Gerstenbraur, who took care of the Professor, led him all about the place, where there had been terrible stinks in former times, for the soldiers were Polonians from Galicia; but all these stinks had been done away with by Liernur and his ventilating closets at the end of every corridor, which are as cleanly as can be expected under such circumstances. There are syphons under each closet, made to block up the iron tubes that go down the walls into the ground, and have never been frozen up. The health of the garrison has been perceptibly better than in pre-Liernurian times. Then there is another military gentleman, Captain Cornetzki, turning up, to show the Professor the more serious business like ground. He tells him first that the Austrian Government is highly contented with the working of the patent, which it seems has now been bought by the Government, and that some other barracks in Prague and Vienna are going to be provided in the same manner. He is permitted to have a look at the documents belonging thereunto, which, however, are less interesting to the reader than satifactory to the Liernurian disciple. The chief is a contract for daily removal of the feeces from all the Prague barracks, and for the due provision with all the apparatus for the purpose and the working by the Liernur Company, in pay for which services the Liernur Company asks and demands no more than the right of disposing and selling the feces on their own terms.

The sale of the manure is insured by contracts with certain great Beetroot cultivators near Prague, one of whom has contracted for 1000 tons per annum, paying 7½*d.* per 1 lb. of nitrogen, the manure containing 1 per cent., and being regarded as equal to five times the weight of common stable dung. The like contracts have now been made in Berlin, Cologne, Hanover, Leipzig, and other towns of the Netherlands. The transport by rail (in petroleum casks, containing 3 cwt. each) is charged at 4*s.* per 10 tons carried 20 English miles. Under these circumstances, not exceedingly fortunate at all events, the rather expensive machines, tubes, syphons, air-pumps, &c., and the pumps, &c., besputting aside one-half of the income at 10 per cent. for redemption, and leaving the other half to pay for coals, workmen, horses, inspectors, and officials—renewable, so to say, in every period of 15 years. However, if the system be once adopted generally, and going on on a larger scale, the replacement will take place in the time of three years at most—such, at least, is stated in the calculations of the Berlin project. Here there will be a great central engine-house, doing the work for whole quarters of the town, in the same way as a gas-engine-house does the night-service, that the reservoirs will be localised, and merely connected with the central station by evacuation tubes.

The tubes can be of any possible length. The Professor is quite assured that technical difficulties have been and will be most successfully vanquished. He has taken down rats, soldiers' breadbags, boots, caps, and even brooms, that had passed the whole course of the tubes at the barracks, which are indeed highly complicated, by the foundation walls not being allowed to be injured, and which had turned up like cannon balls bounding against the side of the tender. The velocity inside the tubes must be something quite shot-like, even with but half a vacuum employed. In the beginning they had once, with inexperienced workmen, evacuated down to 25 inches, and had forgotten to shut the valve of the air-pump, in consequence of which the main flooded and had to be dried emptied by five minutes' pumping. This, indeed, seems to be the only accident that ever happened, except a piece of iron rod once obstructing the syphon of one of the closets, and being driven down into the main pipe. This had to be got out by unscrewing, and they found it quite safe in the tube, where it was seen to be covered by a thin film of slime, protecting the material, and diminishing both adhesion and friction. Such accidents are owing to the closets not being constructed anew, and according to the Liernur plan, which has provided against anything whatever passing the system, by narrowing the prime syphon, and giving it an extra bend. The air-pump now is self-regulating, so that there is no longer any flooding it.

The Professor, who saw things going on at 6 o'clock next morning, found the whole process of evacuation, both of the subsoil-reservoir and of the tender, finished in five minutes' time, without bustle, smoke, smell, and anything except fire-engine-like expertness. He followed the tender to some back-yard place, saw its contents decanted into barrels, put on waggons, and then pulled out of sight by sundry pairs of oxen, which was quite a lyrical end to the matter. There is a factory, too, at Prague, with 300 workmen, provided with the Liernur machine, and the Professor went there, slyly entered the office, and asked the principal (Mr. Hüse, maschinenfabrik, Carolinenthal) what he thought about it; whereupon the gentleman had very little thought at all upon the matter ever since it was going on, which it has been ever since the month of November, 1869, and that he only knew about the tender coming every morning, and something being done outside the building in a most gentlemanly manner, which the Professor means to say was the best answer to be had.

I will put a stop to this letter now, apologising for its extreme length, however, I cannot do so without

Foreign Correspondence.

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

THE close of a successful annual meeting, when readers are most impressed by a sense of the valuable services rendered by our national society, is perhaps the fairest time in which to lay before them a criticism of the management of its affairs; and we therefore reproduce, now, from the columns of the agricultural papers of May last, the discussion which took place on that subject before the general meeting then held. We had not room for a report of this discussion at the time:—

Sir J. H. MAXWELL moved the adoption of the report.

Mr. MECHI, in seconding the motion, said that the Society was conferring great benefits on British agriculture. Its publications would have alone entitled it to the thanks of the agricultural community; while the annual shows, by causing comparisons to be made between various implements and various kinds of machinery, had done a great deal towards removing that prejudice, self-esteem, and pride which were to be found among agriculturists as well as other classes of the community. As regarded the objects of the Society, "Practice with Science," it was impossible to deny that one great difficulty of that Society had been that it had had to contend against a want of education among agriculturists, and a sort of abhorrence on the part of many practical farmers of the very name of science. This had compelled the Council to be very cautious in its movements, but they had at length succeeded in bringing considerable influence to bear fully upon agriculture. Witness the lectures and papers of Professor Voelcker, which were of very great importance and value to the interests of agriculture. Another evidence of progress was furnished by the Royal Agricultural College at Cirencester, which was now somewhat improved in the estimation of practical farmers. He could not help remarking that the number of members of that Society was not at all to be compared to the British agriculture. There were in England and Wales about 300,000 farmers, and it appeared that only about 6000, or 1½ per cent., could afford £1 a year to belong to that Society, or else only that number desired to participate in gaining the knowledge which was communicated in the admirable papers published in the Journal. He (Mr. Mechi) believed that British agriculture was now entering upon a new phase. Ever since the Education Act was passed, which passed last session would indirectly so change the position of British farmers as regarded education and science within the next half century, that if some of them could come back again they would wished they could take into account they would find agriculture presenting an aspect altogether different from that which it now wore.

Dr. CRISP said Mr. Mechi had remarked that the numbers of members of that Society was not as great as it ought to be. Everybody knew that, and everybody felt that there must be something wrong and rotten at the very foundation of the Society, seeing that it had under 6000 members. It behoved them to ask what was wrong —why it was that that Society was not more popular? It was clear to him that before it could become popular there must be a revision of the Charter, and they must be enabled to introduce many matters intimately connected with agriculture, and with the welfare of the people, the exclusion of which had been a clog, and exceedingly detrimental to the advancement of agricultural science. He had found that during the first decennial period of the Society's career, that is from 1840 to 1851, the number of members was 60,545, and that during the last ten years the number was only 6057, showing a diminution of 5476 in the latter as compared with the former. At the same time he found that the number of members of Chambers of Agriculture was 18,000. One great reason, he believed, why they had not progressed as a society was, that the Charter had crippled them, so that they had been unable to touch upon matters which were most important in reference to the advancement of agriculture. He must, however, now call attention to the fact, that the Council had positively deviated from the Charter. In some respects they had, in fact, never adhered to it; they had broken their own laws, and might be called poachers, having gone beyond the powers which the Charter gave. At the last meeting he spoke particularly of improvement as this might and should be effected in the Journal, remarking that the members ought to know what was going on in other countries, such as Germany and America; and that if the abstract were given of such matters, it might convey many useful hints to farmers in this kingdom. He had read the Charter say with regard to the objects of the Society? The Charter said that as the Society was—"First, to embody such information contained in agricultural publications, and in other scientific works, as should be found by practical experience to be useful to the cultivators of the soil; 2d, to correspond with agricultural, horticultural, and other scientific societies, both at home and abroad, and to select from such correspondence all information which, according to the opinion of the Society, may be likely to lead to practical benefit in the cultivation of the soil." Now, that had never been done. Having looked very carefully through the Journals, he had never seen an abstract of any single foreign publication. It was all very well for gentlemen to visit Belgium or some other country on a sort of holiday tour; but he believed that if the published results of practical knowledge abroad were put into a small compass and concentrated as it were in the Society's Journal, that would be of infinitely more service than many of the papers which had appeared there. Another object stated in the Charter was "to collect information with regard to the management of woods, plantations and fences, and on every other subject connected with rural improvement." Now, how had that been carried out? There had been a constant avoidance there of the question of the Game Laws, which he had not the slightest hesitation in saying had been very injurious both to tenant-farmers and to agricultural labourers. If that were a proper occasion for doing so, he could adduce evidence which would convince anyone that what he said on that point was correct. He thought they properly investigate "the management of woods, plantations, and fences," without saying something about hares and rabbits; or how could cultivation be properly carried on where game abounded as it did in many places? It is believed that the connection between that Society and the Veterinary College had been extremely detrimental to the veterinary profession and to veterinary science. Let him explain what he referred to. Although Edinburgh not only had other journals, nearly all persons in the scientific world read their Journal. In reports in their Journal mention was made of the worm Filaria Bronchialis (he must know something about that worm, for he was the first to speak about it in this country) as very destructive to lambs. There was no such thing as the Filaria Bronchialis; that was altogether a misnomer. The worm that injured and destroyed the lamb was the Strongylus Filaria, a different genus altogether. You might as well call a badger a bear, or a bear a lion, as call the worm in question Filaria Bronchialis. It might be said that was a matter of no importance; but he presumed that the Council wished the Journal to stand well before the scientific world, and it could not do that while it contained such a monstrous misnomer as that. He had said that the object of the Charter was "to promote the comfort and welfare of labourers." He did not see how the comfort and welfare of labourers could be promoted in many districts while the game laws remained in their present form. He might remark that, being anxious to ascertain beforehand whether he would be allowed to introduce the subject of the Game Laws, he applied to the secretary for information, but he was not in office long enough to be a side-wind, advocating a revision of the Charter, and giving his reasons for so doing. He would not enter into the matter then, but he had desired to bring the subject before them in a manner which would secure a hearing. He had some future time the Council might propose a revision of the Charter. It was, he repeated, impossible that the comfort and welfare of labourers could be promoted in many districts while the game laws remained in force. In the operations of the Game Laws. He had known little children sent out to get possession of the pheasants' eggs, for which a shilling would be obtained; and what was the result? Those children were taught that they were led to steal, and liable to the demoralisation of a prison? Again, it seemed to him a great hardship to farmers that they should be obliged to keep poachers that they might be available as witnesses in game-keeping prosecutions. He knew that that subject was not a very pleasant one, and as he was precluded from entering into it on that occasion, he should take another opportunity of bringing it before them. He had also stated that he considered the connection between that Society and the Veterinary College was detrimental to veterinary science. In France a veterinary student could not pass his examination without having been in the country a student might pass at the end of one year, and all kinds of animals might then pass through his hands. It appeared to him a great stigma upon that Society that while £2000 a year was paid to the College, a condition that the members should have their horses and pigs examined—a matter about which nothing was said in the Charter—and when £200 had been granted towards it by the Queen, and £100 had been given by the Prince Consort, when an application was recently made for a grant in aid of the French Farmers' Seed Fund, it was refused by the Council, on the ground that compliance would be against the Charter. He thought it required a good deal of hair-splitting to defend such a distinction, or to show why, if it were right to grant £100 for the memorial, it would have been wrong to grant £500 for the Seed Fund. Feeling great interest in the subject of the Game Laws, and in scientific matters connected with agriculture, he had ventured to make these remarks, in the hope that they would hereafter be discussed at a much fuller meeting.

After remarks by Sir Walter Stirling, in corroboration of Dr. Crisp's argument, and a denial by Sir G. Jenkinson of its justice, so far as the game question was concerned, the CHAIRMAN (Lord Vernon) said:—

Gentleman, it is always a very healthy thing for the Council to be brought face to face with the constituents whom they represent, and to receive the measure either of censure or of praise which, in the opinion of the agricultural public, they deserve. I must say, with regard to the speech which my Dr. Crisp of the constituents of this Society that the statistical comparison drawn by him between two periods of ten years does not convey the same impression to my mind as it does to his. I think it would be much more satisfactory if he were to compare one period with another more directly antecedent to the present for the purpose of making comparison, because I cannot tell what causes may have operated in the early years of the Society; though I think I may fairly assume that the existence of Farmers' Clubs and of Chambers of Agriculture and other societies has tended to diminish the amount of support received by this Society. If you compare the number of subscribers in December, 1869, with the number in December, 1870, you will find that there is a gain of 12; while if you compare the number in May, 1870, with the number in May, 1871, you will find a gain of 100, and that it is quite clear that an increase has recently been going on. I quite admit, however, that in the case of a great society like this—a society which has, I may say, created agriculture in this country, and is still doing so much to improve it in matters of detail—it is a surprising thing that it should not be more largely supported than it is. The discussion to-day has, I believe, gone beyond the strict limits of what is authorised by the Charter, and it appears to me that the proper course for a gentleman who holds such views as Dr. Crisp does is, not to write in a newspaper to complain that certain subjects which are unpalatable to the Council are not allowed to be introduced, but to ask the Society to entertain the question whether the Charter should not be revised; and until that question has been decided in *one* way or other, the subject of the Game Laws should not, I think, be introduced at a meeting like this. At the same time I must remark that the position of the Chairman on an occasion like the present is not a very easy one. I see myself a very great distinction between Game Laws and game, game being an agricultural question, and Game Laws a political one. I did not, therefore, feel it to be within my province to stop the discussion which has taken place, but I am glad that it has not gone beyond the limits which it reached. I must say that I was very much afraid it would go further, and I am obliged to those gentlemen who met my wishes by not entering more fully into the question. Now, it appears to me that there is one very grave reason why this Society could not undertake to deal with those questions which have been taken up by the Chambers of Agriculture, and that is the practical one that the business of the Society occupies for several days in each month the close attention of gentlemen who come from all parts of England; and I have never been associated with a body of gentlemen who more thoroughly and conscientiously performed their duty. The greatest attention is paid by the Council to the opinions of agriculturists outside; and if you were to tack on to their duties the consideration of such questions as those which occupy the attention of the Chambers of Agriculture, coming as the members of the Council do from all parts of England, I could not but think that you would put on them an amount of work under the pressure of which they would break down. If the question of an alteration of the Charter is to be raised —and my opinion a few years ago was a strong favour of altering it—I should certainly not wish to see it altered in such a way as to lead to the including of those questions which are now so ably, satisfactorily, and carefully dealt with by Chambers of Agriculture.

Mr. ROBERTS, in seconding a vote of thanks to the auditors, alluded to the last paragraph in the report, where the Council say they "cannot but express their regret that the entries were not more numerous for the prize offered, and that out of the number entered more than half did not present themselves for examination," said he hoped that regret would not lead to an abandonment of the plan of offering prizes, the comparative failure of the examinations proved how much such a stimulus was needed; adding that, if the offering of prizes for implements had ceased after the first Oxford meeting, agriculture would have suffered great loss in consequence. It was, he added, an open question whether the best way for a young man to learn farming was to live with a farmer, and daily observe with him the operations of husbandry, or to go to an agricultural college; but in his opinion the latter course was on the whole the best. He thought something should be done to afford an agricultural education to the children of agricultural labourers, and it occurred to him that the most inexpensive and effectual mode of accomplishing that object would be for that Society to offer prizes to persons in training for the office of village schoolmasters for a knowledge of agriculture and the power of teaching it. Children would always take an interest in lessons on agriculture if they saw a practical application of them near the school. He did not see why the Society might not maintain its connection with the Veterinary College, while the Council abstained from forming any connection with an agricultural college.

NOTTINGHAM.

The Tenure of Land.—At a recent meeting of the Notts Chamber of Agriculture, Mr. CHRISTOPHER NEVILLE, of Thorney, said that although he professed to be acquainted with subjects as affecting landlord and tenant, he would not rise to speak on the point, except in the expectation that it would elicit some observations from gentlemen besides himself, and especially from tenants, because the parties who were deeply affected were the landlord who let the land, and the tenant who took it. His notion was, that both parties had to be considered. With this little preface he would move a formal resolution, which he had hastily drawn up, to the following effect:—That a tenant tenancy with six months' notice to quit on either side, does not in all cases give sufficient security to the tenant for the investment of his capital in the due cultivation of his farm." This might be a matter of opinion; but, as a matter of fact, he knew there were many cases where the tenant had cultivated his farm very highly, and had invested a good deal of capital, and from some, perhaps accidental, circumstances, had received notice to quit at six months, and could not possibly get his capital out again. No man in his senses, who knew anything about farming, would disagree with him when he said that it was impossible, if a man received notice to quit in October to go out in April, that he could get his capital out of that farm, for he must leave a great amount of artificial manure and other things in the land. He thought, therefore, that it was unjust to the tenant and injurious to the country; and he maintained that it would be a good thing if an arrangement could be made by lease, tenant-right agreement, or anything else, to render such an injustice an impossible occurrence. He, as a landlord, did not approve of the present Game Preservation Act in London, though he was a great Liberal, for they spoke of landlords as trying to rob the tenants, and that sort of thing. This was all a heap of rubbish. The majority of landlords did nothing of the sort. He knew estates of 50,000 acres, where the landlord was as honest and liberal as possible, and did not want to do anything wrong. If any gentleman would show him one tenant who had been robbed by being turned out

of his farm unjustly, he would show 50 or 100 who had never been robbed at all. Of course, if a tenant had been robbed of £1000 or £1500, it was no consolation for him to be told that there were others who had not been robbed at all; but, as a landlord, he declared he should be glad if some agreement could be hit upon to suit all parties, and to render it possible for the tenant to feel that, in any event, he would be fully compensated. The difficulties at first sight seemed enormous, but when the Government were obliged to do it, they did it, for they granted a measure of great security to the Irish tenants. He did not approve of the whole of that Irish Bill, but he approved of the principle of it, and as an honest man he could not see why, if the Irish tenants were to be rendered secure from any casualty, the English tenantry should not have the same advantage. He had been all over Ireland three times, and knew a good deal about the country, but the only difference he found between the Irish and English was this, that the Irish tenant farmed a great deal worse than the English, that the Irish tenant shot his landlord, which the English did not, and that the English tenant paid his rent a good deal better. These were the only differences he could see, and so far from sanctioning their going on year after year without trying to do anything, he thought that if landlords had honour and honesty about them it was a reason why they should exert themselves more. The better their tenants behaved, the better they ought to try to behave with them in return; and for his own part he was very willing to bring forward the subject if no one else had made a motion. He had hoped it might receive some consideration at Worksop, and he was glad to find Mr. Foljambe, who was a larger landowner than himself, express his willingness to enter into any discussion of the sort so as to grant the tenant greater security. He thought he had now stated enough for any reasonable person that the object was a good one, and he would therefore go on to consider what could be done towards giving the tenant the security necessary.

The Lease.—The Scotch plan was that of a lease of say, 21 years, but this involved some other conditions. He found the Scotch papers full of advertisements of farms to let for 21 years upon offer, and it seemed to him like a sort of auction. He knew a great many tenant-farmers whom this arrangement would not suit, because they would rather go on under a large landlord year after year, than have their farms advertised in the papers, and have to bid for them by auction, as it were, for 21 years, for they could often go on under a landlord for much longer period. There was another objection that was felt against leases. If a tenant held a farm he might leave to get a better under a larger landlord; and on his (the speaker's) own estate, for instance, if a farm of 200 or 300 acres was vacated, and a tenant who had hitherto held only 50 or 100 acres was able to take it, he always let it to him in preference to a stranger, so on. Men of enterprise and capital would not, under these circumstances, like to tie themselves for 21 years to a farm of 100 acres or so, because they were hoping to get larger and better farms. Another disadvantage of a lease was that it necessarily involved some agreement as to cropping. An able land-agent would say to a landowner, If you part with your land for 21 years, you ought to have a strict agreement as to cropping, to provide for the due cultivation of the farm. He had heard that this had been admitted by tenants to be just and reasonable, and not outrageous at all; but still, his tenants being from year to year, he had no occasion to do this. He let them crop as they pleased, with one condition—namely, that they did not injure the estate. If they did not injure him or his family, the more money they got the better for him. In this way a good agent was of great use, but he should only act as an impartial mediator between landlord and tenant, doing equal justice to both. He told his agent at his rent-day, "I think you are a good agent, for if anything you rather favour me, and that is a good fault." If a tenant was not injuring his farm, it is a great advantage to him to be able to crop as he pleased, and he had never heard how it could be arranged under a 21 years' lease. He granted a lease was absolute security, but there were those disadvantages, and he had set them forth for their consideration.

Tenant-right.—Another security was that of tenant-right, and they had carried this so far in Ireland that now, when a man took a farm he had to have two capitals, one to buy the tenant-right, and another to stock his farm. It was consequently no unusual thing for a man to exhaust all his capital in buying tenant-right, and then to have none to put upon the farm. He considered it was quite right for a tenant to be compensated; but several gentlemen had put the matter in this way:—Suppose a farmer had two or three sons, and placed them upon farms, and the tenant-right on one was £6 and £7 an acre, and on another £8 or £10, he had a great difficulty in fixing his sons. Therefore, in the management of his estate, with Mr. Bartholomew, his agent's, assistance, he endeavoured to keep the tenant-right as low as he possibly could; and, in order to do this, he had adopted a principle which he had not the smallest doubt whatever would be the best for both landlord and tenant, and it was this, that he never allowed a tenant to invest a single farthing in the permanent improvement of his farm. Perhaps he ought not to say that he did not allow it; but he told his tenants, when he came to the property 25 years ago, never to spend a farthing on building or draining, or any really permanent improvement. If they wanted any building or draining done, and Mr. Bartholomew said it ought to be done, he did it, and told them they must pay him interest by way of rent. The tenant thus kept his capital to work his farm with instead of burying it in his landlord's estate, and when he quitted his farm he was able to put his money in his pocket. He had proposed to Mr. Gladstone, when he saw him, before that gentleman introduced his Irish Bill, that a court of equity should be established for the adjustment of these matters, as things seemed to be in such confusion in Ireland. He suggested that whenever a landlord gave a tenant notice to quit he should have the power of calling in a court of equity or an arbitrator, or some one to judge whether he really had a claim or not. It was a thing which he, as a landowner, would be quite willing to do himself if the tenantry desired it. A running lease of three and a half or four years had also been suggested, so that when a tenant received notice to quit he should have the opportunity of having a year's cropping before leaving, and should thus be able to get back what he had spent on the land. The objection, however, which would strike everybody, to this arrangement was, that if a tenant was farming badly the landlord would be precluded by giving so long a notice; and then, again, if a tenant had a disposition to farm a better farm, he would be three or four years before he could leave, and might thus lose it. Some arrangement might, perhaps, be made for a landlord to give his tenant six months' notice to quit, and then keep his farm on six months, and the tenant to be able to quit in six months, an arbitrator to be called in to give a just claim to either party. A court of equity would obviate the cost of a trial at the assizes, if the matter should ever be pressed so far as that; but if the landlord was willing to have an arbitration, and they could not agree as to who should be the man, he would leave the selection to the chairman of the Council of the Chamber of Agriculture in the county. He did not want Acts of Parliament; his plan was entirely voluntary; but if some arrangement could be made to grant the tenant greater security, he was confident that in the long run it would be for the interest of both parties.

Mr. Barrow, M.P., said he had followed the plan Mr. Neville had recommended. He did not think there ought to be any hesitation on the subject to tie the hand of either landlord or tenant. He was for freedom of action very much on both sides. He agreed for the most part with almost everything that had fallen from Mr. Neville. Having himself been a landlord for 50 or 60 years, and in a larger way for between 30 or 40, he could only say that his tenants were all from year to year, and he had never given one notice to quit, and he had never received one. He did not, therefore, see that there was any difficulty in landlord and tenant agreeing on a yearly tenancy. On his estate, if there was any drainage or building to be done, he did it himself; but at the same time, if the tenant thought he could obtain rather more on more particular land under his agreement he found it to his benefit if they did the work by their agreement they were entitled on leaving to be repaid what they had paid for labour, so long as it expired within a certain number of years, within which he supposed they might have taken back all the benefit from them. If a man did any permanent improvement, it was to be subject to the same valuation as Mr. Neville had mentioned. He believed it to be perfectly practicable, for he had found it so himself with the small number with which he had to do. There was one difficulty Mr. Neville had suggested regarding compensation, and with respect to these permanent improvements whether or not it was binding on the landlord to pay for them it was worth while for the tenant to pay additional rent on account of them. He only wished, however, to second what Mr. Neville had suggested.

Mr. R. Butler, of Ratcliffe, thought that tenure of land was in an unsatisfactory state with a yearly tenancy. A farmer had not the advantages which a tradesman received, because he was not in the same position for investing his capital. He might cultivate his land as well as he could wish, but he did not know what might happen. His landlord, or Mr. Neville, had pointed out at a previous meeting, might be killed in a railway accident, and another succeed who would be a bad one. He should say leases would be very beneficial to the country, subject to certain restrictions, and to investigations on behalf of the landlord or his agent, to see that the land was not deteriorated, and subject to dilapidations and to enhanced tenant-right, supposing the tenant had improved his land. A tenure which would be for the protection of the landlord and the security of the tenant would be very beneficial to the country. He had great pleasure in seconding the motion which Mr. Neville had proposed.

Mr. Gilbert, of Barnby, said Mr. Neville objected to legislative enactment, but he thought that that was just what they wanted. Suppose, for instance, that a landlord could not afford to make necessary improvements, and the tenant was to make them himself, what that tenant wanted was security for the permanent improvements which he had made; and he himself would have a legislative enactment, to the effect that every tenant on quitting his farm should receive an equivalent for the permanent improvements that he had made. He did not see how they could compel landlords to grant leases or tenants to take them, and, besides, it might be a very adverse thing either one way or the other. A man knew when his lease would expire, and he would get as much out of the land as he could before he left. He did not see any remedy at all except a uniform system of tenant-right and compulsory payment for permanent improvements.

Mr. Hemsley, of Shelton, said he should be sorry if the impression was left on the meeting that they, as a body, were desirous of having leases. His own opinion was, that where they had large landed proprietors they were far better off without leases, where they had a sufficient feeling of confidence between landlord and tenant. There were certain matters binding on leases, and certain things which rather disengaged the two parties. He should be rather sorry, therefore, if Mr. Butler's remark as to leases went from the meeting without a little dissent. He occupied land under a liberal and worthy landowner, and he should insult him and his agent if he asked for a lease, and should be extremely hurt himself if they, on their part, desired one. It was the same on many other noblemen's estate, and he, in fact, declined in favour of leases. He thought the question before them was the small amount of notice to quit, and this he considered might be discussed with a good deal of advantage. With reference to running tenant-rights, as a rule, they were not too high, and in a country like this, where capital could find employment, surely they ought not to say there was not sufficient capital to farm land. It was rather away from what they might expect for the improvement of land to say that tenant-right might be a little more confined. He himself did not think that advisable at all. It was a point of more consequence now than it was, because farms were becoming very much enlarged; but at the same time he did not think, as a rule, that landlords found it difficult to meet with tenants with sufficient capital. He thought the arguments that had been used were rather in favour of extending tenant-right than curtailing it.

Notices of Books.

Poultry, their Varieties, Management, Breeding, and Diseases. By Hugh Piper, Author of "Pigeons," &c. Groombridge & Son.

Pigeons, their Varieties, Management, Breeding, and Diseases. By Hugh Piper. Groombridge & Sons.

The Homing or Carrier Pigeon (*le Pigeon Voyageur*): *its History, General Management, and Method of Training.* By W. B. Tegetmeier, F.Z.S. G. Routledge & Sons.

We have not before met with Mr. Piper's name in the literature of the poultry-yard, but these little books, which bear it, appear to us to be the productions of a practical man and a trustworthy writer. From the first we make an extract on food and feeding:—

"Over-feeding is a common mistake with inexperienced poultry-keepers. A fat hen ceases to lay, or nearly, and is subject to many diseases, while an over-fed cock becomes lazy and useless, and runs a risk of apoplexy. Half-fed fowls never pay, whether kept for the table or to produce eggs. A fowl cannot get fat or make an egg a day upon little or poor food. A hen producing eggs will eat nearly twice as much food as an unlaying hen.

"Barley, reckoned by weight, costs less than Wheat or Oats, and possesses a very fair proportion of flesh-forming substances, but contains a lesser amount of fatty matters than other varieties of corn. Barley-meal contains the same component parts as the whole grain, being ground with the husk; but only inferior Barley is made into meal.

"The best Wheat is dearer than Barley both by weight and measure, and contains about 12 per cent more flesh-forming material; but it is fortunately the cheap Wheat is the best for poultry, for Professor Johnston says, 'the small or tail corn which the farmer separates before bringing his grain to market is richer in gluten (flesh-forming food) than the plump, full-grown grain, and is therefore more nutritious.'

"Oats are dearer than Barley by weight. The heaviest should be taken as they contain very little more husk than the lightest, and are cheaper in proportion. Oats and oatmeal contain more flesh-forming material than any other grain, and double the amount of fatty material than Wheat. The less frequently refuse the lighter samples of Oats, but if soaked in water for a few hours, so as to swell the kernel, they will not refuse them.

"Maize or maize-meal must not be given in too great a proportion, as it is very fattening from the large quantity of oil it contains; but mixed with Barley or barley-meal, it is a most economical and useful food. Whether whole or in meal, the Maize should be scalded, that the swelling may be done before it is eaten.

"Buckwheat is about equal to Barley in flesh-forming food, and is used greatly on the Continent.

"Peas, Beans, and Tares contain an extraordinary quantity of flesh-forming food, and very little of fat, but are too stimulating for general use, and would harden the muscular fibres and give too great firmness of flesh.

"The meal of Wheat and Barley are much the same as the whole grain, but oatmeal is drier, and separated

from a large portion of the husk, which makes it too dear, except for fattening fowls and feeding the youngest chickens, for which it is the very best food.

"Fine 'middings,' also termed 'thirds,' and in London coarse country flour, are much like oatmeal, and may be cheaply and advantageously employed, mixed with boiled or steamed small Potatos or roots.

"Potatos, from the large quantity of starch they contain, are not good unmixed, as regular food, but mixed with bran or meal are most conducive to good condition and laying. A good morning meal of soft food for a few fowls may be provided daily almost for nothing by boiling the Potato peelings till soft, and mashing them up with enough bran, slightly scalded, to make a tolerably stiff, dry paste. The peelings will supply as many fowls as there are persons in the dinner-table. A little salt should always be added, and in winter a slight sprinkling of pepper is good.

"If the soft food is mixed boiling hot at night and put in the oven, or covered with a cloth, it will be warm in the morning, in which state it should always be given in cold weather. It should be put into a trough railed across at the top, to prevent its being trodden upon by the fowls, and should always be mixed rather dry, for fowls do not like sticky food.

"Rice is not a cheap food. When boiled it absorbs a great quantity of water, forms a large substance, but, of course, only contains the original quantity of grain, which is of inferior value, especially for growing chickens, as it consists almost entirely of starch, and does not contain quite half the amount of flesh-forming materials as Oats.

"Fowls should be fed at regular hours, and will then soon become accustomed to them, and not loiter about the house and kitchen-door all day long, causing food, which they will do if fed irregularly or too often, and neglect to forage about for themselves, and thus cost more for food.

"A little chopped raw meat may be given occasionally, especially to fowls that do not get many insects or worms, but the latter are more natural food when they can be had. Greaves, so much advertised for fowls, are very bad, rapidly throwing them out of condition, causing their feathers to fall off, and spoiling the flavour of the flesh.

"Where they have no grass plot, fresh vegetables must be thrown in daily, or it will be impossible to keep them in health. Cabbage and lettuce leaves, Turnip-tops, Turnips cut into small pieces, and scattered like grain, or cut in two, or any refuse vegetables will do, but the best thing is a large sod of fresh-cut turf.

"A constant supply of fresh clean water is indispensable, and should be kept in a vessel so contrived that the fowls cannot make it dirty. In frosty weather it should be emptied every night, and snow must never be allowed to fall into it, snow-water being most injurious to poultry.

From the book on pigeons, by the same author, we take the concluding sentence :—

"In conclusion, we can confidently boast that this little manual contains more complete directions for the management of pigeons than have been given in any other work. The larger part of most books upon the subject is devoted to descriptions of the different varieties, which appears to us to be beginning at the wrong end; for through the want of plain and full directions upon some important point inadvertently omitted, the pigeon-keeper may lose valuable birds. We have consequently had to limit the descriptions of the varieties, both in number and length, although we have treated of all the most important breeds; but should this little manual meet with the patronage that we hope it deserves, we may present the public with a more complete, and elaborate work upon this interesting subject."

Mr. Tegetmeier's book on the carrier pigeon is the work of a naturalist, and will be received as the production of an unquestionable authority on its subject. It is an extremely interesting work, and any one taking it up will read it to the end. The history of the carrier-pigeon, its training, and its long flights and performances—the interest taken in it, especially in Belgium, where every small town has its pigeon club—will be new to a large number of our readers, and they will do well to procure the book. The following passage may serve as an illustration of the style and material of the performance :—

"It is certain that hereditary-trained intelligence has much more to do with the goodness of homing pigeons than their size or the exact nature of the variety. The process of 'natural selection,' or the 'survival of the fittest' in the struggle for life, eliminates all those carrier animals when in a state of nature, and, by a perfectly parallel course of artificial selection, the Belgian colombophiles have got rid of their inferior birds, and are continually breeding, year after year, from those that have performed the longest journeys in the shortest space of time. If a stranger wishes to know the value these experienced pigeon-fanciers set upon their best birds as breeders, let him visit, as I have done, the Belgian lofts in the spring, and hear £10 or £12 refused for a single pair of birds; and if still pressed to sell, listen to the remonstrance of those genuine colombophiles :—'Do not ask us to sell our best birds, we do not like it, but wait a couple of months, and we will give you plenty of young ones.'

"This process of selection of the best stock is continually being carried on. Each pair of old birds will breed seven or eight young ones every season; of these, let us regard five or six as being reared, and ask what becomes of them.

"The very worst are lost in training; the weakest are struck down by the hawks; the slowest, those that return, but not in good time, find their way to the dealers; and, during the summer season, thousands weekly are shot at the pigeon-shooting clubs in this country, where aristocratic gunners stand with double-barrelled guns, 25 yards from the traps, and think they are worthy of the title of sportsmen if they succeed in butchering their prey in this ignoble manner. I am no maudlin sentimentalist; I know that Nature is prodigal of life, and that of every 20 pigeons born, not more than one can be allowed to arrive at maturity, and increase its kind, or the world would soon be overstocked with pigeons, but this does not increase my respect for their slayers. I believe the best possible use you can put a deliberate murderer to is to hang him, *pour encourager la autres*; but this belief does not raise the hangman to the dignity of a gentleman in my estimation; nor can I see any more true sport or manly dignity in the performance of a languid swell who backs himself to kill 25 pigeons out of 50, his *sub-de-chaine* by looking his gun, than in that of the vulgar snob who wagers that he will kill and dress a dozen sheep in less time than any other butcher—gambling, not sporting, is the aim of both.

"This baneful business of shooting pigeons, universally followed by the Belgians, has eventually produced good birds of various types, all having, however, the common characteristics of a large brain, and consequently a capacious forehead or skull, a well-developed chest, with large pectoral muscles to move the wings, and broad overlapping flight feathers, the ten primary feathers being exceedingly well developed, so as to overlap each other to a much greater degree than in any of the ordinary varieties."

Farm Memoranda.

HAMPSHIRE: *July* 5.—The cold, cloudy weather which prevailed up to the middle of June, together with the absence of rain, gave to the crops a very unpromising appearance. The fine showers which have since fallen have greatly improved the face of the country, and offer a more hopeful prospect for the harvest. The harvest, under any circumstances, must now be late, and should the weather continue dark and wet, with the present low temperature, it may be unusually late; and it is this prospect which threatens the Wheat crop, as it is well known that late harvests are proverbially unproductive as regards the Wheat crop, and should the present weather prove favourable we cannot now expect an average crop of Wheat, the plant being so very deficient and the blooming time too cold and sunless, taking also into consideration the quantity ploughed up and re-sown with Lent corn will tell against the average produce of the county. The appearance at present of the Barley crop is favourable, the plant being strong and stiff in the straw, and is showing a good ear. There is no doubt a large breadth has been sown and got in early, but should the weather prove favourable it may give an abundant yield. Still, however, this crop delights in a warm climate peculiar to our eastern and southern counties. If the weather continues as at present, there may be a large crop of straw, producing inferior grain.

Oats may be said to be a very promising crop, as they thrive best in the western and northern counties, where the rainfall is greatest, therefore the late rains have proved highly favourable, and the crop is likely to be over the average.

Beans, winter-sown, are not a good plant, and are affected by the black aphis in some instances. This crop will be a deficient. Spring Beans, on the other hand, as well as Peas, are looking altogether exceedingly well, perhaps never better, Peas being especially well podded, and show no blight.

Trifolium has been a remarkable good and valuable produce this year, in fact, the late varieties are at present in full value for feeding, and will continue available for early cattle for another fortnight. Thus we shall have had this excellent food in use for a period of ten weeks, showing the advantage of sowing the early and late crops for a succession. Vetches are also an abundant produce, but will not bear comparison with Trifolium for stock feeding. The produce of feeding grass has been under an average, and only about one-fourth got up before the rains set in, consequently the remainder has been seriously damaged, and in many instances can only be used for litter, and thus prove a substitute for straw, for which it must be considered valuable, because the latter will require more to utilise straw for feeding purposes. This being the case, the loss of the hay crop will not be so severely felt, especially as there is promise of an excellent second cut of Clover. All late pastures are loaded with a very large crop of grass, now awaiting favourable weather to be converted into hay. The prospect of Mangel, Swedes, Turnips, &c., is very fine, and the land being in excellent tilth, there is probably a good crop of all the later sorts to be expected. Potatos also are looking well at present, but the early sorts are not yielding a heavy crop.

Both fat and store cattle are excessively dear and scarce, and are likely to continue so. As regards sheep, the draft upon the stock of the county has been enormous. The companies, or gangs, of sheep shearers who traverse the county during the months of May and June, all report a great diminution of numbers offered for shearing; in some districts, several thousands less than usual. This is strong evidence of the encroachment made upon the stock of the county. We may therefore expect sheep to be a brisk sale, and dear at the coming fairs, the principal being at Stockbridge, Overton, and Alresford, during the present month. The fine and abundant rains fallen lately have so altered the appearance of the chalk hills and light land farms, that no doubt it will compensate and revive the spirit of many occupiers of land who have suffered severely from the effects of several dry and unproductive seasons. *Joseph Blundell, Southampton.*

TILLYFOUR, DORSELL, AND BRIDGE END, ABERDEENSHIRE.—These farms are all in the occupation of Mr. W. M'Combie, M.P. for West Aberdeenshire, and together comprise about 1200 acres of arable and pasture land, besides between 200 and 300 acres of valuable hill pasture. Tillyfour measures about 600 acres, of which 120 are in permanent pasture; Dorsell includes 325 acres of arable land, and the hill pasture just mentioned; and Bridge End consists of 225 acres, which are exclusively arable. Mr. M'Combie also rents 50 acres of probably the best grass land in Aberdeenshire, from Sir W. Forbes, of Craigie Var. It is almost unnecessary to state that on these farms the whole management is arranged with a view to breeding and feeding a large number of cattle, chiefly of the polled black Angus or Aberdeenshire breed.

Permanent grass land, as already stated, is by no means abundant in Aberdeenshire; but, without it, there would be great difficulty in keeping on, in improving condition, a large feeding stock from the time that the supply of turnips fail, which is in the middle of July, until Turnips are ready to commence upon. Even with the advantage of this grass, it has been found desirable to tie up the most forward beasts before the early Turnips are ready, and it is probable that Mr. M'Combie will increase as a feature in the to a considerable degree to the judicious manner in which this gap has been filled up.

Some of the grass land is of remarkable feeding quality, and will carry bullocks of any size, making them fat, so as to fetch prices ranging from £30 to £50 per head, without any adjunct, whether roots, cake, or corn. The beasts are always bought in good condition, and the best land, in a favourable year, will feed nearly one beast per acre, so as to bring it into this first-rate marketable condition.

The old grass is never cut, being far too valuable for pasturing. Some of it was laid down about 40 years ago, in exactly the same manner as seeds are now sown in the usual course of cropping; and about 10 years afterwards it was top-dressed with a compost of lime and earth.

The three farms are situated on the somewhat steep sides of the valley of the Don and its tributaries, at a height of 750 to 800 feet above the sea-level. The climate is therefore too rough for the profitable cultivation of Wheat, and Barley not unfrequently gives place to the more hardy Bere on the stronger land. The subsoil consists of the disintegrated Aberdeenshire granite, the decomposition of which results in the formation of a fertile, but somewhat heavy soil.

The farms are worked on an alternate five and six-course system, the former being Oats, Turnips, Barley, and seeds for two years; the six-course is an extension of the same, by adding the seeds down another year. A small breadth of Tares is sown every year, either in the Oat course, or instead of Turnips; these are cut when three-fourths ripe, and given with Clover to the forward beasts until the early Turnips are ready. A portion of the new grass is pastured in the early part of the season for a few weeks, after which it is relieved so as to be ready for cutting by the end of July, and thus produce the valuable fodder given with the Tares.

CROPS.

1. *Oats.*—After harvest, the first operation is to plough the Oat stubble, and, when that is finished, the Clover lea is broken up by a strong furrow of from 7 to 10 inches in depth, the whole being finished by Martinmas, if possible. The climate being very backward in spring, a large quantity of seed is required; and, in a bad season, as much as 6 bolls or 2240 lbs. per imperial acre may be deemed necessary. As a rule, the seed is sown broadcast on the furrows; but in some seasons it is possible to go over the land with harrows, and afterwards to drill the seed. After the seed is in, a plain roller is drawn over the land to prepare it for the scythe or the reaping-machine, thus completing the operations of seed-time. Harvesting Oats generally commences about the beginning of September, and finishes from the middle to the end of the month. Cutting is now sometimes done with the reaping-machine, although the implement is not held in such high estimation for Oats as for Barley. It is said that the Aberdeen labourers are such good hands with the scythe, that the machine possesses but little advantage over them. With a good bottom, they can cut from 2 to 2½ acres per day of 11 hours; and, as they leave a shorter stubble than the machine, they get more straw, which is an important consideration to the cattle-feeder. Piecework is not much in vogue, but sometimes the field operations of harvesting have been done by contract, at from 7*s.* to 9*s.* per acre. The most general practice is to get hands at the hiring fairs, which are held in anticipation of the harvest throughout the county. These are men engaged at a stipulated sum (from £3 to £4, with food and beer), for the whole period of harvest, however long it may last. This period varies in length from five to eight weeks, according to the weather; and it was once known to last as long as eleven weeks. Women are employed for sheafing and other of the lighter operations, and get from 55*s.* to 60*s.*, with food, for the whole harvest. Stacking and thatching are done by

the harvestmen and the ordinary farm servants, who work at their usual rate of payment.

2. *Turnips.*—Immediately after harvest the oat-stubble is ploughed as deeply as possible, the deeper the better, from 7 to 13 inches, according to the depth of soil. It is then left until after Oat sowing is finished, generally until about the middle of April, when it is grubbed as deeply as possible, sometimes, if the land is not very clean, getting a cross-ploughing before the grubber is used. Ridging is delayed until immedi tely before seed-time, which commences with Swedes about May 12. When this work is commenced, no time is lost in completing it. Farmyard manure, to the weight of from 10 to 20 tons, is put in the drills, and upon it not less than 10 or 12 bushels of bone dust, and probably from 2 to 3 cwt. of guano; but the quantities of manures used vary with the quality and condition of the land. After the ridges have been split, from 2 to 4 lb. of seed are immediately drilled, the sorts most used being Skirving's Purple-top Swede, Shepherd's Swede, and Aberdeen Yellow Turnips. No white Turnips are grown, as they are not considered to possess sufficient feeding properties, being regarded as fit only for cows and young stock; but the yellow Aberdeens constitute about one-half of the root-course. The plants are horse-hoed two or three times as may be required, and are finally hand-hoed, and singled by the hoe. The quality of the land determines the distance apart to which they are set out, and which varies from 9 to 13 or 14 inches. About the middle or end of October is the time when it is usual to commence topping and tailing, care being taken not to bleed the bulbs, which are "pitted and secured every night to keep them free from frost and rain."

In his book, just quoted, Mr. M'Combie states, "I have adopted my friend Mr. Porter of Monymusk's plan (in a late climate, and where Swedish Turnips in some years never come to full maturity) of pitting them upon the land where they grow, from one to two loads together; and, although not quite ripe, I have never seen a Turnip go wrong when stored in this manner. The land also escapes being poached as the Turnips are eaten in frost, and at a time when the other operations of the farm are not pressing. A foot of earth will keep them safe, and they are easily covered by taking a couple of furrows with a pair of horses on each side of the line of pits."

Twenty-seven or 28 tons of yellow Turnips, topped and tailed, are considered a fair average crop, and from 32 to 35 tons a good crop of Swedes.

For Tares the land is prepared as for Turnips, and the seed is mixed with Oats. If the land is heavy, white Peas and Beans are also mixed to hold up the crop. Tares are sown at different times, the earliest being in spring with the first portion of the Oat crop.

3. *Barley.*—The Turnip land is not touched until after all other spring cultivation has been completed, which is about the middle of April, when it is ploughed from 6 to 8 inches deep, and, without further preparation, sown with 4 bush. per acre of Barley on the light land, or Bere on the heavier soils.

4. *Seeds.*—The preparation for seeds consists of harrowing until a sufficiently fine tilth is obtained, when the roller is passed over the land previous to sowing, and the harrow and roller are again used after the seed is in. The mixture of seeds generally used is 1 bush. of Pacey's Rye-grass, 5 or 6 lb. of red Clover, and 4 or 5 lb. of white Dutch, if the land requires it; but some portion of Mr. M'Combie's occupation grows white Clover naturally. Upon the poorer soils an addition is made, consisting of 4 or 5 lb. of Alsike, but this is omitted on the better land, as the cattle are not fond of it. Occasionally a few acres of Italian Rye-grass are sown for early cutting; but red Clover is the "seed" which is considered the great stronghold of the cattle-feeder. The quantity of hay made is only just enough for the horses, and never exceeds 30 acres. So great is Mr. M'Combie's dislike to cutting hay, that he frequently prefers to buy hay, especially as he considers pasturing by cattle equal to a year's rest.

STOCK.

1. *Herd.*—The breeding stock consists of about 80 head of the black-polled Angus breed, including one old bull, two yearling bulls, and 30 cows, the remainder being 1 and 2-year-old heifers. The bull calves are generally sold privately, and there is also a sale of breeding stock every second or third year. Cows are put to at any season; but is preferred that the calves should drop early in spring, when they are allowed to suck their dams until October. The treatment of cows during winter, previous to calving, is based on the principle of keeping them as low as possible. They run over the grass that has been left by the feeding beasts, and are never taken under cover until the end of October, when they go in at night; but they get no food except that afforded by the fields until after Martinmas, or even the end of November. About this time, or the beginning of December, the most forward of the feeding beasts go out, and the breeding cows take their places in the stalls; but their food is still kept down, consisting merely of straw, and once a day a barrowful of Turnips divided between three or four of them; and, except in very bad weather, they still go out two or three hours every day. The only difficulty is to keep the breeding stock from becoming too fat.

After calving, the feeding regulations are very much relaxed in favour of Turnips, so that the cows may give enough milk for their calves, which remain with their mothers for several months. The older calves are weaned about the end of October, no matter how early they drop; and the late calves remain with their dams throughout the winter. The latter lie behind their mothers at night; during the day they get the run of the steading, and sometimes are given a turn in the park; they also get from 1 to 2 lb. of oilcake daily, with a little meal, the trough being placed in the stall behind the dam. By this method Mr. M'Combie has made some of his best beasts from late calves; it enables them always to retain a good coat, and to withstand the cold and ungenial climate in spring.

When the older calves are weaned, they are put into a strawyard, and given as much as they can eat of straw and sliced Turnips, with from 1½ to 2 lb. of oilcake each per day. After the first winter, and when the young breeding stock are rising two and three years old, they are kept upon Turnips and straw, without any allowance of cake. The calves are all carefully setoned, a good hold of the dewlap being considered necessary, as well as the renewal of any seton that may slip. These measures have been so effectual that not more than one case of blackleg has occurred amongst the high-bred stock at Tillyfour. Weaning time, however, is not quite so simple a matter for the cows, as some will not allow themselves to be milked. In these cases, the practice is to let their calves suckle once a day at first, then once in two or three days, and thus, in the course of a fortnight, the cow gradually becomes dry. When these milk-producing glands are taken, the cow may lose two or three of her teats, and be ever afterwards useless as a milker. The younger calves are treated in precisely the same manner.

The calves are kept regularly growing on until the earliest grass is ready for them, after which time it is considered that there is little or no further risk from quarter-ill or other diseases incidental to young stock.

The after treatment of heifer calves is a matter which requires sound judgment; and if the allurements of shows are avoided, Mr. M'Combie finds it comparatively easy to get breeding animals that will pay, and will exhibit very fine quality. The system he has adopted, except in cases of show pets, is to give them good grass during the summer, and during the ensuing winter to keep them on unlimited oat-straw and a fair supply of Turnips. It is essential to keep them in good growing condition until 2½ or 3 years, but at the same time to guard against their laying on too much flesh. Open strawyards, in the winter, are thought best both for young breeding cattle and for store beasts to be grassed the next summer; and a covered yard is therefore regarded as an abomination. The principle of treatment of store or breeding animals is to avoid making the high-bred heifers valuable to the butcher; and as it is well known that they have a great tendency to lay on fat if well fed, it behoves the farmer to work accordingly, for servants in charge of high-bred stock seem to take a pride in over-feeding them. Heifers are not put to the bull until fully two years old, as the polled Angus females become stunted in growth and otherwise deteriorated if used before they arrive at that age. In-and-in breeding is also found to produce a diminution in size and delicacy of constitution, though it undoubtedly produces fineness of quality, as Mr. M'Combie has shown in his work already quoted.

2. *Feeding Beasts.*—Between 300 and 400 head of cattle are fed off between October and March, the number varying with the weight of the Turnip crop and the quantity of straw and seeds hay. About 9 of these beasts are bred and wintered on these farms, and the remainder are bought in Morayshire in March and April, arriving at all times up to the beginning of May. After arrival they are kept on the remnant of the Swede crop, or, in default of that, on hay and cake, in sufficient quantity to keep them growing. Their cake, until the grass is ready. This is not until from the 10th to the 15th of the month, although a certain breadth of first-year's seeds on each farm is top-dressed with from 2 to 3 cwt. per acre of sulphate of ammonia, dissolved bones, or guano, for the purpose of providing early bite for the best beasts. From about May 1 until May 20, the cattle begin to go on ordinary first-year's seeds, where they remain for two or three weeks, when they are removed for a change of bite to a piece of two-year-old seeds, or an old pasture. It is considered a valuable part of good grazing to give beasts a clean pasture and fresh grass at frequent intervals, say once a fortnight at farthest. In July seeds begin to fail, and without the assistance of old and late grass it would be almost impossible to carry on the stock in a thriving condition. No cattle are sold off grass, as Mr. M'Combie's experience shows that beasts do not pay unless they get at least two months' Turnip feeding. The interval between the failure of the seeds and the maturing of the early Turnips is therefore a critical period; and there can be little doubt that Mr. M'Combie's success as a grazier is, to a great extent, due to the manner in which he has kept his cattle supplied with nutritious food at this time of the year.

Part of the cattle are sent to the old pastures in the middle or end of July, and by the middle of August one of the best part of the strawyards, and receive Clover, Tares, &c.; thus reducing the numbers on the pastures, and giving more chance to those that remain, by reserving the second bite of the early-fed first-year's seeds until that time. As the seeds contain plenty of red Clover, they form a most valuable food, and enable cattle to be kept on in thriving condition until the Turnips are ready.

The forward bullocks are tied up very early; and, at the time of my first visit to Tillyfour (August 30), no less than 125 beasts were under cover. Sixty of these were 3-year-old bullocks, in strawyards getting food consisting of Tares (three-fourths ripe), and Clover, mixed with Oats, white Peas, and Beans, and 3 lb. of linseed cake each per diem. In about a week's time they would be entirely on Turnips and cake with straw. They were in good condition when bought from the Moraysbire strawyards, and they had got some of the finest Swedes grown in Scotland, and they had been kept during the summer on capital grass in Aberdeenshire, so that they were in high condition when turned in. By giving them as many Turnips as they could eat, it was expected to turn most of them off quite "ripe," without any addition to their allowance of cake, by the first or second week in October.

The remaining 65—the largest and best of Mr. M'Combie's feeding stock—were intended for the Islington Christmas market, Liverpool, and Edinburgh. At the end of August they were feeding on yellow Turnips, remarkably well matured for so early a period in the season—and such a season!—with a proportion of partially ripened Tares, but without cake or corn. Cake is never given to "commercial beasts" until within six weeks of the date when they are destined for market, when they get from 2 to 4 lb. per day to give them the "last dip" when necessary A great many of the beasts sent to London by Mr. M'Combie never taste cake or corn, but only those pushed early to market, and the sluggish feeders amongst the lot that come afterwards. Indeed, some of those sent to the Christmas market are not even frequently considered too fat by certain butchers. Many of the best of these beasts had been bred by Mr. M'Combie himself, and in April were worth, he considered, from £28 to £30 each. The remainder had been bought in the autumn of last and in the spring, and had cost from £25 all the way up to £32 per head.

All these cattle had been selected as better adapted for the earlier than the later markets; but we now come to the description of those which take the places of the 125 whose treatment has just been sketched, and which, in the fields, have cost from £20 to £24 each in the spring, and would be all tied up immediately after the first 60 had been disposed of, getting Turnips and straw as the others. They would go off gradually during the months of January, February, and March. The stalls vacated by the Christmas beasts are filled up by half-fed beasts, bought in the neighbourhood, and either finished for the London market the same spring or kept on for the grass, and sold the following autumn or winter. For the latter purpose a bullock that has not been too well kept, especially if from the high grounds, well-bred, and not stunted in growth, will pay for its keep far better than one that has been kept on the higher priced lands in the valleys.

3. *Sheep.*—From 400 to 800 three-shear blackfaced wedders from Deeside are bought at Braemar or on the hills, about the beginning of September, and put on the grass left by the feeding cattle until Martinmas. They then get Turnips for a couple of months, and go to the Edinburgh and Glasgow markets. Occasionally they get a little corn or cake, but they seldom require it, as they thrive very fast on the lowland pasture after coming off the hills. An average sheep will weigh about 17 lb. per quarter, but some are much heavier. It does not answer to buy lambs, as they get braxey and die very fast; but aged sheep stand the change very well. The profit on one lot of 400 sheep paid Mr. M'Combie's election expenses; but it does not appear whether the profits were very large or the expenses very small.

4. *Horses.*—A somewhat light but active breed of carthorse is preferred; and as so large a proportion of the arable land is in seed, it is not found necessary to have more than ten pair in addition to the needs of working oxen. The horses are turned entirely into the fields after Turnip sowing is finished, and until the commencement of leading at harvest time. When taken in, they are given as much hay as they can eat, and are allowed a bush. of Oats each per week. Every night they get a mash divided into two portions, one being given before the dry food and the other in the course of an hour or two; it consists of light Oats or Bere, mixed with cut Swedes, and boiled together. About a bucketful is given to each horse every night, and in the spring a good feed of Swedes is also given in the forenoon.

LABOUR.

Married servants are engaged by the year, at Whitsuntide, for from £20 to £22 per annum with house and fuel, and unmarried servants are engaged for six months at Whitsuntide and Martinmas, getting from £10 to £11 10s. for the term, with the usual allowances. The "allowances" are 2 pecks of oatmeal per week, as many Potatos as they can eat, and either milk or 2½d. per week in lieu of it. The unmarried men get their food cooked for them in the "bothy," as already described. The bailiff, or "grieve," as he is termed, is allowed to keep a cow,

and sometimes a pony. Unmarried women are not employed, as a rule; but for hoeing Turnips and at harvest time they are in great request. *Journal of the Royal Agricultural Society of England Paper on Scottish Agriculture, by Mr. H. M. Jenkins.*

The Week's Work.

JULY 22.—*Winter Peas* are generally harvested by the close of the month in our southern provinces. The crop is commonly cut with a long-handled bagging-hook, and left in loose parcels on the stubble when grown broadcast, and across the stetches when thus grown. Harvest operations in the field are simple in dry weather, all that is necessary being once turning or so, to prevent the haulm roasting and the pods opening. In wet weather, however, it is otherwise. The crop soaked with rain, the crop is difficult to dry in the field, and liable to mould in the stackyard. Pea stacks are bad defenders of rain, and, therefore, whether stacked in a good condition or a bad, they should be thatched immediately they are built, or be covered with the rick-cloth until they can be thatched. Some thatch to the eaves, others down to the bottom, purposely to protect both roof and sides from harm. The sides may be covered with webs of machine-wove straw, made fast with pegs in the same way as the ridge-gables and eaves are secured.

Scotch Harvest.—Rye-grass, when left to ripen its seeds, is generally harvested during this month. In Scotland, where from a fourth to an eighth of the farm is annually sown with Rye-grass and Clover, most farmers grow their own Rye-grass seed; Clover seed cannot be profitably grown in the North, consequently seed is obtained either from the South of England, the Continent of Europe, or America. Like Wheat, Rye-grass is cut before it is dead-ripe, and it is better to cut rather green than otherwise, to avoid losing the best seed in the harvesting. The crop is usually bound in sheaves, and stacked as Wheat is stacked in Aud Cants. It requires to be thoroughly dry before carrying, as it is very liable to heat in the stack, and thus destroy the vitality of the seed. To avoid heating some farmers allow the grass to lie in the swathe until the hay is fit for the trampcock, and trampcock in difficult weather; they then thresh and spread the seed thinly over the granary, turning it frequently until thoroughly dry. Others thresh out what seed they require during the general operation of haymaking, the hay from the temporary threshing floor in the field being built into cocks of a size depending on the weather. But this practice cannot be commended, for the grass must either be too ripe before it is cut, or else there is much inferior seed in the sample. There are besides two objections to threshing in the harvest field and storing the seed in the granary, for broken straw does not keep well in the stack, and the seed is liable to injury in the granary. The best plan is to stook and stack and then thresh, when the seed and hay can both be used fresh. Some lands produce finer seed than others, and therefore it is common for the occupiers of such to grow for market, and for those farmers whose seed degenerates to get their supplies from this source. Again, farmers who allow their land to lie two years in grass, take their seed from the second crop, purposely to avoid annual seed degeneracy.

Flax intended for the finest muslin and cambric fabrics, requires to be pulled earlier than that for the coarser description of linen, or for rippling seed. There may be a week to fourteen days difference, according to the weather. This year, much of the flax crop in Ireland is said to have ripened heavily from the cold, dry, east winds, so that it will be no easy matter to determine whether the crop is best suited for coarse or fine linen, especially when not very equally grown. A considerable diversity in the primary and secondary processes of preparing Flax fibre for the market, has recently been introduced; but the old familiar plan of pulling, steeping, and dew-retting on the grass, continues to be the common practice. When the crop is fit for yielding the finest quality of fibre, it is pulled when it comes into flower, or shortly after, as the peculiarities of the crop may direct. In pulling, the operator stands with his or her right or left side to the standing Flax, going backwards, and with both hands firmly laying hold of small parcels of the standing Flax at a time, so as not to raise earth and injure the fibre as he gets a handful; he lays it down, so that the next handful or two can be laid across; the object of laying the Flax crosswise being to keep it as much as possible off the ground. In this position it is allowed to lie until fit for being tied up in small sheaves for the steep, with a band made of a few stems of the Flax. As the sheaves are tied, they are carted to, and placed upright in the steep, and loaded with wood and stones to keep them under water. A slow fermentation sets in, depending for degree and force upon the temperature of the water and the atmosphere; and when sufficiently far advanced to allow the fibre to separate freely from the stem when broken—which in warm weather will be in about a week's time; and in cold weather from ten to fourteen days—the Flax is ready for the next process, dew-retting, which is done by spreading the steeped Flax evenly over a grass field, previously mown, so as to have an even surface. Spreading Flax is a very dirty but nice operation, and we have always found women better spreaders than men. In spreading the spreader goes backwards, shaking out gently with both hands sheaf after sheaf, thinly, evenly, and equally over the points of the fingers. Like all similar manipulations in art, it must be learned by an apprenticeship, and not bookrule. When sufficiently dew-retted, the fibre separates freely from the stem by rubbing. The retted Flax is next tied up in large sheaves or bundles and stacked, where it remains until sent to the flax-mill Stacking Flax is a work *per se*. In the first course the sheaves are placed vertically on their butts, slanting over these the next course is laid horizontally, projecting about a foot over the vertical course. The body of a large stack rises perpendicularly, but smaller ones are of a pear-shaped form from the base course, and this is the finish of both large and small, so that a few handfuls of straw at the top secures the stack from rain. When straw is not to be had, a sheaf or two of Flax is used as thatch, and here we may observe that Flax forms excellent thatch for houses, and is frequently grown for this express purpose. When the seed is to be used for sowing or crushing, or when the bolls are to be given to cattle, the Flax is allowed to become more ripe before it is pulled, but the stage of ripeness is just about as diversified as the opinions of growers. For seed and bolls it is common amongst the larger farmers of Ireland to ripple into the body of a cart, one person supplying two or three ripplers with handfuls of Flax as pulled, another binding up the rippled handfuls for steeping. The work of steeping, spreading, and dew-retting are as above described.

Sheep Shearing in the highlands of Scotland, north of England, and Wales, will this year be attended with greater risk from frosty nights than usual, and on that account the shearing may be later. Some shepherds put their newly-shorn sheep through the pool, in order to prevent catching cold. *W. B.*

Markets.

ENGLISH WOOL.

During the last week Wool has continued in good demand, at hardening rates. Many classes of foreign Wool are as dear or dearer than during the American war, though English grades are still below these values, and must, we consider, still advance considerably between this and Christmas; so that our advice to farmers would be to hold out for advanced rates.

HOPS.

BOROUGH MARKET, July 20.

Messrs. Pattenden & Smith report that the accounts from the plantations are still very unfavourable, and although the bine has made considerable progress during the last week, still vermin follows up, and there are reports of fresh fly this morning. The market is very firm, though not active, but for choice samples there are always buyers at full rates.

METROPOLITAN CATTLE MARKET.

MONDAY, July 17.

We have a larger supply of Beasts to-day, and the weather unfavourable for slaughtering largely; consequently trade is dull, and prices rather lower. The number of English Sheep is unusually small, of good about the same as lately. Trade is, however, slow, the demand is smaller than of late, and prices on the average are not higher. Choice Lambs and Calves find purchasers, at about late rates, but inferior are lower. Our foreign supply consists of 1370 Beasts, 10,900 Sheep, 550 Calves, and 50 Pigs; from Scotland there are 12 Beasts; from Ireland, 240; from Norfolk and Suffolk, 500; and 1470 from the Midland and Home Counties.

Beasts, 3600; Sheep and Lambs, 21,930; Calves, 574; Pigs, 100.

THURSDAY, July 20.

We have a fair supply, both of foreign and English Beasts; trade is not brisk, but Monday's quotations are well maintained. The number of Sheep is smaller than last Thursday; trade is active, and a good clearance is effected, at an advance on Monday's quotations. Choice Lambs are in demand, and rather dearer. There is a large supply of Calves; prices are rather lower. Our foreign supply consists of 400 Beasts, 4500 Sheep, and 824 Calves.

MARK LANE.

MONDAY, July 17.

There were very few samples of English Wheat at this morning's market; millers were not anxious buyers, and the sales made were at a decline of 1s. to 2s. per qr. upon the prices of this day week. The attendance was good, but the business done in foreign was in retail, at a similar reduction. Barley and Peas were unchanged in value. Beans 1s. per qr. cheaper. The Oat trade was steady; Russian and inferior qualities 3d. to 6d. per qr. lower. Flour was 6d. per barrel and 1s. per sack cheaper.

WEDNESDAY, July 19.

The Corn Exchange was thinly attended by millers; the business doing was very limited, at prices favouring buyers. The supply of English Wheat was short, but of foreign the arrivals were on a liberal scale; sales were effected slowly, at about the reduced rates current on Monday last. Barley, Beans, and Peas were purchased cautiously, at prices tending downwards. Oats were in good supply. The demand was inactive, and prices were exceedingly weak. The Flour trade ruled dull, at declining prices.

LIVERPOOL, July 18.—There was only a moderate consumptive business done in Wheat, at a decline of 1d. on white, and 1d. to 2d. per cental on red from last Tuesday's prices. Flour was exceedingly dull, and nominally cheaper. Beans 6d. per qr. cheaper. Peas unchanged. No sound Barley in the market. Oats and Oatmeal at previous rates. Indian Corn at last Friday's improvement, and must be quoted 3d. per qr. under last Tuesday's rates; a fair business was done.

SEED MARKET.

The weather is now more settled, and consequently favourable for harvesting seeds. New Essex Dwarf Rape seed is now at market, and offering at a very considerate reduction from the price of old, and is of good quality and condition. The same remarks may be applied to new Trifolium, which is offering in large quantities, and it is expected that prices will go still lower. Mustard is in fair demand, and rather cheaper. Hemp and Canary quiet, at late rates. Linseed rather little offering.

THE ALEXANDRA PALACE AND MUSWELL HILL ESTATE TONTINE.

(TO TERMINATE ON THE 30th JUNE, 1886.)

This being a "TRUST," Subscribers incur no Liability.

Certificates representing 850,000 Guineas (of which 1*l.* of each Guinea is to be appropriated to Insurance of Subscribers), will be issued at the following Rates:—

A (or Single Right) Certificates	.. ..	each £1 1 0	**D (or 50 Right) Certificates**	.. ..	each £52 10 0
B (or 10 Right)	,, ..	,, 10 10 0	**E (or 100 Right)**	,, ..	,, 105 0 0
C (or 25 Right)	,, ..	,, 26 5 0	**Payable on application.**		

CERTIFICATES PASS TO AND ENTITLE THE BEARER:—

1. To participation in the proceeds of sale of the property if the representative life upon which the Tontine privilege depends shall be living on the 30th June, 1886.
2. To the receipt from a life assurance of the sum of 20*s.* in respect of each Guinea paid upon any Certificate, if the representative life shall die before the said 30th June, 1886.
3. To admissions to the Palace and Park.
4. To participation in Art Union Distributions proposed to be hereafter established.

(As explained in detail in the body of the Prospectus.)

The acceptance of a Certificate involves no liability. The rights and privileges of Certificate holders are governed by the Trust Deed.

The whole nett Income of the undertaking, after defraying interest charges and management expenses, will be devoted to the improvement of the Property, and also (when power is obtained) to Art Union Distributions.

PROSPECTUS.

An advantageous Contract has been concluded for the purchase, free from incumbrance, of the Alexandra Palace Park and Lands adjoining, situate at Muswell Hill, Hornsey, in the county of Middlesex (comprising about 400 acres of Freehold and 200 acres of Leasehold Land), and the contents of the Palace, for the sum of £675,000. Of this amount £450,000 may remain on security of the Property for 5 years, represented by Mortgage and Debentures. Power is taken to raise further capital not exceeding £150,000, if deemed desirable, for the improvement or enlargement of the property and for the benefit of the Tontine.

The object of the Tontine is to complete the purchase and improve the property, and thus to provide for all classes of the inhabitants of the Metropolis, and especially of its northern and eastern portions and suburbs, and for the many thousands of country excursionists, a Grand Institution of healthful recreation and elevating instruction, which will combine the social advantages of the Crystal Palace, Kensington and Schools of Art, with the lighter pleasures and pastimes of the Crystal Palace at Sydenham, thus giving effect to the large and enlightened views of the late Prince Consort.

In furtherance of this design it is proposed to inaugurate a series of Exhibitions, Art Unions, and distributions, by the Executive, which, and as soon as the necessary power can be obtained for the purpose, it is proposed that the whole portion of the profits of the Palace and Palace, after making proper provision for management, improvement, and other charges, should be applied.

Under "The Muswell Hill Estate and Railway Act 1866" the Palace and about 200 acres (which then constituted the Grounds) are to continue a place for public resort and recreation, subject to the observance of such rules and regulations as may be prescribed by the owners, and to the payment of such reasonable sums as may be fixed for admission to the Grounds and Palace or to any exhibition or sights therein.

It is now intended to enlarge the Park, and to lay out the whole of the lands as pleasure grounds, with the exception of about 80 acres of beautiful freehold land on the borders, which will be reserved for building purposes, so that there will be a Park surrounding the Palace, and within it ring fence, of about 400 acres in extent. But power is taken with the consent of the Trustees to sell or lease for building purposes any part of this land and subject to the provisions of the Act of 1866, should such a course appear desirable in the interest of the Tontine or of subscribers.

The Palace is a splendid, capacious, and substantial structure, requiring but a comparatively small outlay to keep it in repair, admirably adapted for Exhibitions, Museums, and Lectures, and for Musical Festivals and Concerts, as well as for festive and social gatherings of the greatest magnitude.

A grand organ, which is reputed to be one of the largest and most perfect in the world, has been erected in the Palace by Mr. Willis, under the direction of Sir Michael Costa.

Archery, Cricket, and Croquet Lawns, Turfed Rides, a Race Course with Grand Stand, well leveled Carriage Drives, Groves and Gardens, will be found in the Park, which is nobly timbered, and commands extensive and magnificent views into several counties. This Institution, therefore, which can be opened to the public in every shape at any of time, will combine the advantages afforded by museums, exhibitions, and schools of art, with scenery of the amenity and beauty and air, thus contributing alike to the instruction, amusement, and health of the visitor.

There will be easy access to the Palace by railway communications in connection with the Great Northern and Metropolitan Lines, and a Bill in aid thereof, the Royal Assent for authority to construct which of a short line to connect the Park with the Midland and Great Eastern systems, is now before Parliament, and will pass this Session, and these enterprises, which are of great importance to the success of this undertaking.

The Exhibitions and Art Union Distributions will constitute a distinctive feature of the general plan, and will contribute to the popularistic of the Fine Arts. An Inaugural Exhibition will be held as soon as the requisite powers are obtained.

It is intended to apply to Parliament for power to devote part or the whole of the surplus income to Art Union Distributions, to be held every third year during the term of the Tontine, and to increase the number or chance in each Distribution to every Certificate in respect of every 21*s.* paid thereon. It is estimated that each such distribution will amount triennially to £100,000, and the prizes will range from £500 to £2.

The following Table indicates what any Certificate holder may derive from the Tontine:—

ANALYSIS OF THE PROBABLE ART UNION PRIZES AT EACH OF SAY FIVE TRIENNIAL EXHIBITIONS.

The value represented by the Prize Tickets is to be applied wholly in the selection of articles connected with the Alexander Art Union Exhibitions, and it will be seen that it is possible for the holder of a single right Certificate to receive Five Prizes of £500 each for his investment of £1.

The Certificates will be issued under the powers of the Trust-Deed, which will define and regulate the rights and privileges of the Certificate Holders, and a covenant will be contained therein on their part to observe the provisions of the Deed.

The whole of the nett income of the Tontine during its existence will be applied as above explained, to the improvement of the property and to Art Union Distributions.

An established Insurance Company has agreed, in consideration of the payment to them of a premium of one shilling for every A (or single right) Certificate, and so on in proportion for any plural rights certificate (*i.e.* one shilling for each right), to pay to the holder £1 for each guinea paid on such Certificate upon the death of the representative life in respect of which the Tontine privileges depend, if such death happens before the 30th June, 1886, provided such Certificate shall not have been previously surrendered, or the bearer of such Certificate for the time being shall not have drawn a prize in an Art Union Distribution in respect of the right representing such guinea. Such premium will be paid out of the Tontine funds. The agreement is subject to 20,000 representative lives being nominated.

For the purposes of the Insurance and Tontine, every applicant for a Certificate will be required, pursuant to the Deed, to nominate (which may be his own), between the ages of 10 and 30 years; such lives should not be those of persons in delicate health, but, if possible, of members of the applicant's family, or friends. Applicants may nominate a life for each right the certificate they apply for represents. If the applicant chooses to waive the insurance he may nominate any life.

To meet the case of any selected life having been previously nominated and insured to the amount of £500, an applicant may be required to furnish some other life or lives in substitution for that first nominated.

Upon the 30th June, 1886, the Tontine will absolutely cease; and as soon as may be after that date the whole property will be realised, and the nett proceeds will be distributed amongst the Certificate holders in existence.

The holder of an A, or single right Certificate, in addition to his right to participate in the selection of prizes, will be entitled to one admission on two days (not being fête days), to be fixed by the Committee, for himself and two others, either on foot, horseback, or in single horse carriage.

The holder of an E, or 100 right Certificate, will be entitled to free admission for himself and four other persons at all times, either on foot, horseback, or with any carriage.

The Tontine rights and privileges attaching to certain Certificates may, at the option of the holder, be surrendered for the right of admission on other days, according to a plan or scale to be published by the Executive Committee. The surrender will involve the loss of every right and privilege offered in this Prospectus to the holders of Certificates, except so far as the same are reserved as part of the consideration for the surrender.

The holder of a Certificate which shall not have been surrendered, will be entitled to participate in the proceeds of the property, at the end of the Tontine, in respect of every right depending on a representative life not surviving on the 30th June, 1886.

Thus every subscriber of 21*s.* and upwards to the Tontine, or the holder for the time being of a Certificate (the same not having been previously surrendered) will, in addition to the privileges of entry to the Park and Palace as above enumerated, obtain the repayment, in case of the death of the representative life or lives, of 20*s.* in respect of every 21*s.* paid thereon, for which the representative life shall be then in existence, the right to a share in the proceeds of the Tontine property. Looking at the rapidly increasing value of Building Land near London there can be no doubt that at the expiration of the Tontine, in 15 years, the property to be then distributed amongst the holders of Certificates entitled to participate will be of enormous value.

For the convenience of management of the Tontine and property, and with that object only, a Company (limited by guarantee), has been incorporated under the Act of "The Alexandra Palace and Muswell Hill Estate Management Company Limited." The Executive Committee of the Tontine are the Directors of that Company. The certificate holders will not be members or contributories of such Company.

All the landed property to be acquired for the purposes of the Tontine will be vested in the Trustees upon trust, to permit the Management Company to manage the same, and with the consent of the Trustees, so far as required by the Trust Deed, to grant leases, and deal therewith for the benefit of the general undertaking, and raise further capital, not exceeding £250,000, if required, for the undertaking by mortgage or debentures (in addition to the working [ap tal provided by the Tontine), and upon the termination of the Tontine by the 30th of June, 1886, or so soon thereafter as may be necessary, to Sell the Tontine property and distribute the proceeds.

By the terms of the Trust Deed all questions (if any) which may arise relating to the Tontine, during its existence or on its termination, must be referred to such counsel as the Attorney-General for the time being may appoint.

The Purchase Contract, the Trust Deed, the Insurance Contract, and the Memorandum and Articles of Association of the Management Company may be perused at the offices of the Solicitors.

If no Lease is made the subscription will be returned in full.

The following documents have been executed:—

(1). An Agreement, dated 31st July, 1871, between the Muswell Hill Estate Company Limited and the Alexandra Palace Company Limited of the one part, and the Alexandra Palace and Muswell Hill Estate Management Company Limited of the other part.

(2). A Deed of Trust, dated 19th July, 1871, between the Alexandra Palace and Muswell Hill Estate Management Company Limited of the one part, and Henry Markby of the other part.

(3). A Deed of Covenant, dated 19th July, 1871, between the London and Lancashire Insurance Company of the one part, and the Alexandra Palace and Muswell Hill Estate Management Company Limited of the other part.

Prospectuses (with an outline sketch of the Palace) and Forms of Application for Certificates may be obtained of the Secretary at the Offices of the Tontine and of the Brokers.

Applications for Certificates must be left with the Bankers at the time of payment of the deposit; and no application will be noticed unless the sum of 20*s.*, in respect of each single right, or the amounts specified for plural rights applied for as above stated, shall have been paid.

THE ALEXANDRA PALACE AND MUSWELL HILL ESTATE TONTINE.

FORM OF APPLICATION FOR A OR SINGLE RIGHT CERTIFICATE.

To be left with the Bankers or authorised Agents.

TO THE EXECUTIVE COMMITTEE.

GENTLEMEN,—Having paid the sum of 21*s.* to the Bankers or authorised Agents, I desire to have issued to me a Single Right Certificate in the Alexandra Palace and Muswell Hill Estate Tontine; and I hereby agree to accept the same upon the terms of the Prospectus and of the Trust Deed of July 19, 1871.

Upon hearing that you are prepared to issue the Certificate, I agree to nominate a representative life of the age stated in the Prospectus, upon which I desire the Tontine privilege in respect of such Certificate to depend.

Special Offer at Low Prices.

ORCHIDS.—Broughtonia sanguinea, 5s.; Cattleya Dowiana, 10s. 6d.; Dendrobium nobile var. Cooksonianum grandiflora, 10s. 6d.; Epidendrum dichromum, 5s.; Vanda gigantea, 5s.; Oncidium barbatum, 5s.; Dendrobium japonicum, 5s.; Dendrobium macrophyllum, 7s. 6d.; Vanda Batemanni, 31s. 6d.; Epidendrum scutigerum, 7s. 6d.; Cattleya Aclandiæ, 12s. 6d.; Oncidium Kramerianum, 15s.; Eulophia lurida, 5s.; Eulophia scripta, 10s. 6d.; Odontoglossum phalænopsis, 15s.; Oncidium Roezlianum, 21s.; Oncidium panchyrium, 31s. 6d.; Oncidium tripartitum, 7s. 6d.; Cypripedium Rensonize, 21s.; Saccolabium Blumei majus, 15s.; Aerides Lindleyanum, 21s.; Calanthe vestita lutea-oculata, 5s.; Calanthe vestita rubro-ocellata, 5s.; Aerides crispum, 10s. 6d.; Brassia verrucosa major, 10s. 6d.; Ionopsis utricularioides, 10s. 6d.; Cypripedium Sedeni Leopoldi, 10s. 6d.; Cypripedium barbatum, 3s. 6d.; Dendrobium Dayanum, 10s. 6d.; Dendrobium speciosum, 5s.; Dendrobium Devonianum, 15s.; Epidendrum erubescens, 10s. 6d.; Angræcum falcatum, 5s.; Lælia autumnalis, 10s. 6d.; Lælia purpurata, 10s. 6d.; Lycaste Skinneri, 5s. 3; Lycaste lanipes, 10s. 6d.; Lycaste Deppei, 7s. 6d.; Miltonia Moreliana, 15s.; Odontoglossum Bictoneuse, 7s. 6d.; Odontoglossum citrosmum, 10s. 6d.; Odontoglossum pulchellum, 10s. 6d.; Odontoglossum nebulosum, 15s.; Saccolabium curvifolium, 21s.; Trichopilia suavis, 5s.; Cypripedium barbatum bellorum, 21s.; Brassavola cuculata, 7s. 6d.; Vanda Roxburghii, 21s.; Vanda Roxburghii cærulea, 31s.; Cypripedium insigne, 21s.; Cypripedium grandiflora, 63s.; Aerides Warneri, 21s.; Cypripedium Stonei, 15s.; Oncidium marginatum, 7s. 6d.; Dendrobium densiflorum, 15s.; Dendrobium primulinum, 15s.; Phalænopsis Schilleriana, 84s.; Phalænopsis amabilis, 84s.; Odontoglossum grande, 5s.; Godyera Dawsoniana, 5s. 6d.; and numerous other Orchids at equally low prices. Selections of 12 Orchids made for £3. Many extremely rare species, almost unique, at equally low prices. Apply at

MR. WILLIAM BULL'S Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

"PHYTOSMEGMA," or PLANT CLEANSER, destroys Scale, Mealy Bug, Red Spider, &c., without injury to Plants; 6d. and 1s. per box.
The NEW SHOWERER, for applying the above, 6d., 1s. and 3s. 6d. each.
Wholesale of T. A. POOLEY, Sussex Wharf, Wappiog, E.; and Retail of all Nurserymen, Seedsmen, and Florists.

TOBACCO TISSUE, for FUMIGATING GREENHOUSES.—Will destroy all the Insects, and not injure the Plants, and burns without the assistance of lighted Paper. 6d. per Packet; carriage free on receipt of stamps. Liberal terms for large quantities.

To be had of Messrs. R. ROBERTS AND SONS, 112, St. John Street, Clerkenwell, London, E.C.; and of all Seedsmen and Nurserymen.

Blight.

GARDENERS TROUBLED WITH THE ABOVE, WOULD DO WELL TO TRY "WILKIE'S BLIGHT COMPOSITION" for their DESTRUCTION. It offers a safe and speedy remedy, and at a moderate price. Taken in quantities, A.W. would be happy to make a considerable reduction. Sold in 1 and 2-gallon jars at 5s. 6d. and 6s. each. It is beside being considerably diluted. Post Office orders from unknown Correspondents.

WILKIE'S CONDENSED COMPOSITION, in bottles at 2s., 3s. 6d., and 6s. each.

The above articles may be had through all the principal Nurserymen and Seedsmen, and wholesale of

A. WILKIE, Oak Lodge Gardens, Addison Road, Kensington, W.

FREEMAN'S LIQUID COMPOUND, for the DESTRUCTION of INSECTS of all kinds, and MILDEW. INFESTING PLANTS, has been proved to be the most effectual application for destroying Aphis of all kinds, Scale, Thrip, Mealy Bug, American Blight, Green and Brown Fly, Red Spider, Wasps, Ants, &c., hitherto offered to the Public. It will be found invaluable for Vines, Peaches, and Fruit Trees of all kinds, as in most cases one dressing will keep off the ravages of Insects for a whole season.

The Liquid Compound will not injure the most tender foliage of Stove or Greenhouse Plants; and, if mixed occasionally with the water ordinarily used for syringing, will, if applied before the formation of any insects, prove a certain preventive. Broccoli and other Greens may be thoroughly cleansed from insects and vermin of all kinds by sponging, or using the Liquid Compound by means of the "Horticultural Vaporiser."

We select two voluntary Testimonials from a great number we have recently received:—

"Elvaston Nurseries, Borrowash, June 26, 1871.

"DEAR SIR,—We beg to bear testimony to the efficacy of your Liquid Compound, which we have used in our Nursery, both out-of-doors and under glass, with perfect success. We consider it the best preparation we have tried. It thoroughly destroys the insects without injuring the foliage.—We remain, dear Sir, yours faithfully,

"W. H. & J. LAING.

"Upton Nurseries, Chester, July 11, 1871.

"DEAR SIR,—We have much pleasure in giving you a testimonial of your Liquid Compound for destroying insect life. We have tried it upon most of the pests which prey upon vegetable life, and find it very effective in cleansing all kinds of plants from scale, mealy bug, aphis, and thrip. Specially in fact all kinds of insect life seem to succumb to its power most effectually. Fly, and that without any injurious effect upon the plants, as far as we can observe. We consider the Compound most valuable to all gardeners.

"FRANCIS & ARTHUR DICKSON & SONS."

Voluntary Testimonials have also been received from the following:—R. G. Rackstraw, Esq., The Ash Hall.
Mr. G. Weatley, Gr. to Lord Dudley, Witley Court.
Mr. Wm. Jackson, Gr. to Lord Scarsdale, Keddleston Hall.
Mr. H. Gadd, Gr. to Lord Middleton, Wollaton Hall.
Mr. Speed, Gr. to the Duke of Devonshire, Chiswick.
Mr. Wm. Parker, Gr. to the Misses Strutt, Derwent Bank, Derby.
Mr. F. Harrison, Gr. to F. Wright, Esq., Osmaston Manor, Ashbourn.
Mr. W. S. Milford, Gr. to T. W. Evans, Esq., M.P., Allestree Hall.
W. P. Evans, C.M.R.S., Consulting Horticultural Gardener, Nottingham.
Mr. W. Thompson, Gr. to Sir Seymour Blane, Bart.
Thos. Crump, Esq., Quarndon, near Derby.
Richard Wright, Esq., The Hayes, Swanwick.
Mr. James Teyle, Gr. to the Duke of Newcastle, Clumber Gardens.
Messrs. G. & W. Yates, Market Place, Manchester.
Mr. H. Ellis, The Gardens, Alfreton Park.
Messrs. Cole & Son, Manchester.

PRICE LIST.—One gallon bottles, 5s. 6d.; half-gallon bottles, 3s.; pints, 1s. 6d., bottles included. In Casks:—10 or 12 gallons, 4s. 6d. per gallon; 30 gallons and upwards, 4s. per gallon, casks returnable. Carriage paid on all orders to the amount of 20s. and upwards.

May be obtained of the principal Seedsmen and Nurserymen throughout the country.

Manufacturers, PARR AND ATHERTON, Long Row, Nottingham.

THE LONDON MANURE COMPANY (Established 1840), have now ready for delivery, in fine dry condition—
PURE DISSOLVED BONES.
CONCENTRATED AMMONIACAL MANURE, for Top-Dressing.
PURSER'S BONE TURNIP MANURE.
SUPERPHOSPHATE OF LIME.
NITROPHOSPHATE.
MANGEL, HOP, and POTATO MANURES. Also,
PERUVIAN GUANO (as imported by Messrs. Thomson, Bonar & Co.), NITRATE of SODA, SULPHATE of AMMONIA, &c.
115, Fenchurch Street, E.C.

REES AND CO.'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in fine condition. It is believed to be the best Artificial Manure yet produced. The Peruvian Government Guano; it contains 21 per cent. of Soluble Phosphates, 3 to 3½ per cent. Ammonia with Soda Potash, &c. See reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Ogston, and Mr. Sibson. Delivered in Bags, ready for use, and other packages as required, bearing the Company's Trade Mark. The analysis is guaranteed so long as the Company remains solvent.
REES AND CO. (Limited), 32, King William Street, London, E.C.

REPORT and ANALYSIS by DR. A. VOELCKER.
Consulting Chemist to the Royal Agricultural Society of England.
"Analytical Laboratory, 11, Salisbury Square, Fleet Street, E.C.
"London, January 18, 1870.

"SIR,—Enclosed you will find the results of a careful analysis of a sample of your Biphosphated Peruvian Guano. These results speak for themselves. I need therefore hardly add anything in commendation of the high fertilising value of this valuable Artificial Manure. The samples examined by me contained only 10 per cent. of moisture, and fully the percentages of soluble and insoluble phosphates which I understand you guarantee to furnish, and was in a fine state of preparation. The more generally this Manure will become known to Agriculturists, the more, I am convinced, will it be appreciated by them.—Believe me, Sir, yours respectfully.

(Signed) "AUGUSTUS VOELCKER.

"The Secretary, REES AND CO. (Limited), 32, King William Street, London, E.C."

The Cheapest and Best Insecticide.

POOLEY'S TOBACCO POWDER. Of all Nurserymen and Seedsmen.

GISHURST COMPOUND.

Used by many of the leading Gardeners since 1850, against Red Spider, Mealy Bug, Thrips, Green Fly, and other Blights, in solutions of from 1 to 2 ounces to the gallon of soft water, and at from 4 to 16 ounces as a Winter Dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it.

Sold Retail by Seedsmen, in boxes, 1s., 3s., and 10s. 6d.

Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited), Battersea, London, S.W.

Caution.

F. J. DRECHSLER'S ADDRESS is now, and has been for several months past, No. 63, ARLINGTON STREET, LONDON, W.
See this year's PORTABLE WINNOWING-MACHINES, FURNITURE, SENATORS, &c.; only made at the above address, and not at North Street, &c.
See Notice in *Gardeners' Chronicle*, page 938.

THE HYDRONETTE (ROBIN'S PATENT).

For Gardens, Greenhouses, Conservatories, Hothedges, Washing Windows, Carriages, &c.

Unrivalled ease of action, simplicity, convenience, and force.

The HYDRONETTE is a more useful, easy-working, reliable, and convenient water-throwing machine than any other in use. In five sizes, viz.:—No. 1, with 4 feet of Suction Hose, Strainer, Jet and Rose, per doz. £ 1 10 0
No. 2, 55 feet; No. 3, 65 11 1 0
No. 4, 75 " No. 5, 85 " 12 12 0
Extra Hose and Union Joints to order.

PATENT WATER BRINGER.

HAYNES AND SONS' PATENT WATER BRINGER, price 21s.—This simple Machine will draw water from a pond or well 10 feet below the level of garden, and 100 feet over the surface, with the Hydronette or any other Garden Engine.

HAYNES AND SONS, 227, 229, and 231, Edgware Road, W.
CAUTION.—Beware of the genuine unless labelled "HAYNES & SONS, Proprietors, London."

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS are made in materials of durable character, and sorts are especially suited for KITCHEN GARDENS, as they harbour no insects, make up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings. Also cheaper being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.

F. AND G. ROSHER, Manufacturers, Upper Ground Street, Blackfriars Bridge, S.E., and Upper Thames Street, S.W., Kingsland Road, E.
Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROTECTORS. Also for POOLEY'S PATENT BEADED GARDEN WALL BRICKS.
Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., from 9s. per square yard upwards. Pattern Sheets of plain or more elaborate designs, with prices, sent free on application.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchens, Bakehouses, Conservatories, &c., from 1s. per square yard. Strong of great durability, Wall Copings, Drain Pipes and Tiles of all kinds, Roofing Tiles in great variety, Slates, Cements, &c.
F. AND G. ROSHER, Brick and Tile Merchants.—See addresses above.

SILVER SAND, fine or coarse grain as desired. Fine 14s., Coarse 17s. per Ton. In Truck Londs 1s. per Ton less. Delivery by Cart within three miles, or to any London Railway or Wharf, 9d. per Ton extra. Samples of Sand free by post.
FLINTS and BRICK BURRS for Rockeries or Ferneries. KENT PEAT for Orchids. Lowest prices on application.
F. AND G. ROSHER.—Addresses see above.
N.B. Orders promptly executed by Rail or to Wharves.
A liberal discount to the Trade.

Great Reduction in Prices for 1871, OF GREEN'S PATENT SILENS MESSORS OR NOISELESS LAWN MOWING, ROLLING AND COLLECTING MACHINES.

During the last few years our Machines have been submitted to numerous practical tests, and found to possess all the advantages in working and keeping a lawn in the greatest possible state of perfection. We therefore have no alterations to report, as they are unnecessary.

The above Machines have carned off every Prize that has been given in all cases of competition.

They are warranted to be superior to any others. We guarantee them to give entire satisfaction, otherwise they can be returned, free of cost to the purchaser. With the increased facilities we possess for the Manufacture of Lawn Mowers, we are enabled to let them at a reduced rate on former years, as will be seen from the following Scale of Prices :—

To cut 8 inches	.. Price	£	s.	d.	
" 10 "	..	3	0	0	Can be worked by one person.
" 12 "	..	4	0	0	
" 14 "	..	5	0	0	
" 16 "	..	6	0	0	This can be worked by one person on an even Lawn
" 18 "	..	7	0	0	by Man and Boy.
" 20 "	..	7	10	0	"
" 22 "	..	8	0	0	"
" 24 "	..	8	10	0	"

T. GREEN & SON have pleasure in announcing that the demand for their Lawn Mowers this season far exceeds all previous ones, and from this fact they are led to believe that the machines of their manufacture are held higher in the estimation of the public than ever.

Prices of HORSE, PONY, and DONKEY MACHINES on application.

☞ *Repairs executed with efficiency and despatch, both at Leeds and London Establishments.*

GREEN'S IMPROVED PATENT ROLLER,

FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS, Suitable for Hand or Horse-power.

PRICES of HAND ROLLERS.

Diameter.	Length.	£	s.	d.	Diameter.	Length.	£	s.	d.
30 in.	32 in.	7	10	0	20 in.	22 in.	3	10	0
24 in.	26 in.	4	10	0	16 in.	17 in.	2	15	0

PRICES of ROLLERS, fitted with Shafts, Suitable for Pony or Horse-power.

Diameter.	Length.	£	s.	d.	Diameter.	Length.	£	s.	d.
30 in.	32 in.	10	0	0	30 in.	60 in.	15	10	0

30 in.	42 in.	11	15	0	30 in.	84 in.	19	10	0
30 in.	48 in.	13	10	0					

These ROLLERS possess many advantages over all others; they are made in two parts, and are free to revolve on axis, affording greater facility for turning, and the outer edges are rounded off, or turned inwards, thus avoiding the unsightly marks left by other Rollers. They are manufactured of the best materials, and are got up in a manner surpassing any ever yet brought out.

The ROLLERS, 24 by 26 inches, or by 22 inches, and 16 by 17 inches, are also made in one part, at a reduced price; and for Rollers of that size, will be found to answer many requirements, as the Handle can be reversed to either side of the Roller at pleasure.

The Gardeners' Chronicle

SATURDAY, JULY 29, 1871.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY, Aug. 2 { Royal Horticultural (Fruit and Floral Committees), at S. Kensington .. 11 A.M. Ditto (General Meeting) .. .. 3 P.M.

In the course of certain observations, made some few years since, on the Growth of Cuttings, we had abundant opportunity of ascertaining that nutritive materials, and in particular starchy matters, were stored up in the young shoots used as cuttings, and that as these commenced to callus, and subsequently to produce roots, the solid starchy material disappeared, just as in the case of germinating seeds. We were also led to the conclusion that the occasional failure in getting cuttings to strike properly might, other things being equal, be attributable to a deficient store of nutritive material in the cutting, in consequence of which the desired growth can not take place. Circumstances prevented us at the time from following up the subject, and the only record we made of the fact is contained in some notes of lectures delivered before the Royal Horticultural Society. M. Ernest Faivre, of Lyons, has, however, pursued the subject much more fully than we did; and, as the results at which he arrived are of much importance horticulturally, we believe we shall be doing good service by calling attention to them. M. Faivre's experiments were made, from October till April, on cuttings of the Mulberry. One object of the experimenter was to ascertain the nature of the material stored in the tissues of the cutting, its mode of formation, and its purport. M. Faivre early saw, as we had done, that the callus and the exuded matters were formed at the expense of material previously stored in the shoot, and, moreover, proved the fact by causing the cutting to strike, and even produce new leaves, branches, &c., in pure sand, watered with distilled water only.

In further proof of this, M. Faivre made a ring-like cut round a branch at about half an inch from its point, a large callus was produced at the expense of the material above the incision, while the bud placed in that situation ceased to grow. Another experiment of M. Faivre's showed that if by any means the deposit of nutritive matter could be exhausted, no callus was formed in the cuttings. This was accomplished by allowing the cuttings to develope as freely as possible long weak blanched shoots, and then making a ring-like cut below them, when no callus was produced. In autumn the cuttings readily callus, while the new shoots are tardy in their formation. In spring, on the other hand, the shoots are active, and grow rapidly while the callus is not developed to so great an extent?]. M. Faivre's further experiments go to show that the nutritive material, at whose expense the callus and the young growths are formed, is stored in the bark, and especially in the liber. Now, in the case of the Mulberry, the liber is permeated with latex-vessels, and hence the inference that the latex supplies at least in part the exuded material and that deposited in the callus. In confirmation of this, M. Faivre states that in those cases where the growth of vigorous shoots had used up the stored material, the latex-vessels, when examined under the microscope, were found void of latex.

M. Faivre's next experiments were devoted to the object of ascertaining how the nutritive material accumulated in the wood or bark could be made available. In the first place the absorption of water was found to be essential. Moreover, it was determined that water could be absorbed by the wood alone, or by the bark alone. These facts were proved by cutting off access of water to the bark, leaving the wood free to absorb it, and *vice versâ*. These experiments not only prove the fact of absorption, either by the bark or by the wood, but also show that there must be a lateral, as well as a vertical diffusion of the absorbed liquid.

That the wood alone, even though it is known to contain a store of nutritive material, is not sufficient of itself to promote the growth of shoots, is shown by the circumstance that the buds on a cutting from which the bark is entirely removed, will not push, and moreover, that a cutting so decorticated will not callus over. On the other hand, the bark alone is not sufficient to cause the bud to push, the co-operation of bark and wood is necessary to ensure the growth of the shoot.

These experiments of M. Faivre then prove, that for the successful striking of cuttings, as for the successful germination of seeds, a proper store of nutritive material must exist beforehand, and, moreover, that the other conditions for insuring growth are the same in the two cases.

Other observations go to show that the swellings which occur above the obstruction, when an incision is made, or a ligature tied round a branch, do not, as they are generally assumed to do, necessarily prove the descent of the sap, because these swellings are sometimes formed in situations, and under circumstances, which preclude the idea of any special descent of elaborated fluids having taken place.

Again, the fact that the ascending sap, usually considered as not nutritious, is really a source of nutriment, has been shown by the circumstance that cuttings grown in sand, and watered with distilled water only, will grow and produce shoots. In this case, of course, the notion of a special nutritive fluid descending is out of the question.

Few matters probably are of more vital importance in the management of a garden at the present juncture, than the treatment to which Wall Fruit Trees are subjected. Crippled by summer drought and winter frost, and attacked in this disabled condition by the bitter blighting blasts of such a wintry spring as the past, they need every care and every encouragement to reinstate themselves, if their permanent health and persistence is made a consideration. Indoor culture, when it can be adopted, is no doubt the plan best suited to cope with the vicissitudes of our climate, but outdoor wall trees there must also be, and the remedial measures to secure their return to a convalescent state must be prompt to be effectual—if indeed we have enough of summer weather in store, to really mitigate the evil which is, in too many places, so painfully apparent.

In order to secure the improved health of trees, which have been affected in the manner indicated, two things are essential in an eminent degree; first, a free growth of new wood must be promoted and secured; and secondly, the new wood must be thoroughly ripened. These objects being realised, we may be tolerably certain that the trees will recoup themselves for any losses which may have been sustained, if only they have time to do so.

To secure healthy and vigorous growth in the trees, root-action must be encouraged by measures which suggest themselves to the judgment according to the circumstances and conditions of each case. In light soils, where watering would be beneficial, give the roots a good soaking with tepid water, and follow it up by occasional doses of liquid manure. If the circumstances, either as regards soil or subsoil, are such, that the application of water is not considered judicious, have recourse to mulchings of warm dung, or even of any light, dry material, not in a fermenting state. By these or other means, such as loosening the surface to admit sun-heat, supplemented by such pruning as may seem judicious under the circumstances, including the removal of all dead or dying parts, the development of young wood must be secured; and this, reacting on the roots, will do what is possible towards keeping up a healthy state of progressive growth.

As to ripening the new wood thus secured, where a tree has been much punished there is a strong tendency to retain more young wood than can be duly exposed to the influence of light, and this is antagonistic to ripening. Rather let the shoots be thinned beyond the average so that they are fully and completely matured, or, at least, that maturation may not be arrested by overcrowding. Secure and retain as many leaves as may be able to perform their functions in a complete and satisfactory way, but rigorously remove any surplus beyond this. In the same way, blistered or disordered and therefore useless leaves should be removed, so that they may not rob those which are healthy and active.

The two points, then, to be aimed at in the treatment of tender wall fruit trees from this time onwards, is to get growth out of them by any means, and to take care that that growth shall be thoroughly matured before the trees are exposed to the rigours of another winter and spring such as the past.

— We regret to hear that one of our most distinguished amateur collectors of Orchids, and one whose name has for many years been, amongst Orchidologists, familiar as a household word—Sigismund Rucker, Esq., has determined to relinquish the culture of these marvellous plants. The celebrated and unrivalled collection which has been gathered together at Wandsworth—probably the richest as regards rarity and variety which has ever been formed—has, we understand, passed into the hands of the Messrs. Veitch & Sons, of Chelsea, by whom the plants, which are in the finest possible condition, will shortly be offered for sale at Protheroe's rooms. An opportunity will thus be offered to those who have already entered on the culture of these magnificent flowers to improve their collections, while others may be induced by the occasion which thus presents itself to commence forming an Orchid collection, and thus fill up the gaps in the ranks of Orchid growers occasioned by Mr. Rucker's withdrawal therefrom.

The Oxford Botanic Garden was the subject of a petition presented to Vice-Chancellor Malins' court on the 21st inst. The petition was presented under Sir Samuel Romilly's Act (52 George III., cap. 102) by the University of Oxford, the Vice-Chancellor of the University, Dr. Liddell, and the Professor of Botany, Mr. M. J. Berkeley, for the purpose of obtaining a variation of a scheme made in pursuance of a Master's report, dated in 1833, whereby a perpetual committee, consisting of the Vice-Chancellor, the Proctors for the time being, and the Regius Professor of Physic, with "the seven seniors resident upon the physic line," was established for the management of the Physic Garden at Oxford, in accordance with the will of Dr. William Sherrard, made in April, 1728. Dr. Sherrard by his will gave £3000 for the maintenance of a Botany Professor of the Physic Garden at Oxford, upon condition that the University should settle a perpetual fund for maintaining the garden. A suit was instituted shortly after Dr. Sherrard's death, in which it was settled that the University should pay £150 a-year for keeping up the garden in question, and the Royal College of Physicians were appointed visitors of the gardens. It was now proposed that the committee constituted as above-mentioned should be replaced by three resident members of Convocation, who should be nominated by the Vice-Chancellor and Proctors of the University, subject to the approbation of Convocation, and should hold office for ten years, and be styled "Curators of

the Botanic Garden." The Vice-Chancellor approved the proposition, and made an order to carry it into effect.

—— On Tuesday last a special meeting of the Market Gardeners, Nurserymen, and Farmers' Association was held at the Bedford Head, Maiden Lane, Covent Garden, under the presidency of Mr. H. Meyers, to consider the question of Removing the business of Covent Garden Market to Farringdon Market. The Chairman and several speakers addressed the meeting, and from their statements it appeared that the refusal of the Duke of Bedford to afford proper accommodation to the saleskeepers in the market, whereby they suffered considerable loss, was the cause of the present movement. The consequence of his Grace's refusal was that in wet weather the stalls were flooded—the water standing 5 or 6 inches on the ground. Hence the fruit became useless, and having been thrown aside, found its way to the barrows and baskets of the costermongers, by whom, in its half-decayed state, it was retailed in the poor districts, creating diarrhœa and other diseases among the humbler classes. One speaker, who was corroborated by others, said that Mr. Gye, the lessee of the Royal Italian Opera premises, had asked the permission of the Duke of Bedford to open the Floral Hall as a fruit and vegetable market, offering at the same time to indemnify his Grace against the expense of alterations, and to pay 25 per cent. on the tolls. His Grace, however, refused the offer. Under these circumstances the market gardeners and stall-keepers felt themselves compelled to look out for some other place. Application had been made to the Corporation respecting the site of Farringdon Market. The plans of the proposed improvements at the latter place, prepared at the instance of the Markets Committee of the City of London, by their architect, Mr. Horace Jones, were laid on the table, and inspected by the meeting. The Chairman then read a letter he had received from Mr. Bontems, of the Architect's Office, Guildhall, stating the Markets Committee were not quite prepared to speak definitely as to the question of rent, but when ready to do so they would ask the Association to meet the Committee. Mr. Potter, living at Farringdon Market, was in favour of having the new floral and vegetable market closer to the new meat market than Farringdon Market was. Mr. Rudkin, Common Councillor, explained the plans, and assured the tenants of the old (Farringdon) market that the Corporation were not antagonistic to their interests. The interests of the old tenants would be the first to be considered. There was a larger area in Farringdon Market than in the other suggested site, and if the site between the railway and the new meat market were fixed on, the streets in the neighbourhood must be widened to accommodate the additional traffic, and the stall-keepers would have to pay the cost. At present Farringdon Market was almost a dead letter in the hands of the Corporation, as it brought them in only £350 a year. It was intended to lower the market to a dead level in Farringdon Street, and to do the same with Stonecutter Street, just leaving an incline sufficient to carry off the water. As to rent, he could say in his individual capacity—not pledging the Corporation—that the rent would not exceed that paid in Covent Garden. Within a month he thought the Corporation would be able to provide the needful accommodation. After further discussion, a deputation, consisting of five vegetable growers and five florists, was appointed to wait upon the City Markets Committee as to rent, tolls, &c., and to report to a future meeting. Votes of thanks to the Chairman and Mr. Rudkin closed the proceedings.

—— The ornamental Gardens on the Thames Embankment, of which we gave a plan and description (p. 1600, 1870), were formally thrown open to the public on Saturday last. The designs were made by Mr. M'Kenzie, and the works were executed by Mr. Meston. We have Shakspeare's authority for the statement that Roses flowered once in the Temple Garden: we can aver of our own knowledge that they are now to be seen in bloom on the Thames Embankment.

—— The *Times* states that the Potato Crop in Cornwall has thus far turned out exceedingly satisfactory, the yield larger than for some years and the quality very good. Unfortunately, however, the disease is reported to be spreading rapidly in many localities, owing to the long-continued rain.

—— The Maximum Temperatures recorded at the different stations in England during the week ending July 22 attained to a much greater height than at any other period of the summer. The highest temperature recorded was 82°.6 at Blackheath, Portsmouth being second with 81°.4, closely followed by three other stations with 80° and upwards. As might be expected, the temperatures decline as we proceed northwards, for while the mean of the extreme temperatures of the eight southern stations was 79°.4, that for the eight northern was 75°.7, and for the Scotch stations was over 6° less, being 69°.6. Of the Minimum Temperatures, 46° at Edinburgh and 46°.7 at Salford were the two lowest, the former showing a range of 8° compared with the minimum at Blackheath. Of the groups, the eight northern stations of England were slightly warmer than the eight southern, and these in their turn were rather more than a degree warmer than the Scotch stations, the mean of which was 49°.3. Mean Temperatures.—As in the other two values, so in this, Blackheath is first with 65°.5, Portsmouth retaining its second place with 64°.6, following which we have Norwich with 63°.1; these three stations mainly contributing to raise the mean of the southern English stations to 62°.8, or about 1¾° above the mean of the northern English stations, and nearly 2¾° above the mean of the Scotch. Rainfall.—At two or three of the stations in the two countries the falls have exceeded 1 inch, but not to any great extent, without we except Greenock with 1.52 inch. The mean for Scotland was above that of England: the mean fall for the former country being 0.74 inch, and for the latter 0.37 inch. (See Mr. Glaisher's Tables in our present issue.)

—— Of a different strain entirely from the Zonal Pelargoniums noticed at p. 869 are those bred by Dr. Denny, and which we have lately seen in Mr. W. Paul's nurseries at Waltham Cross. They are specially distinguished for the form and size of their flowers amongst the hybrid nosegay race, to which they belong. Wellington is a magnificent crimson-scarlet, with immense trusses, and in every respect fine; Sir John Moore is a lighter scarlet, and very effective; Iago is an orange-scarlet, of remarkable brilliancy; while Ianthe is one of those beautifully rose-tinted varieties, in which the suffused blue comes out so charmingly. They are all of free-blooming habit, and take rank in one of the most advanced lines of the host of Zonal Pelargoniums by which we are surrounded.

—— The accompanying illustration (fig. 212) represents one of a great many forms of flower pots—Fern and Floral Arborets, as the designer calls them—which were exhibited at Wolverhampton by Mr. W. Hudspith, of the South Tyne Works, Haltwhistle, Northumberland. Great taste and skill were shown in

Fig. 212.—Arboret.

the various forms of gnarled and knotted tree stems, here turned to useful account in providing stands for flowers and Ferns.

—— The Corporation of Rochester is, it stated, about forthwith to proceed with the laying out of the Rochester Castle Gardens for a public garden, and to perform certain works at the Castle itself, which will form a great attraction to the place. Plans have been approved, and a good sum has been subscribed towards the cost of the work.

—— A few days ago Mr. W. Baxter Smith (of Little and Ballantyne's, Carlisle), and Mr. James Watt (of Roughead and Parks, Haddington), were entertained by their friends of the trade at a complimentary dinner at the Albert Hotel, Edinburgh, on the occasion of their entering into partnership with the view of taking over the old established and well-known business of Little and Ballantyne, Carlisle. The large company, including representatives from nearly all the leading firms in Scotland, showed the feelings of esteem and respect in which the guests of the evening are held by the seedsmen and nurserymen throughout the country. Mr. David Roughead, Haddington, occupied the chair.

—— The present season seems to be an exceptional one for the Fruiting of Conifers. We learn from Mr. Bennett, Enville, that nearly all the trees there are very heavily laden, and that the cones are remarkably large, even very small plants of Picea nobilis having some exceedingly fine, full cones upon them. The large specimen tree there, which is upwards of 50 feet high, is so heavily laden with them, that he will be compelled to take them off for fear of injury to the tree, which presents just now a grand, majestic appearance, the cones being of immense size. Mr. Bennett also sent us a few cones of great beauty of Picea nobilis, taken some weeks since from a tree only 12 feet high.

—— Reference has been made, says the American correspondent of the *Times*, to the "Condurango Plant of Ecuador, an alleged remedy for cancer, to which the attention of the United States' Government was called in an official communication from the American Minister in that country. The samples of the plant sent here were distributed by the State Department as an efficient remedy, and a physician was quoted as having experimented with it and vouched for its healing powers. But it appears that a board of physicians have been conducting experiments in Washington at the hospitals, and although they have made no final report, yet their judgment, so far as the experiments have gone, is against the plant, which is said to be entirely inefficacious. A decoction of the wood of the Condurango is used, but careful analysis fails to show that it has any unusual properties. The bark contains an insoluble gum, but no recognised medicinal principle. Both the wood and the bark have been subjected to minute examination, and are pronounced worthless. The patients afflicted with cancer who have been placed under treatment with Condurango are said to fail to show any improvement in condition. There are hints that the stir which has been created about this alleged remedy was a part of a well-laid plan to pave extensive advertising for a new quack medicine, for which a patent has already been obtained, and of which Condurango is an ingredient."

—— A good hint for fixing Screws in oil Holes is contained in the American "Gardeners' Monthly." The ordinary method is to drive into the hole a piece of wood, cut it off flush with the surface, and then put the screw in. It often happens that wood, screw, and all work out after a few days; hence the suggestion to make the plug of some elastic material, for which purpose strips of cork are recommended as very serviceable.

New Garden Plants.

Cœlogyne sulphurea, *Rchb. fil. in Seemann's Bonplandia*, 1857, p. 43.

Pseudobulbo ovato nitido subtetragono seu tetragono monophyllo; folio cuneato oblongo-lanceolato obtuse acuto; racemo elongato, parviloro; sepalis oblongis extus carinatis; petalis lineari-ligulatis reflexis; labello ima basi subsaccato dein utrinque unidentato, intus medio 4-lamina; setaceo-fimbriatis; bilobo separato carina una laterali utrinque a basi ad basin laciniæ anticæ; columna integrimarginata.—*Chelonanthera sulphurea*, Blume! Bijdr. 383; *Cœlogyne Cumingii crentata*, Teysm. et B. Tijds., Ned. Ind. iii. 666, et ind. hort. Bogor.

A modest Coelogyne, with flowers in the way of those of Coelogyne undulata, yellowish green, bearing a white lip with yellow streaks, and a yellow two-shanked blotch at the base of the column, with a pale brownish streak on each side of it below the stigmatic hollow. The original discoverers may have been Blume's collectors in Java. We obtained also specimens from Von Schierbrand and Zollinger. At length it came to us in a living state from Messrs. Veitch. *H. G. Rchb. fil.*

Rodriguezia lecohilina, *n. sp.*

Pseudobulbis oblongo ancipitibus; folio oblongo ligulato obtuse valde carnoso, rhachi obscura, apice flexuosa racemosa; bracteis ovatis obtuse acutis ovaria pedicellata terna sequantibus; sepalis ligulatis obtuse acutis, externis lateralibus linea media extus carinatis; petalis sequalibus obtusis; labello ima basi angulato, ligulato, pandurato retuso emarginato; lamella angulata parva utrinque ante basin, carinis geminis in disco; columna angulis porrectis obtusis.

A neat little Orchid in the way of Rodriguezia maculata, but at once seen to be distinct by the totally different even white lip. The sepals and petals are yellowish, with brown dots. It came from Costa Rica, and flowered in the Royal Exotic Nursery of Messrs. Veitch & Sons. *H. G. Rchb. fil.*

PATENT IMPERISHABLE HOT-HOUSES.

Pondering over the perishability of hothouses built of wood, and the constant attention required to keep paint and putty perfect even in those constructed of metal, the idea occurred to Mr. Ayres that they might be advantageously built without either sash-bars or putty, and that they might also be made up by a mere multiplication of similar parts, such as might be fitted together with ease and facility by any intelligent workman. Thus originated the Patent Imperishable Hothouses, of which we subjoin one or two illustrations, and the advantages of which, as claimed by the inventor, are imperishability, superior warmth and lightness, portability, and reduction of material, and of the cost of maintenance.

The framework of these houses is constructed of cast and wrought iron in combination, while the side walls are formed of terraced sections of cement. The framework is both light and strong, and through the combination of the necessary maximum of strength with the minimum of material, the actual shade cast by a span-roofed house 30 feet long by 12 feet wide, is only 76 feet, or 8½ yards super. Then the houses are as light as day, and may be said to form a continuous sheet of glass, supported by strong light rafters of T-iron, 6 feet apart, and with purlins to receive the ends of the squares of glass, 30 to 40 inches from each other. In this dull climate it is essential that in constructing plant-houses the light admitted should be as little intercepted as possible, for though for a few months in the height of the growing season we have more light than we may consider beneficial, and hence use shading, yet for the remaining portion light is frequently painfully deficient and the plants suffer accordingly. Nor is the gain of light the only advantage derived from this system of

building. The great fault and failing of iron houses, as ordinarily constructed, is that metal is a rapid conductor of heat; but glass is an insulator of heat, and taking advantage of this property the patent hothouses have been made externally, as far as possible, a continuous sheet of glass, both to protect the more perishable metal, and also to act as an insulator of the internal (warm) and external (cold) atmospheres.

Another advantage claimed for these structures is their perfect portability. Where this is desired, as it is with all leaseholders, yearly tenants, or even freeholders who have a life interest only in the property upon which they may find it necessary to build, it is important to be able to put up hothouses which in the legal sense of the word shall be "tenant's fixtures." In this case the iron standards, which are fixed into blocks of stone or concrete, have a recess or chasing, into which the concrete or terra-cotta slabs, which form the walls of the houses, fit with perfect ease, and can be removed at any time, and consequently no brickwork or masonry is required. The shelves or stages for the plants to stand upon are formed of the same material, and thus the cost and annoyance of wooden stages are done away with. As to the reduction of material and cost of maintenance, the houses are formed of an iron-work skeleton, the parts of which are the standard or mullion, the spandril or head-piece, and the rafters of T-iron connecting the two together, and forming a span; they may be called the principals, and are connected and tied together by light recessed purlins, which receive the ends of the squares of glass, the latter being held in place perfectly tight by metallic clips, which pass through the purlins and fasten with a pin. These, with the front and lower ventilators, complete the house, so that it will be seen that it presents but a small surface upon which it will be necessary for the painter to exercise his vocation.

The accompanying sketches (213, 214) show the general character of one of these houses as adapted for plant culture. It will be seen that, except the ends, the structure has no perpendicular glass, the fronts or sides, which other designers make perpendicular, being here on the slope. The reason assigned for this is, because no light — speaking comparatively — passes through perpendicular glass. To obtain the power of the sun's rays the glass must stand at a right angle with them, and in perpendicular glass almost every ray is refracted, and for positive life-invigorating purposes rendered almost useless; but with sloping sides some direct light may be obtained, and that at a most important season, viz., in the dark months of winter. The house is ventilated through the side panels, which admit the cold air in contact with the heating and evaporating troughs; through the side lights, which open simultaneously; and through movable sashes in the louvre box. This house is designed either for the cultivation of stove or greenhouse plants, the heating power introduced constituting the difference.

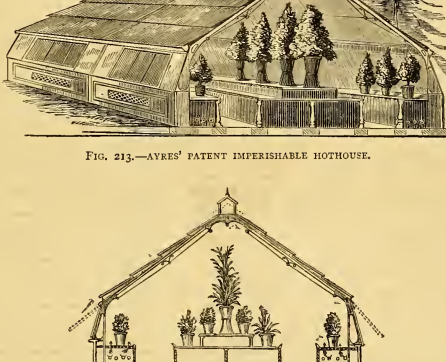

FIG. 213.—AYRES' PATENT IMPERISHABLE HOTHOUSE.

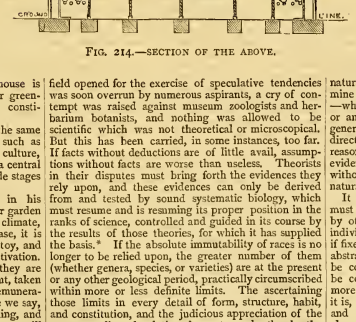

FIG. 214.—SECTION OF THE ABOVE.

Various other forms of building, applying the same principles, are designed for different objects, such as Grape growing, Pine growing, orchard-house culture, &c. The latter house has a sunk path, with a central border and trellis, for planted out trees, and side stages for fruit trees in pots.

"Orchard-houses," remarks Mr. Ayres, in his descriptive pamphlet, "have become a regular garden institution, and as, from the fickleness of our climate, the demand for them appears likely to increase, it is desirable that we should leave the region of toy, and take our stand upon the ground of solid cultivation. Pot fruit trees are all very well; indeed, they are admirable, as managed by some cultivators; but, taken upon the average, they are by no means a remunerative, not to say a profitable investment. Hence we say, for a permanent supply adopt open border planting, and you may do so with the conviction that the trees will serve you when the daily trouble of pots has ceased to charm. For this reason we recommend a central trellis, which, having from base to base 23 feet in girth, offers a training surface nearly equal to two 12 foot walls. It may be argued that upon the permanent plan we cannot have so great a variety of fruit, but that is a mistake, for nothing is so easy to bud as a Peach, Apricot, or Plum; so that, if so desired, every main branch (or even branchlet) may be a different variety of fruit. Amateur pomologists may seek a great variety of fruit; gardeners, whose reputation centres in an abundant supply of good fruit at all seasons, are content to confine themselves to proved kinds of superior excellence, and sure bearing properties."

A company has been formed for carrying out Mr. Ayres' patent, with works at Newark-on-Trent.

LINNEAN SOCIETY.

[The following are extracts from Mr. Bentham's Presidential Address, recently published. EDS.]

SINCE 1862 systematic biology has to a certain degree been cast into the background by the great impulse given to the more speculative branches of the science by the promulgation of the Darwinian theories. The great thunderbolt had indeed been launched, but had not yet produced its full effect. We systematists, bred up in the doctrine of the fixed immutability of species within positive limits, who had always thought it one great object to ascertain what those limits were, and by what means species, in their never-ending variations and constant attempts to overstep those limits, were invariably checked and thrown back within their own domain, might at first have been disposed to resist the revolutionary tendency of the new doctrine; but we felt shaken and puzzled. The wide field opened for the exercise of speculative tendencies was overrun by numerous aspirants, a cry of contempt was raised against museum zoologists and herbarium botanists, and nothing was allowed to be scientific which was not theoretical or microscopical. But this has been carried, in some instances, too far. If facts without deductions are of little avail, assumptions without facts are worse than useless. Theorists in their disputes must bring forth the evidences they rely upon, and these evidences can only be derived from and tested by sound systematic biology, which must resume and is resuming its proper position in the ranks of science, controlled and guided in its course by the results of those theories, for which it has supplied the basis.* If the absolute immutability of races is no longer to be relied upon, the greater number of them (whether genera, species, or varieties) are at the present or any other geological period, practically circumscribed within more or less definite limits. The ascertaining those limits in every detail of form, structure, habit, and constitution, and the judicious appreciation of the very complicated relations borne to each other by the different races so limited, is as necessary as the supplementing the scantiness of data from the depths of Teutonic consciousness by the vivid flashes of Italian imagination, or as the magnifying minute as yet undeveloped organisms, with a precision beyond what is fully justified by our best instruments.

I am, however, far from denying on the one hand how much biological science has of late been raised, since it has been brought to bear through well-developed theories and hypotheses upon the history of our globe, and of the races it has borne; and on the other, how very much the basis upon which it rests has been improved and consolidated by the assiduous use of the microscope and the dissecting knife; but I would insist upon the necessity of equal ability being applied to the intermediate process of method or nomenclature and classification, which forms the connecting link between the labours of the anatomist and the theorist, reducing the observations of the one to forms available for the arguments of the other. All three, the minute observer, the systematist, and the theorist, thus assisting each other, equally contribute to the general advancement of science, and for all practical application, the systematist's share of duty is the most important.

The quicksands to which I have alluded as besetting thus the foundation of biological science, may be classed as imperfect data, imperfect method and false method. To show what progress is making in removing or consolidating them, it may be useful to consider what these data are, and what are our means of fixing them so as to be readily available for use.

It must, in the first place, be remembered that the races whose relations to each other we study, can only be present to our minds in an abstract form. In treating of a genus, a species, or a variety, it is not enough to have one individual before our eyes, we must combine the properties belonging to the whole race we are considering, abstracted from those peculiar to subordinate races or individuals. We cannot form a correct idea of a species from a single individual, nor of a genus from a single one of its species. We can no more set up a typical species than a typical individual. If we had before us an exact individual representative of the common parent, from which all the individuals of a species or all the species of a genus have descended—or, if you prefer it, an exact copy of the model or type after which the whole species or genus had been created, we should have no possible means of recognising it. I once heard a lecture by a German philosophical naturalist, of considerable reputation in his day, in which he thought he proved that the common Clover was the type of Papilionaceæ. His facts were correct enough, but his arguments might have been turned in favour of any other individual species that might have been selected. Suppose two individuals of a species, two species of a genus, two genera of a family, in one of which certain organs are more developed, more differentiated, or more consolidated than in the other, if we agree upon the first question of which is the most perfect, a point upon which we do agree, we to determine which represents the common parent or model?—whether the perfect one is an improvement upon, or an improved copy, or the imperfect one a degeneracy from or a bad imitation of the other? No direct evidence goes beyond a very few generations; reasoning from analogy is the most direct evidence to start from, and the imagining a type without either is the business of the poet, not of the naturalist.

It follows that every such abstract idea of a race must be derived from the observation, by ourselves or by others, of as large a number of the constituent individuals as possible. However fixed a race may be, if fixed at all in Nature, that is not the case with our abstract idea of it, no species or genus we establish can be considered as absolutely fixed, it will ever have to be completed, corrected, or modified, as more and more individuals come to be correctly observed. Hence it is, that a species described from a single specimen, and even a genus established on a single species, always excites more or less of suspicion unless supported by strong reasoning from analogy or confirmed by repeated observation.

Our means of observing and methodising biological facts, of establishing and classifying those abstract ideas we call varieties, species, genera, families, &c., consist in the study (1) of living individual organisms; (2) of preserved specimens; (3) of pictorial delineations; and (4) of written descriptions. Each of these sources of information has its special advantages, but each is attended by some special deficiencies to be supplied by one or more of the others.

* The great importance of morphology and classification, the elements of systematic biology, has been forcibly illustrated by Prof. Flower in his last year's introductory lecture at the Royal College of Surgeons.

1. The study of living individuals in their natural state is without doubt the most satisfactory, but very few such individuals can be simultaneously observed for the purpose of comparison, and no one individual, at any one moment, can supply the whole of the data required relating even to that individual. Some additional facilities in these respects are given by the maintenance of collections of living animals and plants, particularly useful in affording the means of continuous observation during the various phases of the life of one and the same individual, and sometimes through successive generations, or in facilitating the internal examination of organism immediately after death, when the great physiological changes consequent upon death have only commenced. But there are drawbacks and difficulties to be overcome, as well as a few special sources of error to be guarded against, and in this respect, as well as in the progress recently made in their application to science, there is a marked difference between zoological and botanical living collections, or so-called gardens.

The great drawback to living collections, especially zoological, is their necessary incompleteness. At the best it is individuals, not species, that they are, a few cases genera that are exposed to observation; genera, indeed, can always be better represented than species, for a few species bear a much larger proportion to the total number contained in a genus, than a few individuals to the total number which a species contains. Whole classes are entirely wanting in zoological gardens, which are usually limited to vertebrata. Of late years means have been found to include a few aquatic animals of the lower orders, but insects, for instance, those animals which exercise the greatest influence on the general economy of Nature, the observation of whose life and transformations is of every day acquiring greater importance, are wholly unrepresented in zoological gardens. The shortness of duration of their individual lives, their enormous power of propagation, the different mediums in which they pass the different stages of their existence, will long be obstacles to the formation of living entomological collections of anything like a satisfactory scale. The cost also of the formation and maintenance of living collections is very much greater in the case of animals than of plants; but on the other hand zoologists have the advantage of the attractiveness of menageries as a means of general and scientific but paying public, and, under judicious management, some sacrifices to popular tastes are far outweighed by the additional funds obtained towards rendering their collections useful to science.

The false data or errors to be guarded against in the observation of living zoological collections are chiefly owing to the unnatural conditions in which the animals are placed. Ungenial climate, unaccustomed food, want of exercise, &c., act upon their temper, habits, and constitution, and confinement materially modifies circumstances connected with their propagation. Such errors are false data are, no doubt, as very few and unimportant compared to those which have arisen from the reliance on garden plants for botanical observations, but, as zoological gardens multiply and extend, they will have to be more and more kept in view.

In my younger days there were already a number of small collections of living animals, but mostly either travelling or local menageries exhibited for money by private individuals, or small collections kept up as a matter of curiosity for the benefit of the public, such as those of the Pfauen-Insel at Potsdam, the park at Portici, or our own Tower menagerie. At Paris alone, at the Jardin des Plantes, the furnishing of which the Jussieus and Cuviers, was the living zoological collection rendered essentially subservient to the purposes of science. Since then, however, matters have much changed: the Jardin des Plantes, which so long reigned supreme, has, by remaining stationary, sunk into a second rank. She indeed be a mother to be ever proud of her Milne-Edwards, her Brongniart, her Decaisne, and many others, but long out of favour with the Government and the paying public, who transferred their patronage to the high-sounding Jardin d'Acclimatation and more, she has been almost abandoned to the resources of pure science, always of the most restricted in a pecuniary point of view. We in the mean time, and after our example several Continental states or cities, have made great advances. The formation of our Zoological Society and Gardens opened a new era in the cultivation of the science. After various vicissitudes, the Society had the good fortune to secure the services of one who combined in the highest degree zoological eminence with administrative ability, and thus our great living zoological collection is now raised to the proud relative position which the Jardin des Plantes once held, and which there seems every reason to hope it will long maintain. With an annual income of about £23,000 the Zoological Society is enabled to maintain a living collection of about a thousand species of Vertebrata, and although subject to all the surplus funds is necessarily applied for the sole gratification of the paying public, yet a fair share is devoted to the real promotion of that science for which all the fellows are supposed to subscribe, the accurate observation of the animals maintained, the dissection of those that die, and the publication of the results. Physiological experiments are either actually made in the garden, or promoted and liberally assisted, such, for instance, as those on the transfusion of blood, the effects or non-effects of which were recently laid before the Royal Society by Mr. F. Galton. A very rich zoological library has been formed, and last year's accounts show a sum of about £1800 expended in the Society's scientific publications.

Zoological gardens, after the example of the London one, have been established not only in several of our provincial towns, but in various Continental cities, amongst which the more important ones, as I am informed, are those of Amsterdam, Antwerp, Hamburgh, Cologne, Frankfort, Berlin, Rotterdam, and Dresden; the receipts of the one at Hamburgh, for instance, amounting annually, according to the published reports, to between £8000 and £9000. There are also so-called gardens of acclimatisation; but these have not much of a scientific character; their professed object indeed is not so much the observation of the physiology and constitution of animals as their modification for practical purposes, and practically they are chiefly known as places of recreation, and are not always very successful. The great one in the Bois de Boulogne, now destroyed, out of an expenditure in 1868 of about £7200 showed a deficit of about £1600; a smaller one at Vincennes is enabled to pay an annual dividend to its shareholders.

Living collections of plants have great advantages over those of animals, they can be so much more extensively maintained at a comparatively small cost. In several botanical gardens several thousand species have been collected and maintained at a comparatively small cost, and species can be represented by a considerable number of individuals, a great gain especially where instruction is the immediate object, the lives of many can be watched through several successive generations, and great facilities are afforded for physiological experiments and microscopical observations on plants whose organs whilst still retaining more or less of life. On the other hand the false data recorded from observations made in botanical gardens have been lamentably numerous and important. A plant in the course of its life so alters its outer aspect that each one cannot be individually known by the figure of it collected, and at one period, that of the seed in the ground, it is wholly withdrawn from his observation. He is therefore obliged to trust to labels, these are often mismatched by accident or by the carelessness of the workmen employed, or again, one seed has been sown and another has come up, or, sometimes by want of experience and made room for a sucker or seedling from an adjoining species. The misnomers arising from these and other causes have become perpetuated and sanctioned by directors who, for want of adequate libraries or herbaria, or sometimes by want of experience or ability, have been unable to detect them. They have also been so disguised or essentially altered by cultivation that it has become difficult to recognise their identity, and new varieties or hybrids, which, if left to themselves, would have succumbed to some of the innumerable checks of destruction they are constantly exposed to in a wild state, have been preserved and propagated through the protective care of the cultivator, and pronounced at once to be new species. If, moreover, a misplaced label indicates that the seed has been received from a country where no plants of a similar type to those in question are known to exist, he notes it as a new genus, and, proud of the discovery, gives it a name and appends a so-called diagnosis to his next seed-catalogue, adding one more to the numerous puzzles with which the science is encumbered. So far, indeed, had this nuisance been carried in several Continental gardens in the first quarter of the present century, that, excepting perhaps Fischer & Meyer's and a few other first-rate indexes, the great majority, perhaps nine-tenths, of the new species published in these catalogues have proved untenable, and, from my own experience, I am now obliged, *a priori*, to set down as doubtful every species established in a garden list without confirmation from wild specimens. Fortunately the custom is now abating, and directors of botanic gardens are beginning to perceive that they do not add to their reputation by having their names appended to those of bad species.

Living collections of trees, or botanical gardens, are of much older date than zoological ones, and since the sixteenth century have been attached to the principal universities which have medical schools, that of Padua, dating from 1525, that of Pisa, from 1544, and of Montpellier, from 1597. The Jardin des Plantes of Paris, which in botany, even more than in zoology, so long reigned supreme, was established in 1610, our own first one at Oxford in 1632. These university gardens having been generally more or less under the control of eminent resident botanists, have contributed very largely to the means of studying the structure and affinities of plants, especially in those Continental cities where a milder or more steady climate has facilitated the maintenance of large collections in the open air or with little protection. Continental gardens have also been long and are still made largely available for the purposes of instruction in the scientific experiments, of which the recent labours of Naudin and Decaisne are an excellent illustration. For these scientific purposes the arrangement in large and small square compartments is peculiarly suitable, and I confess that I have frequently had greater pleasure in witnessing the facilities afforded to zealous students in following up, book in hand, the straight rows of scientifically-arranged plants in there formal university gardens, than in watching the gay crowds that flock to the more ornamentally laid out public botanic gardens.

I do not think that generally much advance has been made of late years in Continental botanical gardens. Those that I first visited in 1830 appeared to me to be but little improved when I again went over them in 1860. Some have acquired additional space, others have paid more attention to ornament, but most have remained nearly stationary, and a few have even fallen back. In our own country we have made great progress. Kew Gardens had indeed, in former days, rendered assistance to the investigations of Robert Brown and a few other favoured individuals, but they were the Sovereign's private property, and were kept very close, with little encouragement to science at large. But 30 years' unceasing exertions on the part of its distinguished directors, the two Hookers, father and son, have raised them to a point of scientific usefulness far beyond any other establishment of the kind at home or abroad. Of the large sums annually voted for it by Parliament, a portion has indeed to be applied to mere ornament and to the gratification of visitors, but yet, with all the drawbacks of our climate and consequent expenditure, still the largest named collection of species ever brought together in one spot, representatives of all parts of the globe, are there maintained, freely exhibited to the public, and submitted to the examination of scientific botanists.

RHODODENDRON EXCRESCENCES.

At the meeting of the Scientific Committee of the Royal Horticultural Society, held on the 19th inst., the Rev. M. J. Berkeley exhibited fragments of Rhododendron ferrugineum with a large, fleshy, gall-like body on the leaves, and which he considered to be the result of a Fungus mould, a species of Ascomyces, similar to that which produces blister in Peach trees (p. 944). I do not know on what grounds the learned gentleman has formed his opinion, and I willingly bow to the decision of a veteran in science, who made galls before I was born; but I would respectfully suggest a further investigation of these excrescences, as in their location, build, and substance they show an exceedingly close resemblance to the galls caused by some saw-flies. The present seems precisely one of those cases in which botanists and entomologists can work hand in hand. If the latter have lately had occasion to relieve the former of the study of the large genus Erineum, by proving its exponents to be excrescences caused by the presence of four-footed mites belonging to the genus Phytoptus, perhaps botanists will render their entomological brethren a like service, by proving experimentally that the gall-like excrescences of Rhododendrons are real Fungi.

In the meantime I offer a first instalment of the knowledge extant on the subject, hoping that other observers will follow suit.

In 1859, Dr. Laboulbène communicated to the Entomological Society of France an extract from a letter written by M. Léon Dufour, on the subject of the gall of the Rhododendron, observed near the Grande Chartreuse, and of which gall mention has been made in the "Rapport au Congrès de Grenoble." (*Vide* Annales de la Soc. Ent. de France, 1858, p. 839.) The extract reads as follows: "Your gall of the Rhododendron, which I have often met with in the Pyrenees, has much intrigued me, and I have never been able to make out its originator. It has been described by Tournefort, a Cynipid, which produces the gall *en pomme d'api* of the Oak." (Bulletin de la Soc. Ent. de France, 1859, p. 96.)

In 1868 I penned the following note:—"Alpine Rose (Rhododendron ferrugineum): Fleshy, fruit-like galls on the leaf, of about the size of a Raspberry, smooth; outer crown rather like that of a Pine-apple. For an inspection of these to me novel galls on the far-famed Alpine Rose I am indebted to Mr. Stainton . . . who, at my request, has furnished the following precise particulars, which will enable any tourist to investigate the subject further, if they are not already observed somewhere. Mr. Stainton writes: —'They were common enough at Andermatt, from 100 to 200 feet above the chapel, which is itself just above Andermatt; the colour was green, with a slight rosy tinge in places. The date was July 30' (1866). Insect unknown to me." ("Zoologist," s.s. 1868, p. 1206).

In 1869 I wrote a hint respecting the Nematus gall of Rhododendron ferrugineum. On July 30, 1866, Mr. Stainton first met with this gall near Andermatt, in the Ursern Valley, and his courtesy enabled me soon afterwards to examine specimens, and to offer a few particulars on the subject in the "Zoologist" (p. 1206, s.s.), but these specimens were too far decayed to give any clue to the insect. On June 23, 1868, and the days following, during a journey devoted almost entirely to the search after galls, I had the pleasure of finding the authentic plenty of these excrescences near the road above Hospenthal, in the same valley, at an altitude of about 4500 feet. The galls, looking with their glowingly red cheeks not unlike small-sized White Heart Cherries of irregular shape, were most conspicuous amongst the sober, dark-green foliage of their foster-plants, which at that time only just began to expand their lovely blossoms. An examination of many specimens showed that at first

they are filled with a spongy white substance enveloping a solitary egg, and that subsequently, when this hatches, the larvæ begin to feed on the surrounding matter, thus gradually forming a chamber around itself. The location of the galls is either each separate upon a leaf or else in the centre of a top of a shoot, in which case the latter, instead of bringing forth its bunch of leaves or blossoms, produces a bundle of more or less crowded galls, *i.e.*, converted leaves or blossoms. Taking into account all I have seen of this gall, I consider it to be the production of a saw-fly, belonging, probably, to the genus Nematus; but, although there is ample precedent for doing so, I abstain from burdening nomenclature with a new appellation, which will I leave to the finder of the perfect insect; adding that it will probably occur in August or September, when sweeping the Rhododendrons would probably lead to the desired result, for the attainment of which I appeal to all entomologists who may happen to be in the subalpine region at that time of the year. ("Zoologist," s.s., p. 1838.)

Then followed a memorandum on the Nematus gall on Rhododendron hirsutum. In the September number of the "Zoologist," s.s., p. 1838, I called attention to the occurrence of the gall of a saw-fly on R. ferrugineum in the Tavern Valley. I have now to record, that this same gall also occurs on Rhododendron hirsutum in the Bernese Alps, whence specimens collected by Herr Bischoff-Ehinger, of Basle, on the Gemmenalphorn, near Interlaken, at an altitude of about 6000 feet, have just reached me, but, I am sorry to say, in a condition which precludes the possibility of rearing the insect. However, this production, being now signalled as occurring in two localities on different species of the so-called Alpine Rose, is likely to be found all over the alpine range, and I hope that entomological tourists will bear in mind that the perfect insect is unknown to us. ("Zoologist," s.s., 1869, p. 1869.)

Now, Mr. Editor, I hope you will not cancel any of the circumstantial evidence repeated above, for the sake of saving space. I claim a full hearing in the matter, and that it is worth while ventilating is shown by the fact that, hardly a month ago, while visiting Professor Heer, at Zurich, he deliberately put to me the question—"Do you know that gall on Rhododendrons? I meet with it everywhere in the Alps, and cannot fathom its origin, &c." What could I do but shrug my shoulders, and relate my repeated attempts to get at the perfect insect? And now we are told, on the highest authority, that it is a fungoid growth.

Have my eyes deceived me—is it a gall or a Fungus? "that is the question." If the former, who will first show its maker; if the latter, then I shall console myself with the thought of having procured information of its geographical range, for let it be known that there is a rumour afloat of its having been seen also on cultivated Rhododendrons in Scotland, and as to its insect origin, in which I still firmly believe, I shall then, but then, have to excuse myself with the unphilosophical saying that *errare humanum est!*

It would be interesting to learn whether this excrescence also occurs on the Rhododendrons from Sikkim. *Albert Müller, July* 24.

BOTANY FOR BEGINNERS.—XII.

THOSE who are inclined to twit botanists with the *cui bono* argument—and the race is not quite extinct—may be met by the fact that neither they nor anyone else could exist without plants. Plant life is essential to animal life, animal life is the complement to that of plants. Hence some knowledge of plant life may be deemed essential. We do not intend at present to enter upon physiological questions, but it may surely be said that an acquaintance with the plants producing the *staff of life* comes under the head of useful knowledge. Nevertheless, we think we do not err when we state that even among those who have a smattering of botanical lore less is known of the grasses than of almost any other group of plants. This arises no doubt from the difficulty of dissecting their flowers, and from the fact that their construction is, at first sight at one, so different from that of other plants. The difficulty of dissecting the flowers of grasses arises from their general small size, their dense approximation, and from the dryness and rigidity of their flowers, which renders the dismemberment of them a matter requiring some patience and dexterity. For these reasons we have deferred the consideration of their structure till the beginner, presuming that he has followed us so far, may be supposed to have attained something of the requisite dexterity from practice on flowers of easier construction.

The Wheat (Triticum), chosen for our illustration, will now be in flower, or if, in the south, a little past its flowering stage, will hardly be too far advanced to prevent its parts being clearly made out; or at any rate, if Wheat be not available, what we are now about to say is applicable, *mutatis mutandis*, to other grasses now in full flower. Before passing on to the flower, however, let us glance at the other parts of the plant.

The fibrous roots demand but little explanation at our hand, but the stems of the grasses—the straw, being in many respects different from that of other plants, requires some notice. In the first place, it is herbaceous, that is, not woody; then it may be noted that its form is cylindrical, and that it is hollow in the interior. The stem, in fact, is tubular, but the tube is interrupted here and there by partitions which will be found at the points whence the leaves proceed—points, moreover, marked in the case of the grasses by a little thickening called technically a *node* or knot. It is useful to know that the spot whence a leaf proceeds is always called in botany a node, even though a swelling be not always present in that situation. The space between two nodes is in like manner called the *internode*. When the leaves are crowded together the internodes are necessarily very short; but here in the Wheat the leaves are separated by rather long internodes. The tubular form of the stem, or straw of Wheat, secures considerable strength, at the same time that economy of material is secured. Strength is also secured by the hard flinty substance which is contained in the skin or rind of all the grasses, and which exists in such quantities that the stem may with care be burnt, or destroyed by strong acids, and yet the skeleton of the plant as it were will remain, showing the form of the stem. To do this, however, requires some skill, and the beginner will probably realise the fact almost as well when we tell him that the rigidity of grasses as well as the glossy appearance of the straw is due to this silex, or flinty material. All grasses, with the exception of the

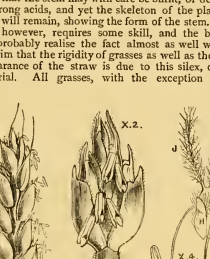

FIG. 216.

FIG. 217.

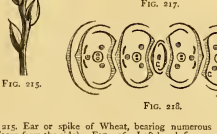

FIG. 218.

FIG. 215. Ear or spike of Wheat, bearing numerous spikelets (seen from the side).—FIG. 216. Left-hand figure: Spikelet separated, the two lowermost scales are the glumes. Right-hand figure: The flower divested of the glumes and pales (see text).—FIG. 217. Flower of Wheat invested by the flowering glume and pale (see text).—FIG. 218. Diagram showing the arrangement of the parts in a spikelet of Wheat (see text).

Sugar-cane, and one or two others, have these tubular jointed stems. The leaves, too, of grasses are characteristic. If the leaf of the Wheat plant be carefully stripped off, it will be seen to consist of a sheathing portion wrapping round the stem, and a flat, ribbon-like portion, the *blade*, quite detached from the stem, and having no one rib larger than the rest—no midrib, in fact, but a great number, all of about the same size, and running parallel from the base to the point of the leaf. The blade of a grass-leaf is always entire, not notched or divided in any way. Just at the junction between the sheath and the blade of the leaf may be seen in all grasses a small but characteristic membranous outgrowth, technically called a *ligula*, and which is peculiar to grasses.

A botanist seeing a fragment of a leaf with this little membranous process emerging from it, would at once pronounce the fragment to have belonged to some grass. Sedges, which in so many cases resemble grasses, and are constantly confounded with them, may be recognised at once by their triangular stems, and their leaves destitute of *ligules*.

Coming now to the flowers of the Wheat, we find them closely packed on either side of the top of the stem, and if they be pulled off from the ear, the inflorescence, that is, the stem, may be seen to have lost its cylindrical form, and to have become flattened and bent zig-zag fashion. Here again is a provision for securing economy of space; the flattening allows more room for the flowers, and the zig-zag bends allow the flowers above, as it were, to fit into those below. It may be well to state that the inflorescence of the Wheat is called a *spike*, and its flattened portion is called the *rachis* (fig. 215).

It might at first be supposed that what we have just called the flowers, and which we recommended to be stripped off to show the flattened rachis, were single flowers; this, however, is not the case: they are groups of flowers, and to each little packet or group the term *spikelet* is applied (fig. 216). These spikelets are densely packed in the case of Wheat, but in the Oat they are more loosely arranged, and form a panicle. We have then to see what these spikelets are composed of. The beginner must not be disheartened if at first he can see nothing but a confused mass of scales; let him be assured that there is no confusion, and that a little patience will enable him to see that each spikelet consists, first, of two scales, one to the right hand, the other to the left. By seizing with the fingers the top of the spikelet, these two lower scales, or *glumes*, as they are called, may be left *in situ*, and may then be seen to be attached to the main stem or rachis, and to be of the nature of bracts, enclosing three or more small flowers, supposed to be pulled off by the observer.

Each of these tiny flowers (the numbers vary in different grasses, and even in different varieties of Wheat) has an exceedingly short stalk or peduncle, so short, indeed, that the beginner may be pardoned if he fail to see it. Proceeding with his dissection of a flower, he will next come to a scale like those already referred to in form and appearance, but clearly not attached to the main stem or rachis, inasmuch as it is pulled off with the flower; it must, then, belong to the exceedingly short peduncle already referred to as supporting the flower, and is indeed the best evidence we have of the existence of the stalk, as that is too short to be readily seen. These scales or bracts belong to the flower is seen by the fact that it completely encircles the flower below, which it would not do if it formed part of the flower proper. This scale is called the *flowering glume*, and is of the nature of a bract; it is often provided with a long thread at the top, called an *awn* (fig. 217, F). The "beard" of some varieties of Wheat or of Barley or Oats is constituted by the awn springing from the flowering glume. If this be now carefully removed with the needle or point of the penknife, yet another scale may be seen on the other side of the flower, on the one last mentioned, and a little higher up (fig. 217, G); this may be readily recognised, because it is marked by two ribs, whence it is supposed that it may really be made up of two scales united together. But this is still a moot point, as is also the question whether we are to consider this two-ribbed scale or *pales* as a bract or a part of the flower proper.

The beginner will do well to fix his attention on the form and position of this pale, and to leave the consideration of its structural significance to more experienced botanists. If the pale be now removed, three (in some grasses, as Rice, six or even more) very delicate stamens will be seen (fig. 216, K). As the student should proceed in all things systematically, before he examines these stamens let him carefully search for two very minute white membranous scales at the base of the stamens (fig. 216, H); he will very probably fail to see them at first, but a little patience will enable him to disentangle them. These two scales or lodicles are fringed at the top in the case of the Wheat, and are the only representatives of the sepals or perianth of more perfect flowers (unless, indeed, what is popularly the pale really represents the outer investment of the flower); the filaments of the stamens are entirely separate, both from each other and from other parts of the flower, and each bears a long narrow anther, so delicately poised that it moves with a touch, hence the term *versatile* as applied to the anthers of grasses. Each anther (fig. 216, K) is divided into two lobes, which are separate at each end, thus forming a notch at both extremities of the anther. Next we come to the pistil (fig. 216, J), here composed of a single oblong carpel, downy at the top, and provided with two rather long feathery stigmas. In the young state of the carpel is the seed or grain, which as it ripens becomes confluent with the carpel, and ultimately inseparate from it. In the young state the carpel may be distinguished by its white or colourless appearance, while the outer portion of the seed is green. The interior seed consists of a mass of floury substance, the albumen (flour), and at one end, from a little cavity of it, may be picked out a little button-like mass, which is the embryo plant, and on whose structure we may perhaps say more at another time.

Complicated as the structure of the inflorescence of grasses seems, it is not so much so in reality—thus, to sum up:—There is a main stem (the rachis) which bears at each notch two glumes or bracts, arranged alternately. Within these latter the rachis divides, and on each secondary branch or peduncle so formed are again two bracts, arranged alternately one over the other, *i. e.*, the flowering glume and the pale, then comes the flower proper with its two lodicles. In some grasses three are present, and then we have a whorl of three lodicles, like a calyx of three sepals. The stamens

* Naturalists have over and over again bestowed specific names upon insects, of which only the galls or cases, &c., were known to them at the time they published their writings.

are regular enough. The pistil is peculiar in having but one carpel, it may be assumed that two are suppressed, as very rarely, by accident, the other two are developed. The fruit is remarkable for the intimate blending that occurs between it and the contained seed.

The diagram fig. 218 represents a plan of the arrangement of the parts in a spikelet of Wheat, supposed to be cut across to show it, four perfect and one imperfect flower in the centre; A represents one of the two glumes common to all the flowers; B is the flowering glume, of which there is one to each flower; C, the two-ribbed pale, with one of which each flower is also provided; D shows the lodicle, of which each flower possesses two, rarely three; E indicates a stamen, of which there are generally three, and F is the pistil.

To make our account of the Wheat complete, we ought to add that the topmost flower (or in some cases flowers) of the spikelets are rudimentary merely. In other grasses, *e.g.*, Barley, two of the lower flowers are rudimentary, the central one alone perfect. The man who can make two blades of grass grow where only one did before is a benefactor to his kind, so also is he who can induce the Wheat or the Barley to perfect there usually barren flowers and make them productive, and to a certain extent this has been done. As we started with an allusion to the *cui bono* cry, let us end by asking how this could be done if the benefactor knew nothing of the structure of the flower of grasses?

Home Correspondence.

New Pears.—"Pari Passu" (p. 943), in reviewing the list of new Pears, as quoted by me at p. 903, does not appear to me to be up to the usual high standard of the sorts he mentions. I will begin at the beginning, as Byron has it, and allow Doyenné du Comice to be an A 1, generally speaking, and, I may say, always upon a Quince stock. As to Marie Louise d'Uccle, it is so very near, in all its bearings, to Marie Louise, as to be scarcely different, if there is a difference at all, as was pointed out in the *Gardeners' Chronicle*, p. 1060, 1865, where it is figured and described, and the following observations made regarding it:—"This very excellent Pear differs from its type in having a peculiar fine aroma—that of Gansel's Bergamot—and also in growing, by whose stock upon the Quince I don't know, on which it forms a robust and prolific pyramid." All this is perfectly correct with regard to this locality, and the fact that the Marie Louise does not do on the Quince, whilst the M. L. d'Uccle does, is evidence that there is a constitutional difference, however near they may be in outward appearance. Beurré Bachelier is both large and handsome, with an abundant juice, which is sugary, acidulated and vinous, although without perfume. This, like Easter Beurré, should be gathered before getting quite ripe, as both sorts are inclined to get dry and mealy if not caught at that happy time. Beurré Durand is a very different Pear from Dr. Durandeau, more properly Durondeau, or Tongre, one of the most juicy and melting Pears I know. B. Durand is a highly perfumed and savoury fruit, rarely otherwise here. Beurré Six, ripened here October 27, 1870. My note against it is: "Rich, delicious, rich, juicy, and sugary, one of the very best—A 1, xxx." I have had some of the fruit keep to December, and still excellent. Can your correspondent have had the kind true? Calebasse Deivigne: My note against this sort is: "Ripe September 22: a beautiful fruit, tinged with bright vermilion, and of excellent flavour." This, like many others, requires to be gathered before being too ripe, and to be carefully watched, as it rots without giving outward signs. Désiré Cornelis is one of our largest and earliest sorts, ripe here August 12, 1870; melting, very juicy, very sugary, and nicely perfumed. Désiré Nelis is generally second-rate. On September 30, 1870, it was juicy and rich; it is a pretty little Pear. Dr. Trosseau is not always good. On November 14, and December 24, 1870, it was rich, refreshing, and aromatic; it is one not always to be trusted, excepting against a wall, on which it is a reliable fruit. Duchesse d'Orléans: My note of this says: "Ripe October 10, 1870; a fine and delicious fruit, beautifully coloured on the sunny side; very melting, very juicy, acidulated, sugary, and exquisitely savory." General Todtleben: If this is a worthless fruit, then I must think myself no judge. Note: "Ripe October 16; a beautiful, large, and handsome fruit, finely covered with vermilion on the sunny side, and spotted like the Forelle; variable in shape, from pyriform to turbinate. Some of the fruit remain quite green, whilst others are highly coloured; these last are the best flavoured, and are A 1. Flesh tinged with rose, more so than any Pear I know, and is melting, juicy, sugary, and finely aromatic." This must not be confounded with Triomphe de Jodoigne, which is much like it in shape and size. The trees are very different, so are the fruit, in quality; it is just probable that this has reached it by Pear stock, as The General. I shall have no fruit this season, otherwise I would have sent him a dozen of each. Leopold I.: My note against this is: "November 16.—Fine, very melting, very juicy, aromatic, and delicate. January 28.—Getting woolly and dry." This was a seedling of Van Mons, but did not fruit until several years after his death, and was considered worthy of bearing the name of a truly worthy man. Madame Elise I know as rather an indifferent Pear. Madame Elisa I know as follows:—Note made of November 1, 1870: "A delicious fruit; flesh fine and melting, juice excessively abundant, rich, sugary, and very savoury, very variable in size and outline." Marie Guise: Note, January 24, 1871: "A handsome and fine fruit, skin golden-yellow, much covered with netting and reticulations of fine cinnamon-coloured russet, with a tinge of vermil on the sunny side; flesh rich, aromatic, and highly-flavoured." Napoléon Savinieu, one sort, received from France; not true: it ripened September 15, and was not above second-rate. Another tree received from Belgium is the sort described by Bivort, and is the true one, for, peeling the fruit, it seems like a Rose or Violet, and has also an odoriferous taste. My fruit are exact in figure and description with Bivort's sort; it is a beautiful fruit, ripened December 25, 1870, and kept till January 28, 1871. At both periods it was rich, juicy, sugary, and slightly musky, with a fine delicate flavour. Passe Crassane I grow largely as a first-class fruit. I have unfortunately made no note against it, but am at one with Mr. Rivers about it, and with all who have grown it, excepting "Pari Passu." Tèche: Note says: "Ripe September 3, 1870. From Quinquin; good, delicious, flesh very melting and fine, juice more abundant, very sugary and vinous, with an excellent perfume." Dr. Hogg gives a description of the Peach Pear almost the same as I have, and I am surprised to find it belie its general character in Middlesex. Poiteau has not described it, however, except in name, as Noveau Poiteau. The first is a nice, high-flavoured fruit, of a Bergamot shape; whilst the second is a very large pyriform fruit, ripening here from November to January. My note says: "Ripe October 30; flesh excessively fine, rich, juicy, and delicious. This is very variable in size, like my other notes, verbatim—as they were taken in my fruit-room. Both Thompson and Hogg give this a high character. As above, I have faithfully given the qualities of all the Pears objected to by your correspondent, whose remarks I could well pass over, but considered it my duty to bring them incorrect. It was evident, on perusing his article, that he did not well know all the Pears of which he has taken notice, and, therefore, I wish to put him right in a friendly manner. I decry personalities as much as he does. I do not think that I imported any personalities into the article I wrote, but merely tried to place facts before your readers. That all the Pears I have enumerated are good, in all places or in all seasons, I never for a moment supposed to be the case. No one knows better than I do the extreme variability of the Pear, whether we take its size, figure, flavour, texture, season, or any other account. No other fruit presents so much variation as it does, and "Pari Passu" may be right with regard to the sorts he has mentioned, as regards his locality, but he will allow me to doubt whether he has got some of them true to name. He makes use of the expression that I am a walking mine of extreme optimising power as regards foreign fruit, &c. I do not quite understand his meaning, but may say that our soil is one admirably adapted to the healthy development of fruit trees. He says that I seem to pay small heed to the effect of season. I don't know where he can have ever given cause for such a supposition. He is right about Doyenné du Comice. I hope he has it upon the Quince, if not, let me advise him to get it on that stock. I think, then, he will nearly always have it first-rate. I have grown it as Beurré Robert for some years, and have found it to be about the same. Your correspondent says Knight's Monarch has been "twice A 1" (in how many years?). I have never known it to be otherwise than A 1. I suppose that all good pomologists know, or should know, that when Knight's Monarch was first intended to be sent out a gross mistake was committed, whereby Passe Crassane was sent out instead of the true sort. I believe Mr. Knight would have rather given any reasonable amount of money than that the mistake should have occurred. "Pari Passu" may not have Knight's Monarch true. It is indeed a fruit of which England may well be proud. I do not wish to draw a special line, nor could I if I wished; the variability of the Pear, clime, soil, and situation, all forbid it. Will "Pari Passu" say what a "normal" climate is? I have during my life been in a great many climates, several of them in the same locality, in the same day, but what of them was the normal state I am not philosopher enough to tell. I have been drenched to the skin and have had my clothes almost frozen to the said skin, in one locality, in little less than one short hour; but I suppose "Pari Passu" has never lived in the mountains. Another of his ambiguous phrases is about a Pear accepting "the Chiltern Hundreds." I cannot see any point to it; I think some of our law-makers might do so with advantage to themselves and the country, but how a Pear is to do so is a little *trop* for me. He says he has cultivated 400 sorts of Pears, and I take credit to myself for having produced a list of 120 sorts, out of which a man, with such an extensive acquaintance with sorts, could only pick out so few faulty ones from the list. As to 25 sorts being enough for any "nurseryman who wishes to please his customers," I need only say that I think your correspondent has never been a nurseryman. Again, I am at a loss about "the tale that is all sound and fury." What does it mean? Nor do I exactly know what is meant by my being incorrect in my "ethnology" of "Beurré d'Aremberg, Uvedale's St. Germain, and Gansel's Bergamotte." "Pari Passu" must mean Early Beurré d'Aremberg. Mr. Rivers, I believe, claims it; and although we find it in the South to be rather austere, it belongs to the Estrangulation section. I believe in the North it is considered nearly first-class; it is at least a great bearer. Uvedale's St. Germain is of English origin; see Lindley's "Guide to the Orchard," p. 414. It has for many years been extensively cultivated in France, and especially in the Channel Islands, under the name of Tonneau, and I have brought it several times in the Weymouth market, under the name Belle de Jersey. Your correspondent, I think, alludes to Belle Angévine, and supposes that it is the Uvedale's St. Germain. The fruits are somewhat alike, but the Tonneau never gets to so high and brilliant a colour as does the B. Angévine. As to Gansel's Bergamot, I refer your correspondent to p. 358 of Lindley's Guide. I never heard that it was ever claimed by the French, although they have it under the name of Bonne Rouge, and consider it of hardly second quality, being too astringent. As to Huyshe's Bergamot, I refer your correspondent to Prince of Wales. As the Editor remarks, Thompson's is not an English fruit, and I refer "Pari Passu" to M. Decaisne's "Jardin Fruitier," 1863—4, for its history. I may say that I do not know a more delicious sort, it is a pity it bears so badly upon a Pear stock. It, however, does pay well upon a Quince or double grafted; it is an excellent bearer, and far surpasses Doyenné du Comice in richness. Your correspondent is so palpably at sea about Marie Louise, that in this instance he requires no correction; Broom Park and Bhurmore may be, as "Pari Passu" says, now provided with him: the first with me is always good, and the second often so. Your correspondent is lucky with Gansel's Late Bergamot; of all worthless Pears I think it the most worthless. I will be happy to send "Pari Passu" all the trees I have got of it. Bacon's Incomparable is so well known throughout the country to be good that I need not debate the question. I now come to the most sweeping clause of "Pari Passu's" criticism, where he says, "No amateur should place any faith in foreign catalogues, nor even in an English one, unless it be that of Mr. Rivers, nearly the whole of" "Pari Passu's" (the errors?) "all of which is true." Mr. Rivers should be highly obliged to "Pari Passu" for his great and distinguishing recognition; I could myself drive a waggon and six horses through any fruit catalogue printed in this country—my own amongst the rest. I would like to know your correspondent's name. I do not like fighting a myth, yet I have faithfully tried to correct him, although he has been unable to convince me that he is *au fait* at "Pear" ethnology, &c. *Y. Scott, Merriott.*

——. It is no doubt very hard to decide as to the native places of fruit, and even the great Van Mons has been charged with sending out, as of his own raising, Pears which he received from other people and from other countries. Therefore I speak with great diffidence when I venture to differ with Mr. Scott, who has evidently paid no little attention to the subject. The older writers in botany had no means open to search the authorities, but if one impression of mine was wrong, viz., that "Thompson's" is an English Pear, another seems to be right enough, viz., that Beurré d'Aremberg is of foreign origin. In that beautiful work, "Pomologia Britannica," fol. 73, Hogg truly says:—"This is now duly characterised in the Horticultural Transactions as deserving to be placed at the head of all the Pears in cultivation. We certainly do not know any variety which can, upon the whole, be said to equal it, &c." "It was introduced from Flanders about eight or nine years ago, along with a variety called the Glou Morceau." I cite this because I raised the question, not in contradiction to Mr. Scott, for upon looking at his list again I find that I may have mistaken his meaning, and that he does not quote the old B. d'Aremberg as of English race, but some variety found in England named after the B. d'Aremberg." The distinctive adjective should have been written with a capital letter, if this last supposition of mine is correct. As to the origin of Thompson's Pear, I find nothing in any of my books, but have heard that it was raised in England, and named after Dr. Lindley's well-known syndicutor; finding also no French or German synonym, I believed it to be of English birth. Uvedale's St. Germain (which some would identify with our old Warden Pear, although it is but a stewer), and which appears so regularly in Covent Garden, is the acknowledged by the natives, under the name of Belle Angévine, seems, on the whole, a foreigner. I owe Mr. Scott an apology for suggesting that he omits from the English list Huyshe's Bergamot; he has it under its *alias*, Prince of Wales, but without the name of the raiser. There is already so much confusion in the nomenclature of fruit, that it is most desirable that all pomologists should comply with a suggestion long since made in your columns, and always quote in their catalogues (when known) the name of the originator of any variety worth a name [as Mr. Scott has already done in a supplement to "The Orchardist"]. This would save a great deal of vagueness and uncertainty, and is no more than a patient and skilful originator may fairly claim. As to the orthography of the word "Bergamot," there is a great deal to be said, with

which I will not trouble you; but as it can scarcely be maintained that the word is of French extraction (but either Italian or Turkish), it seems a needless relapse from our usage to encumber it with a French termination. In fine, my object in entering into this discussion was, not to assert the excellence of any English varieties, or to depreciate those of France and Belgium, or any other country, but simply to raise the question, whether we should admit, without thorough test both of excellence and of distinctness, a vast number of new names into a list which seems already too long by a thousand per cent. It has been proved by cultivators that many a newly imported fruit is of high quality for a year or two, and then falls off in our English climate.

"Pomaque degenerant, succos oblita priores."

This happened to me with Prince Albert, Fortunée, and Fondante d'Ingendäel, and several others. Virgil, Pliny, and Columella all complain of the perplexing and wearisome length of the Grape list (which only a man of the name of Democritus ever could keep at his fingers' ends). Pear catalogues are just as bad, therefore I beg all your readers to make much allowance for *Pari Passu*. P.S. Mr. Scott omits from English Pears the well-known Autumn, York, or English Bergamot; and from the Continental list B. Hardy, a grand gain.

——I have been amused, on looking over the list of 120 sorts given by Mr. Scott, who says he has "proved their claim to the first rank," and so it seems has M. André Leroy in his "Dictionary," for he describes the greater portion of them as first-rate at Angers, which, I have no doubt, is quite correct; but as to their quality, when cultivated in England, I fear I must tell a different tale, for most of them have borne fruit in my garden. In my experience, Williams' d'Hiver, Beurré Flon, Napoléon Savinien, Henri Bivort, and some of the others, described in his list as having a claim to the first rank, are not worth much positively. From all that I have seen and tasted I should find some difficulty in selecting 20 from his list as worthy of cultivation in England. As to American Pears the less said about them the better, for 2 or 3 per cent. will be a fair calculation of sorts worthy of culture here. The American bright climate brings out qualities which our cloudy atmosphere fails to do. As regards new Belgian and French Pears their name is legion, and if I pleased I could at once select from 150 to 200 varieties not as yet known in this country. Like new Roses, they amuse an amateur, and if he can be blessed with an early Pear as Madame Treyve or Beurré de l'Assumption out of 50 new Pears, he will be repaid for his trouble. Incorrectness of nomenclature in good English fruit nurseries is almost unknown. Mr. Scott may easily grapple with his imaginary "hydra." He has merely to exercise close observation and couple it with long experience, which, to look at his list, one fears he has not. Williams' Bon Chrétien, when gathered in a seasonable time, is quite A 1. King Edward is not an English Pear, neither is Uvedale's St. Germain, neither is Tillington nor Beurré d'Aremberg. *Bon Chrétien*.

Caterpillars *v.* **Fruit.**—For several years I could never get a single ripe Gooseberry, because green caterpillars were kept down on my bushes, and the fruit dropped off. I tried hot lime, hand picking, shaking the trees at night, and, in fact, every suggestion that was made, but all in vain, until a friend happened to mention "Hellebore Powder" as a certain cure. I tried it, and since then have never missed a crop. I use from 3 to 4 lb. weight of it every year, and the moment my green friends make their appearance the trees are dosed with it, by simply throwing it upwards out of the hand. It is usually done in the morning or the evening, while the leaves are damp. The caterpillars shrivel up, blacken, and drop off, and those which escape at first are poisoned by what adheres to the leaves on which they feed. I have now had six successive crops since I began using the Hellebore, and have never lost a single bush by caterpillars, although I have many hundreds of bushes—I believe, over a thousand. *G. A. H.*

Laxton's Alpha Pea.—My note upon the merits of this new Pea seems to have elicited quite a chorus of dissentients as my conclusions of approval were given; I do not complain, as I asked for practical experience, and no doubt got it. I may, however, take exception to the "Broad Bean" comparison, put forward by Mr. Morgan, as being rather too stiff. Another correspondent says that I am "in error" when I state that Alpha produces but one pod to a stem. As I distinctly stated that I wrote only of my own growth, I trust I may be permitted to give expression to the results of my own growth of Alpha without being esteemed mendacious, and I distinctly state again that with the whole of the produce of the quart of it that I grew, not a single case of double blossom could I detect. If his sample produced twin pods, as he states, I trust I know good manners too well to cast a doubt upon his assertion. As evidence, however, that "all is not gold that glitters," I can quote the evidence of a well-known Irish gardener, published recently in the "Gardeners' Record," who states that he was greatly disappointed with Alpha, and that it fell a long way short of the character he received with it. A well-known gardener in Hants also writes privately his opinion that "Alpha is no good," so it will be seen that I am not alone in my ideas of its merits. I trust that the expressed intention of the Fruit Committee not to grant any more certificates to new Peas until they have been grown for trial at Chiswick will be fully adhered to. A fair, public, and impartial trial of their merits before being sent out may in the future save much disappointment and such discussions as this. It is a step in the right direction, and I should imagine that with the large promise of new Peas that is before us, there will be no lack of sorts for trial. *A. D.*

Bickley's Mode of Glazing.—I cannot understand how the glass is kept tight between the sides of the panes. They seem simply to butt against each other right and left; but glass is not always cut parallel or truly square; if so, how is this joint kept tight? Glass, too, is often not flat; one piece may be slightly bent upwards, the next piece may be flat and straight, and another piece bent downwards. How are all these to fit together, side by side, so as to keep out wet? In the old plan of glazing with putty, the two sides of the glass are bedded in putty, and these inequalities do not signify, as they rest in a bed of putty on the top and down bars on each side; but in fig. 203, p. 943, there are no up and down bars. *G. A. H.*

The Weather at Aberdeen.—A glance at the Table appended will give a general idea of the character of the weather during the first six months of the present year in the Aberdeen district. But two circumstances that tended to intensify the injurious effects of the month of June do not appear from the Table. One is the mean temperature of June was 5° under the average day temperature of June during the last 15 years; and on the mornings of the 24th, 25th, 26th, and 27th, a (verified) thermometer on the grass, in a somewhat position, registered respectively 28°.6, 27°.4, 28°.5, and 28°.6. During these nights much injury was done in low-lying and exposed places; Potatos were quite blackened, young vegetables were nipped, many bedding-out plants were killed outright, and many more were seriously injured.

	Mean Temperature.			Rainfall.		
	Mean 1871.	Mean 15 years.	Difference.	Total. 1871.	Mean 15 years.	Difference.

A. B., Aberdeen.

The Potato Disease.—We are once more face to face with this calamitous visitation. Its ravages are confined to Mr. Earley's neighbourhood, and that gentleman will be as sorry to hear as I am to tell that in West Middlesex it is appearing in all directions. As far as I can gather, no serious results have yet accrued to the tubers; the most visible appearance of it in the haulm here took place last week, since when it has been spreading rapidly in the haulm. Plots of Potatos that look one day the picture of health are on the next day found to be largely marked with the plague spot, and from thence the entire destruction of the haulm, resulting from moisture or chanting out in the heat, is only a question of time. The weather now is very cold, and a large rainfall looks imminent; should it be so, then woe betide our darling Potatos. One scarcely knows what to do for the best, especially where a winter's supply has to be maintained. Market gardeners are pushing their crops upon the market with all possible speed, but at a great sacrifice; they wish to be rid of them as early as possible. Other gardeners are not so situate, and having the knowledge that all the late or keeping kinds are not more than half matured, unhesitatingly lift before lifting them, even with the disease staring them in the face. That early kinds are best got up as speedily as possible there can be no doubt; the sacrifice with them will not be great, but if ering at all it will be on the safe side. I wish to warn everyone not to expose their intended seed stock to the influence of the extreme heat before a month longer than needful this ungenial season. Store them in a dry place as soon as possible—that is the most efficient safeguard that can be adopted. It would be well if this renewed attack of the disease could be the means of once more inducing our scientific men to turn their attention to the operating causes of this visitation, and endeavour to discover wherein lies the fountain-head of the offence. We seem still to be ignorant of its mode of operation in the vegetable growth, whether it originates in the cold in a somewhat too sheltered or exposed position, from the soil into the sap by means of the rootlets, or whether it comes first into the foliage by atmospheric means, and is thence conveyed through the physical system of the plant. We want to know really what the disease is, and how it operates, and this needful information cannot be got for us by means of off-hand discussions, or by the publication of mere assertions. We want the power of enlightened science brought to bear upon the question for its elucidation. This is no Fungophobia sentiment, neither is it one to be settled by the enunciation of a few theological platitudes. It relates to the important subject of the food of the people, and is a question of paramount interest. A week of wet weather may destroy 50,000 tons of Potatos throughout the three kingdoms. Should such a sad calamity ensue, the effects that it will exert upon the labouring classes of the community will be most disastrous; but we may not come to that, let us hope not. Still it would not be too much to ask the natural scieoce teachers and students of the Royal Horticultural and Agricultural Societies, and the British Association, to direct just now, whilst the evidences of the disease are abundant, their energies and experience to the study of the disease and all its concomitants. A hundred recipes for its cure or alleviation have been told to us long since, and they will be again, but they all too much resemble a quack's medicine; for whether applied or whether left alone, the result is much the same. When we fully comprehend the nature of the disease, we may then be better able to apply a remedy. *A. D.*

Bedding Plant Trials at Chiswick.—I notice that several First-class Certificates have this season been awarded to dwarf bedding Lobelias, amongst which are some white ones. Now, white Lobelias, as bedders, have not hitherto been altogether satisfactory, some of them lacking good habit, others constancy of colour—defects not noticeable in plants got up expressly for the Floral Committee, but which are too often revealed when submitted to the ordeal of a summer's bedding-out. Would it not be a matter of general interest to gardeners if a good trial for one season of all good bedding Lobelias, of whatever colour, and whether new or old, could be afforded at Chiswick? And if the granting of certificates to such plants in future were to be consequent upon a successful passing of that ordeal, would not purchasers of these novelties be the gainers? Further, as other classes of plants of considerable attention has of late been called, a trial of which at Chiswick would certainly be a matter of great interest also. I allude to bedding Pansies, including Violas. Some of these are better adapted for spring work than for summer bedding; some for summer only, and others will flower all through the season. To hundreds of horticulturists a trial on a large scale of these interesting plants would be productive of much more pleasure than a survey of the eternal scarlets and pinks of the bedding Pelargonium. Possibly in the future it may be arranged, both with regard to bedding plants and to vegetables, that sections of each may get a public trial at Chiswick in each succeeding year. Mr. Barron might thus be able to do as good service to gardeners, by telling us what to grow and what to avoid, as does Professor Voelcker to the farmers in relation to manures. I only assist, but a little, too, in adding some much needed popularity to the doings of the Royal Horticultural Society. *A. D.*

The Giant Puff-ball.—The Fuzz or Puff-ball sent herewith was gathered from the foot of a large Oak in one of the coverts here by the Earl of Stamford and Warrington, and forwarded by his lordship's request. These, as well as Mushrooms, seem to attain an immense size this season; some of the latter have been sent to me in relation to them. *Bennett, The Gardens, Enville.* [The specimen, which was very fresh, measured 12 inches in diameter. Eds.]

State of Peach and Nectarine Trees.—I believe in many cases the failure of these fruit-trees may safely be attributed to the exhaustion of the soil. Perhaps Mr. Radclyffe's trees have not been planted many years, and also that they were planted in good soil and well drained. I am almost certain the latter point is correct. But there has more to do with the health of his trees than all his attention all the year round at the top. I have had to do with Peach and Nectarine trees in different localities, and under different circumstances over 20 years. I have seen fine trees covering spaces, individually, measuring from 30 feet to 40 feet by 16, carrying yearly immense crops, and continued in perfect health for years, yet under precisely the same treatment as regards the top I have seen them fail and yearly sicken, not from "gross ignorance," but for want of means to supply fresh nutritive soil. Some trees want no more than care of, when first taken in hand, made scarcely any wood; their leaves fell in August, and they produced no fruit. These trees, however, have since for many years never missed in producing a fine crop of fruit, tens of thousands (as has been the case in my own locality) picked off. The trees have also been healthy, and although I cannot copy your correspondent's description exactly, yet I am seldom troubled with any of the blights he enumerates until late in the season, when a little spider will come, so that I very rarely have occasion to use the engine for that purpose. This change was brought about, not by long or short pruning (for I had nothing to prune), but by taking away the soil which had become exhausted, and replacing it with fresh, securing good drainage, which is the best antidote for blighted trees. If the trees are saturated with cold water all through the winter and spring, when the blossom and leaves are unfolding, it is impossible that they can make growth or keep up supplies and nourish the blossom or the young fruit. The system of the whole tree is checked in such a situation, warm days force the top to the utmost of its power, while the

roots are cold, wet, and sour. In such a state the sap comes to a standstill. In seasons like the present is, and has been, when checks are also constantly repeated on the top of the trees as well as at the bottom or roots, the effects of bad root-action are more clearly seen. The exciting influence of a warm day is more than counterbalanced by cold nights; cold wind neutralises all efforts of the top. If the roots were in a comfortable healthy condition, they would push on the top against these odds; instead of that, the whole tree is waiting, as it were, in this enfeebled state for the increase of its adversaries. Blister comes on, the leaves curl, the few winged aphides which the warm sun has brought forth get into those uneven blistered leaves for shelter, and they soon multiply by the thousand, and before the tree has sufficient energy to grow out of reach it is assailed at every shoot by swarms of these pests. The fruit will set, but get little supply of sap, and many will fall to the ground. Now, under good drainage such a state of things is never seen; the roots would be ready to supply the top, and the tree would have made shoots and hardy shining leaves before the insect pest could be ready to pounce upon them; and if they would, they would find little place among the leaves, as in the case of blister. I believe if those two matters were more attended to there would be less complaints of the Peach and Nectarine trees being so blighted. In many gardens the Peach border is stopped more than any other spot in the garden. This is, to my mind, a great mistake. Where this is done, it certainly takes two or more years out of the tree instead of one, but I know in some cases this practice is almost unavoidable; and if your correspondent had to please French cooks, and supply their master with fruit, would have no place for Peach trees, if they did not suffer in other ways as well. I believe Mr. Radclyffe is right in not allowing more wood in his trees than is wanted for the coming year. The more exposure the leaves and fruit have all over the trees the better for both. Insects dislike nothing so much as exposure; I therefore positively advise early disbudding. This destroys in a great measure the means used, especially by the aphis, spider, &c., in affording shelter for propagation. As some thousands of those whom Mr. Radclyffe has accused will not (like myself) be able to go to see his trees, we can only hope he will give us a clue through your columns to the means he uses to prevent his trees—or, to use his own words—"not suffering them" to become afflicted by winter or spring, or aphis or spider. I think we have a right to say to him, after what he has said to us—*Scire facias. Henry Mills, July 7.*

The Artisans' Gardens around Nottingham.—Your admirable description of these gardens made me anxious to visit them. Consequently I was up with the lark on the last morning of the show (Saturday, July 1), and on the road to the Arboretum Hills, the head-quarters of the St. Ann's Horticultural Society. Towards 6 o'clock I found several of the gardeners at work, and from one and all of them received a hearty welcome. Although it was the morning of their great show in connection with the Royal Horticultural Society, and all of them were engaged in getting and arranging their show Roses, they were most kind and courteous, showing me the flowers they intended to take to the show with the utmost openness and frankness. I can safely say that I never saw such Roses before. Nearly half a dole of the plants were dwarfs. To my inquiry, "On their own roots?" "Yes, *now*," was the answer. I found the practice was to graft or bud very low on the Manetti, bury the point of union an inch or two deep, and thus induce the scion to root on its own account. The Manetti was looked upon as a sort of nurse, to induce the rapid increase of choice varieties; but the best blooms were almost invariably cut from plants on their own roots. The foliage was even more extraordinary than the flowers, so large, green, and glossy, without spot. Doubtless, a powerful aid to this perfection of leaf and flower is given by the multiplicity of hedges that surround and subdivide these gardens in all directions; these average from 6 to 7 feet in height, and tower far above the dwarf, or, indeed, any standard Roses seen here; hence the stiff breezes that play around the outskirts are refined down into zephyr-like gentleness before they reach the Roses. Almost each favourite flower again has its little roof of sloping pasteboard to cover its beauty from the mid-day sun's broad glare, and to pitch all heavy rains clean over it, so that the Roses are neither tarnished by friction, their beauty burnt out by the fierce sun, nor their purity spotted with big drops of rain pattering heavily upon their delicate petals. These growers take marvellous care of their favourites, they have a keen eye for insects, and are adepts in the use of shelter; their skill is likewise very special and particular, they know the peculiarity of each Rose, and at one time by swelling or opening buds to a day or hour almost. Their affection for their flowers is unbounded, and the Roses seem to respond to their gentle and loving touch. Is the weather dry?—they water or dew their Roses, the latter by a peculiar process, new to me, which it would hardly be safe to indulge in unless for show Roses. Clean water is taken into the mouth and blown out upon the Roses in an invisible stream of the finest dew, so like Nature's own, that it would take an expert in such matters to tell the difference. It is quite thrilling to see how gently and lovingly hard-handed mechanics handle their Roses. They cut them affectionately, set them up tenderly, and the Roses respond by displaying their full beauty. It is impossible to estimate the effects of this passionate attachment to Roses and other flowers upon character. It softens, refines, elevates, gladdens. On the early morning of Saturday I met a veritable-looking Nottingham "lamb"—the only one I saw. He was a powerful, ill-favoured-looking man; but I noticed he carried a handful of Roses. When we met I congratulated him on their sweetness and their beauty. His whole face lighted up instantly; in fact it was transformed as I smelt his Roses, and he told me where much better were to be seen, grown by others. These were only to take home, not for the show. Surely these Roses, dripping with dew and bathed in sweetness, were veritable messengers of light, laden with blessings to that poor (and he looked very poor) man's home. But these town gardeners put more into their gardens than love and skill. They have boundless faith in manure. The gardens average 400 square yards, and one of these gardeners told me that he generally bought from 4 to 5 tons of manure every year. Four or five tons of manure on 400 yards, that would satisfy Mr. Mechi! All the crops grow, as it were, in dung; the roots find dung above, dung below, dung on each side, dung wherever they go. The consequence is that everything is fed to the full. Pears, Plums, flowers or fruits, are as near perfect as may be. In some of the gardens the Gooseberries seemed to be as great a favourite as the Rose. The largest Lancashire sorts are grown as cordons within 4 and 6 inches of the ground. A few tall Peas or other vegetables are allowed room, to cover them, for partial shade. The surface is mulched with strong muck, the fruit thinned, and where two very large ones grow close together, they are tied apart by threads attached to their corolla, or nose, as they call it. It is thus that the prize Gooseberries are developed into such monstrous bodies of juicy sweetness. Now the perfection of culture is reached on the Hunger Hills—a piece of poor, comparatively worthless, sandy soil, that a few years ago would not have paid for labour and seed. It would do the farmers as well as the gardeners of Britain good to spend a day amid these gardens. If any one wants to know what the earth will bring forth when man feeds it well, attends it lovingly and skilfully, let him go to the Hunger Hills around Nottingham—mark, learn, and inwardly digest the full purport of all he sees and hears there. He will be sure of hearty welcome from the horticulturists. Horticulturists that he will find there swarming like bees. However wise and clever he may have been before, he will return a wiser, and, if he reads his lesson aright, a happier, ay, and a better man. This passion, and it is nothing less, of the artizan for gardening is one of the most hopeful signs of the times. It receives the earnest attention of social reformers and statesmen, and, indeed, of all who care to see the world grow wiser, happier, better. Men absorbed in such pleasing and engrossing pursuits are like seats ticketed with the word "engaged." They have no room and less time for vice, and it hardly aside to find other words. Were all equally well employed, it would find it difficult to entrap any. Every one ought to be able to find a fragment of Eden in his home and his garden, and then fewer would roam after forbidden pleasures. Gardens for the million really mean, in the end, virtue, yes, and I will add, godliness for the million. *D. T. Fish.*

The Produce of a Peach Tree.—Having read in the *Gardeners' Chronicle* of May 19, 1866, a record of the value of forced Peaches, the produce of one tree from 1862 to 1866, both years included, at Roehampton Park, Surrey, I paid a visit to the place on June 25 last, to see how the tree has fared since then, and to my gratification I found it looking exceedingly well. Mr. Davis, the gardener, told me that on an average the tree bore since then as well as before, and gave me the following account of the quantity of forced fruit which it produced, and the sums realised by the sale of the fruit for the last five years:—

Date.	Fruit Ripe.	Produce.	Sum Realised.
		Dozen.	£ s. d.
1867 ..	May 3	393	49 17 0
1868 ..	April 21	59	10 0 0
1869 ..	April 29	84	60 0 0
1870 ..	May 3	8	0 3 0
1871 ..	June 3	74	37 0 0

The total for the past 10 years amounts to 454½ dozen of fruit, which realised the sum of £530, or £53 per annum. In 1870 the tree produced only 5 dozen of fruit, the failure being ascribed to no other cause than over-forcing in previous years. Many gardeners who saw the tree last year advised Mr. Davis to take it up, as in their opinion its constitution was too far exhausted to do any more good, but he determined to give it another chance, and allowed it a longer period of rest. Mr. Davis says, "I commenced forcing it on the 1st of February of this year, and have given it no more fire-heat since than was necessary for the health of the tree and the security of the crop." The well-doing of the tree this year he entirely attributes to sewage water from the house, with which he watered the border once a week during the growth. In the same house, which is 38 feet by 16 feet, Mr. Davis planted a young tree of the same variety (Grosse Mignonne) three years ago, and this year it produced 33 dozen of fruit equal to those from the old tree. *M. O'D.*

Large Carpet Beds.—A bed, such as that of Mr. Cannell at Woolwich, 34 feet long by 11 feet wide, only gives an area of 41½ square yards, which is small compared with many beds of a like kind, for within some 3 or 4 miles of this place, I could point to half-a-dozen or more very much larger. At East Sutton Place and Newton Court are circular beds of 45 and 48 feet diameter respectively, giving an area of 176 and 200 square yards, or four and five times the size of Mr. Cannell's; while our largest bed here is an oval of 90 feet by 67½, from which, however, a grass margin of 3 feet wide has to be deducted: still, it leaves an area of 450 square yards, or nearly 11 times the size of the one you mention, and this bed has been planted carpet (or, as we often call it, embroidered) fashion every season for the last 14 years, as well as two curved beds or borders that adjoin it, each upwards of 80 feet long by 18 wide. Such beds as these places are not uncommon, and I should think the London parks exhibit larger beds than you have described. If my memory serves me right, there is one or more in Victoria Park of more than 42 square yards, and a very neatly planted bed of the kind on an Irish cottage or building in Kensington Gardens that I remember seeing last year, seemed also as large as the Woolwich one. Of the number of plants in Mr. Cannell's bed I have no doubt, as it would give something like eight to the square foot, which is not too many for Alternanthera, Sempervivum, Golden Feather, and such-like. *J. Robson, Linton.*

Foreign Correspondence.

ALLAHABAD: *May* 4.—The new Phalænopsis, from Darjeeling, is showing a flower-spike with me; when it opens I will send it to you. The species I have are *P. grandiflora aurea*, amabilis, Parishii, now in bloom; Cornu-Cervi, rosea, Schilleriana, and the new one. What a magnificent sight that grand lot of Lady Ashburton's must have been. I think myself fortunate if I can produce 10 or 12 flowers. In 1869 there were 24 flowers on my large plant of P. Schilleriana. Last year nearly all my Phalænopsis flowered twice, in April and May, and again in October. I gave a very beautiful spray to Lady Napier a few weeks ago. I only use the Pâu Garden plan for bulbs and seedlings, it is not sufficient protection for Orchids in the North-west Presidency; the hot winds are very penetrating and certain destructive. I have a Pâu house, portable, thatched and tiled, in two places, *i. e.*, two-fifths of the whole roof is removed, and replaced by frames of white cloth (do-soottie), all the sides and entrances are closed in with the same, except the west end, where there are kuskus tatties. The cloth is wetted two or three times a-day, and there is a large open tank inside the house. You would be surprised at the state of the thermometer in this house on the hottest day in May; it seldom rises above 90°, and immediately after watering it falls to 80°, or less.

At the present moment I have the following in bloom:—Phalænopsis grandiflora, aurea, amabilis and Parishii; Aerides Fieldingii, with three fine sprays; Saccolabium Blumei miniatum; Dendrobium macrophyllum secundum, and a pretty canary-coloured one I do not know; Oncidium ampliatum majus, and another; and a number of the Wreath Orchids and Phalænopsis coming on fast.

I do not know much about the American Orchids. Many of the Catteyas I have are looking well, but never show a flower. I fancy their beauty lies more in the excellence of their single flowers, whilst the beauty of our East Indian varieties is their splendid masses of bloom.

I am surprised to hear that the Renanthera is so seldom seen at home. Have you got that beautiful pendent Renanthera, arachnites, in any of the English gardens? I would gladly send home any of my plants which would be rarities in England.

You will have heard that Dr. King has got the appointment vacant by the death of poor Anderson. He is a young man, and a very clever botanist. I visited him when he was in charge of the Saharumpore Gardens. *Samuel Jennings.*

Societies.

ROYAL CALEDONIAN HORTICULTURAL: *July* 13.—Upon the whole, this was the smallest show we have ever seen under the auspices of the Royal Caledonian in the Music Hall. Pot plants, that contribute so much of the furnishing to all shows, were deficient, and what there was of them were by no means conspicuous. The various nurserymen in and around the city do their share,—indeed, but for their united contributions it would have merely been a show of Roses and of fruit. Peter Lawson & Son took 1st prize for a miscellaneous table, and Thos. Methven & Sons 2d prize with plants of a mixed foliage and flowering character. The former firm had a very well-grown lot of variegated Pelargonium seedlings, not of that huge character we sometimes see, but neat, and distinct and uniform. P. N. Fraser, Esq., Canonmills, had a collection of upwards of 80 varieties of the

sporting Harts's-tongue Fern (Scolopendrium vulgare), some of them very beautiful, and all fresh and healthy, and, and captivating. Mr. John Paterson, gr., Millbank, had the best plants in the ordinary competition classes, taking several prizes. One of the most distinct and noteworthy objects in the show was a set of three Ivy-leaved Pelargoniums, grafted on the top of stems of some of the old scarlets. The stem would be about the size and length of a walking-stick, very like indeed in general appearance to an Ash sapling. The grafts had thriven well, and the growths were depending in their irregular gracefulness to great advantage. The Silver Gem, or some variety very much like the one named, was a great beauty, and the set indeed elicited much admiration. They well deserved the special prize voted to them; the grower was Mr. McMillan, Broad Meadows.

Cut flowers of Roses were numerous, by far the best coming from Mr. Hugh Dickson, Belmont, Newtonards. These Irish Roses were in splendid style, —quite as good as is to be seen at metropolitan exhibitions, and showed, from the great disparity of size and condition of bloom, that Modern Athens is either not the climate for perfecting Rose blooms of first excellence, or that the growers in and around its neighbourhood have something to learn before they can take rank with accomplished rosarians. The same were very much the same as we remarked over and over again, and the only special one that we would note as grand in every respect was Paul's Duke of Edinburgh. Mr. Henderson, gr. to John Christie, Esq., Cowden Castle, had a very good lot; and Mr. Marshall's name might also be mentioned as showing well for Miss Hay, of Kingston Grange. All the nurserymen's 1st prizes in all the classes went to Ireland, and the 2d and 3d prize lots were so distant that it would seemed injudicious to place them at all. Messrs. Dickson & Co. had a First-class Certificate for a very dense habited bedding Pansy,—a really good thing, named Regina.

Fruit is always fairly grown in Edinburgh, and there was no exception in this instance. Mr. Temple, Balbirnie, took the principal prizes with a collection of Black Hamburgh and with Duchess of Buccleuch, in a small house for best flavoured White Grape, as well as 1st for best flavoured Black with Muscat Hamburgh. His Hamburghs were quite ripe, the bloom and finish very good; indeed, although the bunches looked a little clumpy, their colour and general style rendered them successfully past 11 other shows, some of them thrice the weight, but red instead of black. Mr. John Laing, Fitcairlie, took 2d place for Hamburghs, and for flavour in the first class. White Grapes were not in the best, but looked magnificent in form and in size. The two 1st prize lots, gained respectively by Mr. John Laing and by Mr. George Greig, were Golden Champion, in quite as good style as we ever saw it at Dalkeith; so that, in practice to the raiser and to the vendors, it must be said that possibly opinions were too hastily expressed against its qualities. Certainly it looked well on the exhibition table, and would have done with better shewn a fortnight hence. Peaches were in very fine condition from Mr. Mackay, Dunse Castle, and from Mr. Kirkpatrick, gr. to Lord Abercromby; while Nectarines, of the Hunge variety, were very fine indeed, and from Mr. Vair, were as fine as we ever saw staged. There were lots of Strawberries of all sorts, prominent among them being Moffat's Duke of Edinburgh, shown by Mr. Anderson, Oxenfoord Castle, in dishes large enough to fill the famous Scotch gill-stoup; it looked a capital market garden fruit, lightly coloured. Vegetables, as usual, were good, Mr. Robert Robertson and Mr. Cockburn showing excellent collections. The day was fine, the attendance not at all what it might have been, looking to the numbers interested in horticulture in the district.

ROYAL HORTICULTURAL OF ABERDEEN: *July* 20.—The summer show of this Society was held on the Links of Aberdeen, in connection with the show of the Royal Northern Agricultural Society. The number of plants, &c., shown was perhaps a fourth or fifth less than on former occasions, but the specimens were in quality fully equal to those sent in to previous exhibitions. The falling off in number is to be accounted for in part by the comparative deficiency on this occasion of large pot plants, but chiefly, we believe, by the character of the season. In fact, the show, though held at the usual time, according to the almanac, was still a fortnight too early from a meteorological point of view. But, notwithstanding this, the exhibition as a whole was a very successful one. Generally speaking, the pot plants were admirable, especially the Heaths, Ferns, Fuchsias and Zonal Pelargoniums. The Fuchsias and Caladiums were also a good show, though scarcely equal to those exhibited on previous occasions. Many of the so-called "new and rare" plants were very interesting and beautiful specimens, especially the variegated ones. Three in one collection were deservably much admired—Yucca quadricolor, Y. filamentosa variegata, and Begonia Pearcei. Among other plants deserving attention, though neither very new nor rare, were a large, well-grown, and richly-flowered Polygala Dalmaisiana, some magnificent specimens of Ferns, the elegant Gleichenia dicarpa, Lygodium scandens, and several fine plants of Thannopteris Nidus. One Fern, named Platycerium superbum (a name, by-the-by, we cannot find in Hooker & Baker's Synopsis, or in John Smith's Ferns) interested us very much, and it is certainly different from any Platycerium we have ever seen. There were also some excellent and well-grown varieties of our native Ferns.

The cut flowers of the amateurs were fully equal in quality, and perhaps superior in arrangement to those shown by the professionals. The specimens of Lilium auratum shown on the table were fine, handsome plants, and most of the Ferns were remarkably good.

Among the cut flowers, the Roses were the most remarkable feature—indeed, they formed the great attraction of the show. We believe we are not overstepping the mark when we say, that so varied and superb a show of Roses was never before seen in Aberdeen; and this arose, not from some exhibitors sending in good stands, but from the fact that, almost without exception, every bloom shown in the tent was in excellent condition. We are glad that the Rose has at last come to the front at Aberdeen shows, and we hope it will long continue. There are many admirers of the "Queen of Flowers" in the district, but somehow or other the Rose has rarely before been a prominent feature in the shows. A firm that has sent in the exhibition year after year Roses of high character, on the present occasion also exhibited three magnificent stands. The other cut flowers shown were remarkably good, considering the character of the season. The show and fancy Pansies were never, we believe, surpassed. The cut Pelargoniums also were admirable blooms; the Pinks and Verbenas were excellent, and altogether the Floricultural was highly creditable. The working classes made a highly creditable display. The Stocks and Antirrhinums they exhibited were very fine; and their Roses, Pinks, and Pansies were, in quality at least, in no respect inferior to those shown by the professionals and amateurs.

Some very pretty bouquets for the table, the hand, and the button-hole were shown; but on the whole we could with help thinking that the taste for making up and arranging bouquets deserves more cultivation than it receives in Aberdeen.

From the backwardness of the season, it was anticipated that the show of fruit would be somewhat deficient, and to a considerable extent it was a failure. The chief exception we must make is the fruit for which Aberdeen has long been famous—the Strawberry, and the display in this case was splendid.

The vegetables were remarkably good, in spite of the unfavourable season. The collections of vegetables were most excellent, and indicated great labour and care in the leading up. We were agreeably surprised to see so large and beautiful Potatos after the damage done by the June frosts. The vegetables shown by the amateurs, though not so various, were in size and excellence quite equal to those shown by the professionals. The table shown by the working classes were rather below the mark—a circumstance which gave us considerable disappointment.

Notices of Books.

Domestic Botany; *an Exposition of the Structure and Classification of Plants, and of their Uses for Food, Clothing, Medicine, and Manufacturing Purposes.* By John Smith, A.L.S., Ex-Curator of the Royal Botanic Gardens, Kew. London: Lovell Reeve & Co. Pp. 547.

The amount of ignorance on the subject of economic botany, or the nature and source of the commonest articles of daily use, which prevails, even amongst those who would be called educated people, is very great. We believe that not more than one person out of every hundred of the middle-class population would be able to answer questions satisfactorily as to what plants yield—let us say tapioca or sago, and from what part of the plants, and how the substances in question are obtained. Nevertheless, we believe that economic botany is more important than any other department in Kew, the food collection at South Kensington, together with similar institutions, have done much to show to the thinking portion of the community the importance of this branch of science; and we are glad to find that the author of the work before us has in his preface pointed out the desirability of "a general and complete work on this subject."

"Domestic Botany," as will be seen from its full title, which we have quoted above, is not confined entirely to economic botany, the first part being devoted to an "explanation of the structure, properties, uses," &c., commencing with Cryptogams, and proceeding to the higher organisations. Each order is placed with its relative order, or orders, under its own alliance, according to the system of Dr. Lindley, in the "Vegetable Kingdom." Then follows a short description of the character of the plants comprising the order, the number of species, and their geographical distribution, concluding with an enumeration of those plants which are either useful or are well known in gardens or hothouses.

Mr. Smith tells us that "the purpose of this work is to enable the botany to those not conversant with Greek and Latin;" and it is evident that another, and perhaps the chief purpose, is to impart a knowledge of and taste for applied botany.

We cannot help thinking that, bearing in mind the numerous introductions to botany that are in existence at the present time, and even since little more than amongst the most recent—and also bearing in mind the absolute want of a good work on Economic Botany, it would have been far better if the whole volume had been devoted to that branch of the science; and even if this had been done, the subject is so large that it would be far from having been exhausted. Mr. Smith's greatest difficulty must have been in deciding what to say and what to leave unsaid. It is much more trying to an author to have to squeeze into a small space a large quantity of important matter, than it is to enlarge upon any given subject. The necessary consequence of this *embarras de richesse*, and the restriction of space to bring the book within its present bounds, is a much too short notice of many important plants. The author has, however, been careful in his selection to bring together a great many species, some of which must needs, in point of space, give place to others having a greater claim.

The work is illustrated by 16 coloured and tinted plates by Fitch, each plate representing the characteristic plants of one or more orders, as well as groups of plants of similar habit, as, for instance, that devoted to the pitchers of Nepenthes, Sarracenia, Cephalotus, and Darlingtonia, which plate forms the frontispiece. Woodcuts are also inserted to exemplify the various botanical terms.

Before concluding our notice, we must say a few words about the index. We think it is a mistake to have given references only to the natural orders and common names of the plants. Thus, we find Leguminosæ, but we look in vain for the name of any genus in that large order, without the generic name happens to be the common name likewise: so we find Judas Tree, but not Cercis; Crab's-eyes, but not Abrus; Cow-itch, but not Mucuna, &c. It is well, indeed necessary, to have vernacular names in an index to a book of this description, but the addition of the scientific names would make the book more useful for reference, and would accommodate all readers, scientific and unscientific alike. The addition to the size of every genus named in the index would of course have somewhat increased the number of pages, but we think such increase would have been fully compensated, and we hope the addition will be made in a future edition.

It is a pity that the work should not have been more carefully revised. The author's experience is so extensive, and his knowledge so great, that the reader will the more regret the infirmity which has prevented him from exercising that careful superintendence which he assuredly would have exercised under happier circumstances.

On the whole, we may state that the book contains a great deal of valuable matter, and much information that scarcely any one but Mr. Smith could give us. A thoroughly good manual of Economic Botany, however, remains a desideratum, and we know not where such a manual could be better drawn up than at Kew.

—— From the annual report of the *Royal Society of Arts and Sciences of Mauritius* we learn that a fine butterfly (Papilio Demoleus) has recently been seen in considerable numbers in Mauritius. Its interest, however, as the insect is a native of Madagascar and Natal. Another Madagascar species, Junonia Rhadama, has also made its appearance in the island; while several other butterflies, *e. g.*, Vanessa Cardui, which were common 30 or 40 years since, are becoming scarcer and scarcer. The Lepidopterous fauna of the introduced Lepidoptera is a fact worthy to be placed among those collected by M. Albert Müller, and alluded to at p. 901. We are also told that several plants introduced into the colony have increased with such rapidity as to vigour that in certain parts of the island they have covered the soil and the borders of the forests to the prejudice of the indigenous plants, which seem to be daily losing ground before them. One such introduction to St. Brandon, a neighbouring island, is the Entada Pursætha, the seeds of which have been largely distributed by currents.

The same report contains some information from Sir Henry Barkly, the late Governor of Mauritius, and whose communication to the Linnean Society on the Flora and Fauna of Round Island, last year, excited so much attention. From this communication it appears that the number of reptiles found in that island is much less in point of species than was at first supposed; nevertheless the island has a genus of snake of which no other species is known, and whose nearest congener, according to Dr. Günther, is only found in Lord Howe Islands, in the South Seas, while the common lizard of the island is peculiar to its own shores and to distant Madagascar, and is not in existence either in Mauritius or Bourbon, close by.

—— A third edition of the Rev. J. Fountaine's pamphlet on a *New Method of Growing Fruit* (Swaffham, Farr) is before us. As will be remembered, the method is one advocating the growing of fruit in circumstances do not permit of their being kept distinct, of a vinery, orchard-house, and conservatory, and in which Grapes, stone fruit, and flowers may be grown together in perfection in the same house. This is accomplished by growing the fruit trees, &c., in pots, sunk in holes in the surface of a truck which runs on wheels over railway metals. In this manner the plants can be taken out for an airing, and returned when necessary. In summer time the Peaches and Nectarines are forced under cover during the day, and run out in the evening, the radiation at night being thought to enhance the flavour of the fruit. How radiation does this it were difficult to say, but no doubt the rest, or rather the change of work in the plant, consequent on its exposure to the cool night air, is highly beneficial when judiciously managed. Even human beings would be better for having their bed-room windows open summer and winter under proper regulations.

—— Dr. George Bennett has lately issued a paper on the *Introduction, Cultivation, and Economic Uses of the Orange, and others of the Citron Tribe, in New South Wales.* The author has got together a great deal of information concerning these plants; and some relating to the disease of the Orange tree is new to us in this country. We may take an

opportunity of alluding to this subject at greater length hereafter.

—— Mr. G. W. Yapp, a gentleman well qualified for the task he has undertaken, has just published a *Popular Guide to the London International Exhibition of* 1871 (Johnson & Sons), which we recommend intending visitors to peruse before paying a visit to the Kensington labyrinth.

—— Dr. Ferd. v. Mueller has recently published a very useful report on the principal *Timber Trees* readily eligible for industrial culture in the *Colony of Victoria*, with indications of their native countries, and some of their technologic uses. The list comprises nearly 160 coniferous trees, and an almost equal number of miscellaneous trees.

—— Amongst New Publications we have received the following:—*The Horticulturist*, by J. C. Loudon, edited and revised by William Robinson (F. Warne & Co.).—*Kelly's Post Office Guide to London* (Kelly & Co.).—*Explanatory Mensuration*, by the Rev. Alfred Hiley (Longmans).— *Handbook of the British Fungi*, Part II., by M. C. Cooke, M.A. (Macmillan).

Florists' Flowers.

I have just returned from a tour in the West of England, and being a great admirer of the Gladiolus, as well as an amateur cultivator of this beautiful flower, I availed myself of the pleasure of visiting the nurseries of the renowned growers, Messrs. Kelway & Son, of Langport, Somerset. I will not attempt a description of the nurseries, which are well kept, and contain most of the new, as well as old, kinds of florists' flowers, nursery stock, &c.; but I wish to note the extent and mode of culture of the Gladioli adopted by the Messrs. Kelway, who have deservedly gained some notoriety in this particular branch of culture, carrying off as they do many first prizes at the London and other exhibitions.

The soil I found to be a mixture sandy clay and gravel, about 2 feet deep. The situation is open and exposed to the west and north-west winds. Upwards of 300,000 bulbs, comprising 2000 named sorts, are planted, exclusive of seedlings, the latter being also very largely grown. The planting is commenced in February, and continued at intervals of a fortnight until May. Those grown for exhibition are planted in rows from 18 inches to 24 inches apart, with a broader space at every second or third row, to allow for a narrow path; the ground being previously trenched 2 feet deep When the plants have attained about a foot in height, the soil has a good mulch of half-rotten manure; and as soon as the spikes show for bloom, a liberal supply of manure water made from a concentrated manure which they have prepared for the purpose, is applied. Unfortunately I was too early to see many blooms, but from the extraordinary substance of hundreds of the plants we may anticipate a great show at their forthcoming exhibitions at South Kensington and the Crystal Palace. I ascertained that the Messrs. Kelway intend staging 100 spikes at the International Exhibition, South Kensington; these will be renewed and displayed during the latter part of August and the early part of September. I observed that the bulbs after arrived at maturity are planted from 3 to 9 inches apart, in beds about 5 feet wide. The spawn or bulblets are all grown in the open air, in pots, during the first year. I saw many thousands of these, each variety carefully kept apart and numbered.

I need but say that this visit proved very pleasurable to me; and I hope I may profit by what I saw. Upon my return home, I felt very dissatisfied with my own culture of the plant; and I was further led to reflect that floriculture is deeply indebted to the Messrs. Kelway for the wonderful advance which they have helped to bring about in the growth of the Gladiolus. We have only to compare the old varieties with the new to see this. The elder Mr. Kelway has devoted very many years to the culture of the plant, and the raising of seedlings is a study with him. I am quite convinced that if his valuable life and that of his son be spared, they must produce many more marked improvements in this lovely flower, which every one can and should grow. Monsieur Souchet is held in high estimation, and properly so, as a grower, and more especially as a raiser of seedlings of the Gladiolus; and so also should be the Messrs. Kelway. One only regrets that the lamentable war between France and Germany at once prevented the great international exhibition of Gladioli, which was to have taken place at South Kensington last autumn. We lost a golden opportunity of comparing notes and of placing our two distinguished Englishmen in rivalry and contrast with our Continental neighbours. As regards seedlings, the Messrs. Kelway will recognise nothing but that which is of the highest standard. *F. W., Croydon.*

The Apiary.

Endosmosis, or Feeding the Bee Larvæ.—I have to apologise for having taken up so much space to describe a simple fact in natural history—that the bee larvæ grow by absorption of the honey and water, or bee pap, which any bee-master may prove during the summer months by a little close inspection, remembering that 12 hours in the night is a life-time for bee metamorphosis.* If the eggs be seen laid by the queen bee in the cells, a simple mode of inspection of the interior of these cells will be, by attaching "tale," in slips, along one side of a series of hexagons, cutting out the intervening cells or sight-obstructing sides. These adjusted combs and cells should be fixed at proper positions in a common observatory hive, or two "bar frames" and combs, may be treated in the same way, in a glass case, which may be made for these experimental purposes. For an absorbing coloured material, sugar, honey and water with a grain of madder makes the most harmless ingredient. The best brush for moving larvæ or eggs will be found in the pinion feather of a woodcock, fixed in the end of a porcupine's quill. Distilled water had better be used in removing eggs or the larvæ for the microscope. The brush takes up the moisture too freely, whilst the feather is a soft-edged scoop not holding the water. With regard to the pollen feeding, or its being used as a forcing hotbed in queen or worker brood raising, it is not my intention to enter upon this subject, as I shall therefore take leave. I am quite ready to accept the term proposed by two of my medical friends, viz., "osmosis," nourished by absorption, and not feeding until the last stage of growth; and wish also to record my objections to the accepted notion of the eggs being "fertilised" "that the spermatozoa which are found at the top of the egg, and seen on it;" whilst, if these filaments are deposited with the eggs, the base with its fluid is the point of entrance of the spermatozoids. But the proof is wanting that the eggs may not have already been fecundated in the mouths of the ovaries; and that "parthenogenesis," as it is the honey-bee is concerned, would be difficult to prove with all the voluntary muscles in the bees's abdomen, or any pressure of the sides of the cells that might be brought to bear on the oviparous worker bee. I beheld with the most accurately described the spermatozoa, as found attached within the egg to the superior pole of the egg, when the egg has been ruptured at the lower pole to discharge the yelk; but we are apt to jump to conclusions as to time in these most minute investigations, when we have simply taken the statements of careful and earnest physiologists; and thus when we see the spermatozoa at one time described as active, and at another as motionless filaments, we have forgotten the succession of time at which these eggs were laid, and have forgotten to examine whether the absorption of the fluid, the oviparous worker bee, is beheld in

vexed question for the first part of the best pot Vines have been grown with bottom-heat, or at least in a root-temperature equal, very often considerably in excess of, that of the top. *F.*

STATE OF THE WEATHER AT BLACKHEATH, LONDON,
FOR THE WEEK ENDING WEDNESDAY, JULY 26, 1871.

| 1871. MONTH AND DAY. | At 9 A.M. Reading of | | | | | | | Hygrometrical Deduction from Glaisher's Tables, 5th edition | | | | | | |

chances are that the cutting will decay. When taken off they should be potted into dry, gritty, open soil, or they should be partially dried by being laid by on a dry shelf for a week or 10 days. I generally put three or four cuttings into 2 or 3-inch pots, according to the size of the cuttings. The soil used for this purpose is composed of three-fourths of road grit, with the remainder mellow loam, charcoal, and lime rubbish, all tolerably fine. The cuttings being of a very succulent nature, they should not be placed in a humid atmosphere, but on a dry shelf in some warm and airy house, where they can be kept tolerably dry. This treated, they will be found to emit roots in a very short time, and may be potted singly into small pots, using plenty of drainage, such as charcoal or old mortar. As the plants grow they must be shifted into larger pots, using the soil somewhat coarser at each successive shift, and giving abundant drainage; this is essential, as the plants, although required to be liberally watered when growing and blooming, require that the water should percolate freely, and dry off quickly. One or two waterings during the flowering season with weak manure water will assist the blooming materially. During the dormant months of winter very few waterings will be necessary. As regards tying and training, the plants may be made to assume a variety of forms according to the taste of the cultivator. If large plants be the object, liberal shifts, with a higher temperature than that of a cool greenhouse will be necessary, especially as under the pot could be plunged in a dry, half-spent tan or bark bed. The soil, too, may consist of a small portion of peat, chopped up, but not too small, and of very old thoroughly-decomposed cow-manure, added to equal parts of good fibrous loam and road grit, which is for the most part of a siliceous stone. The season of blooming can be prolonged by removing the plants into a cool house, and well shading them from intense sun-heat. Should they become at all sickly, and the soil about the roots sour and stagnant, they may be carefully shaken out of the pots, and repotted into smaller pots, the shoots being pruned in proportion, and the whole subjected to the treatment advised for plants when rapid growth is desired. In such cases it is necessary to be careful and judicious in the application of water. *F. K., in "Florist and Pomologist."*

THE RED CLOVER, which is now naturalised in many parts of the United States, was introduced into general cultivation in Chester county, Pennsylvania, between the years 1790 and 1792, the price of the seed at that time being 1s. 6d. per lb. It was introduced, according to Watson's "Annals of Philadelphia," Bartram had fields of it before the American revolution. The white Clover, which is very generally distributed in the States, may also have been introduced, although it was observed by the roadside, and recorded as early as 1719.

It is too vast a genus we cannot pretend to identify species unless information as to their habit and habitat is supplied. But your Dendrobe is a poor thing.—*A Subscriber.* The common yellow Viscum europæum.—*Devon.* Ficus thus ruber.—*H. M.* 1, Agrostis vulgaris; 2, Avena pubescens; 3, Aira caryophyllea.—*W. E.* 1, Some Chara, we cannot tell the species; 2, Myriophyllum, probably M. spicatum (no flowers).

PEACH TREES: *W. Stevens.* The condition of your Peach tree is exactly like what has been submitted to the Scientific Committee of the Horticultural Society several times earlier in the season. It is very difficult to suggest the cause without personal inspection. You should remark whether the tree is exposed to sudden changes of temperature or to drip from above, which is quite able to produce such an effect. The foliage seems over-luxuriant. *M. J. B.*

PRIZE MONEY: *W. C.* It is, we believe, the rule of the London societies to pay the prize-money, at the end of the season, to the person in whose name the entries and the exhibitions have been made.

ROSE FUNGUS: *A Northern Reader.* Your Roses are attacked by a parasitic Fungus, Coleosporium pingue, which is so prevalent this year that it is hopeless to attempt its destruction by picking off the leaves and burning the shoots, which is the usual remedy. *M. J. B.—P. H.* The Fungus on your Rose leaves is Aregma mucronatum. We know of no remedy. The yellow Fungus is merely a peculiar condition of the same species. *M. C.*

SEEDLING CHERRY: *Geo. Rawlings.* We cannot see that the seedling Cherry differs in any respect from the Morello. It is too acid for cultivation as a dessert fruit.

SYRINGING CATTLEYAS: *R. C.* Not in the growing season.

VASCULUM: *A Young Botanist.* Capital boxes of this kind are made by Mr. James How, 2, Foster Lane, Cheapside, E.C.

VINES AND MILDEW: *D.* Your Vines seemed to be but slightly affected with this pest. We can only advise you to persevere in the application of sulphur, and to employ a suitable amount of fire-heat to enable you to ventilate thoroughly and constantly.

CATALOGUE RECEIVED.—William Rollisson & Sons, a General Catalogue of Plants, Trees, and Shrubs.

ERRATA.—There are two or three errors in my letter on "Caterpillars and Fruit Trees," at p. 942. "*Ctisiocampa* Neustria" should be *Clisiocampa*; Hyborna should be Hybernia; Nematus should be Nematus; Trochilama should be Trochilium. *H. Harpur-Crewe.*

COMMUNICATIONS RECEIVED.—F. C.—W. S.—Mr. C.—C. H. D. T.—J. B. S., Jersey.—F. H. G.—N. C.—W. T.—R. D.—F. W. B.

Markets.

COVENT GARDEN.—July 27.

A fair amount of business is doing here in most of its branches. The northern markets still take a considerable quantity of soft goods, which have been better in quality the last few days. We have heavy importations, chiefly in Apricots and Plums. Hothouse Grapes are now very plentiful, and the price rules low. No improvement can be noticed in the demand for hothouse Pines, which are more plentiful than they have been for some years; the fruit is, however, still large, well coloured, and good. In the Potato market there is a fair average supply, principally from Kent, very few indeed coming in from the Channel Islands, the disease being so bad there.

Land Wanted, near London.

WANTED, a FEW ACRES of rich, productive GARDEN GROUND, within a circle of 30miles of London.—Apply to A. B., 68, Welbeck Street, Cavendish Square, London, W.

TO BE LET, GARDENS, PINERIES, VINERIES, and PEACH HOUSES, well stocked, and fitted up with the latest improvements, extending over one Cheshire acre of land, of which one-fourth is covered with glass.
E. LLOYD WRIGHT, Esq., Wigan.

TO BE SOLD, the BUSINESS of a SEEDSMAN and FLORIST, with Jobbing Business, in a first-rate position, and doing a good trade. This is a splendid opportunity for any person in want of the above, and to be sold cheap.
A. B., 227, Brixton Road, London, S.W.

TO BE LET, ELM COTTAGE, Taunton.—The Garden attached to this complete Residence is full of choice Plants, Shrubs, and Trees, collected by the late Mr. John Young. A Tenant who would preserve the collection would be preferred. A good Kitchen Garden, Coach-house, and Stable attached.
Apply to W. YOUNG, at the above address.

FOR DISPOSAL, with immediate possession, a small first-class NURSERY and SEED BUSINESS, in the West of England, in good working order. Satisfactory reason for present Proprietor retiring, and every facility will be given for a thorough investigation, as it is a genuine concern. Full particulars of
A. W., Messrs. Hurst & Son, 6, Leadenhall Street, London, E.C.

FLORIST'S BUSINESS FOR SALE, in the improving Town of Hampstead. The Stock-in-trade, Seeds, and FRUIT TRADE (capable of great extension), is connected therewith. The Premises are held on Lease at a moderate Rental, containing Houses, 30 large Lights for Frames, and every requisite. About 1600 square yards of Ground, with a substantial brick wall on three sides and palisads in front, an opportunity like this is rarely presenting; Man seldom occurs. Satisfactory reasons for leaving.
J. W. BAINES, Florist, Leicester Road, Uppingham.

Important to Nurserymen, Florists, and Others.

TO BE DISPOSED OF, by Private Treaty, the LEASES, with possession, of the old established and well known CHISWICK NURSERIES, comprising a substantial ve neered Dwelling-house, Shop and Counting-house, Packing-shed, Cottages in occupation, 12 Greenhouses and several ranges of Pits heated by hot-water piping, with the whole of the choice Stove and Greenhouse Plants; also about 12½ acres of rich and productive Land, cropped as the Nursery Stock may require. Held under Two Leases at low rents. The whole to be sold as a fair valuation in the usual way.
For further particulars apply to Messrs. PROTHEROE AND MORRIS, Auctioneers and Valuers, Leytonstone, E.

In one of the finest and largest Towns of Germany.

TO BE SOLD, on account of the illness of the Proprietor, a very extensive HORTICULTURAL ESTABLISHMENT, consists of a fine comfortable Mansion, good Stables and Coach-house, standing in a very tastefully laid-out Garden, whilst other parts of the ground are reserved for Horticultural purposes. There are several fine and extensive Houses for the Culture of Stove, Warm and Cool Greenhouse Plants. A splendid Palm-house has been built quite recently, and a new Heating Apparatus of the most perfect system, laid in all Houses, has just been finished. The whole would be well adapted for an Amateur, as well as in the Market, at the same time so as the name of the present Proprietor enjoys a just reputation, and the Business is carried on in the highest style of the profession.
For further particulars address (prepaid) F. G., *Gardeners' Chronicle* Office, W.C.

SALES BY AUCTION.

THOMAS AND GEORGE HARROLD are honoured with instructions from the Executor of the late Thomas Coudley, Esq., Bosworth House, Hinckley, to SELL by AUCTION, on TUESDAY, August 8, the whole of the valuable COLLECTION of STOVE and GREENHOUSE PLANTS, and a quantity of CUTTING and SUCCESSION PINES, &c.
Particulars in Catalogues, to be had of the Auctioneers, Castle Street, Hinckley.

Farnley Hall, near Otley.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions from the Executors of the late Francis Hawksworth Fawkes, Esq., to announce that the SALE of the entire and far-famed FARNLEY HERD of PURE-BRED SHORTHORNS will take place on TUESDAY, August 1 next, being the day previous to the Yorkshire Agricultural Society's Meeting at York, and will consist of 56 Head of Bulls, Cows, and Heifers, that have been long and carefully bred, and maintained in high position at the various Meetings of the Royal Agricultural Society of England, and the Yorkshire County Shows.
Catalogues, with Pedigrees, may be had on application to Mr. SCOTT, Farnley Hall, near Otley, Yorkshire; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Duncombe Park, Yorkshire.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions to announce for SALE by AUCTION, without reserve, at Duncombe Park, Helmsley, on THURSDAY, August 10 next, some very superior PURE-BRED DURHAM BULLS, and a selection of COWS and HEIFERS, the property of the Right Hon. the Earl of Feversham, which have been bred from the best Shorthorn blood and most fashionable sorts. Bulls of distinguished character have been used, principally of the Kirklevington blood.
Catalogues, with Pedigrees, may be had on application to Mr. MCLAUGHLIN, Duncombe Park Estate Helmsley; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Buckland, near Faringdon.

IMPORTANT SALE of SHORTHORNS.

MR. STRAFFORD has received instructions to announce that the ANNUAL SALE by AUCTION of PURE-BRED SOUTHDOWN SHEEP, belonging to Mr. William Townsend Borton, Burt, will take place at Buckland, near Faringdon, on FRIDAY, August 25 next, when 80 Lots consisting of 30 Tups and 50 Shearling Ewes will be offered, a few of which will be let for the season; among them will be found the splendid Prize Rams at the Royal Show at Wolverhampton.
Catalogues, with particulars, may be had on application to Mr. GEO. WILLIAMS, at Buckland, near Faringdon; or of Mr. STRAFFORD, 13, Euston Square, London, N.W.

Bulbridge Farm, Wilts,

Ten minutes' walking distance from Wilton and South-Western Railway Stations at Wilton.

ANNUAL SALE and LETTING of RAMS and EWES of the IMPROVED HAMPSHIRE DOWN BREED.

MESSRS. EWER and WINSTANLEY will SELL, on the Premises, Bulbridge Farm, Wilton, near Salisbury, Wilts, on WEDNESDAY, August 2, at 1 o'Clock (Refreshments at 12), about 140 RAM LAMBS and RAMS, of the improved Hampshire Down Breed, the property of Mr. James Rawlence.
Mr. Rawlence has been awarded during the present year Five Prizes for his Specimens at the Bath and West of England Agricultural Show at Guildford, at the Royal Agricultural Show at Wolverhampton (2 Prizes), and at the Salisbury Meeting of the Society, for Pen of Ram of any age, and First and Second for Shearling Ewes; and his well-known Specimens of Rams at the Royal Show at York have been further awarded comment from the Auctioneers unnecessary.
The Farm adjoins the South Western Railway will stop at Wilton Station on the day of Sale.

Model Farm, Upper Winchendon, Bucks.

Seven miles each from Aylesbury, on the London and North-Western Railway, and from Thame, on the Great Western, nine miles from the Quainton Road Station on the Aylesbury and Buckingham Line, at the Junction of the Railways, conveyance to and from the Morning Trains, returning in time for the Evening Trains.

MR. JOHN TREADWELL has fixed his ANNUAL SALE by AUCTION, at the Premises, SPEAKING RAMS, and a few OLDER SHEEP, for WEDNESDAY, August 2, a half-past 2 precisely, when a Choice Selection is expected to be favoured with the Company of his Friends. The Sheep this year have all been bare shorn, are very big, and full of Wool, although darker in colour than usual.
N.B.—This Flock has obtained during the past four years Forty-four Prizes and Commendations, including the First and Five Pens of Ewes at Oxford, Birmingham, and London; and this year First for Shearling Rams at the Royal Agricultural Show, Seven Prizes at Wolverhampton, and at the Bath and West of England Show at Guildford, including Extraordinary.
J. A. MUMFORD, Auctioneer, Chilton Park, Thame, Oxon.

Important Sale of Pure-bred Shorthorns at York.

MR. JOHN THORNTON will SELL by PUBLIC AUCTION, at the Show Ground at York, on THURSDAY, August 3 (the week of the Great Yorkshire Society's Meeting), and a Pure-bred Shorthorn Sale at Carlisle, August 10 next, about FORTY very superior SHORTHORNS, from the Herd belonging to the Rev. J. D. Jefferson, of Thicket Priory. Among them are some first-class animals by the Grand Duke, Lancaster, Lord Lieutenant, and other fashionable tribes. Duke of Waterloo (21,626) and Lord Waterloo (24,247) are the Sires of the majority of the produce intended for this sale. The stock, which consists principally of young animals, including several Bulls, is very promising.
Catalogues, with Pedigrees, may be had of Mr. BEARLAND, at Thicket Priory, York; or of Mr. JOHN THORNTON, 15, Langham Place, London, W.

THE LANDS IMPROVEMENT COMPANY.
(Incorporated by Special Acts of Parliament.)
Drainage, Reclamation, Farm Buildings, Labourers' Cottages, &c.
DIRECTORS.

John Clutton, Esq.
Frederick L. Dashwood, Esq.
Thomas Farmer, Esq.
Lord Garlies, M.P.
John Gilbert Lloyd, Esq.
Granville R. Ryder, Esq.
Granville R. H. Somerset, Esq., Q.C.
Henry W. Tancred, Esq.
Charles Watkin Williams Wynn, Esq., M.P.

The Company advances money, unlimited in amount, for all purposes of Agricultural Improvement, including the Erection of Cottages and Farm Buildings, to the Owners of settled and other Estates, and to the Clergy in respect of their Glebe Lands.
Tenants, with the consent of their Landlords, execute the necessary Improvements upon the Farms which they occupy, charging them with the cost.
UTILISATION of SEWAGE.—The Company also advances money for the Utilisation of the Sewage of Towns.
The whole outlay and expenses are liquidated by a rent-charge upon the land, redeemable principle and interest, over 25 years.
No investigation of title is required.
For Forms and further information, apply to GRANVILLE R. RYDER, Parliamentary Director, No. 1, Great George Street, Storey's Gate, Westminster, S. W.

Agricultural Land Improvements.

DRAINAGE, SEWAGE, FARM BUILDINGS, LABOURERS' COTTAGES, &c.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY
(Incorporated by Act of Parliament in 1849.)
DIRECTORS.

T. Chapman, Esq., F.R.S.
George Thomas Clark, Esq.
John C. Colthurst, Esq.
Henry William Currie, Esq.
The Right Hon. Viscount Combermere.
Edward John Hutchins, Esq.
Sir William Tite, M.P., C.B.
Thomas Wilson, Esq.

Agricultural Improvements of every kind are executed by the Company, or the outlay thereon repaid to Landowners who prefer carrying out the works by their own agents.
Tenant Farmers may also, by agreement with their Landlords, procure the execution of such Improvements.
The outlay, with all official expenses, may be charged upon the Estate, and paid by a Rent-charge of Interest and Sinking Fund, in 25 years, or at the option of the Landowners in a shorter term.
No investigation of title necessary, and no legal expenses incurred.

UTILISATION of SEWAGE.
Special arrangements will be made with Boards of Health, Sewer Authorities, and others, for undertaking Works of Sewage Irrigation, together with all Works incidental thereto. The outlay in respect thereof may be repaid either by a sum in gross, or by a terminable yearly payment, discharging in a fixed period the principal amount with interest thereon.
Applications to be made to ARTHUR MILMAN, Esq., the Secretary, at the Offices of the Company, 22, Whitehall Place, S.W.

MANCHESTER and LIVERPOOL AGRICULTURAL SOCIETY.—Prize Lists for the Show at Liverpool in SEPTEMBER NEXT may be had on application to the Secretary. Upwards of THREE THOUSAND POUNDS are offered in PRIZES, including £300 for the best Horses, £80 for the best Shorthorned Bull, upwards of £200 for Dogs, £250 for Poultry, upwards of £80 for Pigs, and £200 for Sheep. ENTRIES CLOSE AUGUST 1.
Winsford, Cheshire. THOMAS RIGBY, Secretary.

MEETINGS FOR THE ENSUING WEEK.

Aug. 1 } Annual Meeting of the Royal Agricultural Society of
to } Ireland, at Dublin; and of the Yorkshire Agricul-
Aug. 3 } tural Society, at York.

HINTS on SNATCH CROPS and double green crops can hardly come amiss when beef is *10d.* a pound; and if the subject has no longer the attraction of novelty, it possesses a still more substantial interest from the pecuniary advantages that are reaped by increasing the green crops of the farm.

We fear the present season will be late and unfavourable for sowing snatch crops on stubbles, and we do not propose to repeat what has been often urged in reference to growing Trifolium, Turnips, Tares, Rye, &c., on stubbles, previous to next season's Turnips; but as we are likely to be disappointed in these crops, except on the earliest and most favourable soils, we propose to call attention to the cultivation of the Cabbage, to be grown on next year's fallow as a snatch crop, followed by a succession crop of Cabbage, or transplanted Mangel, or Turnips.

There are two ways of managing—1st, sowing now, *i.e.*, in the first week in August, and transplanting in the field in November; 2d, sheltering the plants in seed-beds during the winter, and transplanting them early in spring.

The first is the garden plan for early Cabbages, to heart in May and June; and where there is no longer from game it is to be preferred. The second is the safer plan where there are rabbits or hares, but the crop will not be ready for folding before June and July, and cannot then be followed by anything more useful than Turnips. In both cases the Cabbages are a manuring and cleaning crop. They must themselves be well manured; and they introduce fatting tegs, cake, &c., on the land and prepare it for the second green crop, will be folded or removed. We know of no other method by which 50 or 60 tons of green food may be grown in a year by ordinary farming, and the land improved at the same time.

With regard to the details of cultivation, if the Cabbages are for early folding, an early sort should be sown, unless you sow a large hardy kind, or the Thousand-headed Cabbage, in spring, and transplant them after Tares, early Peas, Potatos, &c., in which case they will be ready for the ewes and lambs, and may be followed by a root-crop, if it is desired to give the land the benefit of a double green crop. Returning, however, from this digression; for the early sort the land should be in good heart and tillage, and dunged and ploughed in November, and the plants set at 30 inches by 2 feet. At this distance the number of plants required will be 8712 per acre; the quantity of seed will be 1 lb. if it be good, and it should be sown thinly in the seed-bed. As soon as the weather permits, in spring, the plants should be well hoed to encourage their growth.

The same general rules will apply to the growing of Cabbages at the other seasons, except that the larger varieties may be planted a yard by 30 inches apart, and only 5800 plants will be required for an acre of land.

With respect to tillage we hesitate to give rules for the preparation of the land. The Cabbage, if planted in spring, requires the same tillage as would be required for Mangel, and if planted in summer and autumn it requires similar tillage as for Turnips. The reader will determine the points of cultivation according to the character of his soil. There is, however, one

rule we may mention: dung should not be ploughed under with a furrow exceeding 5 inches, or perhaps 6 inches, in depth. The nearer it is to the surface, the sooner the plants will come away and commence vigorous growth; and the deeper the dung is covered, the longer they will be in starting, and possibly they may break down altogether.

Plants feed chiefly at the surface, where atmospheric influences are greatest, and—not to discuss the matter on scientific grounds—even garden-farmers, whose annual purchase of dung is perhaps 1000 tons per 100 acres, take care not to cover it too deeply; and in the case of Onions, which must be started quickly, they apply the whole of an enormous dressing at the surface, in a rotten state, and do not cover it at all. A dressing of guano at the time of hoeing will, of course, be useful.

Having folded the Cabbages, the stalks should, if necessary, be raked into the furrows, or removed by boys as the land is ploughed. It will depend on circumstances whether the land will require twice ploughing or not. Garden farmers, from whose book we are borrowing a leaf, very seldom plough twice for any crop. The heavy dressings make their land friable. Manure in large quantities changes even stiff land into a kinder soil, which is worked much more easily, and it also has the effect of bringing the crops to maturity eight days earlier.

If the Cabbages were folded and the land properly cultivated not later than July 1, there is no second crop so desirable as Mangel, provided they are transplanted about the above date, or in favourable weather, and on land in high condition, up to July 10. The Mangel seed should have been sown in beds at the usual time in April or early in May. There is no root crop, not even Kohl Rabi, which transplants better than Mangel. During this showery season we saw scores of acres of transplanted Mangel, which received only a few days' check by removal.

Mangel should be hoed so soon as they have taken good hold of the ground. The cost of transplanting the small plants referred to in this article is generally 1s. per 1000, or about 6s. an acre, for several of the crops named. In many instances the advantages of transplanting prove greater than the costs, considering that time is gained for tillage and double crops are obtained.

IF any one could convince the town populations of England that they have committed a great blunder in adopting water-closets, SEWERS and SEWAGE IRRIGATION, it would be our clever correspondent, Herr BETA, of Berlin (see p. 956). He knows that the whole system is doomed—all Germany knows that Mr. MECHI has given up the liquid plan of applying manure—everybody knows that LIERNUR'S vacuum carts for emptying cesspools is a perfect success, whether as a sanitary or an economical institution, or for the mere cleanliness and comfort of the arrangement. "The glorious waves that surround England make her winters warm and her summers cool [and so they favour the irrigation remedy for the sewage nuisance]: they make her verdure broad and full, her air pure and everchanging, and her people vigorous, so that they can afford to squander money and manure in sewers, water-carriage, irrigation—even irrigation dinners—all for the sake of the comfort of their national economists." So says our German critic, who then proceeds to comment, with equally genuine approval, on German stinginess, and on the German idea of comfort, which consists, according to him, in saving money, storing knowledge, utilising everything, even Englishmen and English institutions, if so be they are worth the trouble. They do not mean, however, it would appear, to turn our ideas of sewerage and sewage to account, except by way of beacon for their warning.

We, on the other hand, holding that two things are inevitable, viz., first, on the score of the English idea of comfort, the universal adoption of the water-closet; and second, the coming enactment which shall forbid river pollution by it—are, we fear, committed past all power of German persuasion to our fatal blunder. Acting on a wholesome prejudice in favour of the ancient maxim, "Wash and be clean," we have supplied our towns with an enormous daily quantity of pure water, which washes them and their people, and thus makes sewers necessary. The sewage thus produced and delivered into the nearest watercourse is inevitably foul, whatever be the accommodation provided for the houses, and will not be allowed much longer to pollute the neighbouring river. It must be cleansed, and a great surface of soil, whose surface and whose substance is occupied by living plants, is the only practicable agency for this purpose. Being thus shut up to irrigation, let us load on this water all the filthy but fertilising matter it can carry, and thus increase the produce and the profit of our cleansing machinery—let us, in fact, universally adopt the water-closet and discard the privy.

We have come to the conviction in this country that the provision of cesspools for cleanness sake in the midst of wells for water supply is both disgusting and unwholesome—that a water supply of adequate amount from without the town necessitates some remedy for sewage pollution—and that sewage irrigation is the only remedy that is at once successful and productive.

We can leave our German critics for their ridicule of English wastefulness and sneers at English cleanliness to the statistics of scavenging and health; and for their "facts," which "everybody" on this subject knows, we can leave them in the hands of Mr. MECHI.

—— THE few samples of English Wheat at Mark Lane on Monday were sold at the prices of that day week. Anticipations of a wet harvest affected sales on Wednesday, and rates were 1s. per qr. lower.—A short supply of beasts and sheep on Monday at the Metropolitan Cattle Market sent prices up—choice lambs and calves participating; a larger supply on Thursday lowered prices, and a clearance was not effected.—Accounts from the Hop plantations are not yet satisfactory.——English wool continues to rise, and the tendency is still upward.——The Seed Market has been affected this week by the supply of new seeds.

—— THE HIGHLAND AND AGRICULTURAL SOCIETY'S SHOW AT PERTH, this week, is considered on all hands to be most successful, as is evidenced in comparing the entries with those of last year. Then there were 61 Shorthorns, while on the present occasion there have been 92; then there were 46 Polled Angus, this week 61; then there were 76 Ayrshires, now 76. All the cattle classes, except the Ayrshires, participate in this increase, but it is somewhat strange to notice the ranks of this favourite dairy breed thinned from 154 down to 90 entries. Horses remain almost *in statu quo* with reference to numbers; sheep have slightly diminished, from 322 entries to 300; swine have increased in numbers from 39 to 43, and poultry have increased from 34 to 225 entries! Altogether, the show of 1871 compares favourably with those of recent years. In giving a brief sketch of the Perth show we cannot but notice the salient points of difference between it and the English shows. First with regard to cattle; Shorthorns are well represented, while at the same time not a Devon, Sussex, or Hereford appears on the ground. This we look upon as a somewhat significant fact, bearing upon the adaptability of our many admirable breeds for diverse situations. Scotland, however, boasts her own most characteristic races of cattle, and it is no small novelty to an Englishman to walk through long ranges of sheds containing the beautifully symmetrical black polled cattle of Galloway and Aberdeen. Uniformity is always a "point" in considering the number of animals which a race constitutes the flock. Nowhere, perhaps, can such perfect uniformity be met with as in the sheds of the Highland and Agricultural Society, where the cattle just noticed are exhibited in such perfection. Neither must we omit to mention the Ayrshires, which formed such an important section of the late show. These cattle are bred for milk, and have assumed the milking type or form. The colour is, however, exceedingly diversified, some of the bulls being really more properly black and white than red and white. A breed can be made, so to speak, "to order;" and the varied colour, especially the black shade in the Ayrshire cattle, indicates that small value is attached to this particular attribute. There was a noble show of Clydesdale horses, and a considerable number of thoroughbreds, carriage-horses, hacks, and ponies. It was, however, a pity to notice the large number of unfilled places in these as in other classes; the words "not forward" being far too commonly paraded over vacant stalls or pens. Another remarkable feature of the Highland and Agricultural Show is the large class of black-faced sheep, which, however, have more white about their features than we have been accustomed to in years gone by. We miss the hardy Cotswold, which might be reasonably expected to fare as well upon a north country district as the more delicate Leicester. It is indeed an important question how far the Border Leicester might not be improved by more frequent crosses with the hardy Cotswold sheep of the south-western counties. The Border Leicester has completely monopolised the field this year with respect to Leicesters proper, and there is not a single entry under the latter head. We were glad to see a class of Shropshire sheep, which may be looked upon as a novelty in the Scotch show. There were 29 entries under this head, while last year, and, we suppose also in previous years, there were none. This class, although containing a few excellent sheep, also comprised some very poor specimens; and, after the magnificent show of these sheep in their own district at Wolverhampton, a few middling sheep of the same breed, with a good one or two interspersed, does not invite special comment. That Shropshires were represented at all is, however, a matter of no small importance, and we trust the entries in this section may every year become more numerous. Even Southdowns appeared, though in numbers under the dozen; and there were a few entries as extra sheep stock, among which were some singular four-horned Barbary sheep, bred and exhibited by Mr. C. H. DRUMMOND MORAY, of Abercairney, Crieff. The pig show compared favourably with that of last year, and white breeds were well represented. Black pigs do not seem to make much way in North Britain, and the Berkshires were not very characteristic of their breed. The array of large implements was small, and the array of articles not in the remotest way connected with agriculture far too great. Pictures, photographs, jewellery, glass, and ornaments of various kinds, were exhibited in far too considerable profusion. There were also the usual useful appliances for assisting farm operations, upon which we have not more space to dwell, except to mention the want of shedding—a large proportion of the implements being exposed to the rain. The arrangements of the show grounds were excellent, although we might suggest a few improvements, such as some sort of indication as to where one class ended and another began. "Reserve number," too, which is in constant use in the English Society's shows, is here wanting, and high commendations do not seem to be given in addition to commendations.

—— THE GREAT ANNUAL EXHIBITION OF THE ROYAL AGRICULTURAL SOCIETY OF IRELAND, which will take place during the coming week in Dublin, will be one of the largest and most important held under the auspices of the Society since its formation in the year 1841. This is the third time that the Irish capital has received the Society, and unusual success is anticipated, owing to its being honoured this year with a visit from His Royal Highness the Prince of WALES, President of the Society; H.R.H. Prince ARTHUR, the Princess LOUISE, the Marquis of LORNE, the Duke of CAMBRIDGE, and His Excellency the LORD-LIEUTENANT of Ireland will also be present. The last Society's show (1867) held in Dublin proved to be a most successful exhibition. The entries in stock amounted to 628, and in implements 105. The entries for the coming show will be about double those numbers. Besides above there will be 600 animals brought forward, only 258 having been shown in 1867. The prizes to be offered include, among others, the Purdon Challenge Cup, value 60 gs., for the best Shorthorn bull; the Purdon Challenge Cup, value 60 gs., for the best Shorthorn cow; the Cork Challenge Cup, value 40 gs., for the best fat-stock fearing ram; the Croker Challenge Cup, value 100 gs., for the best thorough-bred sire; the Kerr Challenge Cup, for the best jumper. There are also money prizes to the amount of £600, besides a large number of gold and silver medals, honorary certificates, and other commendations. The judges, designated by the Stewards, will commence the adjudication on Tuesday morning, and in the afternoon the Royal party will visit the show. On Wednesday the Royal party will again make an inspection of the exhibition, and in the evening the banquet of the Society will be held in the Winter Palace Exhibition, at which His Royal Highness the Prince of WALES will preside. Amongst the English agricultural implement exhibitors coming over on the occasion are Messrs. Garrett & Co., Howard & Co., Richmond & Norton, Ashby & Jeffrey, Young & Co., Burgess & Key, Fowler & Co., Ransome & Sims, Samuelson & Co., Hornsby & Co., Brigham & Bickerton, &c.

—— We have received from Whitfield Farm, Gloucestershire, the following note, with accompanying specimens, entirely bearing out last week's remarks on the WHEAT CROP:—

"By to-day's post I send you a few specimens of injured Wheat, which will bear out the opinion expressed in your leader this week. The crop looked well a fortnight ago has become very much scrawled. We at first thought that it must have been caused by the rough wind and heavy rain, but upon a close examination the real cause is but too plain. The seed in some instances appears to be decayed, and is in consequence easily blown aside, while in others the straw is much damaged by the ravages of some insect which has nearly eaten it off, so that it is easily sent down the wind and rain. The scrawled state of the crop reminds us of the year 1867, when the yield was far below an average."

—— Hear Mr. DISRAELI on the influence and independence of the English tenant-farmer. He spoke thus on Monday evening in the House of Commons—disputing the allegation "that the county constituencies are subjected to a certain degree of intimidation, and the old story of the tenant-farmer unduly influenced by his landlord:"—

"The tenant-farmers of this country are an influential body. I owe my seat in a great degree to them. I believe them to be on the whole the most independent body of

men in the country. No doubt there are exceptions in which a proprietor may unduly exercise his influence over them, though to me those instances are unknown, and I believe they will soon be as obsolete as the dodo. But, after all, what is the influence of the tenant-farmer in the English counties? There are 800,000 electors in the counties, and only 100,000 tenant-farmers. How absurd, then, to contend that those returns of county members are owing to tenant-farmers unduly influenced by landlords."

—— The AGRICULTURAL SOCIETY of NEW SOUTH WALES, one of whose most active managers is Mr. HOWARD REID, well known in agricultural circles here, proposes to make its judgment of merit and award of prizes in the cattle classes of its annual exhibition more a question of authentic and exact calculation than it has hitherto been. The judgment of cattle by separate valuation of points is not unknown in this country. The Channel Islands cattle are thus invariably judged in their own district. Each particular in the estimate has a possible value assigned to it, and in the proportion in which it reaches the ideal of perfection, a number is awarded within the maximum. The total effect of the several points is ascertained by a process of simple addition; and thus an animal of double merit in the matter of colour, hair, head, and chine, may beat one which in these points is deficient, although it is itself not worthy of a single figure under the head of general symmetry and style. We extract this possible result of the adoption of such a Table as is given below, although, perhaps, it is hardly probable that a bull or cow, possessing merit under other heads, should be altogether deficient in the matter of style and symmetry. It seems, however, plain that a system of valuation which excludes, as incapable of arithmetical computation, the supreme influence of health, vigour, and constitution, in determining the *status* of an animal, cannot be safely adopted. The following is the proposed award paper to which we have referred :—

1871. SECTION II.—(CATTLE.) CLASS ——.

[*Proposed*] *Award Paper, showing the Relative Value of Points. Maximum attainable,* 1000.

No.	Age	Colour and Hair.	Handle or Touch.	Head.	Neck and Shoulder.	Chest and Brisket.	Chine.	Fore Ribs.	Loin.	Hips and Quarter.	Twist and Thigh.	Flank and Belly.	Bone.	Evenness of Fat.	Size.	General Symmetry and Style.	TOTAL.	AWARD.

—— MARKET GARDENING, whether with aid of sewage or without that help, is suffering from that which we once heard Lord ROBERT MONTAGU laugh to scorn as an impossible source of injury—a plethora of produce. Everything is abundant, and prices are bad. The comparison between sewaged fields and others under the highest ordinary cultivation, in a year like this, preceded by a drought, is rather disappointing to the sewage farmer. The manure put on the land last year by his neighbour, and not taken out again on account of loss of crop from drought, is joined by a fresh quantity this year; and the rain being the match which sets the lot on fire, up there come tremendous crops. That which has done them good has, so to speak, done him harm. There was never any want of water in his case. He could not even cease sewaging on account of rain, because he wanted to apply the manure which is thus carried. The additional water was, however, so much more a setting together of the cropped land, and a consequent injury, especially to the Potato crop; and when his neighbour dug five and six tons per acre, he has dug a smaller quantity, much later. He will learn from this experience that he cannot altogether abandon ordinary dung, if he wants the best prices in early years. There is, no doubt, a good deal yet to learn of many kinds in sewage farming, and one problem is how to get an even crop. Myatt's Kidneys, in a case known to us, have yielded well—4 tons an acre—over good and bad places; but they produced 7 tons per acre at the top of the beds, and but one and two at bottom. Among other reasons one is plain—the bottom gets most wetted, and (being the line of approach to beds) it also gets most trampled on or poached with carting. It ploughed up hardest, and most clung together, but it was impossible to stop to work it and to weather it, for the routine of cropping would have been lost. This necessity has, however, resulted in a very uneven crop.

—— On Wednesday evening the House of Commons spent some hours in technical discussion of the METRIC SYSTEM. The compulsory adoption of it is proposed in a Bill entitled the Weights and Measures (Metric System) Bill, the second reading of which was moved by Mr. J. B. SMITH. In its support he traced the history of the system from the time of its adoption by the first French Republic, and read numerous quotations from the reports of committees and commissions and the *dicta* of scientific men in favour of the superior convenience and precision of the system.—Mr. PEREDFORD HOPE moved the rejection of the Bill, and in his turn quoted scientific authorities copiously to show the superior convenience of our present mode of measurement. The Metric System he ridiculed as an absurd product of French vanity, which had not even the merit of scientific accuracy. —Mr. STEVENSON, who seconded the amendment, dwelt chiefly on the practical objections to the change.—Sir C. B. ADDERLEY, in supporting the Bill, pointed out that our colonies had made the change without any trouble, and argued that our home trade was more embarrassed by the infinite local varieties of our present weights and measures than it could be by any transition to a new system. As to our foreign commerce, he showed how constantly and invariably we lost in all exchanges and other transactions, and pointed out that in most cases the approximation was so close as to make but a small change necessary. He advised Mr. SMITH to accept a permissive bill if the Government would agree to it.—Mr. CHICHESTER FORTESCUE referred at length to previous debates and divisions to show that no direct decision had ever been given by the House, and, arguing against a compulsory system, he urged that it was impossible to make such a change unless the opinion of the people went with it.—Mr. HENLEY also opposed the Bill, which he treated as a product of the first French Revolution, and thought it time enough to make the change when there seemed a prospect of the system being universal.—Mr. C. S. READ and Mr. PELL expressed the strong desire of the agriculturists for an uniform system of weights and measures, and the Bill was also supported by Mr. BAINES, Colonel SYKES, and Mr. ILLINGWORTH. On a division, it was thrown out by the narrow majority of 82 to 77.

—— An East Essex farmer writes thus of the APPROACHING HARVEST in the columns of the *Times* :—

"I fear we must reconcile ourselves as best we may to the anticipation of a deficient yield of Wheat this year. Probably few of the gentlemen who write sanguine agricultural reports based on cursory observation of the crops as they drive or go by rail past them are aware of the extent to which the Wheat especially is blighted. Not only is there an unusually large number of completely blighted ears, which are plain enough to any one who walks into a field of Wheat, but partially blighted ears are in most fields that I have seen—especially where the crop is forward—the rule, and not the exception. Indeed, it is quite uncommon to find an ear which has the top set healthy, while what in healthy seasons would be the middle kernel, or one of the two middle kernels of each set (according to its position in the ear), is almost invariably nothing but chaff. Now it is common enough, indeed usual, to see one small false kernel in a set, but not two, or three. I looked in a field of white Wheat for some time this morning before I could find an ear containing a set of more than three kernels in the thickest part of the ear, where there should always be four, and where, if one apparently are five in prolific seasons. Besides this, many of the side kernels are either apparently rotten or contain maggots.

"Barley and Oats are also affected by the blight, though less extensively. In Barley it shows partly in the number ot withered ears, but especially in the false kernels that may be seen on close examination oo a considerable proportion of the ears. In Oats the strips of white 'flight' in place of grain are plain enough to see, even from the roadside."

—— The ensuing month brings round the sixth anniversary of the BIRMINGHAM HORSE SHOW. Considerable alterations have been made in the schedule of prizes. The principal one is the omission of the agricultural horses' classes, the funds devoted to this section being applied to increasing the prizes for hunters, for which there are four classes besides those for 2 and 3-year-old colts. The hack and harness horses classes have been remodelled, so as to secure more equality in the height of the horses competing, and those for ponies are altered so that in no case do the saddle and harness points come into competition together. The interesting classes for tandems, both horses and ponies, and also those for pairs in harness, are continued. The prize list is on a most liberal scale, no less than £630 being offered. The days of exhibition are August 15, 16, 17, and 18, and the last day of entry is Saturday, the 29th inst.

OUR LIVE STOCK.

CATTLE.

THE following are among the important sales which have recently been transacted among Shorthorns :—Mr. Beattie has sold his *Sonzie* by BRIGADE MAJOR, and bred by the Messrs. Angus, of Broomley, to Sir Tatton Sykes. Mr. John Outhwaite, of Bainese, has sold his *Lady Drought*, the 1st prize yearling heifer at Wolverhampton, to Mr. Gibson. Mr. Cochrane, of Compton, Canada, purchased the Rev. R. B. Kennard's 2-year-old heifer, *Oxford Duchess*; Lord Sudeley's 2d prize yearling bull, CHERUB; Mr. Chas. Barnett's roan heifer, *Belinda Oxford*; and Messrs. Thomas Garne & Son's *Nellie Booth* by ROYAL BENEDICT (27,348). Colonel Towneley has sold his red BARON HUBBACK 2D, the 1st prize yearling bull, and his roan yearling heifer *Alice of Oxford*, to Mr. Gibson; and his red yearling heifer, *Baron Oxford's Duchess*, the 3d prize winner, to Mr. Miller, for America.

—— Respecting the Farnley Hall Shorthorn sale, we are authorised to state that, notwithstanding the decease of the Rev. A. Fawkes, it has been determined that the sale of the herd shall take place, as originally fixed, on Tuesday next.

—— Mr. Finlay Dun, in a very interesting paper recently delivered before the Midland Farmers' Club, thus speaks of the important class of facts gathered together under the term "*reversion*, or calling back" :—

"In the breeding of stock, the progeny not only resemble their own immediate parents, they call back or revert to bygone generations. This constitutes the law of reversion or atavism. It is difficult to say during how many generations old peculiarities will continue to crop up. Shorthorn authorities demand four distinct crosses of accredited blood as the minimum amount, without which no animal can be admitted into the Herd Book, or regarded as of sufficiently pure Shorthorn descent. Such an animal would possess one-sixteenth of the unrecognised blood. But four generations do not certainly suffice to wipe out any stain, shortcoming, or defect. Such faults will slumber unsuspectedly during these and other generations, and then from accidental influences, as from an infusion of some dissimilar blood, may again re-appear. In this way we believe, from their old Dutch descent, crops up every now and then the objectionable dark nose, which from time to time appears in some Shorthorn families. So, doubtless, arises the staring white stockings which still disfigure some Shorthorns, and which Mr. Strafford says often come down during six or eight generations from KETTON 2D, who possessed these conspicuous markings. Southdown and many other sorts of improved sheep have for many generations been bred without horns; but every now and then the old tendency comes out, and lambs are dropped which grow more or less perfectly developed horns.
