Supplement to Nature, November 29, 1894

Nature

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME L

MAY to OCTOBER, 1894

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH

London and New York
MACMILLAN AND CO.

Richard Clay and Sons, Limited,
London and Bungay.

INDEX

Abbé (Prof. C.), Meteorology and Geodesy, 141 ; Remarkable Hailstones at Vicksburg, 430 ; Schools of Meteorology, 576
Abbott (Charles Conrad), Travels in a Tree-top, 295
Abbott (Miss E. C.), on the Evolution of the Vertebral Column of Fishes, 516
Abney's (Capt.) Photographs of Flames, 285
Aborigines of Western Australia, the, Albert F. Calvert, 474
Abraham (H.), Method for Measuring Self and Mutual Induction, 15
Academy, American ; Election of Officers, 153
Accademia dei Lincei, the, Annual Meeting at Rome, 304
Acoustics : New Method for Determining Pitches of High Tuning-forks, F. Melde, 155 ; Transmission of Sounds, H. Gilbault, 167 ; Hawksley's Sonometer, 182 ; on the Velocities of Sound in Air, Gases, and Vapours for Simple Tones of Different Pitches, James Webster Low, 334 ; Prof. Münsterberg and Mr. A. H. Pierce on the Localisation of Sound, 621
Acquired Characters, the Inheritance of, Leonard Hill, 617
Adam (Paul), the Emetics, 167
Adler (Dr. Hermann), Alternating Generations : a Biological Study of Oak Galls and Gall Flies, 545
Adulteration of Compressed Oxygen, 620
Aero-Therapeutics, or the Treatment of Lung Diseases by Climate, Charles Theodore Williams, 99
Aeronautics : Herr Otto Lillenthal's Serious Accident, 393 ; towards the Efficiency of Sails, Screw-Propellers in Water and Air, and Aeroplanes, Lord Kelvin, P.R.S., 425 ; Aeroplanes, Hiram S. Maxim, 489 ; Steam and Aerial Navigation foreshadowed by Roger Bacon, 481 ; Progress in Flying Machines, O. Chanuté, 569 ; Manual Pratique de l'Aéronaute, V. de Fonvielle, 569
Aerotonometer, a New, Prof. Fredericq, 461
Æsthetics, Pain, Pleasure, and, Henry Rutgers Marshall, 3
Affiliated Societies of the American Association for the Advancement of Science, the, 608
Africa : Scheme for the Protection of African Mammals, 130 ; Timbuktu, 154 ; Stratigraphy and Physiography of Libyan Desert of Egypt, Capt. H. G. Lyons, 166 ; Geology of South Africa, D. Draper, 167 ; Occurrence of Dolomite in South Africa, D. Draper, 167 ; Geology of British East Africa, Dr. J. W. Gregory, 167 ; the Yoruba-Speaking Peoples of the Slave Coast of West Africa, Col. A. B. Ellis, 221 ; the Cultivable Land on Kilimanjaro, Dr. Brehme, 305 ; Mr. Scott Elliot's Ruwenzori Expedition, W. T. Thiselton-Dyer, F.R.S., 549 ;
Agamennone (Dr. G.) on the New Continnous-Record Seismometrograph of Collegio Romano, 362
Agassiz (Alexander), the Coral Reefs of the Bermudas, 235
Agriculture : the Potato Disease *Phytophthora infestans*, Thomas Carrol, 63 ; the Origin of Cultivation, Grant Allen, 66 ; Manures and the Principles of Manuring, C. M. Aikman, 75 ; Carbon Bisulphide as a Fertiliser, Aime Girard, 94 ; the Employment of Disease-causing Microbes for Destroying Field Vermin, Gerald McCarthy, 131 ; Agricultural Entomology, Handbook of the Destructive Insects of Victoria, C. French, 243 ; Grass-destroying Caterpillar Plague in Scotland, Miss Ormerod, 251 ; Insect Ravages in India, Hon. J. Buckingham, 274 ; Algæ and Nitrogen-Fixation, Herr Kossowitch, 276 ; Pasteur Institute, Paris, Experimental Study of Means of Defence against Destructive Insects, 482 ; Assimilability of Potash by the Action of Nitrates in poor Siliceous Soils, P. Pichard, 491 ; on Diptera harmful to Cereals, Paul Marchal, 516 ; Agricultural Zoology, Dr. J. Ritzema Bos, 567
Aikman (C. M.), Manures and the Principles of Manuring, 75
Air, the Electrification of, Lord Kelvin, P.R.S., and Magnus Maclean, 280 ; Prof. J. J. Thomson, F.R.S., 296
Akas, the Poisoned Arrows of the, Prof. L. A. Waddell, 395
Albany Museum, Grahamstown, Report of, 275
Albatross, Flight of the, A. Kingsmill, 572
Albion Colliery Explosion, the, Prof. H. B. Dixon, 429
Albrecht (Prof. K. M.), Death of, 553
Alchemy : The Alchemical Essence and the Chemical Element, M. M. Pattison Muir, Prof. Herbert McLeod, F.R.S., 50
Algæ and Nitrogen-fixation, Herr Kossowitch, 276
Algæ which deposit Calcareous Matter in their Tissues, Prof. Johnstone on, 434
Algedonics : Pain, Pleasure, and Æsthetics, Henry Rutgers Marshall, 3
Allen (Edgar J.), Studies on the Nervous System of Crustacea, 611
Allen (Grant), the Origin of Cultivation, 66
Alloy, Separation and Estimation of Tin and Antimony in Air, M. Mengin, 311
Alloys, Electrical Resistance of some New, M. van Aubel, 84
Alloys, Experiments with Tin-lead, ranging from $PbSn_{12}Pb_{12}Sn$, Bernhard Wiesengrund, 394
Alloys, Thermoelectric Heights of Antimony and Bismuth, C. C. Hutchins, 515
Alpenverein, German and Austrian, 414
Alpine Geology : Ein Geologischer Querschnitt durch die Ost Alpen, A. Rothpletz, Dr. Maria M. Ogilvie, 27
Alps, M. Bertrand on the Structure of the French, 510
Alps, Prof. Suess on the Southern and Northern, 510
Alps, Eastern, with Prof. Heim in the, 526
Alps, the Glacial System of the, B. Hobson, 602
Alps of Dauphiny, Observations of the Pendulum in the, 635
Alsace and Lorraine Meteorological Observations, 1892, 430
Aluminium upon the Carbon in Ferro-carbon Alloys, Mr. T. W. Hogg on the Influence of, 460
Aluminium Violins, Mr. Springer, 485
America : American Meteorological Journal, 21, 141, 188, 334, 612 ; American Journal of Mathematics, 69, 283 ; American Journal of Science, 91, 235, 334, 440, 515, 634 ; Mount Logan the loftiest Peak in North America, 131 ; American Academy, Election of Officers, 153 ; Biological Station established at Havana, Illinois River, 275 ; Migration and the Food Quest, a Study in the Peopling of America, O. T. Mason, 361 ; International Congress of Americanists, 393 ; American Association for the Advancement of Science, Dr. W. H. Hale, 458 ; Meeting at Brooklyn, 458 ; Prof. Harkness on the Magnitude of the Solar System, 458, 532 ; George C. Comstock on Binary Stars, 458 ; Dr. Daniel G. Brinton on the Aims of the Association, 485 ; Miss Mary Noyes on the Influence of Heat and Electricity upon Young's Modulus for a Piano Wire, 485 ; Aluminium Violins, Mr. Springer, 485 ; some Peculiar Lightning Flashes, A. McAdie, 485 ; on a Phonographic Method of Recording the Change in Alternating Electric Current, C. J. Rollesson, 485 ; on the Resistance of Materials under Impact, Dr. Mansfield Merriman, 486 ; Methods of Testing Automatic Fire Sprinkler Heads, Prof. Jacobus, 486 ; Niobrara Chalk, Samuel Calvin, 486 ; on the Water Resources of the United States, Major J. W. Powell, 486 ; the Age of Niagara Falls, Prof. Spencer, 486 ; the Relation of the Age of Type to Variability, Prof. L. H. Bailey, 487 ; on the Struggle for Existence under Cultivation, Prof. L. H. Bailey, 487 ; Human Faculty as determined by Race, Dr. Frank Boaz, 487 ; Variations in the Human Skeleton and their Causes, Dr. Daniel G. Brinton, 487 ; Conclusions on the Hieroglyph "pax," M. H. Saville

Dr. Brinton, 487; Salt in Savagery, F. H. Cushing, 487; Ears of Corn from Prehistoric Grains, W. Sturtevant, 488; Indexing of Chemical Literature, 539; Affiliated Societies of the American Association for the Advancement of Science, 608; the Effect of Glaciation and of the Glacial Period on the Present Fauna of North America, Samuel H. Scudder, 515; on the Reproductive Habits of the American Lobster, F. H. Herrick, 553; North American Moths, Dr. John B. Smith, W. F. Kirby, 619; on the Arachnid Affinities of the American King-Crab *Limulus*, 621

Amphioxus, Johannes Muller and, 54

Amsterdam Royal Academy of Sciences, 24, 144, 240, 311

Anæsthesia, Dr. W. T. G. Morton's Claims to the Discovery of, L. Snell, 420

Anatomy: Anatomy of Dumb-bell Shaped Bone in Ornithorhynchus, Prof. J. T. Wilson, 96; External Anatomy of the Chinese Brain, C. H. Bond, 111; the Presternal Muscle, O. Lambert, 490

Ancient Astronomy, Paul Tannery, 265

Andromeda, the Great Nebula in, C. Easton, 547

Animal, the, as a Machine and a Prime Motor and the Laws of Energetics, R. H. Thurston, 474

Animal Variation: Materials for the Study of Variation, treated with especial regard to Discontinuity in the Origin of Species, W. Bateson, Prof. W. F. R. Weldon, F.R.S., 25

Annalen des K. K. Naturhistorischen Hofmuseums, 21

Annals of the Russian Geographical Society, 621

Anthropology: Morphological Peculiarities in Natives of Panjab, Prof. R. H. Charles, 16; Prehistoric Remains in Florida, Dr. De W. Webb, 16; Bulletins de la Société d'Anthropologie de Paris, 21, 441, 490; Mémoires de la Société d'Anthropologie de Paris, 441; the Natives of Lifou, J. Deniker, 21; L'Anthropologie, 91, 490; Notes for History of Primitive Art, Ed. Piette, 91; the Female Deity and Sculptures of the Allée Converte of Épone, E. Cartailhac, 91; the Hamites of Eastern Africa, Maurice Delafosse, 91; Probable Age of Swiss Lacustrine Stations, E. Vouga, 91; the Yoruba-Speaking Peoples of the Slave Coast of West Africa, Colonel A. B. Ellis, 221; Among the Tarahumaris, Dr. Carl Lumholtz, 234; Supposed Aboriginal Hoe, R. Etheridge, 239; Opening Address in Section H of the British Association by Sir W. H. Flower, F.R.S., 387; the Poisoned Arrows of the Akas, Prof. L. A. Waddell, 395; on the Various Forms of the Teeth of Different Races, Dr. F. Regnault, 441; Recherches Ethnologiques sur le Morvan, Ab. Hovelacque and Georges Hervé, 441; the Anthropology of France, Dr. R. Collignon, 441; Monument erected in honour of Armand de Quatrefages, 481; Dr. Frank Boaz on Human Faculty as determined by Race, 487; Variations in the Human Skeleton and their Causes, Dr. Daniel G. Brinton, 487; Salt in Savagery, F. H. Cushing, 487; Photographs of the Inhabitants of the Mergui Islands (the Selungs), 490; Prehistoric Crania of Patagonia, Dr. R. Verneau, 490; Pottery of the Gallic Epoch, Octave Vauvillé, 490; Funeral Rites in Madagascar, Antony Jully, 490; Instinctive Attitudes, Hiram M. Stanley, 596; R. Etheridge on the Kurditcha Shoes of Central Australia, 636 (*See also* Section H of the British Association)

Anthropometrical System of Identification used in Bengal, 326

Anthropometrical System of Measurement of Criminals to be adopted in England, 481

Anthropometry: Incomparability of Nasal Indices derived from Measurements of the Living Head with those deduced from Observation of Skulls, Dr. R. Havelock Charles, 482

Anti-Vivisectionists, the, Dr. Louis Robinson, 234

Anti-Vivisectionists and Pasteur's Anti-Rabic Treatment, the, 14

Antigua, Drought at, C. A. Barber, 475

Antitoxic Properties of the Blood of the Terrestrial Salamander (*Salamandra maculosa*) against Curare, on some, C. Phisalix and Ch. Contejean, 444

Apis Period of the Ancient Egyptians, the, Dr. E. Mahler, 254

Appleyard (Rollo), Dielectrics, 93

April, Recent Change in the Character of, 246; Dr. O. Z. Bianco's Researches at Turin, on the, 393

Arabia, South, Exploration of the Hadramut, J. T. Bent, 90

Arachnid Affinities of the American King-crab *Limulus*, on the, 621

Ararat, Thermometric Observations on the Summit of, M. Venukoff, 585

Archæology: Death of Sir Henry Layard, 250

Archæopteryx, on the Wing of, viewed in the light of that of some Modern Birds, W. P. Pycraft, 435

Archoplasm, the, and Attraction Sphere, J. E. S. Moore, 478

Arctic and Antarctic Marine Fauna, Dr. John Murray, 443

Arctic Exploration: the Arctic Expeditions of 1894, Dr. Hugh Robert Mill, 57; How I discovered the North Pole, J. Munro, 140; the Peary Expedition, 581; Sailing of the Peary Auxiliary Expedition, 250; Letter from Lieut. Peary, 603; Two Arctic Expeditions in one Day, Dr. W. H. Hale, 296; Wellman Arctic Expedition, 273, 304; News of the, 360; Supplies for the Wellman Expedition, 393; Cook's Greenland Expedition, 429; Return of Dr. Cook's Arctic Expedition, 481; Death of Sir Edward Augustus Inglefield, F.R.S., 480; the *Windward* Expedition, 603; the Trevor-Battye Expedition, 603

Arctowski (H.), Properties of Carbon Bisulphide, 165; Solubilities of Haloid Salts of Mercury in Carbon Bisulphide, 165

Arctowski (Prof.), Mode of Converting Oxide of Iron into Haematite Crystals, 306

Arizona, the Lowell Observatory, John Ritchie, jun., 149

Arkansas, Tornado at Little Rock, 580

Arloing (S.), the Microbe of Contagious Peripneumonia in Cattle, 287

Armstrong (Dr. H. E., F.R.S.), on the Publication of Scientific Literature, 159; Scientific Education and Research, 211; Scientific Method in Board Schools, 631

Army Examinations, the Report of the Committee on, 125

Army Regulations, New, Rev. Dr. A. Irving, 245

Arno (Riccardo), New Electrical Rotation Experiment, 155

Arnold (Prof. J. O.), Physical Influence of certain Elements on Iron, 38; Conditions in which Carbon Exists in Steel, 143

Arnold-Bemrose (H. H.), Derbyshire Carboniferous Dolerites and Tuffs, 190

Arrows, the Poisoned, of the Akas, Prof. L. A. Waddell, 395

Articulates, Derivation and Homologies of, J. D. Dana, 91

Ascent of Man, the Lowell Lectures on the, Henry Drummond, 147; Mrs. Lynn Linton, 489

Ascoli (M.), on the Radial Distribution of the Induced Magnetism in an Iron Cylinder, 604

Asia, "Ritter's," Russian Addenda, P. P. Semenoff, I. D. Chersky and G. G. Von Petz, 471

Aspects of Modern Study, R. A. Gregory, 422

Asterina gibbosa, Variations in Larva of, E. W. MacBride, 143

Asterina gibbosa, the Deposition of Ova by, Henry Scherren, 246

Asteroids, the Mass of the, B. M. Roszel, 87

Astor (John Jacob), a Journey in Other Worlds, R. A. Gregory, 592

Astrology: a Treatise of Natal Astrology, G. Wilde and J. Dodson; the Soul and the Stars, A. G. Trench, 219; Studien uber Claudius Ptolemaus, ein Beitrag zur Geschichte der griechischen Philosophie und Astrologie, Franz Boll, 398

Astronomy: an Astronomical Expedition from Harvard, 18; Our Astronomical Column, 18, 36, 64, 87, 113, 132, 157, 181, 206, 230, 254, 277, 307, 327, 364, 395, 416, 433, 457, 484, 504, 531, 556, 583, 606, 623; Elements and Ephemeris of Gale's Comet, 18, 36; Prof. Kreutz, 87, 181; the Planet Saturn, 32; the Moon's Apparent Diameter, M. P. Stroobant, 36; Denning's Comet, M. L. Schulhof, 37; Stars having Peculiar Spectra, Mrs. Fleming, 37; Principia Nova Astronomica, Henry Pratt, 51; Finder Circles for Equatorials, 64; Harvard Observatory in Peru, Prof. W. H. Pickering, 64; Diameters of some Minor Planets, Prof. E. E. Barnard, 65; Return of Tempel's Comet, 65; Ephemeris for Tempel's Comet, 206; M. Schulhof, 113; Moon-Man or Moon-Maid, William Canton, 66; Sun-spots and Weather, W. L. Dallas, 113; Sun spot Observations made at Lyons Observatory during first quarter of 1894, J. Guillaume, 143; the First Observation of Sun-spots, Prof. E. Millosevich, 230; Sun-spot Observations at the Potsdam Observatory, 556; on the Rotation of Solar Spots, M. Flammarion, 564; Recent Observations of Jupiter's Satellites, Dr. E. S. Holden, 87; Jupiter's Satellites in 1664, Frank H. Clutz, 113; the Discs of Jupiter's Satellites, Prof. Barnard and Prof. Pickering, W. J. S. Lockyer, 320; the Mass of Jupiter, Prof. Simon Newcomb, 458; on the Eccentricity of the Orbit of Jupiter's Fifth Satellite, M. F. Tisserand, 612; the Fifth Satellite of Jupiter, Prof. E. E. Barnard, 624; the Mass of the Asteroids, B. M. Roszel, 87; Results obtained with Prismatic Camera during Total Eclipse of Sun, April 16, 1893, J. N. Lockyer, F.R.S., 118; a Daylight Meteor, Jas. G. Richmond, 124; the August Swarm of Meteors, 365; a Remarkable Meteor, Edward Wesson, 399; the Meteor Streak of August 26, 1894, John W. Earle, 452; Edward F. Linton; T. B. Cartwright; Thos. Ward, 474; W. F. Denning, 537, 617; the Semi-Annual Variation of Meteors, G. C. Bompas, 504; an Instrument for Photographing Meteors, 556; Bright Meteors, Prof. A. S. Herschel, F.R.S., 572; Astronomical Congresses at Utrecht and Vienna, 132; Proposed Astronomical Congress in 1896, Dr. Gill, 133; the Law and Greenwich Time, 133; the Report of the Astronomer-Royal, 139; the Lowell Observatory, Arizona, John Ritchie, jun., 149; Report of the Astronomer-Royal for Scotland, 157; Award of the Watson Medal to S. C. Chandler, 157; Two New Catalogues, 157; Finder Circles for Equatorials, 64; Prof. Wm. Harkness, 173; Bright-Line Stars, Prof. W. W. Campbell, 181; the Native Calendar of Central America and Mexico, Dr. D. G. Brinton, 206; the Appearance of the Helium Line, A. Bélopolsky, 206; the Progress of Astronomical Photography, H. C. Russell, F.R.S., 230; Mr. Tebbutt's Observatory, New South Wales, 231; a New Spiral Nebula, Dr. Roberts, 231; Sir William Herschel, Sir Robert Ball, 234; Results obtained with Slit Spectroscopes at Total Eclipse of April 16-17, 1893, Capt. E. H. Hills, 236; The Starry Skies, Agnes Giberne, 244; the Spectrum of the Orion Nebula, Prof. J. E. Keeler, 254; Prof. W. W. Campbell, 254; the Nebulous Character of Nova Aurigæ, Prof. E. E. Barnard, F. Renz, 254; the Apis Period of the Ancient Egyptians, Dr. E. Mahler, 254; Observations of the Planet Mars, 255, 457; Percival Lowell, 395; Prof. Pickering, 396; Stanley Williams, 606; a Strange Sight on Mars, Prof. Krueger, 319; Mars as he now appears, W. J. Lockyer, 476; Bright Projections on Mars' Terminator, W. J. S. Lockyer, 499; Recherches sur l'histoire de l'Astronomie Ancienne, Paul Tannery, 265; Variations of Latitude, F. Gonnessiat, 277; Photographs of the Moon, MM. Lœwy and Puiseux, 278; Photographic Exploration at Nice Observatory, M. Perrotin, 287; the Results of Imprudent Solar Observations, Dr. George Mackay, 307; a Novel Method of Solar Observation, Dr. Deslandres, 307; Spectroscopic Velocities of Binaries, 327; the Magnesium Spectrum as a Criterion of Stellar Temperature, Prof. J. E. Keeler, 364; Rotation of the Terrestrial Poles, Dr. S. C. Chandler, 396; Solar Electrical Energy, Dr. M. A. Veeder, 416; a New Variable Star, Rev. T. E. Espin, 417; Death of Richard Langdon, 428; Solar Eclipse Photography, Albert Taylor, 433; Observations of Saturn and Uranus, Prof. E. E. Barnard, 433; on certain Astronomical Conditions favourable to Glaciation, G. F. Becker, 440; Researches on the Movements in the Solar Atmosphere, M. H. Deslandres, 468; Verzeichniss der Elemente der bisher berechneten Cometenbahnen, Dr. J. G. Galle, 473; the Harvest Moon, 484; Eclipse of the Moon, 484; M. Tisserand on Satellite Orbits, 484; the Distribution of Nebulæ and Star-Clusters, Sidney Waters, 484; on the Motion of the Satellites of the Planets with respect to the Sun, P. Stroobant, 490; Latitude by Ex-Meridian, J. White, 498; Celestial Objects for Common Telescopes, Rev. T. W. Webb, 523; Extraordinary Phenomenon, Admiral Sir Erasmus Ommanney, F.R.S., 524; the Accuracy of Astronomical Observations, Prof Cornu, 531; Liverpool Observatory, 531; the Variable R. Lyræ, Herr A. Pannekoek, 531; the Cleaning of Object-Glasses, 531: Shooting-stars observed in Italy, P. François Denza, 540; the Great Nebula in Andromeda, C. Easton, 547; Photographic and Visual Refracting Telescopes and Spectroscope presented to the Cape Observatory by Mr. Frank McClean, 552; a Treatise on Astronomical Spectroscopy, Dr. J. Scheiner, Dr. J. L. E. Dreyer, 565; Nebulosities near the Pleiades, Prof. E. E. Barnard, 583; a Journey in Other Worlds, John Jacob Astor, R. A. Gregory, 592; Death of George Knott, 603; the Rio de Janeiro Observatory, 606; the Mass of Mercury, M. Backlund, 607; Brorsen's Comet, 1851, III, 607: Triangulation of Sixteen Stars in the Pleiades, Dr. Leopold Ambronn, 623

Athens, the Plague of, Dr. Keser, 62

Athens, Earthquake at, 428

Atkinson (W. N.), Colliery Explosions and Coal Dust, 419

Atlantic, North, Dr. J. W. van Bebber on the Daily Synoptic Weather Charts of the, 362

Atlantic, North, Derelicts in the, 502

Atmosphere of Paris, M. J. Jaubert on the, 454

Attitudes, Instinctive, Hiram M. Stanley, 596

Attraction Sphere, the Archoplasm and, J. E. S. Moore, 478

Aubel (M van), Electrical Resistance of some New Alloys, 84

August Swarm of Meteors, 365

Aurelia aurita, Edward T. Browne, 524

Aurelia, with Pentamerous Symmetry, H. W. Unthank, 413

Aurelia aurita, Symmetry of, Dr. H. C. Sorby, F.R.S., 476

Aurelia, Variations of, Prof. W. A. Herdman, F.R.S., 426

Aureobasidium vitis, on a Vine Disease caused by, M. P. Eloste, 540

Aurora, J. Shaw, 499

Aurora of Feb. 22, Dr. M. A. Veeder, 54

Aurora Australis, H. C. Russell, F.R.S., 319

Aurora, Fine, in Tasmania, H. S. Dove, 482

Aurora and Fog, H. C. Russell, 428

Auroral Display in New Zealand and Australia, 620

Australasia, the Proposed Palæographical Society of, 325; Australasian forms of *Gundlachia*, Charles Hedley, 431; Glacial Action in Australasia in Tertiary or Post-Tertiary time, 483

Australia: The Horn Expedition for the Scientific Exploration of Central Australia, 174; Return of, 528; the Recent Discovery of Fossil Remains at Lake Calabonna, South Australia, Dr. E. C. Stirling, F.R.S., 184, 206; New Snake, J. D. Ogilby, 288; Aurora Australis, H. C. Russell, F.R.S., 319; the Aborigines of Western Australia, Albert F. Calvert, 474; Report of the Australian Museum, Sydney, for 1893, 581; Auroral Display in New Zealand and Australia, 620; R. Etheridge on the Kaditcha Shoes of Central Australia, 636

Austrian Alpenverein, German and, 414

Autobasidiomycetes, Vascular Hyphæ of the Mycelium of the, Ch. van Bambeke, 214

Axis of the Earth, the Displacements of the Rotational, Prof. W. Foerster, 409, 488

Aymonnet (M.), Calorific Radiations included in Luminous Part of Spectrum, 287

Baccarini (P.), Fungus Diseases of Cultivated Trees, 309

Backlund (M.), the Mass of Mercury, 607

Bacon (Roger), Steam and Aerial Navigation foreshadowed by, 481

Bacteriology: The Action of Light on the Diphtheria Bacterium, J. Erede, 8; Inquiry into Pollution of Danube by Vienna Drainage, Dr. Heider, 16; Inoculation against Cholera, Drs. Sawtschenko and Sabolotny, 15; Action of Sunshine on Cholera Bacillus, Dr. Palermo, 755; Dr. Sabolotny's Animal Experiments on the Cholera Bacillus, 85; the Detection of Cholera Vibrios in River-Water, Dr. Dunbar, 204; Bacteriology of Cholera, Prof. Max Gruber, 511; M. Metchnikoff, 512; Treatment of Typhoid Fever by Injection of Culture of Bacilli, E. Fraenkel, 35; Apparatus for Microscopic Observation of Micro-Organisms, Prof. Marshall Ward, 40; New Researches on Association among Bacteria, V. Galtier, 48; the Danger of Milk, 111; the Employment of Disease-causing Microbes for destroying Field Vermin, Gerald McCarthy, 131: the Self Purification of Rivers, 131; New Method of preparing Culture Media, Dr. Lorrain Smith, 143; Microbian Diseases not transmissible by Ova or Spermatozoa, 165; Polymorphism among Bacteria, Ali Cohen and Uffelie, 179: the Polymorphism of Micro-Organisms, 253; Micro-organisms and Bread, Dr. Troitzki, 204; Photograph of a Landscape in Living and Dead Bacteria, 250; the Microbe of Contagious Peripneumonia in Cattle, S. Arloing, 287; M. Yersin on the Hong-kong Plague, 368; Bacteriology of the Ocean, Dr. B. Fischer, 431; Soap as a Germicide, 431; on the Chemical and Bacteriological Examination of Soil, with special reference to the Soil of Graveyards, Dr. James Buchanan Young, 443; Sunshine and Water-Microbes, Mrs. Percy Frankland, 452; Dr. Duenschmann on the Effects of associating a Virulent with a Non-Virulent Micro-organism in Animal Inoculation, 456; Micro-Organisms in Water, Prof. Percy Frankland and Mrs. Percy Frankland, Dr. E. Klein, F.R.S., 469; the Berridge Laboratory for the Chemical and Bacteriological Examination of Water Supply and the Investigation of Processes of Sewage Purification, 501; some of the Micro-

Organisms causing the Diseases of Beer, Mr. Fellows, 503; the Problem of Immunity, Prof. Buchner, 511
Baden, Geological Map of, J. Edmund Clark, 426
Bagard (Henri), on the Thermoelectric force between two Electrolytes, and on the Thomson Effect in the case of Electrolytes, 554
Bailey (G. H.), Volatilisation of Salts during Evaporation, 71
Bailey (Prof. L. H.), the Relation of the Age of Type to Variability, 487; on the Struggle for Existence under Cultivation, 487
Baily (F. G.), on Hysteresis in Iron and Steel in a Rotating Magnetic Field, 408
Baker (Brereton), Experiments on the Influence of Moisture on Chemical Substances, 409
Baker (H. B.), Influence of Moisture on Chemical Change, 166
Balfour (Prof. I. Bayley, F.R.S.), Opening Address in Section D of the British Association, 371
Ball (Sir Robert), Sir William Herschel, 234
Baltic and North Seas, Swedish Hydrographic Research in the, Prof. Otto Pettersson, 305
Baly (E. C. C.), Relations of Pressure, Volume, and Temperature of Rarefied Gases, 143; Experiments on Relations of Pressure, Volume, and Temperature of Rarefied Gases, 215
Bambeke (Ch. van), Vascular Hyphæ of the Mycelium of the Autobasidiomycetes, 214
Barbary, M. A. Pomel, on the Later Geological and Climatic Phases in, 368
Barber (C. A.), Drought at Antigua, 475
Barber (Samuel), Halo of 90° with Parhelia, 269
Barbier (Ph.), an Unsaturated Natural Ketone, 48; Constitution of Licareol, 144; on the Constitution of Rhodinol from Essence of Pelargonium, 368
Barcroft (Mr. Henry), on the Application of Screw-propellers to Canal Boats, 365
Bardeleben (Prof. Karl von), the Rudiments of Sixth and Seventh Digits or Rays in Mammals, 22
Barker (Capt. D. Wilson), Flight of Oceanic Birds, 617
Barlow (Dr. Lazarus), Experiments upon the Flow of Lymph from the Hind Limbs, 462
Barlow (W.), Ueber die geometrischen Eigenschaften homogener starrer Structuren und ihre Anwendung auf Krystalle, 593
Barnard (Prof. E. E.), the Diameters of some Minor Planets, 65; the Nebulous Character of Nova Aurigæ, 254; the Discs of Jupiter's Satellites, W. J. S. Lockyer, 320; Observations of Saturn and Uranus, 433; Nebulosities near the Pleiades, 583; the Fifth Satellite of Jupiter, 624
Barometer, Height of, Karl Pearson, 338; Henry Mellish, 400
Bartoli (Prof.), Effect of a Thin Veil of Cloud or Mist upon the Intensity of Solar Radiation, 482; Temperature Variation in the Electrical Resistance of Esters of the Fatty Acids, 502
Barton (E. H.), Electrical Interference Phenomena, 69
Barus (Carl), Spiral Goniometry in its Relation to the Measurement of Activity, 334; when two Metals are Thermoelectrically Identical, 91; the present Status of High Temperature Research, 635
Bassaris, the Cunning, a Recent Addition to the Zoological Society's Menagerie, 128
Bassett-Smith (P. W.), Results of Dredgings on Macclesfield Bank in the China Sea, 552
Batavia, Eruption of the Volcano of Galoenggoen, 620
Bateson (W.), Materials for the Study of Variation, treated with especial regard to Discontinuity in the Origin of Species, Prof. W. F. R. Weldon, F.R.S., 25
Bath, an Electric Light, Dr. Gebbardt, 432
Bathometer, Universal, Captain G. Rung, 431
Bathymetrical Survey of the Lake of Garda, Prof. Richter, 581
Bauer (L. A.), Wilde's Theory of the Secular Variation of Terrestrial Magnetism, 337
Baur (Dr. K. W.), Death of, 130
Bayard (Mr. F. C.), on the Rainfall at Greenwich, 457
Bayliss (Mr.), Experimental Inquiry into the Innervation of the Portal Vein, 462; Vaso-dilator Nerves, 462
Beaulard (M. F.), on the Specific Inductive Capacity of Glass, 335
Bebber (Dr. J. W. van), on the Daily Synoptic Weather Charts of the North Atlantic, 362
Becker (G. F.), on certain Astronomical Conditions favourable to Glaciation, 440
Beddard (Frank E., F.R.S.), another New Branchiate Oligochæte, 20
Beer, some of the Micro-Organisms causing the Diseases of, Mr. Fellowes, 503
Beer Money, the Work of the, John Rae, 583
Bees and Wasps, some Oriental Beliefs about, Kumagusu Minakata, 30
Bees-wax, the Bleaching of, J. S. D., 452
Behrens (Prof. H.), Alloys of Iron with Chromium and Tungsten, 24; a Manual of Micro-chemical Analysis, 122; Detection of Alkaloids by Micro-chemical Methods, 311
Belgique, Bulletin de l'Académie Royale de, 165, 214, 489
Belgium: A. Gillon, on the Iron and Steel Industries of, 459; Mr. D. Selby Bigge, on Electrical Power in Belgian Iron Works, 460
Bell (Sir Lowthian), on the Use of Caustic Lime in the Blast Furnace, 459
Bélopolsky (A.), the Appearance of the Helium Line, 206
Beneden (Prof. E. van), on the Origin and Morphological Signification of the Notochord, 434; on the Relations of Protoplasm, 434
Bengal, the Anthropometrical System of Identification in use in, 326
Benham (Dr. Wm. Blaxland), Vermes, 7; on the Blood of the *Magelona*, 435
Bennettites, some New Facts with regard to, A. C. Seward, 594
Benson (General Robert), Death of, 620
Benson (Miss), on the Fertilisation of the Chalazogamic Amentiferæ, 434
Bent (J. Theodore), Exploration of the Hadramut, 90; on the Natives of the Hadramut, 440
Bergen, Norway, the Biological Institution in, 271
Berlin Meteorological Society, 95, 191
Berlin Physical Society, 95, 192, 287
Berlin Physiological Society, 95, 192, 335, 491
Bermudas, the Coal-Reefs of the, Alexander Agassiz, 235
Bernard (H. M.), Has the Case for Direct Organic Adaptation been fully stated? 546
Bernthstein (Dr.), on a New Bacterium which occurs in Milk, 409
Berridge Laboratory, the, for the Chemical and Bacteriological Examination of Water Supply, &c., 501
Bersier (Lieut.), New Form of Automatic Steering Compass, 252; on the Automatic Transmitter of Steering Directions, 587
Berthelot (M.), Sulphuric Acid Compounds of Isomeric Propylene, 72; Researches on Trimethylene and Propylene, 120; the Explosive Decomposition of Ammonium and Mercury Salts of Diazoimide, 253; Researches on Phenylhydrazine, 263
Berthollet-Proust Controversy, the, and the Law of Definite Proportions, Philip J. Hartog, 149
Bertillon's System of Identification to be adopted in England, 481
Bertrand (C. Eg.), on Coprolitic Bacteria of the Permian Age, 396
Bertrand (G.), the Latex of the Lacquer Tree, 144
Bertrand (M.), on the Structure of the French Alps, 510
Bertrand (Prof.), Jubilee Presentation to, 130
Bessemer Process, Spectroscopic Phenomena and Thermo-Chemistry of, Prof. W. N. Hartley, F.R.S., 261
Bianco (Dr. O. Z.), Researches at Turin as to Recent Change in the Character of April, 393
Bidwell (Shelford, F.R.S.), on the Effect of Magnetisation upon the Dimensions of Iron Rings in directions perpendicular to the Magnetisation and upon the Volume of the Rings, 442; on the Recurrent Images following Visual Impressions, 466
Bifilar Pendulum for Measuring Earth-Tilts, C. Davison, 246
Big Game Shooting, Clive Phillipps-Wolley, 298
Bigge (D. Selby), on Electrical Power in Belgian Iron Works, 460
Biggs (C. H. W.), First Principles of Electrical Engineering, 423; Electrical Distribution, its Theory and Practice, part ii, 423
Bigourdan (G.), Determination of Relative Intensity of Gravity, 94
Bigourdan (M.), on the Micrometric Measurement of Small Angular Celestial Distances, MM. Loewy, Tisserand, and Wolf, 368

Biles (Prof. J. H.), on the Design of Mail Steamers with special reference to their use for War purposes, 329
Binaries, Spectroscopic Velocities of, 327
Biology: Introduction to Elementary Practical Biology, C. W. Dodge, 77; Obituary Notice of George John Romanes, F.R.S., by Prof. E. Ray Lankester, F.R.S., 108; the Biological Institution in Bergen, Norway, 271; Biological Station established at Drobatt, Norway, 275; Biological Station established at Havana, Illinois River, 275; Prof. J. M. Macfarlane on the Irrito-contractility of Plants, 361; Opening Address in Section D of the British Association by Prof. I. Bayley Balfour, F.R.S., 371; a Theory of Development and Heredity, Henry B. Orr, 445; Alternating Generations: a Biological Study of Oak Galls and Gall Flies, Dr. Hermann Adler, 545; Marine Biology, the Projected Station at Cumbræ, 13; Johann von Müller and the Gulf of Naples, 14; Ocean Meadows, 65; Ouramœba, Wm. L. Poteat, 79; Clavatella Prolifera, Henry Scherren, 104; Annual Report of Wood's Holl (Mass.) Laboratory, 130; the Marine Biological Association, 203; Reports of, 251; Interesting Marine Animals, Prof. W. A. Herdman, F.R.S., 475; Bacteriology of the Ocean, Dr. B. Fischer, 431; Wood's Holl, Mass. Laboratory, 481; Results of Dredgings on Macclesfield Bank in the China Sea, P. W. Bassett-Smith, 552 (*See also* Section D of the British Association)
Bird (Charles), Geology, 171
Birds, Early Arrival of, J. Lloyd-Bozward, 8; Rev. W. Clement Ley, 31
Birds, the Flight of Oceanic, Capt. D. Wilson Barker, 617
Birds, Rate of the Flight of, F. W. Headley, 269
Birkeland (M.), Experiments on the Magnetisation of Iron and Paraffin by Hertzian Waves, 203
Biskra and the Oasis and Desert of the Zibans, Alfred E. Pease, 317
Bittner (Dr. A.), the Newer Literature of the Alpine Trias, 283
Bitumen, California, on the Nitrogen Content of, S. F. Peckham, 515
Black (Alex.), First Principles of Building, 616
Black (Surgeon-Major W. G.), the Teeth and Civilisation, 148
Blandford (W. F. H.), on a Sand Flea, or Chigoe, from China, 635
Blandford (Dr. W. T., F.R.S.), Gohna Lake, 596
Blanshard (C. T.), New Element in the Sulphur Group, 571
Blast-Furnace, Sir Lowthian Bell on the use of Caustic Lime in the, 459
Bleekrode (Dr. L.) on the use of Quartz Fibres in Telescopes, 174
Blondlot (R.) on the Propagation of Electromagnetic Waves in Ice, 604
Blood, Researches on the Causes of the Toxicity of the Serum of, MM. Mairet and Bosc, 335
Bloxam (A. G.), Cataloguing Scientific Papers, 104; Prof. Ostwald on English Chemists, 224
Boa-constrictor swallowed by another in the Zoological Gardens, one, 620
Board Schools, Scientific Method in, Prof. H. E. Armstrong, F.R.S., 631
Boaz (Dr. Frank) on Human Faculty as determined by Race, 487
Boilers: on the Influence of Circulation on Evaporative Efficiency of Water Tube, J. I. Thornycroft, 328; Recent Experience with Cylindrical Boilers and the Ellis and Eaves Suction Draught, F. Gross, 329
Boisbaudran (M. Lecoq de), Crystals, 420
Boll (Franz) Studien uber Claudius Ptolemaus: ein Beitrag zur Geschichte der griechischen Philosophie und Astrologie, 398
Bolton (Herbert), New Goniatite from Lower Coal Measures, 70
Boltzmann's Theorem on Permanence of Distributions, Dr. Watson's Proof of, Edwd. P. Culverwell, 617
Bompas (G. C.), the Semi-Annual Variation of Meteors, 504
Bond (C. H.), External Anatomy of the Chinese Brain, 111
Bonney (Prof. T. G., F.R.S.), Mesozoic Rocks and Crystalline Schists in Lepontine Alps, 22; Relations of the Older Fragmental Rock in North west Carnarvonshire, 286
Bonnier (Gaston), Structure of Plants of Spitzbergen and Jan Mayen Island, 216
Books, the Dendritic Crystals on Pages of, A. T. Tait, 112; Means adopted in Indian Museums for Preservation of, against Insects, 155
Bornand's (Dr.) Bequest to the Académie de Lausanne for the Endowment of a Chair of Embryogeny, 325
Bos (Dr. J. Ritzema), Agricultural Zoology, 567
Bosc (M.), Researches on the Causes of the Toxicity of the Serum of Blood, 335
Bossi (A.), Formaldoxime, 22
Botany: Irritability of Plants, R. W. Deeley, 8; the Natural History of Plants, from the German of Prof. Anton Kerner von Marilaun, Prof. F. W. Oliver, 28; Death and Obituary Notice of Adolph Leipner and of A. Derbès, 33; Number of Species at present known, Prof. Saccardo, 35; the Earliest Mention of Dictyophora, Kumagusu Minakata, 54; Death of Dr. E. H. Vinen, 60; Death of Prof. Thomas Morong, 60; Size and Age of Largest Native Trees in Britain, Dr. D. Christison, 62; Habits of *Lemna*, Dr. H. B. Guppy, 71; the Fertilisation of *Clerodendron tomentosum* and *Candollea serrulata*, A. G. Hamilton, 95; Botanical Charts and Definitions, Miss A. E. Brooke and Miss A. C. Brooke, 101; Practical Botany for Beginners, F. O. Bower, 123; the Latex of the Lacquer Tree, G. Bertrand, 144; Structural Botany (Flowering Botany), Dukinfield Henry Scott, 147; Mohl's Primordial Utricle, Thomas Hick, 173; Death of Ed. Lefèvre, 177; Structure of Plants of Spitzbergen and Jan Mayen Island, Gaston Bonnier, 216; the Root of *Lyginodendron Oldhamium*, Dr. W. C. Williamson, F.R.S., and Dr. D. H. Scott, 261; Methods of Fertilisation of *Goodeniaceæ*, A. G. Hamilton, 288; the Royal Botanic Garden, Calcutta, 308; Annual Report of the Royal Botanic Garden, Calcutta, 326; Fungus Diseases of Cultivated Trees, P. Baccarini, 309; Nuovo Giornale Botanico Italiano, 309; Journal of Botany, 309; a Handbook to the Flora of Ceylon, Henry Trimen, F.R.S., James Britten, 316; Prof. J. M. Macfarlane on the Irrito-Contractility of Plants, 361; Records of Kaffrarian Plants, Thos. R. Sim, 416; Miss Benson on the Fertilisation of the Chalazogamic Amentiferæ, 434; Miss Pertz on the Hygroscopic Dispersal of Fruits in certain Labiatæ, 434; Prof. Johnstone on Algæ which deposit Calcareous Matter in their Tissues, 434; on the Periodic Variation in the number of Chromosomes, Prof. Strasburger, 434; Prof. Douglas H. Campbell on the origin of the Sexual Organs of the Pteridophytes, Notes upon the Germination of the Spores of the Ophioglosseæ, 435; Prof. F. O. Bower on Sterilisation and a Theory of the Strobilus, 435; Researches on the Respiration and Assimilation of the Muscineæ, B. Jönsson, 444; on Nucleoli and Centrosomes, J. E. Humphrey, 503; Death of Prof. Pringsheim, 580; Two Letters of Charles Darwin, 580; Some New Facts with regard to *Bennettites*, A. C. Seward, 594; A Student's Text-Book of Botany," Prof. S. H. Vines, F.R.S., the Student's Introductory Handbook of Systematic Botany, Joseph W. Oliver, Harold Wager, 613; Death of General Robert Benson, 620
Bouchardot (G.), Action of Sulphuric Acid on Camphor, 264
Bourru (M.), the Homologues of Quinine, 191
Bouty (E.), Capacity of Polarised Surface of Mercury, &c., 35; on the Capacity of the Capillary Electrometer, 455
Bouveault (L.), an Unsaturated Natural Ketone, 48; Constitution of Licareol, 144; on the Constitution of Rhodinol from Essence of Pelargonium, 368
Bovey (Henry T.), Theory of Structures and Strength of Materials, Prof. A. G. Greenhill, F.R.S., 97
Bower (F. O.), Practical Botany for Beginners, 123; on Sterilisation and a Theory of the Strobilus, 435
Bower (John A.), Simple Experiments for Science Teaching, 123
Boyle (Robert), the Sceptical Chemist, 349
Boys (Prof. C. V., F.R.S.) on the Newtonian Constant of Gravitation, 330, 366, 417, 571
Bozward (J. Lloyd), Early Arrival of Birds, 8
Bradbury's (Chas.) "Brunsviga" Calculating Machine, 182
Brain, External Anatomy of the Chinese, C. H. Bond, 111
Brains, Two Microcephalic, Dr. Telford Smith and Prof. D. J. Cunningham, F.R.S., 287
Bramwell (Sir Frederick), some Reminiscences of Steam Locomotion on Common Roads, 437

Branchiate Oligochæte, another New, Frank E. Beddard, F.R.S., 20
Brauner (B.), Fluoplumbates and Free Fluorine, 22
Bread, Micro-organisms and, Dr. Troitzkè, 204
Brehme (Dr.), the Cultivable Land on Kilimanjaro, 305
Brinton (Dr. D. G.), the Native Calendar of Central America and Mexico, 206; on the Aims of the American Association for the Advancement of Science, 485; Variations in the Human Skeleton and their Causes, 487; Conclusions on the Hieroglyph "pax," 487
BRITISH ASSOCIATION: Meeting at Oxford, 151, 270, 297, 338, 369, 400; Inaugural Address by the Most Hon. the Marquis of Salisbury, F.R.S., Chancellor of the University of Oxford, President, 339; Conferences of the Delegates of the Corresponding Societies, 461
Section A (*Mathematics and Physics*)—Opening Address by Prof. A. W. Rücker, F.R.S., President of the Section, 343; Lord Kelvin, P.R.S., and Mr. Maclean on some Preliminary Experiments to find if Subtraction of Water from Air electrifies it, 406; Prof. Oliver Lodge, F.R.S., on Photo-electric Leakage, 406; G. H. Bryan on the Present State of Knowledge in Thermodynamics, 406; Prof. Henrici on Integrators, Harmonic Analysers, and Integraphs, and their Application to Physical and Engineering Problems, 407; Prof. Osborne Reynolds on the Successive Stages in the Motion of Water passing under gradually increasing Pressure through a Vertical Tube constricted in the Middle, 407; Lord Rayleigh, F.R.S., on Experiments made to Determine the Minimum Current audible in the Telephone, 407; on the Quantitative Theory of the Telephone, 408; Prof. J. A. Ewing on an Apparatus for Measuring Small Strains, 408; F. G. Baily on Hysteresis in Iron and Steel in a Rotating Magnetic Field, 408; Prof S. P. Thompson on the Magnetic Analogues of well-known Propositions respecting Optical Images in Plane Mirrors, 408; Prof. A. M. Mayer on Beats and Beat-Tones, 408; Prof. Oliver Lodge, F.R.S., on Maxwell's Theory of Light, 408; Prof. J. J. Thomson on the Velocity of the Cathode Rays, 408; Prof. W. Forster on the Displacements of the Rotational Axis of the Earth, 409, 488
Section B (*Chemistry*)—Opening Address by Prof. H. B. Dixon, F.R.S., President of the Section, an Oxford School of Chemists, 348; Prof. Clowes' Experiments on the Proportions of Carbonic Acid in Air which are extinctive to Flame, and which are irrespirable, 409; Dr. Lobry de Bruyn's Experiments demonstrating the Properties of Free Hydroxylamine, 409; Dr. Bernthstein on a New Bacterium which occurs in Milk, 409; Prof. J. J. Thomson, Experiments illustrating the Connection between Chemical Change and Electrical Discharge through Gases, 409; Brereton Baker, some Experiments on the Influence of Moisture on Chemical Substances, 409; Dr. Ewan on the Rate of Oxidation of Phosphorous Sulphur and Aldehyde, 409; Prof. Hartley on some New Methods of Spectrum Analysis and some Bessemer Flame Spectra, 410; Lord Rayleigh and Prof. Ramsay on the Existence of a New Gas in the Atmosphere, 410; Prof. Roberts-Austen on some Experiments on the Electrolysis of Glass, 410; Dr. J. H. Gladstone on the Rate of Progress of Chemical Change, 410; Philip Hartog on the Distinction between Compounds and Homogeneous Mixtures, 410; Prof. J. A. Wanklyn on the Atomic Weight of Carbon, 410; A. P. Laurie on the Diffusion of very Dilute Solutions of Chlorine and Iodine, 410; Prof. J. W. Bruhl on Tautomerism, 411; Dr. Caro on a Method of Obtaining a New Rhodamine, 411, Drs. G. G. Henderson and A. R. Ewing on Tetrarsenites, 411; Dr. J. B. Cohen on the Constitution of the Acid Amides, 411; Report of the Committee upon the Action of Light upon Dyed Colours, 411; Dr. W. Meyerhoffer on Certain Phenomena of Equilibrium during the Evaporation of Salt Solutions, 411
Section C (*Geology*)—Opening Address by L. Fletcher, F.R.S., President of the Section, 353; H. A. Miers on a New Method of Measuring Crystals, 411; Howard Fox, Remarkable Rock at Dinas Head in Cornwall, 412; Profs. Green and W. Boyd Dawkins on Oxfordshire Geology, 412; Plateau Implements of Kent, 412; Pleistocene Geology, 412; Dr. Hicks on the Stratified Gravels, Sands, and Clay of the Plateaux of Hendon, Finchley, and Whetstone, 412; E. P. Culverwell, an Examination of Croll's and Ball's Theory of Ice Ages and Genial Ages, 413; Montgomerie Ball on the Palæolithic Section at Wolvercote, 413; Geologies and Deluges, Prof. Sollas, F.R.S., 505
Section D (*Biology*)—Opening Address by Prof. I. Bayley Balfour, F.R.S., President of the Section, 371; Report of Committees, 434; J. E. S. Moore, Investigations on the Reduction Division in Cartilaginous Fishes, 434; Prof. Hubrecht on the Didermic Blastocyte in Mammalia, 434; W. Garstang on the Ancestry of the Chordata, 434; W. E. Collinge on the Structure of the Integument in *Polyodon*, 434; Prof. Johnstone on Algæ which deposit Calcareous Matter in their Tissues, 434; Prof. E. Van Beneden on the Relations of Protoplasm, 434; Prof. Strasburger on the Periodic Variation in the Number of Chromosomes, 434; Prof. Ray Lankester on Chlorophyll in Animals, 434; Prof. E. Van Beneden on the Origin and Morphological Signification of the Notochord, 434; Prof. Struthers on the Carpus of the Greenland Right Whale, 434; Miss Benson on the Fertilisation of Chalazogamic Amentiferæ, 434; Miss Pertz on Hydroscopic Dispersal of Fruits in Certain Labiatæ, 434; Dr. O. Maas on Temperature as a Factor in the Distribution of Marine Animals, 434; Prof. W. A. Herdman on the Marine Zoology of the Irish Sea, 434; Prof. D'Arcy Thompson on some Difficulties of Darwinism, 435; Prof. C. V. Riley on Social Insects and Evolution, 435; Prof. Haycraft on the *rôle* of Sex in Evolution, 435; Prof. Osborn on Certain Principles of Progressively Adaptive Variations observed in Fossil Series, 435; W. P. Pycraft on the Wing of *Archæopteryx* viewed in the light of that of some Modern Birds, 435; Prof. Douglas H. Campbell on the Origin of the Sexual Organs of the Pteridophytes, and Notes upon the Germination of the Spores of the Ophioglosseæ, 435; Prof. F. O. Bower on Sterilisation and a Theory of the Strobilus, 435; Dr. W. B. Benham on the Blood of *Magelona*, 435; J. T. Cunningham on the Significance of Diagnostic Characters in the Pleuronectidæ, 436; Dr. F. A. Dixey on the Plantar Surface in Infants, 436; W. E. Collinge on the Relations of the Cranial Nerves to the Sensory Canal System, 436; Dr. H. B. Pollard on Cranial Skeletons of South American and African Siluroid Fishes, 436
Section E (*Geography*)—Opening Address by Capt. W. J. L. Wharton, F.R.S., President of the Section, 377; Oceanographical Observations, H. N. Dickson, 436; J. Y. Buchanan, F.R.S., on Researches carried out on board the Prince of Monaco's Yacht in the Mediterranean and North Atlantic, 436; Dr. John Murray on the Geographical and Bathymetrical Distribution of Organisms in the Ocean, 436; Somers Clarke on the Geography of Lower Nubia, 437; Norman Lockyer on the Projected Nile Reservoir, 437; G. G. Chisholm on the Spelling of Geographical Names, 437
Section G (*Mechanical Science*)—Opening Address by Prof. A. B. W. Kennedy, F.R.S., President of the Section, the Critical Side of Mechanical Training, 383; Sir Frederick Bramwell on some Reminiscences of Steam Locomotion on Common Roads, 438; Prof. T. Claxton Fidler on the Strength and Plastic Extensibility of Iron and Steel, 438; Sir Andrew Noble on Methods that have been adopted for Measuring Pressures in the Bores of Guns, 438; B. Donkin on the most Economical Temperature for Steam Engine Cylinders, 438; Prof. D. S. Capper on Engineering Laboratory Instruments and their Calibration, 438
Section H (*Anthropology*)—Opening Address by Sir. W. H. Flower, F.R.S., President of the Section, 387; Dr. E. B. Tylor on the Distribution of Mythical Beliefs as Evidence in the History of Culture, 439; Discussion on the Plateau Flint Implements of North Kent, 439; Arthur Evans on the Discovery of a new Hieroglyphic System and Pre-Phœnician Script in Crete, 439; Rev. G. Hartwell Jones on the Relation between the Body and Mind, as expressed in Early Languages, Customs, and Myths, 440; Prof. J. Kollmann on Pygmies in Europe, 440; General Pitt-Rivers on the Explorations of British Camps and a Long Barrow near Rushmore, 440; Theodore Bent on the Natives of the Hadramut, 440; J. Gray on the Distribution of the Picts in Britain as indicated by Place-Names, 440; Prof. L. Manouvrier on the Brain of a Young Fuegian,

440; Rev. Lorimer Fison on the Classificatory System of Relationship, 440; J. Graham Kerr on the Tobas of South America, 440; Alfred P. Maudslay on Native Buildings at Chichen Itsa, Yucatan, and the Customs of the Maya Indians, 440

Section I (*Physiology*)—Opening Address by Prof. E. A. Schäfer, F.R.S., President of the Section, 401; M. S. Pembrey on the Reaction of Animals to Changes of External Temperature, 460; Mr. Harris on the Results of an Investigation into the Muscular Rhythm of Voluntary Tetanus in Man, 461; Prof. McKendrick on the Phonograph, 461; Prof. Gaule on Microscopic Specimens and Slides illustrating the Remarkable Changes observed by himself as following the Section in the Rabbit of the Inferior Cervical Sympathetic Ganglion or its Branches, 461; Prof. Haycraft upon the Development of the Kidney, 461; Prof. Heger on the Unequal Diffusion of Poisons into the Organs of the Body, 461; Prof. Schafer and Dr. Oliver on the Functions of the Suprarenal Bodies, 461; Prof. Rutherford on Observations in which the Reaction Time was Measured for Sight, Hearing, and Touch, 461; D'Arcy Power on a Series of Preparations of the Conjunctival and Vaginal Mucous Membranes taken from Rabbits and Guinea-Pigs which had been subjected to Mechanical and Chemical Irritation, 461; Prof. Hermann upon the Production of Vowel and Consonant Sounds, 461; Prof. Fredericq on a New Aerotonometer and Gas Pipette for investigating the Causation of the Gaseous Interchange between the Blood and Air of the Lungs, 461; L. Cobbett and Mr. Melsome on the Results of an Investigation on the Production of Local Immunity through a Localised Specific Inflammatory Condition, 462; Lorrain Smith and Mr. Trevithick, Research on Local Immunity, the Initial Inflammatory Process brought about by a Simple Irritant, 462; Dr Mann, Microscopic Specimens and Microphotographs in which changes could be observed in various Nerve Cells as the Result of their Functional Activity, 462; Dr. L. Hill on the Effect of Gravity in altering the Mammalian Blood-pressure, 462; Dr. Mott, Microphotographs of the Medulla Cord, &c., 462; Dr. Starling, Experiments showing that the Flow of Lymph from the Thoracic Duct was dependent upon the Amount of the Blood-pressure in the Liver Capillaries, 462; Dr. Lazarus Barlow, Experiments on the Flow of Lymph from the Hind Limbs, 462; Messrs. Bayliss and Starling on the Results of an Experimental Inquiry into the Innervation of the Portal Vein, 462; Mr. Bayliss upon Vaso-dilator Nerves, 462; Prof. Waymouth Reid on the Alteration in the Mucous Membrane of the Lateral Pouches of the Pigeon's Crop, 463; Prof. Dubois on the Production of Heat in Hybernating Animals, 463; Prof. Lodge, Experiments upon the Reflection, Polarisation, and Refraction of Hertz Waves, 463; D. Haldane on the Cause of Death by Suffocation in the Recent Colliery Explosion in South Wales, 463; W. G. Smith, Observations illustrating some of the Mental Conditions which influence the Association of Ideas, *i.e.* Memory, 463; Method Employed by Profs. Gotch and Lodge in order to Study the Physiological Effects produced by Rapidly Alternating Currents of High Intensity, 463; a New Kymograph, Prof. Engelmann, 463; Photographs of the Excursions of a very Sensitive Capillary Electrometer when projected on a rapidly Travelling Plate and actuated by speaking into a Telephone placed in the Circuit, Prof. G. J. Burch, 464

British Isles, Climbing in the, W. P. Haskett Smith, 267
British Lichens, Rev. James M. Crombie, 295
British Museum, Catalogue of the Mesozoic Plants in the Department of Geology, A. C. Seward, 294

Buchanan (J. G., F.R.S.), Rapid Changes of Atmospheric Temperature, especially during Föhn, and Methods of observing them, 165; Researches carried out on board the Prince of Monaco's Yacht in the Mediterranean and North Atlantic, 436
Buchner (Prof.), the Problem of Immunity, 511
Buckingham (Hon. J.), Insect Ravages in India, 274
Budapest, International Congress of Hygiene and Demography at, 19, 454, 511
Building, First Principles of, Alex. Black, 616
Bulgaria: Publication of Means of Observations for Sophia for 1891-3, 14
Bullet Proof Shields, Mrs. Emma Hubbard, 148; Frederick J. Smith, 174
Bullets, the Penetrative Power of, Rev. Frederick J. Smith, 124
Bulletin de l'Académie Royale de Belgique, 165, 214, 489
Bulletin of New York Mathematical Society, 91, 235, 309, 441
Bulletin de la Société d'Anthropologie de Paris, 21, 441, 490
Bulletin de la Société des Naturalistes de Moscou, 141
Bulletino della Societa Botanica Italiana, 309
Burch (Prof. G. J.), Action of Concentrated Acids on Pairs of Metals in Contact, 71; Photographs of the Excursions of a very Sensitive Capillary Electrometer when projected on to a rapidly Travelling Plate and actuated by speaking into a Telephone placed in the Circuit, 464
Burcker (E.), Stability of Aqueous Solutions of Mercury Bichlorides, 191; Action of Camphoric Anhydride on Benzene in presence of Aluminic Chloride, 444
Burmah, the Fauna of British India, including Ceylon and, G. F. Hampson, 4
Burton (C. V.), Mechanism of Electrical Conduction in Metals, 69
Butterflies, Absence of, 225; J. Shaw, 297; D. Wetterhan, 319

Calcutta, the Royal Botanic Garden, 308; Annual Report of, 326
Calderon (Laureano), Death of, 13
Calendar, the Native, of Central America and Mexico, Dr. D. G. Brinton, 206
California Bitumen, on the Nitrogen Content of, S. F. Peckham, 515
Calvert (Albert F.), the Aborigines of Western Australia, 474
Calvin (Samuel), Niobrara Chalk, 486
Cambridge, the new Engineering Laboratory at, opening of, by Lord Kelvin, 65
Cambridge Philosophical Society, 143, 190
Camel, the, its Uses and Management, Major A. G. Leonard, 195
Campbell (Prof. Douglas H.), on the Origin of the Sexual Organs of the Pteridophytes, 435; Notes upon the Germination of the Spores of the Ophioglosseæ, 435
Campbell (J. MacNaught), Iron Crows' Nests, 125
Campbell (Prof. W. W.), Bright-line Stars, 181; the Spectrum of the Orion Nebula, 254
Canal Boats, Mr. Henry Barcroft on the Application of Screw-propellers to, 365
Canton (William), Moon-Man or Moon-Maid, 66
Canu (F.), Précis de Météorologie Endogéne, 498
Capper (Prof. D. S.) on Engineering Laboratory Instruments and their Calibration, 437
Carbon Atom, the Tetrahedral, 596; Dr. G. S. Turpin, 548
Carbon in Ferro-carbon Alloys, Mr. T. W. Hogg on the Influence of Aluminium upon the, 460
Carbonic Acid in Air, Experiments on the Proportions of,

which are extinctive to Flame, and which are irrespirable, Prof. Clowes, 409
Carlyle's (A. C.) Collection of Minute Stone Implements from the Vindhya Hills (India), 132
Carnegie (Douglas), Law and Theory in Chemistry, MM. Pattison Muir, 98
Caro (Dr.) on Method of obtaining a New Rhodamine, 411
Carpmael (Charles), Death of, 620
Carroll (Thomas), the Potato Disease, *Phytophthora infestans*, 63
Cartailhac (E.), the Female Deity and Sculptures of the Allée Couverte of Epone, 91
Cartwright (T. B.), a Remarkable Meteor, 474
Carvill (Henry), Papers and Notes on the Glacial Geology of Great Britain and Ireland, Rev. E. Hill, 421
Cash (Dr. J. Theodore, F.R.S.), the Physiological Action of the Paraffin Nitrites, 550
Cassell's Family Magazine, Science in, 140, 234
Cataloguing Scientific Papers, A. G. Bloxam, 104
Cataract Construction Company at the Falls of Niagara, the Recent Work of the, 11
Caterpillar Plague in Scotland, Grass-destroying, Miss Ormerod, 251
Cathode Rays, the Magnetic Deflection of, Herr P. Lenard, 114
Cathode Rays, on the Velocity of the, Prof. J. J. Thomson, 408
Cattle, the Microbe of Contagious Peripneumonia in, S. Arloing, 287
Causse (H.), Synthesis of Mesoxalic Acid and Bismuth Mesoxalate, 311
Cavalier (J.), Monoethylphosphoric Acid, 167
Cave-Dwellers: among the Tarahumaris, Dr. Carl Lumholtz, 234
Cayeux (M. L.), Radiolarians from Rocks in Brittany, 326
Celestial Objects for Common Telescopes, Rev. T. W. Webb, 523
Celestial Photography, a Selection of Photographs of Stars, Star Clusters and Nebulæ, together with Information concerning the Instruments and the Methods employed in the Pursuit of, Isaac Roberts, F.R.S., Dr. A. A. Common, F.R.S., 447
Centenary of the Paris Polytechnic School, 82
Centipedes and their Young, Dr. R. v. Lendenfeld, 8; J. J. Quelch, 124
Century Magazine, Science in the, 66, 140, 420
Cereals, on Diptera harmful to, Paul Marchal, 516
Ceres, Diameter of, Prof. E. E. Barnard, 65
Ceylon, a Handbook to the Flora of, Henry Trimen, F.R.S., James Britten, 316
Ceylon and Burmah, the Fauna of British India, including, G. F. Hampson, 4
Chambers's Journal, Science in, 66
Chandler (S. C.), Award of the Watson Medal to, 157; Rotation of the Terrestrial Poles, 396
Chanute (O.), Progress in Flying Machines, 569
Chappuis' (James) New Method of determining Critical Temperatures by Critical Index, 48
Charles (Prof. R. H.), Morphological Peculiarities in Natives of Panjab, 16; Incomparability of Nasal Indices derived from Measurements of the Living Head with those deduced from Observation of Skulls, 482
Charpy (Georges), Rôle of transformation of Iron and Carbon in handling of Steel, 167; Relation between Density of Saline Solution and Molecular Weight of dissolved Salt, 287
Chassy (M. A.), on the Electrolysis of Copper Sulphate, 335
Chemistry: Death of J. C. G. de Marignac, 13; Death of Laureano Calderon, 13; Ratio of Atomic Weights of Hydrogen and Oxygen, Prof. Julius Thomsen, 15; Free Hydroxylamine, Lobry de Bruyn, 17; Wiedemann's Annalen der Physik und Chemie, 21, 118, 188, 236, 515, 635; Chemical Society, 22, 71, 143, 166, 238, 335; Formaldoxime, W. R. Dunstan and A. L. Bossi, 22; Chlorocamphene, J. E. Marsh and J. A. Gardner, 22; a Sulphate of Oxamide, J. E. Marsh, 22; Fluoplumbates and Free Fluorine, B. Brauner, 22; Tetramethyleneamine, W. H. Perkin, jun., 22; β-2-Dimethylglutaric Acid, W. Goodwin and W. H. Perkin, jun., 22; Sodium Derivative of Ethyl Acetoacetate, M. de Forcrand, 23; Ethylic Acetoacetate, M. de Forcrand, 94; Alloys of Iron with Chromium and Tungsten, Prof. H. Behrens, 24; Explosive Halogen Compounds of Nitrogen, Dr. Seliwanow, 36; Cupric Bromide, Paul Sabatier, 48; an Unsaturated Natural Ketone, Ph. Barbier and L. Bouveault, 48; the Alchemical Essence and the Chemical Element, M. M. Pattison Muir, Prof. Herbert Mcleod, F.R.S., 50; Nitrate of Soda in Egypt, Prof. W. C. Mackenzie, 61, 360; Sodium Peroxide, Prof. Poleck, 64; Agricultural Chemistry, Manures and the Principles of Manuring, C. M. Aikman, 75; Magnetic Rotations of Acetic and Propionic Acid, W. H. Perkin, 71; Action of Concentrated Acids on Pairs of Metals in contact, G. I. Burch and J. W. Dodgson, 71; Action of Light on Oxalic Acid, A. Richardson, 71; Volatilisation of Salts during Evaporation, G. H. Bailey, 71; Constitution of Glycocine and its Derivatives, Toji Sakurai, 71; Constitution of Glycocine, T. Walker, 71; Oxidation of Alkali Metals, W. Holt and W. E. Sims, 71; Sulphuric Acid Compounds of Isomeric Propylenes, M. Berthelot, 72; Direct Method of preparing β-Alkyl-Hydroxylamines, Lobry de Bruyn, 86; Stability of Dilute Solutions of Corrosive Sublimate, Léo Vignon, 94; Law and Theory in Chemistry, Douglas Carnegie, M. M. Pattison Muir, 98; Sodium and Uranium Peroxides, Thomas Fairley, 103; the Pyromellitic Acid Crystals formed in the preparation of Sulphur Dioxide, M. Girard, 112; a Sodium-Nitrogen Compound, L. Zehnder, 118; Researches on Trimethylene and Propylene, M. Berthelot, 120; Combinations of Ammonia with Silver Salts, MM. Joannes and Crozier, 120; a Manual of Microchemical Analysis, Prof. H. Behrens, 122; Structure and Chemistry of Cyanogen Flame, A. Smithells and F. Dent, 143; Conditions in which Carbon exists in Steel, J. O. Arnold and A. A. Read, 143; Hexamethylenedibromide, E. Haworth and W. H. Perkin, jun., 143; Constitution of Licareol, Ph. Barbier and L. Bouveault, 144; the Berthollet-Proust Controversy and the Law of Definite Proportions, Philip J. Hartog, 149; Three Iodo-Sulphides of Phosphorus, M. Ouvrard, 156; the Density of Nitrogen Gas, Lord Rayleigh, Sec.R.S., 157; Properties of Carbon Bisulphide, H. Arctowski, 165; Solubilities of Haloid Salts of Mercury in Carbon Bisulphide, H. Arctowski, 165; Influence of Moisture on Chemical Change, H. B. Baker, 166; New Volatile Compounds of Lead Sulphide, J. B. Hannay, 166; Effect of Heat on Iodates and Bromates, E. H. Cook, 166; a Hydrobromide of Cupric Bromide and a Red Bromide of Copper and Potassium, Paul Sabatier, 167; the Analytical Separation of Chlorine and Bromine, R. Engel, 167; Combinations of Pyridine with Permanganates, T. Klobb, 167; Monoethylphosphoric Acid, J. Cavalier, 167; the Emetics, Paul Adam, 167; a Chemical Method of Isolating Fluorine, A. E. Tutton, 183; Absorption of Hydrogen by Water and Aqueous Solutions, Paul Steiner, 188; the Homologues of Quinine, MM. Grimaux, Laborde, and Bourru, 191; the Estimation of Iodine, MM. Villiers and Fayolle, 191; Action of Primary Aromatic Bases on Disymmetrical Ketonic Compounds, L. Simon, 191; Stability of Aqueous Solutions of Mercury Trichloride, E. Burcker, 191; Cancerine, A. B. Griffiths, 191; Chemistry Demonstration Sheets, 196; Dimethyl Arsine, Dr. Palmer, 205; the Hydrates of the Alkyl-Amines, Louis Henry, 214; Detection of Traces of Chlorine, A. Villiers and M. Fayolle, 216; Influence of Fluorine Compounds on Beer Ferments, J. Effront, 216; a Laboratory for Physical and Chemical Research, 217; Prof. Ostwald on English Chemists, A. G. Bloxam, 224; Presentation to Dr. Tilden, 227; Prof. Rowland on Chemical Training, 228; the Nature of the Molecule of Calomel, Prof. Victor Meyer and Mr. Harris, 230; Twenty-five Years of Chemistry in Russia, 231; New Method of Discovering Relative Affinities of certain Acids, M. C. Lea, 235; Crystallography of Normal Sulphates of Potassium, Rubidium, and Cæsium, A. E. Tutton, 238; Phosphorescence, H. Jackson, 238; Action of Methyl Iodide on Hydroxylamine, W. R. Dunstan and E. Goulding, 238; the Hydroximes of the Lapachol Group, S. C. Hooker and E. Wilson, 239; Chemical Study of Native Arseniates and Phosphates, Prof. A. H. Church, F.R.S., 239; Oxygen, J. H. van't Hoff, 240; Equilibrium of Solutions and Solid Phases formed of System: HCl, H_2O and Fe_2Cl_6, Bakhuis Roozeboom, 240; the Explosive Decomposition of Ammonium and Mercury Salts of Diazoimide, MM. Berthelot and Vielle, 253; the Chemistry of Cleaning, Prof. Vivian Lewes, 256; Researches on Phenylhydrazine, M. Berthelot, 263; Preparation of a Crystallised Aluminium

Carbide, Henri Moissan, 264; Differentiation of Aldoses and Ketoses, A. Villiers and M. Fayolle, 264; Piceine, M. Tanret, 264; Action of Sulphuric Acid on Camphene, G. Bouchardot and J. Lafont, 264; Action of Acid Molybdates of Sodium and Ammonium on Rotatory Power of Rhamnose, D. Gernez, 264; Change of Sign of the Rotatory Power, Albert Colson, 264; Influence of Pressure on Combination of Hydrogen and Selenium, H. Pelabon, 264; Systematic Survey of the Organic Colouring Matters, Drs. G. Schultz and P. Julius, 267; further concerning the New Iodine Bases, A. E. Tutton, 278; Mode of converting Oxide of Iron into Hæmatite Crystals, Prof. Arctowski, 306; Detection of Alkaloids by Microchemical Methods, Prof. Behrens, 311; New Researches on Chromium, Henri Moissan, 311; Separation and Estimation of Tin and Antinomy in an Alloy, M. Mengin, 311; Synthesis of Mesoxalic Acid and Bismuth Mesoxalate, H. Causse, 311; Detection of Alkaloids by Microchemical Methods, Prof. Behrens, 311; Drs. Thiele and Lachman on the Remarkable Nitrogen Compound Nitramide, 327; on some Methods for the Determination of Water, S. L. Penfield, 334; the Detection of Alkaline Perchlorates associated with Chlorides, Chlorates, and Nitrates, F. A. Gooch and D. Albert Kreider, 334; the Interaction of Sulphide with Sulphate and Oxide of Zinc, J. B. Hanney, 335; Organo-Metallic Combinations of Borneol, Camphor, and Monochlor-Camphor with Aluminium Chloride, M. G. Perier, 335; the Oxidation of Tartaric Acid in presence of Iron, H. J. H. Fenton, 335; the Specific Character of the Fermentative Functions of Yeast Cells, A. J. Brown, 335; Observations on the Influence of Temperature on the Optical Activity of Organic Liquids, P. Frankland and J. MacGregor, 335; the Preparation of Sulphonic Derivatives of Camphor, F. S. Kipping and W. J. Pope, 335; on the Combination of Chlorine with Carbon Monoxide under the Influence of Light, G. Dyson and A. Harden, 335; Opening Address in Section B of the British Association, by Prof. H. B. Dickson, F.R.S., 348; the Sceptical Chemist, Robert Boyle, 349; Prof. von Pechman on Diazomethane, 364; on the Action of Thionyl Chloride on some Inorganic Acids and Organic Compounds, M. Ch. Moureu, 368; on the Constitution of Rhodinol from Essence of Pelargonium, MM. Ph. Barbier and L. Bouveault, 368; on Carbonic Hydrate and the Composition of Hydrates of Gases, P. Villard, 396; Basic Salts of Calcium, M. Tassilly, 396; the Physiology of the Carbohydrates, their Application as Food, and Relation to Diabetes, F. W. Pavy, F.R.S., 397; on Benzoylquinine, M. A. Wunsch, 420; Crystals collect at the upper part of a less dense Solution, M. Lecoq de Boisbaudran, 420; on the Specific Heat of Liquid Sulphurous Anhydride, M. E. Mathias, 420; the Generation of Chlorine for Laboratory Purposes, F. A. Gooch and D. A. Kreider, 440; on the Chemical and Bacteriological Examination of Soil, with special reference to the Soil of Graveyards, Dr. James Buchanan Young, 443; Action of Camphoric Anhydride on Benzene in presence of Aluminic Chloride, E. Burcker and C. Stabil, 444; a Text-Book of Physiological Chemistry, O. Hammersten, 449; Death of Prof. Josiah Parsons Cooke, 480; Assimilability of Potash by the Action of Nitrates in Poor Siliceous Soils, P. Pichard, 491; Organic Chemistry, W. H. Perkin, jun., F.R.S. and F. Stanley Kipping, 494; Lessons in Organic Chemistry, G. S. Turpin, 494; New Boron Compounds containing Fluorine and Alcohol Radicles, M. Casselin, 530; Indexing of Chemical Literature, 539; the Tetrahedral Carbon Atom, 596, Dr. G. S. Turpin, 548; Careless Writing, F. G. Donnan, 549; the Physiological Action of the Paraffin Nitrites, Dr. J. Theodore Cash, F.R.S., and Prof. Wyndham R. Dunstan, 550; Isolation of Symmetrical Hydrazo-ethane, Dr. Harries, 555; New Element in the Sulphur Group, C. J. Blanshard, 571; New Substance obtained by the Action of Alcohol upon Peroxide of Sodium, Prof. Tafel, 582; Action of Hydrogen Phosphide on Potassammonium and Sodammonium, A. Joannis, 588; Researches on Mercuric Picrate, Raoul Varet, 588; Action of Picric Acid and Picrates on Metallic Cyanides, the Isopurpurates, Raoul Varet, 588; the Antiseptic Properties of the Vapours of Formaldehyde, A. Trillat, 588; Paracelsus, MM. Pattison Muir, 598; Messrs. J. J. Griffin and Sons' Chemical Apparatus, 606; Chemical History of Hydrazine or Diamide and its Derivatives, Prof. Curtius, 606; Double Salts containing Diammonium, Prof. Curtius and Herr Schrader, 606; on the Preparation of Absolutely Pure Water, Herren Kohlrausch and Heydweiler, 621; Nitrogen Trioxide, Prof. Lunge and Herr Porsehnew, 623; on the Detection of Minute Quantities of Arsenic in Copper, F. A. Gooch and H. P. Moseley, 634; the Standardisation of Potassium Permanganate in Iron Analysis, Charlotte F. Roberts, 634; M. W. Longuinine on the Application of Trouton's Law to the Saturated Alcohols of the Fatty Series, 636; M. Raoul Pictet on the Congelation of Sulphuric Acid, 636 (*See also* Section B of the British Association)

Epping Forest Controversy, the, 12
Epping Forest Question, the Settlement of the, Prof. R. Meldola, F.R.S., 225
Equatorials, Finder-Circles for, 64; Prof. Wm. Harkness, 173
Erede (J.), the Action of Light on the Diphtheria Bacterium, 8
Erman (A., Life in Ancient Egypt, 615
Erosion of the Muir Glacier, Alaska, T. Mellard Reade, 245; Prof. G. Frederick Wright, 245
Espin (Rev. T. E., a New Variable Star, 417
Essex Field Club, the 273; Meeting of, in the Navestock District, 325
Etheostoma caprodes, Study of, W. J. Moenkbaus, 431
Etheridge (R.), on the Kurdaitcha Shoes of Central Australia, 636; supposed Aboriginal Hoe, 239
Etheridge (R., jun., the Glossopteris Fossil Plant, 288
Ethnography: Internationales Archiv fur Ethnographie, 21; Ethnography of Inishbofin and Inishshark, Dr. C. R. Browne, 110
Etna, Mount, Thermometrical Station established on, 14
Euclid's Problems, the Geometrography of, Dr. J. S. Mackay, 466

Europe, East, M. Nitikin on the Supposed Inter-Glacial Deposits in, 621
Evans (Arthur), on the Discovery of a New Hieroglyphic System and Pre-Phœnician Script in Crete, 439
Evolution: Prof. Haycraft on the Rôle of Sex in Evolution, 435; Social Insects and Evolution, Prof. C. V. Riley, 435; Darwinianism is not Evolution, 524; Nature's Method in the Evolution of Life, Dr. Alfred R. Wallace, F.R.S., 541; Has the Case for Direct Organic Adaptation been fully stated? H. M. Bernard, 546
Ewan (Dr.), on the Rate of Oxidation of Phosphorous Sulphur and Aldehyde, 409
Ewan (Thos.), on the Absorption Spectra of Dilute Solutions, 491
Ewing (Dr. A. R.), Tetrarsenites, 411
Ewing (Prof. J. A.), on an Apparatus for Measuring Small Strains, 408
Ex-Meridian treated as a Problem in Dynamics, the, H. B. Goodwin, 76
Ex-Meridian Latitude, J. White, 498
Examinations, the Report of the Committee on Army, 125
Explosion, the Albion Colliery, Prof. H. B. Dixon, 429
Explosives, Researches on Modern, Wm. Macnab and E. Ristori, 236
Explosives, Researches on, Captain Sir A. Noble, F.R.S., 309
Extraordinary Phenomenon, Admiral Sir Erasmus Ommanney, F.R.S., 524

Fabre (Charles), on the Use of Selected Ferments, 396
Fairley (Thomas), Sodium and Uranium Peroxides, 103
Faulds (Henry), the Identification of Habitual Criminals by Finger-Prints, 548
Fauna of British India, including Ceylon and Burmah, G. F. Hampson, 4
Fauna of North America, the Effect of Glaciation and of the Glacial Period on the Present, Samuel H. Scudder, 515
Fay (Edward Allen), Histories of American Schools for the Deaf, P. Macleod Yearsley, 100
Faye (H.), Geodesy and its Relations with Geology, 564
Fayolle (M.), the Estimation of Iodine, 191; Detection of Traces of Chlorine, 216; Differentiation of Aldoses and Ketoses, 264
Fayrer (Sir J., F.R.S.), Ophiophagus, 172; Preservation of Health in India, 616
Fellowes (Mr.), some of the Micro-Organisms causing the Diseases of Beer, 503
Fenton (H. J. H.), the Oxidation of Tartaric Acid in Presence of Iron, 335
Ferro-carbon Alloys, Mr. T. W. Hogg on the Influence of Aluminium upon the Carbon in, 460
Fertilisers and Feeding Stuffs, their Properties and Uses, Bernard Dyer, 569
Festoon Cumulus or "Pocky" Cloud, H. N. Dickson, 79
Fever, Sewer Gas and Typhoid, 19
Fidler (Prof. T. Claxton), on the Strength and Plastic Extensibility of Iron and Steel, 438
Fifth Satellite of Jupiter, the, Prof. E. E. Barnard, 624; on the Eccentricity of the Orbit of Jupiter's Fifth Satellite, M. F. Tisserand, 612
Finder-Circles for Equatorials, 64; Prof. Wm. Harkness, 173
Finger Prints, the Identification of Habitual Criminals by, Henry Faulds, 548
Fischer (Prof. D.), Death of, 153; Obituary Notice of, 272
Fischer (Dr. B.), Bacteriology of the Ocean, 34
Fish: the Hatchery for Sea Fishes at Dunbar, Dr. T. Wemyss Fulton, 18: Prizes offered by German Fisheries Association, 251; Fishery Board for Scotland, 305; Proposed Fish-hatching Station at Horsethief Springs, Rocky Mountains, 306; Report of the Director of the Aquarium of the U.S. Fish Commission at the Chicago Exhibition, 361; Results of a Search for a Fish hatching Station in the Gulf States U.S. Fish Commission, 432; on the Evolution of the Vertebral Column of Fishes, Dr. H. Gadow, F.R.S., and Miss E. C. Abbott, 516
Fisher (Prof. W. R.), Studies in Forestry, Dr. John Nisbet, 193
Fison (Rev. Lorimer), on the Classificatory System of Relationship, 440
Fitzgerald (Prof.), Herr Lenard on the Magnetic Deflection of Cathode Rays, 179
Flame, the Composition of Atmospheres which extinguish, Dr. Frank Clowes, 283
Flammarion (M.), on the Rotation of Solar Spots, 564
Flannery (J. F.), the Ventilation of Steamships, with special reference to the removal of Explosive and Foul Gases from Bulk Oil Steamers, 329
Fleming (Mrs.), Stars having Peculiar Spectra, 37
Fletcher (L., F.R.S.), Opening Address in Section C of the British Association, 353
Flight of the Albatross, A. Kingsmill, 572
Flight of Birds, Rate of the, F. W. Headley, 269
Flood and Ice Age Question, the, Richard Herring, 178
Flora of Ceylon, Handbook to the, Henry Trimen, F.R.S., James Britten, 316
Florida, Prehistoric Remains in, Dr. De W. Webb, 16
Flower (Sir W. H., F.R.S.), Opening Address in Section H of the British Association, 387
Fluid Motion, on the Doctrine of Discontinuity of, in connection with the Resistance against a Solid moving through a Fluid, Lord Kelvin, P.R.S., 524, 549, 573, 597
Fluid Motion, Study of, by means of Coloured Bands, Prof. Osborne Reynolds, F.R.S., 161
Fluorine, a Chemical Method of isolating, A. E. Tutton, 183
Fluorspar, F. Paschen on the Infra-Red Dispersion of, 635
Flying Machine, Device used by Mr. Maxim in making the Boiler of his, 329
Flying Machines, Progress in, O. Chanute, 569
Fog, Aurora and, H. C. Russell, 428
Folk-lore: Old German Legend concerning the Weather, Die Siebenschlafer, 455
Folk-lore: Songs of the Russian People, Th. M. Istomin and G. O. Dütsch, 594
Fomm (L.), on the Motion of Dielectric Bodies in the Homogeneous Electrostatic Field, 515
Fonvielle (W. de), Steam and Aerial Navigation foreshadowed by Roger Bacon, 481: Manual Pratique de l'Aéronaute, 569
Foraminifera, Contributions to the Life-history of the, J. J. Lister, 237
Forcrand (M. de), Sodium Derivative of Ethyl Acetoacetate, 23; Ethylic Acetoacetate, 94
Forestry: the Epping Forest Controversy, 12; the Settlement of the Epping Forest Question, Prof. R. Meldola, F.R.S., 225; Studies in Forestry, Dr. John Nisbet, Prof. W. R. Fisher, 193; Faults in the Treatment of Woods in Great Britain, 419; the Great Forest Fires in Minnesota and Wisconsin, 454
Förster (Prof. W.), on the Displacements of the Rotational Axis of the Earth, 409, 488
Fortnightly, Science in the, 66, 234, 489
Fossils: Tertiary Tipulidæ, S. H. Scudder, 111; the Recent Discovery of Fossil Remains at Lake Calabonna, South Australia, Dr. E. C. Stirling, F.R.S., 184, 206; the Glossopteris Plant, R. Etheridge, jun., and Prof. T. W. E. David, 288; on Coprolitic Bacteria of the Permian Age, MM. Renault and Bertrand, 396; on certain Principles of Progressively Adaptive Variations observed in Fossil Series, Prof. Osborn, 435
Foster (C. Le Neve), a Text-book of Ore and Stone Mining, Bennett H. Brough, 543
Foster (Prof. G. Carey, F.R.S.), Platinum Resistance Thermometers, 399
Fox (Howard), some Fossils from the Coast Sections in Parishes of Padstow and St. Mervyn, 203
Fraenkel (E.), Treatment of Typhoid Fever by Injection of Culture of Bacilli, 35
France: French Association for the Advancement of Science, M. Mascart's Presidential Address, 429: the Anthropology of France, Dr. R. Collignon, 441; Marine Biological Laboratory established on Tatihou Island, 503; on some Temperature Variations in France and Greenland, 571
Francotto (P.), Experiments in Experimental Pathological Embryology, 165
Frankland (P.), Observations on the influence of Temperature on the Optical Activity of Organic Liquids, 335
Frankland (Prof. Percy) and Mrs. Percy Frankland, Micro-Organisms in Water, Dr. E. Klein, F.R.S., 469
Frankland (Mrs. Percy), Les Femmes dans la Science, A. Rebière, 279; Sunshine and Water-Microbes, 452
Fredericq (Prof.), on a New Aerotonometer and Gas Pipette for

investigating the causation of the Gaseous Interchange between the Blood and Air of the Lungs, 461
Frena Camera, the, 229
French (C.), Handbook of the Destructive Insects of Victoria, 243
Friedel (C.), Composition of Apophyllite, 167
Frog, an Intelligence of the, Kumagusu Minakata, 79
Froggatt (W. W.), New Wasps' Nest Mite (*Heteropes alastori*), 288
Fromm (O.), the formation of Floating Metallic Films by Electrolysis, 21
Fromme (Carl), Magnetic Experimental Investigations, 635
Fruit Culture for Profit, C. B. Whitehead, 569
Frye (A. E.), Primary Geography, 473
Fulton (Dr. T. Wemyss), the Hatchery for Sea Fishes at Dunbar, 18
Funeral Rites in Madagascar, Antony Jully, 490
Fungi, the Earliest Mention of *Dictyophora*, Kumagusu Minakata, 54
Fur and Feather Series—the Grouse, Rev. H. A. Macpherson, A. J. Stuart-Wortley and George Saintsbury, 546
Fuss (W. E.), Award of the Count Lütke Medal to, for his Researches on Chronometers, 360

Gadow (Dr. H. F.R.S.), on the Evolution of the Vertebral Column of Fishes, 516
Gaisford (H.), Elementary Lessons in Steam Machinery and the Marine Engine, 220
Gale's Comet 36, Elements and Ephemeris of, 18; Ephemeris of, Prof. Kreutz, 87, 181
Gall Flies, Dr Adler's Observations on, 545
Galle (Dr. J. G.), Verzeichniss der Elemente der bisher berechneten Cometenbahnen, 473
Gallic Epoch, Pottery of the, Octave Vauvillé, 490
Galtier (V.), New Researches on Association among Bacteria, 48
Galton (Francis, F.R.S.), the Relative Sensitivity of Men and Women at the Nape of the Neck, 40
Garda, Lake, Bathymetrical Survey of, Prof. Richter, 581
Gardner (J. A.), Chlorocamphene, 22
Garhwal Landslip, the, 35, 109, 231, 250, 393, 428, 501; R. Strachey, F.R.S., 124; Dr. W. T. Blandford, F.R.S., 596
Garnett (H.), a White Swallow, 481
Garstang (W.), on the Ancestry of the Chordata, 434
Gas, Lighting, in Argand and Auer Burners, Comparison of Combustion Products of, N. Gréhant, 287
Gas Engineering: Death of Alfred Williams, 304
Gas, the Density of Nitrogen, Lord Rayleigh, Sec. R S. 157
Gas, on the Existence of a New, in the Atmosphere, Lord Rayleigh, F.R.S., and Prof. Ramsay, 410
Gases: Specific Heat of Carbon Dioxide at Constant Volume, Dr. J. Joly, F.R.S., 92; Experiments illustrating the Connection between Chemical Change and Electrical Discharge through Gases, Prof. J. J. Thomson, 409; Specific Heat of Gases at Constant Pressure, Dr. Silvio Lussana, 503
Gasselin (M.), New Boron Compounds containing Fluorine and Alcohol Radicles, 530
Gaule (Prof.), Microscopic Specimens and Slides illustrating the Remarkable Changes observed as following the Section in the Rabbit of the Inferior Cervical Sympathetic Ganglion or its Branches, 461
Gauss's Plate, the best Position of a, B. Walter, 431
Gebbardt (Dr.), an Electric Light Bath, 431
Geikie (Sir Archibald, F.R.S.), Banded Gabbros in Skye, 190; on the Banded Structure of the Oldest Gneisses and Tertiary Gabbros, 510
Geitel (Dr. H.), Electro-Optical Experiments, 236; Photo-Electric Phenomena, 451
Gelatine, Experiment made on a Dog as to the Nutritive Value of, Dr. J. Munk, 335
Geley (Gustave), Peripheric Applications of Alkaloids in the Treatment of Acute Maladies with Cutaneous Determination, 396
Geneva, International Congress of Orientalists at, 454
Geneva, on Spring Rains in, 475
Geodesy: Meteorology and Geodesy, Prof. C. Abbe, 141; Death of Prof. Fischer, 153; Meeting of the Association Géodésique Internationale at Innsbruck, 454; Geodesy and its Relations with Geology, H. Faye, 564
Geography: the Bakhtiari Mountains and Upper Elam, Lieut.-Col. Sawyer, 34; the Arctic Expeditions of 1894, Dr. Hugh Robert Mill, 57; the Horn Expedition for the Scientific Exploration of Central Australia, 174; Return of the, 528; the Wellman Arctic Expedition, 273, 304, 360, 393; Atlas of French Lakes, André Delebecque, 62; Mr. H. G. Bryant's Journey in Labrador, 85; the Great Globe—First Lessons in Geography, A. Seeley, 101; Influence of Ancient Village Communities on Map of England, H. T. Crofton, 110; Anniversary Meeting of the Royal Geographical Society, 113; Timbuktu, 154; Climbing and Exploration in the Karakoram-Himalayas, William Martin Conway, F.S.A., 199; Kafiristan, Surgeon Major G. S. Robertson, 211; the Cultivable Land on Kilimanjaro, Dr. Brehme, 305; Prof. J. A. C. Oudemans on the Geographical Position of the Astronomical Observatory at Utrecht, 312; Biskra and the Oases and Desert of the Zibans, Alfred E. Pease, 317; Award of the Constantine Medal to Prof. A. N. Veselovsky for his Studies on Folk-lore, 360; Opening Address in Section E of the British Association by Capt. W. J. L. Wharton, F R.S., 377; on the Orography of the Nang Shan, V. M. Obrucheff, 432; on the Tundras of North-East Russia, G. I. Tanfilieff, 432; Annual Report of Russian Geographical Society, 456; East Siberia, P. P. Semenoff, I. D. Cherskv and G. G. von Petz, 471; Primary Geography, A. E. Frye, 473; Normal Line of Separation between East and West of the Ancient World, Elisée Reclus, 583; Recent Explorations in British New Guinea, 609; La Géographie littorale, Jules Girard, 615
Geology: on some Sources of Error in the Study of Drift, Prof. T. McKenny Hughes, F.R.S., 5; Geologists' Association—Proposed Excursions, 13; Geological Society, 22, 70, 92, 166, 190, 285; Mesozoic Rocks and Crystalline Schists in Lepontine Alps, Prof. T. G. Bonney, F.R.S., 22; Ein Geologischer Querschnitt durch die Ost Alpen, A. Rothpletz, Dr. Maria M. Ogilvie, 27; the Newer Literature of the Alpine Trias, Dr. A. Bittner, 283; M. Bertrand on the Structure of the French Alps, 510; with Prof. Heim in the Eastern Alps, 526; on the Calcareous Tuffs of the Col de Lauterel (Hautes Alpes), W. Kilian, 588; the Glacial System of the Alps, B. Hobson, 602; Prof. Suess on the Southern and Northern Alps, 510; Igneous Rocks on Western Flank of Dartmoor, Lieut.-Gen. C. A. McMahon, 23; the Bhaganwala Coal-Field of the Salt Range, T. D. la Touche, 34; the Echinoidea of Cutch, Dr. J. W. Gregory, 35; the Landslip at Gohna Garwhal, 35, 109, 231, 250, 393, 428, 501; R. Strachey, F.R.S., 124; Dr. W. T. Blandford, F.R.S., 596; a Manual of the Geology of India, R. D. Oldham, 52; the Niagara River as a Geologic Chronometer, Prof. G. K. Gilbert, 53; Niagara Falls as a Chronometer of Geological Time, Prof. J. W. Spencer, 237; Niagara River since the Ice Age, Prof. Warren Upham, 198; Time Gauge of Niagara, Thos. W. Kingsmill, 338; the Age of Niagara Falls, Prof. Spencer, 486; the Scandinavian Ice Sheet, Victor Madsen, 54; the North Sea Ice Sheet, Sir Henry H. Howorth, F.R.S., 79; the Geology of Mashonaland, A. R. Sawyer, 70; Thames Valley Beds and Boulder Clay, T. V. Holmes, 70; Pleistocene Deposits at Twickenham, Dr. J. R. Leeson and G. B. Laffan, 70; New Goniatite from Lower Coal Measures, Herbert Bolton, 70; the Carrock Fell Gabbro, Alfred Harker, 92; Banded Gabbros in Skye, Sir Archibald Geikie, F.R.S., and J. J. H. Teall, F.R.S., 190; Sir. A. Geikie, F.R.S., on the Banded Structure of the Oldest Gneisses and Tertiary Gabbros, 510; Relation of Granite to Gabbro of Barnavave, Carlingford, Prof. W. J. Sollas, F.R.S., 252; the Geology of Monte Chaberton, A. M. Davies and Dr. J. W. Gregory, 92; Monograph of the Stalactites and Stalagmites of the Cleaves Cove, near Dalry, Ayrshire, John Smith, 100; Economic Geology of the United States, with briefer mention of Foreign Mineral Products, Ralph S. Tarr, 145; Stratigraphy and Physiography of Libyan Desert of Egypt, Capt. H. G. Lyons, 166; Geology of South Africa, D. Draper, 167; Occurrence of Dolomite in South Africa, D. Draper, 167; Geology of British East Africa, Dr. J. W. Gregory, 167; Geology, Charles Bird, 171; the Recent Discovery of Fossil Remains at Lake Calabonna, Dr. E. C. Stirling, F.R.S., 184, 206; Magnetic Rock, S. Skinner, 191; Derbyshire Carboniferous Dolerites and Tuffs, H. H. Arnold-Bemrose, 190; Origin of Permian Breccias of Midlands, R. D. Oldham, 190; some Fossils from the

Coast Sections in Parishes of Padstow and St. Mervyn, Howard Fox, 203; Discovery of Devonian Rocks in California, J. S. Diller and Charles Schubert, 235; Stalagmite from Lava Caves of Kilauea, A. H. Phillips, 235; Erosion of the Muir Glacier, Alaska, T. Mellard Read, Prof. G. Frederick Wright, 245; Geology of Torres Straits, Profs. Haddon, Sollas, and Cole, 276; Sir Andrew Ramsay's Physical Geology and Geography of Great Britain, H. B. Woodward, 277; Jahrbuch der K. K. Geologischen Reichsanstalt Wien, 283; Deep Borings at Culford, Winkfield, Ware, and Cheshunt, W. Whitaker, F.R.S., and A. G. Jukes-Browne, 285; Deposits from Snow-drifts, Charles Davison, 286; the Formation of Coal-Seams, W. S. Gresley, 286; the Origin of Anthracite, W. S. Gresley, 286; Relations of the Older Fragmental Rocks in North-West Carnarvonshire, Prof. T. G. Bonney, F.R.S., and Catherine A. Raisin, 286; Popular Lectures and Addresses by Sir W. Thomson (Baron Kelvin), P.R.S., Prof. O. J. Lodge, F.R.S., 289, 313; Catalogue of the Mesozoic Plants in the Department of Geology, British Museum, A. C. Seward, 294; the International Geological Congress, W. Topley, F.R.S., 319; the International Geological Congress at Zurich, 510; Geology and Scenery in Ireland, Prof. Grenville, A. J. Cole, 323; the Shasta-Chico Series, J. S. Diller and T. W. Stanton, 326; Radiolarians from Rocks in Brittany, M. L. Cayeux, 326; Opening Address in Section C of the British Association, by L. Fletcher, F.R.S., 353; M. A. Pomel on the later Geological and Climatic Phases in Barbary, 368; Papers and Notes on the Glacial Geology of Great Britain and Ireland, Henry Carvill, Rev. E. Hill, 421; Glacial Action in Australasia in Tertiary or Post-Tertiary Time, 483; M. Nitikin on the supposed Inter-Glacial Deposits in East Europe, 621; Geological Map of Baden, J. Edmund Clark, 426; on the Orography of the Nang Shan, V. M. Obrucheff, 432; Niobrara Chalk, Samuel Calvin, 486; Sach- und Orts-Verzeichniss zu den Mineralogischen und Geologischen Arbeiten von Gerhard vom Rath, Frau vom Rath, 498; Magnetism of Rock Pinnacles, Lieut.-General C. A. McMahon, 499; Dr. William King's Work in India, 502; Geologies and Deluges, Prof. Sollas, F.R.S., 505; the New International Geological Map, Report on Progress of Geology, Dr. Hauchecorne, 510; Michel Lévy on the Principles to be followed in a Universal Classification of the Rocks, 510; Phylogeny, Ontogeny, and Systematic Arrangement, Prof. von Zittel, 510; Tertiary and Later History of the Island of Cuba, Robert T. Hill, 515; Geodesy and its Relations with Geology, H. Faye, 564; Obituary Notice of William Topley, F.R.S., 579 (*See also* Section C of the British Association)
Geometrography of Euclid's Problems, the, Dr. J. S. Mackay, 466
Geometry: Modern Plane Geometry, G. Richardson and A. S. Ramsay, 196; the Geometrography of Euclid's Problems, Dr. J. S. Mackay, 466; Grundzüge der Geometrie von Mehreren Dimensionen und Mehreren Arten Gradliniger Einheiten in Elementarer Form entwickelt, Guiseppe Veronese, 493, 520; Ueber die Geometrischen Eigenschaften homogener starrer Strukturen und ihre Anwendung auf Krystalle, W. Barlow, 593; Abstract Geometry, Edward T. Dixon, 596
Geophysical Observatory on Jungfrau, Projected, 130

Arnold, 38; an Introduction to the Study of, Prof. W. C. Roberts-Austen, F.R.S., W. Gowland, 147: Rôle of Transformations of Iron and Carbon in Hardening of Steel, Georges Charpy, 167; the Metallurgy of Gold, T. Kirke Rose, 170; a Handbook of Gold Milling, Henry Louis, 170; Electrical Apparatus for Discovering Internal Flaws in Iron and Steel, 228; on Manganese Steel, M. H. Le Chatelier, 335; on the Structure of Steel, M. F. Osmond, 368; Determinations of a Bore made at Cremorne Point, New South Wales, Prof. T. W. E. David, 415; M. W. Spring on the Cold Welding of Metals, 455
Metals, on the Diselectrification of and other Bodies by Light, Prof. Oliver J. Lodge, F.R.S., 225
Metals, Method for Determining Thermal Conductivity of Metal, Jos. H. Gray, 261
Metchnikoff (Prof. Elias), Lectures on the Comparative Pathology of Inflammation, 194
Metchnikoff (M.), Bacteriology of Cholera, 511
Meteorology, Thermometrical Station Established on Mount Etna, 14; Temperature-Variations on Mount Etna, Prof. Riccò and Saija, 85; Publication of Means of Observations for Sophia (Bulgaria) for 1891-3, 14; Icebergs and their Relation to Weather, H. C. Russell, F.R.S., 15; A. Sydney D. Atkinson, 31; Rainfall Observations for 1892 in East Indian Archipelago, Dr. van der Stok, 17; American Meteorological Journal, 21, 141, 188; New Chart of Equal Ranges of Temperature, J. L. S. Connolly, 21; Thunderstorms, M. Renou, 34; Connection between Certain Squalls which accompany large Barometric Depressions and Thunderstorms F. Durand-Greville, 430; Annual Distribution of Thunder-

storms over the Globe, Prof. A. Klossovsky, 581; Aurora of February 22, Dr. M. A. Veeder, 51; Aurora Australis, H. C. Russell, 319; Aurora and Fog, H. C. Russell, 428; Fine Aurora seen in Tasmania, H. S. Dove, 482; Aurora, J. Shaw, 499; Auroral display in New Zealand and Australia, 620; the Climate of Odessa, Prof. Klossovsky, 62; Sunspots and Weather, P. Polis, 62; W. L. Dallas, 113; Festoon Cumulus or "Pocky" Cloud, H. N. Dickson, 79; a Monochromatic Rainbow, Charles Davison, 84; Proposed Tidal Observatory in Madras Harbour, 84; the Week's Weather, 84, 110, 228, 251; Kew Observatory Report for 1893, 85; Sonnblick Society's Report for 1893, 86; Investigation on Daily Period of Wind Velocity on Sonnblick Summit, Dr. J. Hann, 228; Relative Frequency of different Velocities of Wind, W. Ellis, F.R.S., 94; Audibility of Big Ben at West Norwood, W. Marriott, 94; Royal Meteorological Society, 94, 215; Berlin Meteorological Society, 95, 191; Cloud-height Measurements at Eiffel Tower, Dr. Kassner, 95; Changes in the Definitions of Clouds since Howard, H. H. Clayton, 334; the Transmission of Weather Forecasts to Rural Telegraph Offices, 109; Mr. J. H. Collins' Arrangement for finding Tidal Streams round Isle of Wight, 112; Increase of Temperature with Depth in Low Algerian Sahara, George Roulland, 120; Ebb and Flow of the Earth's Atmosphere, Dr. J. Hann, 130; Meteorology and Geodesy, Prof. C. Abbe, 141; Violent Hailstorm in Vienna, 153; Hailstones at Cleveland, Ohio, Francis H. Herrick, 173; Remarkable Hailstones at Vicksburg, Prof. Cleveland Abbe, 430; Diurnal Oscillations of Barometer at Paris, Prof. L. Descroix, 155; Height of Barometer, Henry Mellish, 400; Meteorologische Zeitschrift, 165; Meteorological Observations on the Pic du Midi, Dr. F. Klengel, 125; Rapid Changes of Atmospheric Temperature, especially during Fohn, and Methods of observing them, J. Y. Buchanan, F.R.S., 165; the Employment of a Trigonometrical Series in Meteorology, Dr. A. Schmidt, 178; Report of Canadian Meteorological Service for 1889, 179; the Names of the Winds, Dr. Umlauft, 188; a Winter Sojourn on the Brocken, Dr. Süring, 191; Symons's Monthly Meteorological Magazine, 214; the May Frost of 1894, Mr. Symons, 214; Night Frosts, T. Homén, 276; Fogs with Strong Winds in British Isles, 1876–90, R. H. Scott, F.R.S., 215; Characteristic Features of Gales and Strong Winds, R. H. Curtis, 215; Report of German Meteorological Institute for 1893, 228; Recent Change in the Character of April, 246; Dr. O. Z. Bianco, Researches at Turin, on the, 393; Halo of 90° with Parhelia, Samuel Barber, 269; Elementary Meteorology, William Morris Davis, 293; on some Methods in Meteorology, 318; Rainfall in Great Britain during July, 325; British Rainfall, G. J. Symons, F.R.S., 416; Mr. F. C. Bayard on the Rainfall at Greenwich, 457; Rainfall of Scotland, Dr. Buchan, 604; Researches made at Hong Kong Observatory during 1893, Dr. W. Doberck, 325; Admiral S. Makaroff, on an International Agreement for the Publication of Meteorological Information contained in Ships' Logbooks, 360; Dr. J. W. Van Bebber, on the Daily Synoptic Weather Charts of the North Atlantic, 362; Report of the Maryland State Weather Service, 364; Meteorological Observations in Alsace and Lorraine, 1892, 430; M. J. Jaubert on the Atmosphere of Paris, 454; Meeting of the International Meteorological Committee, 454; Old German Legend concerning the Weather, Die Siebenschläfer, 455; on Spring Rains in Geneva, 475; Deutsche Seewarte, Report for 1893, 482; Effect of a thin veil of Cloud or Mist upon the Intensity of Solar Radiation, Profs. Bartoli and Stracciati, 482; Precis de Météorologie Endogène, F. Canu, 498; Disastrous Cyclone in the United States, 528; Meteorology of the United States, Major H. H. C. Dunwoody, 608; Destructive Storm in Japan, 528; Meteorology in Italy for 1893, 552; on some Temperature-Variations in France and Greenland, 571; Meteorology of India for 1893, John Eliot, 553; Thermometric Observations on the Summit of Ararat, M. Venukoff, 588; Schools of Meteorology, Prof. Cleveland Abbe, 576; Tornado at Little Rock, Arkansas, 580; a Long Period Meteorograph, Jules Richard, 617; Death of Mr. Charles Clark, 620; the Past Summer, Charles Harding, 624; A. H. S. Lucas on the Formation of a Mackerel Sky, 636

Meteors: a Daylight Meteor, Jas. G. Richmond, 124; the August Swarm of Meteors, 365; a Remarkable Meteor, Edward Wesson, 399; on the Path of the Meteor of May 18, 1894, Prof. Copeland, 443; the Remarkable Meteor of August 26, 1894, John W. Earle, 452; Edward F. Linton, T. B. Cartwright, Thos. Ward, 574; the Meteor and Meteor-Streak of August 26, 1894, W. F. Denning, 537, 617; Bright Meteors, Prof. A. S. Herschel, F.R.S., 572; the semi-Annual Variation of Meteors, G. C. Bompas, 504; Shooting-Stars observed in Italy, P. François Denza, 540; an Instrument for Photographing Meteors, 556

Metrology: the Metals suitable for Manufacturing Standards of Length, C. E. Guillaume, 111

Metrophotography, M. Laussedat, 274

Meyer (Prof. Victor), the Nature of the Molecule of Calomel, 230

Meyerhoffer (Dr. W.), Certain Phenomena of Equilibrium during the Evaporation of Salt Solutions, 411

Michael (Mr.), the Eye in Hydrachnea, 119

Michigan, Mining School Report of the Director of, 364

Micro-Chemistry: a Manual of Microchemical Analysis, Prof. H. Behrens, 122

Micro-Organisms in Water, Prof. Percy Frankland and Mrs. Percy Frankland, Dr. E. Klein, F.R.S., 469

Micro-Organisms causing the Diseases of Beer, some of the, Mr. Fellowes, 503

Microbes: Sunshine and Water-Microbes, Mrs. Percy Frankland, 452

Micrometer: Report on M. Bigourdan's Memoir on the Micrometric Measurement of small Angular Celestial Distances, MM. Loewy, Tisserand, and Wolf, 368

Microrheometer, on the, J. B. Hannay, 311

Microscopy: Apparatus for Observation of Micro-Organisms, Prof. Marshall Ward, 40; Quarterly Journal of Microscopical Science, 60, 441, 515, 611; Royal Microscopical Society, 94, 119, 286; Quekett Microscopical Club, 119; New Photo-Microscopic Apparatus, C. L. Curties, 119; Living Specimens of Gromia, Mr. Shrubsole, 119; the Eye in Hydrachnea, Mr. Michael, 119; a Manual of Microchemical Analysis, Prof. H. Behrens, 122; Detection of Alkaloids by Microchemical Methods, Prof. Behrens, 311; Studies on the Nervous System of Crustacea, Edgar J. Allen, 611

Microsporidiæ, Presence of Thread Cell in Spores of, P. Thélohan, 216

Middleton (G. A. T.), Surveying and Surveying Instruments, 221

Midland Union of Natural History and Scientific Societies at Ellesmere, Annual Meeting of, 360

Miers (H. A.), on a new Method of Measuring Crystals, 411

Migration and the Food Quest, a Study in the Peopling of America, O. T. Mason, 361

Milk, the Dangers of, 111

Milk Jug, the Tell Tale, J. Lawrence, 554

Mill (Dr. Hugh Robert), the Arctic Expeditions of 1894, 57; a Survey of the English Lakes, 184

Millosevich (Prof. E.), the First Observation of Sun-Spots, 230

Milne (Prof. John, F.R.S.), the Miners' Handbook, 145; Seismic Magnetic and Electric Phenomena, 415

Minakata (Kumagusu), some Oriental Beliefs about Bees and Wasps, 30; the Earliest Mention of Dictyophora, 54; an Intelligence of the Frog, 70

Minchin (Prof. G. M.), Behaviour of certain Bodies in presence of Electro-Magnetic Oscillations, 94

Mineralogy: a Manual of Micro-Chemical Analysis, Prof. H. Behrens, 122; Economic Geology of the United States, with briefer mention of Foreign Mineral Products, Ralph S. Tarr, 145; Composition of Apophyllite, C. Friedel, 167; Mineralogical Society, 239; Chemical Study of Native Arseniates and Phosphates, Prof. A. H. Church, F.R.S., 239; Death of Prof. Mallard, 250; Obituary Notice of Ernest Mallard, M. G. Wyrouboff, 428; L. Fletcher, F.R.S., 353; Separation of Minerals of High Specific Gravity by the use of Dr. J. W. Retgers's Fused Double Nitrate of Silver and Thallium, Messrs. Penfield and Kreider, 415; Sach- und Orts-Verzeichniss zu den Mineralogischen und Geologischen Arbeiten von Gerhard vom Rath, Frau vom Rath, 498

Mining: Economic Geology of the United States with briefer mention of Foreign Mineral Products, Ralph S. Tarr, 145; the Ore Deposits of the United States, James F. Kemp, 145

Mining: an Elementary Treatise on the getting of Minerals, Arnold Lupton, 145; the Miners' Handbook, John Milne,

F.R.S., 145; Science and Mining, Hon. James Martin, 273; Report of the Director of the Michigan Mining School, 364; a Textbook of Ore and Stone Mining, C. Le Neve Foster, Bennett H. Brough, 543
Minnesota and Wisconsin, the Great Forest Fires in, 454
Mint Report, the, 83
Miquel (P.). Re-establishment of the Size of Diatoms, 414
Mistletoe, Prof. Weisner on the, 456
Moenkhaus (W. J.), American Freshwater Percidæ, Study of *Etheostoma caprodes*, 431
Mohl's "Primordial Utricle," Thomas Hick, 173
Moissan's (M. Henri) Electric Furnace, 39; Preparation of a Crystallised Aluminium Carbide, 264; New Researches on Chromium, 311
Mollusca: *Testacella Haliotoidea*, J. Lloyd-Bozward, 224; W. M. Webb, 296; Australasian Forms of *Gundlachia*, Charles Hedley, 431
Montreal, Physics and Engineering at the McGill University, 558
Moon, Apparent Diameter of the, M. P. Stroobant, 36
Moon, Eclipse of the, 484
Moon, the Harvest, 484
Moon, Photographs of the, MM. Loewy and Puiseux, 278
Moon Man or Moon-Maid, William Canton, 66
Moore (J. E. S.), Investigations on the Reduction Division in Cartilaginous Fishes, 434; the Archoplasm and Attraction Sphere, 478
Morbology: Notes on some of the more Common Diseases in Queensland in Relation to Atmospheric Conditions, 1887–91, Dr. David Hardie, 28; the Plague of Athens, Dr. Keser, 62; Experiments on Frogs in Studying Pancreatic Diabetes, Dr. Marcuse, 336
Moreau (G.), on the Periodicity of the Absorption Rays of Isotropic Substances, 444
Morgan (Prof. C. Lloyd), the Scope of Psycho-Physiology, 54; Observations on Young Pheasants, 575
Morong (Prof. Thos.), Death of, 60
Morphology of Muscles of Shoulder-girdle in Monotremes, W. J. S. McKay, 288
Mortillet (G. de), Proposed Reform in Chronology, 21
Morton's (Dr. W. T. G.), Claims to the Discovery of Anæsthesia, E. L. Snell, 420
Morvan, Recherches Ethnologiques sur le, Ab. Hovelacque and Georges Hervé, 441
Moscou, Bulletin de la Société des Naturalistes de, 141
Moseley (H. P.), F. A. Gooch and, on the Detection of Minute Quantities of Arsenic in Copper, 634
Moth, the Yucca, J. C. Whitten, 229
Moths, North American, Dr. John B. Smith, W. F. Kirby, 619
Motion, Fluid, on the Doctrine of Discontinuity of, in connection with the Resistance against a Solid moving through a Fluid, Lord Kelvin, P.R.S., 524, 549, 573, 597
Mott (Dr.), Microphotographs of the Medulla Cord, &c., 462
Mount Logan, the Loftiest Peak in North America, 131
Moureaux (M.), Magnetic Disturbance corresponding in time with Earthquake Shock at Constantinople, 394
Moureu (M. Ch.), on the Action of Thionyl Chloride on some Inorganic Acids and Organic Compounds, 368
Muir (M. M. Pattison), the Alchemical Essence and the Chemical Element, Prof. Herbert McLeod, F.R.S., 50; Law and Theory in Chemistry, Douglas Carnegie, 98; Paracelsus, 598
Muir Glacier, Alaska, Erosion of the, T. Mellard Reade, 245; Prof. G. Frederick Wright, 245
Müller (Johann von), and the Gulf of Naples, 14
Muller's (Joh.), Lehrbuch der Kosmischen Physik, Dr. C. F. W. Peters, W. J. Lockyer, 49
Muller (Johannes) and Amphioxus, 54
Mummery (J. Howard), the Teeth and Civilisation, 123
Munk (Dr. J.), Experiment made on a Dog as to the Nutritive Value of Gelatine, 335; Experiments on Fasting Dogs, 491
Munro (J.), How I Discovered the North Pole, 140
Munsterberg (Prof.) and Mr. A. H. Pierce on the Localisation of Sound, 621
Muntz (A.), Utilisation of Vintage "Marcs," 144
Murché (Vincent T.), Object Lessons in Elementary Science, 497
Murray (Dr. John), on the Geographical and Bathymetrical Distribution of Organisms in the Ocean, 436; Arctic and Antarctic Marine Fauna, 443
Muscineæ, Researches on the Respiration and Assimilation of the, B. Jonsson, 444
Muscular Energy, Experiments to determine whether any one alone of the Food-stuffs, Proteids, Fats, or Carbohydrates, can be regarded as the Source of, Prof. Zuntz, 336
Museum, Albany, Grahamstown, Report of, 275; Report of the Australian, Sydney for 1893, 581
Myers (F. W. H.), the Drift of Psychical Research, 584
Mygind (Holger), Deaf-Mutism, P. Macleod Yearsley, 449
Mylius (F.), the Formation of Floating Metallic Films by Electrolysis, 21
Mythical Beliefs as Evidence in the History of Culture, on the distribution of, Dr. E. B. Tylor, 439

Naber (H. A.), New Form of Gas Voltameter, 252
Naden (Constance), the Complete Poetical Works of, 594
Nape of the Neck, the Relative Sensitivity (by Weber's Test) of Men and Women at the, Francis Galton, F.R.S., 40
Naples, Johann von Muller and the Gulf of, 14
Nasal Indices, Incomparability of, derived from Measurements of the Living Head with those deduced from Observations of Skulls, Dr. R. Havelock Charles, 482
Natal Astrology: a Treatise of Natal Astrology, G. Wilde and J. Dodson, the Soul and the Stars, A. G. Trench, 219
National Home Reading Union, the Summer Assemblies of the, 130
National Magazine, Science in the, 489
National Review, Science in the, 419, 584
Natural History: the Fauna of British India, including Ceylon and Burmah, G. F. Hampson, 4; Iron Crows' Nests, Walter G. McMillan, 8; J. MacNaught Campbell, 125; Annalen des K. K. Naturhistorischen Hofmuseums, 22; the Natural History of Plants, from the German of Prof. Anton Kermer von Marilaun, Prof. F. W. Oliver, 28; the Effect of External Conditions upon Development, Prof. August Weismann, 31; Shakespeare's Birds and Insects, 65; Centipedes and their Young, J. J. Quelch, 124; Recent Additions to the Zoological Society's Menagerie, 127; Bulletin de la Société des Naturalistes de Moscou, 141; Memoirs of Kazan Society of Naturalistes, 141; a Handbook to the Study of Natural History, for the Use of Beginners, 221; Trituberculy and Polybuny, E. S. Goodrich, 208; the Essex Field Club, 273; Annual Meeting of Midland Union of Natural History and Scientific Societies at Ellesmere, 360
Natural Selection, Panmixia and, Dr. Alfred R. Wallace, F.R.S., 196
Nature's Method in the Evolution of Life, Dr. Alfred R. Wallace, F.R.S., 541
Naval Architecture: the Institute of Naval Architects, 328; on the Harbour and Docks of Southampton, John Dixon, 328; on the Importance of Economy in Fuel in very Fast Vessels, and on the advantages to be derived from Heating the Feed-water, J. A. Normand, 328; on the Influence of Circulation on Evaporative Efficiency of Water Tube Boiler, J. I. Thornycroft, 328; on the Design of Mail Steamers with Special Reference to their use for War Purposes, J. H. Biles, 329; Device used by Mr. Maxim in making the Boiler of his Flying Machine, 329; Recent Experience with Cylindrical Boilers and the Ellis and Eaves Suction Draught, F. Gross, 328; the Ventilation of Steamships with special reference to the removal of Explosive and Foul Gases from Bulk Oil Steamers, S. H. Terry and J. F. Flannery, 328
Naval Engineering: Elementary Lessons in Steam Machinery and the Marine Engine, J. Langmaid, H. Gaisford, 220
Navigation: the Ex-Meridian Treated as a Problem in Dynamics, H. B. Goodwin, 76; New Form of Automatic Steering Compass, Lieut. Bersier, 252; Twelve Charts of the Tidal Streams on the West Coast of Scotland, F. Howard Collins, 318; Latitude by Ex-Meridian, J. White, 498; on the Automatic Transmitter of Steering Directions, Lieut. H. Bersier, 587
Nebula, a New Spiral, Dr. Roberts, 231
Nebula in Andromeda, the Great, C. Easton, 547
Nebulæ and Star Clusters, the Distribution of, Sidney Waters, 484
Nebulosities near the Pleiades, Prof. E. E. Barnard, 583
Nebulous Character of Nova Aurigæ, the, Prof. E. E. Barnard, 254; F. Renz, 254
Neck, the Relative Sensitivity of Men and Women at the Nape of the, Francis Galton, F.R.S., 40

Neolithic Period, Discovery of an Interment of the, at Saint Mammès, Eugene Toulouze, 490
Nervous System of Crustacea, Studies on the, Edgar J. Allen, 611
Nests, Iron Crows', Walter G. McMillan, 8 ; J. MacNaught Campbell, 125
Netherlands Entomological Society, 312
Neumann (Dr. Carl), Death of, 454
Newcomb (Prof. Simon), the Mass of Jupiter, 458
Newfoundland as it is in 1894, Rev. M. Harvey, 523
New Guinea, Recent Exploration in British, 609
New Review, Science in the, 66
New South Wales, Linnean Society of, 95, 239, 288, 444, 492, 636 ; Royal Society of New South Wales, 287. Mr. Tebbutt's Observatory, 231 ; Proposed Government Metallurgical Works, 415 : Determination of the Temperature of a Bore, made at Cremorne Point, Prof. J. W. E. David, 415
Newtonian Constant of Gravitation, on the, Prof. C. V. Boys, F.R.S., 330, 366, 417, 571
Newtonian Law of Attraction for Crystalline and Isotropic Masses at Small Distances, Experiments in Tests of Validity of, A. S. Mackenzie, 262
New York Mathematical Society, Bulletin of, 91, 235, 309, 441
New Zealand and Australia, Auroral Display in, 620
New Zealand, Earthquakes in, 84
Niagara : the Recent Work of the Cataract Construction Company at the Falls of, 11 ; the Niagara River as a Geologic Chronometer, Prof. G. K. Gilbert, 53 ; Niagara River since the Ice Age, Prof Warren Upham, 198 ; Niagara Falls as a Chronometer of Geological Time, Prof. J. W. Spencer, 237 ; Time-Gauge of Niagara, Thos. W. Kingsmill, 338 ; the Age of Niagara Falls, Prof. Spencer, 486
Niblett (J. T.), Portative Electricity, 423
Nice Observatory, Photographic Exploration at, M. Perrotin, 287
Nicholson (Prof. H. Alleyne), Science in the Medical Schools, 524
Nicolaieff (M. de), on Two Methods for the Study of Currents in Open Circuits, and of Displacement Currents in Dielectrics and Electrolytes, 491
Niobrara Chalk, Samuel Calvin, 486
Nisbet (Dr. John), Studies in Forestry, Prof. W. R. Fisher, 193
Nitikin (M.), on the Supposed Inter-glacial Deposits in East Europe, 621
Nitramide, a Remarkable Nitrogen Compound, Drs. Thiele and Lachman, 327
Nitrate-bearing Clays of Egypt, Prof. W. C. Mackenzie on the, 61, 360
Nitrogen-Fixation, Algæ and, Herr Kossowitch, 276
Nitrogen Gas, the Density of, Lord Rayleigh, Sec. R.S., 157
Nitrogen Trioxide, Prof. Lunge and Herr Porschnew, 623
Noble (Capt. Sir A., F.R.S.), Researches on Explosives, 309 ; on Methods that have been adopted for Measuring Pressures in the Bores of Guns, 438
Norfolk and Norwich Naturalists Society, Presidential Address, Thos. Southwell, 432
Normand (J. A.), on the Importance of Economy of Fuel in very Fast Vessels, and on the advantages to be derived from Heating the Feed-water, 328
North Pole, How I discovered the, J. Munro, 140
North Sea Ice Sheet, the, Sir Henry H. Howorth, F.R.S., 79
Northern Alps, Prof. Suess on the Southern and, 510

Ohm, Value of Theoretical, A. Leduc, 167
Oil upon Water, on the Spreading of, Miss Agnes Pockels, 223
Oldham (R. D.), a Manual of the Geology of India, 52 ; Origin of Permian Breccias of Midlands, 190
Oliver (Prof. F. W.), the Natural History of Plants, from the German of Prof. Anton Kerner von Marilaun, 28
Oliver (Joseph W.), the Students' Introductory Handbook of Systematic Botany, Harold Wager, 613
Oliver (Dr.), on the Functions of the Suprarenal Bodies, 461
Ommanney (Admiral Sir Erasmus, F.R.S.), Extraordinary Phenomenon, 524
Onnes (Prof. Kamerlingh), C. H. Wind's Measurements on Kerr Phenomena in Polar Reflexion of Nickel, 24 ; M. de Haas's Measurements of Coefficient of Viscosity of Methyl Chloride, 24 ; Dr. T. H. Meerbury's Experiments on Electrolytic Polarisation, 24 ; on the Coefficients of Viscosity of Fluids in Corresponding States, calculated by Mr. de Haas, 312
Open-Hearth Steel, J. A. Lencauchez on the Manufacture of, 460
Ophioglosseæ, Notes upon the Germination of the Spores of the, Prof. Douglas H. Campbell, 435
Ophiophagus, Sir J. Fayrer, F.R.S., 172
Optics : Theorie der Optischen Instrumente (nach Abbe), Dr. Siegfried Czapski, 74 ; a New Form of Colour Blindness, Prof. Koenig, 95 ; the Elliptic Polarisation of Reflected Light, K. E. F. Schmidt, 118 ; Similarity between After-glow of Geissler Tube and First-Glow of Solid Bodies, Carl Kirn, 131 ; Dr. Zeeman's Measurements of Reflection of Polarised Light, 144 ; Electrical Theory of Vision, Prof. Oliver J. Lodge, F.R.S., 172 : Dr. E. Obach, 172, 199 : Experiments with a Rectangular Glass Prism, W. C. Röntgen, 179 ; the Pupils of the Felidæ, Lindsay Johnson, 189 ; the Change of Phase of Light by Reflexion at Thin Films, W. Wernicke, 236 ; Electro-Optical Experiments, J. Elster and H. Geitel, 236 ; Experiments on Retina with Monochromatic Light, Prof. Konig, 287 ; Optical Characters of Crystals, 356 ; Prof. Ladd on the Direct Control of the Retinal Field, 416 ; Best Position of a Gauss's Plate, B. Walter, 431 ; on the Periodicity of the Absorption Rays of Isotropic Substances, G. Moreau, 444 ; on the Recurrent Images following Visual Impressions, Shelford Bidwell, F.R.S., 466 ; Dr. Greef on the Neuroglia Cells of the Retina and Chiasma of the Optic Nerve, 492 ; Prof. Koenig on the Absorption of Light by Visual Purple from a freshly extirpated Human Eye, 492 ; Handbuch der Photographie, Prof. Dr. W. H. Vogel and Prof. R. Mendola, F.R.S., 589
Oran, Earthquake at, 202

Ore and Stone Mining, a Text-Book of, C. Le Neve Foster, Bennett H. Brough, 543
Organic Adaptation, Has the Case for Direct, been Fully Stated, H. M. Bernard, 546
Organic Chemistry, W. H. Perkin, jun., F.R.S., and F. Stanley Kipping, 494
Organic Chemistry, Lessons in, G. S. Turpin, 494
Organic Colouring Matters, Systematic Survey of the, Drs. G. Schultz, and P. Julius, 267
Oriental Beliefs about Bees and Wasps, Some, Kumagusu Minakata, 30
Orientalists at Geneva, International Congress of, 454
Origin of Species, Materials for the Study of Variation treated with special regard to Discontinuity in, W. Bateson, Prof. W. F. R. Weldon, F.R.S., 25
Orion Nebula, the Spectrum of the, Prof. J. E. Keeler, Prof. W. W. Campbell, 254
Ormerod (Miss), Grass-Destroying Caterpillar Plague in Scotland, 251
Ornithology: Early Arrival of Birds, J. Lloyd Bozward, 8; Rev. W. Clement Ley, 31; the Date of the Cuckoo's Arrival, J. E. Hartwig, 34; Lost British Birds, W. H. Hudson, 63; Iron Crows' Nests, Walter G. McMillan, J. MacNaught Campbell, 125; Rate of the Flight of Birds, F. W. Headley, 269; the Changes of Plumage in the Red Grouse, W. R. Ogilvie-Grant, 275; W. P. Pycraft on the Wing of Archæopteryx viewed in the Light of that of some Modern Birds, 435; a White Swallow, H. Garnett, 481; the Flight of Oceanic Birds, Captain D. Wilson Barker, 617
Ornithorhynchus, Anatomy of Dumb-bell-shape Bone in, Prof. J. T. Wilson, 96
Orography of the Nang Shan, V. M. Obrucheff, 432
Orr (Henry B.), a Theory of Development and Heredity, 445
Osborn (Prof. H. F.), Characters and Faunal Relation of the Larimie Mammals, 326
Osborn (Prof.), on Certain Principles of Progressively Adaptive Variations Observed in Fossil Series, 435
Osmond (M. F.), on the Structure of Steel, 368
Ostwald (Prof.), on English Chemists, A. G. Bloxam, 224
Oudemans (Prof. J. A. C.), on the Geographical Position of the Astronomical Observatory at Utrecht, 312
Ounce, or Snow Leopard, a Recent Addition to the Zoological Society's Menagerie, 127
Ouramoeba, Wm. L. Poteit, 79
Ouvrard (M.), Three Iodo-Sulphides of Phosphorus, 156
Oxen, English, Evolution of Breed of, Prof. McK. Hughes, F.R.S., 182
Oxford, Meeting of the British Association at, 151, 270, 297, 338; Inaugural Address by the Most Hon. the Marquis of Salisbury, F.R.S., 339
Oxford School of Chemists, an Opening Address in Section B of the British Association by Prof. H. B. Dixon, F.R.S., 348
Oxfordshire Geology, Profs. Green and Boyd Dawkins, 412
Oxidation of Phosphorous Sulphur and Aldehyde, on the Rate of, Dr. Ewan, 409
Oxygen: J. H. van't Hoff, 240; the Line Spectrum of, Max Eisig, 15; the Spectrum of Oxygen in High Temperatures, Dr. J. Janssen, 249; Adulteration of Compressed Oxygen, 620

Pain, Pleasure, and Æsthetics, Henry Rutgers Marshall, 3
Palæographical Society of Australasia, the proposed, 325
Palæolithics: Mr. A. C. Carlyle's Collection of Minute Stone Implements from the Vindhya Hills (India), 132; the Palæolithic Section at Wolvercote, Montgomerie Bell, 413
Palæontology: on the Tritubercular Theory, E. S. Goodrich, 6; Trituberculy and Polybuny, Dr. C. J. Forsyth Major, 101, E. S. Goodrich, 268, 101; Marsupites in the Isle of Wight, C. Griffith, 8; the Echinoidea of Cutch, Dr. G. W. Gregory, 35; the Crinoidea of Gotland, 59; the Recent Discovery of Fossil Remains at Lake Calabonna, South Australia, Dr. E. C. Stirling, F.R.S., 184, 206; Dyrosaurus Thevestensis, A. Pomal, 216; Characters and Faunal Relations of the Larimie Mammals, Prof. H. F. Osborn, 326; Creatures of Other Days, Rev. H. N. Hutchinson, 426; W. A. Sanford on his Discovery of a Large Dinosaur at Wedmore, 456
Palazzo (Dr. Luigi), Small Portable Unifilar Magnetometer, 582
Palermo (Dr.), Action of Sunshine on Cholera Bacillus, 155
Palimpsest Manuscripts, Application of Photography to the Deciphering of, E. Pringsheim, 604
Pallas, Diameter of, Prof. E. E. Barnard, 65
Palmer (Dr.), Dimethyl Arsine, 205
Palmieri (Signor L.), Earth-Currents at the Vesuvius Observatory, 622
Panjab, Morphological Peculiarities in Natives of, Prof. R. H. Charles, 16
Panmixia, Prof. W. F. R. Weldon, F.R.S., 5; Dr. G. J. Romanes, F.R.S., 28
Panmixia and Natural Selection, Dr. Alfred R. Wallace, F.R.S., 196
Pannekoek (Herr A.), the Variable R. Lyræ, 531
Papavasiliore (M.), on the Greek Earthquakes of April, 1894, C. Davison, 607
Paper Making, Practical, George Clapperton, 73
Paracelsus, M. M. Pattison Muir, 598
Paraffin Nitrites, the Physiological Action of the, Dr. J. Theodore Cash, F.R.S., and Prof. Wyndham R. Dunstan, 550
Parc Saint-Maur Observatory, Magnetic Disturbance at, Corresponding in Time with the Earthquake Shock at Constantinople, M. Moureaux, 394
Parenty (H.), New Experiments permitting the Comparison of the Delivery of Liquids, Gases, and Vapour from the same Orifices, 444
Parhelia, Halo of 90° with, Samuel Barber, 269
Paris: Bulletins de la Société d'Anthropologie de, 21, 441, 492; Memoires de la Société d'Anthropologie de, 441; Paris Academy of Sciences, 23, 48, 72, 94, 120, 143, 167, 191, 216, 263, 287, 311, 335, 368, 396, 420, 444, 468, 491, 516, 540, 564, 587, 612, 635; Centenary of the Paris Polytechnic School, 82; Annual Report of the Paris Observatory, 255; Paris Société d'Encouragement pour l'Industrie Nationale, Proposed New System of Screw-pitch and Wire-gauge 414; M. J. Jaubert on the Atmosphere of Paris, 454; Paris Municipal Council: Competition for the best means of Suppressing the Smoke and Purifying the Water of Cities, 454; Pasteur Institute, Experimental Study of means of Defence against Destructive Insects, 482
Paris (Comte de), Death of, 480
Pascher (F.), the Radiation of Gases, 188; on the Infra-Red Dispersion of Fluorspar, 635
Pasteur Institute, Paris, Experimental Study of means of Defence against Destructive Insects, 482
Pasteur Institute, the Projected, for India, 33
Pasteur's Anti-Rabic Treatment, the Anti-Vivisectionists and, 14
Patagonia, Prehistoric Crania of, Dr. R. Verneau, 490
Pathology: Lectures on the Comparative Pathology of Inflammation, Elias Metchnikoff, 194; Methods of Pathological Histology, C. von Kahlden, A. A. Kanthack, 218; Deaf-Mutism, Holger Mygind, P. Macleod Yearsley, 449; the Thompson Yates Laboratories, 304
Pavy (F. W., F.R.S.), the Physiology of the Carbohydrates, their Application as Food and Relation to Diabetes, 397

Petz (G. G. von), East Siberia, 471
Pharmacy; Death of Dr. Louis von Uslar, 60
Pheasants, Observations on Young, Prof. C. Lloyd Morgan, 575
Philadelphia, the Zoological Society of, 109
Phillipps-Wolley (Clive), Big-Game Shooting, 298
Phillips (A. H.), Stalagmite from Lava Caves of Kilauea, 235
Philology; Death of Prof. W. D. Whitney, 153
Philosophy; Studien uber Claudius Ptolemaus: ein Beitrag zur Geschichte der griechischen Philosophie und Astrologie, Franz Boll, 398
Phisalix (C.), on some Antitoxic Properties of the Blood of the Terrestrial Salamander (*Salamandra maculosa*) against Curare, 414
Phonograph, the, Prof. McKendrick, 461
Phonograph, New Simple Form of, A. Koeltzow, 275
Phosphorescence, Influence of Low Temperatures on the Phenomena of, Raoul Pictet, 564
Photo-Electric Leakage, Prof. Oliver J. Lodge, F.R.S., on, 406
Photo-Electric Phenomena, Dr. J. Elster, Dr. H. Geitel, 451
Photo-Micrography; Practical Photo-Micrography, Andrew Pringle, 318
Photography: the Determination of Latitude and Longitude by Photography, Prof. C. Runge, 102; the Frena Camera, 229; Edison's Kineto-Phonograph, A. and W. K. L. Dickson, 140; the Photography of the Splash of a Drop, R. S. Cole, 222; the Progress of Astronomical Photography, H. C. Russell, F.R.S., 230; Photograph of a Landscape in Living and Dead Bacteria, 250; Photographs of the Moon, MM. Lœwy and Puiseux, 278; Photographs of Flames, Captain Abney, 285; Solar Eclipse Photography, Albert Taylor, 433; a Selection of Photographs of Stars, Star Clusters and Nebulæ, together with Information concerning the Instruments and the Methods employed in the Pursuit of Celestial Photography, Isaac Roberts, F.R.S., Dr. A. A. Common, F.R.S., 447; Photographic and Visual Refracting Telescope and Spectroscope presented to the Cape Observatory by Mr. Frank McClean, 552; Photography by Artificial Light, 553; an Instrument for Photographing Meteors, 556; the Royal Photographic Society; Address of the President, Sir H. Trueman Wood, 577; on the Development of the Latent Image in Photography by Alkaline Peroxides, G. A. Le Roy, 588; Handbuch der Photographie, Prof. Dr. H. W. Vogel, Prof. R. Meldola, F.R.S., 589; Application of Photography to the Deciphering of "Palimpsest" Manuscripts, L. Pringsheim, 604
Phyllium [illegible], M. Sappey, 216
Phylogeny, Ontogeny, and Systematic Arrangement, Prof. von Zittel, 510
Physicians, Royal College of, Harveian Oration, Dr. T. Lauder Brunton, F.R.S., 625
Physics: H. Poincaré on Maxwell and Hertz, 8; Elasticity and Tenacity of Glasses as Dependent upon Chemical Composition, A. Winkelmann and O. Schott, 21; the Formation of Floating Metallic Films by Electrolysis, F. Mylius and O. Fromm, 21: Weidemann's Annalen der Physik und Chemie, 21, 118, 236, 515, 635; Variation of Rotatory Power under Influence of Temperature, A. Le Bell, 23; C. H. Wind's Measurements on Kerr Phenomena in Polar Reflection on Nickel, Prof. Kamerlingh Onnes, 24: M. de Haas's Measurements of Coefficient of Viscosity of Methyl-Chloride, Prof. Kamerlingh Onnes, 24; Physiological Psychology and Psycho-Physics, Prof. E. B. Titchener, the Writer of the Note, 28; the Mass of the Earth, The Reviewer, 30; the Weight of the Earth, "K.," Prof. A. G. Greenhill, F.R.S., 52; the Mean Density of the Earth, Prof. J. H. Poynting, F.R.S., 542; Heat Experiments, Dr. V. Dvorák, 35; New Method of Determining Critical Temperatures by Critical Index, James Chappuis, 48; New Method for Determination and Lowering of Freezing-Points of Solutions, A. Ponsot, 48; Joh. Muller's Lehrbuch der Kosmischen Physik, Dr. C. F. W. Peters, W. J. Lockyer, 49; Physical Society, 69, 93, 142, 215, 285; Transformations of Mechanical into Chemical Energy, M. C. Lea, 91; Specific Heat of Carbon Dioxide at Constant Volume, Dr. J. Joly, 92; the Stability of a Tube, Prof. Greenhill, 93; Electro-magnetic Induction in Current Sheets and its Representation by Moving Trails of Images, G. H. Bryan, 93; Dielectrics, Rollo Appleyard, 93; Behaviour of Certain Bodies in Presence of Electromagnetic Oscillations, Prof. G. M. Minchin, 94; Determination of Relative Intensity of Gravity, G. Bigourdan, 94; Physical Properties of Pure Nitrous Oxide, P. Villard, 94; Stability of Dilute Solutions of Corrosive Sublimate, Leo Vignon, 94; Berlin Physical Society, 95, 192, 287; the Destructive Effect of Small Projectiles, Prof. Victor Horsley, F.R.S., 104; Measurement of Surface Tension of Water and Mercury in Capillary Tubes, G. Quincke, 118; the Stress and Strains in Isotropic Elastic Solid Ellipsoids in Equilibrium under Bodily Forces Derivable from Potential of Second Degree, C. Chree, 119; the Superficial Tension of Saline Solutions, H. Sentis, 120; Thermo-electric Properties of Salt Solutions, G. S. Emery, 236; Relation between Density of Saline Solution and Molecular Weight of Dissolved Salt, George Charpy, 287; Death of Prof. A. Kundt, 130; the Passage of Hydrogen through a Palladium Septum, Prof. W. Ramsay, F.R.S., 142; Relations of Pressure, Volume, and Temperature of Rarefied Gases, Prof. W. Ramsay, F.R.S. and E. C. C. Baly, 143, 215; Exhibitions of Physical Apparatus, 151; Obituary Notice of August Kundt, Dr. H. du Bois, 152; Study of Fluid Motion by Means of Coloured Bands, Prof. Osborne Reynolds, F.R.S., 161; Experimental Demonstration of Purely Accidental Character of Critical State, P. de Heer, 165; the Abnormal Phenomena near the Critical Point, Dr. Kuenen, 240; Experiments made by Dr. Kuenen in the Leiden Laboratory on the Abnormal Phenomena observed by Galitzine near the Critical Point, 312; the Radiation of Gases, F. Paschen, 188; the Isothermals of Ether, Rose Innes, 215; a Laboratory for Physical and Chemical Research, 217; New Methods of obtaining Specific Inductive Capacity of Solids under either Slowly or Rapidly Changing Fields, E. G. Northrup, 229; Researches on Modern Explosives, Wm. Macnab and E. Ristori, 230; the Viscosity of Solids, J. Dewar, 238; Experiments in Test of Validity of Newtonian Law of Attraction for Crystalline and Isotropic Masses at Small Distances, A. S. Mackenzie, 252; on the Newtonian Constant of Gravitation, Prof. C. V. Boys, F.R.S., 330, 366, 417, 571; Method for Determining Thermal Conductivity of Metals, Jos. H. Gray, 261; the Composition of Atmospheres which Extinguish Flame, Dr. Frank Clowes, 283; Captain Abney's Photographs of Flames, 285; an Elementary Theory of Planimeters, Prof. O. Henrici, 285; the Hatchet Planimeter, F. W. Hill, 285; Popular Lectures and Addresses by Sir William Thomson (Baron Kelvin), P.R.S., Prof. Oliver J. Lodge, F.R.S., 289, 313; on the Viscosity of Water as determined by Mr. J. B. Hanney, by means of his Microrheometer, R. E. Barnett, 311; Graphical Representation of Heterogeneous Equilibrium in Systems of One to Four Substances, B. Roozeboom, 312; the Coefficients of Viscosity of Fluids in Corresponding States calculated by Mr. de Haas, Prof. Kamerleigh Onnes, 312; Opening Address in Section A of the British Association, by Prof. A. W. Rucker, F.R.S., 343; Experiments in Tin-Lead Alloys ranging from $PbSn_{18}$ to $Pb_{12}Sn$, Bernhard Wiesengrund, 394; on the Specific Heat of Liquid Sulphur-

ous Anhydride, M. E. Mathias, 420; Practical Work in General Physics, W. G. Woollcombe, 425; New Experiments permitting the Comparison of the Delivery of Liquids, Gases, and Vapour from the same Orifices, H. Parenty, 444; Comparative Study of the Isothermals observed by M. Amagat and the Isothermals calculated from M. Van der Waal's formula, P. de Heen and F. V. Dwelshauvers-Dery, 489; on some Phenomena in Vacuum Tables, Sir David Salomons, 490; Physikalisches Prakticum, mit besonderer Berücksichtigung der Physickalischchemischen Methoden, Eilhard Wiedemann und Hermann Ebert, G. F. C. Searle, 496; Elementi di Fisica, Antonia Roiti, 498; Specific Heat of Gases at Constant Pressure, Dr. Silvio Lussana, 503; on Refractive Power and Density of Dilute Solutions, W. Hallwachs, 515; Lord Kelvin, P.R.S., on the Doctrine of Discontinuity of Fluid Motion in connection with the Resistance of a Solid moving through a Fluid, 524, 549, 573, 597; Changes in Physical Society, 527; on the Mixture of Liquids, M. J. De Kowalski, 540; Exact Measurement of the Density of very Dilute Aqueous Solutions, F. Kohlrausch and W. Hallwachs, 553; Physics and Engineering at the McGill University, Montreal, 558; Differences of Pressure, G. Guglielmo, 581; on the Latent Heats of Vaporisation of the Saturated Alcohols of the Fatty Series, M. W. Longuinine, 612; the Present Status of High Temperature Research, Carl Barns, 635; on the Change of Volume during Melting, Max Toepler, 635. *See also* Section A of the British Association

Physiography: the Earth; an Introduction to the Study of Inorganic Nature, Evan W. Small, 593

Physiology: Physiology Practicums, Burt G. Wilder, 4; another new Branchiate Oligochaete, Frank E. Beddard, F.R.S., 20; Preponderating Rôle of Liver in formation of Urea, 24; Determination of Uric Acid and Nuclein Bases in Urine by Precipitation with Copper Sulphate and Sodium Bisulphide, Dr. Krüger, 95; Dr. Krüger on Epiguanin, a new Base of the Xanthin Group isolated from Human Urine, 492; Formation of Urea in Liver after Death, Charles Richet, 120; Production of Glycosurie in Animals by Physical Means, 24; Physiological Psychology and Psycho physics, Prof. E. B. Titchener, 29; the Relative Sensitivity of Men and Women at the Nape of the Neck, Francis Galton, F.R.S., 40; Digestion without Digestive Ferments, A. Dastre, 48; Death of Dr. A. Schmidt, 60; Relation of Sensation-Areas to Movement, Prof. W. O. Kohn, 61; Berlin Physiological Society, 95, 192, 335, 491; a Case of Leukæmia, Dr. Jacob, 95; Experiments on Condensation of Glycocol Ether, Dr. Lilienfeld, 95; Influence of Rarefied and Compressed Air on Circulation, Dr. Ad. Lœwy, 95; Prof. A. Kossel's Further Researches on Thymin, 95; Anatomy of "Dumb-bell shaped" Bone in Ornithorhynchus, Prof. J. T. Wilson, 96; the Polar Excitation of Cells of Galvanic Currents, Dr. Max Verworn, 192; the Clotting of Blood, Dr. Lilienfeld, 192; Hereditary Malformation of Hands and Feet, Drs. W. Ramsay Smith and G. S. Nerwell, 253; Degeneration consequent on Experimental Lesions of Cerebellum, Dr. J. S. R. Russell, 284; Co-existence of Sternum with Shoulder-girdle and Lungs, Alexis Julien, 287; Two Microcephalic Brains, Dr. Telford Smith and Prof. D. J. Cunningham, F.R.S., 287; the Thompson Yates Laboratories, 304; the Influence of Intra-Venous Injection of Sugar on the Gases of the Blood, Dr. Vaughan Harley, 309; Researches on the Excitability of Rigid Muscles and on the Causes of the Disappearance of Cadaveric Rigidity, J. Tissot, 311; Experiments made on a Dog as to the Nutritive Value of Gelatine, Dr. J. Munk, 335; Experiments on Fasting Dogs, Dr. J. Munk, 491; Researches on the Causes of the Toxicity of the Serum of Blood, MM. Mairet and Bosc, 335; Experiments to Determine whether any one alone of the Food-Stuffs, Proteids, Fats, or Carbohydrates can be regarded as the Source of Muscular Energy, Prof. Zuntz, 336; the Physiology of the Carbohydrates: their Application as Food, and Relation to Diabetes, F. W. Pavy, F.R.S., 397; Opening Address in Section I of the British Association by Prof. E. A. Schäfer, F.R.S., 401; W. E. Collinge on the Relations of the Cranial Nerves to the Sensory Canal System, 436; on Histological Changes produced in Nerve Cells by their Functional Activity, Dr. Gustave Mann, 443; a Text-Book of Physiological Chemistry, O. Hammersten, 449; the Archoplasm and Attraction Sphere, J. E. S. Moore, 478; Spinal Respiratory Tracts, Mr. W. T. Porter, 491; Observations on the Blood-Corpuscles of Incubated Hen's-eggs, Dr. Engel, 491; Dr. Greef on the Neuroglia Cells of the Retina and Chiasma of the Optic Nerve, 492; on the Femoral Gland of Ornithorhynchus, C. J. Martin and F. Tidswell, 492; the Physiological Action of the Paraffin Nitrites, Dr. J. Theodore Cash, F.R.S. and Prof. Wyndham, R. Dunstan, 550 (*See also* Section I of the British Association)

Retgers's (Dr. J. W.) Fused Double Nitrate of Silver and Thallium Separation of Minerals of High Specific Gravity by the use of, Messrs. Penfield and Kreider, 415
Review Reviewed, a, Prof. Ralph S. Tarr, 268

REVIEWS AND OUR BOOKSHELF:—
The Incandescent Lamp and its Manufacture, Gilbert S. Ram, 1
Pain, Pleasure, and Æsthetics, Henry Rutgers Marshall, 3
Physiology Practicums, Burt G. Wilder, 4
The Fauna of British India, including Ceylon and Burmah, G. F. Hampson, 4
Materials for the Study of Variation, W. Bateson, Prof. W. F. R. Weldon, F.R.S., 25
Ein Geologischer Querschnitt durch die Ost Alpen, A. Rothpletz, Dr. Maria M. Ogilvie, 27
The Natural History of Plants, Prof. F. W. Oliver, 28
Notes on the more Common Diseases in Queensland, David Hardie, 28
Joh. Muller's Lehrbuch der Kosmischen Physik, Dr. C. F. W. Peters, W. J. Lockyer, 49
The Alchemical Essence and the Chemical Element, M. M. Pattison Muir, Prof. Herbert Macleod, F.R.S., 50

Principia Nova Astronomica, Henry Pratt, 51
A Manual of the Geology of India, R. D. Oldham, 52
Practical Paper-Making, George Clapperton, 73
Theorie der Optischen Instrumente (nach Abbe), 74
Manures and the Principles of Manuring, C. M. Aikman, 75
The Ex-Meridian treated as a Problem in Dynamics, H. B. Goodwin, 76
Odorographia: A Natural History of Raw Materials and Drugs used in the Perfume Industry, J. Ch. Sawer, 76
Introduction to Elementary Practical Biology, C. W. Dodge, 77
Notes on the Ventilation and Warming of Houses, Churches, Schools, and other Buildings, Ernest H. Jacob, 78
A History of the Elasticity and Strength of Materials, Isaac Todhunter, Prof. A. G. Greenhill, F.R.S., 97
A Treatise on the Mathematical Theory of Elasticity, A. E. H. Love, Prof. A. G Greenhill, F.R.S., 97
Introduction to the Mathematical Theory of the Stress and Strains of Elastic Solids, Benjamin Williamson, F.R.S., Prof. A. G. Greenhill, F R.S., 97
Theory of Structures and Strength of Materials, Henry T. Bovey, Prof. A. G. Greenhill, F.R.S., 97
Law and Theory in Chemistry, Douglas Carnegie, M. M. Pattison Muir, 98
Aero-Therapeutics; or, the Treatment of Lung Diseases by Climate, Charles Theodore Williams, 99
Histories of American Schools for the Deaf, P. Macleod Yearsley, 103
Monograph of the Stalactites and Stalagmites of the Cleaves Cove, near Dalry, Ayrshire, John Smith, 100
Botanical Charts and Definitions, Miss A. E. Brooke and C. A. Brooke, 101
The Great Globe: First Lessons in Geography, A. Seeley, 101
Synopsis der Höheren Mathematik, Johann G. Hagen, Dr. J. W. L. Glaisher, F.R.S., 121
A Manual of Microchemical Analysis, Prof. H. Behrens, 122
Practical Botany for Beginners, F. O. Bower, 123
Simple Experiments for Science Teaching, John A. Bower, 123
Economic Geology of the United States, Ralph S. Tair, 143
The Ore Deposits of the United States, James F. Kemp, 145
Mining: an Elementary Treatise on the Getting of Minerals, Arnold Lupton, 145
The Miners' Handbook, John Milne, F.R.S., 145
A Standard Dictionary of the English Language, 146
An Introduction to the Study of Metallurgy, Prof. W. C. Roberts Austen, F.R S., W. Gowland, 147
Structural Botany, Dukinfield Henry Scott, 147
The Lowell Lectures on the Ascent of Man, Henry Drummond, 147
Two great Scotsmen, the Brothers William and John Hunter, George E. Mather, 169
The Metallurgy of Gold, T. Kirke Rose, 170
A Handbook of Gold Mining, Henry Louis, 170
Geology, Charles Bird, 171
The New Technical Educator, 171
Studies in Forestry, John Nisbet, Prof. W. R. Fisher, 193
Lectures on the Comparative Pathology of Inflammation, Elias Metchnikoff, 194
The Camel, its Uses and Management, Major A. G. Leonard, 195
Modern Plane Geometry, G. Richardson and A. S. Ramsey, 196
Chemistry Demonstration Sheets, 196
Methods of Pathological Histology, C. von Kahlden, A. A. Kanthack, 218
A Treatise of Natal Astrology, G. Wilde and J. Dodson, The Soul and the Stars, A. G. Trench, 219
Elementary Lessons in Steam Machinery and the Marine Steam Engine, Staff Engineer J. Langmaid, R.N., and Engineer H. Gaisford, R.N., 220
The Yoruba-speaking Peoples of the Slave Coast of West Africa, A. B. Ellis, 221
A Handbook to the Study of Natural History, 221
Surveying and Surveying Instruments, G. A. T. Middleton, 221
Catalogue of Scientific Papers (1874–1883), 241
Gestaltung und Vererbung, Eine Entwickelungsmechanik der Organismen, Dr. Wilhelm Haacke, 242
Handbook of the Destructive Insects of Victoria, C. French, 243
Proceedings of the Edinburgh Mathematical Society, 244
The Starry Skies, Agnes Giberne, 244
Recherches sur l'Histoire de l'Astronomie Ancienne, Paul Tannery, 265
Scottish Land-Names, Sir Herbert Maxwell, 266
Systematic Survey of the Organic Colouring Matters, Drs. G. Schultz and P. Julius, 267
A Handbook to the Marsupialia and Monotremata, Richard Lyddeker, 267
Climbing in the British Isles—England, W. P. Haskett Smith, 267
Popular Lectures and Addresses, Vol. I., by Sir William Thomson (Baron Kelvin), P.R.S., Prof. Oliver J. Lodge, F.R.S, 289
Elementary Meteorology, William Morris Davis, 293
Catalogue of the Mesozoic Plants in the Department of Geology, British Museum, A. C. Seward, 294
A Monograph of Lichens found in Britain; being a Descriptive Catalogue of the Species in the Herbarium of the British Museum, Rev. James M. Crombie, 225
Travels in a Tree Top, Charles Conrad Abbott, 295
Big Game-Shooting, Clive Phillipps-Woolley, 298
Annals of the Royal Botanic Gardens, Calcutta, Dr. G. King, 308
Popular Lectures and Addresses, Vol. II., by Sir William Thomson (Baron Kelvin), P.R.S., Prof. Oliver J. Lodge, F.R.S., 313
A Handbook to the Flora of Ceylon, James Britten, 316
Biskra and the Oases and Desert of the Zibans, Alfred E. Pease, 317
Practical Photo-Micrography, Andrew Pringle, 318
Twelve Charts of the Tidal Streams on the West Coast of Scotland, F. Howard Collins, 318
The Physiology of the Carbohydrates: their Application as Food and Relation to Diabetes, F. W. Pavy, 379
Studien über Claudius Ptolemäus; ein Beitrag zur Geschichte der Griechischen Philosophie und Astrologie, Franz Boll, 398
Papers and Notes on the Glacial Geology of Great Britain and Ireland, Henry Carvill Lewis, Rev. E. Hill, 421
Aspects of Modern Study, R. A. Gregory, 422
Electric Traction on Railways and Tramways, Anthony Reckenzaun, 423
Portative Electricity, J. T. Niblett, 423
First Principles of Electrical Engineering, C. H. W. Biggs, 423
Electrical Distribution, its Theory and Practice, Martin Hamilton Kilgour, 423
Town Councillors' Handbook to Electric Lighting, M. Scott Russell, 423
The First Technical College, A. Humboldt Sexton, 424
Practical Work in General Physics, D. G. Woollcombe, 425
Manual of Practical Logarithms, W. N. Wilson, 425
Creatures of Other Days, Rev. H. N. Hutchinson, 427
A Theory of Development and Heredity, Henry B. Orr, 445
A Selection of Photographs of Stars, Star Clusters and Nebulæ, together with Information concerning the Instruments, and the Methods employed in the Pursuit of Celestial Photography, Isaac Roberts, Dr. A. A. Common, F.R.S., 447
Deaf-Mutism, Holger Mygind, P. Macleod Yearsley, 449
A Text-book of Physiological Chemistry, O. Hammarsten, 449
Electricity, Electrometer, Magnetism and Electrolysis, G. Chrystal and W. N. Shaw, 450
Micro-Organisms in Water, their Significance, Identification, and Removal, Prof. P. Frankland and Mrs. P. Frankland, Dr. E. Klein, F.R.S., 469
East Siberia, P. P. Semenoff, J. D. Chersky and G. G. von Petz, 471
Verzeichniss der Elemente der bisher Berechneten Cometenbahnen, Prof. Dr. J. G. Galle, 473
Primary Geography, A. E. Frye, 473
Theoretical Mechanics, J. Edward Taylor, 474
The Animal as a Machine and a Prime Motor and the Laws of Energetics, R. H. Thurston, 474

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

THURSDAY, MAY 3, 1894.

'HE MODERN INCANDESCENT ELECTRIC LAMP.

'he Incandescent Lamp and its Manufacture. By Gilbert S. Ram. (London: *The Electrician* Printing and Publishing Company, Limited.)

NOW the Swan-Edison monopoly is a thing of the past, the manufacture of incandescent lamps ; assuming considerable proportions; consumers are lready deluged with applications for orders by con-nental firms, and it is to be hoped that we shall not ›ng be obliged to send abroad for what can so easily be ıade in our own country. The information in this book ; of a unique and valuable nature, and the author seems › have a thoroughly practical acquaintance with the ıbject, and goes into minute details when dealing with ll the different branches of the manufacture. Indeed trade secretism" seems to have been abolished in these ages, and the wealth of technical information here met ·ith will go far towards the production of a more efficient ımp than those at present in use.

Chapter i. treats of the filament, and after briefly touch-ıg on the early efforts to produce lamps with incandescent latinum, and the possibilities of making use of some of ıe metallic oxides, the author passes to the consideration f carbon filaments now used. It is here noted that great improvements may yet be looked for in the carbon self." This is a matter of supreme importance, for the ıcandescent lamp is as yet in such an early stage of volution as to make it more than probable that the ·idening of the sphere of manufacture will soon bring bout an advance upon its present excellence; and lthough, as the author points out, the volatilisation of arbon in vacuo will prevent us from attaining to the rightness of the crater of an arc lamp, still there is onsiderable room for improvement. The "electrical olatilisation" or dissociation of particles of carbon from ıe filament is noted, and the conclusion is drawn that the best carbon is one which at the highest possible emperature disintegrates at the slowest rate."

The value of a lamp from the consumer's point of view must now be modified, since, by the lowering of the price to 1s., the filament can be run at a much higher temperature; for although the life will be thus reduced, this will be more than compensated by the smaller quantity of current used.

The materials at present used for the production of carbon filaments—silk, hair, wood fibre, cellulose—are described, and then chapter ii. begins with the practical preparation of filaments. Swan's process for the parchmentising of cotton thread is taken first, and a good working sketch is given of an apparatus for producing the thread, together with full instructions for the manipulation and drying. Details are also given of the jewelled draw-plates used for bringing down the dried thread to a uniform diameter. This process is the one to which the author devotes most attention. Other processes, such as those in which zinc chloride, furfurol, cuprammonia, pyroxyline and bamboo are used, are mentioned with more brevity.

Carbonisation is very fully treated of, and excellent drawings are given of frames and blocks for holding the filaments during heating. The furnace is then considered, and a drawing is given of a convenient form of carbonising furnace, the chapter closing with instructions for removing the fragile carbons from their frames.

Chapter iv. treats of mounting the filaments on their leading-in wires, and after describing the early form of crayon holder used by Swan, the carbon tube of Lane Fox, and the bolt and nut of Maxim, he passes on to the perfection of all joints—that of deposited carbon. Drawings are shown of machines for making this joint, both in the "socket" and "butt" form, and minute instructions are given for depositing the carbon on the junctions, particularly from a liquid hydrocarbon. That recommended is a mixture of four parts kerosine to one part turpentine.

The next chapter goes thoroughly into the subject of "flashing." Touching briefly on the early days when carbon was deposited on the filament to remedy defects in their uniformity and remove bright spots, the author gives as the reason why it is still necessary to use the process "that the carbon deposited by the flashing process under certain conditions is much more durable than any that can be produced by any other methods." The various means that have been proposed and used for producing the deposit are then shown, and drawings are given for an apparatus for "coal gas flashing" at atmospheric pressure. It is, however, recommended that the pressure should be reduced, as otherwise there is danger of getting a soft deposit. A detailed description is next given with drawings of an apparatus for flashing in "pentane" vapour at reduced pressure. Different methods for flashing filaments to a uniform resistance or candle-power are described, and it is noted that the specific resistance of hard white carbon deposited from pentane is one-tenth that of carbon deposited from amyloid. Several pages are given to a consideration of the best thickness for the deposited carbon, and a curve diagram is given, showing the effect of reduction of resistance due to flashing for filaments of various diameters.

In chapter vi. are given useful formulæ for finding the sizes for filaments for lamps of various candle-powers, with either round, flat, square, or tubular filaments, based on the data obtained from amyloid carbon with unpolished surface. In connection with tubular filaments, the fallacy of supposing them to be more economical than the solid form "because all the power is used in heating the surface," is explained.

Chapter vii. gives the sizes necessary for the production of lamps of various candle-powers, using flashed filaments. This is far more difficult than in the case of unflashed carbons, and instead of giving the cumbrous formula necessary, a number of different cases are worked out separately, and the results given in a series of curves from which the sizes for any other candle-power can be quickly obtained. At the conclusion of this chapter, the author alludes to a very amusing instance of what he calls the "happy-go-lucky" method of working that he encountered in a factory some few years ago. The name of the works in question is not divulged, and as he speaks of it being in a country where "very badly matched lamps" could be sold as of the same voltage, we hope England is not responsible. We thoroughly endorse his opinion that the most carefully made lamps, even though the price may be higher, will prove the cheapest in the end. This is a point in the manufacture of lamps which deserves more attention than is usually given to it, and a thorough grasp of the contents of these chapters will be of great value to anyone intending to take up the subject seriously. The aim of the manufacturer should be to turn out the most perfect lamp possible, and one in which the limit of endurance has been attained. Practice will then reduce the cost of production.

Chapter viii. contains a brief description of various gauges used for measuring the diameters of filaments. Although it is not mentioned, we should think the beautiful little instrument used for measuring the thickness of microscopic cover glasses would answer the purpose admirably.

A chapter is devoted to glass-making, including a list of ingredients necessary for the manufacture of lead glass, the kind of pots for melting the "metal" in, and a short description of the method of blowing "pot-bulbs" in a mould. Glass-blowing is fully gone into, and, after describing the playful way in which the old-fashioned orthodox glass blowers "spoiled" the electricians in the early days of lamp-making, we come to the invention of the glass-blowing machine, and the final springing into existence of a race of girl glass-blowers free from the vices of drink, strikes, and "Saint Monday."

We then have a few pages with illustrations showing the various forms of blowpipes, ending with practical instructions for making lamp bulbs from glass cylinders. This is given somewhat briefly, doubtless owing to the fact that it is pretty evident that the day is not far distant when this method of forming bulbs will entirely give place to the quicker and more suitable method of "pot-blowing."

Chapter xi. is headed "Sealing in," and contains some good drawings and descriptions of the methods used for fixing the filaments in the glass bulb. The small annealing oven to stand on the workman's bench, and receive the lamps as they are finished, is a very useful piece of apparatus, and is a great advance upon the old method of holding the work in a smoky flame, a practice which is not only dirty, but wastes both time and gas.

Touching upon glass grinding and the manufacture of taps, it is remarked that good taps can be bought cheaply made of German glass, but there is very great difficulty in joining them to the lead glass used in the exhausting apparatus. It is not generally known that this can be easily and effectually done by interposing between the German and the lead glass a thin stratum of soft white enamel or "arsenic" glass, used as a solder. Compound joints made in this way are perfectly sound, and are not at all liable to crack.

The important subject of exhausting is treated of in chapter xii. and it is pointed out that to produce a good lamp a high vacuum is absolutely necessary. The reasons against leaving a residual atmosphere of nitrogen or other inert gas are discussed, and then follows a complete description of the various forms of mercurial pumps in use. Several kinds of short-legged pumps are shown and described in detail. The "Sprengel pump" does not hold the prominent place it occupied some years ago, preference being given to the various forms of Geissler pump. The reason for this may lie in the great number of india-rubber joints that appear to be used. This way of making pumps always gives constant trouble through leakage, and poor efficiency is unavoidable. We cannot agree with the author that india-rubber joints are to be allowed. There is no doubt that india-rubber joints are almost universal in modern lamp factories, but we have equally little doubt that the short life of many of the lamps now on the market is due to imperfect exhaustion; and having had considerable experience in high vacua, we have no hesitation in saying that a vacuum sufficiently good for a long-lived incandescent lamp can only be obtained if all the joints are hermetically sealed together. We have still in use lamps dating from 1882 exhausted properly with sealed joints, and they have outlived generations of bought lamps made with the use of india-rubber joints.

For testing the vacuum the McLeod gauge is noted, but is not considered to be of much use to the lamp-maker. The size of the bubble in the chamber of the "Geissler," and the appearance and "hammer" of the mercury in the legs of the "Sprengel," are taken as sufficiently good indications for the purpose. This certainly savours of the "rough and ready" method, but in the absence of any good indicator it probably answers the purpose. The coil test is mentioned, but it is very properly pointed out that the appearance of the luminosity in an exhausted bulb is not "under all conditions an indication of the state of the vacuum."

A good chapter is devoted to the testing of voltage and candle-power. The methods of using the photometer are fully described; the "Harcourt" pentane lamp is said to make the most trustworthy standard, but for regular factory use an argand burner with a Methven screen is recommended. This is occasionally tested with the pentane lamp. Then follows a full description, with drawings, of Evershed's wattmeter; and the chapter closes with a method of finding the mean horizontal candle-power of lamps with either flat or cylindrical filaments.

A short description is given of the method of capping the finished lamp. The author finds that the addition of a small percentage of dextrine to the plaster of paris makes a very hard cement, and he warns makers against using an acid flux for soldering the wires and connections. Nothing but rosin should ever be used.

In the chapter on efficiency and duration, allusion is made to the expression "watts per candle-power," instead of the more correct term "candle-power per watt," pointing out that it is more easy to grasp the meaning of a certain number of watts than of a particular fraction of a candle-power. In connection with duration tests, it is very justly said that "life tests pure and simple" are worthless unless the actual candle-power of the lamp at different periods of its life are given.

In the life of a lamp the advantage of the hard coating of deposited carbon shows itself. This hard carbon, combined with a good vacuum, greatly retards the falling off of candle-power due to the blackening of the bulb. It is explained that the disintegration of the carbon acts in three ways. Firstly, by coating the glass with deposited carbon and thus obscuring the light; secondly, by altering the surface of the filament and increasing its emissivity so that it is at a lower temperature; and thirdly, by increasing its resistance so that it takes less current. The data of experimental tests on several lamps for efficiency and duration close the chapter.

The last chapter takes up the relation between light and power in incandescent lamps, and details are given of the recent tests made under the direction of Prof. Ayrton at the City and Guilds of London Institute, with drawings of curve diagrams showing the candle-power and watts of lamps of various makes, up to the breaking point. In conclusion it is said that the ideal lamp would be one in which the radiation is wholly luminous, and that the carbon incandescent lamp falls very short of this desirable consummation. Brief reference is made to the beautiful experment of Nicola Tesla.

On the whole, readers will find the book to be of very considerable interest, dealing as it does with an entirely new industry of very great elegance; and the practical knowledge diffused by its publication will certainly help to advance the evolution of an efficient lamp which can be sold for a reasonable price.

ALGEDONICS.

Pain, Pleasure, and Æsthetics; an Essay concerning the Psychology of Pain and Pleasure, with special reference to Æsthetics. By Henry Rutgers Marshall, M.A. (London: Macmillan, 1894.)

ALGEDONICS is the term which Mr. Marshall suggests for the science of pain and pleasure. In his sixth chapter he gives the derivation of the term thus: "ἄλγος, pleasure; ἡδονή, pain"; the discovery of which, when he glanced over the pages of the completed volume, must, we fear, have given him an algedonic thrill. There is good stuff in the work, and the author is evidently well up in the literature of his subject.

In the first chapter, on the classification of pleasure and pain, Mr. Marshall discusses the psychological status of algedonic states. He argues, successfully we think, against the view that pleasure and pain are psychical elements *sui generis* with special nerves and specialised cerebral centres; and for the view that they are due to algedonic tone associated with any or all of the psychical elements. "Pleasures and pains," he says, "may be differential qualities of all mental states of such nature that one of them must, and either of them may, under proper conditions, belong to any element of consciousness." In his discussion, however, he does not bring out the fact, which is readily explicable on his view, that in popular speech we apply the term pain to the somewhat heightened affections of common sensibility, even when these affections are pleasurable. If, for example, we lightly touch a slight bruise, we term the sensation pain; but such "pain" may be, if we can trust our own experience, distinctly pleasurable. Since the fibres by which impulses from the nerve endings of common sensibility are transmitted, have special cortical endings, and seem to run, in part at least, along different tracts or in a different manner in the spinal cord, some colour has been lent to the view, that there are specialised fibres and centres for pain. If, however, such "pain" is merely the algedonic tone of common sensibility (as hinted, but not in so many words, by Mr. Marshall, on p. 18), these observations are quite in accordance with the view which our author advocates. Mr. Marshall quotes Mr. Herbert Spencer's opinion that "a relation proves itself to be itself a kind of feeling—the momentary feeling accompanying the transition from one conspicuous feeling to another." The word "feeling" is here used in its most general sense as an affection of consciousness. But Mr. Marshall appears to miss the importance of the fact that such feelings of relation have their algedonic tone no less than sense-impressions, a realisation of which would, we think, have helped him in his consideration of æsthetics.

In accordance with the view adopted in chapter i., we find that the emotions are regarded in the second chapter as deriving their character from the algedonic tone of complex co-ordinations of motor activity. Describing the psychological equivalents of these complex co-ordinations as, in their sensation aspect, "instinct-feelings," he regards them in their algedonic aspect as emotions. But here again he is rightly anxious to lay stress upon the fact, that the emotions, like pleasure and pain, are not something apart from but are inseparably bound up with sensory complexes. It is probable that the difficulty or impossibility of the psychological analysis of emotional states is due to the fact that their synthesis is effected in the physiological field below the threshold of consciousness, so that consciousness can deal only with the net result of inherited physiological co-ordinations—a view which is, again, in full accord with Mr. Marshall's own conclusions.

We must pass over the interesting discussion of "a group of co-ordinated activities tending to bring about attraction of other individuals," which Mr. Marshall terms the art-impulse, artistic creation having this end in view, though not cognised as the end. His contention is to some extent corroborated by that thirst for appreciation and recognition which forms part of the artistic temperament, and it harmonises with many observations on animal activities.

Coming now to the field of æsthetics, the author seeks to find some criterion by which æsthetics may be differentiated from algedonics. The conclusion to which he is led is as follows:—"That object is to be considered beautiful which produces a psychosis that is permanently pleasurable in revival," while "that object is to be considered ugly which produces a psychosis that is permanently disagreeable in revival." Thus "only those pleasures are judged to be *æsthetic* which (relatively speaking) are permanently pleasurable in memory." We believe that the author is here on the road to, but falls somewhat short of, the true criterion of æsthetics. The key of the problem, we think, lies in the recognition of the algedonic tone of *perceived relations*. It is this superadded element which raises the algedonics of sensory experience to the level of æsthetics. The æsthetic effect of the geometrical tracery in the chapter-house of Wells Cathedral is due to the emotional tone associated with perceived relationships. And it is just because in memory the relationships with their emotional tone are more abiding than the sense-elements, that to be permanently pleasurable in revival becomes a criterion of æsthetics. This criterion is, however, secondary. The primary criterion is the perception of relations with its associated emotional tone.

It is difficult to do justice, in the short space which remains to us, to the author's views as to the physical basis of pleasure and pain. These primitive qualities of psychical states are conceived to be "determined by the relation between activity and capacity in the organs, the activities of which are concomitants of the psychoses involved." When an organ during rest has stored up energy, the response of the organ to stimulus is pleasurable. But when the organ is spurred to activity beyond the limits of its stored up energy, its functioning is painful. "Pleasure thus results when the balance is on the side of the energy given out, and pain when the balance is on the side of the energy received. Where the amounts received and given have equivalence, then we have the state of indifference." We have seen that Mr. Marshall does not accept the hypothesis that there are separate end organs, nerve fibres, or cerebral centres for pleasure and pain. Unless, therefore, there is a qualitative difference in the impulse transmitted from an organ according as it is well-stored with energy or exhausted, a position which is hardly tenable, the algedonic tone must be due to quantitative difference that is to say, difference in the intensity of stimulus. Hence it would be better, so far as the organ is concerned, to lay the primary stress on the intensity of stimulus therefrom, and to make the state of the organ a condition of this intensity. Mr. Marshall ought also, we think, to supplement his view by reference to the condition of the cerebral centre concerned. The condition of the centre is possibly of even greater importance than the condition of the organ from which afferent impulses are transmitted. We cannot, however, further discuss the question here, and must refer our readers to the author's own treatment of the question in the fourth and fifth chapters of his work.

Although we do not agree with all his conclusions, we have no hesitation in saying that the book is written in the right spirit and on right lines. Fully aware of the necessity for careful introspection, he sees that the results so reached must be correlated with the conclusions arrived at through the investigations of the physiologist. It is only where the two modes of investigation thus go hand in hand that progress in psychology can be secured.

OUR BOOK SHELF.

Physiology Practicums. By Burt G. Wilder, Professor of Physiology, Vertebrate Zoology, and Neurology in Cornell University, U.S.A. (Published by the Author, 1893.)

THESE consist of a series of twenty-seven plates, with accompanying descriptions (large octavo), said by their originator to embody "explicit directions for examining portions of the cat, and the heart, eye, and brain of the sheep, as an aid in the study of elementary physiology." The author is well known in anatomical circles as the founder of a notoriously ambitious terminology, not wholly destitute of useful points. The present venture has furnished him a new peg upon which to hang this, and his title savours of the kind of treatment which the subject receives at his hands. Plate xviii. Fig. 19 (which deals with the "pelvic viscera, etc." [*sic*], of the female cat), and Plate xiii. Fig. 14 (which is said to represent the "head and neck of cat partly dissected"), may be taken as fair examples. With their faulty delineation of things which may be at once determined from descriptions alone, their ugly letters sprawling over them, and their apologetic descriptions, they are useless and uncalled for; and the matter is the more nauseous, as more than one finished anatomical treatise happens to deal with this animal. We put the plates down with the feeling that they are calculated to repel rather than encourage the student, and that although they may be of service in the work of the Cornell University, in connection with which they have arisen, there would be cause for alarm should they be adopted elsewhere.

The Fauna of British India, including Ceylon and Burmah. Published under the authority of the Secretary of State for India in Council. Edited by W. T. Blanford. "Moths." Vol. ii. By G. F. Hampson. (Pp. xxii. 609, 325 woodcuts). London: Taylor and Francis, 1894.)

THE second volume of Mr. Hampson's important work on the moths of India includes the *Arctiidæ*, *Agaristidæ*, and the bulk of the *Noctuidæ*, and considerably exceeds the first volume in bulk, 1545 species being described in vol.

ii. as against 1158 in vol. i. Under *Arctiidæ* the author includes the following groups as sub-families, which have usually been treated as families by previous authors:—*Arctiinæ*, *Lithosiinæ*, *Nycteolinæ*, and *Nolinæ*. The *Agaristidæ* are a small family of handsome day-flying moths, and certainly look rather out of place in the position which they occupy in this book. The extensive family of *Noctuidæ* is divided into ten sub-families (*Trifinæ*, *Acontiinæ*, *Palindiinæ*, *Sarrothripinæ*, *Euteliinæ*, *Stictopterinæ*, *Gonopterinæ*, *Quadrifinæ*, *Focillinæ*, and *Deltoidinæ*), of which the two last are held over to the forthcoming third volume of the book.

Concerning the *Noctuidæ*, Mr. Hampson remarks, "The lowest forms are those of which the larvæ have five pairs of abdominal prolegs, and the perfect insects have vein 5 of the hind wing fully developed, and from the centre of the discocellulars, this ancestral form being only found in some *Deltoidinæ* and *Sarrothripinæ*."

As the plan of the second volume is identical with that of the first, which we had the pleasure of noticing in NATURE for February 23, 1893 (pp. 387–388), we need only add that there seems no falling off in its execution. It is hoped that the third volume, including the *Epicopiidæ*, *Uraniidæ*, *Epiplemidæ*, and *Geometridæ* will be completed in the course of the present year.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Panmixia.

MR. ROMANES has requested those students of natural history who cannot accept the doctrine of Panmixia to show the error which they believe to lie in his reasoning. I therefore ask leave to explain why I am unable to accept either the first proposition put forward by Mr. Romanes in NATURE of to-day, or the doctrine itself. Mr. Romanes says:—

The survival-mean must (*on cessation of selection*) *fall to the birth-mean*, &c. This statement involves neglect of a way in which selection may, and often must, operate. A simple example will show this. The mean height of adult Englishmen is roughly 67½ inches; and if I offer to enroll in a regiment every adult Englishman who is more than 66 and less than 69 inches high, the mean height of my regiment will, as every statistician knows, be still 67½ inches, but I shall be obliged to reject more than half the population. A form of selection, involving the destruction of more than half the population, may therefore occur without affecting the mean value of the character selected. I hope shortly to publish evidence, based on the measurement of many thousands of animals of one species, at many stages of growth, showing that selection does in fact operate in this way in particular cases. That it must so operate in many cases is obvious from the fact that many wild animals remain for several generations without sensible change in their mean character. In these cases either selection acts as I suggest, or it is incapable of affecting a change in the mean, or it does not act at all.

The second and third propositions put forward by Mr. Romanes are not demonstrated by any statistics with which I am acquainted; and with regard to the extreme statement that "*any* failure in the perfection of hereditary transmission will be weeded out" by selection in a wild state, I would urge the need, which has lately been well pointed out by Bateson, of a *quantitative* measure of the efficiency of selection. The frequency of even considerable abnormalities in specialised organs of wild adult animals, of which so many admirable examples are described in Mr. Bateson's recent work on variation, show, if it needed showing, that natural selection is in most cases an imperfect agent in the adjustment of organisms.

But my main difficulty is that neither Mr. Romanes, nor Prof. Weismann, nor any other advocate of the doctrine, has shown that in some given case Panmixia does in fact occur, and that the results predicted are in fact produced. On the other hand, Mr. Galton has shown that civilised Englishmen are themselves in a condition of Panmixia, at least with respect to several characters, especially stature and the colour of the eyes. Now the mean stature of Englishmen is known to be slowly increasing, and there is no evidence of the disappearance of coloured eyes.

My objections to the position of Mr. Romanes and others are therefore two: first, that it is based on the assumption that selection, when acting on a species, must of necessity change the mean character of the species—an assumption incompatible with the maintenance of a species in a constant condition; and secondly, that in the only case which has been experimentally investigated, the consequences said to result from a condition of Panmixia do not, in fact, occur.

University College, London, April 26.

On Some Sources of Error in the Study of Drift.

As a general rule we may feel sure that the boulders scattered over the surface of a district which consists chiefly of boulder clay, have been derived from the underlying deposit. There are, however, some cases in which the inference is unsafe. For instance, the Thames now marks the southern limit of the glacial drift—a curious circumstance, and one of which a wholly satisfactory explanation has not been given. Many think that this sharp definition of the southern limit of the glacial drift is so improbable that they would fain attribute some deposits in North Kent to the glacial period, or at any rate would expect to find a few sporadic boulders stranded on the slopes of the North Downs; and there far-transported fragments do not unfrequently occur.

But there is this great source of error. All along the lower Thames barges carry refuse and rubbish of every description from London, and this is taken, such as it is, and laid on the adjoining lands.

So you find carried on, with road scrapings, fragments of every kind of road metal; with soil turned out in digging foundations, specimens of all the materials used for building; with the contents of middens, every variety of object of domestic use or ornament. It is marvellous what large lumps get on to the land in this way. When, then, anyone produces a specimen, even a large specimen eight or ten inches in diameter, and perhaps taken out of a deep loam, the evidence is rejected. The stone may have been carried on to the land with the manure, and the loam may in that district be quite recent rain-wash. It may be that some of them were really of glacial origin, but all are equally distrusted. Some of them certainly cannot be referred to ice action. I have seen large pieces of Napoleonite found on the surface in North Kent. By what accidents they came to be there we cannot tell, but we may, at any rate, acquit the ice of having had anything to do with the transport of that peculiar Corsican rock.

When walking along the base of a cliff of boulder clay, we may generally infer that the far-travelled boulders that lie at its base have just been washed out of it. In most cases they have been; but in some, and those often the cases in which it is of greatest consequence to have the origin of the boulders clearly established, we have another serious source of error, of which I have just seen a good example.

A Norwegian vessel, carrying timber from Christiansund to Boston, in Lincolnshire, ran aground and became a total wreck off Old Hunstanton last winter. I saw her in January. The vessel looked sound enough to a landsman's eye; but she was dismasted and gutted, and the salvage was on the sand dunes close by. About her a pool of varying breadth had been formed by the swirl of the water round the hull. The currents had been deflected by various circumstances here and there, as especially where a quantity of ballast had been thrown out. This consisted of large boulders of various kinds of gneiss and porphyry, and the weighty pile looked as if it were little affected by the currents of the incoming and receding tides.

In April, I visited the spot again, expecting to find that the boulders had been driven along the shore by the fierce storms which had raged along that coast since my previous visit, and intending to make note of their dispersal and the distance to which they had travelled. I found, however, that the keel and a portion of the lower part of the wreck remained, and that the surrounding pool was greatly deepened and extended.

Through the deep clear water I saw the heap of ballast, which had been undermined and was settling down into the depths, being already far below the level of the surrounding sand. When the last of the timbers shall have yielded to the axe and the waves, the sand will soon level up the hole caused by the scour round the obstructing mass, and this heap of Scandinavian boulders will lie buried in the sand till some exceptional storm shall shift the banks, and expose them again, and perhaps transport them along the shore.

Had this vessel been thrown on a hard rocky shore instead, the ballast would have started at once with the other boulders on the shore, and been scattered, according to size and form, along the coast. As it was, however, these have got buried deep in sand, and preserved till, perhaps, the habit of using such boulders for ballast shall have been given up, and then, washed out by the accidents of weather, of coast destruction, and of shifting sand, they will appear among the fallen fragments of a boulder clay cliff, and be appealed to in proof of its origin.

How many ships with Scandinavian ballast have been wrecked along our eastern coast ever since the time of the Vikings? How many hundred tons of such boulders are still travelling round our shores?

Another source of error I observed, this spring, along the Norfolk coast near Lowestoft. A perpetually changing undercliff is formed by slips along the base of the cliffs. When the wind blows hard from the north-east, the shingle is thrown up against these broken masses, and much of it rests on the ledges and terraces at various heights above the sea. Shells are tossed up still higher, and gravel and sand from the upper part of the cliff slide and pour down, and find a resting-place here and there on its irregular face. When all these various processes are seen going on around, and the easily identified patches of recent shingle and shells or ancient sand and gravel can be observed, with their track from above, or their obvious equivalent below, there is not likely to be any difficulty. But when, in subsequent storms, landslips have covered these diversified patches with the samples of the various deposits that make up the cliffs on that changeful coast, the interpretation is not always so clear. Here we find in the boulder clay a mass of gravel with shells derived largely from the crag, there a streak of shelly sand tossed up from the recent shore, and covered by a slipped mass of boulder clay. Large boulders from the glacial drift lie side by side with others that have travelled along the shore from buildings or from wrecks; the explanation of the companionship being here and there given by the occurrence of a tobacco-pipe or the thick end of a glass bottle.

These are some of the more recent sources of error in our attempts to learn the history of deposits from their boulders. We must remember also in East Anglia that much of the drift is derived from cretaceous boulder-bearing beds, and where these appear sporadically in the drift they cannot be distinguished from others which the ice has received first hand from the parent rock—except when clear traces of glaciation have been preserved. It is not enough, therefore, to record that a boulder has been found on such a shore, or even in such a cliff, unless the observer has been careful to note the exact conditions and the surroundings of each find.

Cambridge. T. McKenny Hughes.

On the Tritubercular Theory.

In a brilliant address, read last year before the American Association for the Advancement of Science,[1] Prof. H. F. Osborn has brought together and laid before us the latest results of American research to which Mammalian Palæontology owes so much. Necessarily much space is given to the exposition of the theory of the development of the cusps of mammalian teeth. Never before has the tritubercular theory been so lucidly explained, so logically followed out; never before have its weaknesses been so obvious, its errors so plain.

Prof. Osborn first calls attention to "Cope's demonstration of the tritubercular molar as the central type in all the mammalia" as "a great step forward. In looking over the odontographies of Cuvier, Owen, Tomes, and Baume, we find there is no suspicion of this common type around which the highly diverse mammalian molars centre." Further on he states that "all the specialised mammalian series, ungulates, primates, carnivores, insectivores, rodents, and marsupials are found playing similar, yet independent adaptive variations upon one type," that of the Marsupials and Placentals "every known triassic, Jurassic, cretaceous, and basal eocene fossil (excepting Dicrocynodon) is in some stage of trituberculy," and that he is "able to bring forward evidence that the multitubercular molar instead of being primitive was derived from the tritubercular." In short, the arguments from palæontology and embryology in favour of considering the tritubercular pattern of molar as the primitive type are forcibly put before us. The place occupied by this common type amongst teeth, is compared to that held by the pentadactyle type in the morphology of the limbs of the four-footed vertebrates. What trituberculy is for the teeth, "pentadactyly has long been for the feet," and later, "the molars of the clawed and hoofed mammals can now be compared, as we compare the hand or foot of the horse with that of the cat, because they spring from a common type." At the risk of being tedious, I have thought it necessary to give all these quotations to make Prof. Osborn's position quite clear.

What is our astonishment, then, when a little further on we come upon the statement that, "upon the polyphyletic theory of the origin of the mammals here advocated [namely, the independent origin of the Monotremes, Marsupials, and Placentals from a common ancestral stock, the Pro-mammalia], we must admit, first, the independent evolution of trituberculy in different phyla; and second, the branching off of several great groups in the pre-tritubercular stages." (!) We are then told that the Prototheria, the Metatheria, the Insectivora, and the higher Placentals have all independently, and more or less rapidly, entered "into trituberculy."

How do these statements agree with the evidence mentioned above? What becomes of the comparison with foot structure? Are we to believe that the pentadactyle limb has been considered to be the common or central type, because the various vertebrate groups have acquired it independently? The words "common" and "central," as applied to a type of structure, have no significance nowadays unless equivalent to ancestral. It seems hardly necessary to point out that such mythical types hovering over organs, and compelling them to assume a certain form, have no place in modern biology. We might be willing to accept the tritubercular as a generalised, archaic, or ancestral type; but it is out of the question, at the same time, to claim that it has been independently acquired by the groups in which it occurs. Could the divergence in general structure, and habits within the Marsupials, and the Placentals, lead to a convergence to one type of tooth? And, more extraordinary still, to the same type in both cases?

Moreover, many of the mammals, which, according to Prof. Osborn, so readily pass "into trituberculy," only do so, apparently, to pass no less readily out of it. According to this theory the living forms which possess triconodont teeth, amongst the Marsupials on the one hand and the Placentals on the other, have been derived from ancestors with triconodont molars, which passed through the tritubercular, and again back into the triconodont type.

There is a very grave objection to such a fickle mode of cusp development, which seems to have escaped the notice of the supporters of the theory. All the various types of teeth met with amongst the mammalia are adaptations to particular kinds of food, and methods of feeding; the appearance or disappearance of a few cusps here and there may seem a matter of trivial importance to anyone forming a theory of cusp development, but there is no reason to think that it is so to the animal which possesses the teeth. The independent passage of all these groups of mammalia through a triconodont stage would imply, that they all and severally took to a particular kind of food (that for which the triconodont molar is an adaptation), and again their passage into a tritubercular stage would imply, that they afterwards took to another method of feeding (that for which the tritubercular molar is an adaptation). It is evident that the difficulties encountered in the attempt to derive the tritubercular tooth from a triconodon form in each group are overwhelming; we must, therefore, fall back on the supposition that the original mammalian teeth were provided with many cusps, not placed in one line, and the exact pattern of which remains still to be found.

There is much evidence for the view that the upper molars of the Pro-mammalian ancestor were of the tritubercular, and the

[1] "The R[illegible] of t[illegible] M[illegible] in N[illegible] A[illegible]." Studies from the Biol. Laboratories [illegible] College, [illegible] reprinted in NATURE, [illegible] vol. xlix. [illegible]

lower molars of the tubercular-sectorial types [1]; in fact, I think, we cannot do better than accept Prof. Cope's generalisation,[2] if not as a definitely established theory, at all events as an excellent working hypothesis, "that the superior molars of both ungulate and unguiculate mammalia have been derived from a tritubercular type; and that the inferior true molars of both have been derived from a tubercular-sectorial type." These, indeed, are the types which occur most constantly amongst the earlier fossil forms, and the most primitive living representatives both of the Marsupials and Placentals. The Pro-mammalia, when they first arose as a small group struggling amongst their reptilian and amphibian rivals, very possibly adopted some method of feeding for which teeth of these or similar patterns were well adapted. Subsequently, with increasing number and divergence, just as in the pentadactyle limb some digits have been lost and others become unduly developed, the tritubercular teeth have been modified to suit various needs; with this difference that, although digits are not easily added, new cusps often have arisen in the course of adaptation.

Oxford, April 21. E. S. GOODRICH.

[1] In a former paper, "On the Fossil Mammalia from the Stonesfield Slate" (*Quart. Jour. Micr. Sci.* xxxv. 1894), I brought forward some additional evidence in favour of this theory.

[2] "On the Trituberculate Type of Molar Tooth in the Mammalia" (*Proc. Am. Phil. Soc.* 1883), and "Origin of the Fittest."

Zoological Regions.

WITH reference to the paper of Mr. Wallace in NATURE (vol. xlix. page 610), I agree with Mr. Wallace's aim and with his estimate of the importance of the subject.

A naturalist, who deals with a single large genus as Pedicularis, makes his own map, showing the distribution of the species and his own view of the lines of descent of his sections in geologic periods. He cannot do this on a map showing the division of the world into six biologic regions according to the Mammalia in them. Or, at all events, none of our monographers, so far as I know, has done it. The difficulty in dealing with a whole natural order is still greater.

The consequence is that, if some other botanic writer wishes to compare the distribution of Pedicularis with that of some allied genus, or to give a view of the distribution of the sub-order to which Pedicularis belongs, he cannot make any use of the results of the Pedicularis monograph without taking it all to pieces and re-arranging the whole material. This is in every case a laborious, in many cases an impossible task.

I therefore agree with Mr. Wallace that we require a division of the globe into "areas absolutely defined, easily remembered," so that, after the monographer has treated his genus or order in natural regions, he may also "tabulate" his facts on these standard areas; in order that his numerical results may be (at least in the rough) accessible for immediate use by others who may not have time (or sufficient special knowledge) to get up the monograph.

It is evident that Mr. Wallace has overlooked my paper on biologic regions and tabulation areas in *Trans. Linn. Soc.* vol. clxxxiii. [1892] (B) pp. 371-387. Otherwise he could hardly have written (NATURE, vol. xlix. p. 612) that his regions readily enable us to tabulate the distribution of a group (and many other statements). In my paper I have pointed out that where I know, as in the case of many Sikkim plants, the exact boundary line of distribution of many species, I cannot tell whether these should be tabulated in Wallace's Region 1, or in his Region 3, or in both. The number of species which are in this predicament is so great that by exerting a choice how I would tabulate them I could bring out any result that might be wished. The more accurately I know the distribution of a species the more impossible is it for me to tabulate it on Wallace's map. And the more perfectly a region is biologically laid down (with peninsulas, islands, &c.) the more impossible it is to use it as an "area" for tabulating on. But, I must not trouble you with a recapitulation of my paper above cited, to which I refer Mr. Wallace and others who may be interested. C. B. CLARKE.

Kew, April 30.

The Earthquakes in Greece.

THE severe earthquake felt in Greece on April 27 at 9.20 p.m. was observed in Birmingham by the aid of a delicate bifilar pendulum, with which observations are now being made on behalf of the Earth Tremor Committee of the British Association. This instrument, designed by Mr. Horace Darwin, and made by the Cambridge Scientific Instrument Company, is described in the Report of the Committee presented at the Nottingham meeting last year.[1] I may merely mention here that a tilt of the ground in an east-west direction is magnified about 3000 times by the rotation of a mirror about a vertical axis; and that the image of a fine wire in front of a movable gas-jet, after reflection by the mirror, is observed in a fixed telescope in the passage outside the cellar in which the pendulum is erected.

Shortly before 8 p.m. (Greenwich mean time), I went down to take the usual reading, and found the image of the wire moving slowly from side to side of the field of view, showing that the ground was rocking gently backwards and forwards, the time of a complete pulsation being from twelve to fourteen seconds. It was difficult under the circumstances to make any exact measurements, but the maximum east-west component of the tilting cannot have been less than a quarter of a second. The pulsations were first observed at 7h. 59m., and my impression is that the range slightly increased until 8h. 3m. It then rapidly diminished, being about $\frac{1}{30}$ of a second at 8h. 12m., and never less than $\frac{1}{300}$ of a second until 8h. 28m., after which the pulsations ceased to be perceptible.

The time given by the newspaper correspondents is, I suppose, Athens time, and corresponds to 7h. 45m. Greenwich mean time. The interval between the occurrence of the earthquake and the arrival of the pulsations in Birmingham was therefore not greater than 14m., and, the distance traversed being roughly 1550 miles, it follows that the average velocity of the pulsations cannot have been less than 1·84 miles per second.

Gillott Road, Birmingham, May 1. C. DAVISON.

[1] An account of a new and improved form of the pendulum will appear shortly in NATURE.

"Vermes."

I WISH to enter a protest against the continued use of the word "Vermes" as a term of systematic significance with the same value as "Mollusca," "Arthropoda," &c. Linnæus used the term to include all soft-bodied invertebrates—*i.e.* everything then known except the Arthropoda (his "Insecta") and Vertebrata. Then Lamarck employed the word in a much more definite and unexceptional sense, to include the parasitic worms, the Chætopoda being separated as "Annelida." But what do modern writers meant by "Vermes"? Why, it has nearly as indefinite a limit as that given to it by Linnæus, for it is used to include almost *any* invertebrate animal—never mind its structure—which does not fit in the Mollusca, Arthropoda, Echinoderma, Cœlentera, or Protozoa. In fact, the term, as employed in such authoritative publications as the *Zool. Record*, *Zool. Jahresbericht*, &c., as well as by Jackson in "Forms of Animal Life," and in Lang's text-book, &c., embraces all, or most, of the following groups of animals:—Cestoda, Trematoda, Planaria, Nemertina, Archiannelida, Chætopoda, Hirudinea, Gephyrea, Polyzoa, Brachiopoda, Nematoda, Acanthocephala, Rotifera, Sagitta, Echinoderes, and sundry other small worm-like forms, and even Balanoglossus, and occasionally Chætoderma and Neomenia.

I do not intend to enter into the classification of this heterogeneous assemblage of forms, nor need I do more than refer to the fact that definite terms with scientific limitations are in existence under which the members of the assemblage can be (and are) grouped.

I am perfectly ready to admit that "Vermes" may be a useful descriptive term, if used to imply a certain general form of body, as opposed to some other groups; but I do wish to urge the abolition of it from text-books or titles of papers by well-known zoologists. That the eradication of the word presents considerable difficulties, I am aware; since it is not in England alone that "Vermes" still holds sway, but in all the European countries the equivalents "Vers," or "Würmer," &c., are employed with a more or less equivalent indefiniteness. Nevertheless, several such terms *have* been abolished, and no one nowadays would think of speaking, even in a popular, still less in a scientific work, of "Radiata" or "Zoophytes" or "Infusoria," in the antique significance of these words.

Oxford, April 18. WM. BLAXLAND BENHAM.

On Iron Crows' Nests.

Three years ago, the removal of an old tree in the Cossipore Ordnance Factory, near Calcutta, brought to light a singular bird's nest, composed mainly of bent and twisted fragments of stout iron wire, such as is used to bind up bundles of bar iron for transport. The pieces, which were all about as thick as stout telegraph wire, were of considerable length and weight, and were keyed together by their own irregularities; but as there was no evidence by which to identify the builder, I merely made a note of the circumstances.

Last year, however, attracted by the laboured flight of a crow carrying in its bill a very unwieldy and apparently heavy load, I watched the bird until, frightened by a passing object when about two feet from the ground, it dropped its burden, which I at once secured. I found it to be a piece of crumpled iron wire, which on measurement in my laboratory proved to be 23½ inches long between its apparent extremities (straightened out it measured 35½ inches in length), to have a diameter of 0·125 inches (= No. 11 B.W.G.), and to weigh 55·72 grammes, or nearly 861 grains. The bird was in the main road, about 300 yards from the site of the original nest.

This evidence as to the ownership of the nest, and of the weight which an Indian crow can carry, may perhaps interest some of your readers.

Early Arrival of Birds.

Mr. Prideaux, in the last issue of Nature, having recorded the unusually early arrival of the summer migrants in Surrey, it may perhaps be permissible to state the date of arrival here. The cuckoo, uttering its festive note, flew into a tree in my garden on March 25, attracting the attention of the whole household, and has been heard at intervals in the neighbourhood of Worcester ever since. The swallow and martin were here on the 4th inst., the willow warbler and the white-throat on the 7th, and the red-start on the 16th. Nidification was remarkably early this season. In my garden the song thrush, blackbird, and robin hatched out by March 30, and the missal thrush in an orchard close by was, as usual, earlier in its family arrangements. I heard the swift on the 26th inst. The spring flora was also early: lilac, hawthorn, bluebell, cowslip, primrose, wood anemone, spotted orchis, and orchis morio were in blossom on the 20th inst.; the sweet violet gone, and the dog violet blooming profusely in its place.

There is nothing wonderful in the cuckoo being here in March. The wonder is that it was then vocal.

Irritability of Plants.

In your issue for April 19 (vol. xlix. p. 586) there is a short notice of a paper by Prof. Pfeffer on the "Irritability of Plants." In it you say: "Pfeffer instances the remarkable researches of Hegler on the effect of mechanical traction on growth stems, which when stretched by a weight, gain mechanical strength through the development of the mechanical tissues, which follows as a response to the pull to which they are subjected."

This recalls to mind the interesting passage in Tennyson's "Idylls of the King":

> S[illegible] the part [illegible] fl[illegible]h[illegible] in ar[illegible].
> I[illegible] n a[illegible] t[illegible] a[illegible] k the [illegible]ield
> A[illegible] n[illegible] a [illegible]pear of grain
> [illegible] en[illegible] n[illegible] ite, and tight
> W[illegible] tre[illegible] tee

The Action of Light on the Diphtheria Bacterium.

Some time ago it was reported that colonies of the diphtheria bacterium do not thrive well when exposed to light, and it occurred to me that the electric light might afford a means of checking the development of the false membranes by projecting a very powerful arc light on the throat, for it is known that the tissues are to some extent penetrated by light. Or possibly the arc light could be sent into the throat through the mouth. I know that in Germany microscopic objects have been lighted with the aid of a lamp placed at some distance, and connected to the microscope by a curved glass rod, which conveyed the light by internal reflection. Incandescent lamps might be used in a similar manner, and some means could be devised in order to intercept the heat they produce, if it be objectionable.

A few days ago I noticed an article on Dr. Phillips' electric lamps, which he has employed to light the mouth, and the cavities between the mouth and the nose, and you recently published a paper read before the Royal Society, by Prof. H. M. Ward, on the bactericidal action of light, which partly confirms my views. It seems worth while, therefore, to make experiments with arc rays projected indirectly as above, and with incandescent lamps, and that especially upon diphtheria membranes.

Centipedes and their Young.

In No. 1275 of Nature (vol. xlix. p. 531), Mr. Urich, of the Trinidad Field Naturalists' Club, asks for information about the breeding habits of centipedes.

Similar observations to those made by the members of the Trinidad Club, and described by Mr. Urich, have been published by Kohlrausch ("Beitrage zür Kenntniss der Scalapendriden." Diss, Marburg, 1878), and these are referred to in the standard work on Myriapoda by Latzel ("Die Myriapoden der Osterreichisch-Ungarischen Monarchie." Wien, 1880, p. 136), and also in the "Lehrbuch der nerglischenden Entwicklungsgeschichte" (Jena, 1890), by Korschelt and Heider, p. 725.

Marsupites in the Isle of Wight.

In a recent visit to the Isle of Wight, plates of *Marsupites* were found by Mr. R. M. Brydone and myself at Freshwater.

The locality is one in which these fossils might be expected to occur, but so far as I know they have not been recorded hitherto from any part of the island; certainly not by Barrois, nor in the last edition of the "Survey Memoir."

POINCARÉ ON MAXWELL AND HERTZ.[1]

At the time when Fresnel's experiments compelled all researchers to admit that light is due to the vibrations of a very subtile fluid filling the interplanetary spaces, the researches of Ampère made known the mutual actions of currents, and founded electrodynamics.

But one step more was required to suppose that this same fluid, the ether, which is the cause of luminous phenomena, is at the same time the vehicle of electrical actions. This step Ampère's imagination enabled him to take; but the illustrious physicist, while announcing this seductive hypothesis, did not see that it was so soon to take a more precise form, and receive the beginning of its confirmation.

It was still, however, but a dream without consistence, till the day when electric measures indicated an unexpected fact—a fact recalled by M. Cornu in the last *Annuaire*, at the end of his brilliant article devoted to the definition of electric units. To pass from the system of electrostatic units to the system of electrodynamic units, a certain transformation-factor is employed, the definition of which I will not recall, as it is to be found in M. Cornu's article. This factor, which is also called the ratio of unities, is precisely equal to the velocity of light.

The observations soon became so precise that it was impossible to attribute this concordance to chance. One could not doubt therefore that there were certain intimate relations between the optic and the electric phenomena. But the nature of these relations would perhaps still have escaped us if Maxwell's genius had not guessed it.

[1] Translation of an article by M. Poincaré, in the *Annuaire* of the Bureau des Longitudes for 1894.

Currents.

Everyone knows that bodies can be divided into two classes: conductors where we prove the transference of electricity, that is to say, of voltaic currents, and insulators or dielectrics. To the old electricians dielectrics were purely inert, and their part consisted in opposing the passage of electricity. If this were so, we could replace any insulating body by another of a different kind without changing the phenomena. Faraday's experiments have shown that it is nothing of the kind. Two condensers of the same shape and dimensions put in communication with the same sources of electricity will not take the same charge (even if the thickness of the isolating wire be the same), if the *nature* of the isolating matter differs. Maxwell had made too deep a study of Faraday's works not to understand the importance of dielectric bodies and the necessity of restoring to them their proper function.

Besides, if it be true that light is but an electric phenomenon, it follows that when it is propagated through an insulating body, this body is the place of the phenomenon, therefore there must be electric phenomena localised in dielectrics; but of what nature are they? Maxwell answers daringly: they are currents.

All the experiments up to his time seemed to contradict this; currents had never been observed except in conductors. How could Maxwell reconcile his audacious hypothesis with such a well-founded fact? Why do the hypothetical currents under certain circumstances produce manifest effects, which under ordinary conditions remain absolutely unobservable?

It is because dielectrics oppose to the passage of electricity, not a greater resistance than the conductors, but a resistance of a different kind. A comparison will make Maxwell's thought clearer.

If we endeavour to bend a spring, a resistance is encountered which increases in proportion as the spring is bent. If, therefore, we have at our disposal only a limited force, a moment will come when the resistance being unsurmountable, the movement will stop and equilibrium be established; at last, when the force ceases to act the spring will bound back, giving back all the work expended to bend it.

Suppose, on the contrary, that we wish to move a body immersed in water. Here again we meet with resistance which will depend on the velocity, but which, if this velocity remains constant, will not increase in proportion as the body advances; the movement will therefore continue as long as the force acts, and equilibrium will never be attained; finally, when the force ceases to act, the body will not tend to return, and the energy used for making it advance cannot be restored; it will have been entirely transformed into heat by the viscosity of the water.

The contrast is manifest, and it is necessary to distinguish between *elastic* and *viscous* resistance. Then dielectrics would behave, for electric movements, like elastic solids in the case of material movements, whilst conductors would behave like viscous liquids. Hence two categories of currents: current of displacement or Maxwell's currents which traverse dielectrics, and the ordinary conducting currents which circulate in conductors.

The first, having to overcome a sort of elastic resistance, can be but of short duration; for, this resistance increasing continually, equilibrium will be rapidly established.

The currents of conduction, on the contrary, having to overcome a sort of viscous resistance, can consequently last as long as the electromotive force which causes them. Let us look again at the convenient comparison which M. Cornu has borrowed from hydraulics. Suppose we have water under pressure in a reservoir; let us put this reservoir in communication with a vertical tube; the water will rise in it, but the movement will stop so soon as the hydrostatic equilibrium is reached. If the tube is large, there will not be any friction, or loss of charge, and water thus raised could be used for producing work. We have here a picture of displacing currents.

If, on the contrary, the water of the reservoir flows out by a horizontal tube, the movement will continue so long as the reservoir is not empty; but if the tube is narrow, there will be a considerable loss of work, and a production of heat by friction. We have here a picture of conducting currents.

Although it is impossible and of little use to try to represent to ourselves all the details of this mechanism, one may say that all happens as if the displacement currents had a number of little springs to bend. When the currents stop electrostatic equilibrium is established, and the springs are so much the more bent as the electric field is more intense. The work accumulated in these springs, that is to say, the electrostatic energy, can be wholly restored so soon as they can unbend themselves. It is thus that mechanical work is obtained when the conductors are allowed to obey the electrostatic attractions. These attractions would thus be due to the pressure exercised on the conductors by the bent springs. Finally, to follow the comparison to the end, the disruptive discharge must be likened to the rupture of overstrained springs.

On the other hand, the work employed for producing conduction currents is lost and wholly transformed into heat like that expended in overcoming the friction or the viscosity of fluids. *It is for this reason that the conducting wires get hot.* From Maxwell's point of view there are only closed currents. For the old electricians this was not so; they looked upon a current as closed which circulates in a wire joining the two poles of a battery. But if, instead of reuniting the two poles directly, one puts them in communication respectively with the two armatures of a condenser, the instantaneous current, which lasts until the condenser is filled, was considered open; it went, it was thought, from one armature to the other across the wire of communication and the battery, and stopped at the surface of the two armatures. On the other hand, Maxwell supposed that the current traverses the insulating plate, which separates the two armatures, under the form of a displacement current, and that it is thus completely closed. The elastic resistance which it meets on the passage explains its short duration.

Currents can manifest themselves in three ways: by their calorific effects, by their action on magnets and currents, by the induced currents to which they give rise. We have already seen why conduction currents develop heat, and why displacement currents do not do so. On the other hand, however, according to Maxwell's hypothesis, the currents which he imagines, must, like the ordinary currents, produce electromagnetic, electrodynamic, and inductive effects.

Why have we hitherto been unable to put these effects in evidence? It is because a displacement current, however feeble, cannot last long, in the same direction; for the tension of our springs, ever increasing, would soon stop it. There cannot therefore be in dielectrics, either continuous currents of long duration, or sensible alternating currents of long period. The effects will, however, become observable if the alternation is very rapid.

The Nature of Light.

According to Maxwell, this is the origin of light. A luminous ray is a series of alternating currents produced in dielectrics, or even in the air or the interplanetary vacuum, which changes its direction a thousand billion times every second. The enormous induction due to these frequent alternations produces other currents in the neighbouring parts of the dielectric, and it is thus that the luminous waves spread from point to point.

Calculation shows us that the rate of spreading is equal to the ratio of the units, that is to say, to the velocity of light.

These alternating currents are a kind of electrical vibrations; but are these vibrations longitudinal like those of sound, or transversal like those of Fresnel's "ether"? In the case of sound the air undergoes condensation and rarefaction, alternatively. On the contrary, Fresnel's ether, when vibrating, behaves as if it were formed of incompressible layers, capable only of sliding one over the other. If there were *open* currents, the electricity going from one extremity to the other of one of these currents would accumulate at one of the extremities; it would condense or rarefy itself like air; its vibrations would be longitudinal. But Maxwell admits only closed currents; this accumulation is impossible, and electricity behaves like Fresnel's incompressible ether; its vibrations are transversal.

Experimental Verification.

So we find again all the results of the undulatory theory. But this was, however, not enough to induce the physicists, who were more charmed than convinced, to accept Maxwell's ideas. All that could be said in their favour was that they did not contradict any of the observed facts, and that it was a great pity if they were not true. But experimental confirmation was wanting; it had to be waited for during twenty-five years.

A divergence had to be found between the old theory and Maxwell's, which was not too delicate for our rough means of investigation. There was only one which afforded an *experimentum crucis.*

The old electrodynamics required electromagnetic induction to be produced instantaneously; but according to the new doctrine it must, on the contrary, be propagated with the velocity of light.

The question was therefore to measure, or at least to ascertain, the rate of propagation of inductive effects; this has been done by the illustrious German physicist, Hertz, by the method of interferences.

This method is well known in its applications to optical phenomena. Two luminous rays issuing from the same source interfere when they meet at the same point after having followed different paths. If the difference of these paths is equal to the length of a wave—that is to say, to the path traversed during one period, or a whole number of wave-lengths—one of the vibrations is later than another by a whole number of periods; the two vibrations are therefore at the same phase, they are in the same direction, and they reinforce each other.

If, on the contrary, the difference of path of the two rays is equal to an odd number of half wave-lengths, the two vibrations are in contrary directions, and they neutralise one another.

The luminous waves are not the only ones susceptible to interference: all periodic and alternating phenomena propagated with a finite velocity will produce analogous effects. It happens with sound. It ought to happen with electrodynamic induction, if the velocity of propagation is finite; but if, on the contrary, the propagation be instantaneous, there will not be any interference.

But one cannot put these interferences to the proof if the wave-length is greater than our laboratories, or greater than the space that the induction can traverse without becoming too feeble. Currents of very short period are absolutely essential.

Electric Exciters.

Let us first see how they may be obtained with the help of an apparatus which is a veritable electric pendulum. Suppose two conductors united by a wire; if they are not of the same potential, the electric equilibrium is broken in the same way as the mechanical equilibrium is deranged when a pendulum is swung from the vertical. In the one case as in the other, the equilibrium tends to re-establish itself.

A current circulates in the wire, and tends to equalise the potential of the two conductors in the same way as a pendulum seeks the vertical. But the pendulum will not stop in its position of equilibrium; having acquired a certain velocity, it passes this position because of its inertia. Similarly, when our conductors are discharged, the electric equilibrium momentarily re-established, will not maintain itself, and will be destroyed by a cause analogous to inertia; this cause is *self-induction.* We know that when a current stops it gives rise in the adjacent wires to an induced current in the same direction. The same effect even is produced in the wire in which the induction current circulates, which finds itself, so to speak, continued by the induced current.

In other words, a current will persist after the disappearance of the cause which produced it, as a moving body does not stop when the force, which had put it in motion, ceases to act.

When the two potentials shall have become equal, the current will therefore continue in the same direction, and will make the two conductors take opposite charges to those which they had to start with.

In this case, as in that of the pendulum, the place of equilibrium is passed; in order to re-establish it, a backward movement is necessary.

When the equilibrium is regained, the same cause immediately destroys it, and the oscillations continue without ceasing.

Calculation shows that the duration depends on the capacity of the conductors; it suffices, therefore, to diminish sufficiently this capacity, which is easy, to have an electric pendulum susceptible of producing alternating currents of extreme rapidity.

All this was well established by Lord Kelvin's theories and by Feddersen's experiments on the oscillating discharge of the Leyden jar. It is, therefore, not this which constitutes the original idea of Hertz.

But it is not sufficient to construct a pendulum; it must also be put into movement. For this, it is necessary for some agent to move it from its position of equilibrium, and then to stop abruptly—I mean to say, in a time very short in relation to the duration of a period; otherwise the pendulum will not oscillate.

If, for example, we move a pendulum from its vertical position with the hand, and then, instead of loosing it suddenly, we let the arm relax slowly without unclasping the fingers, the pendulum, still supported, will arrive at its place of equilibrium without velocity, and will not pass it.

We see then, that with periods of a hundred-millionth of a second, no system of mechanical unclamping could work, however rapid it might appear to us with regard to our usual units of time. This is the way in which Hertz has solved the problem.

Taking again our electric pendulum, let us make in the wire, which joins the two conductors, a cut of some millimetres. This cut divides our apparatus into two symmetric halves, which we will put in communication with the two poles of a Ruhmkorff coil. The induced current will charge our two conductors, and the difference of their potential will increase with a relative slowness.

At first the cut will stop the conductors from discharging themselves. The air plays the part of an insulator, and keeps our pendulum away from its position of equilibrium.

But when the difference of potential becomes large enough, the jar spark will pass, and will make a way for the electricity accumulated on the conductors. The cut will all at once cease to act as an insulator, and by a sort of electric unclamping, our pendulum will be freed from the cause which prevented it returning to its equilibrium. If the complex conditions, well studied by Hertz, are fulfilled, this unclamping is sudden enough to enable oscillations to be produced.

The apparatus, called an "exciter," produces currents which change their direction from 100,000,000 to 1,000,000,000 times per second. Because of this extreme frequency they can produce inductive effects at a great distance. In order to render these effects simple, another electric pendulum, called a "resonator," is employed. In this new pendulum, the cut and the coil, which only serve for the unclamping, are suppressed; the two conductors reduce themselves to two very small spheres, and the wire is bent back in a circle in a way to approach the spheres to each other.

The induction due to the exciter will put this resonator in vibration the more easily as the periods of the two are less different. At certain phases of the vibration, the difference of potential of the two spheres will be large enough to produce sparks.

Production of Interferences.

We have thus an instrument which shows the effects of an inductive wave emitted from the exciter. We can study what happens in two ways: either expose the resonator to the direct induction of the exciter at a great distance, or else make this induction work at a short distance on a long conducting wire, along which the electric wave will go, and which will work in its turn by induction at a short distance on the resonator.

Whether the wave propagates itself along a wire or across the air, one can produce interferences by reflection. In the first case, it will reflect itself at the extremity of the wire, which it will follow again in an inverse direction; in the second, it will reflect itself on a metallic leaf which acts as a mirror. In the two cases the reflected wave will interfere with the direct wave, and we can find places where the spark of the resonator will cease to pass.

The experiments made with the long wire are easier; they furnish us with very precious instruction, but they will not serve as *experimenta crucis;* for in the old as well as the modern theory, the quickness of an electric wave along a wire must be equal to that of light. The experiments on the direct induction at a great distance are, on the contrary, decisive. They show that not only the quickness of propagation of induction across the air is finite, but that it is equal to the quickness of the wave propagated along a wire, complying with the ideas of Maxwell.

Synthesis of Light.

I shall insist less on other experiments of Hertz, more brilliant, but less instructive. Concentrating with a parabolic mirror the wave of induction taken from the exciter, the German savant obtains a veritable cluster of electric rays, capable of reflecting and refracting themselves regularly. The rays, if the period, already so small, were a million times shorter still would not differ from the luminous rays. We know that the sun gives out several kinds of radiation, some luminous because they act on the retina, others obscure ultra-violet or infra-red, which manifest themselves by their chemical or calorific effects. The first only owe their qualities, which make them appear to us of a different nature, to a kind of physiological chance. To the physicist the infra-red does not differ more from the red, than the red from the green; the length of a wave is only greater; those of the hertzian radiations are much greater still, but there are only differences of degree, and one may say, if Maxwell's theories are true, that the illustrious Professor of Bonn has realised a veritable synthesis of light.

Conclusions.

But our admiration for so much unhoped-for success must not make us forget the progress which still remains to be accomplished. Let us therefore try to exactly summarise the results which are definitely attained.

First, the velocity of direct induction across the air is finite, without which the interferences would be impossible. The old electro-dynamics are therefore condemned. What must one put in its place? Is it Maxwell's theory (or at least something approaching it, for one would not expect the divination of the English savant to have foreseen the truth in all its details)? Although the probabilities accumulate, the complete demonstration is not yet reached.

We can measure the length of a wave of hertzian oscillations; this length is the product of the period by the velocity of propagation. We should, therefore, know this velocity if we knew the period; but this last is so small that we cannot measure it; we can only calculate it by a formula due to Lord Kelvin. This calculation leads to numbers which agree with Maxwell's theory; but the last doubts will only be done away with when the velocity of propagation has been directly measured.

This is not all: things are far from being so simple as one might think, from the above short account. Diverse circumstances come to complicate them.

First, there is round the exciter a radiation of induction; the energy of this apparatus radiates, therefore, externally, and as no fresh source comes to supply it, it soon disperses, and the oscillations die out very rapidly. It is here that one must look for the explanation of the phenomenon of multiple resonance, which was discovered by MM. Sarasin and De la Rive, and which at first appeared irreconcilable with the theory.

On the other hand, we know that light does not precisely follow the laws of geometrical optics, and the difference which produces diffraction, is more considerable as the length of the wave is greater. With the great length of the hertzian undulations these phenomena must assume an enormous importance, and trouble everything. No doubt it is fortunate, for the moment at least, that our means of observation are so coarse, otherwise the simplicity which seduced us at the first sight would give place to a labyrinth where we should be lost. It is from this probably that different anomalies arise, which have hitherto not been explained. It is also for this reason that the experiments on the refraction of rays of electric force have, as I said above, but little demonstrative worth.

There still remains a difficulty which is more serious, but which is no doubt not insurmountable. According to Maxwell, the coefficient of electrostatic induction of a transparent body ought to be equal to the square of its index of refraction. This is not so; the bodies which follow Maxwell's law are exceptions. We are evidently in the presence of phenomena much more complex than we thought at first; but one has not been able to explain anything, and the experiments themselves are contradictory.

There still remains, therefore, much to be done; the identity of light and electricity is from to-day something more than a seducing hypothesis: it is a probable truth, but it is not as yet a proved truth.

THE RECENT WORK OF THE CATARACT CONSTRUCTION COMPANY.

SOME arrangements recently made by the Cataract Construction Company show that the works are extending in a very satisfactory manner. The Niagara Falls Paper Company is now well under way. They make paper from wood pulp, and a large amount of power is used for grinding the trees down into pulp. They have fixed turbines in their own wheel-pit, and take water from the Cataract Construction Company's canal, and pass it after use into the tunnels belonging to this Company. The turbines drive a vertical shaft which, at the surface of the ground, is geared by bevel wheels to the main shaft, on which are the pulp grinders. This is the only case likely to occur where the power is used directly. In all other cases it is likely to be transmitted electrically. The first electrical application is to the works of the Pittsburgh Reduction Company for the manufacture of aluminium. The Niagara Falls Power Company has undertaken to supply them with continuous current at 160 volts to the extent of 7000 horse-power. The first 1500 horse-power is now being put in. In order to do this, Prof. Forbes has arranged to carry the alternating current by two circuits in two phases. This is the character of current generated by the dynamos. At the works, 2500 feet from the power-house, the current is to be transformed from 2000 volts to 115 volts alternating. It is then passed through three of the commutating machines, like those shown by Schuckert and others at the Frankfort Exhibition of 1891. These are continuous current machines, each with four rings attached to certain bars of the commutator. The alternating current is passed to these rings by brushes: the armature revolves synchronously with the generator in the power-house and with the turbine. The other brushes, which rub on the commutator, give off continous current to the aluminium baths at 160 volts, the E.M.F. being in normal conditions raised in its change form alternating to continuous current in the ratio of $\sqrt{2}:1$. A shunt direct current with variable resistance in the circuit excites the field magnets. It is found that the electromotive force of the direct current can thus be regulated. The explanation of this remarkable fact has been worked out by Mr. Steinmetz. The whole of this plant, transformers, commutating machines, and switchboard was tendered for by different firms, and the bid of the General Electric Company has been accepted; 33 per cent. of spare plant is held in reserve. The dynamos and power-house switch-board, on the other hand, are in the hands of the Westinghouse Company. It is expected that both types of machinery will be in operation in the course of a few months.

The patent for Prof. Forbes' construction of dynamo, which is being built, has been just allowed by the United States Patent Office. One object to be attained was to have a fixed armature, so that the armature might be wound so as to give a very high E.M.F. without being subjected to the enormous centrifugal forces of the revolving part. Another object was to attain a maximum fly-wheel effect with a minimum weight. The revolving parts of the turbine and dynamo, and the vertical shaft connecting them, are all supported hydraulically by means of a piston in the turbine. The supporting power of this piston amounted to the weight of the revolving part of the dynamo to [illegible] lbs. The governor of the turbine demanded to fulfil the required conditions of regulation a momentum equal to that of 1,100,000,000 lbs., moving at the rate of 1 foot per second.

Both of these objects are attained by Prof. Forbes' construction, which consists in making the armature fixed and ring-shaped, with a space inside for getting at the bearings, and in making the fields of a bell-shape, the poles being on the inside of a nickel steel ring, which is supported by the top piece or cover, which in its turn is rigidly fixed to the vertical axis. This novel construction gives all the fly-wheel effect required without making the weight too great. Every design which had been made previously required the addition of a fly-wheel costing at least £[illegible] or £1[illegible]. The construction for which Prof. Forbes' patent has now been granted has also the great merit that the magnetic pull between the armature and the fields tends to diminish the breaking strain of centrifugal force on the revolving part to a very sensible amount. When the revolving part is inside the magnetic pull assists centrifugal force in its destructive effect.

THE EPPING FOREST CONTROVERSY.

THE meeting of the Essex Field Club, which, as we announced last week, had been convened for the inspection of the thinned districts of Epping Forest, was in every way a remarkable gathering. Nearly 150 members and visitors assembled in Monk's Wood, among them, in addition to the conductors and officers of the Club, being Sir John Lubbock, Mr. J. Bryce, M.P., Chancellor of the Duchy of Lancaster, Prof. Boulger, Prof. W. R. Fisher, Dr. Church, Mr. Arthur Lister, Mr. Andrew Johnston (chairman of the Essex County Council), Mr. David Howard, Mr. Salmon (chairman of the Epping Forest Committee), Sir Frederick Young, Mr. Bernard Gibson, and others interested in the question of the Forest management. A thorough examination of Monk's Wood was made, Mr. E. N. Buxton giving a detailed explanation of the policy which the Conservators had been pursuing, and pointing out the reasons that had led to the present necessity for thinning. The party were then conducted to Lord's Bushes, which, as an example of the beautifying effect of judicious thinning, is almost unrivalled, this district having been submitted to the operation repeatedly since the Forest was taken over by the present Conservators. After tea at the Royal Forest Hotel, Chingford, a meeting of the Club was held, Mr. F. Chancellor, the President, in the chair. The discussion was opened by Prof. Meldola, who commenced by explaining that the statements which had been inserted in the newspapers respecting the attitude taken by the Club in the present controversy had been made without authority, and were devoid of foundation. He then went on to show that the observations made by him in 1883 in connection with the agitation against the railway scheme with which the Forest had then been threatened (see the article quoted in our columns in last week's note), had recently been applied to the present thinning operations without his concurrence, and in direct opposition to the views which he had formed after five visits to the districts now being dealt with, and after an intimate acquaintance with the Forest for a period of more than twenty years. Having explained the general grounds on which he based his opinions, he stated that in his belief the Forest as a whole showed a marked improvement since it had been under the care of the present management, and he considered that much of the recent criticism had been most unjust, and the newspaper accounts exaggerated to an extent bordering on the ludicrous. Two or three speakers took an adverse position, but Prof. Boulger, Mr. Howard, Mr. F. C. Gould, Mr. W. Crouch, the President, Mr. William Cole, and others who knew the Forest well, expressed general approval of the recent operations. Mr. Angus Webster, the Duke of Bedford's forester, who accompanied the party, was of course obliged to reserve his opinion owing to his official connection with the committee of experts appointed by the Corporation, the report of this committee not having as yet been presented. As the outcome of the discussion, it may safely be said that the public will not be so ready in future to give credence to the opinions of irresponsible and inexperienced scribblers who, often with the best of motives, may seriously hamper the work of the Conservators in their endeavour to restore the Forest to a more natural condition in those parts which have for so many centuries been made unnatural and unsightly by the existence of the rights of lopping. Although it had not been the original intention of the officers and conductors to allow a formal motion to be put, a strong desire was expressed that this should be done, and on taking a vote a large majority decided that some resolution should be framed. Not the least important feature of the meeting were the speeches made by Sir Frederick Young (formerly chairman of the "Forest Fund"), and others who had taken up an antagonistic attitude in the correspondence. Having visited the place and heard the explanations given on the ground, these gentlemen admitted that as the result of the afternoon's inspection they had seen good reason for modifying their views, and they finally voted for the following resolution, moved by Prof. Boulger and seconded by the Rev. W. C. Howell, of Tottenham:—"That in the opinion of this meeting the general action of the Conservators in the recent thinnings has been judicious." Forty-one voted in favour of this resolution, and eight against. The views of those whose opinions should count for much in reassuring the public that no alarm need be felt as to the future of the Forest, have thus been expressed in very decided terms.

THE UNIVERSITY OF LONDON.

A GENERAL meeting of the Association for Promoting a Professorial University for London, was held in the rooms of the Chemical Society, Burlington House, on Saturday, April 28; the Right Hon. T. H. Huxley was in the chair.

The committee reported that having carefully studied the report of the Gresham Commission, they considered it is generally in accord with the principles of the Association.

In accordance with this report a resolution, moved by Prof. Rücker, and seconded by Prof. Ramsay, was unanimously carried, expressing general approval of the scheme. The committee were also empowered to draw up a memorial to the Government, to be signed by members of the Association, and others who may agree with it, urging the Government to appoint a Statutory Commission to establish a Teaching University in London on the basis of the scheme of the Royal Commission.

This action on the part of the Association is, we hope, another step towards the realisation of the scheme of the "Gresham Commission."

It was at one time to be feared that it would be impossible to reconcile the various divergent views which had been expressed as to the best constitution for the University. Now, however, that the Colleges of Physicians and Surgeons, the Governing Body and Senate of University College, and the Professorial Association, have all expressed a general approval of the scheme, while the London County Council finds in it nothing inconsistent with its own views, it is evident that the Commissioners have achieved a remarkable success. The University of London has not yet spoken, but the opponents of the scheme in Convocation were unable to carry their resolutions, and it is to be hoped that the University may yet be saved from the discredit of blocking the way.

NOTES.

A STATUE of Durand-Claye, the pioneer of the system for the agricultural utilisation of sewage, was unveiled at Gennevilliers, on Friday last. The funds for the erection of this monument were raised by international subscription, in accordance with a proposal made at the Congress of Hygiene held in Paris in 1889.

WE regret to announce the death, at Geneva, of the eminent chemist, J. C. Galissard de Marignac. We have also to record the death of Laureano Calderon, Professor of Biological Chemistry in Madrid University.

THE Kazan Society of Naturalists will celebrate the twenty-fifth anniversary of its foundation on May 25, by a general meeting of members, at which a statement will be read of the works published by the Society during its existence.

THE *Times* says that the Attorney-General has given his sanction to the sum of £25,000, the residue of the legacy of the late Mr. Richard Berridge, being given, in trust, to the British Institute of Preventive Medicine, for the endowment of a laboratory devoted to the bacteriological and chemical examination of the water supply, with special reference to the best means of preventing the conveyance of disease through water. A large laboratory is now in course of erection for the purpose on the site secured by the institute at Chelsea.

EARTHQUAKES continue to be felt in Greece. A severe disturbance, having its centre in Atalanti, occurred on Friday, April 27 (see p. 7), and the *Times* correspondent says that the inroads of the sea in this district have extended inland for a distance of three kilometres. The surface of the sea in many places is coloured with the products of submarine eruptions. A chasm has opened in the ground not far from Atalanti, and extends in a south-westerly direction for about twelve kilometres.

AT the anniversary meeting of the Zoological Society, held on Monday, Sir William H. Flower, K.C.B., F.R.S., was re-elected President, Mr. C. Drummond, Treasurer, and Dr. P. L. Sclater, F.R.S., Secretary to the Society for the ensuing year. The following were elected into the Council, in the place of retiring members:—Dr. John Anderson, F.R.S., Mr. Herbert Druce, Sir Joseph Fayrer, F.R.S., Major Henry P. St. John Mildmay, and Prof. A. Newton, F.R.S.

THE opening meeting of the British Association this year will take place on Wednesday, August 8, when Prof. Burdon Sanderson, F.R.S., will resign the chair, and the Marquis of Salisbury will assume the presidency and deliver an address. On Thursday, August 9, a soirée will be held. On August 10, a discourse will be delivered by Dr. W. H. White, C.B., F.R.S., on "Steam Navigation at High Speeds"; on August 13, Prof. J. S. Nicholson will lecture on "Historical Progress and Ideal Socialism"; on August 14 there will be another soirée, and the concluding meeting will be held on Wednesday, August 15.

THE committee for the establishment of a station at Cumbræ, for the study of marine zoology and botany, are making good progress with their arrangements. The *Ark* has now been put into order for the summer months, and the services of an experienced keeper secured. Mr. David Robertson, the well-known "naturalist of Cumbræ," takes a warm interest in the scheme, and is giving it his personal supervision. A number of students have intimated their intention of availing themselves of the facilities for research thus provided. A considerable sum has been subscribed for the erection of a permanent building, and also for the annual expenses of the station—about half of what is required in each case; and the committee have good hopes that the remaining half will soon be obtained.

THE Geologists' Association have arranged an excursion to Oxted and Titsey for Saturday next, under the direction of Mr. G. Leveson Gower and Mr. W. Topley, F.R.S. The district is not only interesting geologically, but contains a number of archæological remains. During Whitsuntide a long excursion has been arranged to Cambridge and Ely, and on May 26 Mr. John Hopkinson and Mr. Worthington G. Smith will conduct a party to Luton, Caddington, and Dunstable. In the neighbourhood of Caddington are numerous pits in Drift (brick-earth, &c.), and Tertiary remanié beds, worked for clay and sand for brick-making, and for gravel. In these pits Mr. Smith discovered an old Palæolithic land-surface on Tertiary remanié, surmounted by re-laid Tertiary clay, and contorted, implementiferous red plateau drift. On this Palæolithic floor flint flakes of all kinds occur in hundreds, nearly all as keen-edged as knives. That these flakes were made on the spot is shown by the fragments found, which have been struck off, and in many instances have been replaced in their original position, the flint being thus rebuilt. A large Saxon tumulus is also to be seen at Caddington. Close to Zouches Farm is an old pasture, believed to have been a place for making bricks or tiles in mediæval or, perhaps, Roman times; and near Blows Downs is a group of early British hut-foundations. From this it will be seen that the excursion will be one of unusual interest.

Two lectures on "The Æther and its Relations to Material Phenomena" will be delivered at Gresham College, Basinghall Street, on the evenings of May 8 and 9, by Dr. J. Larmor, F.R.S. Prof. Karl Pearson will deliver two final lectures on "The Geometry of Chance," on May 9 and 10.

For misleading statements, and the suppression of facts, commend us to the opponents of Pasteur's anti-rabic treatment. If the general public are gulled into believing half of what it sees posted on the public hoardings concerning the results of the treatment at the Pasteur Institute in Paris, it must liken the eminent head to a veritable Frankenstein. In our issue of April 19 we noted a few of the facts from the official report contained in the current number of the *Annales de l'Institut Pasteur*. This brought us a letter from Mr. F. E. Pirkis, accompanied by a black-edged document, published by the Victoria Street Society for the Protection of Animals from Vivisection, and headed "M. Pasteur's Double Hecatomb. The Tale of the 257 Dead. (New Edition. Revised to November 20, 1893.)" In our note we recorded that only 72 deaths had occurred amongst the Institute patients since the commencement of the inoculations in 1886. But this fact does not tally with the misrepresentations widely advertised by the anti-vivisectionists; so Mr. Pirkis essays to put us right. In reply to his remarks, we would first point out that the note in question simply gives a summary of the published statistics without any critical commentary thereon. This summary, however, clearly indicates that only those deaths which take place *after* the lapse of fifteen days from the date of the last inoculation are included as having occurred *in spite* of the treatment. Our correspondent has apparently not understood this part of the statement, otherwise he would not express surprise at the discrepancy between the 72 deaths given in the statistical report and the 195 deaths which is the total alleged in "M. Pasteur's Double Hecatomb" to have taken place amongst all-comers to the Pasteur Institute. Further, he contrasts the 72 deaths mentioned in the note in Nature with 257 deaths given in the anti-Pasteur circular; but he has apparently not noticed that only 195 of the latter are alleged to have been treated at the Paris Pasteur Institute. A superficial glance at the black-edged document at once shows that many of the deaths there recorded took place *within* fifteen days of the last inoculation, and would, therefore, certainly be excluded from the official statistics of the Pasteur Institute, for the reasons already given. Assuming the total of 195 deaths to be correct, and there are no grounds for impugning the accuracy of the figure, and taking the total number of persons inoculated at the Paris Institute as 14,553—a figure obtained by adding to 14,430, which is the total number of those inoculated at Paris *given* in the official statistics, the number 123, which assuming the correctness of the figures in the anti-Pasteur document represents the number of those patients who were excluded from the official statistics, owing to their death having taken place *within* fifteen days of the last inoculation—it appears that the *total mortality* amongst all the inoculated is only 1·3 per cent. The mortality amongst persons bitten by rabid dogs, and not submitted to treatment, is commonly accepted to be from 15–20 per cent. If the agitators against the establishment of Pasteur Institutes would only look such facts as these in the face, there might be more hope that they would be led to see the error of their ways.

After the close of the recent Medical Congress at Rome, many of the members took part in various excursions organised for their recreation and instruction. It was during an excursion to the Island of Capri that Prof. Todaro related the following interesting story, which we take from the *Lancet*. Early in this century the riches of the Gulf of Naples for naturalists came to be appreciated by local investigators, and their reports attracted the special notice of Cuvier, from whom the reported riches were communicated, always with fresh increment, through Milne Edwards to Quatrefuges. Another and still mightier name to be attracted to the Gulf was Johann von Müller of Berlin, the most encyclopædic of biologists, who, long interested in the inferior vertebrata, had written a classical monograph on them. A contemporary of his, Oronzio Costa of Naples, an investigator of rare powers, had discovered in these waters the *amphioxus*, already known to British and Russian naturalists as the *Branchiostoma lanceolatum*. Costa recognised its true nature, and described it as the first and lowest of the vertebrata. His description at once engrossed von Müller's attention, insomuch that he had barely read it when he said to his wife, "My dear, you must come with me to the Bay of Naples." Travelling in those days was effected by diligence, and it was not till after some weeks that the great German biologist and his lady reached the bay. Alighting at the Albergo di Roma at Santa Lucia, he sent at once for a mariner to get him a specimen of the *amphioxus*. This man turned out to be Costa's own mariner, Giovanni by name, who forthwith in the grey morning, as the result of a "miraculous draught" under Posillipo, obtained the animal and brought it to von Muller, who was still in bed. Overjoyed with his possession, von Muller put it at once into alcohol, woke his wife, who, tired with the long journey, was sleeping profoundly, and said, "My dear, get up immediately, we are going back to Berlin." Von Muller's enthusiasm was caught up by his compatriot Krohn, who from his sojourn at Messina in 1844 drew his German friends to those waters, till year by year, each spring and autumn, the Teutonic universities sent relays of young naturalists to that seaboard—among them Anton Dohrn—a most accomplished student of nature, to whom we owe the scientific institute founded at Naples and opened in 1873. Since that year the Stazione Zoologica has become more and more the resort of biologists, and now there is hardly a seat of learning in Europe which does not contribute to its maintenance in return for facilities afforded to the student for prosecuting research.

The Italian Meteorological Office has succeeded, after some difficulty, in establishing a fairly satisfactory thermometrical station on Mount Etna, at an altitude of about 9850 feet, by means of a recording instrument made by Richard, of Paris, which goes for 40 days. By this method 207 days' observations were secured in the year 1893, and direct observations were also made on 72 days. During seven months of the year the mean temperature was below the freezing point. The maximum temperature observed was 60°·8 in September, and the minimum 13°·5 in March. The characteristic of the annual variation is that the low temperatures are prolonged until June, and, in the autumn, the mild temperatures extend up to December.

An important contribution to the meteorology of South-eastern Europe has been made by the publication of the means of observations for Sophia (Bulgaria) for the years 1891–3, for three hours each day, and for the month and year. During this period the extreme temperatures have varied between −24°·2 in January 1893 and 97°·7 in August 1891. The mean annual rainfall was 31·2 inches, and the greatest daily fall 2·76 inches, in September 1891. The mean annual relative humidity was 74·1 per cent. At the meteorological conference at Munich, in 1891, the wish was expressed for observations (especially telegraphic reports) from Bulgaria, and the publication of these results by Prof. Watsoff, director of the Central Meteorological Station at Sophia, is a good step in the right direction.

IN a letter to the local press, Mr. H. C. Russell, F.R.S., the Director of the Sydney Observatory, recently brought together some facts concerning icebergs and their relation to weather. The letter was written with the view of showing that the icebergs seen near Australia do not influence the weather in the manner commonly supposed. All the reports of icebergs seen within the last two years or so, were collected, and it was found that they numbered eighty-four. In order to locate these icebergs, the position of each ship when ice was seen, was plotted on a map of the world. Of the eighty-four positions thus marked on the map, sixty-one, or 73 per cent., were under the lee of Patagonia, as if they had been carried there by the strong winds and the Cape Horn current, which sets northwards after passing Cape Horn. Round the Cape of Good Hope was another, though less numerous, group of positions, numbering thirteen, and making 90 per cent. of the whole collected in the two localities. About the Crozets two ships reported ice, and two ships reported seeing ice on the same day and in the same longitude at a point 500 miles south-west from Albany. Six other locations were between New Zealand and Cape Horn. Of the eighty-four ships reporting, only two saw ice anywhere near Australia, and that was more than two years ago, on December 14, 1891. As to the effect of icebergs in lowering the temperature, Mr. Russell points out that many observers have reported that the thermometer is not a good indicator of the proximity of ice, no matter whether it is placed in air or in the sea; and this is not surprising if it be remembered that fresh supplies of ocean water and wind are always flowing past the icebergs, and distributing their cold over such wide areas that it becomes inappreciable. Even under the lee of Patagonia, where, in a sense, the ocean is full of icebergs for an area measured by hundreds of miles each way, it does not appear that any very remarkable effect on the temperature is produced, and near Australia, where now and then a few scattered icebergs are seen in the distant offing, no appreciable effect can result from their presence.

AT a recent meeting of the Academy of Sciences of St. Petersburg, Dr. S. Wild read an interesting paper on some improvements in the design and construction of magnetic instruments. The paper is divided into four parts, the first containing the results of some experiments which show that metallic wires are preferable to the silk threads usually employed for the suspension of the magnets in magnetographs. The second part deals with the question of the accuracy of the readings given by the instruments employed to record the variations in the magnetic elements, when these instruments are contained in buildings composed of a material (such as ordinary red brick) containing iron. The experiments on this subject, commenced in 1878, have been continued, and show very clearly that a brick building has no influence on the measurements of the strength of the field, while the influence on the dip is quite negligible. The above result has also been deduced theoretically by M. Chwolson by means of the known value of the susceptibility of the bricks. The third part of the paper contains a description of a small magnetometer for determining the value of the horizontal component of the earth's magnetism, designed for the use of travellers in countries where it would be difficult to carry the ordinary instruments. The instrument fits on Hildebrandt's small universal theodolite, which instrument is fitted with a compass. The combined instrument, although of small weight, is capable of giving results of considerable precision. Thus the dip can be determined to within half a minute of arc, and the horizontal component to within one part in four thousand. Lastly, the paper contains a description of some changes which Dr. Wild has introduced into the portable magnetometer.

IN the April number of the *Journal de Physique*, M. H. Abraham gives an account of a method for measuring self and mutual induction, which he says is capable of giving the quantity which is being measured to within one part in a thousand. The method employed consists essentially of balancing a steady current passing through one pair of coils of a differential galvanometer against a succession of induced currents sent, by means of a commutator rotating at a known speed, through the other coils. The commutator then being stopped, the secondary circuit, containing one pair of coils of the galvanometer, is connected with the extremities of a resistance r in the primary circuit. The value of r is altered till the galvanometer is undeflected, then, from a knowledge of the value of r and the speed of rotation of the commutator, the value of the mutual induction can be calculated. In many ways the method resembles that employed by Profs. Ayrton and Perry in their secohm-meter.

THE line spectrum of oxygen has recently found another careful investigator in Max Eisig, who gives an account of his work in *Wiedemann's Annalen*. The wave-lengths photographed and measured ranged from 2433·6 to 4710·4. The oxygen was generated by the electrolysis of water acidulated with pure phosphoric acid. The form of vacuum tube adopted was that consisting of two vessels joined by a thin tube at right angles to their length, which allowed the gas to be seen through the length of the tube. The end was closed by a plate of quartz to permit the passage of the ultra-violet rays. The tube was cleaned by flushing it with oxygen for several weeks. Of the four different oxygen spectra described by Schuster, only the elementary line spectrum was studied; 93 lines were recorded and measured. A comparison of these lines with a Rowland solar spectrum led to the conclusion that no identity between these oxygen lines and lines in the solar spectrum can be established.

PROF. JULIUS THOMSEN, universally known from his researches in thermo-chemistry, has just finished a series of observations on the ratio of the atomic weights of hydrogen and oxygen (*Zeit. für phys. Chem.* xiii. 398). In order to avoid the errors incidental to the direct methods of estimating the ratio, he employs an indirect method, which consists in estimating the ratio of the molecular weights of hydrogen chloride and ammonia. Pure hydrogen chloride is passed into a flask containing water, and the increase in weight is determined. Pure dry ammonia is then introduced into the solution until the hydrochloric acid is neutralised, and the weight again determined. After introducing all corrections, a large number of observations, in which the initial amount of hydrogen chloride varied between 4 and 20 gr. indicate that the value for the ratio, HCl/NH_3 is $2·13934 \pm 0·00009$. This number leads to the result that 1 : 16 represents the value of the ratio H : O with an accuracy as great as is warranted by the numbers in use for the atomic weights of chlorine and nitrogen, and which have of course to be employed in the calculation. Dumas and Erdmann and Marchand, from the synthesis of water from copper oxide and hydrogen, found respectively 1·0025 : 16 and 1·0017 : 16 as values of the ratio, and more recently Scott, from the volume composition of water, gives the higher value 1·0087 : 16.

IN a recent number of the *Centralblatt für Allgem. Pathologie* some exceedingly interesting experiments are recorded on immunity from the attacks of cholera germs artificially induced in the human subject. Drs. Sawtschenko and Sobolotny succeeded in preparing a vaccine from cultures of the cholera bacillus which so profoundly modified the system, that when they subsequently swallowed virulent cholera germs they experienced absolutely no evil effects whatever. But perhaps the most interesting results obtained, and which proved in a very remarkable manner the modification induced in the system by this vaccine, was the transmission of this induced immunity by means of blood serum to animals. Thus, twenty-five days after the last dose of vaccine had been taken, Sawtschenko and Sobolotny introduced some of their serum into guinea-pigs, and the latter were afterwards inoculated with virulent cholera bacilli. Instead, however, of these animals dying, as they usually do when treated with cholera bacilli, they remained alive. It was found that 0·01 g. of this human serum was sufficient to protect one of these animals subsequently treated with 0·006 g. of virulent cholera bacilli.

An inquiry into the pollution of the River Danube by the drainage from Vienna was carried out last year by Dr. Heider (*Das Österr.-Sanitätswesen*, 1893, No. 31). This river reaches Vienna in a satisfactory condition, containing about 2000 bacteria per cubic centimetre. The Danube canal on its way through the city receives the greater part of its sewage, resulting, as was to be expected, in an enormous accession of bacteria, 21,000—120,000 per c.c. being present. On uniting with the main-stream and becoming mixed with about seven times the volume of water, the pollution is chemically hardly discoverable. Bacteriologically, however, even 40 kilometres below the entrance of the canal, the contamination is still very easily perceptible, the rapidity of the current and the constant disturbance of the water by steam-boat traffic interfering with the efficient sedimentation of the bacteria present. Dr. Heider states that though the existence of disease germs in the water may be interfered with by the severe competition they would have to endure with the numerous harmless microbes, yet the vitality of, for example, cholera bacilli in river water has been shown to persist for several days, and in sewage for very considerable periods of time, so that too much reliance cannot be placed upon the efficiency of this factor. The action of light in destroying disease germs in the river, should they be present, is also discounted. Those who so ardently uphold the comfortable doctrine of the self-purification of rivers, permitting, as it does, of so inexpensive and ready a method of getting rid of sewage by turning it, without let or hindrance, into our streams, will gain but little support for their theories from Dr. Heider's report.

In the April number of the *Journal of Anatomy and Physiology*, Prof. R. Havelock Charles concludes an article on morphological peculiarities in natives of the Panjab, and their bearing on the question of the transmission of acquired characters. He shows that the bones of the lower extremity of the Panjabi adult have certain markings differentiating them from those of Europeans. Though these markings are found on the bones of the fœtus, the infant, and the child of the Panjabi, they are not found in the skeleton of either the European adult or child. Some of them have been found in the remains of Neolithic man in Europe, but are absent in the bones of peoples of the present day of similar geographical distribution. According to Prof. Charles, the explanation of this lies in the fact that the habits as to sitting postures of Europeans differ from those of their prehistoric ancestors, the cave-dwellers, &c., who probably squatted on the ground. The Orientals, however, have retained the sitting postures of their ancestors, and therefore exhibit similar markings. "Want of use," concludes Prof. Charles, "would induce changes in form and size, and so gradually small differences would be integrated till there would be total disappearance of the markings on the European skeleton, as no advantage would accrue to him from the possession of facets on his bones fitting them for postures not practised by him. The facets seen on the bones of the Panjabi infant or fœtus have been transmitted to it by the accumulation of peculiarities gained by habit in the evolution of its racial type—in which an acquisition having become a permanent possession 'profitable to the individual under its conditions of life' is transmitted as a useful inheritance. These markings are due to the influence of certain positions, which are brought about by the use of groups of muscles, and they are the definite results produced by actions of these muscles. . . . They are instances of the transmission of acquired character, which heritage in the individual function subsequently develops."

There are many evidences that a portion of the east coast of Florida was thickly populated in prehistoric times, and remains of this settlement are found in refuse heaps of villages and single habitations. These heaps are from a few square yards to many acres in extent, and from one to fifteen feet in depth. Some of their contents are described and figured by Dr. De Witt Webb, in an excerpt from the *Proceedings* of the U.S. National Museum (vol. xvi. No. 966). In connection with the remains, various members of the human skeleton have been found in positions which suggest cannibalism. There are hearths with accumulations of ashes and shells mingled with pottery (mostly in fragments) and implements and weapons of shell, all of which tell something of the mode of life of the race which apparently inhabited the region for many generations. As to the age of the heaps, Dr. Webb concludes it must be left to conjecture. Trees hundreds of years old are scattered over the remains, all instruments and implements of wood have long since perished, and not even a tradition is left to throw light upon the matter.

A second edition of "A Manual of Ethics" designed for the use of students, by Mr. John S. Mackenzie, has been published by the University Correspondence College Press.

Messrs. Cassell and Co. have commenced a new serial issue, in monthly parts, of Mr. W. Swaysland's "Familiar Wild Birds." In Part i. the Goldfinch and the Magpie are described and pictured. The descriptions, though brief, are very instructive, and the plates are extremely good.

In addition to the usual excellent summary of current researches, the *Journal of the Royal Microscopical Society* for April contains the fifth part of Mr. F. Chapman's paper on the foraminifera of the gault of Folkestone; a description of an inexpensive screen for monochromatic light, by Mr. J. W. Gifford; and an account of a gall-producing Copepod, *Enalstrogus Rhodymeniae*, sp. n., by Dr. G. S. Brady, F.R.S.

The long-expected work on the Carboniferous Insects of Commentry, France, upon which M. Charles Brongniart, of the Paris Natural History Museum, has been engaged some fifteen years, is now finished, and will appear in a few weeks. It forms a volume of 450 pages in quarto and an atlas of thirty-seven plates in folio. About 60 new genera and 100 new species are described. The work also contains a detailed study of the nervation of living *Neuroptera*, *Orthoptera*, and *Fulgoridae*.

A pamphlet, entitled "Notes on Birds of Central Mexico, with Descriptions of Forms believed to be New," by Mr. P. L. Jouy, has been issued as an excerpt from the *Proceedings* of the U.S. National Museum (vol. xvi. pp. 771-791). Most of the species enumerated are from the temperate table-land region corresponding to the southern borders of Arizona and New Mexico, and though few common tropical birds are given, the list will certainly be found valuable.

A propos of the early return of birds this year, Mr. J. H. Barbour, writing from Ballyholme, Ireland, says that on Saturday, April 28, about 10 p.m., he heard the corncrake several times, and it was heard in the district a fortnight before.

A LETTER has been received in reply to the one on "The Mass of the Earth," which appeared in our issue of April 19 (p. 575), but it was not accompanied by the author's name. If the author will send his name, the Editor will be glad to print his reply to "K."

DR. JENTINK, the Director of the Leyden Museum, reminds us that two specimens of *Rhinoceros simus* have formed part of the Museum collection for more than forty years, one of them being a remarkably fine animal. These are described in *Notes from the Leyden Museum* (1890, pp. 241–245), and we regret that they were not mentioned in the note on the two specimens recently modelled by Mr. Rowland Ward, printed in NATURE of April 19 (p. 584).

WE know of no collection of text-books in which the theory underlying industrial machines and processes is set forth in a more scientific and thorough manner than it is in the works of the Encyclopédie Scientifique des Aide-Mémoire series, edited by M. Léauté, and published by Gauthier Villars, and by Masson. Two of these volumes, which have recently appeared, deal with freezing machines, one being devoted to the machines depending upon easily liquefiable gases, and the other to machines in which air, or one of the so-called permanent gases, is caused to expand rapidly, and thus bring about a decrease of temperature. The titles of the two books are, respectively, "Machines Frigorifiques a Gaz Liquéfiables" and "Machines Frigorifiques a Air," and their author is M. R. E. de Marchena. Another volume, just added to the series, is "Construction and Resistance des Machines a Vapeur," by M. Alheilig.

WE have received the sixteenth yearly volume of *Aus dem Archiv der Deutschen Seewarte*, 1893, containing seven important discussions in meteorology and terrestrial magnetism. The current number of this valuable publication inaugurates a new departure, as a considerable amount of routine matter has been removed to another periodical, in order to make room for scientific discussions, and to allow of the work being brought out with less delay than heretofore. It is not practicable to mention here the whole of the subjects dealt with: among the most original investigations not already referred to in our columns are papers by Dr. C. Kassner on "Circular Cyclones," and by Dr. W. Köppen and Dr. H. Meyer, on the frequency of the various amounts of cloud as a climatological element. This last paper embraces the results of a number of long series of cloud observations in different parts of the globe, and a part of the North Atlantic Ocean.

IN general, a work which has reached a seventh edition needs no better testimony of its good qualities than that to be found in the fact of its survival. This is the case with Sir David Salomon's "Electric Light Installations and the Management of Accumulators," which is being issued by Messrs. Whittaker and Co. The edition has been mostly rewritten, and will be completed in three volumes. The first volume appeared a short time ago, and was confined entirely to the treatment of accumulators. Vol. ii., which has just been issued, deals with engines, dynamos and motors, and numberless pieces of apparatus concerned in the generation and utilisation of electricity. Special applications of such apparatus are reserved for description in vol. iii., now in the press. In the three hundred pages of which the second volume consists, as many as 296 illustrations are crowded; but as the author has confined himself to the representation of typical forms of instruments, he has saved the book from being merely an illustrated trade catalogue.

THE Cambridge University Press will shortly publish a treatise on the "Steam Engine and other Heat Engines," by Prof. Ewing; the seventh volume of the edition of Prof. Cayley's collected papers, and the first volume of the collected papers of the late Prof. Adams. An "Elementary Treatise on Electricity and Magnetism," by Prof. J. J. Thomson, is in the press, and also a new edition of Prof. Lamb's "Hydrodynamics," largely rewritten and extended. An "Elementary Treatise on Hydrostatics," by Mr. John Greaves, has just appeared, and a Key to Mr. C. Smith's "Arithmetic" is nearly ready. The completion of Mr. H. M. Taylor's "Euclid" is also announced, and will be published in August. The second volume of Dr. Creighton's "History of Epidemics" may be expected shortly, and a new volume of the Royal Society's Catalogue. In the series of Cambridge Natural Science Manuals, Mr. Glazebrook's volumes on "Light" and "Heat," recently published, will be followed by volumes by the same writer on "Mechanics and Hydrostatics," and on "Electricity and Magnetism," and by Messrs. Darwin and Acton's "Physiology of Plants."

DR. J. P. VAN DER STOK, the Director of the Batavia Meteorological Observatory, has sent us a report of the rainfall observations made in the East Indian Archipelago during 1892. This "Regenwaarnemingen in Nederlandsch-Indie" has now reached its sixteenth year. From it we learn that observations were made in 192 stations during 1892, of which 104 were in Java and Madoera, and 88 in Sumatra and other islands in the Archipelago. In addition to the volume of rainfall observations, the Government of Netherlands India has published one containing the observations made at the magnetic and meteorological observatory at Batavia during 1892, being the fifteenth volume of the "Observations" of the Observatory. No science can claim so many disciples as meteorology. There is scarcely a corner of the world, inhabited by civilised man, in which the temperature is not recorded and the rainfall measured. Indeed, the thermometer and the rain-gauge are the instruments by means of which the first continuous scientific observations are made in most parts of our globe. Meteorological observations, therefore, rapidly accumulate, and the volumes containing them have almost become unmanageable, both as regards number and size. One is sometimes tempted to ask whether these masses of statistics are worth publication, but the remembrance of past discoveries—such, for instance, as Schwabe's discovery of the solar cycle from his daily records of the state of the sun's surface during a quarter of a century—shows the importance of recording all observations that good may come from them.

A FURTHER paper by M. Lobry de Bruyn, of Amsterdam, upon the subject of free hydroxylamine, is contributed to the current issue of the *Berichte*. It contains an account of a number of experiments upon the stability of the isolated base, together with additional observations upon the mode of preparation. When M. de Bruyn prepared his large quantity of solid hydroxylamine three years ago, several small quantities, amounting to five or six grams in each case, were sealed up in small bottles previously cleansed with acid, and preserved in a dark room. Upon recently examining the contents, they were found to be mostly liquid, indicating a certain amount of decomposition. The melting point of pure hydroxylamine is 33°; two of the liquefied specimens referred to solidified again at 28°·5 and 25°·2 respectively. The amount of decomposition, however, is not very great, three of the specimens being found to contain 93, 84, and 73 per cent. respectively. Hence free hydroxylamine appears to be a tolerably stable substance at ordinary low temperatures, but the stability diminishes rapidly with rise of temperature. The decomposition is accompanied by the liberation of bubbles of nitrogen and nitrous oxide. The change appears to be one of self-oxidation and reduction, one portion eliminating oxygen and forming ammonia, and another part suffering oxidation to nitrous and hyponitrous acids, which combine or react with the ammonia and a further quantity of hydroxylamine. As hydroxylamine nitrite spontaneously decomposes, as M. de Bruyn has shown by experiment, it is probable that the hyponitrite of the base is incapable of existence; hence the liberation of nitrogen and nitrous oxide is fully accounted for. M. de Bruyn states that in preparing large quantities of the solid base by fractional distillation of the methyl alcohol solution under diminished pressure it is preferable, after distilling off the methyl alcohol, to divide the residue rich in hydroxylamine among several distilling flasks, and to thus complete the fractionation in small portions. For it is a somewhat remarkable fact that the yield is very much larger when the distillation occurs in this manner; it would appear that the amount of decomposition considerably increases with the bulk of liquid distilled. Moreover, the risk of explosion upon temporarily arresting the distillation in order to change the receiver, is greater with larger quantities, but usually an explosion may be prevented by immersing the distilling flask in cold water during the rapid change of receivers. Taking this precaution, M. de Bruyn has safely distilled as much as half a kilogram of the pure base.

ERRATUM.—In NATURE of April 26 (p. 603), and on the tenth line from the bottom of the first column, for "mosses" substitute "mirses."

THE additions to the Zoological Society's Gardens during the past week include two Macaque Monkeys (*Macacus cynomolgus*) from India, presented respectively by Mr. C. Palmer and Miss A. Orvis; two —— Jackals (*Canis variegatus*), two Fennec Foxes (*Canis cerdo*), two Pale Fennec Foxes (*Canis pallidus*), a Syrian Fennec Fox (*Canis famelicus*), an Egyptian Cat (*Felis chaus*), a —— Genet (*Genetta*, sp. inc.), a —— Zorilla (*Ictonyx frenata*), a Crested Porcupine (*Hystrix cristata*), two —— Gerbilles (*Gerbillus*, sp. inc.), two Lesser Egyptian Gerbilles (*Gerbillus aegyptius*), three Spiny Mice (*Acomys*, sp. inc.), six —— Uromastix (*Uromastix ornatus*) from Suakin, a Libyan Zorilla (*Ictonyx lybica*), two Dwarf Jerboas (*Dipodillus*, sp. inc.), four Spiny Mice (*Acomys*, sp. inc.), three —— Hedgehogs (*Erinaceus auritus*), two Egyptian Jerboas (*Dipus aegyptius*) from Egypt, presented by Dr. John Anderson, F.R.S.; a Wattled Crane (*Grus carunculata*), two Cape Crowned Cranes (*Balearica chrysopelargus*) from South Africa, presented by Sir H. B. Loch, G.C.B., G.C.M.G.; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mr. John Penn, M.P.; two Robben Island Snakes (*Coronella phocarum*) from South Africa, presented by Mr. Barry McMillan; an Indian Civet (*Viverricula malaccensis*) from India, a Long-Legged Buzzard (*Buteo ferox*) captured in the Red Sea, a Mexican Deer (*Cariacus mexicanus*) from Mexico, deposited; four Red-headed Pochards (*Fuligula ferina*), European, purchased.

OUR ASTRONOMICAL COLUMN.

AN ASTRONOMICAL EXPEDITION FROM HARVARD.—A party, in charge of Prof. W. H. Pickering, will soon set out from Harvard College Observatory (says *Astronomy and Astro-Physics*) to establish an observing station somewhere in the State of Arizona, the principal object of the expedition being to observe Mars during the favourable opposition this year. The chief instrument to be conveyed to the site chosen is an eighteen-inch refractor by Brashear, the objective of which was exhibited at the Chicago Exposition. Mr. Percival Lowell, of Boston, who has generously provided the funds for the expedition, will accompany it as an observer.

ELEMENTS AND EPHEMERIS OF GALE'S COMET.—*Edinburgh Circular*, No. 42, contains the subjoined ephemeris for Gale's comet, computed by Mr. A. J. Ramsay.

Ephemeris for Greenwich Midnight.

The brightness at the time of discovery has been taken as unity.

THE HATCHERY FOR SEA FISHES, OF THE FISHERY BOARD FOR SCOTLAND AT DUNBAR.

IN recent years, owing to over-fishing, the scarcity of certain important marine food-fishes has become manifest in many countries, and as one way of meeting the constant drain on the fishing grounds, sea-fish hatcheries have been established in the United States, Newfoundland, Canada, and Norway. A year or two ago the Fishery Board for Scotland began the erection of a similar establishment at Dunbar, which has lately been completed; and for the last five or six weeks active operations have been going on in hatching plaice, with complete success, under the charge of Mr. Harald Dannevig, a Norwegian expert, whose services have been obtained by the Fishery Board. The hatchery consists of (1) a tidal pond; (2) a large "spawning" tank; (3) a chamber for the collection of the eggs and for filtering the water; and (4) the house in which the hatching apparatus is placed. The spawning fishes, male and female, number about 350, and are confined in the large elevated spawning tank (made of concrete) through which a constant current of sea water is maintained. They range from about 14 to 27 inches in length, and are vigorous and feed well. In this tank, which has a capacity of over 60,000 gallons, the fishes spawn naturally, just as they would in the sea; and as the eggs are buoyant they rise to the surface, or near it, and are collected in hundreds of thousands at a time in a specially constructed apparatus placed at the point where the overflow from the tank occurs. The fertilised eggs, which are among the largest of the pelagic forms, are then transferred to the apparatus in the hatching room, through which a continuous circulation of pure sea water is kept up. The hatching takes nearly three weeks to accomplish, and the little fishes are retained for some time after hatching until the yolk is almost absorbed. In smaller vessels with a higher temperature, hatching occurs more rapidly, but the period named (three weeks), probably approaches the normal period in the sea. The number of plaice eggs and larvae at present in the hatching boxes is 8,500,000, and over 7,700,000 fry have been already put in the Firth of Forth by the s.s. *Garland*. The supply of sea water required is considerable, and is obtained by means of two double-acting steam pumps, capable of throwing over 7000 gallons an hour, and driven by an 8 h.p. locomotive boiler. Before being conducted to the hatching apparatus, the water passes through a series of flannel filters, but from its purity when it comes from the sea the filtration gives little trouble. Strong evidence of the suitability of the water for the purpose, and of the satisfactory working of the arrangements, is afforded by the very low death-rate, that is to say, the proportion of eggs which succumb in the process of hatching. At Dunbar it has not exceeded 4 per cent.—a much lower death-rate, so far as known, than at any other marine hatchery. At the Newfoundland hatchery the death-rate has varied from about 37 per cent. to nearly 50 per cent. in different years:

and at the Norwegian hatchery the rate has been even higher. At these establishments, however, the ova of the cod have alone been dealt with, and they are somewhat more delicate than those of the plaice. Nevertheless, check observations with 500,000 cod eggs at Dunbar show a death-rate under 4 per cent. The density of the water has remained practically constant at a little over 1027; the temperature, which at the beginning of March was 4°·5 C., has gradually risen to 6°·3 C., and the hatching process is becoming accelerated.

So far as can be judged at this period, it is probable that the "turn-out" of young plaice during the present season will exceed 30,000,000—a much larger number than has been turned out in the first year at any other sea-fish hatchery. In Norway the first year's issue was 5,095,000 cod (it is now over 200,000,000), and at the Newfoundland establishment it was 17,000,000 cod. This is the first occasion in which plaice, or indeed any flat-fish, have been hatched on a large scale. It was anticipated that there might be difficulties in getting the fishes to spawn under the somewhat unnatural conditions; but none occurred. It is expected that, in the course of the summer, when the spawning period of the plaice is over, that somewhat valuable fish, the common sole—which is rare in Scottish waters—will be dealt with, as well as the lemon sole, and possibly the turbot. All these fish are becoming scarcer and dearer.

The present plant at the Dunbar hatchery—viz., the spawning pond, filtering apparatus, boiler, pumps, &c.—is adapted for a hatching house about three times as large as the present one. When the latter is extended, and the hatching apparatus increased, there will be no difficulty in turning out many hundreds of millions of the fry of the food-fishes every year. The actual hatching—and in many cases the rearing—of almost all the food fishes, has been accomplished for scientific purposes by Prof. McIntosh at the neighbouring laboratory at St. Andrews, and the experience thus gained will be of the greatest utility in carrying on the work from the commercial point of view. It is anticipated that large rearing ponds will be added, to enable the young flat-fish to be kept until they assume the habits of the adult, and thus greatly increase the usefulness of the establishment to the fishery industry.

T. WEMYSS FULTON.

THE FORTHCOMING CONGRESS OF HYGIENE AND DEMOGRAPHY.

FROM a circular just received, we learn that satisfactory progress has been made with the arrangements for the eighth International Congress of Hygiene and Demography, to be held at Budapest, from September 1 to 9. The work of the Congress will be carried out in two divisions, relating respectively to hygiene and demography. Hygiene comprises nineteen, and demography seven, sections. In Section I. of the former division (the etiology of infectious diseases, or bacteriology), notices of thirty papers had been received up to March 31; in Section II. (the prophylaxis of epidemics), thirty-six papers are at present announced; in Section III. (the hygiene of the Tropics), twelve papers; in Section IV. (the hygiene of trades and agriculture), twenty-nine papers; in Section V. (the hygiene of children), twenty-eight papers; in Section VI. (the hygiene of schools), thirty-nine papers. Thirty-six papers have been notified in Section VII. (articles of food); thirty-eight in Section VIII. (the hygiene of towns); eleven in Section IX. (the hygiene of public buildings); nine in Section X. (the hygiene of dwellings); seventeen in Section XI. (the hygiene of communications, that is, of railroads and navigation), and twenty-four in Section XII. (military hygiene). Fourteen papers are promised on the saving of life (Section XIII.), thirty-three on State hygiene (Section XIV.), six on the hygiene of sport (Section XV.), twenty on the hygiene of baths (Section XVI.), thirty-eight on veterinary matters (Section XVII.), seventeen on pharmacology (Section XVIII.), and eleven on general sanitarian affairs (Section XIX.).

The demographic sections of the Congress are (1) historical demography; (2) general demography and anthropometry; (3) the technicalities of demography; (4) the demography of the agricultural classes; (5) the industrial workmen from a demographic point of view; (6) the demography of towns; (7) the statistics of bodily and mental defects. Papers for each of these sections have been received or promised. Up to the end of March the total number of papers announced was 535, of which 437 belong to the hygiene division, and 98 to demography. There seems every probability that the Congress will be a worthy success or to former ones as regards the scientific value of the work, and its international character is vouched for by the fact that nearly 250 official delegates have been nominated.

In accordance with a resolution passed at the Congress of Hygiene and Demography held in London in 1891, an international committee has been formed to prepare for discussion questions relating to the cause and prevention of diphtheria. This committee contains the representatives of fifteen different nationalities, as follows:—Austria, Prof. Wiederhofer; Bavaria, Prof. Henry Ronde; Belgium, Dr. E. Tordeus; England, Dr. Edward Seaton; France, Dr. F. Roux; Germany, Prof. Frederic Loffler; Hungary, Dr. Cornelius Chyzer; Italy, Prof. Luigi Pagliani; Norway, Prof. Axel Johanessen; Roumania, Prof. Maldarescu; Russia, Prof. Nicolas Filator; Spain, Prof. Francisco Criado y Aquilar; Sweden, Prof. E. Almquist; Switzerland, Prof. Haganbach-Burkhardt; United States of America, Prof. S. Billings.

An exhibition will be held in connection with the Congress, but only of objects which serve to elucidate and exemplify questions brought up for discussion, and those which mark real progress in sanitary matters and public health. This is done in order to prevent the exhibition from becoming a vehicle for trade advertisement. No awards will be made, but objects of special importance will be named in the minutes of the closing meeting. No charge will be made for space, and objects sent in are duty free. Intending exhibitors must give notice before May 15 to the General Secretary, Prof. Dr. Coloman Müller, St. Rochus Hospital, Budapest, who will supply the proper application forms.

Membership of the Congress can be obtained by transmitting the amount of £1 (for ladies the sum is 10*s.*) to Prof. Müller. This fee entitles the sender to admission to all the meetings, excursions, and various social gatherings arranged, to a copy of the Proceedings of the Congress, and to railway journeys at reduced rates.

The Corporation of Budapest will hold a reception in the halls of the Town-Redonte, and a garden party in the grounds of the National Museum. All the learned societies and bodies interested in the work of the Congress have also made arrangements for receptions. At the Royal Opera House, the National Theatre, and the People's Theatre, special representations will be given in honour of the meeting; in fact, there is every reason for believing that members will come away with a favourable impression of Hungarian hospitality. As to the more serious side of the meeting, the list of papers down to be read shows that there will be no dearth of subjects for discussion. A number of important questions will therefore be ventilated, and even if many of them fail to elicit a definite opinion, a clearing of ideas is bound to result from their discussion.

SEWER GAS AND TYPHOID FEVER.

IT is now more than thirty years ago since two eminent physicians discussed, with some heat, in the columns of the medical papers and elsewhere their theories on the origin and distribution of typhoid fever. While Dr. Murchison and his party regarded the exhalations from drains as the *specific cause* of typhoid, Dr. Budd and his supporters argued that the gases from putrid liquids were only capable of producing this disease in the presence of some particular contagion. The discussion was taken up on the continent, and the sewer-gas theory was vigorously fought over, but towards 1880 the whole subject was revived, and its supporters were later confronted with the results of bacteriological investigations on sewer-air, which showed that there were not more organisms present in drains than in the outside air, and that under normal conditions, currents of air were unable to detach disease microbes, should they be present, from the effete materials present in the sewer.

Meanwhile English hygienic authorities, without waiting for the scientists to make up their minds on this crucial question, preferred to act, at any rate, on the assumption, supported as it was by much experience and many facts, that the exhalations from drains were undesirable and dangerous in our houses and surroundings, and should be rigorously excluded. The advance in sanitation, and its splendid results during the past ten years or so, is a sufficient testimony to the wisdom of the agitation which determined the crusade against bad drainage and unsanitary appliances in this country.

But the inquiring spirit of the scientist, which abhors blind empiricism, and seeks always to reach the root of the matter, has again been exercising itself on the question of the spread of disease by sewer-gas, and it is significant that in the most recent report to hand on sewer-air, the direct connection of the latter with the distribution of zymotic disease is declared to be still wrapped in mystery and uncertainty, and we find our precise and scientific information on this subject as meagre as it was some thirty years ago. All the more important and welcome, therefore, are some very original investigations which have just been published by Dr. Alessi, who has not contented himself with finding very few and harmless microbes in sewer-air, but has submitted the whole question of its relation to typhoid fever to a searching experimental inquiry.

For this purpose the effect of inhaling sewer-air and the gases from putrifying materials was examined on animals—rats, rabbits, and guinea-pigs being selected. After exposure to sewer-air, which was accomplished by placing them in a box with a perforated bottom communicating directly with a drain, they were inoculated with a small quantity of only a slightly virulent cultivation of the typhoid bacillus, whilst other animals were similarly treated, except that they were not compelled to inhale these noxious gases, but were kept in their ordinary surroundings. The rats, after inhaling this foul air, began to lose their vivacity, and after a time grew thin, although they eat voraciously, and out of forty-nine which were inoculated with typhoid germs thirty-seven died exhibiting the typical symptoms of typhoid infection. Of those forty-one rats, however, which, although infected with typhoid, had not inhaled sewer-air, only three succumbed. Thus the inspiration of drain-air had so far predisposed these animals to infection from typhoid that a small dose of an almost harmless growth of this organism proved very fatal to them. Guinea-pigs and rabbits exposed in like manner to gases from materials in a condition of active decomposition also acquired a predisposition to typhoid infection, for out of seventy-two guinea pigs inoculated, fifty-seven died, whilst not one of those treated with typhoid germs in ordinary surroundings succumbed. Every one of the eleven rabbits similarly treated died, but not one of the inoculated animals kept in ordinary surroundings. Dr. Alessi also found that the inhalation of these gases from putrid substances enabled a small dose of a weakened culture of the *B. coli communis*, normally present in the intestine, to produce fatal results when purposely introduced into the animals thus exposed.

It was also ascertained that it was during the first two weeks of exposure to these noxious gases that the animals were most easily predisposed to typhoidal infection, for no less than ninety per cent. of all the animals inoculated during the first fortnight died, whilst seventy-six per cent. succumbed of those inoculated in the third week. This fact may, says Dr. Alessi, partly explain how it is that some people who habitually breathe contaminated air do not appear to suffer any evil results, having gradually in course of time become accustomed to it, whilst a stranger exposed to the same conditions without previous experience may suffer very severely. The degree of predisposition, however, whilst varying in different animals, would also vary in different people.

These investigations must be regarded as a noteworthy and an important contribution to our knowledge of the distribution of hygiene, affording as they do so remarkable an experimental confirmation of the wisdom of a policy of sanitation dictated by instinct and intuition.

ANOTHER NEW BRANCHIATE OLIGOCHÆTE.

About two years since I described in the columns of this journal (vol. xlv. p. 189) an Annelid belonging to the family Tubificidæ, which was unique in that family in the possession of a series of branchial processes upon the posterior segments of the body. This worm, as I reminded the readers of NATURE in Jan. 11 (vol. xlix. p. 247) was found in the "Victoria Regia tank" at the Botanical Society's Gardens—a locality which has produced many interesting invertebrate animals. I have now to record the existence of another Oligochætous Annelid in which branchial processes of a very similar nature to those of *Branchiura sowerbyi* are found. This worm was sent to me by Dr. Michaelsen, of Hamburg, a well-known authority upon this group of animals; it had been collected by him in South America during a recent expedition for collecting purposes to that country. With great generosity he has handed over to me for study the bulk of the Oligochæta which were brought home by him from Patagonia, the Argentine, and Chili; and the species upon which I desire to say a few words here was among those worms. It was discovered in the river at Valdivia, in Chili. The worm, like *Branchiura*, is a member of the family Tubificidæ, but it clearly represents a new genus of that family, into the general characters of which I do not propose to enter here. The collection contains several species of this new genus, for which I suggest the name of *Hesperodrilus*. The gilled species is not unlike the common *Tubifex* of our streams and lakes in outward appearance, but it differs from *Tubifex* and agrees with *Branchiura* in having a series of branchial processes attached to some of the posterior segments of the body; as I have only examined one specimen, it is impossible to say whether the limited number of these gills, in comparison with those of *Branchiura*, is a distinguishing mark; but, in any case, they differ by reason of the fact that they are lateral in position, being attached to the body just below the lateral setæ; in *Branchiura* it will be remembered that they are dorsal and ventral in position (cf. *Quart. Journ. Micr. Sci.* March, 1892, for the more complete description of *Branchiura*). It is well known that the Tubificids, as a rule, live imbedded in the mud with the tail—and not the head—end extruded, and generally waving about in the water; it is thus intelligible how the development of gills upon the posterior, rather than the anterior, end has come about. The single specimen which I have examined possessed about thirteen pairs of branchiæ; these were at first very small, but gradually increased in size towards the end of the body, those upon the terminal segments being, if anything, larger than those upon any of the preceding segments; in *Branchiura* the gills diminish in length towards the extremity; it may be that my specimen of *Hesperodrilus branchiatus* had recently lost the tail, but there were no obvious signs of this. The genus differs from *Branchiura*—and, indeed, from any other genus of Tubificidæ known, unless my *Phreodrilus* be accounted a Tubificid—in that the spermathecæ (which are unusually long) open *behind* the male pores, instead of, as in the other Tubificidæ, *in front of* them. I mention this point to show that I have not confounded this new gilled Tubificid with *Branchiura*.

FRANK E. BEDDARD.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—In a congregation held on April 26, Prof. A. H. Green and Prof. C. Lapworth were appointed Examiners in the Final School of Natural Science (Geology), and Prof. H. Marshall Ward and Prof. F. W. Oliver were appointed Examiners in the same school in Botany. All the appointments were made for one examination only.

Notice is given that the final examination for the degree of Bachelor of Medicine will begin on Monday, June 4. Names to be sent in by May 19. The examination for the degree of Master of Surgery will begin on Wednesday, June 13. Names to be sent in by May 30. The first examination for the degree of Bachelor of Medicine will begin on Friday, June 22. Names to be sent in by June 7.

The degree of D.C.L. *honoris causa*, was conferred on Wednesday on Prof. August Weissmann.

At a meeting of the Board of Faculty of Natural Science on Tuesday last, new regulations for the preliminary examinations in Animal Morphology and Animal Physiology were approved of. The new regulations will come into force in Michaelmas Term, 1894.

At a meeting of the council of University College, Liverpool, held on Tuesday, it was announced that Lord Derby had telegraphed his intention to provide for the endowment of the chair of Anatomy. It was resolved that Lord Derby be requested to allow his name to be permanently associated with the chair. Formal intimation was also given of the endowment of a chair of Pathology by Mr. George Holt with £10,000. It was decided that the new chair should be called the George Holt Chair of Pathology, and that candidates for the chair should be invited to send in their names. Another announcement made was that Mr. Henry Tate would present to the Tate Library a collection of standard books of the value of £5,500. The endowment of the chairs of Anatomy and Pathology completes the provision necessary in order to bring the medical department of the College into rank with similar departments at the older Universities and at Owens College, Manchester.

THE arrangements for the University Extension Congress, to be held in London in June next, have been announced. There are several reasons which render the present year opportune for such a gathering. In the first place, the University Extension movement attains its majority, the first Courses of Lectures having been arranged by the University of Cambridge in the autumn of 1873. And secondly, University Extension work has a defined place in the scheme for the establishment of a Teaching University for London. In view of the anticipated establishment of a Teaching University on the lines laid down in the Report of the Royal Commission, it is important to sum up and present the educational results of the twenty-one years' work in University Extension, and to consider, in the light of past experience, practical proposals and a general policy for the future of the whole movement.

The Congress, which will meet in the Lecture Theatre of the University of London, will include three sessions, to be held on Friday afternoon, June 22, and Saturday morning and afternoon, June 23. The Marquis of Salisbury, the Duke of Devonshire, and Lord Herschell, will preside at the three sessions respectively.

The subjects for discussion will be :—

(1) The means of preserving and further developing the educational character of University Extension work, and the relation of the more popular to the more strictly educational side of the movement.

(2) The essentials of efficient central and local organisation, and the relation, educational and financial, of the University Extension Movement to the State and to local authorities.

(3) The educational possibilities of University Extension work and methods in relation to regular University studies and University degrees.

These subjects will be considered beforehand by a committee or committees of experts, who will present reports and formulate the resolutions to be submitted for discussion to the Congress. The Right Hon. the Lord Mayor has intimated his intention of inviting the members of the Congress to a reception at the Mansion House on the evening of Friday, June 22.

AT the last meeting of the Council of the Durham College of Science, Mr. Henry Palin Gurney, formerly Fellow of Clare College, and Deputy-Professor of Mineralogy in the University of Cambridge, was appointed Principal.

SCIENTIFIC SERIALS.

American Meteorological Journal, April.—"Storms of the Gulf of Mexico and their prediction," by W. D. Stearns. Many of the storms which enter the United States from the Gulf of Mexico are very destructive, and give scarcely any indication of their approach by means of the barometer. The author has made a special study of local conditions and cloud movements which preceded a number of storms in 1892 and 1893, and thinks that by those means their presence may be detected in every case some hours in advance of their arrival. Notes are given of the phenomena preceding several storms.—A new chart of equal annual ranges of temperature, by J. L. S. Connolly. The chart was constructed on the basis of Dr. Buchan's "Challenger" isothermal charts. It shows that the torrid zone is, on the whole, a region of moderate annual range of temperature, while the north temperate zone has extreme variations compared with the south temperate. The effects of solar and terrestrial radiation are well shown; in northern Asia there is a range of 120°, and of 80° in the northern part of North America.

Bulletins de la Société d'Anthropologie de Paris, tome iv. No. 12.—This number contains a valuable memoir by M. L. Manouvrier on the normal and abnormal variations of the nasal bones in the human species. Whatever may be the original cause of variation, it is interesting to observe that that cause is sufficient to produce in one and the same race individual varieties suggesting all kinds of ethnic types. In one case, figured by M. Manouvrier, the nasal bones are entirely suppressed, their place being supplied by the frontal bone.—M. G. de Mortillet proposes an important reform in chronology; he points out the inconvenience of using several different eras, such as the Foundation of Rome, the Birth of Christ, the Flight of Mohammed, or the Proclamation of the Republic, and suggests that 10,000 years before the Christian era should be adopted as a general starting point; this would not only include all Egyptian chronology, as known at the present day, but would also leave 5000 years at the disposal of future discoverers.—At the Broca conference, Dr. Capitan delivered a lecture on the rôle of microbes in society.—M. J. Deniker has contributed a paper on the natives of Lifou, one of the Loyalty Islands. The average stature of these islanders is somewhat below middle height (1642 mm.), although in the case of four individuals out of the ten examined by Dr. Francois, whose observations form the basis of this communication, the stature was from 1670 to 1690 mm.; the head is dolichocephalic (cephalic index = 72·4), and the nose is platyrrhine (nasal index = 97·8); five out of the ten subjects were hyperplatyrrhine (index 101 to 117). The colour of the skin, in the majority of those examined, resembled chocolate with a reddish tinge (28–29 Broca), while one of them had a light brown skin, and two others were black. The colour of the iris varied from brown to dark brown, the darker tinge predominating.—In a paper on family property in Anam, M. Paul Denjoy describes the organisation of the family, the prescriptions of the law with regard to succession and wills, and the extensive system of registration employed. He gives a good general idea of Anamite legislation, and of the principles that underlie it. The number includes several short communications of much interest.

Wiedemann's Annalen der Physik und Chemie, No. 4.—On the formation of floating metallic films by electrolysis, by F. Mylius and O. Fromm. A zinc plate is laid on the bottom of a glass jar, and is covered with a layer of 50 per cent. solution of zinc sulphate. A platinum wire 0·2 mm. thick touches the surface of the solution vertically. On passing a current from a 3-volt battery through the solution, a bright film of metallic zinc is formed round the platinum cathode, which gradually expands, and exhibits an approximately circular form, but subsequently becomes irregular. The phenomenon does not take place unless the surface of the solution is tainted with some substance insoluble in water, such as oil of turpentine. This may form a separate thick layer, and the film is produced at the separating surface. It may also be produced at the lower surface of the zinc sulphate solution by first pouring a layer of chloroform on to the zinc anode. Other metals, such as iron, cobalt, cadmium, silver, show analogous phenomena.—On the elasticity and tenacity of some new glasses as dependent upon their chemical composition, by A. Winkelmann and O. Schott. The coefficients of elasticity, and those of resistance to tension and pressure, were determined experimentally for eighteen kinds of glass. The first lies between 4699 and 7592 kg. per sq. mm. The second lies between 3·5 and 8·5 kg. per sq. mm., and the third between 60·6 and 120·8. These results may be represented by formula depending upon chemical composition, the calculated values varying by 3 per cent. from the observed ones in the case of elasticity, and about 8 per cent. in the case of tenacity.—On the coefficient of thermal resistance of different glasses as dependent upon chemical composition, by the same authors. The thermal resistivity is the property enabling glasses to withstand sudden cooling without breaking. It depends upon the elasticity, the tenacity, the thermal expansion and conductivity, the specific heat, and the specific gravity of the glass in question. In most cases the resistivity can be calculated with fair approximation if these properties are known.

Internationales Archiv für Ethnographie, vol. vii. parts 1 and 2.—The new volume of this useful journal is continued along the same lines as the previous volumes; the publisher only is changed. Heer Trap still prints the letter-press, and turns out the plates in his usual skilful manner. Prof. G. Schlegel gives the first published illustration and full description of "A Canton Flower-boat," or, as it should be called, "Gaudy Boat." These are really floating cafe-chantants, in which the greatest decorum prevails; they are hired for evening festivals and suppers, by wealthy officials and others.—Leo V. Frobenius has an interesting article, illustrated by three plates, on "Ceramics and their origin from Wood-carving in the Southern Congo Basin." He deals with the pottery trade, the form of clay vessels, wooden vessels, ornamentation, images in wood and clay, &c. He comes to the conclusion that the leather-work is the oldest industry of the Negro, and was followed by wood and plaited work, from which finally arose ceramics. The author agrees with Schurtz that a Wooden age replaced the Stone age in Africa, and was followed by the Iron age: the latter took place quickly on account of the superiority of iron weapons and utensils over wooden ones, but pottery slowly superseded wooden vessels and gourds, and has undergone only a slight development. The second part is mainly taken up with an elaborate article by J. Walter Fewkes, on the "Dolls of the Tusayan Indians." These are carefully described, and their symbolism is noted; coloured illustrations are given of forty-three of them. He points out that the characteristic details are always found on the head, and adds, "this fact is one which gives a great importance to the study of helmets, masks, and all cephalic decorations which are used in ceremonial dances."—Prof. P. J. Veth, on "Signature-lore" (De Leer der Signaturer; signature being "the resemblance of a vegetable or a mineral to any part of a man's body."—The first part of an essay of a branch of sympathetic magic deals with the subject in general, and a detailed account of the Mandrake (*Mandragora*).—R. Parkinson sends a note, which is illustrated, on the boring of shells in the manufacture of armrings, &c. The shell is partially embedded in and lashed to a board, and the hole is drilled by means of a bamboo cylinder, to which a flat stone is fastened as a fly-wheel, sand and water is used as emery; when half cut through, the piece of shell is reversed.

Annalen des K.K. naturhistorischen Hofmuseums, Bd. viii. Nos. 2, 3-4. (Wien: A. Holder, 1893.)—Dr. O. Finsch, in the last number of this publication, completes his "Ethnologische Erfahrungen und Belegstücke aus der Südsee." The sub-title describes this as a descriptive catalogue of a collection in the Vienna Museum. It rarely happens that an ethnological collection in a museum is so fully described as this has been, but in this case the author describes the specimens he has himself collected. The catalogue commenced in the third volume (1888) of the *Annalen*, and now concludes, having run to 675 pages, and having been illustrated by twenty-five plates and numerous illustrations in the text. But it is more than a mere illustrated catalogue, for the author has incorporated original ethnological investigations as well as given authentic accounts of the various objects enumerated. The whole series of papers forms an invaluable addition to the libraries of museums and of those interested in such subjects. The current numbers contain Dr. Finsch's account of the Marshall Archipelago and of the Caroline Islands, including Kuschai, Ponape, Ruk, and Mortlock; to this are appended addenda to and corrections of statements in the earlier papers, and several indices.—Eight new species of Hymenoptera belonging to the genus *Gorytes*, Latr., are described by A. Handlirsch (p. 276).—Prof. F. Toula has (p. 283) a preliminary communication on the fauna of the Miocene beds of Kralitz in Mähren; the Foraminifera are most fully noted.—Dr. A. Zahlbruckner gives a description (p. 438) and plate of a new species of lichen (*Pannaria austriaca*).—Dr. F. Berwerth follows, also with a coloured plate, "On Alnoit from Alnö."—F. F. Kohl (p. 455) has a monograph, with three plates, on *Ampulex*, Jur. (s.l.) and allied genera of Hymenoptera. Numerous new species are described.—F. Siebenrock has an illustrated and carefully worked-out paper on the skeleton of *Uroplates fimbriatus*, Schneid., one of the Geckos.

SOCIETIES AND ACADEMIES.

London.

Chemical Society, March 15.—Dr. Armstrong, President, in the chair.—The following papers were read:—Formaldoxime, by W. R. Dunstan and A. L. Bossi. Formaldoxime has previously only been known as a gas or in solution; the authors have obtained it as a colourless liquid boiling at 84°–85°.—Derivatives of camphene containing halogens, by J. E. Marsh and J. A. Gardner. Chlorocamphene, $C_{10}H_{15}Cl$, is prepared by distilling camphene dichloride, and bromocamphene is obtained by the action of bromine and phosphorous chloride on camphor.—A sulphate of oxamide, by J. E. Marsh. A hot solution of oxamide in strong sulphuric acid deposits crystals of oxamide disulphate $(CONH_2,H_2SO_4)_2$, on cooling.—Fluoplumbates and free fluorine, by B. Brauner. The author has prepared a fluoplumbate of the composition $3KF, HF, PbF_4$; on treatment with sulphuric acid it yields lead tetrafluoride.—The action of nitrosyl chloride on unsaturated compounds, by W. A. Tilden and M. O. Forster.—Note on the action of nitrosyl chloride on amido-derivatives of benzenoid hydrocarbons, by W. A. Tilden and J. H. Millar. Nitrosyl chloride acts on aromatic amido-compounds yielding a diazo-derivative, a nitroso-compound, or a chloro-derivative.—Action of aluminium chloride on heptylic chloride; a correction, by F. S. Kipping.—Oximidosulphonates or sulphazotates, by E. Divers and T. Haga. A number of salts of oximidosulphonic acid have been prepared and their reactions studied.—Derivatives of tetramethylene, by W. H. Perkin, jun. Tetramethyleneamine is obtained as a colourless oil, by the action of potash and bromine on the amide of tetramethylenecarboxylic acid.—β-2-Dimethylglutaric acid, $COOH.CH_2.CMe_2.CH_2.COOH$, by W. Goodwin and W. H. Perkin, jun. This acid, which is probably closely allied to camphoric acid, yields an anhydride of the constitution

$$CMe_2\langle{}^{CH_2.CO}_{CH_2.CO}\rangle O.$$

—The products of the action of fused potash on camphoric acid, by A. W. Crossley and W. H. Perkin, jun.—Conversion of ortho-into para-, and of para- into ortho-quinone derivatives. II. Dinaphthyldiquinone, by S. C. Hooker and J. G. Walsh, jun.

March 22.—Anniversary meeting.—Dr. Armstrong, President, in the chair.—After the reading of the President's address and the Treasurer's report, a ballot was taken for the election of officers and Council for the ensuing session. The ordinary members of Council are the following:—C. F. Cross, H. Dixon, B. Dyer, R. J. Friswell, A. G. Green, F. S. Kipping, W. H. Perkin, jun., W. A. Shenstone, T. Stevenson, J. A. Voelcker, W. P. Wynne, and S. Young.

Zoological Society, April 17.—W. T. Blanford, F.R.S., Vice-President, in the chair.—Mr. Sclater made some remarks on the possibility of breeding the African Mud-fish (*Protopterus*) in the Society's Gardens, and called attention to a recently published paragraph in "Le Mouvement Géographique" in which some account was given of the phenomena of reproduction of this Mud-fish, as observed by the French missionaries on Lake Tanganyika.—Prof. Karl von Bardeleben, of Jena, read a paper on the bones and muscles of the mammalian hand and foot, in which he explained his views on the rudiments of the sixth and seventh digits or rays. These rudiments, as he showed, are situated both on the inner and the outer borders of the hand and foot; they are present in nearly all the orders of mammals, especially in the lower forms, and are always provided with special muscles.—Dr. G. Herbert Fowler pointed out the characters of a new species of Sea-Pen of the family *Veretillidæ* from a specimen belonging to the Madras Museum, and proposed to call it *Cavernularia malabarica*. Dr. Fowler likewise exhibited and made remarks on an example of *Lidaria phalloides* belonging to the same Museum.—Mr. F. E. Beddard, F.R.S., described two new genera comprising three new species of Earthworms from Western Tropical Africa.—A communication was read from Mr. Oldfield Thomas containing an account of a new Antelope from Somaliland, which he proposed to call *Neotragus rupicola*. Capt. H. G. C. Swayne, R.E., and his brother, Capt. E. Swayne, had discovered this Antelope during their recent explorations in that country, but had not been able to bring back specimens. Two skins and a frontlet, lately received by Capt. H. G. C. Swayne from his native hunters, had enabled Mr. Thomas to establish the species.

Geological Society, April 11.—Dr. Henry Woodward, F.R.S., President, in the chair.—Mesozoic rocks and crystalline schists in the Lepontine Alps, by Prof. T. G. Bonney, F.R.S. The author described the results of an examination of the infold of Jurassic rock in the Urserenthal, undertaken in the hope of finding some definite evidence as to the relations of the marble, exposed near the old church at Altkirche, and the adjacent Jurassic rocks.—The easternmost of the sections described occurs high up on the slopes north of the Oberalp road. Read off from the northern side it exhibits (1) gneiss, (2) phyllites with bands of subcrystalline limestone, &c.—Jurassic, (3) a little rauchwacke, (4) "sericitic" gneiss. The next section (about 250 feet above the St. Gothard-road at Altkirche) gives (1) gneiss, (2) covered ground, (3) slabby marble, (4) phyllite, (5) thicker mass of slabby marble, (6) phyllite, &c., (7) "sericitic" gneiss. The third section runs thus, using numbers to correspond with the last:—(1) gneiss, (4) phyllite, (5) slabby marble, (6) phyllite, &c., (7) "sericitic" gneiss. It must be remembered that on the slopes of the Oberalp farther south, between the "sericitic" gneiss and the "Hospenthal Schists," another dark phyllite is found, generally considered by the Swiss geologists to be carboniferous. The marble in the third section is in places distinctly banded with white mica, and passes on the northern side into fairly normal mica schist and quartzose schist. The fourth section, about a mile away, on the left bank of the Reuss valley, gives a practically continuous section in phyllite and dark limestone, without any marble. In the fifth section, rather more than a mile farther, if any marble is present, it is very thin and shattered. At Realp, about 3¾ miles farther, the next good section is obtained. Here the rocks go in the following order (from the northern side):—(1) Gneiss; (2) phyllite and limestone; (3) subcrystalline limestone, looking very crushed; (4) the marble; (5) phyllite, etc.; (6) Hospenthal schists. The last group of sections occurs near the Furka Pass. In the first, crossed by the high road, there is no marble, but a little rauchwacke on the southern side. The next one, on the slopes below the pass, seems to show two masses of the marble parted by a subcrystalline limestone like that at Realp, with phyllite above and below. Of the two masses of marble the southern one can be traced right across the pass, but the extent of the other is not so clear. Examination of the marble mentioned above shows in all cases that it has been considerably modified by pressure since it became a crystalline rock. The author discussed the evidence of these sections, and maintained that the hypothesis that the marble is an older rock intercalated by thrust-faulting among Jurassic strata leads to fewer difficulties than to consider it as belonging to the same system. In the latter part of the paper the results of a re-examination of the ravine-section in the Val Canaria, and of some studies of the south side of the Val Bedretto are described, which, as the author maintains, confirm the view already expressed by him, viz. that the schists with black garnets, mica, kyanite, dolomite, and calcite (the last sometimes becoming marbles) are not altered Jurassic rocks but are much older.—Notes on some trachytes, metamorphosed tuffs, and other rocks of igneous origin, on the Western Flank of Dartmoor, by Lieut.-General C. A. McMahon. In this paper the author noticed the occurrence of felsite and trachyte at Sourton Tor; of rhyolite and of aluminous serpentine at Was Tor; and of a dolerite at Brent Tor in the exact situation indicated by Mr. Rutley as the probable position of the throat of the Brent Tor volcano. The author described extensive beds of tuffs at Sourton Tor and Melton, the matrix of which has been converted, by contact-metamorphism, into what closely resembles the base of a rhyolite, and which, in extreme cases, exhibits fluxion-structure, or a structure closely resembling it. The fragments included in this base were so numerous that six or seven different species of lavas may be seen in a single slide; this fact, and a consideration of the extensive area over which these beds extend, led the author to believe that these beds were metamorphosed tuffs and not tufaceous lavas. He then described some beds on the flank of Cock's Tor, which give evidence on their weathered surface of an original laminated structure by exhibiting a corded appearance like corduroy cloth. These beds are composed of colourless augite, set in a base which in ordinary light looks like a structureless glass, but which between crossed nicols is seen to be an obscurely crystalline felspar. The author compared these rocks with that portion of the Lizard hornblende-schists for which a tufaceous origin was proposed by De la Beche and other writers, including Prof. Bonney and himself. He showed that the Lizard schists and the Cock's Tor rocks agree in specific gravity and in some other characteristics; and he concluded that at Cock's Tor the first stage in the conversion by contact-action of beds of fine volcanic ash into hornblende-schist had been completed, and the final stage, due to aqueous agencies, had just begun.

Linnean Society, April 19.—Prof. Stewart, President, in the chair.—Sir Joseph Hooker exhibited a portrait of Jeremiah Bentham, father of Jeremy and Sir Samuel Bentham, born 1710, died 1792.—Dr. Prior exhibited specimens of *Pinus Pinsapo* with undeveloped catkins, like berries, and other specimens of conifers in flower.—Mr. J. R. Jackson exhibited an Afghan knife, the sheath of which was bound with bark of *Caragana decorticans*, selected on account of its bronze-like appearance, and gave some account of the various native uses to which this bark is put.—On behalf of Mr. George Mayor and Mr. F. R. Maw, some photographs of abnormally situated nests of the robin were exhibited, one of which had been built upon a book-shelf in one of the studies at Tunbridge School, and another in an old tin teapot which had been flung aside as useless, and had lodged in a poplar.—Mr. B. Shillitoe exhibited and made remarks upon an abnormal hyacinth.—An account of British Trap-door spiders was then given by Mr. F. Enock, and by the aid of the oxy hydrogen lantern and some excellent slides, their appearance and mode of life was graphically delineated and described.—In view of the approaching anniversary meeting, the election of auditors was next proceeded with, when Mr. Batters and Prof. Howes were nominated on behalf of the Council, and Mr. Michael and Mr. J. Groves on behalf of the Fellows.—In the absence of the author, Mr. George Murray gave an account of Graf zu Solms-Laubach's monograph of the *Acetabularieæ*, and the principal points were illustrated with lantern slides. The limits of the group were defined as excluding *Dasycladeæ*, and containing the living genera *Acetabularia*, *Polyphysa*, *Halicoryne*, and *Pleiophysa*, of which the author maintained only the first and third named. The extinct forms, principally *Acicularia*, were dealt with very exhaustively, and their relation to the living ones indicated. The paper consisted of a morphological account of all the forms, as well as a detailed systematic review of them, and the author's views of the relationship of the grasses to the forms of *Dasycladaeæ*, *Cymopolia*, *Neomeris*, *Bornetella*, &c., possessed much novelty and interest.

PARIS.

Academy of Sciences, April 23.—M. Lœwy in the chair.—On an example of divergent successive approximations, by M. Émile Picard.—Some preliminary remarks on the mechanism for excretion of albuminoids, and the formation of urea in the economy, by M. Armand Gautier.—Observations on the remarks of M. Armand Gautier, by M. A. Chauveau. M. Berthelot followed with a further observation, affirming M. Gautier's view of the production of carbonic anhydride without direct oxidation by means of free oxygen.—On the fossils collected at Montsaunès by M. Harlé, by M. Albert Gaudry. The author brings forward a number of these remains as proving the warm-temperate climate obtaining at Montsaunès at the period to which the remains of a monkey found there belong.—A note by M. Potain explaining the scope and production of a work presented—"Clinique médicale de la Charité."—On rolling movements, by M. Hadamard.—On the agglomeration of explosive substances, by M. P. Vieille. The author continues his experiments showing the effect on the speed and character of combustion of the state of aggregation of a powder produced in its manufacture.—On the variation of rotatory power under the influence of temperature, by M. A. Le Bel. A decrease in amount of rotation is recorded, for several substances, with lowering of temperature. This is not due to polymerisation, but may be accounted for by a loss of mobility in the molecule—"la molécule subirait alors comme une sorte de congélation interne."—On the electrical capacity of mercury and the capacities for polarisation in general, by M. E. Bouty.—On the partition of the discharge of a condenser between two conductors, one having an interruption, by M. R. Swyngedauw. If the sparking distance in a part of the unbranched circuit be I_1 and in the interrupted branch I_2, then with I_1 constant the quantity of electricity passing through the uninterrupted branch increases continuously with the distance I_2, becoming greater than the total charge when I_2 exceeds a certain value. The value of I_2 giving this quantity equal to the total charge increases with I_1.—On the sodium derivative of ethyl acetoacetate, by M. de Forcrand. The preparation of the pure derivative is described, and, from experiments on the partially dehydrated salt, the heat of hydration of the anhydrous substance is given as 4·19 Cal., and the heat of solution in 4 litres of water at 12° is found to be 4·39 Cal.—On the detection of "abrastol" in wines, by M. L. Briand.—The parasitic Diptera of the Acridians: Bombylides. Larval "hypnodic" and metamorphosis with period of activity and period of repose, by M. Künckel d'Herculais.—On the circulatory apparatus of *Dreissensia polymorpha*, by M. Toureng.—Researches on the structure of lichens, by M. P. A. Dangeard.—On ligneous tumours produced by an Ustilago among the eucalyptus, by M. Paul Vuillemin.—Observations *àpropos* of the note by M. Calmette, relative to the poison of serpents, by MM. C. Phisalix and G. Bertrand. A claim for priority.—Experimental researches on the place of formation of urea in the animal organism. Preponderating rôle of the liver in its formation, by M. Kaufmann. The formation of urea is not entirely localised in the liver; all the tissues produce a certain quantity, though they are not so active as this organ. The production of urea seems to be allied to the phenomena of nutrition in the various tissues, and the phenomena of elaboration of nutritive materials in the blood by the hepatic gland.—The production of "glycosurie" in animals by psychical means, by M. Paul Gibier. The case of a dog is quoted in which isolation from its usual companions is followed after about three days by the appearance of sugar in the urine. The phenomenon persists during deprivation of liberty and companionship, but immediately ceases on restoration of the animal to its usual conditions.—On a new and special sense, by M. Danion.—A contribution to the study of the pest of fresh waters, by M. E. Bataillon. The diplobacillus described attacks fish at all stages of life. It also attacks crayfish.

AMSTERDAM.

Royal Academy of Sciences, January 27 (supplement).—Prof. van de Sande Bakhuyzen in the chair.—Prof. Kamerlingh Onnes gave the results of the measurements of Mr. C. H. Wind on the Kerr phenomenon in polar reflexion on nickel. The result is that the difference between the observed phase and that given by the theory of Prof. H. A. Lorentz has a constant value, as pointed out by Sisfingh and introduced in Goldhammer's theory. For the phase of Sisfingh the value of 37° was found. According to Drude's theory, it ought to be 60°. The difference is here much more marked than in the case of cobalt, from which Zeeman concluded in favour of Goldhammer's theory, and it leaves no doubt as to the validity of this conclusion. The experiments were described of Mr. M. de Haas, who has repeated the measurements of the coefficient of viscosity of methyl-chloride at temperatures approaching the critical temperature, previously made in his laboratory by Dr. L. M. T. Stoel. The results of Stoel were confirmed, and the method was modified so as to give the viscosity in absolute measure. The viscosities of CH Me and CO_2 in the neighbourhood of the critical point were also confirmed. A sufficient accordance was found with the theorem, that in Van der Waals' corresponding states of two fluids the viscosity is in a definite ratio that can be calculated from the critical data.

March 31.—Prof. van de Sande Bakhuyzen in the chair.—Prof. H. Behrens gave an account of experiments on alloys of iron with chromium and tungsten, performed by Mr. van Lingen and himself in the laboratory of the Polytechnic School at Delft. In a ferrochrome with 13·3 Cr, 5·5 C, a ground mass was found, showing a hardness a little superior to iron, and yielding Fe and Cr to hydrochloric acid. By treatment with aqua regia the metal was disintegrated, and when observed under the microscope showed well-defined monoclinic prisms, which had a hardness between that of quartz and topaz (7·5), and resisted the corrosive action of aqua regia for a fortnight. After washing with a heavy solution (s.g. 2.8), the composition of this compound was found to be 75·8 Fe, 16·8 Cr, 6·7 C. Chromium steel, with 7·5 Cr, 2·5 C, was subjected to the same treatment, yielding grains and small prisms of the same form and hardness. Analytical examination gave the following result:—73·5 Fe, 20·0 Cr, 6·7 C. From this the empiric formula $Cr_2C_3Fe_7$ can be deduced. Similar crystals were isolated from a ferrochrome with 50 per cent. Cr, much chromium being dissolved in strong hydrochloric acid. From ferrotungsten, containing much Mn and S, beautiful rhombic octahedra were obtained, containing 69·5 Fe, 28·9 W, 1·6 S; from another sample, poor in Mn and S, similar crystals, composed of 65·2 Fe, 28·6 W. Both have a hardness superior to felspar. Evidently the great hardness of these alloys must be ascribed to well-defined compounds of *three elements*, not, as heretofore, to allotropic modifications of iron. This investigation will be extended to ferromanganese and to bronzes, containing Al and S.—Prof. Kamerlingh Onnes described the experiments on electrolytic polarisation, made by Dr. T. H. Meerbury in Prof. V. A. Julius' laboratory at Utrecht. The polarisation during the first second was measured with a capillary electrometer by a zero method on the Fuchs principle, the apparatus giving the means of registering the time. The maximum of Cathodic polarisation was reached one second after the beginning of the polarising current. A formula for the increase of polarisation with time differing from that of Witkowski was deduced from theory. A careful repetition of Root's experiment on the transmission of electrolytic hydrogen by platinum foil of $\frac{1}{50}$ mm. gave a negative result. Insufficient isolation or some other error may have been the cause of what Root had observed.

BOOKS, PAMPHLETS, and SERIALS RECEIVED

BOOKS.—A Vindication of Phrenology: W. M. Williams (Chatto and Windus).—Exkursionsbuch zum Studium der Dogelstimmen: Dr. A. Voigt (Berlin, Oppenheim).—Electric Light Installations: Sir D. Salomons, Vol. 2, Apparatus. 7th edition (Whittaker).—A Manual of the Geology of India. R. D. Oldham, 2nd edition (K. Paul).—A Manual of Ethics: J. S. Mackenzie. 2nd edition (Clive).—Primer of Navigation: A. T. Flagg (Macmillan).—Eight Hours for Work: J. Rae (Macmillan).

PAMPHLETS.—Die Abstammungslehre und die Errichtung eines Institutes für Transformismus: Dr. R. Behla (Kiel, Lipsius and Tischer).—The Principles of Elliptic and Hyperbolic Analysis: Dr. A. Macfarlane (Boston, Cushing).—Les Femmes dans la Science: A. Rebière (Paris, Nony).

SERIALS.—Zeitschrift für Physikalische Chemie, xiii. Band, 4 Heft (Leipzig, Engelmann).—Memoirs of the Geological Survey of India. Palæontologia Indica, series 9, Vol. 2, Part 1; The Echinoidea of Cutch: J. W. Gregory (K. Paul).—Familiar Wild Birds; W. Swaysland, Part 1 (Cassell).—Zeitschrift für Wissenschaftliche Zoologie, lvii. Band, 3 Heft (Leipzig, Engelmann).—Mittheilungen der Prähistorischen Commission der Kais. Akad. der Wissenschaften, 1 Band, No. 2 (Wien, Tempsky).—Natural Science, May (Macmillan).—American Journal of Mathematics, Vol. xvi. No. 2 (K. Paul).—Quarterly Journal of Microscopical Science Special Complimentary No. dedicated to E. THURSDAY, MAY 10, 1894.

THE STUDY OF ANIMAL VARIATION.

Materials for the Study of Variation, treated with especial regard to Discontinuity in the Origin of Species. By W. Bateson, M.A., Fellow of St. John's College, Cambridge. (London: Macmillan and Co., 1894.)

MR. BATESON is to be congratulated on the completion of the first part of his work on variation in animals, which treats of variation in the number and position of organs forming parts of linear or symmetrical series. Variation in the structure of such organs is only partially dealt with, a fuller account being promised in a future volume. The present work may be divided into two parts—one purely descriptive, the other critical. These require separate notice.

It is impossible in a short space to give a proper account of the information brought together in the purely descriptive part of the book. Mr. Bateson has carefully examined many of the principal European collections, both public and private, and has in other ways collected a great store of original matter, which alone would make a respectable volume. In addition, he has compiled a series of abstracts, containing the essentials of a large number of records made by others. The labour expended upon the work of compilation alone may be gathered from the list of authors referred to, which contains some six hundred names.

The facts recorded are grouped in numbered paragraphs, on a system which makes reference to individual cases easy; the descriptions are for the most part admirable, and they are supplemented, where necessary, by adequate woodcuts. Full references are given, either to the actual specim ns described, where such reference is possible, or to the source from which descriptions are quoted.

The first twelve chapters deal with organs forming parts of linear series—such as the ribs, vertebræ, or teeth of vertebrates, and similarly "repeated" structures in other animals. In these chapters special attention is drawn to cases of variation, such as the assumption by a cervical vertebra of the characters proper to a dorsal vertebra; and many remarkable examples of analogous phenomena are given. For variation of this kind, in which an organ in one region of the body is "made like" a serially homologous organ in an adjacent region, the convenient word "homœosis" is proposed. Another interesting group of cases is described as showing that the number of specialised organs in a series may be altered by a process of actual division, such as that by which an increase in the number of eyes is effected in Planarians.

The thirteenth and fourteenth chapters deal with increase and reduction in the number of digits in the vertebrate limb, and should be read in connection with the twentieth and twenty-first chapters, where closely analogous phenomena, leading to duplication of arthropod appendages, are described. The wonderful relations of symmetry, which are shown to hold in so many cases between the "normal" and the "extra" limbs, have been shortly described by Mr. Bateson on previous occasions; but the fuller statement here given forms perhaps the most interesting portion of the book.

The remaining chapters deal with variations in radial series, such as those formed by many organs of cœlenterates and echinoderms, and with cases which involve the doubling of structures normally single, or the fusion in the middle line of organs which are normally bilateral and paired.

Such in bare outline is the subject-matter of the descriptive portion of the book. No quotation of isolated passages is attempted, because no such proceeding could give an adequate idea of its importance. The whole work must be carefully read by every serious student; and there can be no question of its great and permanent value, as a contribution to our knowledge of a particular class of variations, and as a stimulus to further work in a department of knowledge which is too much neglected. It is to be hoped that Mr. Bateson will not rest content with his already great achievement, but will proceed with his promised second volume, which will be eagerly looked for by those who read the first.

If the criticism and enunciation of opinions had been performed with the same care as the collection of facts, the commentary which runs through the book would have gained in value, and several inaccuracies, due partly to want of acquaintance with the history of the subject, would have been avoided. The only contention which can here be noticed is that alluded to on the title-page, namely that variation frequently proceeds in such a way that changes in an organ occur only by steps of definite and measurable magnitude; and that discontinuous variation of this kind is necessary for the evolution of new species. In Mr. Bateson's words:

"The first question which the study of variation may be expected to answer, relates to the origin of that discontinuity of which species is the objective expression. Such discontinuity is not in the environment; may it not, then, be in the living thing itself?"

The statement that discontinuity is not in the environment, is justified as follows:

"Here then we meet with the difficulty that diverse environments often shade into each other insensibly, and form a continuous series, whereas the specific forms of life which are subject to them on the whole form a discontinuous series. . . . Temperature, altitude, depth of water, salinity, in fact most of the elements which make up the physical environment are continuous in their gradations," and so on.

Here the reference is only to the physical conditions which form a part of the environment affecting animals. That these physical conditions do often form a "continuous series" is no doubt true, although it is also true that in a large number of cases they do not. But Darwin, Wallace, and the greater number of subsequent writers on the doctrine of natural selection, agree in believing that the most important part of the environment against which a species has to contend consists of other living things. This view is dismissed in the following short foot-note:

"It may be objected that to any organism the other organisms coexisting with it are as serious a factor of the environment as the strictly physical components; and that inasmuch as these coexisting organisms are discontinuous species, the element of discontinuity may thus be introduced. This is true, but it does not help in the attempt to find the cause of the original discontinuity of the coexisting organisms."

Now since the deposition of the earliest palæozoic rocks animals have demonstrably been surrounded by such "discontinuous" organic environment. The statement, that the environmental conditions "form a continuous series," is therefore untrue of all animals known to us. If it has ever been true, we cannot know. The question, whether the first living things which appeared upon the earth were alike or not, is as unprofitable as speculation about the beginning or the ending of any part of the order of things from which our experience is derived must always be.

These preliminary arguments in favour of Mr. Bateson's main contention therefore fail, when applied to any part of the process of evolution of which we can know anything. It remains to consider what experimental evidence is brought forward to prove that variation is in fact "discontinuous" in any living animals.

No definition of what exactly is meant by "discontinuous" variation is given; and the conception adopted is difficult to grasp, since such domestic animals as the bull-dog are taken as examples of its occurrence. It will therefore be necessary to examine the treatment of some special group of variations: and for this purpose the chapters on teeth may be selected. The question is propounded—

"What is the least size in which a given tooth can be present in a species which sometimes has it and sometimes is without it?"

And it is remarked that—

"Considered in the absence of evidence it might be supposed that any tooth could be reduced to the smallest limits which are histologically conceivable; that a few cells might take on the character of dental tissue. . . . Indeed, on the hypothesis that variation is continuous, this would be expected."

Mr. Bateson considers his evidence sufficient to show that "the least size of a tooth is different for different teeth and for different animals," and that therefore variation in the teeth of those animals discussed by him proceeds by integral steps, the magnitude of the step differing in different cases. But he gives no evidence that he has ever looked for teeth reduced to the smallest histological limits. The greater number of observations recorded are made upon dry skulls, in which such rudiments could not be demonstrated. It is notorious that in many animals, such as marsupials and whales, a whole set of teeth exists, which can only be demonstrated by careful histological examination of the entire jaw, at a definite period in the life of these animals. But more important is the fact that teeth have been demonstrated, consisting of a few cells, which have hardly progressed beyond the histological condition of an enamel germ, in several of the animals used by Mr. Bateson to support his view. These cases (*Cercopithecus*, probably *Cynocephalus*, the dog, and the cat) have been completely overlooked by Mr. Bateson; and similar cases in other vertebrates have been recorded. The condition, which is said to be necessary on the hypothesis that variation is continuous, does, therefore, in fact occur; and the contention as to the least possible size of particular teeth fails.

In somewhat similar cases Mr. Bateson lays stress upon the rarity of slight variations, as compared with more considerable abnormalities. In the present case, few persons have examined the jaws of mammals in such a way as to enable them to find the smaller abnormalities and there is no evidence worth discussion which shows whether they are rare or not. The only case in which large numbers of jaws have been examined by proper methods is that of man, in whom a fourth molar tooth is commonly present as a mere uncalcified rudiment, the cases in which this extra tooth becomes calcified and breaks through the jaw being rarer in proportion to the perfection of the extra tooth. A similar continuous series of variations is presented by the "wisdom tooth," which is most commonly a fairly perfect molar, cases of imperfection being rarer in proportion as the tooth approximates to the condition of "a few cells," hardly "taking on the character of dental tissue" at all, which it does occasionally assume. It is therefore curious, that in commencing his attempt to exhibit the discontinuity of dental variation, Mr. Bateson should dismiss the case of human teeth with the remark—

"I do not know that among these human variations are included phenomena different in kind from those seen in other groups, except perhaps certain cases of teeth united together."

Surely variation which proceeds by integral steps of the magnitude of a tooth may justly be held to differ in kind from variation which proceeds by indefinitely small gradations?

In the case of teeth, and in many other cases discussed, the method employed is not adapted to a determination of the least possible magnitude of variations. For in judging evidence based largely upon museum preparations and on printed records, it must always be remembered that there is a tendency among curators and others to regard a slight abnormality as not worth bottle, spirit, and a place on the shelf, or to think it too trivial for printed record. Anyone who has tried to obtain specimens for a museum knows that many persons will take pains to present a rare or striking specimen, who cannot be induced to send quite common things.

The only way in which the question can be settled for a given variation seems to be by taking large numbers of animals, in which the variation is known to occur, at random, and making a careful examination and record of each. Mr. Bateson's chapter on teeth, like all his chapters, is of great interest, and will doubtless serve to throw important light on many things. But a careful histological account of the jaws of five hundred dogs would have done more to show the least possible size of a tooth in dogs than all the information so painfully collected. And so in many other cases.

W. F. R. WELDON.

ALPINE GEOLOGY.

Ein Geologischer Querschnitt durch die Ost Alpen.—A Geological Transverse Section through the Eastern Alps.—By A. Rothpletz. (Stuttgart: Schweizerbart, 1894.)

THE title of this work at once announces its importance in Alpine geology. Most of us, young and old, are familiar with the section through the Eastern Alps which we owe to the veteran Austrian geologist Hofrath von Hauer. Since 1857, this section, from Passau to Duino, has held its place alone in atlas and text-book. In recent years, Swiss sections, more especially Heim's, have been placed side by side with it, but they only embrace the northern flanks and a part of the central chain. Dr. Rothpletz has given us in this volume the second complete section through the Alpine chain. He has laid the line of section farther east than von Hauer's, beginning at the Bavarian plain in the north, and traversing the Karwendel Mountains in the Bavarian Highlands and North Tyrol, the Tuxer and Zillerthal Mountains, east of the Brenner Pass, the Seisser Alpe, Schlern Rosengarten and the Predazzo district in South Tyrol, and the Sette Communi in the Italian Highlands.

The section, which is printed with colours, extends over a surface area 140 miles in breadth, and has the advantage of being drawn to true scale, vertical and horizontal (1:75000). So accustomed are we to exaggerated heights in Alpine sections, that this true-scale section conveys an impression of rather unimposing mountains and broad valleys. The eye misses also the familiar dotted lines connecting detached parts of the same geological strata, and helping one to a general appreciation of the author's conception of the whole section.

The absence of any such lines is almost a key-note to the character of the work. In the text, the author declares his opinion that (purposes of explanation, of course, excepted) geological sections should represent so far as possible only what has been actually observed, and should not suggest, by means of dotted lines or continued bands of colour, what may be, after all, only imaginary structural relations of the strata. The author's position in this respect is made very clear in the chapter on the "Glarner Double-Fold."

The bulk of the text is devoted to descriptive, stratigraphical, and tectonic details of the various districts surveyed by the author along the line of section, and is illustrated very fully by sketch-maps and sections. Rigid faithfulness of observation is a marked feature throughout. The same care and precision which may be traced in field-methods, has also been bestowed on the literary workmanship of the book. The treatment of the Bavarian Highlands is quite delightful. The drawings display so unmistakably the dependence of the main physical features on the strata, and the contrasts of landscape which tectonic disturbance has frequently produced. We read with equal interest of the synclinal fold in which the Walchen lake and the Jachenau valley now find themselves, and of the transverse faults which divert the Loisach and the Isar rivers out of their easterly course into a northern. On the other hand, in the case of the bend of the Inn Valley at Wörgl, it was a pre-Alpine oligocene basin whose soft strata guided the river northward to the Bavarian plain. Again, the author's powers of exposition are seen to advantage when he demonstrates the important fault-line between the Mesozoic limestones north of the Inn and the old crystalline rocks of the central massif. He proves also beyond dispute the geological independence of the Tuxer and Zillerthal groups north and south of the Inner Pfitsch valley. But we confess to a feeling of disappointment that although the section passes through these groups, it has been able to do so little to clear away the difficulties of the Central Alps. Several important questions are discussed without advancing us far—for example, the age of the granite intrusion north of Brixen, the significance of the serpentine rocks in the "Tarnthal Köpfe," the constant occurrence of a rocklike "sernifit" at the unconformable succession of Permian and Mesozoic strata on the old Palæozoic and crystalline floor.

Strict adherence to the truths observed in nature, while in itself laudable, seems somewhat to cramp boldness and freedom of thought, and we are landed in a mist of possibilities hovering over a conjectured Triassic period of mountain movement in the Central Alps, which may just as well have been post-Neocomian for all that is proved to the contrary. A similar uncertainty envelops the age-relationships of the overthrust at Tristkogl (Karwendel Mountains), whose special misfortune it is to be directed to the south, whereas the overfolding and overthrusting elsewhere in the Northern Limestone Alps are northward. It seems just possible that the overthrusts in this district are not all told?

One of the most striking chapters in the first part of the book is that on the origin of the Schlern Dolomite in South Tyrol.

Part iii. leaves no doubt as to the author's conception of the form of Alpine structure elucidated by his complete section. In his ideas he differs considerably from the recognised tenets either of Suess or of the Swiss school represented by Heim. Dr. Rothpletz puts the actual areal contraction due to late tertiary folding in the Alps at a much lower figure than Heim did. He emphasises the importance of vertical faults and the great part played by previous Alpine movements in determining the occurrence of overthrusting and overfolding during Pliocene pressure. He finds Suess' theory of the causes of mountain-movement insufficient, and suggests that if the earth's cooling resulted in radial expansion instead of radial contraction, as Suess assumed, a quite as likely explanation could be given of the actual facts observed in crust-movements.

Even if we cannot accept the dicta as final, we must welcome the thoroughly scientific spirit in which the author analyses the various doctrines, and shows what part or parts are doctrines of faith only, and what of the remaining are, in his experience, tenable or untenable. His own opinions are fixed upon most points, but he never seeks to impose *opinions* on his reader; *facts* alone are taught; and there is no more thirsty soil for facts than Alpine geology.

MARIA M. OGILVIE.

OUR BOOK SHELF.

The Natural History of Plants, from the German of Prof. Anton Kerner von Marilaun. By Prof. F. W. Oliver, M.A., D.Sc. London, Glasgow, and Dublin: Blackie and Son, 1894.)

THE high praise we gave to Prof Kerner's *Pflanzenleben* when it appeared, makes it almost unnecessary for us to say much about the English edition now in course of publication, and which will be completed in sixteen monthly parts. The German work was said in these columns to be "the best account of the vegetable kingdom for general readers which has yet been produced." This judgment can also be applied to the translation which Prof. Oliver has made, with the assistance of Miss Marian Busk and Miss Mary Ewart. In translating a work, some of the brilliancy of the original is necessarily lost. It is difficult, however, to find awkward expressions in the pages before us; in fact, very few of the idiomatic phrases of the original work have survived. And the translation is scientifically accurate, as well as entertaining and instructive. Lovers of nature will find every page of the book interesting, and the serious student of botany will derive great advantage from its perusal. The illustrations are beautiful, and, what is more necessary, true to nature. The complete work contains about one thousand engravings on wood, and sixteen plates in colours. Botanical science will benefit by the issue of Prof. Oliver's edition of a splendid book.

Notes on some of the more Common Diseases in Queensland in relation to Atmospheric Conditions, 1887–91. By David Hardie, M.D., Hon. Physician Hospital for Sick Children, Lady Bowen Maternity Hospital, Brisbane. (Brisbane: Beal, 1893.)

THE author of this work has a most important aim in view, viz. to establish the connection between the weather and the prevalent diseases in Queensland, and expresses a hope that, in time, he will be able, if furnished with a forecast of the weather, to predict with certainty the diseases likely to predominate during the various seasons of the year, and thus to lay the foundations of a practical system of preventive medicine.

The conclusions are so interesting that some of his leading results may be briefly given.

The annual death-rate of Queensland per 1000 population is 15·11, varying from 13·38 in August and September (spring) to 16·28 in November to March (summer and early autumn), as contrasted with the death-rate of Great Britain for the year, 18·8.

The yearly mortality is lowest in West Southern Queensland (Darling Downs and Warrego), where it is only 8·92 per 1000, a little over half of the average Queensland rate, and the highest is 34·70 in West Northern Queensland (Normanton), a tropical region at the extreme north of the colony. This would point to the great advantage of altitude, combined with dryness, as seen on the Darling Downs, over marine influence and moisture to be found in the sea-coast districts. When we come to different classes of disease, we find that diphtheria, though specially prevalent in April, May, June, and July (winter), is endemic to some extent in all seasons, and causes a mortality of 2·15 per cent. Whatever contributes towards cold and dampness of the air during the autumn and winter, causes an increase in the death rate from diphtheria, and, according to Dr. Hardie, the neighbourhood of swamps and marshes have considerable influence in this respect. Whooping-cough, on the other hand, attains its maximum during the warm and moist months of the year, and its close connection with a medium temperature for all seasons of the year with high relative humidity, is considered to support the assumption of its germ origin.

Phthisis is common along the eastern portion of the colony from Cooktown to Brisbane, reaching a maximum of 12·86 per cent. in the Rockhampton district; but this high mortality is partly to be attributed to the large Polynesian population, employed on sugar plantations in these districts, who are specially liable to phthisis. In the western and northern districts, however, it is much less prevalent, and the average percentage of deaths from all causes gives to phthisis 8·75. The months when the mortality is greatest are July, August, and September, and there seems to be no special connection between atmospheric moisture and phthisis mortality, but a low temperature in summer and autumn is favourable to a low phthisis mortality. Acute respiratory diseases, such as pneumonia, pleurisy, and bronchitis, are observed all over the colony, and vary in mortality in different parts; the highest on the coast and the lowest inland, the months of highest mortality being June, July, August, and September; the maximum is reached during and immediately after the colder period of the year.

The book, with its copious and valuable tables, is an honest attempt to deal with a very difficult problem, and thoroughly merits success, and if the author will only persevere in his researches, still more important results may follow.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Panmixia.

I AM much obliged to Prof. Weldon for having so promptly answered my request, and hope that his example will be followed by any naturalists who may have any other grounds for questioning the doctrine of Panmixia. Meanwhile, however, there are two or three points touching which I should like to be sure that we correctly understand each other.

(1) Hitherto all naturalists who have written upon the subject have agreed, that "*the survival-mean must* (*on cessation of selection*) *fall to the birth-mean.*" And, in now questioning this view, Prof. Weldon appears to contemplate the difference between birth- and survival-means of only the first generation, which would be very unfair. Again, I do not follow Prof Weldon's meaning in what he says with regard to another point. Assuredly "every statistician knows" that selection can maintain the "mean height of a regiment" at 67½ inches, by enrolling only those individuals who are either "more than 66 and less than 69 inches high." But this would be *artificial* (*i.e.* intentional) selection. The "cases" to which he alludes, where *natural* selection could destroy individuals nearest the mean line, while favouring those which lie at greater distances *both above and below* this line, must be very exceptional.

(2) As regards the second cause of degeneration under Panmixia (viz. atavism), Prof. Weldon says merely that it is "not demonstrated by any statistics." This is true enough. But the same has to be said of natural selection. Whether in the building up of a structure by natural selection, or in the subsequent breaking down of a structure by atavism on the withdrawal of selection, the statistical method is equally unavailable for testing either theory: in both cases the most effective variations (*i.e.* deviations from the mean) at any given time are those which are most *numerous*, and therefore most *minute.* Hence, in both cases the best "demonstration" of the theory which can be offered is that which is yielded by the parallel facts in our domesticated animals.

(3) The only objection which is urged by Prof. Weldon against the last of the three causes which I mentioned (*i.e.* irregularities of heredity when uncontrolled by selection) is one which tells against the theory of Panmixia only because it does so against that of Natural Selection. As I understand, the argument is, "Natural selection is in most cases an imperfect agent in the adjustment of organisms": *ergo*, the cessation of

selection will not, in most cases, make much difference in the maintenance of such adjustment. Obviously this ground of objection to the theory of the cessation of selection opens up a much larger question than can here be dealt with, viz. the adjusting or eliminating value of the presence of selection. But if Prof. Weldon will read what I wrote last year in the *Contemporary Review*, during the Spencer-Weismann controversy, he will find that in this matter I am quite on the side of Mr. Bateson and himself. It has always been my endeavour to argue that the ultra-Darwinian school of Wallace and Weismann are pushiog deductive speculation much too far in maintaining "The All-Sufficiency of Natural Selection." I shall never believe —any more than Darwin believed—that what I have called "selection value" is unlimited. But this is not incompatible with the belief that *in whatever degree* natural selection may have been instrumental in the construction of an adjustment, *in some degree* must its subsequent cessation tend to the degeneration of this adjustment, especially where complicity as distinguished from size is concerned, as stated in my last letter.

Summing up his objections to the doctrine of Panmixia, Prof. Weldon says they are two: "First, it is based on the assumption that selection, when acting on a species, must of necessity change the mean character of the species—an assumption incompatible with the maintenance of a species in a constant condition." This refers to the paragraph of his letter which, as already stated, I do not understand. The doctrine of Panmixia, as far as we are now concerned with it, does not refer to "species," but to specific characters, *i.e.* structures, organs, instincts, &c. Again, the doctrine, even with regard to specific characters, makes no "assumption" touching the *presence* of "selection acting on a species"—least of all that such *presence* will not maintain the species in a constant condition. On the contrary, the very essence of the doctrine is, that it is the *presence* of selection which *maintains* the constancy of a species (or specific character), and *therefore* that it is the *cessation* of selection which *upsets* the constancy by withdrawal of the maintaining influence. Hence, I do not understand Prof. Weldon's first objection. His second is, "that in the only case which has been experimentallv investigated, the condition said to result from a condition of Panmixia does not, in fact, occur." This one case, he explains, is:—"Mr. Galton has shown that civilised Englishmen are themselves in a condition of Panmixia, at least with respect to several characters, especially stature and the colour of the eyes. Now the mean stature of Englishmen is known to be increasing, and there is no evidence of the disappearance of coloured eyes." But, as regards stature, it can scarcely be maintained that there is not *some* cause at work to account for the increase; yet, unless this is maintained, the case is clearly irrelevant. Again, the colour of the eyes of our mixed population cannot have had more than thirty or forty generations wherein to be affected by Panmixia, and therefore the most ardent supporters of this doctrine would scarcely expect any result to be yet appreciable in the case of so pronounced a racial character. Surely a better "case" is the one which I have already given in the most ancient and the most rapidly-breeding of our domesticated animals. It was the facts observed in this "case" which first suggested to me the doctrine of Panmixia, and so led me to question the inherited effects of disuse. Similarly, a year later, Mr. Galton, in his "Theory of Heredity" (which anticipated by about ten years all the fundamental parts of Weismann's), wrote of Panmixia thus:—"A special cause may be assigned for the effects of disuse in causing hereditary atrophy of the disused parts. It has already been shown that all exceptionally developed organs tend to deteriorate; consequently those that are not protected by heredity will dwindle. The level of muscular efficiency in the wing of a strongly-flying bird is like the level of water in the leaky vessel of a Danaid, only secured to the race by constant effort, so to speak; let the effort be relaxed ever so little, and the level immediately falls. . . . That this is a universal tendency among races in a state of nature, is proved by the fact that existing races are only kept at their present level by the severe action of selection." GEORGE J. ROMANES.

Oxford, May 5.

P.S.—I gladly accept the verbal correction in Prof. Weldon's third paragraph.

Physiological Psychology and Psychophysics.

OWING to my bookseller's habit of forwarding NATURE in monthly batches, I have only just seen the remarks appended to my letter in the issue of March 15. I think that the terminological question is sufficiently important to warrant a reply to these.

(1) I do not, of course, "subsume" psychophysics to physiological psychology. The latter, I stated, is both wider and narrower than experimental psychology; and wider, because it includes the consideration of certain ("the most important") psychological problems—not of *all* such problems. (For this view of physiological psychology, *cf.* Wundt, "Physiological Psychology," fourth edition, I. p. 9.)

(2) Fechner, "the coiner of the word," defines psychophysics as "eine exacte Lehre von den functionellen oder Abhangigkeitsbeziehungen zwischen Körper und Seele, allgemeiner zwischen Körperlichen und geistigen, physischer und psychischer Welt." (*cf.* "Psychophysik," second edition, I. p. 8.) What my critic says on this head is, therefore, incorrect.

(3) In the most widespread and important school of experimental psychology existing to-day—that of Wundt—there *is* agreement upon definitions. And even if my critic's remarks were true, it would not follow that a number of wrongs made a right.

(4) I might, in my last letter, have adverted upon the term, *psycho-physiological*. I did not understand what it exactly meant. In NATURE of March 29, Prof. Ll. Morgan defines it (p. 504) as the equivalent of Fechner's internal psychophysics. (*op. cit.* p. 10). In this sense it is not wanted; the phrases "external" and "internal psychophysics" are in use. (It might, however, be used to signify that part of physiology which has a conscious correlate.)

(5) My critic triumphantly adduces "reaction-times" as a subject treated of in the University College course. That course, *i.e.* deals with *one* conscious element, and with *one* type (action) of *one* of the two modes of conscious combination (association: fusion is left out of account). Prof. Münsterberg (Preface to *Psychological Laboratory of Haward University*) speaks of "the error, which is so prevalent, that experimental psychology is confined to the study of sensations and simple reaction-times."

(6) I am sorry that Dr. Hill's name should have been mentioned. I should not think of offering any opinion upon his work. I know no more of it than do the other readers of NATURE. If he sees these remarks, I hope he will believe that my original criticism was meant to be quite impersonal.

(7) "By far the larger part of the really fruitful work [in psycho-physiology]" says my critic, ". . . . has been done in the investigation of the senses." If he means by psycho-physiology what Prof. Ll. Morgan does, I must disagree with him. To substantiate either view would need an article. As he writes not as a working psychophysicist (else he would have been acquainted with Fechner's *Psychophysik*), I think that the *onus probandi* lies with him.

(8) As to Prof. Ll. Morgan's paper on "the scope of psycho-physiology [= internal psycophysics]," I must plead guilty to finding the writer's eclecticism somewhat unintelligible, and his whole treatment a little general and superficial.

(9) A very interesting minor question is that of the relation of Wundt's physiology psychology to Fechner's internal psychophysics. (*cf.* Kulpe, *Arch. f. Geschichte du Philosophie*, 1892, pp. 183-4.)

Cornell University, April 16. E. B. TITCHENER.

IT seems hardly profitable to carry on a discussion with Dr. Titchener at intervals of more than a month. I readily confess that through an error of memory, for it is a good while since I read the "Elemente der Psychophysik," I misrepresented Fechner's use of the term psychophysics. The fact, however, that he recognised an "outer psychophysics," and the further fact that, as he shows ("Elemente," i. p. 11), nearly the whole of his inquiry has to do with establishing the relation of external stimuli to psychic phenomena, show that the error I fell into was not altogether unnatural. Are not the inquiries of Weber, Fechner, and their successors still brought under the head of psychophysics by those who reject Fechner's peculiar "psycho-physical" interpretation of the results? And do not nine students out of ten, who are not themselves "working psycho-physicists," associate the term "psychophysics" with these important lines of inquiry? If so, I would contend that there is room for a reconsideration of the terminology of the subject. The retention of Fechner's "outer psychophysics" seems confusing if, as I understand Dr. Titchener to say, "psychophysics" has properly to do with the correlation between psychic processes and intra-organic and (I suppose) more especially, central nervous processes. With respect to the term "psycho-physiological," used by Dr. Hill in his syllabus, it may at least be said that it avoids the ambiguity of "psychophysics," as coined and defined by Fechner, while it is the direct descendant of the term "mental physiology," which is well fixed in British scientific literature.

I have only to repeat that Dr. Titchener's attempt to distinguish between the domains of physiological psychology and psychophysics seems to me far from adequate. It has about it, to my irreverent eyes, something of Wundt's own oracular obscurity.

In calling atttention to reaction-time experiments, I did not refer to *simple* reaction-times. I thought the various lines of experiment in which the processes of hesitation and selection, and so forth, are elucidated by measuring the intervals between sensory stimulus and muscular reaction might be brought under the head of reaction-time experiments. But not being in the privileged circle of working "psycho-physicists," I daresay I erred here too.

This little discussion will not be in vain if it wake up Dr. Titchener, or some other working psycho-physicist, to the obscurities that hang over their new field of research for the outside student. It seems to me that we want careful definitions of the respective scopes of the several departments of research which are either psychological or which bear directly on psychology, more especially experimental psychology as a whole, psychophysics, and physiological psychology. Neither Wundt's nor Dr. Titchener's definitions satisfy some of us who, on this benighted island, provokingly placed between two luminous continents, are doing our best to catch some of the rays which they are shooting forth in such abundance.

THE WRITER OF THE NOTE.

Some Oriental Beliefs about Bees and Wasps.

SINCE Baron Osten Sacken's letter appeared in NATURE (vol. xlix. p. 198), I have been taking an occasional survey in my small library of Oriental literature, to inform him of passages referring to the Bugonia-superstition. So far as I could find, the people of the far East seem not to have possessed any belief about oxen-born bees; however, *à propos* of this matter, I have come across several legends relating to some Hymenoptera, which I may group as follows:—

(1) *Fossores Story.*—Of all the insect stories of the far East, this may claim very high antiquity; it was first celebrated, more than two thousand years ago, by a verse in the Confucianist "Book of Poems," and is, to this date, preserved by a well-known metonymy "Ming-ling" (that is, the caterpillar), meaning the Foster-Child. This story, according to Yang Hiung, a Chinese philosopher (53 B.C.–18 A.D.), was that "the Fossores, having no females, capture infant caterpillars from mulberry-trees, and address them a spell 'Mimic me, mimic me,' whereby they are turned into the young Fossores." Indeed, the Japanese name of the Fossores is Jiga (that is, "Mimic-me"). Against this Tao Hung-King, a Tauist sage (452–536 A.D.), has argued that these insects have had offsprings of their own, but used to deposit the eggs on bodies of other insects to provide them with food in future.

(2) *One-legged Wasp.*—In Li Shi-Chin's work, cited above, we read:—"This production of Ling-nan, resembling a wasp, small and black, has one leg united with the root of a tree; it can move but cannot escape." Also a One-legged Ant is mentioned. I would suggest that these insects were infested by the forms of Cordyceps, as is instanced in the stories of La Guêpe Végétale.

(3) *Fungus-born Wasp.*—Twan Ching Shih's "Miscellanies," book xvii., contains the following note:—"A poisonous and noctilucous Fungus of Ling-nan is, after rain, metamorphosed into a large black wasp with serrate mandibles more than three-tenths of an inch long. At night it tries to enter the ears and nostrils of a man, and hurts him in his heart."

(4) *Production of Amber from Bees.*—In the same work, book xi., is the following quotation from the "Record of Southern Savages":—"The Bees with Broken Waists exist in the sandhills of Ning-chau, and come out when banks fall down; the natives make amber by applying fire to them." Obviously this erroneous inference was drawn from the presence in amber of some hymenopterous remains.

(5) *Diptera mistaken for Hymenoptera.*—Sie Tai-Kang, in his "Miscellanies of Five Phenomena" (Japanese edition, 1661, book ix., p. 43), narrates thus:—"In Chang-sha I saw honey-bees all without stings, so that, when trifled with upon the palms, they were quite harmless: having no difference from flies, that was strange!" No doubt he has seen some Eristalis, as is indicated by Baron Osten Sacken.

(6) *Horse-hair Wasp.*—Tazan Kan, a Japanese literatus (1748–1827), writes on this subject in his "Rambling Notes" (Tokio, 1890, p. 22):—"About 1817 a half-rotten trunk of *Celtis sinensis* gave birth to wasps, whose tails they could not withdraw from the tree, thus causing many to die. Having the tails cut with scissors the survivors gladly departed. One winter a man bought a heap of fuel comprising a half-rotten oak abounding with the similar wasps, several of which were strung on a horse-hair in the same manner as a rosary, there being altogether several dozens of such hairs. The author's informant took home a hair passing through three or four wasps, and folded it in paper; afterwards the hair became divided, and the insects bit through the paper: the informant's suggestion was—'probably these wasps had been transformed from horse-hairs tangled round the rotten wood.'" Several times I have seen in Japan this so-called "Babi-bō" (the Horse-hair Wasp), still an object of popular amazement: it is nothing but an ichneumon-fly, *Bracon penetrator*, whose ovipositor of unusual length has been the principal cause of such a superstition.

KUMAGUSU MINAKATA.

15, Blithfield Street, Kensington, W., April 30.

P.S.—In my letter on the "Constellations of the Far East" (NATURE, vol. xlviii. p. 542), I gave from Twan Ching-Shih's "Miscellanies" portions of the list of the objects of Indian fancy as to the resemblances of the constellations. Last March, my reverend friend, Atchârya Dharmanâga, then in Paris, kindly sent me an extract from Roshin Sennin's Lecture on the Constellations, recorded in Mahâsannipâta Sûtra. After comparison, I find that both quite agree except for a few variations, so that that Chinese author of "Miscellanies" seems to me to have extracted his list from the above-mentioned Indian authority.

K. M.

The Mass of the Earth.

I HAVE no intention of reopening a discussion on the advisability and necessity of carefully separating in our minds those two notions, the *weight* of a body and its *mass*, which to me (and to a great many others) are now so completely distinct. The subject has already been treated of in these pages. Hence, in reply to the letter signed "K." I shall be very brief. The *mass* of a body is simply the quantity of matter which it contains; its *weight* is the force with which the earth pulls the body towards the centre of the earth; this force varies slightly at different points on the earth's surface, varies very much both when the body is removed outwards from the earth or inwards towards its centre, and would be nothing at all at the centre; the *weight* would be practically nothing if the body were removed a few millions of miles away from the earth. But through all these changes, and through all mere changes of *place*, the *mass* of the body is perfectly unaltered. *Weight* is a mere contingent property of *mass*, logically and physically distinct from it; a more contingent property than *shape*; for, while a body must have some shape, it need have no weight. The terms *weight of the earth*, *weight of Jupiter*, *weight of the sun*, &c., are absolutely ridiculous. The mass of the earth is acted upon by no force whatsoever except the attraction of the sun and the disturbing attractions of the moon and the planets. The earth attracts itself with no force; it has no weight. So much for positive statement.

The notion that the earth has weight—the inability or neglect to distinguish the necessary property of constant *mass* from the contingent property of *weight*—has given rise to many absurdities. "If everything on the earth has weight, the whole earth has weight," is a fallacy of composition worthy of a mediæval dialectician. That the earth is a very *heavy* body (with, of course, an inveterate tendency to fall "down"), has supplied us with the assumption that it is supported on the back of an elephant, these two exceedingly *heavy* bodies being together supported on the back of a tortoise, and so on. To compare the *weight* of Jupiter with that of the sun, "imagine a gigantic balance with equal arms and equal pans; let the sun be placed in one pan; then, *in order to preserve the balance*, more than 1000 Jupiters must be placed in the other pan."

I need not multiply examples of this world-wide fallacy. We have the two words *mass* and *weight*; let us keep them distinct, and thereby help towards an understanding of the nature of an absolute unit of force and other physical entities.

"K." says "the earth's weight, or mass, is 6·14 × 10^{21} tons. What is unmeaning or unscientific in this clear, intelligible, and accurate statement?" Answer, the identification of *weight* with *mass*. He is mistaken in supposing that Prof. Poynting's book has a double title. It is simply "The Mean Density of the Earth." The determination of the "constant of gravitation" is a deduction, and is, of course, so treated by Prof. Poynting.

THE REVIEWER.

Icebergs and Weather.

WITH reference to the notice in NATURE of May 3 (page 15), of a letter by Mr. Russell on icebergs and their relation to weather and temperature, I should like to give you a personal experience of my own with an iceberg in mid-Atlantic, when on board the steamship *India*, on its voyage from New York to Newcastle-on-Tyne, in June last year.

Our recorded temperatures of 43° F. and 45° F. of one day fell to 34° F. in water and in air on the next day. On reporting this to the chief officer, an extra look-out was kept, and the vessel put on half-speed, as the weather was foggy, and icebergs were likely to account for the sudden fall of temperature. Twenty minutes afterwards an iceberg was sighted, which showed a length of 1200 feet, and a height of 200 feet above water.

Leeds, May 7. A. SYDNEY D. ATKINSON.

Early Arrival of Birds.

I WAS at Sellack, Ross, Herefordshire, on March 22 and following days. Chiff-chaffs had arrived on the 22nd; cuckoos were heard on the following day. The willow-warbler and garden-warbler followed.

In quest of food, birds follow the path of least resistance. Thus their migrations, in the economy of nature, depend not simply on food, power of flight, distances, temperatures, &c., but on the associated extent of systems of wind.

May 4. W. CLEMENT LEY.

THE EFFECT OF EXTERNAL CONDITIONS UPON DEVELOPMENT.[1]

THERE is now ample justification for the belief that evolution is not due merely to internal causes, though we are as yet by no means quite clear as to the manner in which external influences have formed and transformed organisms. There is still a conflict between rival theories, and important points, though often apparently clear, are in reality not so.

It is often assumed, without sufficient proof, that a particular variation of an organism is the direct consequence of some external influence, simply because some causal connection exists between the two; but such an assumption is based upon a totally false idea as to the interconnection of the phenomena. In many cases this will be readily granted; take, for instance, that of the leaves of *Mimosa*, which close when they are touched. The actual cause of the movement is here due to the peculiar constitution of the plant, and not to the touch. The geotropism of plants, again, is not the direct effect of gravity, but is due to a special power of adaptation possessed by the plant. In reference to the histological adaptation of animal tissues, let us take as an example the structure of the lattice-work in spongy bones. Roux has shown that this is due to processes of selection and for a struggle for existence between the various parts of the body. Prof. Weismann speaks of this process as "intra-selection," and attempts to show that its effects are not inherited, as assumed by Roux, but that heredity only concerns those potentialities from which structures are developed by intra-selection. He believes that the potentialities have not arisen through the struggle between the parts of an organism, but through that between individuals; not by intra-selection, but by the ordinary process of natural selection. The *causa efficiens* of this histological adaptation is not, therefore, the tension or pressure which acts on the bones, but the adaptive material upon which such forces operate. The theory of intra-selection thereby loses nothing of its value, but on the contrary, is admitted to be of the greatest importance in maintaining the "co-adaptation" of parts during the metamorphosis of species.

The organism can, however, also be affected by external influences for which it is not adapted in advance. This is the case as regards the ordinary seasonal dimorphism of butterflies; but even seasonal differences may be produced by adaptation—here a double adaptation—in which the external influences of temperature do not act as the direct causes of change, but only as stimuli, which determine as to which of the two forms of the species shall arise.

In the case of neuters of social insects, the external influence—scanty food—is not, as Herbert Spencer assumes, the true *causa efficiens* which produces the sterility of their caste, but only the stimulus by which the primary constituents (*Anlagen*) of the worker-type are brought into activity. At least three kinds of primary constituents—those of the male, the fertile female, and the worker—must be contained in the eggs of ants, bees, and termites; the nature of the stimulus acting upon the egg determines the kind of primary constituent which shall come into activity. These opinions are confirmed by experiments made on flies, which show that insufficient nourishment supplied to the larva does not in any way affect the development of the ovary. The disappearance of typical organs—such as the ovarian egg-tubes of bees and ants—is thus shown to be a phylogenetic and not an ontogenetic process: it does not depend on mere influences of nutrition, but on variation in the primary constituents of the germ; and thus can only come about in the course of numerous generations. The case of social insects is therefore far from contributing any support to the view that acquired characters are inherited, and that the inheritance of the effects of use or disuse play a part in the transformation of species, as is assumed by Herbert Spencer.

Thus we see that external influences in many cases serve as the impulse which starts the process of development in certain of the primary constituents. The actual cause of these individual dissimilarities is in all cases to be sought in the modification occurring amongst the primary constituents of the body itself; and such purposeful modifications can only have originated by selection. Even when to all appearance external influences have had direct action in causing purposeful modifications, a more careful examination will always show that they have only served to bring some preformed adaptation into activity. This is proved in a specially conclusive manner by the consideration of sterility in the workers of bees and ants: the sterility is not due to poor nourishment, but to natural selection, which has determined the nature of the primary constituents in the ovary. This case is of especial interest, as it has been so much relied on as a support to the Lamarckian principle of the inheritance of acquired qualities. Here, as in all other instances, the Lamarckian hypothesis is untenable; selection has been the only principle on which the development of the organic world has been guided on its course.

[1] Abstract of the Romanes Lecture delivered in the Sheldonian Theatre at Oxford, on May 2, by Prof. August Weismann, Ph.D., D.C.L.

THE PLANET SATURN.

IN these days, when the telescope is in more or less common use, and so many have opportunities of observing the heavenly bodies, it is interesting to look back on the past and survey in a general manner the thoughts and ideas of those who in the earlier period of observational astronomy were not so well equipped. To take the case of the great Florentian astronomer, who practically had the whole Cosmos, so to speak, at the end of his telescope, since he was the first who surveyed the objects in the sky with something in addition to the naked eye—one can picture him sweeping with his "optik tube" or small telescope the starry heavens, and suddenly coming across the planet which we have under consideration. Here he had an object which was quite unique, and which, with his small power of magnification, must have puzzled him considerably.

In a letter to the Grand Duke of Tuscany, he refers to Saturn as appearing triple (tergeminus). Later, in a communication to the Austrian Ambassador (November 13, 1610), he makes the interesting statement: "When I observe Saturn with a telescope magnifying more than 30 times, the largest star appears in the middle; of the others, one lies to the west and the other to the east in a line which does not coincide with the direction of the equator, and seems to touch the central star. They appear to me as two servants, who wait upon the aged Saturn, travelling with him and not departing from his side. With a telescope of smaller magnifying power the star appears elongated and of the form of an olive."

Such, then, is the earliest telescopic observation of this planet that we have on record, and it might be interesting to pursue Galileo's inquiries a little further, and follow his state of mind when these "two servants" disappeared, as was the case in his later observations, causing him to look upon his earlier observations as phantoms or illusions.

With us to-day the case is different, and what we see in place of the "two servants" is the beautiful series of rings which girdle the planet in the region of his equator. Huyghens it was who first announced this ring system, and since then observations have shown many details of great interest, both in the ring itself and on the planet's surface.

Many are the objects of inquiry which lead observers to make a study of the appearance of this planet. The ring system and its varied shades, the belts girdling the planet's surface, the dark and light spots on the belts, the period of rotation &c., are only a few that might be mentioned.

Recent oppositions have enabled much work to be done in these lines, and the one just passed (April 11) has, we hope, still more increased our stock of knowledge. About the present time the planet and the brightest star in the constellation of the Virgin (Spica) make a fine pair in the sky. Both are fairly bright objects, and Saturn is known by the more golden hue with which he shines. At the present moment Saturn is retrograding, *i.e.* moving in the westward direction, and his position about the present time is to the north of Spica. The next stationary point in his orbit will be reached on June 21, conjunction occurring on October 23.

With reference to the general brightness which the planet and his ring system exhibit at different times, Dr. G. Muller[1] has recently made some interesting observations. The light-conditions, on account of the rings, are referred to as very complicated. If sufficient observations be considered, he has found that distinct changes in brightness are apparent depending on the phase of the planet, while much more apparent and naturally greater variations are noticeable, depending on the change of the plane of the ring from the line joining Saturn and the earth. When the rings are broadest, the planet in mean opposition shines a little brighter than Arcturus, and when they are invisible Aldebaran may be taken as their equal in brightness. In referring to some of the larger light changes, such as those which occur at different times with the planets Mars and Jupiter, the proportions here developed do not, we are told, tell us anything. In 1883–85, for instance, the reduced magnitude at opposition (0·85) was a little brighter than that for 1880 (0·90), 1880–83 (0·88), and 1886–88 (0·90). Other magnitudes at opposition, eight in number, have been derived by Sildel: thus in 1852 three values gave the mean opposition magnitude as 1·16 ± 0·07, the remainder (5), made from 1857–58, gave 0·97 ± 0·02. At a later date (1862–65) Zöllner from fourteen observations suggested a magnitude of 0·95; while Müller, in this paper, after a formula of his own, obtains 0·88 as the mean oppositional magnitude.

With regard now to the period of rotation of the planet, Herschel, in 1793, was the first who studied this question, giving its length as 10h. 16m. 0·4s., a value, accurate as he stated, "to much less than two minutes either way."

Since that time several more minute discussions have arisen, from which have resulted different values, among which may be mentioned Prof. Asaph Hall's period of 10h. 14m. 23·8s. ± 2·3s.

The latest important results on this question are due to Mr. Stanley Williams,[1] who has taken every pains for the determination of an accurate value, and to free the results from any possibility of their being influenced by preconceived ideas. With regard to the method of observation employed, and the details of the observations themselves, we must refer the reader to the publication mentioned below, but a brief summary of the results may not be out of place.

The observations were made in 1893, and two kinds of spots were observed: (1) dark spots upon a conspicuous double belt in the northern hemisphere; and (2) bright spots in the equatorial zone.

In the case of the former, the period was obtained from numerous spots, but eleven of them have been used as giving well-ascertained values, a table of these figures showing that they can be arranged into two classes, the means of which are 10h. 14m. 29·07 and 10h. 15m. 0·74s. Between these values there is a difference of over half a minute, a quantity too large, judging from the way sets of observations agree *inter se*, to be due to errors of observation.

With the bright spots a similar result is noticed, only here the difference is not the same. Out of the five series of deduced values, four may be coupled well together giving a mean value of 10h. 12m. 59·36s. The fifth or outstanding value is 13 seconds shorter than this.

These different values for the periods of rotation point out pretty distinctly that the spots that have been observed are by no means fixed relatively to the planet's surface, but are endowed with a proper motion of their own. In the case of the dark spots, the surface material must have rotated over half a minute more quickly in the same latitude upon one side of Saturn than upon the other. Mr. Stanley Williams summarises the results of his discussion in the following words:—

"Between N. Kronometric latitudes 17° and 37° the surface material of Saturn rotated in 1893 at the rate of 10h. 14m. 29·07s. ± 0·27s. between longitudes 45° and 140°, and at the rate of 10h. 15m. 0·74s. ± 0·56s. between longitudes 175° and 340°, whilst between longitudes 340° and 45° there was a region in which the surface material rotated at a rate intermediate between the above values.

"Between N. Kronocentric latitude 6° and about 2° S. latitude, the surface material of Saturn rotated in 1893 at the rate of 10h. 12m. 59·36s. ± 0·27s. between latitudes

[1] "Publicationen des Astrophysikalischen Observatoriums zu Potsdam," No. 30, Stück 4.

[1] *Monthly Notices* of R.A. Society, vol. liv. No. 5, March 1894, p. 297.

0° and 140°, whilst between longitudes 140° and 360° the rate of rotation was rather quicker, the average period of rotation here being well represented by . . . . 10h. 12m. 45·8s."

The importance of such results as those stated above will help considerably to unravel the mystery surrounding the circulation of the envelope of this great planet, but, for the observations to be comparable, they must be accurate, systematically made, and extend continuously over moderately long periods. For the years 1891–93, Mr. Stanley Williams points out that the acceleration in the motion of the bright equatorial spots can be clearly deduced from the different periods of rotation.

They are for—

	h. m. s.
1891	10 14 21·8
1892	10 13 38·4
1893	10 12 59·4

For the determination of the latitudes of Saturn's belts, the Rev. W. Freeman has recently published a method[1] which should prove useful for observers wishing to measure kronocentric latitudes.

Recent work on Saturn has, however, been done in another direction, Miss Klumpke having undertaken a further investigation of the problem of the figure of a fluid ring or a solid ring covered with liquid, in equilibrium about Saturn. This has been previously treated of by Laplace, and in recent times by M. Tisserand and Mdme. Kowalewski. Miss Klumpke has carried on Mdme. Kowalewski's work, but includes terms of a higher order, showing that the main result is very little altered. The second part of her thesis deals with the hypothetical case in which Saturn's mass is taken as zero: the rings thus will be subject only to the centrifugal force of its motion and mutual attraction of its particles. A first approximation gives the cross section of the ring as a circle, the second becomes an ellipse, and the third cross section is inclined to be egg-shaped, one end being oval.

W. J. L.

NOTES.

THE New York Mathematical Society proposes to organise a general session, extending over several days, to be held annually during the summer vacation, at some appropriate place and time. This year the session is to be held in Brooklyn, on August 20, 21, 22, the days immediately preceding the session of the American Association for the Advancement of Science. The Council of the same Society has been considering with great care its present organisation. One of the recommendations made by it is that the name should be changed to the American Mathematical Society.

WE regret to have to announce the death of Mr. Adolph Leipner, Professor of Botany in University College, Bristol. Prof. Leipner occupied the office of honorary secretary of the Bristol Naturalists' Society from its inception in 1862, and was elected President of the Society last year. The loss caused by his death, not only to the Society, and the College he served, but also to all those who are interested in the natural history of the Bristol neighbourhood, is a serious one, for he was a naturalist of wide experience, ever ready to place his stores of knowledge at the disposal of his fellow students.

THE death is announced, at an advanced age, at Marseilles, of M. A. Derbès, one of the pioneers in the study of the life-history of Algæ. His "Recherches sur les zoospores des Algues et les anthéridies des Cryptogames," published in 1847, in conjunction with M. Solier, was a perfect mine of new facts with regard to the reproduction of Cryptogams, and formed the basis of all later observations on the same subject. For many years M. Derbès had been prevented, by the results of an accident, from the pursuits of botany, with the exception of the duties of his professorial chair.

[1] *Monthly Notices*, liv. No. 1, Nov. 1893.

AT the Annual Congress of German Naturalists and Physicians, which will be held at Vienna towards the end of September, there will be an exhibition of objects of interest in natural history and medicine.

THE Government of India are making systematic inquiry into the efficacy of hypodermic injections of strychnine in the treatment of snake-bite. The Punjab Government have at their request forwarded a list of cases so treated in the province during the past year.

AT the congress of the Sanitary Institute, to be held in Liverpool next September, Dr. Klein, F.R.S., will act as President of Section I.—Sanitary Science and Preventive Medicine; Dr. T. Stevenson has accepted the presidency of Section III.—Chemistry, Meteorology, and Geology.

AN earthquake was felt in several districts of South Wales on Wednesday, May 2. At Caerphilly, dwelling-houses were so shaken that light articles of furniture were upset, and crockery-ware fell to the ground. The tremor was also felt at Cardiff, a decided vibration being experienced at about half-past twelve in the day.

THE sum of five thousand rupees has been given by the Maharajah of Bhownagger towards a Pasteur Institute for India. Though the scheme has met with some opposition, the strong committees that have been formed in various parts of India in order to support it, leaves little doubt that the Institute will eventually be established.

THIS year's conversazione of the Society of Arts will take place on Friday evening, June 22, at the Imperial Institute.

THE Institution of Electrical Engineers will hold a conversazione in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly, on the evening of Thursday, May 31.

THE Yorkshire Naturalists' Union will hold a meeting at Sedbergh, for the investigation of the neighbourhood of Dowbiggin, Lune Valley, and Uldale, on Whit-Monday, May 14.

ON Thursday last a public meeting was held in Prince's Hall, Piccadilly, in support of the proposal to erect a memorial to the late Sir Andrew Clark. The Duke of Cambridge took the chair as President of the London Hospital, and the audience contained a large number of persons eminent in all branches of knowledge. Mr. Gladstone testified to his late physician's high character, referring to him as a representative of all that is best and noblest in the medical profession. He concluded by moving:—"That in recognition of the great services rendered to the community by Sir Andrew Clark, Bart., M.D., a memorial be established which shall perpetuate his name and his work." This resolution was carried, and also the following, moved by Canon Wilberforce:—"That steps be taken to raise a sum sufficient for the erection of a block of buildings at the London Hospital, to bear the name of Sir Andrew Clark, which will afford increased facilities for the relief of suffering and the advancement of medical science." Mr. Jonathan Hutchinson, who was one of Sir Andrew Clark's colleagues, made some very appropriate remarks in supporting the first resolution. Medical men did not claim for the deceased physician the discoveries of a Harvey, a Jenner, or a Hunter, he said, but they nevertheless held that he was in the highest and best sense of the word a representative man, to whom it was the duty and the privilege and the interest of the whole community to do honour. Shakespeare had said "one good deed, dying tongueless, slaughters a thousand," and he (Mr. Hutchinson) took that to mean that an injury was inflicted on future ages if a single good deed were allowed to die without suitable commemoration, and in the life of Sir Andrew Clark they had a record which would be a treasure for generations yet to come.

The arrangements for the sixty-second annual meeting of the British Medical Association, to be held at Bristol on July 31, August 1, 2, and 3, are given in the *British Medical Journal*. The President-elect is Dr. E. Long-Fox. An address in Medicine will be given by Prof. T. G. Stewart, one in Surgery will be delivered by Dr. Greig Smith, and Sir Charles Cameron will discourse on Public Medicine. The Sections and their Presidents are as follows:—(A) Medicine, Dr. Frederick T. Roberts; (B) Surgery, Dr. W. Mitchell Banks; (C) Obstetric Medicine and Gynæcology, Prof. J. G. Swayne; (D) Public Medicine, Prof. W. H. Corfield; (E) Psychology, Dr. G. F. Blandford; (F) Pathology, Dr. G. Sims Woodhead; (G) Ophthalmology, Dr. F. R. Cross; (H) Laryngology and Otology, Dr. P. McBride; (I) Dermatology, Dr. A. J. Harrison; (J) Diseases of Children, Dr W. Howship Dickinson. The Annual Museum in connection with the meeting will be arranged in the following sections: Section A.—Food and Drugs, including Prepared Foods, Chemical and Pharmaceutical Preparations, &c. Section B.—Instruments, comprising Medical and Surgical Instruments and Appliances, Electrical Instruments, Microscopes, &c. Section C.—Books, including Diagrams, Charts, &c. Section D.—Sanitary and Ambulance Appliances. All communications on general matters connected with the Museum, and all applications for space, should be addressed to Mr. John Dacre, 14, Eaton-crescent, Clifton, Bristol, before June 20, and a brief description of each exhibit for insertion in the Museum Catalogue must be in the hands of the respective Secretaries before July 1.

At the meeting of the French Meteorological Society on April 12, M. Renou, President, made some interesting remarks upon thunderstorms. He said that they occurred in some parts of France every day of the year, and during six or seven months in 1892 as many as 328 were counted. He remarked that they were more frequent in Europe than in equatorial regions; at Sumatra, for instance, storms occur during the six months of the south-east monsoon, but thunder is never heard. In France they generally traverse a narrow tract from south-west to north-east, but in the hot regions of the globe, on the contrary, the storms are nearly stationary. They are very exceptional in Peru, occurring only once or twice in a century; there was one in January 1877, but none had occurred previously since 1803.

Reports of cuckoos being seen and heard long before the usual date of the arrival of the bird are made every year. Generally the reports cannot be relied upon, but a circumstantial account by Dr. A. J. Fleming, in the *Zoologist* for April, goes to show that he really saw a cuckoo on March 5 of this year. The accuracy of his observations, however, is questioned in the current number of the journal by several naturalists, most of whom assert that March cuckoos do not exist. Mr. J. E. Harting remarks:—"From numerous observations made by competent naturalists in different localities it appears that the usual time of arrival of the cuckoo in this country is between the 20th and 27th April, and the average date of its appearance may be said to be on the 23rd of that month, St. George's Day. In no instance, so far as I am aware, has the bird been heard or seen (by any competent observer) before the 6th of April. It is surprising how few people are to be trusted, either in matter of *eye* or *ear*, in regard to the cuckoo. Many cannot know a cuckoo on the wing from a male sparrow-hawk, and others convince themselves that they have heard this bird's notes when they have been listening to a clever imitation by some village bird-nesting boy, or to the still more deceptive notes of a cuckoo-clock in a neighbouring cottage."

Lieut.-Colonel Sawyer read a paper to the Royal Geographical Society, at its last meeting, on the Bakhtiari Mountains and Upper Elam, a part of Persia which his surveys in 1890 have made it possible to map correctly. In the practical work of the survey he was assisted by the Indian surveyor Imam Sharif, who subsequently accompanied Mr. Bent's expedition to Hadramaut. The country is practically the continuation of the classical Zagros mountains, and the portion surveyed is a tract 30 miles wide between the bordering mountain ridges, and 300 miles in length from north-west to south-east. In the centre the mountains culminate in the mass of Kuh-i-rang, 12,800 feet above the sea, whence flow the chief rivers of Persia, the Zainderud, the Ab-i-diz and the Karun, the upper courses of which have been mapped correctly for the first time. This central mass not only separates two distinct drainage areas, it divides two entirely different ethnographical regions—the country of the Bakhtiari lies to the east, and Upper Elam to the west. Upper Elam is peculiarly rich in ancient remains, few of which have yet been examined, and many of them reach back to a very high antiquity. The expedition, though primarily for the purpose of surveying, did not fail to take account of more specially scientific matters, and although little was said about the geology of the mountains, their flora seems to have been pretty fully studied, as 350 species of plants were collected, of which seventeen at least were new to science. The people, who have been described from observations on this expedition by Mrs. Bishop, struck Colonel Sawyer as proud and warlike, and although warped in character by their isolated habitat, they yet remain possessed of many fine characteristics, physical and mental.

The May number of the *Scottish Geographical Magazine* contains several interesting papers. One on the geographical unity of the British Empire should strictly be entitled the economic unity, as the bond cannot without much straining be called a geographical one. Herr Victor Dingelstedt gives an account of the isolated valley of the Vièze, at the foot of the Dent du Midi, showing how isolation and the physical conditions of configuration, climate, and vegetation have combined to keep the people in a remarkably backward and primitive state. Mr. Stuart-Glennie gives in very brief abstract an outline of his travels on the border-land between Turkey and Greece in an article on "Dodona, Olympos, and Samothrace," which would have been more valuable if the date of his visit had been indicated. He promises to complete the account of the ethnography of the region in a forthcoming work, under the title of "Ancient Hellas."

The *Journal* of the Tyneside Geographical Society is rapidly approaching the form of a well-to-do geographical monthly; and although still relying to a considerable extent on articles reprinted from other publications, the May number includes two original lectures, one by Mr. Clements R. Markham, F.R.S., on Peru, and the other by Lord Roberts, on Delhi and its siege in 1857.

The first part for 1894 of the *Records* of the Geological Survey of India contains a report on the Bhaganwala Coal-field of the Salt Range, by T. D. la Touche. This coal-field was first made known in 1853; reports on it have appeared by Dr. Oldham (1864) and Mr. Wynne (1878). Estimates of its value have recently been published, which Dr. King, the Director of the Survey, believes to be greatly exaggerated; hence the present report. The coal is of Nummulitic age: the seam varies much in thickness, and is irregular in its mode of occurrence. Estimates based on a thickness of from $3\frac{1}{2}$ to 5 feet, and a maximum depth of 2000 feet, give one million tons as the probable quantity available.

THE Director's tri-monthly notes in the same number of the *Records* contain a full account of the gigantic landslip in Garhwal, noticed previously in NATURE (vol. xlix. p. 438). The fall of rock took place last September, and dammed up the valley of the Bihri Ganga by a wall 900 feet high. The water has steadily accumulated behind the dam, and is now daily expected to overflow. The first rush of water will be severe, and probably about 250 feet of the dam will be carried away; after that there may be a permanent lake established with a natural outfall. An investigation of this interesting landslip is in progress by Mr. Holland.

DR. J. W. GREGORY describes the Echinoidea of Cutch in the "Palæontologica Indica" (ser. ix. vol. ii. part 1, 1893). The Echinoids are few and small; they lived probably on sand and in rock-pools in a somewhat rough sea around a series of coral-reefs. More light on the geology of the area may be expected from the large collection of corals. The fauna seems to be homotaxial with the Callovian of Europe.

A RECENT number of the *Comptes Rendus* contains a note by M. E. Bouty on the capacity of a polarised surface of mercury and other substances. By means of the principles of thermodynamics, Lippmann has shown that the polarisation capacity of unit surface of mercury, the surface being kept constant, is equal to $-\frac{d^2A}{de^2}$ where A is the surface tension and e the counter electromotive force of polarisation. M. Lippmann has also calculated the value of this expression for mercury in contact with acidulated water, and found that, at any rate within wide limits, the value is independent of e. On the other hand, the author, as well as Blondlot, finds that in the case of platinum electrodes in different electrolytes, even when the time of charge is evanescent, the capacity increases rapidly with the increase of e. The author has shown that this increase does not take place if we consider that part of the capacity which is capable of producing a discharge current in an external circuit, and that polarisation phenomena are in part irreversible, except for infinitely small values of the electromotive force and the time. The experiments thus show that, if the irreversible parts of the phenomena are omitted, the capacity of platinum is independent of e, just as is the case with mercury. With platinum electrodes and a solution of sodium nitrate the author has found values for the capacity of a square centimetre of the electrode at temperatures between 21° and 25° of from 17·72 microfarads for a solution containing two equivalents of the salt per litre to 9·32 microfarads for a solution of 0·0001 equivalents per litre. In the case of distilled water (platinum electrodes) he finds the capacity per square centimetre to be 8·27 microfarads.

IN a paper read at the Botanical Congress at Genoa, last year, Prof. Saccardo calculates the number of species of plants at present known as 173,706, distributed as follows:—Flowering plants, 105,231; Ferns, 2819; other Vascular Cryptogams, 565; Mosses, 4609; Hepaticæ, 3041; Lichens, 5600; Fungi, 39,603; Algæ, 12,178. Prof. Saccardo thinks it probable that the total number of existing species of Fungi may amount to 250,000, and of all other plants to 135,000.

A SET of simple and instructive heat experiments, illustrating the laws of expansion, radiation, and convection, are described by Dr. V. Dvorák in the *Zeitschrift für Physikalischen Unterricht*. To show the expansion of a solid by heat, a brass wire, 1·5m. long, is suspended horizontally by two clamps. A weight of about 5 gr. is suspended at the middle of the wire, and a small wooden block is placed below it. The expansion produced by passing a lighted match along the wire produces a perceptible lowering of the weight. To prove that emissive power is proportional to the power of absorbing radiant heat, Dr. Dvorák constructs a special thermo-couple, consisting of a disc of thin German silver, to the back of which a thin steel wire is soldered. Both are connected with a delicate galvanometer. When the disc is lamp-blacked and exposed to radiation, a larger deflection is obtained than after the lamp-black has been wiped off. A still larger deflection is obtained when the lamp-black is moistened with olive oil. A comparison of these indications with the deflections obtained from the radiation of a Leslie cube with the corresponding surfaces proves the law referred to. To exhibit the phenomenon of latent heat, a plate of copper foil mounted on a wooden ring is soldered to a German silver wire, and both copper and wire are provided with binding screws, and connected with a galvanometer. By depressing the copper foil into the ring a shallow dish is obtained, in which liquids may be evaporated. The galvanometer shows the loss of heat attending evaporation, the amount of latent heat differing with the liquid used. Convection currents in air and water are, according to Dr. Dvorák, well shown by introducing the liquid or gas between a screen and a point of light. The latter may be produced by placing a screen with a small hole at the principal focus of a lens receiving the sun's rays. A Bunsen burner with a small flame, a glowing match, water containing a wire heated by an electric current, or water cooled by a fragment of ice or salt at the surface, show beautiful ascending or descending clouds on the screen.

WE welcome the May number of "The Country Month by Month," by Mrs. J. A. Owen and Prof. Boulger. What has been said of previous issues applies to this. The book is a chatty and bright companion for country rambles.

PROF. W. R. FISHER wishes us to state that he was not present at the evening meeting of the Essex Field Club at Chingford, reported in our last issue (p. 12).

THE quarterly *Journal* of the Geological Society, No. 198, which has just been published, contains, in addition to the papers read before the Society from November 1893 to February 1894, inclusive, the anniversary address of the President, "On some Recent Work of the Geological Society," part ii. The *Journal* reaches its jubilee this year, and a suitable index to the contents is being prepared to commemorate the occurrence.

MESSRS. HACHETTE AND CO., of Paris, have begun to publish, in parts, a work by M. Maspero, entitled "L'Histoire Ancienne des Peuples de l'Orient." Maspero's book, published under the same title nearly twenty years ago, has become classical. That of which the publication has just been commenced, however, will only be like its predecessor in name and general outline; for the text will be new, and it is to be richly illustrated. It will be divided into three volumes, issued in about 150 separate parts of sixteen pages each. Oriental history will be scientifically treated, and the work will appeal to all who are interested in the discoveries that have been made in Egypt, Assyria, Chaldea, and Asia Minor during the last thirty years.

THE March number of *Modern Medicine and Bacteriological Review* contains a reminiscence of Sir Andrew Clark from the pen of Miss Frances E. Willard. The little article is not only interesting but useful, containing an exact account of general and most simple instructions recommended by Sir Andrew Clark for the maintenance of health, which admit of wide application. Amongst the bacteriological notes, we find a reference to a paper by E. Fraenkel, published in the *Deutsche Medicinische Wochenschrift*, on the treatment of fifty-seven cases of typhoid fever by injection of a sterilised culture of typhoid bacilli. Fraenkel states that the results obtainable by this method of treatment are superior to those of any other method which has been previously employed. The earlier the treatment commences the more successful are the results obtained. The injections are said to be perfectly harmless when made into the muscle, but cause much pain when introduced subcutaneously. Dr. Kellogg contributes an article on the "Relation of Modern Physiological Chemistry to Vegetarianism," which is to be continued. The other longer papers are chiefly of medical interest.

THE explosive halogen compounds of nitrogen form the subject of a memoir contributed to the current number of the *Berichte* by Dr. Seliwanow, of St. Petersburg. Pure trichloride of nitrogen, NCl_3, was prepared for the first time in a state of purity in the year 1888, by Dr. Gattermann, in Prof. Victor Meyer's laboratory at Göttingen. It was shown to be an oily liquid of so unstable a character that strong sunlight, or the light waves emanating from a powerful artificial source such as burning magnesium, instantly provoke its extremely violent explosive decomposition. By working in a dull light, however, Dr. Gattermann succeeded in weighing a quantity of the liquid and analysing it. He showed, moreover, that the crude liquid substance obtained by the action of chlorine on ammonium chloride is a mixture of two or perhaps three different chlorides of nitrogen, and that the pure trichloride is only to be obtained by subjecting this product, after removal of all sal-ammoniac by washing and subsequently draining from water, to the action of a rapid stream of chlorine. Iodide of nitrogen has frequently formed the subject of investigation, and last year Dr. Szuhay, of Buda-Pesth, showed that the substance obtained by adding excess of ammonia to a solution of iodine in potassium iodide consists largely of the compound, NHI_2. The existence of an iodide containing hydrogen had previously been indicated by Dr. Gladstone and M. Bineau, but it appears probable that in presence of excess of iodine, the tri-iodide NI_3 is also produced in large quantity. That halogen compounds of nitrogen containing likewise hydrogen are capable of existence would appear, therefore, to be fully proved by the work of Drs. Gattermann and Szuhay, and the latter chemist actually succeeded in preparing a silver derivative $NAgI_2$, a substance as explosive as the iodide of nitrogen itself. Dr. Seliwanow now brings forward evidence to show that the formation of chloride or iodide of nitrogen by the action of the halogens upon ammonia occurs in two stages, hypochlorous or hypo-iodous acid being first produced. When a dilute instead of a concentrated solution of iodine is employed, no separation of iodide of nitrogen occurs, and the solution is found to contain both ammonium iodide and hypo-iodous acid HOI; the latter is readily detected by means of a reaction with potassium iodide in which iodine is liberated, which Dr. Seliwanow has recently discovered during the course of his work on certain organic derivatives of this acid. Upon increasing the strength of the solution of iodine, iodide of nitrogen at length commences to be deposited, and this is found to occur at the expense of the hypo-iodous acid. Hence iodide of nitrogen appears to be formed directly by the action of ammonia upon the unstable hypo-iodous acid produced in the first stage of the reaction. A similar explanation is also shown to hold with respect to the formation of chloride of nitrogen. It is interesting to observe that Dr. Seliwanow actually proves the existence of hypo-iodous acid in a solution of ammonia, a fact which may perhaps be accounted for by the recent remarkable discovery of Prof. Victor Meyer that this so-called acid is really endowed with basic properties. When it does react with ammonia, the chief product, as above shown, is iodide of nitrogen. The two equations for the formation of the latter are formulated by Dr. Seliwanow as follows:—

$$NH_3 + I_2 + H_2O = NH_4I + HOI.$$
$$NH_3 + 3HOI = NI_3 + 3H_2O.$$

THE additions to the Zoological Society's Gardens during the past week include a De Filippi's Meadow Starling (*Sturnella de filippi*) from La Plata, presented by Sir Harry B. Lumsden, C.B.; two Common Peafowls (*Pavo cristatus*, ♀ ♀) from India, presented by Mr. Richard Hunter; a Chicken Snake (*Coluber quadrivittatus*) from Florida, U.S.A., presented by Master James W. Philips; a Common Boa (*Boa constrictor*), two Tree Boas (*Corallus hortulanus*), a Thick-necked Tree Boa (*Epicrates cenchris*), a Carinated Snake (*Herpetodryas carinatus*) from Trinidad, presented by Messrs. Mole and Urich; a Ring-hals Snake (*Sepedon hæmachates*), two Cape Vipers (*Causus rhombeatus*) from South Africa, presented by Mr. J. E. Matcham; a Jaguar (*Felis onça*, ♂) from South America, two Plumed Ground Doves (*Geopelia plumifera*), two White Storks (*Ciconia alba*), two Vivacious Snakes (*Tachymenis vivax*), two Four-lined Snakes (*Coluber quadrilineatus*), four Green Lizards (*Lacerta viridis*) European, four Dark Green Snakes (*Zamenis atrovirens*), two Glass Snakes (*Pseudopus pallasi*) from Dalmatia, purchased; two Senegal Touracons (*Corythaix persa*) from West Africa, received in exchange; two Barbary Wild Sheep (*Ovis tragelaphus*, ♀ ♀) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE MOON'S APPARENT DIAMETER.—A recent number of *Ciel et Terre* (April 2) contains an article on the moon's angular diameter, by M. P. Stroobant, of which a translation, with copious notes, appears in the *Observatory* for May. The methods employed in the determination of the apparent diameter of our satellite are (1) micrometer measures, (2) meridian passages, (3) heliometer measures, (4) photography, (5) occultation of stars by the moon, (6) eclipses. A comparison of the principal results obtained during the present century by these various methods indicates that occultations give the most accordant values, and M. Stroobant remarks that the method of occultation is the only one in which the apparent diameter of the moon is not augmented by physical or physiological causes. Accurate observations of occultations indicate that the lunar diameter has a value lying between 31′ 5″ and 31′ 6″, but M. Stroobant urges that this approximation is not sufficient. He concludes by saying:—"The application of photography to the determination of the exact instant of disappearance or of reappearance of a star would permit, without doubt, the attainment of great precision, especially when these phenomena occur at the dark limb of the moon, or during eclipses, when a number of small stars can be observed. . . . About every nineteen years the moon passes over the Pleiades in conditions more or less advantageous for observation; this phenomenon will occur next year. Might not the occasion be profitably used in securing a number of photographs at various observations? If these are sufficiently separated from one another, it would be possible to deduce a new value for the parallax of the moon."

GALE'S COMET.—This comet, for which we gave an ephemeris last week, is now very favourably placed for observation in the northern hemisphere. Its track lies from a point near ζ Hydræ (May 7) to near ζ Leonis (May 15). From South Kensington we have received the following report:—"The comet has been clearly visible to the naked eye for some days past, and when viewed with an opera-glass is quite a conspicuous object. Observed with the telescope it appears as a large slightly elongated nebulous mass with a central condensation, but with no obvious tail. The spectrum of the comet was observed by Mr. Fowler on May 7, and was seen to consist of the three carbon bands which have so frequently been recorded in other comets. The bands were found to be coincident with the corresponding bands seen in the spectrum of the blue base of a candle flame, at approximate wave-lengths 4736, 5165, and 5635. There was also a fairly bright continuous spectrum from the nucleus."

DENNING'S COMET.—M. L. Schulhof (*Astr. Nach.* 3227) has computed an elliptic orbit for the comet found by Mr. Denning on March 26, as the parabolic elements previously determined did not satisfy the observations. The period of the comet appears to be 6·745 years. According to the criterion published by M. Tisserand some time ago, the comet is identical with either Grischow's comet (1743 I.) or Blanpain's (1819 IV.), or it may be with both, for the identity of these two objects is admitted by some astronomers. M. Schulhof points out that it is desirable that Denning's comet, which is fading rapidly, should be followed so long as possible with large telescopes. Periodic comets can only throw light upon some obscure points in celestial mechanics and cosmogony when they have been observed during several apparitions. An ephemeris extending to May 15 will be found in NATURE, vol. xlix. p. 586.

STARS HAVING PECULIAR SPECTRA.—In *Astronomische Nachrichten*, No. 3227, Mrs. Fleming gives a list of five faint objects having spectra of Type V., that is, of bright lines, discovered from an examination of photographs of stellar spectra, taken at the Peruvian Station of the Harvard College Observatory, under the direction of Prof. S. J. Bailey. This brings the list of bright-line stars up to sixty. Two new nebulæ have also been found by means of the photographs of their spectra. The positions and descriptions of the objects are stated as follows:—

R.A. 1900. h. m.	Decl. 1900.	Description.
13 46·5	−66·1	Type V.
15 10·0	−45·17	,,
17 11·8	−34·18	,,
17 18·2	−43·24	,,
17 38·2	−46·3	Gaseous nebula.
18 39·3	−33·27	Type V.
19 10·5	−39·47	Gaseous nebula.

THE IRON AND STEEL INSTITUTE.

ON Wednesday and Thursday of last week, the 2nd and 3rd insts., the annual spring meeting of the Iron and Steel Institute was held at the Institution of Civil Engineers; the President, Mr. E. Windsor Richards, occupied the chair. The following is a list of the papers set down for reading and discussion:—

"On the Physical Influence of certain Elements upon Iron." By Prof. A. O. Arnold.

"On the Capacity and Form of Blast Furnaces." By William Hawdon.

"On Scandinavia as a Source of Iron Ore Supply." By Jeremiah Head.

"On the Walrand Process." By G. J. Snelus.

"On the Results of Heat Treatment on Manganese Steel and their Bearing upon Carbon Steel." By R. A. Hadfield.

"On the Analysis of Steel." By H. K. Bamber.

"On the Application of Electricity as a Motive Power in the Iron and Steel Industries." By D. Selby-Bigge.

"On Methods of Preparing Surfaces of Iron and Steel for Microscopic Examination." By J. E. Stead.

"On the Relations between the Chemical Constitution and Ultimate Strength of Steel." By W. R. Webster.

The last four were taken as read. The usual formal proceedings having been transacted, the Bessemer gold medal for 1894 was presented to Mr. John Gjers, of Middlesborough, in recognition of his great services to the iron and steel industry.

The President then proceeded to deliver his address, which dealt chiefly with the economic side of iron and steel production. This industry appears to be passing through a period of extreme depression, more pronounced even than that of 1885. In the latter year the production of Bessemer steel rails was 706,583 tons. That year was designated at the time as a period of great depression, but in 1893 the production of rails was but 579,386 tons, whilst in 1892 the output was 43,550 tons lower even than in 1893. The price of these rails, which in 1886 was £4 13s. 10d. per ton, fell as low as £3 12s. in 1893. The question arose, the President said, whether this diminished demand was due to any falling off in quality of material, excellency in finished products, or increased cost of manufacture. From careful observations which he had made, Mr. Windsor Richards was convinced that our metallurgists and manufacturers still keep a foremost position. The loss of the continental trade was due solely to protective tariffs, and even the importation of continental rails was to be attributed to the same source, strange as it might seem. The reason for this is that to produce steel economically, it is necessary that it should be made in large quantities; in consequence of the protective tariff the continental manufacturer is freed from foreign competition at home, and can therefore obtain an exorbitant price for his goods. This enabled him to sell in foreign markets, where he had to meet competition, at a lower price than those who had not the same lucrative home market. In fact it was necessary to produce largely, and the surplus quantity could in this way be sold at what would otherwise be a loss. In face of these facts, the President said it was useless to expect relief by resource to labour-saving machinery and other methods of cheapening cost, and it was to be remembered that the foreign manufacturers could take these up as readily as we could. Technical education, he also seemed to think, would be powerless to avail us against the conditions he had pointed out. "Never," said the address, "since the organisation of this Institute (a period it may be mentioned of over twenty-five years) has the metallurgist experienced a more difficult time than the depression we are now passing through. Added to his commercial troubles were constant demands from the workmen for either higher wages or fewer hours of work. We may well anxiously look round to see where markets for our products, and employment for our workmen and capital are to come from." Some English steel makers have been building hopes on the relaxation of the American tariff, but these hopes the President looked on as fallacious, and indeed the United States steel makers have been passing through a period of greater depression than even we ourselves in this country. It is to our colonies, therefore, that Mr. Richards tells us we must look for relief, and he points out the vast field there is for the further development of rails in India, Australia, and Africa. The introduction of steel for rails has not proved an unmixed blessing for the iron and steel manufacturer. The President quoted an instance in which Goliath rails of 105 lbs. per yard had been laid down five years ago on a continental railway, and it was shown that on the basis of the wear already observed during those five years, such rails would last a century. The carbon in the steel was from ·4 to ·5. Rails are being laid down even harder than this, containing from ·6 to ·7 carbon. The extreme hardness obtained in this way entailed, the President said, an unnecessary risk. The address next went on to speak of the uncertainty of phosphorus analyses, and to the desirability of dealing with steel in large masses, in the ingot. He stated that Messrs. John Brown and Co., Sheffield, are having constructed a forging press for steel ingots, which will exert a force of 1000 tons, whilst ingots 6 ft. 9 in. square, and weighing up to 70 tons, are being dealt with by the forging press, the appliance used in handling them having a capacity of 100 tons.

The first paper read was by Mr. G. J. Snelus, and was on the Walrand-Legénisel process for steel castings. This process consists of adding to the metal in the converter at the end of the ordinary blow a definite quantity of melted ferro-silicon, then making the after-blow, turning down when the extra silicon has been burned out, and adding the ordinary final additions of ferro-manganese, &c., as circumstances required. The advantages of this process are that firstly an ordinary Bessemer pig can be used with 2 to 3 per cent. silicon, thus insuring a steel perfectly free from carbon; secondly, the combustion of the added silicon produces such a large amount of heat at the right time, and so rapidly that the metal becomes very fluid; the third advantage claimed is that as the silicon burns to a solid, it leaves the metal perfectly free from gas, and the steel is sound and free from gas cavities; fourth, that in consequence of the metal being so fluid and already free from oxide of iron, the ferro-manganese or other substances added, such as aluminium, are more effective and remain in the final steel. Another advantage secured by this process is that in consequence of the fluidity of the metal much more time and facility is given for casting operations. The author gave detailed descriptions of experiments he had seen made with this process, and quoted figures in support of his contentions. The system of casting is, however, confessedly expensive, and it would seem to be more especially suitable for those engineering works where it is desirable to have a steel foundry attached, and in which the demand would naturally not be so continuous as in the case of an establishment devoted entirely to the production of steel castings. It may be stated that the price of steel as it stands in the ladle is given as 4s. 6d. per cwt., whilst the cost of a complete installation of moderate size would be about £3500. In calculating the cost of the steel in the ladle, the author appears to leave out the fixed expenses. It is doubtless a tempting thing to the managers of engineering workshops to have their own steel foundry, especially as it is often difficult to obtain castings with promptness and punctuality, the advantage of producing all parts required at home, and thus having control of delivery, is apparent. It is very easy, however, to carry this principle too far. The time of a works manager is limited, and without the master's eye there is likely to be much leakage in a department. Manufacturing establishments may be too self-contained, and there are many unfortunate instances of works producing everything required, excepting dividends.

A short discussion followed the reading of this paper, those who spoke being altogether favourable to the process. Unfortunately the large number of papers that were on the list made the President fearful that the whole programme would not be carried through in the two days, and he therefore closed this first discussion very abruptly. Had he not done so we believe that the discussion would not have been throughout of so flattering a description.

The next paper read was a contribution by Mr. Jeremiah Head, entitled "Scandinavia as a Source of Iron Ore Supply." Mr. Head has recently made a tour through Norway and Sweden, going to the extreme north of the Scandinavian Peninsula, and in his paper he discussed the iron-producing capabilities of these countries, of which he appears to take a somewhat sanguine view. He pointed out that in the case of export duty being placed on iron ore by the Spanish Government, the steel makers of this country might be put in an awkward position, depending as they did so largely on Bilbao ore. Some of the experienced steel makers present, however, by no means agreed with Mr. Head in his estimate of the value of Scandinavian ore. It would appear that until a railway is constructed to the Norwegian coast, which, unlike the Baltic, is free from ice at all times of the year, there is not much prospect of a continuous supply of ore being obtained from northern Scandinavia. The objection that for half a year there is almost continual night in this district, was, Mr. Head said, an imaginary one, the fact being that the Scandinavians carry on their business all through the year without trouble. The brilliant moonlight, the Northern Lights, and the twilight that exists, aided by the reflection from the snow-covered country, enables work to be transacted. Mr. Head's paper contained a great deal of useful information on the subject, analyses of the ores being given, and figures as to the cost, &c.

On the second day of the meeting the proceedings were opened with a paper by Mr. William Hawdon, on "The Capacity and Form of Blast Furnaces." The author commenced with some interesting figures on the increase in capacity of blast furnaces; in Cleveland during recent years the content has risen from about 6,000 cubic feet to as much as 30,000 cubic feet, with the result of increased economy and larger output. In discussing the proportions of furnaces, he pointed out that the crucible or well of the furnace, that is the part immediately above the hearth, has its diameter governed by two considerations: if it be too large, a pillar of perfectly cold material may be formed in the centre of the mass of ore, fuel, &c., contained in the furnace; whilst if the diameter were too small, there would not be sufficient space to give the required volume for combustion in order to obtain a given output. The melting zone above the crucible must also be designed so as to allow an easy penetration of the blast through the materials. When air is blown into a furnace it has to be expanded by the expenditure of heat, but if air be introduced at a high temperature and already in an expanded state, a more rapid combustion is obtained with a saving of fuel in the furnace. In the case of cold blast being used, intensity of combustion does not spread over a large space, and therefore a smaller well suffices. High temperature of blast requires a larger area in the neighbourhood of the tuyeres, through which it is admitted. It is necessary that the furnace materials should come down from the upper reaches thoroughly heated and reduced, and in as level a manner as possible over the entire area. In order to obtain capacity and to support the material, and also to prevent too dense packing near the tuyeres at the zone of fusion, the blast furnace is made with boshes; that is to say, the interior space enlarges suddenly, the walls taking a slope of 60° to 80, the angle of repose for dry materials being about 45. But when the minerals become plastic, the angle of the bosh requires to be more steep. Above the slope of the boshes there is the maximum diameter of the barrel of the furnace. When, owing to the relative sizes of the wall and the barrel the bosh occupies a large vertical space, thus retiring a long way back, the materials at the sides are too far removed from the ascending current of gas, and will come down in a perfectly raw state. The author gave an amusing example of this error in furnace construction. In one case, after a few months' working it was discovered that some wooden sleepers that were originally placed in to light up the furnace, had not been consumed, and were in fact found only charred on the surface, resting near the top of the bosh of the furnace. In order to get over the somewhat conflicting conditions we have here referred to, Mr. Hawdon and his friend Mr. Howson had designed a furnace of comparatively narrow dimensions, but enlarged at the upper part, thus giving, as it were, a second bosh. In this way in the higher region where the charge is in a dry and porous state and not subject to extreme pressure, capacity is obtained, whilst the direct weight upon the lower portions of the materials is reduced. With a furnace of this nature, which has been in work some short time at the Newport Iron Works, the author obtained in smelting hematite a fuel economy of 15 cwts. of fixed carbon per ton of iron, the weekly output being 932 tons, the ore being 50 per cent. One great advantage in the use of this form of furnace would appear to be regularity of the product, freedom being obtained from that uncertain recurrence of white iron which is so often a trouble to the blast furnace manager. It should be remembered that the furnace had not been in work for any considerable time, and new furnaces nearly always work better than when they have been in blast a few years. On the whole, however, it would seem that Mr. Hawdon has made out a very good case for his new form of furnace, and indeed the promises are so good that doubtless many more will be erected on these lines.

The remaining paper read at the meeting was by Prof. J. O. Arnold, of Sheffield, and was entitled "The Physical Influence of Elements on Iron." We approach this paper with despair. In the first place, it was one of extreme length and is full of facts from cover to cover. In the second place, the discussion which followed its reading was of such a nature that many of the speeches which had been prepared beforehand, and were read by their authors, were really of the nature of papers in themselves. Indeed one speaker, Mr. Hadfield, of Sheffield, had prepared a paper of some length which had been called forth by Mr. Arnold's monograph, and extracts from this were read by the author during the discussion. M. Osmond, Prof. Roberts-Austen, Sir Lothian Bell, and Mr. Gowland had also prepared what in effect were separate monographs on the subject; whilst Mr. Stead, of Middlesborough, spoke at considerable length. In addition to these there were several other speakers. We could not abstract Prof. Arnold's paper in anything approaching the space we have at our disposal here, important and interesting as the subject is; and even could we do so, it would be hardly fair to those who took opposite views to him, as we cannot reproduce their arguments. Under these circumstances we must content ourselves with giving the very briefest idea of the subject, referring our readers to the *Transactions* of the Institute for full information. It will be remembered that at a meeting of the Institute of Mechanical Engineers, Prof. Arnold made a very strong attack upon the report presented by Prof. Roberts-Austen as chairman of the Alloys Research Committee of that Institution. Prof. Roberts-Austen in his report adopted the theories brought forward by M. Osmond in regard to the critical points, or evolutions of heat during the cooling of mild steel, from a temperature of 1000° C. These critical points were: firstly, the slight evolution of heat at 850° C. This point is known as Ar_3. Secondly, a faint disengagement of heat at about 750° C., the point Ar_2, the third point Ar_1, is at about 650; the latter is almost absent in very mild steel, but becomes highly accentuated in steels high in carbon, and was therefore due to a combination of iron and carbon to form the definite carbide Fe_3C. M. Osmond maintained, what Prof. Arnold designated the "startling theory," that the point Ar_3 marked the vital change of the passage into ordinary soft iron of an allotropic modification of iron (existing at temperatures above the critical point) of adamantine hardness. This allotropic form M. Osmond named β iron to distinguish it from α or soft iron. He further stated that the hardness conferred upon tool steel when plunged at a good red heat into cold water was due, not to carbon, but to the presence of β iron, rendered stable at low temperatures on being suddenly chilled in the presence of carbon, the last-named element, as such, possessing a comparatively insignificant hardening influence. M. Osmond also said that an investigation made on a series of alloys had verified Prof. Roberts-Austen's law that the influence of elements on iron is in accordance with the periodic law. These, briefly, are the points on which Prof. Arnold joined issue ; and in order to support his contention, he has made a vast number of experiments which he claims, if we understood him correctly, entirely upset the theories of M. Osmond and Prof. Roberts-Austen.

The paper by Mr. Hadfield, to which we have referred, is entitled "The Results of Heat Treatment on Manganese Steel and their Bearing upon Carbon Steel." Mr. Hadfield's connection with that remarkable alloy of iron known as manganese steel is well known, and the great difficulty with which it is magnetised renders it especially interesting in connection with this subject. During the discussion Mr. Hadfield showed that manganese steel may be made magnetic ; in fact he produced a bar which was distinctly affected by the magnet at one end, whilst at the other end there were no magnetic properties. We must, however, refer our readers to the *Transactions* for the many interesting details contained in this paper. The meeting terminated with the usual votes of thanks.

The summer meeting this year will be held in Belgium, commencing on Monday, the 20th August, when members will assemble in Brussels. The meeting will extend until the following Friday, so as to give members an opportunity to travel home on the Saturday.

THE ROYAL SOCIETY'S CONVERSAZIONE.

THE first (or gentlemen's) soirée of the Royal Society took place on the evening of May 2, in the Society's rooms at Burlington House. There were numerous exhibits, and it will be seen from the following summary that most branches of science contributed evidences of progress.

Prof. Hunter Stewart and Mr. Henry Cunynghame exhibited apparatus for micro-photography.

Experiments in persistence of vision were shown by Mr. Eric S. Bruce.

Mr. J. Theodore Bent exhibited antiquities and anthropological objects from the Hadramoot, Southern Arabia.

Two models of the South Lodge Camp, Rushmore Park, Wiltshire, an entrenchment of the Bronze age, before and after excavation, with the relics therefrom, were shown by General Pitt-Rivers ; and also two models of the Handley Hill entrenchment before and after excavation, on the same scale as the South Lodge Camp, with the relics therefrom.

New Dicynodont reptiles from South Africa were exhibited by Prof. H. G. Seeley ; and a skull of Deuterosaurus.

Mr. Richard Kerr showed an ovate palæolithic implement and two molar teeth of *Rhinoceros tichorhinus*, found by him in brick-earth at St. John's-road, Radnor Park, Folkestone, in August 1893.

Chemistry was represented by Dr. J. H. Gladstone's exhibit of early specimens of partly soluble cotton xyloidin, and of Austrian gun-cotton for military purposes. In 1847 the exhibitor prepared xyloidin from starch and from cotton. His specimens have all spontaneously decomposed, except those shown, which are mixtures of the soluble cotton xyloidin and ordinary gun-cotton.

Some maps and plans which accompany the Report on Nile Reservoirs, recently published by the Egyptian Government, were exhibited by Prof. J. Norman Lockyer.

Mr. J. Wimshurst exhibited models showing an improved method of communication between shore stations and light-ships, or other like purposes.

Mr. R. E. Crompton showed an electrically heated altar and electrically heated soldering bits for soldering and brazing ; and a potentiometer, to measure electromotive forces, from ·0001 to 1500 volts, correctly to 1/2000 ; and Sir David Salomons showed some new phenomena in "vacuum tubes."

Mr. Owen Glynne Jones exhibited his absolute and relative viscosimeters.

Prof. Roberts-Austen's exhibit comprised an ink-recording pyrometer, consisting of a thermo-junction of platinum and platinum iridium attached to a dead beat galvanometer, and a series of pyrometric curves obtained by photographic recorders in different iron works, and showing the temperature of the hot blast used in smelting iron.

Mr. A. E. Tutton exhibited an instrument of precision for producing monochromatic light of any desired wave-length, and an instrument for grinding section-plates and prisms of crystals of artificial preparations accurately in the desired directions. (Both these instruments are described in NATURE, vol. xlix. p. 377.)

Dr. Karl Grossmann and Mr. J. Lomas exhibited crystals of ice (hexagonal hopper) and photographs.

Dr. Karl Grossmann showed some specimens of Obsidian from Iceland. The specimens were brought by the exhibitor from the Hrafntinnuhryggur in Iceland (N.E.) The large specimen showed *conchoidal fracture*, evidently produced on falling from a cliff. The smaller specimen shows *flow structure*.

A twin-elliptic pendulum and pendulum figures were exhibited by Mr. Joseph Goold ; and a glass model, showing a method of transmitting force by spheres or discs, by Mr. Killingworth Hedges.

An exhibit which attracted much attention was M. Moissan's electric furnace, and specimens of chemical elements obtained by means of it : vanadium, chromium, molybdenum, tungsten, uranium. The furnace consists of a parallelopiped of limestone, having a cavity of similar shape cut in it. This cavity holds a small crucible, composed of a mixture of carbon and magnesia. The electrodes are made of hard carbon, and pass through holes cut on either side of the furnace, meeting within the cavity. For the purpose of certain experiments a carbon tube was fixed in the furnace at right angles to the electrodes, and so arranged as to be 10 mm. below the arc, and about the same distance from the bottom of the cavity. This tube contains the material to be heated, and by inclining it at an angle of about 30° the furnace may be made to work continuously, the material being introduced at one end of the tube and drawn off at the other. A temperature of about 3500° C. is produced. The metals are reduced by heating a mixture of their oxides with finely divided carbon, and for this purpose a current of about 600 ampères and 60 volts is employed. M. Moissan has not only succeeded in reducing the most refractory metals, but has fused and volatilised both lime and magnesia. Nearly all the metals, including iron, manganese, and copper, have also been vapourised, whilst by fusing iron with an excess of carbon, and then quickly cooling the vessel containing the solution of carbon in molten iron by suddenly plunging it into cold water, or better into a bath of molten lead, he has been successful in producing small colourless crystals of carbon, identical in their properties with natural diamonds.

A new harmonic analyser was exhibited by Prof. Henrici. This analyser differs from that shown last year by an improved integrating apparatus. The maker, Herr G. Coradi, of Zürich, has introduced a glass-sphere, whereby all *slipping* has been avoided, and greater compactness has been obtained. The instrument exhibited gives only one term (two coefficients) in Fourier's expansion at a time, but on going six times over the curve to be analysed as many terms can be obtained. There is no difficulty in introducing more integrators in the same instrument, and one has been made which gives five terms on going once over the curve, and ten in going twice over it.

Callendar and Griffiths' long distance direct-reading electrical thermometers and pyrometers were shown by Mr. E. H. Griffiths ; and a torsional ergometer or work-measuring machine, used in connection with a mechanical integrator and as an electrical governor, by the Rev. F. J. Smith.

Mr. Henry Wilde showed his magnetarium for reproducing the phenomena of terrestrial magnetism and the secular changes in its horizontal and vertical components, and a magnetometer for showing the influence of temperature on the magnetisation of iron and other magnetic substances.

Polyphase electric currents were illustrated by Prof. Silvanus P. Thompson, with models and experiments.

The Marine Biological Association contributed living pelagic larvæ, &c., from Plymouth, examples of the echinoderm fauna of Plymouth, and a hybrid between brill and turbot.

Mr. Henry A. Fleuss showed a mechanical pump for the rapid production of very high vacua, and vacuum tubes exhausted by it; and Mr. H. N. Dickson his charts and sections showing the temperature of the water in the northern and western parts of the North Sea and the Faroe-Shetland Channel at all depths, August 1893.

Dr. H. R. Mill and Mr. Edward Heawood exhibited bathymetrical maps of Windermere, Ullswater, Coniston Water, Derwentwater and Bassenthwaite, Buttermere and Crummock, Ennerdale Water, Wastwater and Haweswater. Contour lines at each 25-feet of depth beneath the surface were shown, and the configuration of the basins was thus for the first time accurately delineated.

Prof. J. Norman Lockyer exhibited photographs of stellar spectra taken with a 6-inch objective prism of 45°, and photographs of the great sun-spot of February 1894, taken at Dehra Dun.

Living larvæ influenced by the colours of their surroundings were exhibited by Prof. E. B. Poulton; and microscopic slides illustrating the behaviour of the nucleus during spore formation in the hepaticæ, by Prof. J. B. Farmer.

Photographs of diffraction and allied phenomena were exhibited by Mr. W. B. Croft. The photographs showed Newton's rings, reflected and transmitted; Grimaldi's fringes; Fresnel's interference from a bi-prism; Arago's shifting of bands towards the denser medium; Talbot's bands. The shadows of needles, wire gauze, perforated zinc, a screen with circular holes, opaque circular screens with Arago's bright centre. A comparison of the diffraction of Fresnel with that of Fraunhofer and Schwerd; the diffracting object consists of groups of small circles of light. Uniaxal and biaxal crystals; conical refraction.

Specimens demonstrating some phenomena of chemiotaxis in inflammation were exhibited by Mr. W. B. Hardy and Dr. A. A. Kanthack.

Prof. Marshall Ward showed apparatus employed for observing and measuring the growth of bacteria, fungi, and other micro-organisms under different conditions under the microscope. The essential feature is the culture-cell. It has a quartz floor, and is capable of holding large quantities of water, and thus while letting the light-rays pass does not rapidly vary in temperature. By the side of the culture-cell containing the hanging-drop in which is the organism under observation, is an exactly similar cell, but with a small thermometer in it, the blackened bulb of which is in the cell, and gives the temperature *inside* the latter. The rest of the apparatus consists in the measuring eye-piece; the screens of coloured glass, various liquids, &c., for growth in different kinds of light; and a warm chamber in which the whole microscope can be enclosed and kept at known temperature.

A demonstration of the trails of Oscillatoriæ formed the exhibit of Mr. J. G. Grenfell.

Prof. E. Waymouth Reid exhibited microscopic specimens illustrative of the process of secretion in the skin of the eel. The chief point of general interest in the process is the peculiar manner in which the surface of the skin is cast off when the animal is stimulated.

Prof. G. B. Howes exhibited eggs and young of *Ceratodus Forsteri*, and a male of *Lepidosiren paradoxa*.

Mr. E. J. Allen showed nerve elements from the ganglia of lobster embryos; and Dr. D. Sharp a collection of white ants (*Termitidæ*).

A specimen and drawing of the South American mud-fish, *Lepidosiren paradoxa*, was exhibited by Prof. E. Ray Lankester. See NATURE, vol. xlix. p. 555.

Dr. Alexander Muirhead exhibited a new form of Lord Kelvin's siphon recorder, Muirhead's artificial cable, and Muirhead's automatic curb transmitter. Lord Kelvin's siphon recorder and Muirhead's automatic curb transmitter were shown in operation in connection with an artificial cable of the same capacity and conductor resistance as the Atlantic cable, which is to be laid next July by the Anglo-American Telegraph Company. Capacity of artificial cable 800 microfarads; resistance of conductor 3350 B.A. units.

Demonstrations by means of the electric lantern took place during the evening, Dr. D. H. Scott showing photographs from sections in Dr. W. C. Williamson's collection, illustrating the microscopic structure of fossil plants from the coal-measures. The lantern was also used by Prof. E. B. Poulton, who exhibited illustrations of recent work upon the influence of environment upon the colours of certain Lepidopterous larvæ. Variously coloured twigs and shoots, such as occur in nature, have been shown to influence the appearance of many twig-like larvæ in such a manner as to conceal them. During the summer of 1893 certain larvæ of two species (*Gastropacha quercifolia* and *Otontoptera bidentata*) were surrounded, during their growth, with lichen-covered twigs. Larvæ thus treated developed lichen-like marks upon the body.

THE RELATIVE SENSITIVITY OF MEN AND WOMEN AT THE NAPE OF THE NECK (BY WEBER'S TEST).

THE difference in the sensitivity of the two sexes has been discussed often and from various points of view, but still, as it would seem, upon insufficient data. More observations being wanted, I submit the following, partly for such value as they have in themselves, partly to show an easy method of observation which others may pursue with advantage, and partly as a good illustration of the method of percentiles, or centiles.

The test employed is one of a familiar kind, made with the points of a pair of compasses, and usually associated with the name of Weber. If one person becomes just conscious of the doubleness of the pricks when the distance between the points is a, and another person does so when the interval is b, then the ratio of a to b may fairly be taken to express the relative obtuseness of the two persons, so far as concerns the form of sensitivity tested, and the inverse ratio of b to a to represent its relative delicacy. The particular test used was one that has three especial merits: it requires no minuteness of measurement, no uncovering, and the person tested is unable to see the operation. It consists in pressing the points of the compasses against the nape of the neck and across the line of the spine, while the experimentee sits with his or her head bowed forward. The just-perceptible interval at the nape of the neck averages as much as half an inch or thereabouts, while its variation in different persons is large. Consequently there is no need for extreme delicacy of measurement, neither does the varying thickness of cuticle caused by various degrees of usage, interfere materially with the results, as it does when like experiments are made, as is usual, on the finger-tips. The varying delicacy of perception due to differing amounts of practice is here entirely eliminated, because all persons are equally unpractised, no one occupying himself or herself in attempts to discriminate between two simultaneous pressures on the nape of his or her neck, while everybody has life-long practice in discriminating roughnesses, though in various and unascertainable degrees, with his or her finger-tips. There are parts of the body, such as the back, which are still less discriminative than the nape of the neck, but there is no other equally suitable part that is so get-at-able, in respect to the the ordinary dress of man or woman. Lastly, the attitude of the person who is being tested, entirely precludes him from watching the operator, and guessing from the hands or movements of the latter, whether he is applying two points, or only one, at the moment when he asks what is felt. The observations were all made by Sergeant Randall, who superintends my laboratory; he employed the two points of a Flower's craniometer, which was handy for use, as it was wanted to make other measurements of the same persons. The observations were carried on for some months, until a sufficient number had accumulated to justify discussion. Stature was included among them, but, failing on examination to trace any notable relation between stature and the just-perceptible interval on the nape of the neck, I have disregarded stature altogether in the following summary, and age too, so far that the person tested was often not fully grown.

The observations made on males and females, respectively, are summarised in the first and third lines of Table I. Their sums, reckoned in each case from the beginning of the series, are entered in lines 2 and 4, while the percentages of those sums are given in lines 3 and 6, but solely for the purpose of graphic projection in the form of dots, in Fig. 1. Those dots are joined by straight lines, forming traces for the males and females respectively. The lengths of the ordinates to the traces, which are drawn at the 10th, 20th, &c. divisions of the base, are the 10th, 20th, &c. percentiles, or centiles; or, in still briefer language, the 1st, 2nd, &c. "deciles." Their values, obtained by simple interpolation from the entries in lines

1 and 2 of Table I., are entered in Fig. 1. Thus 13·8 millimetres is the just-perceptible interval of the median man, and 11·8 that of the median female. In one sense, but only in an imperfect one, the relative sensitivity of the two sexes is given by these figures as being about 7 to 6. Much more has, however, to be specified before the relation can be adequately expressed, because it is obvious from the diagram, that what is true for persons having medium sensitivity, is not true for those having high, and still less for those having low, sensitivity. We are, however, able to specify what is wanted very compendiously, because both of the traces conform fairly well to the law of frequency of error, at least between the limits of the 1st and the 9th decile. In the case of males, the median is taken at 3·50 millimetres, and the q (= half the difference between the two quartiles, a value which is identical with that of the ± *probable error* of a single observation) at 3·25; in females, the corresponding values are 2·00 and 3·70. A somewhat nearer approximation to the observed values could be obtained by closer attention to the second decimals, but such minuteness is uncalled for in a case like this. It will be seen from columns B, C, and *b*, *c*, in Table II., that the sums of the observed and calculated deciles closely accord, and that the differences between the several pairs of them, headed B—C and *b*—*c*, are as nearly alike as we have a right to expect. The calculated deciles, and the curves drawn through them, in Fig. 2, may therefore be accepted as a just rendering of what is more roughly indicated by the observations in Table I. and Fig. 1. In the following remarks reference will be made almost exclusively to the calculated values, but the results can and will usually be checked by reference to the observed ones, with which they tally sufficiently well.

TABLE I.

Summary of Observations of 932 Males and 377 Females, showing the number in whom a just-perceptible feeling of doubleness was given by the pressure of two points across the nape of the neck, and separated by the various intervals, as below.

—	5 and under.	6.	7.	8.	9.	10.	11.	12.	13.	14.	15.	16.	17.	18.	19.	20.	21.	22.	23.	24.	25 and above.	Total observed.

Sums	—	121·3	121·5	—	—	109·4	108·1	—

The average ratio between the sensitivities of the females and males is the same as that between the sums (or means) of columns C and *c* in Table II., namely as 125·5 to 108·1; or to speak more modestly, as no trust can be reposed on the minute precision of such values as these, the average delicacy of female discrimination between the two points is to that of the male, in a ratio that lies somewhere between 7 to 6 and 8 to 7, or thereabouts. It will be recollected that the former ratio was that between the median female and the median male.

The *variability* of the discriminative power appears from the observations to be distinctly higher among females than among males. Measuring it in the usual way, by the half difference between the two quartiles, which is the same thing as the *probable error* of a single observation, or else by any multiple of this, as by the *mean* error, we find that the variability among females is to that among males as 3·70 to 3·25, say as 8 to 7. It is in consequence of this that so large a difference is shown between the relative sensitivity of the two sexes, at the right and left extremes of their respective curves in Fig. 2. We find from Table II. that the value of C—*c* at the 1st decile is 2·3 millimetres, and at the 9th decile it is only 0·7, the differences between the intermediate pairs decreasing regularly. The regularity of the decrease is not apparent in the actual observations, as shown in Fig. 1, nor in Table I., still there is nothing in what we see there that is incompatible with Fig. 2, while the fact of the difference between the right ends of the traces being much less than that between the left, is conspicuous.

Is it, however, a physiological fact that women are more variable than males in respect to discriminative touch, or are the observations affected by any extraneous cause of variability? I think that the recorded variability may in a very small part be accounted for by the fact that women vary much more than men in the exercise of sustained attention. Carelessness would affect the results in the same direction as diminished sensitivity. Thus suppose one part of a large number of persons who were all really alike in sensitivity, to be very careless, and the remainder to be scrupulously careful; the minds of the careless would be apt to wander; they would then fail to notice the first just-perceptible sense of doubleness, and would appear, in consequence, to be more obtuse than the careful ones. Though the range of variability was in reality *nil*, the existence of carelessness would introduce variability into the records. Some women are religiously painstaking, as much so as any men; but the frivolity of numerous girls, and their incapacity of, or unwillingness to give, serious attention, is certainly more marked than among men of similar ages. Women may, however, be really more variable than men in respect to sensitivity, because they seem more variable in a few other respects, such as in stature and obesity. Many more very tall girls are to be seen now-a-days among the upper classes than formerly, but the run of the statures among men has not altered quite so much. The multitude of extraordinarily obese women who used to frequent Vichy for the cure of fatness, were wonderful to behold; but they are no longer to be seen in their former abundance, as the fashion of treatment has changed within recent years. Again, it appears that women vary much more widely than men in respect of their morality; to which assertion I would quote Tennyson as a corroborative witness, who writes as follows, in Merlin's soliloquy on the character of Vivien:

> "For men at most differ as heaven and earth,
> But women best and worst as heaven and hell."

Since Fig. 2 is true to scale, it is easy to utilise it for ascertaining the class-place of any man or woman in respect to the form of sensitivity now in question. The whole process would be as follows:—Take a pair of compasses, and find with them by experiment the just-perceptible interval across on the nape of the neck of the person tested; then apply the compasses, to Fig. 2, keeping one (the lower) of its points always on the base line of the Fig., and holding the compasses so that the line joining its points shall be perpendicular to that base line. Slide the lower point of the compasses along the base line until the upper point touches the male or female trace, as the case may be; then read off the grade at which the lower point stands on the base line. Suppose it to be 35; we thereby learn that 35 per cent. of the same sex have more sensitivity than the person tested, and that 65 per cent. have less. Similarly for any other value.

It would, I think, be well worth the while of an inquirer to repeat these tests, to revise my results, and to pursue the subject much further. If any one should feel disposed to do so, I would suggest that he should make his measurements with the cheap form of bow compasses, in common use by carpenters. The legs are connected not by a joint, but by a spring which tends to separate them, and they are brought together to any desired interval by turning a screw with the finger and thumb, which overcomes the spring. The interval between the points could easily be measured on a separate scale; all the more easily, if there were a slight depression at the zero point of the scale, in which one leg might be securely rested.

FRANCIS GALTON.

THE RELATION OF MATHEMATICS TO ENGINEERING.[1]

MATHEMATICS has been described in this room as a good servant but a bad master. It will be my duty this evening to prove by suitable illustration the first half of the proposition, and to show the service mathematics has rendered and can render to engineers and engineering.

In our charter the Institution of Civil Engineers is defined as "A society for the general advancement of Mechanical Science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a Civil Engineer, being the art of directing the great sources of power in nature for the use and convenience of man, as the means of production and of traffic in states both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation and docks, for internal intercourse and exchange, and in the construction of ports, harbours, moles, breakwaters and lighthouses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adaptation of machinery, and in the drainage of cities and towns." No better definition can, I think, be found for our profession than that it is the art of directing the great sources of power in nature for the use and convenience of man. It covers all that the widest view of our work can include, and it excludes those applied sciences, such as medicine, which deal with organised beings. Mathematics has to deal with all questions into which measurement of relative magnitude enters, with all questions of position in space, and of accurate determination of shape. Engineering is a mathematical science in a peculiar sense. Medicine, the other great profession of applied science, has but little to do with questions of measurement of magnitudes, or of geometry; but the engineer finds them enter into everything with which he has to deal, and enter in the most diverse ways. The thing he has to determine is that the means he employs is enough and not unnecessarily more than enough to attain the end in view. For this he must numerically measure the end and the means and see that they are justly proportioned to each other. It is useless this evening to waste time proving, what all will admit, that no one can be even the humblest engineer without a knowledge of arithmetic and enough of geometry to enable him to read a drawing, that some trigonometry, some rational mechanics and a knowledge of projections, is a very useful part of the mental equipment of a draughtsman. It is hardly necessary to call attention to the great economy in the labour of calculations effected by the use of logarithms, a mathematical instrument for which we are indebted to Napier. We may with more profit examine what use the higher mathematics can be to the practical engineer, and what has been done in the past for engineering by its aid.

Judging from etymology, mathematics must have been begun by engineers; for surely geometry is the work of the earth measurer or land surveyor. But since the prehistoric times when geometry was initiated, engineers have not added much that is new to mathematics. They have rather sought amidst the stores of the mathematician and selected the handiest mathematical tool they could find for the particular purpose of the moment, but have done little or nothing in return in the way of improving the tools which they borrow. In this respect the relation of engineering to mathematics differs much from its relation to experimental physics. In electricity, magnetism and heat, engineers have from their practical experience repeatedly corrected the ideas of the theorists, and have started the science on more accurate lines. If our subject to-night had been the use of the practical applied science of engineering in promoting the development of pure mathematics, we should speedily find that there was hardly any material for discussion. The account being all on one side, let us see to what the debt of the engineer to the mathematician amounts.

There is no department of practical engineering in which the

[1] The "James Forrest" Lecture, delivered at the Institution of Civil Engineers, by Dr. John Hopkinson, F.R.S., on May 3.

application of mathematics is more familiar than in that which relates to the calculation of the strength and rigidity of structures of various kinds. It is impossible to take up any book dealing with the subject without finding that it is crammed either with mathematical formulæ, or with geometrical figures. The question is not whether mathematics is necessary to an adequate comprehension of the subject, but whether analytical or purely geometrical methods are more convenient. Of course one might occupy many lectures in discussing the practical application of mathematics to the question of bridge building, roofs, guns, shafting, and the like. Our object must be to illustrate by various examples rather than to attempt anything like a complete discussion.

Consider the case of a long strut, so long that its transverse dimensions can be regarded as insignificant in comparison with its length. Whilst the strut remains perfectly symmetrical about its middle line, its strength will depend only upon the resistance of the material to crushing. Everyone knows that this would be an inadequate conclusion; we have to consider another element, namely, its stability, that is, we must examine what will happen to the strut if from any cause it is displaced somewhat from the direct line between its extremities. A mathematical discussion of the question results in a differential equation of the second order with one independent variable. Upon consideration of this we are enabled to see that if the thrust upon the strut be less than a certain critical value, a slightly bent strut will tend to return to its straight condition; but that if the thrust upon the strut be greater than this critical value the displacement will tend to increase, and the strut will give way. Further, that the critical value will depend upon whether one or both of the two extremities of the strut are held free, or whether they are rigidly attached by flanges or otherwise, so that the direction of the axis of the strut at this point must remain unaltered. Again, we infer that if the ends are held rigidly fixed, the length of the strut may be twice as great for a given critical value of the thrust as if the two ends are free to turn. We can also infer what the critical value will be for struts of various lengths and of varying cross sections. This critical value depends not upon the resistance of the material to crushing, but upon its rigidity.

Another example, having a certain degree of similarity with the case of struts, is that of a shaft running at a high number of revolutions per minute, and with a substantial distance between its bearings; for simplicity, we will suppose that there are no additional weights, such as pulleys, upon the shaft. How will the shaft behave itself in regard to centrifugal force as the speed increases? In this case, so long as the shaft remains absolutely straight it will not tend to be in any way affected by the centrifugal force, but suppose the shaft becomes slightly bent, it is obvious to anyone that if the speed be enormously high this bending will increase, and go on increasing until the shaft breaks. In this case also we may use mathematical treatment; we find that the condition of the shaft is expressed by a differential equation of the fourth order, and from consideration of the solution of this equation we can say that if the speed of any particular shaft be less than a certain critical speed, the shaft will tend to straighten itself if it be momentarily bent, but that, on the other hand, if the speed exceeds this critical value, the bending will tend to increase with the probable destruction of the shaft. I do not know that either of these two questions can be properly understood without some knowledge of differential equations.

A problem having a certain analogy to those to which I have just referred is that of hollow cylinders under compression from without, such as boiler tubes. Whether the tubes be thick or thin, so long as they are perfect circular cylinders, they should stand until the material was crushed. But if the tubes are thin, what will happen if the tube from any cause deviate ever so little from the cylindrical form? The solution cannot be obtained without a substantial quantity of mathematics.

The next illustration shows how a mathematical conclusion, correct within the limits to which it applies, may mislead if applied beyond those limits, and how a more thorough mathematical discussion will give a correct result. Considering a case of shafting in torsion it was shown by Coulomb that the stiffness and strength of a shaft having the form of a complete circular cylinder could be readily calculated if the transverse elasticity of the material and its resistance to shearing were known. From the complete symmetry about the axis it is evident that points which lie in a plane perpendicular to the axis before twisting will still be in that plane when the shaft is twisted; it is also clear that the angle through which all points in the same plane move will be the same; hence the problem was as simple as problem could be. But many who had occasion to make use of Coulomb's results gave them an application which was wholly unwarranted. They assumed that they were equally applicable to other cases than complete circular cylinders; they assumed in fact that every point of the material which lay in a plane perpendicular to the axis would remain in that plane when the shaft was twisted, whether the shaft was symmetrical about its axis or not, and they consequently arrived at very erroneous results. That the assumption was erroneous is obvious enough from a consideration of an extreme case. In Fig. 1 is shown in cross-section a hollow cylindrical shaft, which is not complete, but divided by a plane passing through its axis. In this case the shaft when twisted will be as illustrated in the side elevation; two points, A and B, were in one plane perpendicular to the axis when the shaft was free from twist; they cease to be in one plane when the shaft is twisted. St. Venant[1] in 1855 investigated the question of shafts without making incorrect assumptions; he expressed the condition of the material by a partial differential equation of the second order, and gave suitable surface conditions. A general solution of the problem for all forms of shafts has not been obtained, but St. Venant gives a number of solutions for particular forms, and he obtains some general results of interest. In all cases the stiffness of the shaft is less than would be inferred from an erroneous application of Coulomb's theory. Fig. 2 shows diagrammatically the strain in a shaft of triangular section; the full lines indicate that the parts of the shaft which lay in one

FIG. 1.

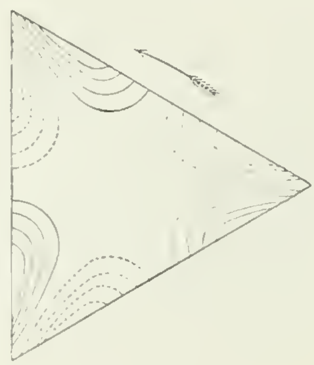

FIG. 2.

plane before twisting when twisted rise above the plane; the dotted lines indicate that they lie behind the plane of the paper. The shearing stress is least at the angles of the triangle, and is greatest at the middles of the sides. At this point then the shaft will begin to break under torsion. The fact is probably well known to men of practical experience, but it is directly contradictory to the conclusion at which one would arrive by a careless use of Coulomb's theory beyond the narrow limits within which it is applicable. The longitudinal ribs which one often sees on old cast-iron shafts are useful enough to give stiffness to the shafts against bending, but are good for very little if torsional stiffness or torsional strength is desired.

Another application of mathematical theory which has been carried somewhat further than the premises warrant is found in the case of girders. It is almost invariably customary to treat a girder as though the sections retain when the girder is bent the form and size which they had before bending. Making this assumption, it is very easy to calculate the strength and stiffness of a girder of any section. Unfortunately, the assumption is untrue; but, fortunately, it is approximately true in the case of most girders with which engineers in practice have to deal. That it is untrue can be readily seen from consideration of a girder of exaggerated form, the section of which is shown in Fig. 3. Any practical man would at once see that the outer parts of the flanges would add little to the strength of the girder, but according to the usual mathematical theory the outer parts of this flange should be as useful as the parts which are nearer to

1 "Memoires des Savants Étrangers," 1855; and Thomson and Tait, "Treatise on Natural Philosophy."

the web. This problem St. Venant also deals with in a rigid mathematical manner. Amongst other things, he showed that a girder of rectangular section, such as shown in Fig. 4, would, when bent, take the form shown by the curved lines in the same Fig. The last two examples show how a little knowledge may be a dangerous thing and how easy it is for anyone who attempts to apply mathematics without adequate mathematical knowledge to be misled.

The theory of thick cylinders under bursting stress from within has many important practical applications to hydraulic presses and to guns. It has been discussed more than once in this room. As usual in considering these cases we are immediately led to differential equations which here are fortunately solved without serious difficulty, and the solution tells us the whole story. We learn that doubling the thickness by no means doubles the strength of the cylinder. And as a converse, that doubling the

Fig. 3.

strength of the material will permit the thickness to be diminished to much less than one-half. Twenty-five years ago hydraulic presses were mostly made of cast-iron. Many people were not a little astonished at the great reduction in thickness and weight which became possible when steel was substituted for the weaker material. In the case of guns it is well known that greater strength can be obtained if the outer hoops are shrunk on to the inner ones.[1] Mathematical theory tells us what amount of shrinkage should give the best results. It may possibly not be worth while to follow the results of theory precisely, but without the guidance of theory it would not be unnatural to give so great a shrinkage that the gun would be weaker than if no shrinkage were used.

The rolling of ships in a seaway gives an illustration of a principle which has very varied application in many branches of physics. Suppose a body is capable of oscillating in a certain periodic time, and that it is submitted to a disturbing force of

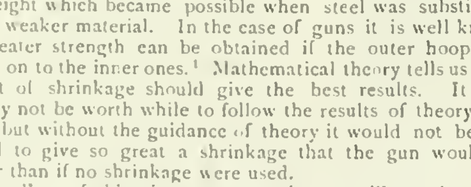

Fig. 4.

given period, the equation of motion easily shows that the resulting disturbance will be great if the two periods are equal or nearly equal. We meet with the principle in acoustics as resonance. If two tuning-forks are tuned to the same pitch, and one is sounded in the neighbourhood of the other, that other will presently be thrown into vibration by the waves transmitted through the air from the first. You may try a similar experiment at any time on any piano. Strike the higher G in the treble, the sound ceases on raising the finger. Now hold down the middle C, and again strike G; the C string at once takes up the note sounded, and can be heard after the exciting string has been silenced by damping. The same fundamental idea is found in the lunar theory in the term in the equation known as the evection, and again in the theory of Jupiter's satellites. The reason why the metals present in the solar atmosphere give black lines in the spectrum by absorption, corresponding in position with the bright lines in the spectrum which the same metals give when incandescent, is again the same. Gas will absorb or take in from the ether waves of the exact period which it is capable of giving to the ether. The general explanation of all these phenomena is easy. Imagine a pendulum, and suppose it experiences a periodic disturbing force, the first impulse of the disturbing force gives the pendulum a slight swing; the effect of the second impulse depends entirely on when it occurs; it may occur so as to neutralise the effect of the first, or it may occur so as to increase it. If the period of the force is the same as the natural period of the pendulum, the effect of the second, third, and later impulses will be added to the effect of the first, and the final disturbance will be great, even though the individual impulses be minute. But the mathematical theory tells us much more than any general explanation can do. It tells us exactly what the character of the effect will be, and its amount if the periods are nearly but not exactly the same. It tells us, too, exactly how friction affects the results. And the beauty of it is that the mathematical theory is much the same in all cases, so that having learned to deal with one case we are enlightened as to a host of others. The oscillating body may be an iron-clad, or it may be an atom of hydrogen; the disturbing periodic force may be the waves of the Atlantic, or it may be the waves in the ether occurring five hundred millions of millions of times in a second; it is all one to the mathematician; the treatment is substantially the same.

The question of the speed of ships and the power to propel them is probably more effectually treated by experiment on models, as was done by the late Mr. Froude, than by mathematics alone; but in order to learn from the experiments all they are capable of teaching, a mathematical understanding is needed. Given that we know by experiment all about a given model, that we know what force is needed to propel it at every speed, we want to know from these experiments how a great ship, 100 times as big, but similar in form in every respect, will behave; and here mathematics come in to aid us in making the inference.

The construction of ships at once leads us on to the methods of navigating them. In navigation I should find much material for my purpose, but navigation is not usually included in engineering, but many of the implements of navigation undoubtedly are. The mariners' compass has for ages been the mainstay of the navigator, and a simple enough instrument it was till it was disturbed by the iron of which ships came to be built. The disturbance of the compass by the iron of the ship was first seriously attacked by two senior wranglers, Sir G. Airy and Mr. Archibald Smith. The disturbance may be divided into two parts, the first due to the permanent magnetism of the ship, the second to the temporary magnetism induced by the earth's inductive action on the iron of the ship—the first causes the semicircular, the second the quadrantal, error. One has only to open the "Admiralty Manual of Deviations of the Compass" to see how the mathematics of Archibald Smith have accomplished a proper understanding of the subject. The errors of the compass are dealt with in two ways: they are compensated by soft iron correctors, and by permanent magnets so placed as to have an effect equal and opposite to the effect of the temporary and permanent magnetism of the ship. Or they are dealt with by formulæ of correction which enable the error to be calculated when the course of the ship and the conditions of the earth's magnetism are given, or a combination of the two methods is used. Either method is based on Archibald Smith's theory. It is not possible to leave the subject of the mariners' compass without referring to the great improvements of Lord Kelvin. The improvements relate to every part of the instrument, and I venture to say that none of them could have been made by anyone but a mathematician. In order to get his card steady he knew that its period must be different to any possible period of the waves, or he would have the resonance to which I have just referred coming in, so he gave his card a considerable moment of inertia; but this was managed with a light card so that small needles could be used. If the needles are small the correction by soft iron masses and by permanent magnets is easier and more accurate. Then the bowl of the compass had to be suitably carried so that it would not be unduly disturbed by shock, and provision had to be made for damping by fluid friction the oscillations of the bowl if they occurred. Lastly, a most beautiful method of correcting the compass, without taking a sight, was discovered. In every detailed improvement one can detect that the inventing mind was that of a most able and trained mathematician.

An essential of safe navigation is an efficient system of light-

[1] Lamé, "Leçons sur la Théorie Mathématique de l'Élasticité des corps solides," 14th Leçon.

houses. The optical problem of the lighthouse engineer is to construct apparatus which shall usefully direct all the light produced. The present forms of apparatus are in their leading features due to Fresnel, the able mathematician, who established on an absolutely firm foundation the undulatory theory of light. To properly design an optical apparatus formulæ must be used, and the advantage is great if the designer can with ease manufacture the formulæ he requires.

Submarine telegraphy yields some interesting examples of the application of the higher mathematics. When a cable across the Atlantic was first seriously entertained, the first point to be settled was, how many words a minute could be sent through such a cable. This was the most practical question possible. Upon the answer depended the prospect of the cable paying commercially if successfully laid. The matter was dealt with by Prof. Thomson,[1] of Glasgow, now Lord Kelvin. He showed that the propagation of an electric disturbance in a cable could be expressed by a partial differential equation, and that the solution of this equation under certain conditions applicable to practice could be expressed either by a definite integral or by an infinite series. The values of these were calculated, and hence before an Atlantic cable was laid at all it was known how long it would take a signal to reach the opposite shore, and how much its intensity would be diminished in transmission. Referring to Fig. 5, abscissæ represent time, reckoned from the time of making contact at the sending end of the cable, ordinates the currents at the receiving ends, curve (1) gives these currents when the contact at the receiving end, after being made, is continuously maintained. It will be observed that for a time a there is hardly any current at the receiving end, that then the current rapidly increases and attains to half its final value after a time equal to about $5a$. Curves (1) . . . . (7) show the currents at the receiving ends when the contact is made at the sending end maintained for times a, $2a$ . . . $7a$ respectively, and then broken. Looking at curve (1) one sees how small is the amount of current and how long it lasts compared with the time during which contact is made. The time a depends on the length and character of the cable; it is equal to $k c l^2 \log_e \frac{4}{3}/\pi^2$, where k is the resistance per unit length, c the capacity per unit length, and l the length of the cable. The knowledge of what is the commercial value of a cable depends on a knowledge of the value of a, and this cannot be obtained without knowing the differential equation $c\,k\,\frac{dv}{dt} = \frac{d^2v}{dx^2}$,[2] to which I have referred, and its by no means simple solution either as a definite integral or as an infinite series. So far as I know, this piece of higher mathematics cannot be evaded by any mere elementary treatment. The transmission of disturbance in a cable is quite different from the transmission of sound waves in air, which move with constant velocity. If the cable be doubled in length, it takes four times as long for the signal to pass through it instead of just twice as long, as would be the case if it were a proper wave motion. In fact the time of passage between the making of contact at the sending end of the cable and the beginning of the resulting disturbance at the receiving end, varies as the square of the length of the cable. The mathematical theory is exactly the same as that of the transmission of heat in a plate, one surface of which is suddenly exposed to a temperature different to the temperature of the plate. This is constantly occurring in the application of mathematics—one piece of mathematical work serves for many physical problems having apparently little in common. Fourier long ago discussed the heat problem, little dreaming that his analysis would be just what was wanted for ascertaining how fast signals could be sent across the Atlantic by a system of telegraphy which in his days had not even been projected in its simplest form. The same differential equation also gives the theory of the transmission of telephonic messages through cables; but the solution is then easier, and tells us exactly why it is so much more difficult to speak through 100 miles of cable than through 1000 miles of overhead line. As I have just stated, the differential equation of the disturbance in the cable is $c\,k\,\frac{dv}{dt} = \frac{d^2v}{dx^2}$. A musical note of period T spoken into the cable through a telephone is properly represented by $A \sin \frac{2\pi t}{T}$; the disturbance in the cable will be—

$$v = A\, e^{-x\sqrt{k c \pi / T}} \sin\left(\frac{2\pi t}{T} - x\sqrt{k c \pi / T}\right),$$

as may be easily verified by differentiating. This equation tells us everything. It tells us the rate at which the waves diminish with the distance. This rate increases with the resistance, with the capacity and with the frequency. If the capacity is at all considerable the diminution is rapid. The velocity of the waves is not the same for all frequencies, as is the case with waves in air, but varies as the square root of the period, so that if two notes were sounded the high note would arrive after the low notes, and the resultant effect would be entirely destroyed. Here, again, it is difficult to see how the differential equation and its solution can be evaded.

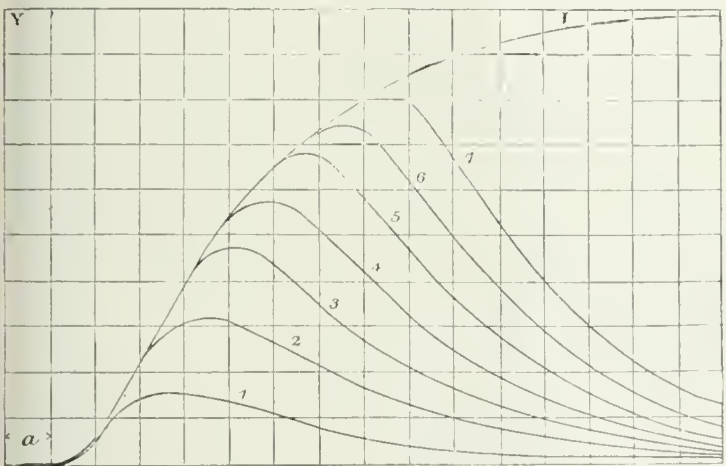

Fig. 5.

Though the history of the telegraph dates only from a little more than fifty years ago, it is ancient in comparison with the other great applications of electrical science, which have received their development during the last fifteen years. Here again mathematics which are not quite elementary have played their part. In the theory of transformers we find another illustration of the need of knowing how formulæ are obtained if they are to be correctly applied. The early transformers were made with unclosed magnetic circuits; there was an iron core, but the lines of magnetic force passed through air for a considerable part of their path. In this case a complete mathematical theory was not very difficult. But speedily closed magnetic circuits were found to be better, and the relation of magnetic induction and magnetic force became all important. If anyone were to apply mathematical formulæ, which were true for the earlier transformers, to the later ones, his results would be inaccurate. Indeed a wholly different method of attack on the problem was needed, taking account of the facts as they are, and not applying results which were true of older apparatus to cases essentially distinct.[1]

The employment of alternating currents has brought into use, as a necessity for understanding the actually observed phenomena, a great deal of mathematics. Why is the apparent resistance of a conductor greater for an alternating current than for a direct current? And by resistance I do not mean the quasi-resistance due to self-induction.[2] The mathematical electrical theory is ready with an answer; it is ready, too, to tell us how the difference depends upon the frequency of the current and on the size of the conductor. In the case of a cylindrical conductor

[1] "Mathematical and Physical Papers," vol ii. p. 61. Sir W. Thomson.
[2] v is the potential, t the time, and x the distance from the sending end of the cable.

[1] *Proceedings* of Royal Society, February 17, 1887.
[2] Lord Rayleigh, *Phil. Mag.*, vol. xxi. p. 381.

the solution involves a knowledge of Bessel's functions. We learn that if the current has a high frequency, or if the conductor be large, there will be very little current in the centre of the cylinder, and that therefore for any practical purpose the centre of the cylinder might just as well not be there; the current is largely confined to the part of the conductor near to its surface. The currents at different depths in the conductor attain to their maximum values at different times; those near the surface of the cylinder occur before those at some distance from the surface. The mathematical conditions are expressed by the same equation as is used to express the disposition of heat in a cylinder the surface of which is submitted to a periodic variation of temperature. Anyone who had thoroughly mastered the heat problem would be quite prepared to deal with the problem of currents in a conductor. It cannot be too often repeated, any piece of pure mathematics which finds one application to a physical problem is almost sure to find, in exactly the same form, applications to other problems which superficially are absolutely distinct. The differential equation in this case is $kc\frac{dv}{dt} = \left(\frac{d^2v}{dr^2} + \frac{1}{r}\frac{dv}{dr}\right)$, the similarity of physical condition to the problem of linear propagation of heat is close, but the mathematics differ materially owing to the presence of the term $\frac{1}{r}\frac{dv}{dr}$ in the equation. Mathematics deals with the relation of quantities to each other without troubling as to what the physical meaning of the quantities may be. Hence it is that the mathematical treatment of two such problems as the distribution of currents in a cylindrical conductor and of heat in a cylinder is identical, whereas the treatment of the distribution of heat in a cylinder is quite distinct from the treatment of the distribution of heat in a sphere or in a solid bounded by two parallel planes.

A curious phenomenon was observed in the large alternate-current machines at Deptford when connected to the long cables intended to take the current to London. The pressure at the machines when connected to the conductors was, under certain conditions, actually greater than when not so connected. The phenomenon is one of resonance very analogous to the heavy rolling of ships when the natural period of roll is about the same as the period of the waves.[1] The period of the alternating current corresponds to the period of the waves, the self-induction of the machine to the moment of inertia of the ship, the reciprocal of the capacity to the stiffness of the ship, and the electrical resistance of the conductors to the frictional resistance to rolling. The mathematics in the two cases is then the same. The effect was predicted long before it was observed in a form calculated to cause trouble.

A problem which is still agitating electrical engineers is that of running more than one alternate-circuit dynamo machine connected to the same system of mains. Before the matter became one of practical concern, it was considered in this room, and it was shown mathematically that it was possible to run independently-driven alternators in parallel but impossible to run them in series. That is to say, that if two alternators were connected to the same mains they would tend to adjust themselves in relation to each other so that their currents could be added, but that if an attempt were made to couple them, so that their pressures should be added, they would adjust themselves so that their effects would be opposed.[2]

Perhaps of all engineering problems which have received their solution in the last hundred years that of the greatest practical importance is the conversion of the energy of heat into the energy of visible mechanical motion. The science of thermodynamics has advanced along with the practical improvement of the steam-engine. By its aid, particularly by the aid of the so-called second law, we know what is possible of attainment by the engineer under given conditions of temperature. I must not trench on the subject of one of my successors, but I may point out that our knowledge of the second law of thermodynamics was first developed by means of mathematics, and that to-day its neatest expression is by means of partial differential equations. The two most notable names in connection with the development of the second law of thermodynamics in harmony with the first are those of Kelvin and Clausius; both dealt with the subject in a mathematical form not comprehensible to those who have not had substantial mathematical training.

Illustrations such as these might be multiplied almost indefinitely. They show that the advancement of the science of engineering has been aided in no inconsiderable measure by the labours of mathematicians directly applying the higher mathematical methods to engineering problems. They show, too, one way in which respect for a formula may be dangerous, one way in which it is true that mathematics may be a bad master. In St. Venant's problems we have an example in which the use of older results of limited application in cases where the assumptions on which they rest are not true will mislead. The examples show the proper remedy; it is a more complete application of mathematical methods. The error is just one which a man will make who has the power to use a formula without a ready understanding of how it is arrived at. A practical man, ignoring mathematical results, might or might not escape the error of supposing that a triangular shaft would break at the angles under torsion; the half-educated mathematician would certainly fall into the snare from which complete mathematical knowledge would deliver him. You can only secure the services of that good servant, mathematics, and escape the tyranny of a bad master by thoroughly mastering the branches of mathematics you use. The mistake caused by the wrong application of mathematical formulæ is only to be cured by a more abundant supply of more powerful mathematics.

There is another drawback to the use of results, taken, it may be, out of an engineering pocket-book by those who are not prepared to understand how they are reached and on what foundations they rest. The educational advantage is lost. The close observation which enabled the earlier engineers to proportion their means to the ends to be attained was no doubt very laborious, and the results could not be applied to cases much different from those which had been previously seen, but the effect on the character of the engineer was great. In like manner, to thoroughly understand the theory of an engineering problem makes a man able to understand other problems, and in addition to this precisely the same mathematical reasoning applies to many cases. The mere unintelligent use of a formula loses all this; it leaves the mind of the user unimproved, and it gives no help in dealing with questions similar in form though different in substance.

But even the use of mathematics by competent mathematicians is not without drawbacks. Mathematical treatment of any problem is always analytical—analytical, I mean, in this sense that attention is concentrated on certain facts, and other facts are neglected for the moment. For example, in dealing with the thermodynamics of a steam-engine, one dismisses from consideration very vital points essential to the successful working of the engine, questions of strength of parts, lubrication, convenience for repairs. But if an engineer is to succeed he must not fail to consider every element necessary to success; he must have a practical instinct which will tell him whether the instrument as a whole will succeed. His mind must not be only analytical, or he will be in danger of solving bits of the problems which his work presents, and of falling into fatal mistakes on points which he has omitted to consider, and which the plainest, intelligent practical man would avoid almost without knowing it.

Again, the powers of the strongest mathematician being limited, there is a constant temptation to fit the facts to suit the mathematics, and to assume that the conclusions will have greater accuracy than the premises from which they are deduced. This is a trouble one meets with in other applications of mathematics to experimental science. In order to make the subject amenable to treatment, one finds, for example, in the science of magnetism, that it is boldly assumed that the magnetisation of magnetisable material is proportional to the magnetising force, and the ratio has a name given to it, and conclusions are drawn from the assumption, but the fact is, no such proportionality exists, and all conclusions resulting from the assumption are so far invalid. Wherever possible, mathematical deductions should be frequently verified by reference to observation or experiment, for the very simple reason that they are only deductions, and the premises from which the deductions are made may be inaccurate or may be incomplete. We must always remember that we cannot get more out of the mathematical mill than we put into it, though we may get it in a form infinitely more useful for our purpose.

Engineers no doubt regard their profession from very different

[1] [illegible] of [illegible] Engineers, November [illegible].
[2] [illegible] Inst. C.E., [illegible]; Institution of [illegible] Engineers, November 13, [illegible]

points of view; some think it a mere means of making money; some regard it as an instrumentality for benefiting the race; whilst others again delight in it as an interest in itself, and delight in it most of all when new knowledge is added to that which we know already. It is just the same with the medical profession; some attend patients for the guineas they receive, some give a very high place to motives of benevolence, whilst others love it as a field where new knowledge may be found and the delight of discovery enjoyed. In regard to the first class of engineers, I have no doubt a little skill in managing a board of directors or impressing a committee of Parliament will be much more useful to the engineer than a great deal of mathematics. Let him manage his board and buy his mathematician, and it is very probable he will make much more money than the mathematician or any other person of skill whom he may employ. But we cannot all of us make money in this way. In the future it is likely that educated men will have to work harder and receive less, and it is a great thing if their work can be made itself a joy, and surely this can best be by a thorough understanding of the reason of all they do by the feeling that they have full competence to form their own judgments without depending much on the authority of others. This can only be in the words of Sir John Herschel by a "sound and sufficient knowledge of mathematics, the great instrument of all exact inquiry, without which no man can ever make such advance in any of the higher departments of science as can entitle him to form an independent opinion on any subject of discussion within their range."

After all, in any department of applied or pure science the highest satisfaction comes from accomplishing that which no one has done before, from disclosing what no one hitherto has known. If a department of the arts or sciences ceases to advance and becomes simply the application in known ways of known principles to obtain known ends, that department has lost its charm till the time comes for a fresh advent of change and development. To effect such advances it is easy to show that mathematics is a most necessary instrument. Here it is no drawback that the mind of the discoverer is too analytical; he may deal at his pleasure with one aspect of a problem, and it does not detract in any way from the value of his solution that he does not touch on incidental matters. Some of you who love the interest of continual advance in our science and practice, may look forward with a shade of sadness to a possible time when all is done or known which can be done or known, and the work of the engineer shall be merely applying principles discovered by his predecessors. In such a state, when the experience of the older generations shall control the practice of to-day, the free use of mathematical methods may be effectually superseded by the application according to rule of mathematical formulæ. But it would be a much less interesting condition than the constant change of to-day, when the practical experience of ten years ago is in many departments rendered worthless by later discoveries. But we need not fear that such a time of petrifaction will come so long as, whilst reverencing the discoverers who have added to our knowledge, we endeavour to replace their methods by better, and expect that those who come after us will, in their time, improve upon ours. Our knowledge must always be limited, but the knowable is limitless. The greater the sphere of our knowledge the greater the surface of contact with our infinite ignorance.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—By a resolution of Congregation, the care of such portions of, as may seem desirable, the Lee collection of anatomical and physiological specimens, which have for many years past been placed in the University Museum under care of the Linacre Professor, may be transferred to the care of other Professors with the sanction of the Trustees of the Lee bequest.

The date of the preliminary examinations in natural science in the Michaelmas term has been fixed for the Monday in the eighth week in Full Term in lieu of the dates hitherto observed.

The resolutions proposed by the committee on the granting of degrees for research were brought before Convocation on Tuesday afternoon. The first resolution, affirming the general principle that it was desirable that such degrees should be established, was agreed to *nemine contradicente*. Some difference of opinion manifested itself in the discussion on the succeeding resolutions. That which suggested that the new degrees should be styled Master of Science and Master of Letters was rejected on a division, with the intention that the titles should be further considered by the committee. The remainder of the resolutions were agreed to, and the drafting of a statute embodying the recommendations of the committee was referred to a committee consisting of the Vice-Chancellor and twelve others.

The annual Boyle Lecture was delivered on Tuesday evening by Prof. A. MacAlister, who chose as his subject, "Some morphological lessons taught by human variations." The lecture, which is held under the auspices of the Junior Scientific Club, was largely attended.

Cambridge.—The new Engineering Laboratory, just completed under the supervision of Prof. Ewing, will be formally opened on May 15, at 3 p.m., by Lord Kelvin, President of the Royal Society. The Vice-Chancellor will preside, and it is expected that Prof. Kennedy and others will deliver addresses on the occasion. After the opening ceremony Prof. and Mrs. Ewing will be "at home" in the laboratory, in order to give members of the University an opportunity of seeing for themselves the provision that has been made for the scientific study of engineering.

The degree of Doctor of Laws will, on May 10, be conferred upon Dr. Carl Theodor von Inama-Sternegg, honorary Professor of Political Science in the University of Vienna, and President of the KK. Statistical Central-Commission of the Austro-Hungarian Empire. Prof. von Inama-Sternegg was President of the Demographic Section of the International Congress of Hygiene held in London in 1891, but was unable to visit Cambridge with the other members of the Congress for the purpose of receiving the degree.

At the same Congregation the complete degree of M.A. will be conferred on Prof. Ewing's able demonstrators, Mr. W. E. Dalby and Mr. C. G. Lamb, who are already Bachelors of Science of the University of London.

Mr. Oscar Browning, who is an officier d'Académie, will next month represent the University of Cambridge at the festal opening of the new Palais des Facultés of the Académie of Caen.

Dr. Hobson, F.R.S., has been appointed a syndic of the library, in the room of the late Prof. Robertson Smith.

A grant of £20 from the University chest has been made to Mr. H. Yule Oldham, University Lecturer in Geography, for maps and apparatus.

The growth of the botanical department under the direction of Deputy-Prof. F. Darwin, F.R.S., has led the General Board of Studies to recommend that his stipend as reader, and that of Mr. W. Gardiner, F.R.S., as lecturer, should be increased to £150 a year. An additional demonstratorship in botany is also proposed. The Board further recommend that the annual stipend of Mr. S. J. Hickson, as lecturer in Advanced Morphology, should be increased to £100.

The Natural Sciences Tripos, for which there are about 130 candidates, begins on May 23, and will extend to June 12.

The Convocation of the University of London met on Tuesday. It was expected that a warm discussion would take place on the Gresham scheme, but the expectation was not realised, as the chairman, Mr. E. H. Busk, ruled out of order all motions relating to that subject. One of these resolutions, standing in the name of Mr. Thiselton-Dyer, was—"That Convocation, while reserving its right to represent its views before the proposed Statutory Commission, hereby expresses its general approval of the Report of the Royal Commission." The *Times* reports that, when this and other motions had been ruled out of order, Prof. Silvanus Thompson moved the adjournment of the House. After some discussion an amendment to Prof. Thompson's motion—that the House should adjourn until seven o'clock—was accepted almost unanimously, the common object of all parties being to ascertain the result of the voting for the annual committee, for the election of which the two parties had their separate lists, one list consisting of those who were practically in favour of the Gresham scheme, and the other desiring to leave the whole question in the hands of the joint committee. The former party carried their whole list.

On the adjournment before the declaration of the poll a body of some 230 graduates met in the Graduates'-room of the University to draw up a protest against their having been again prevented from discussing the report of the Gresham Commission. Sir Henry Roscoe presided, and the speakers were Mr.

Thiselton-Dyer, Mr. Anstie, Q.C., Prof. Silvanus Thompson, Dr. Allchin, Sir Philip Magnus, Dr. R. D. Roberts, and Principal Cave. A resolution was unanimously passed in the following terms—"That this meeting of graduates, while reserving its right to represent its views before the proposed Statutory Commission, hereby expresses its general approval of the report of the Royal Commission." A second resolution expressed regret that, for the second time, discussion in Convocation of the report of the Gresham Commission had been prevented. Further, that an account of the proceedings at this meeting of graduates be prepared by the secretaries, and at once be transmitted to the Senate and to the press. A committee of graduates has been formed under the chairmanship of Mr. H. H. Cozens-Hardy, Q.C., M.P., for the purpose of obtaining from the graduates at large an expression of opinion in support of the scheme of reconstruction proposed by the Gresham Commission.

SOCIETIES AND ACADEMIES.

Paris.

Academy of Sciences, April 30.—M. Lœwy in the chair. —On the equilibrium of ocean waters, by M. Poincaré. A mathematical paper dealing with the theory of tides.—On the soil and climate of the island of Madagascar from an agricultural standpoint, by M. Grandidier. The author warns intending colonists of the comparative infertility of most of the soils in Madagascar, notwithstanding the apparently vigorous vegetable growth supported thereon, and points out the importance of meteorological conditions, which are peculiarly unfavourable in certain districts.—Digestion without digestive ferments, by M. A. Dastre. Fresh proteids (fibrin, albumin, &c.) undergo the same series of changes when subjected to the prolonged action of 10–15 per cent. solutions of ammonium or sodium chloride (or 1–2 per cent. sodium fluoride), as when acted on by gastric juice.—Observations of Gale's comet made at Nice and at Algiers, by M. Tisserand.—Elliptic elements of Denning's comet, 1894, by M. L. Schulhof.—Observations of the same comet made at Toulouse Observatory, by MM. E. Cosserat and F. Rossard.—A theorem concerning the areas described in the movement of a plane figure, by M. G. Kœnigs. If a finite arc AB of any curvature roll upon any arc of equal length successively on the two sides of this arc, the area swept by the radius IM joining the instantaneous centre to a point M on the arc AB is independent of the form of the arc AB.—On the lines of curvature of *surfaces cerclées*, by M. Lelieuvre.—On the analytical integrals of equations of the form

$$\frac{d^n z}{dy^n} = F(z), \; F(z) = \Sigma a_{ik} \frac{d^{i+k} z}{dx^i \, dy^k}, \; i + k < n,$$

by M. Delassus.—A note by M. Bendixon on a theorem by M. Poincaré.—On hysteresis and permanent deformations, by M. P. Duhem.—On a new method of determining critical temperatures by the *critical index*, by M. James Chappuis. The author employs the method of interference fringes for following the variation in the index of refraction of the substance examined. The critical temperature of carbon dioxide determined by this method is 31·40°, a number in substantial agreement with Amagat's determination 31·35.—On a new method for the determination of the lowering of the freezing point of solutions, by M. A. Ponsot. The temperature is read at which a solution is in equilibrium with a quantity of ice with which it is thoroughly agitated, the exterior radiation being minimised, and the solution is then in part withdrawn and analysed.—On cupric bromide, by M. Paul Sabatier. The anhydrous salt and the form $CuBr_2, 4H_2O$ are described. The green crystals of the latter lose water over sulphuric acid and are converted into black $CuBr_2$.—On an unsaturated natural ketone, by MM. Ph. Barbier and L. Bouveault. This ketone is obtained from crude essence of lemon grass (*Andropogon citratus*). It has the composition $(CH_3)_2 : C : CH . CH_2, CH_2, CO, CH_3$. It has a very agreeable but penetrating odour, and boils at 169–170° under ordinary pressure.—A purely mechanical action suffices for Cliona to bore its tunnels in the valves of oysters, by M. Letellier.—On the glandular system of ants, by M. Charles Janet.—Creation of new varieties by grafting, by M. Lucien Daniel. Hybridisation by grafting is possible for certain herbaceous plants which can be made to acquire new alimentary qualities by grafting them on plants superior to them in this respect, and afterwards sowing seed from the graft. The influence on the graft varies, but is particularly marked among the Cruciferæ.—On the chemical composition of wavellites and turquoises, by M. Adolphe Carnot.—On the microstructure of *mélilite*, by M. L. Gentil.—New researches on association among bacteria. Augmentation of the virulence of certain microbes. Increase of receptivity: A note by M. V. Galtier in which the following conclusions are given:—(1) Microbes, attenuated till they cannot alone produce a mortal malady, become again virulent when two species are introduced into the organism. (2) The two species may multiply side by side, but generally one tends to disappear, and the other becomes again pathogenous. (3) When two species of microbes are found associated, it is sometimes one and sometimes the other which regains its virulence according to the conditions. (4) Association of bacteria is able to be employed in the laboratory to render attenuated microbes again virulent. (5) Not only can the return of certain epidemics be explained by it, but the effects of vaccination with mild virus may be aggravated by this means. (6) The passage of one microbe, conferring immunity against a given malady, may predispose to the attack of another.—Properties of serum from animals protected against the poisons of different species of serpents, by M. A. Calmette.

TEXT-BOOK OF COSMICAL PHYSICS.

Joh. Müller's Lehrbuch der Kosmischen Physik. Fünfte umgearbeitete und vermehrte Auflage, von Dr. C. F. W. Peters. (Braunschweig: Friedrich Vieweg und Sohn, 1894.)

NEARLY everyone who has become at all acquainted with popular German scientific works will have at some time fallen in with this well-known book by Dr. Müller. It first appeared in the year 1856, and received particular favour, in that in the first place it was really popularly written, and secondly, that it was useful as a book of reference for many questions which dealt with every-day phenomena. The book reached its fourth edition in 1875, and since then none other has appeared, except the one that we now have under consideration. Nineteen years have thus flown by since Dr. Müller undertook the last revision, and in this period one is not at all surprised to find that accepted views on many points have undergone great changes, and in some cases entire revolutions.

For those of our readers who have not had the opportunity of examining previous editions for themselves, a few words as to the gap which the author intended that the work should fill may not be out of place. Referring, in the preface to the first edition, to the great stir Humboldt's "Kosmos" made throughout Germany, attracting general attention to the study of cosmical phenomena, he stated that he intended to produce a work, in the form of a text-book, in which the physics of the heavens and the earth should be systematically brought together. In astronomy it was true that many popular works were at hand, but in physical geography and meteorology they were to a certain extent wanting. With such an object in view it was necessary to keep the book within certain limits, and not to enter too far into mathematical developments: this accounts for the brevity of some parts in the astronomical and optical sections. On the whole, however, a non-mathematical reader should rest very content with what he has before him.

In this new edition, Dr. Peters, who has undertaken the revision, has not deviated from the original idea of dividing the work into four books, and they are, as formerly, devoted to (1) the movements of the heavenly bodies and their mechanical explanations; (2) cosmical and atmospheric phenomena; (3) heat phenomena on the earth's surface and in the atmosphere; and, lastly, (4) atmospheric electricity and terrestrial-magnetism.

Covering as the work does over 900 pages, a systematic treatment of each section would be impossible, so we will limit ourselves to searching out what is not in the book which ought to be there, and *vice versâ*. With regard to the latter, with the exception of what is referred to later on, there is not much that need be said, except it be that some old incidents of observed phenomena might have made place for others more recent, as, to take one example, that referred to under "Magnetische Störungen" (p. 858).

The first book, dealing with astronomical phenomena consists of over 300 pages, and is the largest of the four. This has received many and various alterations and additions; among the latter may be mentioned references to the new moons of Mars and Jupiter, the discoveries relating to the periods of rotation of Mercury and Venus (Trouvelot's work somehow being overlooked here), variable stars of the Algol type, and photographic and spectrum analysis work. Those important phenomena, the tides, receive due attention, and instead of being dismissed in two pages, as in the last edition, in this one have twelve devoted to them. In the section on time, it is a pity that more is not said about the new system of time-zones, for this is just a typical point to which an ordinary reader might wish to refer. Under the description of what we know about the planet Venus, there are several important points which do not receive mention. Thus, for instance, no reference is made to the snow-caps of which Trouvelot has published so many drawings, nor can an account be found of the curious and quick changes which have been observed to occur on the terminator and limb, and which afford strong arguments in favour of a rapid rotation of the planet. The transit of Venus, on the other hand, is fully discussed and described.

In the chapter dealing with comets, excellent descriptions are given of their gravitational motions, and of remarkable appearances, while the forms of their tails are discussed at some length. During the last few years astronomers have had many opportunities of studying these bodies, and our knowledge has very much increased. Thus we now generally suppose them to be swarms of meteorites under the influence of gravitation pursuing their course round the sun, the particles of which they are composed banging and clashing about near perihelion, and producing light and heat. One might at first be led to consider that the author had overlooked such new knowledge, as the reader is pulled suddenly up by a section on the "meteorite." It is not till after twenty-five pages have been passed over that he is informed of this suggested relation between comets and meteors, and then in only a few words. This subject is mentioned again briefly under the spectra of comets.

Coming now to the second book, our luminary the sun is the first dealt with. In this part we may mention one or two points which we think are deserving of more attention. Thus, *à propos* of sun-spots, such an absorbing question as the unequal period between a maximum and a minimum and a minimum and a maximum receives no mention, or even the important fact of the latitudinal changes that the positions of spots undergo during a period; in fact, in fifteen lines the whole reference to spot-period is treated. In the explanations given to account for spots, Zöllner's ideas are the most modern hinted at; there is no statement as to our present view, that they are caused by down-rushes of cooler matter from the upper regions of the solar atmosphere.

An interesting account of the zodiacal light is followed by a section on planetary photometry, in which G. Müller's recent work is referred to. In the section on variable stars, the Algol type is fully dealt with, but no attempt is made to explain other kinds of variables, although several plausible suggestions are at hand. Under temporary stars exactly the same is the case, in spite of what has been recently done with regard to this most fascinating puzzle in astronomy. The remainder of this book deals briefly, among other things, with nebulæ, star clusters, comets and their spectra, spectroscopes, &c. The chapter on atmospheric light phenomena has received but little alteration; in it are described refraction, mirages, halos, twilight, &c., which call for little if any change.

In the third book we are introduced successively to chapters on the distribution of heat on the earth's surface, the pressure of, and disturbances in, the atmosphere, and hygrometry; these may be all included in the word "meteorology." In the science of meteorology very rapid advance has been made, and the last twenty years have witnessed changes which have been sweeping in their nature. Such being the case, we expect to find here considerable alterations and additions, and indeed we are not disappointed, for we find this part "zum grossen Theile ganzlich umgearbeitet." Thus, to mention one or two instances, the Ice age is dealt with at some length, and is accompanied by an excellent map showing the glacial distribution. The paragraphs on the internal heat of the earth are also likewise lengthened, and much new matter inserted. In the section on earthquakes, on the other hand, we fail to notice any reference to Prof. Milne's important work that he has been carrying out in Japan on a truly scientific basis. A brief description of this, and a few words on the seismograph, would have made an interesting addition.

The fourth and last book will be found to have received little alteration. This seems perhaps striking, in the face of the great amount of work that is now being done in this direction. There is no doubt that at present we are rather gathering facts systematically and accurately acquired, than subjecting those already obtained to detailed discussion. Nevertheless we find no changes or additions under the paragraph entitled "das spectrum des Nordlichtes," or any other explanation of this phenomenon than that of De la Rive, indicating that the work done during the last nineteen years has been void of results worthy of mention. In the part on lightning, we are rather surprised to see no reference to photography, which has enlightened us much on this phenomenon, showing us that a forked flash is by no means "instantaneous," to use a word which is rather ambiguous, but lasts, comparatively speaking, a considerable time.

We cannot conclude without referring especially to the admirable illustrations, which throughout the work form a very prominent feature. The plates at the end of the book may be said to be the same as those that appeared in the last edition, but in the case of those in the atlas which accompanies the volume many important alterations and additions have been made. Thus, to mention some of the more important. Those showing the paths of the planets have been revised and much improved. Two rather startling (as regards colour) pictures of the planet Mars (June 3 and 14, 1858), after Secchi, are inserted, also an excellent map of his surface, after Schiaparelli.

Among other very good plates is one of Jupiter and his spots (Warren de la Rue), Saturn (Trouvelot), two of the moon after negatives taken at the Lick Observatory, Mount Hamilton, a lunar crater after Nasmyth, Roberts' Andromeda nebula, and Langley's enlarged picture of sun-spots.

The maps and diagrams referring to the meteorological and magnetical sections are as numerous as ever, and have all been carefully revised and brought up to date. New pictures of the auroræ, as observed in Kingua Fjord in 1882 and 1883, are also inserted.

In the above rapid survey of the 900 pages which this book contains, one can form an idea of the great difficulty the bringing of such a work as this up to date must have been to the reviser. Having to bear in mind that no part must be more elaborately developed than another, and that the limit of range as regards details must be restricted, Dr. Peters has had no light task before him. Cosmical physics is such a wide-spreading subject, and the information here brought together so plentiful, that the few remarks we have made above fall, for the most part, into insignificance.

As a popular treatise the work should be widely read, and the special index should considerably facilitate the utility of the work in its function as a book of reference.

W. J. LOCKYER.

ALCHEMY AND CHEMISTRY.

The Alchemical Essence and the Chemical Element, an Episode in the Quest of the Unchanging. By M. M. Pattison Muir. Pp. 94. (London: Longmans, Green, and Co., 1894.)

THIS is a very interesting book; its object is stated in a sentence printed on a fly-leaf following the title-page—"This essay is written in the hope that some of the men who exercise their 'wit and reason' in examining the problems of life may help to answer the questions that nature propounds to those of her students who follow the quest of the unchanging."

The author begins by quoting two definitions, one by an alchemist: "There abides in nature a certain form of matter which, being discovered and brought by art to perfection, converts to itself, proportionally, all imperfect bodies that it touches"; and the other by a chemist: "In chemistry we recognise how changes take place in combinations of the unchanging." It may here be said that it would often materially add to the interest of the work if the names of the authors of these and of other quotations in the book had been given.

The difficulties that many have experienced in understanding the writings of the alchemists are accounted for by showing that the names which they used, and which have survived as the names of well-known substances, were applied only to certain principles or properties that matter was supposed to possess: thus the word sulphur represents the principle of changeability, and the word mercury the principle of malleability and lustre which the metals exhibit. The alchemists used expressions of this kind partly to hide their secrets from the uninitiated, and also to preserve themselves from suspicion of dealing with the evil one, who was considered to be the possessor of the earth. The mystical language was derived, to a large extent, from theology, the science which at that time pervaded all the thoughts of the learned. Possibly the alchemists really attached some definite meaning to the fantastical terms they used, which meanings are now lost to us.

When the use of the accurate balance was introduced into natural science, it revolutionised the methods of investigation: it now became possible to trace the changes which occur during the interaction of bodies in a way quite different from that employed in earlier times. Thus the alchemist observed only the changes of properties of the substances with which he experimented; the chemist investigates, in addition, the changes of mass which occur when alterations of matter are produced.

It must not be supposed that the early workers were ignorant of the increase of weight which occurs during the calcination, or, as we now call it, the oxidation of metals, but they gave very fanciful explanations of the fact; thus George Wilson, in his "Compleat Course of Chymistry," printed in 1721 (how many students at the present time would rejoice in a complete course of chemistry in 383 pages!) says, when writing of the calcination of lead, "It gains in weight by calcination, because a greater quantity of igneous particles insinuate themselves into the lead, than the sulphurous ones the fire drives out, for in calcination, the acid of the fire, joins itself to the alkali of the lead, and having driven away its combustible sulphur, makes a new and incombustible body."

Mr. Pattison Muir gives some illustrations of the use of the balance, but one of these seems not quite a happy example. He states that when water was evaporated in an open dish and a residue was left, the alchemist "pointed to the earthy matter in the dish as proof of the transformation of water into earth." He afterwards says that a weighed quantity of water was distilled, the distillate was weighed and was found to be less than the original water; "but the sum of the weights of the condensed water and the earthy matter was equal to the weight of the water before boiling," showing that the residue was dissolved in the water used. It is not stated by whom this experiment was made, but it is inferred that it was performed in the early days of quantitative work. As spring water rarely contains more than one-tenth per cent. of dissolved matter, it would have been interesting if the author had informed us what precautions were taken to secure such a result, which would be difficult even with our modern appliances.

By the use of the balance it was found that some substances differed from others, some being composed of different kinds of matter, and hence called compounds, whilst others could not be thus separated, and were regarded as simple bodies or elements. When an element is transformed into a compound, the latter almost invariably possesses properties very different from those of the element, and the element appears to have been destroyed; the alchemist thought that it was really destroyed, but the chemist shows that it is only hidden, and can be obtained from the compound in the same quantity that was used to prepare the compound; moreover, the weight of the compound is invariably equal to the sum of the weights of the elements composing it.

As far as we know at present the elements are unchangeable; however complex the compounds which are formed by their combination, the elements can always be obtained from them with all their original properties. Thus the formations of compounds from elements and the decomposition of compounds into elements are properly called the "changes in combinations of the unchanging." The alchemical principles could not be weighed or measured, so that it was not possible to explain the properties of bodies by the assertion—for it was nothing more—that they contained more or less of these principles.

The author next tells us that the same elements in the same proportions can form compounds with different properties, and then passes on to the laws of multiple proportions, showing how these are accounted for by the theory of atoms. The periodic law is then explained, and it is pointed out that the periodic properties of the elements and of their compounds contrast very strongly with the ideas of the alchemists with regard to the principles that were supposed to account for the different properties of substances. The striking difference between alchemical and chemical reasoning is well illustrated by the history of the theory of combustion, the escape of the principle of fire, as held by the phlogistians to be the cause of combustion, being contrasted with the combination of the burning substance with oxygen, as discovered by Lavoisier.

The author appears to be rather hard on alchemy when he says "the great business of alchemy was to prevent men from coming into close contact with external realities. Alchemy was a manufacturer of blinkers that shut off the objects on either side, and so distorted the vision." No doubt this was in some ways the result of alchemy, but it can hardly be supposed that it was its object. It is difficult to place ourselves, even in imagination, in the position of the alchemists, but we may hope that they were struggling after truth to the best of their powers, their failure being due more to their holding preconceived notions than to a desire to obscure facts.

Some may not agree with the author in classing together alchemists, spiritualists, theosophists, and theologians; though, no doubt, all have erred in making assertions with an insufficient knowledge of facts. So also it seems not quite justifiable to restrict the term science to the investigation of natural phenomena, for surely the study of the moral and spiritual actions of man are also worthy of the name of science. Some may not accept spiritual truths, considering that they are beyond their experience; but it is hardly scientific to deny their existence, any more than it was reasonable for the inhabitants of Flatland to deny the existence of space of three dimensions.

Mr. Pattison Muir's book will well repay perusal; it will appeal not only to the chemist, but also to the general reader, who cannot fail to obtain much insight into the ideas of the alchemist, and also into the accurate methods of the modern chemist. HERBERT MCLEOD.

OUR BOOK SHELF.

Principia Nova Astronomica. By Henry Pratt, M.D. (London: Williams and Norgate, 1894.)

WE confess to having read a great deal of this book, and to have wasted a corresponding amount of time, in an unsuccessful attempt to wrestle with the novelties submitted to consideration. The only possible consolation or reward is the thought that a brief notice may prevent others from a similar distress and dissatisfaction. To say that the author does not accept the first law of motion, will perhaps serve to indicate the kind of man with whom we have to deal. After this one will be prepared to believe that any amount of curiosities and world-worn paradoxes will be met with in this collection of some two hundred quarto pages.

The feature, however, which distinguishes this production from all other works of the same character is the numerous suns which the author is obliged to introduce in order to explain the motions of the earth and moon. For those who are so benighted as to accept the gravitational theory, as developed by Newton and his school, one sun suffices; but the new Principia requires at least four. First, we have a central sun occupying "the eccentric centre of an ideal sphere." This phrase is hard to understand. It is suggested that it may mean that an imaginary sphere rotates about a point not its centre. Round this "ideal sphere" we have a so-called polar sun, circulating with its cortège of solar bodies and their satellites. This sun is called a polar sun because it revolves in a plane approximately parallel to the axis of the earth; but in what the peculiar necessity of its creation consists, we have failed to fathom with distinctness, and fear to misrepresent the ingenious author. On the surface of this ideal sphere another sun, called the equatorial, also revolves, this time from west to east, in a "mean equatorial plane." These three suns are necessarily made to be non-luminous bodies, only recognisable by the effects their "eccentric attractions and orbital revolutions" exercise on the earth and moon. Finally we have the visible sun. Of these four, the central sun is the master-key of the whole system, from which energy radiates in every direction, upholds all the members of the system, while simultaneously holding them apart. And any one who is at all accustomed to this kind of literature will conclude, without any further warning, that electricity is the energy invoked to sustain this system. It would have been distinctly disappointing not to have had electricity introduced as the mainstay.

Those who wish to see how this complication can be made to explain the precession of the equinoxes, the motion of the lunar nodes and apsides, nay, the predominance of land and water in the northern and southern hemispheres of the earth respectively, and many other strange things, must be referred to the book itself. There is, in fact, only one sentence in the book with which we can cordially and entirely agree, and that is the first "Who," says the author, "Who will believe the theory of astronomical motion set forth in the following pages? Not the astronomers, certainly." We venture to assure him that he is perfectly correct in this conjecture.

W. E. P.

A Manual of the Geology of India. Second edition. Revised and largely re-written by R. D. Oldham, A.R.S.M., Calcutta: Geological Survey Office. London: Trübner and Co., 1893.)

THE first edition of this book has been out of print for some years; meanwhile, Indian geology has greatly advanced, so that a revised and extended issue, bringing the work in line with the new results of the Geological Survey, has long been needed. Few are more capable of doing the re-writing and revision better than Mr. Oldham. He has had a wide and varied experience of survey work in India, and his acquaintance with the literature pertaining to the subject is evidenced by the "Bibliography of Indian Geology," compiled by him in 1838. Mr. Oldham has entirely altered the arrangement of the book. The original edition consisted of a series of descriptions of separate districts; but in the present volume the rocks are described in chronological order. All references to economic geology are excluded, being relegated to the works specially devoted to it, while this deals with stratigraphical and structural geology. In the detailed table of contents, the excellent plan has been followed of indicating by a different type the matter which is new or entirely re-written in the present edition. A glance at this shows at once that Mr. Oldham has produced almost a new book. Especially interesting is the chapter on the "Homotaxis of the Gondwána System." Most geologists will remember the bitter controversy that once raged over the age of this system, but which has now died out. Mr. Oldham has made a detailed study of the rock-groups of the Gondwána system, and has compared them with their representatives in Australia and Africa. He has thus been able to show the relation of the Upper Palæozoic and Lower Mesozoic rocks of India, Africa, and Australia to those of Europe. The two last chapters in the book are entirely new. One deals with the age and origin of the Himalayas, and the other with the geological history of the Indian peninsula. In both of these a number of important questions are discussed in a scientific manner. Wherever Mr. Oldham has interpolated new matter, he has done it well. Unlike many other revisers, therefore, he has produced a restoration which really improves the old structure. The result is that the manual is once more the standard work on the present state of knowledge of the geology of India.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Weight of the Earth.

IN a letter in this week's NATURE, signed "The Reviewer," the writer does not notice that in the English language, and in all legal and common usages of it, including that of all scientific men in speaking of their weighings by ordinary balances, *weights* mean *masses*. The fact that the weight of the earth is $6 \cdot 14 \times 10^{21}$ tons is as clear as that the weight of a parcel of tea is 3 lb. It is the *heaviness* of a weight or mass that is a property accidental to its position, being less at the equator, greater at the poles, and nothing at the earth's centre. I have never yet heard a "box of weights" called a box of masses. I don't believe even "The Reviewer" calls it a box of masses. If carried to the centre of the earth it is still a box of weights, though the heaviness of the weights is zero.

The word "weight" is often used to denote the heaviness of a weight or mass. No dictum, either of "The Reviewer" or of myself can eliminate this ambiguity from the English language. But scientific men may greatly diminish the inconvenience of it, and may even tend to eliminate it altogether, if they persistently use the word "heaviness" when they mean heaviness.

May 12. K.

"THE REVIEWER" makes a number of statements which he does not stop to prove; as, for instance, when he says that "the weight of a body would be practically nothing if the body was removed to a few million miles from the earth." But an appeal to experiment will show that the weight is unaltered. To fix the ideas, consider an astronomical or astrological chart, in which the earth is at the centre of a Zodiacal circle. Now, if a 100-ton gun is weighed in the scales of Libra, the weights required for equilibrium, as given by the lumps of metal in the other scale pan, will amount to exactly 100 tons; so that the weight of 100 tons at the distance of the Zodiacal circle, or at any other distance, is exactly 100 tons.

But if "The Reviewer" takes a ball of the mathematician's imaginary fine, weightless string, which he lets down from Libra to the surface of the earth, to the end of which weights can be attached, so as to equilibrate the 100 ton gun at the distance of the Zodiacal circle; now it is certainly true that a much smaller weight will suffice to produce equilibrium. Suppose, for instance, that the Zodiacal circle has a radius equal to the distance of the moon, or sixty times the earth's radius; then 22,400÷3600, say, 6 lb., suspended near the earth's surface at the end of the string, some 240,000 miles long, will suffice to balance 100 tons in the other scale pan, close up to the Zodiacal circle. But if the 100 tons is also lowered down by another mathematical string to the surface of the earth, then 100 tons is required to equilibrate it; and so it will for any intermediate position, when the lengths of the strings are equal; so that it does not tend to any clear or useful end to say that the weight of 100 tons at the distance of the moon is only about 6 lb. On the contrary, the weight of 100 tons is everywhere 100 tons.

The *weight* of a body is the *that which* is measured in lb., tons, kilogrammes, or other standards of weight; and these standards are certain lumps of metal licensed by Acts of Parliament, and carefully preserved against change or degradation.

The weight of the Earth, for instance, as determined by the Cavendish experiment, is about 6×10^{21} tons; and it is not necessary to dig up the Earth and to weigh the fragments at the surface of the Earth for the determination of this weight.

It is too late now to change the meaning of a word that has been in immemorial use in all languages; such a quasi-Gothic revival would have to restore all literature, as, for instance, the lines of Ovid (Art. Am. 3, 319):—

> "Quæ nunc nomen habent operosi signa Myronis
> Pondus iners quondam duraque massa fuit."

A. G. GREENHILL.

The Niagara River as a Geologic Chronometer.

WHEN we quote an author whose views coincide with our own, we are apt to speak of him as an authority on the subject; but when we dissent from the views we quote, we are not so apt to recognise the high authority of that author. This reflection on a phase of mental bias is suggested by a personal experience with reference to the age of Niagara Falls. The geologists and others who have discussed the length of post-glacial time may be rudely classed as minimists, maximists, and agnostics. Within the past five years I have been frequently and approvingly quoted by the minimists as estimating the portion of time consumed by the Niagara River in cutting its gorge at 7000 years, and the reputation thus acquired has not been noted without personal appreciation. But self-complaisance in that regard has been somewhat impaired by the thought that the honour is ill-founded, and that the insecurity of its foundation would sooner or later be discovered. Not less disturbing was the fear that when the maximists or agnostics took their turn at writing, I should be classed with the goats instead of the sheep. There can be no doubt that the manly and in every way proper course would have been followed had I years ago disclaimed the glory accidentally thrust upon me; but it is easy to bask in the sunshine of even unmerited applause, and conscience was too weak to determine action until another motive was added by a blow from the agnostic side. In his recent book Dr. James Geikie, after quoting me as an authority for the 7000-year estimate, adds that "all such estimates are in the nature of things unreliable." I now hasten to declare that I never said or thought that the period in question was about 7000 years. What I did incautiously say was, in effect, that the time allowance for the cutting of the gorge would be about 7000 years if the rate of the cutting were uniform, but that there was good reason to believe the rate had not been even approximately uniform.

Dropping personalities, which lack interest for your readers unless they involve principles, I beg to say a few words on the actual value of Niagara Falls as a chronometer. In 1844 James Hall made a map of the brink of the Falls, and established bench marks to which changes could be referred. Within a few years several other surveys had been made and connected with the first bench marks. It has thus become known, first, that in the middle of the Horseshoe Fall, where the principal body of water descends, the brink retrogrades at the rate of four or five feet per annum; second, that the American Fall, carrying a much thinner sheet of water, retrogrades so slowly that its rate is concealed by errors of survey. The gorge, which has been cut since the ice sheet retreated from the region, is six miles long, and the division of this distance by the annual rate determined for the Horseshoe Fall yields a period agreeable to the minimists. Had the conditions remained uniform, no fault could be found with this estimate, but there is reason to believe that the conditions have varied enormously in nearly every particular. The thickness of the resistant bed at the crest of the Falls is far from uniform, and it was altogether wanting for part of the distance. During the period of gorge-cutting, the height of Lake Ontario, which gives base-level to the river, has varied through a range of several hundred feet. The volume of the river has doubtless varied somewhat through climate, but it has probably varied enormously by reason of changes in drainage systems, resulting chiefly from differential uplift. The Niagara now carries surplus water from the basins of Lakes Erie, Huron, Michigan, and Superior. There was probably a post-glacial epoch during which three of these lakes discharged their water in other directions, and only the basin of Lake Erie fed the Niagara River. During that epoch the volume of the river was so small that canyon-cutting was effected only by the feeble process now illustrated by the American Fall, instead of the vigorous process illustrated by the Horseshoe Fall. These considerations, which the inquiring reader may find more fully set forth in the annual report of the Smithsonian Institution for 1890, tend strongly to sustain the agnostic view of the Niagara River as a geologic chronometer. G. K. GILBERT.

Washington, April 30.

The Teeth and Civilisation.

ON the 8th inst., Dr. Wilberforce Smith read a short communication before the Anthropological Institute on the teeth of ten Sioux Indians attached to the Wild West Show. His investigation showed that in regard to molars and premolars (the only teeth examined), these Indians were wholly free from caries. In the discussion which followed the reading of the paper, it was mentioned that the same fact was revealed in the skulls of the Fourth Egyptian Dynasty brought to England by Dr. Flinders Petrie, and in some skulls examined by Dr. Wilberforce Smith himself, which were derived from the ruins of Pompeii. The teeth of the Indians, both old and young, and those in the skulls just referred to, all showed more or less wear of the cusps, which is a most unusual circumstance in the teeth of modern civilised people, and it was thought that some difference in the food, or its mode of preparation, would be required to account for the absence of signs of wear in our time.

Now, it has never been proved that the increasing prevalence of caries is due to weakness of the teeth owing to comparative disuse, but there is nevertheless great probability in the inference, especially as signs of wear and freedom from caries appear to occur together, and *vice versâ*. There is, however, a further point in regard to the existing liability to the attacks of caries which I think can be best explained by a transference of nourishment to other parts governed by the same nerves. On inquiry of several dentists, I find that the teeth most subject to decay are the molars, and of these the upper molars are more often attacked than those in the lower jaw. The molars of the upper jaw are fed by a branch of the fifth nerve, and in modern life this nerve has, perhaps, more strain put upon it than any other in the body. We use our eyes, partly supplied by the ophthalmic branch of this nerve, not at intervals, but often closely throughout a long day. And it seems, therefore, that with so many increasing calls on this bundle of nerve fibres, the filaments sent to the teeth are, by an automatic economy of expenditure, robbed of the energy necessary to perform their functions properly. The teeth through lack of use may not excite the nerves to natural action, and thus from both sides there is a failure of function, and the teeth are consequently more and more unable to resist the attacks of caries. I am disposed to attach some importance to this explanation, as I find that those who have great calls on their nervous energy are more liable to caries than people of quieter habit and slower temperament. Dr. Wilberforce Smith mentioned the alarming increase of dental decay amongst hospital nurses, whose occupation is certainly one demanding a constant drain on their nervous energy. It was also noted that people in towns lose their teeth more rapidly than those living in the country, which also bears out the idea here suggested. On the other hand, the savage is seldom required to strain his facial nerves continuously for any length of time, and in reference to general nervous expenditure he enjoys long periods of rest which are wholly denied to the civilised man in towns. No doubt in consequence of the excessive calls on our nervous energy the distribution of it is undergoing modification in civilised man, and parts not used to any extent are being deprived of the supply necessary to healthy growth. It is much to be feared that the teeth, though so essential to the welfare of the body, are in this predicament. But we are sadly in need of more definite information than is at present available, and it is partly in the hope that some of the readers of NATURE, who have opportunities which I do not possess, may be induced to test this and other ideas relative to the increase of caries, that I have written on the subject. The whole question is at present much obscured by misconceptions due to ignorance. One fact, however, emerged only too clearly from Dr. Wilberforce Smith's investigation, namely, that while the grinding teeth of civilised men of middle age are either missing or practically useless for their purpose, the ancients enjoyed a perfect set of teeth till advanced years, and modern savages enjoy the same blessing.

Clapham, May 10. ARTHUR EBBELS.

Johannes Muller and Amphioxus.

THE story of Muller's Neapolitan visit in search of Amphioxus, as copied in NATURE (May 3, p. 14) from the *Lancet*, belongs to the category of those that are *ben trovato* or the reverse. To anyone acquainted with the works of this brilliant morphological genius the tale bears internal evidence of entire lack of foundation.

Müller's chief memoir on Amphioxus appeared in the *Abhandlungen der Berliner Akademie* 1842. If Prof. Todaro had ever read the original, or an earlier note in the *Berichte* 1839, he would scarcely have related the story. Müller's work begins with an historical summary of previous researches on the animal, and in particular he relates (*Berichte* 1839, p. 199) that the first specimens he examined were obtained from Prof. Retzius. Moreover, Costa's description, mentioned by Prof. Todaro as being the immediate cause of Müller's expeditious trip to Naples, *appeared in* 1839, *and in the same year* Müller published observations on the two specimens given him by Retzius. At this period he was in ignorance of its occurrence at Naples, for (p. 200) he says it has been found "on the English, Norwegian, and Swedish coasts." His chief work—the one before mentioned—was carried out on *living* specimens got by Muller himself near Gothenburg, on the Swedish coast, and, as is well known, and also expressly stated by himself, he worked at the microscope for twelve days in order to complete his task on the spot. The evidence goes to show that Muller obtained no Amphioxus—not even the one he is credited with!—from Naples until his work was completed; and (p. 81, foot-note) he remarks: "In Naples the capture of the animal is very easy close inshore, for it lives in great numbers in the sandy ground of Posilipo. In 1842 I brought back from Naples *over* 1000 *specimens* in spirit."

If the journey referred to ever took place, there is no record of the one specimen in any of his works, and Muller, who could sacrifice a very rare Pentacrinus to the scalpel, was not the man to spare an Amphioxus. It must indeed have been a "miraculous draught" that yielded only one specimen of Amphioxus off Posilipo.

However "interesting" and amusing the story may be to those who have a preference for fiction, it is to be regretted that, with no [illegible] of fact to support it, a *zoologist* should have told it of one whom zoology will always rank as a chieftain amongst her greatest sons. To many of us, who regard Muller with something akin to reverence, the fable is less interesting than painful. J. B.

The Scandinavian Ice Sheet.

IN reply to the letter of Prof. T. G. Bonney (NATURE, vol. xlix. p. 338), which I by chance have read to-day, concerning the difficulty of explaining how the Scandinavian land-ice could have crossed the deep channel of Skagerak and Kattegat, and have reached the East Anglian coasts, I should like to remark that this difficulty is not new to me, and will exist after it has been explained how the ice-stream from Norway could have crossed the named channel and extended over Denmark and North-western Germany. It is, however, an undisputed fact that certain Norwegian boulders are very common in the most northern parts of Jylland, and from there dispersed over the whole Jylland (though their rarity increases with distance from Norway), the northern parts of Fyn and Sjœlland, over Slesvig and Holstein and North-western Germany from Fehmarn towards the west, further over Dutchland and Belgium to several localities at the English east coast, under such conditions that they could not have been transported by floating ice. It is consequently a fact that the ice-stream from Norway has crossed the named channel. I think, therefore, that the best explication is that the Skagerak channel in its present condition was at first formed after or during the period of largest glaciation, to which the Norwegian ice-stream belongs, but before the Baltic ice-streams, both of which, I suppose, are posterior to the greatest extension of the land-ice. The chief reason for the formation of these ice-streams is the existence of the above-named channel, which has prevented the ice-stream from Norway from extending over Denmark for the second time.

Copenhagen, May 2. VICTOR MADSEN.

The Earliest Mention of Dictyophora.

TWAN CHING-SHIH'S "Miscellanies," compiled in the ninth century A.D. (Japanese edition, 1697, book xix. p. 7), has the following note:—"In the 10th year of the period (Tá-Túng (544 A.D.) a fungus grew in Yen-hiáng Gardens owned by the Emperor Kién-Wan. It was eight inches long with a black head resembling the fruit (that is, the Torus) of *Euryale ferox*; stem hollowed through inside like the root of *Nelumbium speciosum*; skin all white except below the root, where it was slightly red. Portion like the fruit of Euryale had below a joint like that of the bamboos, and was removable; from the joint a sheet was developed, simulating a network, five or six inches in circumference, surrounding the stem in the manner of a bell, but distant and separate from it. The network was fine and lovely, and also removable from the stem. It is allied to Wei-hi-chi (the Auspicious Fungus of Graveness and Pleasure) of the Taoist writings." This description seems to have been passed over by readers as a mere fiction, but I find that it agrees very well with the figure of a Dictyophora, and may probably be the earliest mention of it. A Japanese botanist, Kōzen Sakamoto, has figured the two forms of Dictyophora in his "Monograph of Fungi" (1834, vol. ii. p. 15), but has not referred to the above-cited description. KUMAGUSU MINAKATA.

May 4.

The Scope of Psycho-physiology.

I HAVE no wish to enter into a triangular duel with Dr. Titchener and "the writer of the note" who has provoked his fire. But since my name has been introduced, a word or two of explanation seems necessary.

Some time before Dr. Titchener discharged his first barrel, I was requested by the editor of this journal to contribute a popular article on "the scope of psycho-physiology." In complying with his request, I accepted (1) the conditions implied by the word popular, which no doubt laid me open to the criticism that my "whole treatment" was "a little general and superficial"; and (2) the title suggested to me, since I regarded it as comprehensive and not specially provocative of terminological controversy. C. LLOYD MORGAN.

Bristol, May 10.

The Aurora of February 22.

THE splendid aurora of February 22-23 began on the Pacific coast of North America on the former date, extending unusually far south in California, New Mexico, and Arizona, but did not become conspicuous on the eastern half of the continent until the day following. The earth currents affecting the telegraph lines were troublesome west of Chicago exclusively on February 22 also, not being felt east of that point until the day following. This localisation of the aurora in longitude has been noted in numerous other instances as well. An arrangement has been made to secure records of the geographical distribution of earth current disturbances on the lines of the Western Union Telegraph Company, which extend very widely over the North American continent. From what appears in the case above described, such records are likely to prove to be of very great interest.

April 30. M. A. VEEDER.

THE ROYAL SOCIETY SELECTED CANDIDATES.

As in former years, we give the qualifications of the candidates for election into the Royal Society, who were selected by the Council at its meeting on Thursday last.

William Bateson,

M.A. Fellow of St. John's College, Cambridge. Balfour Student. Rolleston Prizeman of the University of Oxford. Distinguished as a Zoologist. Author of the following memoirs:—"The Early Stages in the Development of *Balanoglossus* (sp. incert.)" (Quart. Journ. Micros. Sci. vol. xxiv., p. 208); "The Later Stages in the Development of *Balanoglossus Kowalevskii*, with a Suggestion as to the Affinities of the Enteropneusta" (*ibid.*, vol. xxv., supplement, p. 81); "Continued Account of the Later Stages in the Development of *Balanoglossus Kowalevskii*, and of the Morphology of the Enteropneusta" (*ibid.*, vol. xxvi., p. 511); "The Ancestry of the Chordata" (*ibid.*, p. 535); "On some Variations of *Cardium edule*, apparently correlated to the Conditions of Life" (Phil. Trans., 1889, p. 297); "Notes on the Senses and Habits of Marine Animals" (Marine Biol. Assoc. Journ., new ser., vol. i., p. 211); "On the Sense Organs and Perceptions of Fishes" (*ibid.*, in the press).

George Albert Boulenger,

Assistant (First Class) in the Zoological Department, British Museum. Distinguished for his knowledge of Herpetology. Author of the Catalogues of Batrachia (2 vols., 1882); of Lizards (3 vols., 1885-87); of Chelonians and Crocodiles (1889). In these volumes, which are the standard works for the study of these animals, all the species known are described, their systematic arrangement being based on a critical examination of the more recent researches into their anatomical structure and geographical distribution. He is also the author of a volume of the "Fauna of India and Burma," which is devoted to the Reptiles and Batrachians; and of a great number of memoirs and papers published in the Transactions and Proceedings of the Linnean and Zoological Societies, the Geological Magazine, Annali del Museo Civico di Genova, and others. From 1880 to 1890 he has prepared the annual reports on Reptiles, Batrachians, and Fishes for the Zoological Record.

John Rose Bradford,

M.D., D.Sc. Physician. Assistant Professor of Clinical Medicine at University College. Author of "Electrical Phenomena of Secretion" (jointly with Mr. Bayliss) (Proc. Roy. Soc., 1886); "Physiology of Gland Nerves" (Journ. of Physiol., 1887 and 1888); "Innervation of the Renal Blood-vessels" (Proc. Roy. Soc., 1889); "Innervation of the Pulmonary Blood Vessels" (*ibid.*, jointly with Mr. Dean); "Influence of the Kidney on Metabolism (*ibid.*, 1892), and other papers.

Hugh Longbourne Callendar,

Fellow of Trinity College, Cambridge. Lecturer on Physics. Has made important investigations on the measurement of temperature by electrical means. These are described in the papers:—"On the Practical Measurement of Temperature" (Phil. Trans., 1887 A, p. 161); "On the Determination of the Boiling Point of Sulphur, and on a Method of Standardising Resistance Thermometers by reference to it" (*ibid.*, 1891 A) (this paper is written in conjunction with Mr. Griffiths); "On the construction of Platinum Thermometers" (Phil. Mag., July, 1891); "Some Experiments with a Platinum Pyrometer on the Melting Points of Gold and Silver" (*ibid.*, February, 1892).

William Watson Cheyne,

M.B., C.M. (Edin.). F.R.C.S. (Eng.). Joint Professor of Surgery in King's College, London. Distinguished as one who has made discoveries in Bacteriology and Pathology, and as the author of the following works and papers:—"On the Relation of Micro-organisms to Antiseptic Dressings" (Trans. Path. Soc., 1879); "Antiseptic Surgery, its Principles and Practice" (awarded the Jacksonian prize of the Royal College of Surgeons, 1882); "On Micro-organisms in Purpura Hæmorrhagica" (Trans. Path. Soc., 1884); "On *Bacillus Alvei*, the Cause of Foul-brood in Bees," in conjunction with Mr. Cheshire (Journ. Roy. Micros. Soc., 1885); "A Study of certain of the Conditions of Infection" (Brit. Med. Journ., 1886); "On Suppuration and Septic Disease" (Lectures delivered before the Royal College of Surgeons, 1887); "On the Pathology, Etiology, Results and Treatment of Tubercular Diseases of Bones and Joints" (awarded the Astley Cooper prize, open to International competition, 1889); and numerous other valuable contributions to Bacteriology and Pathology.

Robert Edmund Froude,

Superintendent of the Admiralty Experimental Works. Associate Member of Council, Institution of Naval Architects. Distinguished for original mathematical and experimental investigations which have greatly advanced knowledge of (*a*) the resistance offered by water to the movements of ships; (*b*) the forms of ships tending to diminish resistance; (*c*) the efficiency of propellers. In these departments of inquiry, he for many years assisted his father, the late Mr. W. Froude, F.R.S. Since 1878 he has worked independently, and been in full charge of the Admiralty Experimental Works, first at Torquay and then at Haslar. The existing establishment, with its novel mechanical arrangements for experimenting with models of ships and propellers, was designed by him. His advice has been sought and given in organising similar establishments in this country and abroad. His mathematical and experimental work has had great and beneficial influence on ship-designing, primarily for the Royal Navy, but also for the mercantile marine. Under his direction the system of model experiments has been greatly extended, enabling naval architects to proceed with great certainty in dealing with problems of propulsion, and effecting large economies of engine power in steamships. He has published many original papers on these special subjects, most of them appear in Transactions of the Institution of Naval Architects. Amongst these the principal papers are: "The Leading Phenomena of Wave-making Resistance" (1881); "Screw Propellers and their Efficiency" (1883 and 1886); "Theory of the Screw Propeller" (1889 and 1892).

M. J. M. Hill,

M.A., D.Sc., late Fellow of St. Peter's College, Cambridge. Professor of Mathematics in University College, London. Eminent Mathematician. Author of the following papers on pure and applied Mathematics:—"The Steady Motion of Electricity in Spherical Current Sheets" (Quart. Journ. Math., vol. xvi.); "Some Properties of the Equations of Hydrodynamics" ("*ibid.*, vol. xvii.); "On Functions of more than two Variables Analogous to Tesseral Harmonics" (Trans. Camb. Phil. Soc., vol. xiii.); "Calculation of the Equation which determines the Anharmonic Ratios of the Roots of a Quintic" (Proc. Lond. Math. Soc., vol xiv.); "On some General Equations which include the Equations of Hydrodynamics" (Trans. Camb. Phil. Soc., vol. xiv.); "On the Motion of Fluid, part of which is moving rotationally, and part irrotationally" (Phil. Trans., 1884); "On the closed Link Polygons belonging to a System of Co-planar Forces having a Simple Resultant" (Proc. Lond. Math. Soc., vol. xv.); "The Differential Equations of Cylindrical and Annular Vortices" (*ibid.*, vol. xvi.); "On the Incorrectness of Rules for Contracting the processes of finding the Square and Cube Roots of a Number" (*ibid.*, vol. xviii.); "On the c- and p-Discriminants of Ordinary Integrable Differential Equations of the First Order" (*ibid.*, vol. xix.); "On Node- and Cusp-Loci, which are also Envelopes" (*ibid.*, vol. xxii.); "On the Locus of Singular Points and Lines which occur in connection with the Theory of the Locus of Ultimate Intersections of a System of Surfaces" (to be published in Phil. Trans.).

John Viriamu Jones,

B.Sc. (Lond.). Principal and Professor of Physics in the University College of South Wales and Monmouthshire. Fellow of University College, London. Distinguished for his acquaintance with physics. Engaged in the teaching of physics as well as in the organisation of scientific studies, and is anxious to promote the progress of science. Author of a memoir "On the Determination of the Specific Resistance of Mercury in Absolute Measure" (Phil. Trans., vol. clxxxi., 1890). Author also of the following papers:—"On the Calculation of the Co-efficient of Mutual Induction of a Circle and a Coaxal Helix" (Proc. Phys. Soc., vol. x.); "On the Use of Lissajous' Figures to determine a Rate of Rotation, and of a Morse Receiver to measure the Period Time of a Reed or Tuning-fork" (*ibid.*); "Suggestions towards a Determination of the Ohm." Read before the British Association at Leeds, 1890 ("The Electrician," vol. xxv.).

AUGUSTUS EDWARD HOUGH LOVE,

Fellow of St. John's College, Cambridge. Lecturer in Mathematics. Author of the following papers of merit, connected with mathematics:—"On recent English Researches in Vortex Motion" (Math. Ann., vol. xxx., 1887); "On Dedekind's Theorem concerning the Motion of a Liquid Ellipsoid under its own Attractions" (Phil. Mag., 1888); "The small Free Vibrations and Deformation of a Thin Elastic Shell" (Phil. Trans., 1888); "On the Motion of a Liquid Elliptic Cylinder under its own Attraction," and "The Oscillations of a Mass of gravitating Liquid in the form of an Elliptic Cylinder which rotates as if rigid about its axis" (Quart. Journ. Math., 1888); "The Free and Forced Vibrations of an Elastic Spherical Shell containing a given Mass of Liquid" (Proc. Lond. Math. Soc., vol. xix., 1888); "The Oscillation of a Rotating Liquid Spheroid, and the Genesis of the Moon" (Phil. Mag., 1889); "Vortex Motion in certain Triangles" (Amer. Journ. Math., 1888); "The Motion of a Solid in a Liquid when the Impulse reduces to a Couple" (Proc. Phil. Soc., Camb., 1888); "On the Equilibrium of a Thin Elastic Spherical Bowl" (Proc. Lond. Math. Soc., vol. xx., 1889); "On Sir W. Thomson's Estimate of the Rigidity of the Earth" (Trans. Phil. Soc., Camb., vol. xv., 1890); "Note on the Present State of the Theory of Thin Elastic Shells" (Proc. Roy. Soc., vol. xlix., 1891); "Wave Motion in a Heterogeneous Heavy Liquid" (Proc. Lond. Math. Soc. vol. xxii., 1891); "On the Theory of Discontinuous Fluid Motions in two Dimensions" (Proc. Phil. Soc., Camb., vol. vii., 1891).

RICHARD LYDEKKER,

B.A. (Camb.). Formerly on the Geological Survey of India. Distinguished for his acquaintance with the science of Palæontology. Author of a series of illustrated quarto memoirs on the Tertiary and Post-Tertiary Vertebrata of India, "*Palæontologica Indica*" (Memoirs Geol. Surv. India, 1876-86); also a part of the Mesozoic Vertebrata of India (*ibid.*); of "Catalogue of the Fossil Mammalia in the British Museum," in five parts (1885-87), of "Catalogue of the Fossil Reptilia and Amphibia," now in course of publication; and of many papers on Palæontological subjects to the Quart. Journ. Geol. Soc., Proc. Zool. Soc., &c.

Supplementary Certificate.

Author of:—British Museum Catalogue of Fossil Reptiles, 4 vols.; British Museum Catalogue of Fossil Birds; Vol. II. (Vertebrates) of Nicholson and Lydekker's Manual of Palæontology. Joint author, with Sir W. H. Flower, of "The Study of Mammals"; a monograph of the Extinct Argentine Dinosaurs; Cetaceans and Ungulates in the La Plata Museum; and numerous minor papers.

FRANCIS CRANMER PENROSE,

M.A., F.R.I.B.A., F.R.A.S. Honorary Fellow of Magdalene College, Cambridge. Architect. Surveyor to the Fabrick of St. Paul's Cathedral. Late Director of the British Archæological School at Athens. Author of books or memoirs on (1) "Principles of Athenian Architecture," 1851; (2) "On the Prediction and Reduction of Occultations of Mars and Eclipses by a Graphical Process," 1869; (3) "On the Determination of the Elements of the Orbits of Comets by Graphical Processes," Monthly Notices, 1881; (4) "Two papers on the Ancient Hecatompedon, Athens," 1891 and 1893; (5) "On the Orientation of Greek Temples and the Amplitudes of Stars at the time of the Foundation of the Temples," Phil. Trans., 1893. Observer of the Total Solar Eclipses of 1870 and 1878. Inventor of Instruments for drawing the Logarithmic Spiral; for drawing the Hyperbola by continued motion parallel to the Asymptotes; for the Mechanical Solution of Spherical Triangles, &c.

DUKINFIELD HENRY SCOTT,

Ph.D. (Würzburg), F.L.S. Honorary Keeper of the Jodrell Laboratory, Royal Gardens, Kew. Dr. Scott is a person attached to science and anxious to promote its progress. He is distinguished for his acquaintance with Botany, and has made discoveries in that branch of science which have been published in the following papers: "Entwickelungsgeschichte der gegliederten Milchröhren" (Inaug. Dissert., Würzburg, 1881, published in Arbeiten des Bot. Instituts, Würzburg, 1881; translation in Quart. Journ. Micros. Sci., 1882); "On the Laticiferous Tissue of *Manihot Glaziovii*" (Quart. Journ. Micros. Sci., 1884); "On the Occurrence of Articulated Laticiferous Vessels in Hevea" (Journ. Linn. Soc., Botany, 1885); "On the Nuclei of Oscillaria and Tolypothrix" (*ibid.*, 1887); with Mr. Wager, "On the Floating Tissues of *Sesbania aculeata*" (Annals of Botany, I., 1888); with Mr. Brebner, "On the Anatomy and Histogeny of Strychnos" (Annals of Botany, III., 1889); "On some Points in the Anatomy of *Ipomaea versicolor* (*ibid.*, v., 1891); with Mr. Brebner, "On Internal Phloem in the Root and Stem of Dicotyledons" (*ibid.*); "On the Secondary Tissues in Certain Monocotyledons" (*ibid.*, vii., 1893); with Miss Sargant, "On the Pitchers of *Dischidia Rafflesiana* (*ibid.*). Dr. Scott is also the author of many botanical reviews, notes, &c. He co-operated with Prof. Bower, F.R.S., in the preparation of the English edition of De Bary's "Comparative Anatomy of Phanerogams and Ferns" (Oxford, 1884); and with Prof. Howes in the preparation of the new edition (1888) of Huxley and Martin's "Elementary Biology." From 1882-85 Dr. Scott was Assistant to the Professor of Botany at University College, London, and was from 1885-92 Assistant Professor in Biology (Botany) at the Royal College of Science, South Kensington, a position which he resigned to take up that which he at present occupies at the Royal Gardens, Kew.

REV. FREDERICK JOHN SMITH,

Clergyman of the Church of England. Millard Lecturer in Experimental Mechanics, Trinity College, Oxford. Distinguished for his researches in practical mechanics and physics, and the invention of important dynamometric and integrating instruments; also of the chronograph—registering graphically periods of time from ·00005 sec. to 1·0 sec.—now used in the measurement of the flight of projectiles and in physiological research. Author of numerous papers, among which may be mentioned:—"An Experimental Investigation of the circumstances under which a Change of the Velocity in the Propagation of the Ignition of an Explosive Gaseous Mixture takes place in Closed and Open Vessels. Part I.—Chronographic Measurements" (Proc. Roy. Soc., vol. xlv., 1889); "Description of Dynamometer and Integrator for measuring the work done in Driving Dynamos and other machines" (Electrician, 1881); "Ergometer or work measuring machine" (Phil. Mag., vol. xv., 1883, and NATURE, vol. xxx.); "A new form of Electric Chronograph (Phil. Mag., vol. xxix., 1890); "On some new Methods of investigating the Points of Recalescence in Steel and Iron" (*ibid.*, vol. xxxi., 1891); "On some of the Effects of Magnetism on Rods of Iron, Nickel, and other Metals which have received a Permanent Torsional Set" (*ibid.*, vol. xxxii., 1891).

JOSEPH WILSON SWAN,

M.A. (*honoris causa*) Durham. F.C.S. F.I.C. Has devoted himself for many years with great success to experimental scientific work, chiefly in relation to Electric Lighting, the Electro-deposition of Metals, and the Improvement of Photographic Processes. His labours have resulted in material extension of knowledge, and in important inventions, among which are the Incandescent Electric Lamp, the Carbon Process, by which the first permanent photographic prints were produced and which has formed the basis of many processes of photo mechanical engraving (in this relation the property of salts of sesquioxide of chromium to combine with gelatine and render it insoluble was discovered), the highly sensitive Gelatino-bromide Photographic Plate, the result of an original observation of the effect of heat on the gelatino-bromide of silver emulsion, the Cellular Form of Electrical Secondary Battery Plate, the production of Lamp Filaments from Solutions, Integrating Electric Meters, Safety Lamp for Miners, and an Electric Firedamp Indicator.

VICTOR HUBERT VELEY,

M.A., F.C.S. Lecturer on Chemistry. Author of the following papers: "On the Oxides of Manganese and their Hydrates" (Part I., Chem. Soc. Journ., 1880; Part II., *ibid.*, 1882); "On the Rate of Decomposition of Ammonium Nitrate" (*ibid.*, 1883); "On some Sulphur Compounds of Calcium" (*ibid.*, 1885); "On the Lime Process for the Purification of Coal

Gas" (Soc. Chem. Indust. Journ., 1885); "On some Sulphur Compounds of Barium" (Chem. Soc. Journ., 1886); "On the Conditions of Evolution of Gases from Homogeneous Liquids" (Phil. Trans., 1888); "On a Method of Investigating the Dissolution of Metals in Acids" (Chem. Soc. Journ., 1889); "On the Conditions of the Reaction between Copper and Nitric Acid" (Roy. Soc. Proc., 1889).

THE ARCTIC EXPEDITIONS OF 1894.

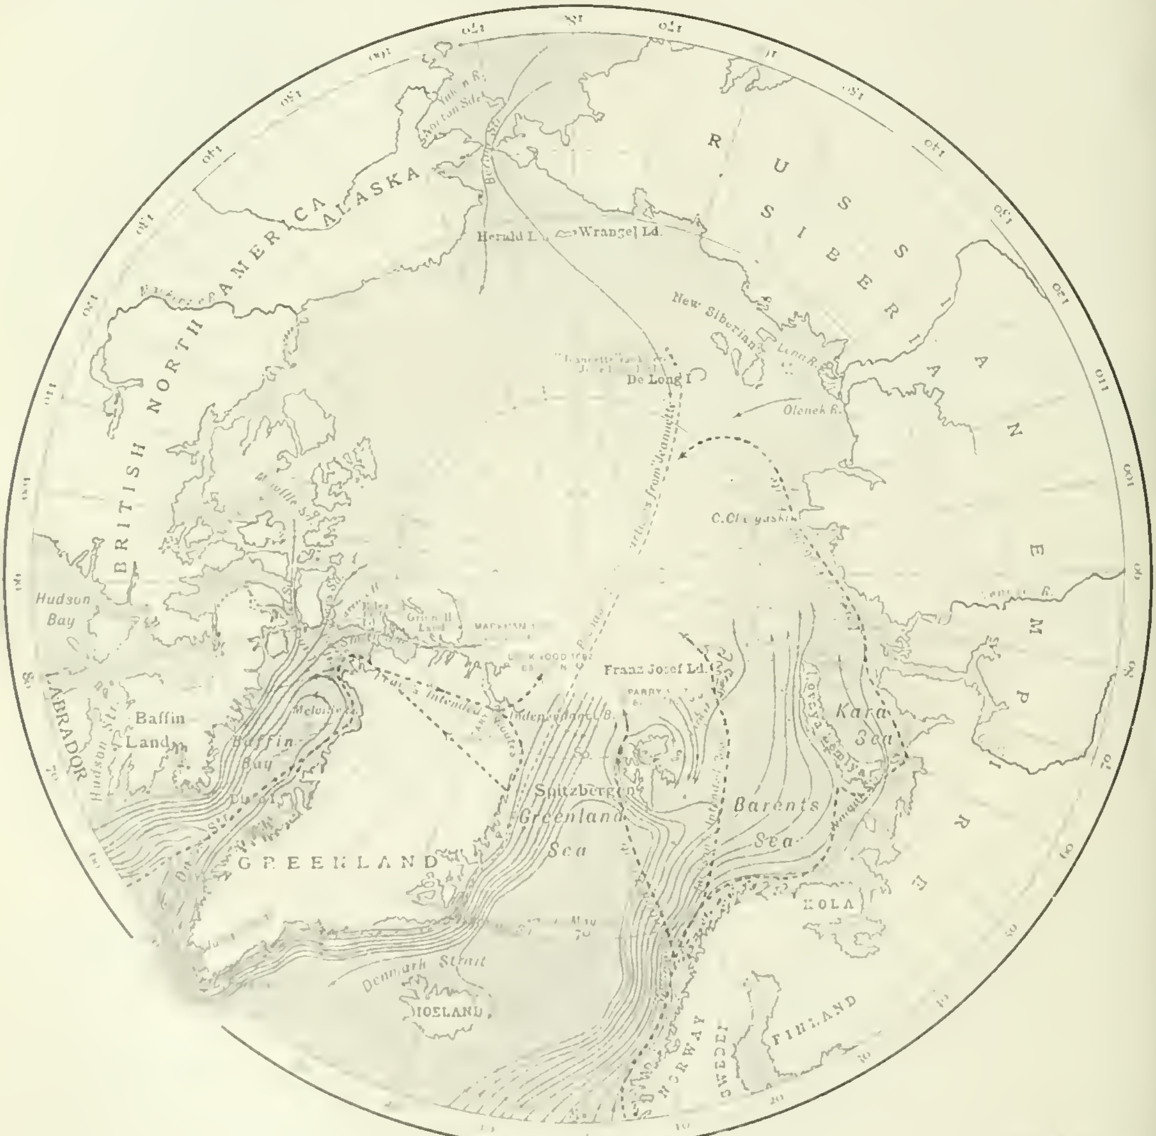
IT is not easy to speak definitely regarding the various Arctic Expeditions which will be in the field this year, for several of the most loudly advertised ventures have collapsed or been postponed, and it is possible that some quiet and determined explorers may set out without calling public attention to their plans. There is undoubtedly to be keen rivalry in the North Polar basin for several years to come, and even an incomplete forecast of the projected work may serve to direct notice to the regions whence good results in the way of Arctic discovery may be looked for. It is unnecessary to insist in the pages of NATURE, however needful the caution may be to the general public, that no credit for Arctic exploration can be given until the intending explorer returns, bringing with him proofs of his achievements which will bear the keenest criticism of experts.

Two well-equipped expeditions have been in the field since last summer, working by different methods, from different sides, but both led by men of experience and manned by tested Arctic travellers. Nansen's expedition in the *Fram* appeals most powerfully to the imagination for the boldness of its plan and the faith with which its leader bases his success and even his life on the truth of his theory of ocean-currents in the far north. The general trend of these currents, as drawn by Dr. Nansen, is shown on the accompanying map, which is reduced from one published in the *Geographical Journal*, vol. ii. His strongest evidence for the existence of a drift across the centre of the polar basin was, as is well known, the discovery on the ice off the south of Greenland of relics from the American exploring ship *Jeannette*, which sank off the New Siberian Islands; but this was fortified by much additional information. The *Fram* sailed from Christiania on June 24, 1893, passed through the Waigatz Strait on August 3, and the last news was that on August 6 some Samoyeds saw her passing along the Yalmal coast between the ice and the land. Nansen intended to call at the mouth of the Olenek River in September before turning finally northward, but he did not do so. If he had called, or even been sighted off the coast, the fact would have been reported to Baron Toll, who was in the neighbourhood of the Olenek until November. It seems probable that, making an easy passage across the Kara Sea, Dr. Nansen found sufficiently open water to induce him to turn northward off Cape Chelyuskin, as he was urged to do by Captain Wiggins, and that the *Fram* has passed the winter fast in the ice somewhere within the 80th parallel, possibly drifting polewards. No news can now be looked for by way of Siberia, and it is very unlikely, though just possible, that one of the expeditions going north this year, by Franz-Josef Land or Spitzbergen, may meet the crew of the *Fram*, where all meridians converge towards the pole.

Mr. Peary, after raising the necessary funds in America by writing and lecturing, returned to the scene of his former triumphs at Independence Bay on the north-east coast of Greenland. He and his party landed at Bowdoin Bay on Inglefield Gulf in Smith Sound on August 3, 1893, and established themselves there for the winter, being comfortably settled when the steamer left on August 20. Sledging parties were at once despatched to *cache* provisions at convenient depôts on the inland ice on the way to Independence Bay. Mr. Peary intended to commence his main journey about the middle of March this year, and to reach Independence Bay in the first week of May. Here the party will divide, three men being despatched to sledge south-eastward and survey the coast along the quite unknown stretch to Cape Bismarck, returning thence across the ice-cap to Inglefield Gulf. The other party will push northward from Independence Bay, and endeavour to completely survey the land which was seen across the strait last year, at the same time trying to attain the farthest north. The position of Navy Cliff, on the south side of Independence Bay, was fixed as 81° 37′, and since Lockwood's farthest north was 83° 24′, it is practically certain that Peary, with his great experience of foot-travel on the ice, will be able to make his way more than the 125 miles which would carry him nearer the pole than any previous traveller. This year he is not to depend entirely on dog-sledges, but to experiment with Mexican donkeys, which are accustomed to carry heavy loads in the low temperature and thick snow of the high Cordilleras. Whatever the result may be in record-breaking of northern latitudes, we may confidently expect a great deal of solid geographical and scientific work from this expedition. A steamer will call at Bowdoin Bay to bring back the party, or at least obtain news of them, in August or September.

The third expedition left Tromsoe on May 1, 1894, for Spitzbergen, with the object of repeating the attempt so gallantly made by Parry in 1827, when he reached 82° 45′. It is under the command of Mr. Walter Wellman, a journalist of Washington, who has carefully thought out his plan of action, and has commenced to carry it into effect without delay. Although he has had no previous Arctic experience, he is a man of great energy and enthusiasm; his companions are as enthusiastic and resolute as himself, and it is by no means improbable that he may be able to give a good account of his time. He terms his enterprise "a dash for the pole," and is determined to be back in America before the end of October. However, as a precautionary measure he is to provision the old seal-hunters' house on Danes Island in the north-west of Spitzbergen for a year, in case of enforced wintering. The object of starting so early in the season is to avoid the strong southerly drift of the ice, which so greatly hampered Parry's sledging parties. Thus, if Mr. Wellman's theory is correct, he will reach his farthest north before the drift becomes serious, and have the southward drifting ice-floes to help him on his return. By the use of very light boats, constructed entirely of aluminium, and provided with runners to convert them into sledges, the weight to be pulled will be greatly reduced. It is to be feared that Mr. Wellman's plan of taking Belgian draught dogs for his sledges will lead to difficulties on account of the difference in climate and in the nature of the work from those to which they are accustomed. The behaviour of the aluminium boats will be looked forward to with much interest.

Finally, the Jackson-Harmsworth expedition will take the field early in July, having for its purpose the exploration of the polar area lying north from Franz-Josef Land. Mr. Harmsworth, who is bearing the whole cost of the expedition, has purchased the *Windward*, of Peterhead, a well-known steam whaler of 320 tons, to take the party out to Franz-Josef Land, but the exploration will be conducted by land or across the ice. Mr. F. G. Jackson, the originator and leader of the expedition, has long thought over this matter, and devoted most of his time for two years to the study of Arctic problems. He spent a great part of last winter in the north of Russia, testing sledges and other appliances for ice-travel and practising surveying on the little-known Waigatz Island. Like Peary, he intends to try the endurance of stronger animals than dogs in Arctic work, proposing to take a number of Russian ponies. The *personnel* of the expedition, although probably not exceeding six, will include trained specialists and collectors, who will map their route, make meteorological and magnetic observations, and collect geological, botanical, and zoological specimens. After calling at Archangel, in the end of July, to take on board a Russian log-house, and then at Khabarova to ship West Siberian dogs and drivers, the *Windward* will proceed to Franz-Josef Land and make a landing somewhere in the south of that region, the exact spot depending on the state of the ice. The route to and his companions will spend the winter at their base, where the conditions of life were found to be quite endurable by Mr. Leigh Smith when he was compelled to spend a winter there, with very poor accommodation and equipment, after the wreck of his yacht, the *Eira*, in 1881. Early in the spring of 1895 the expedition would push northward, moving very slowly because of the necessity of traversing the distance several times over in order to carry the quantity of stores necessary to establish a depôt every thirty or forty miles along the



North Polar Map to illustrate projected Polar Expeditions.

Franz-Josef Land will thus be due north from near Kolguef Island, instead of north-eastward from Norway as shown on the map. The wooden house will be erected on a secure and sheltered site, and stocked with the necessary stores for four years, after which the ship will return. If, as seems possible from Payer's observations, Austria Sound should be found open, provisions will be carried north along it in a steam-launch and *cached* for subsequent use. Mr. Jackson route. This slow progress will, of course, give an opportunity for repeating observations for position, and so add to the accuracy of the map. The direction of advance will probably be along Austria Sound and across Petermann Land, the farthest north sighted by Payer in the Austro-Hungarian expedition, and lying in 83° N. Should Petermann Land extend to the north, Mr. Jackson intends to proceed along it, mapping his route as he goes. Boats would be carried for crossing open water, and if oceanic ice intervenes, it would be traversed as rapidly as possible, and a return made to the farthest north point on solid land, where winter-quarters could be established; but should this be impracticable, the retreat would be continued to the base, where the second winter would be spent. In the spring of 1896 the party would turn northward again, the chain of depôts accelerating their progress. In the summer of 1896 the ship will return with additional stores and men, and to obtain news; but it does not appear to be Mr. Jackson's intention to return, unless he is satisfied that his work is final, until 1897. This expedition ought certainly to extend our knowledge of the most northerly land known, and if fortune favours it, the advances made may be great. Its equipment is of the very best, and no excuse of bad material can be brought forward to explain unsatisfactory results.

The expedition for the exploration of Ellesmereland, to which reference has several times been made in NATURE, planned by Mr. Robert Stein, of the U.S. Geological Survey, has been postponed; we hope only until next season. Still efforts will be made this summer to clear up the fate of the unfortunate young Swedish naturalists, Björling and Kalstennius, with their mate, Gilbert Dunn, and cook, Herbert MacDonald, of whom the last news received was that they intended to seek shelter with the reported Eskimo of Ellesmere Land. Mr. Elis Nilson has been sent out by the Swedish Anthropological and Geographical Societies, on the Dundee whaler *Eclipse*, to visit the Carey Islands and Clarence Head, if the ice permits, and search for any relics of the missing party, whose fate, after two years without supplies, can scarcely be considered doubtful. Baron Nordenskjöld has interested himself particularly in the search, and will probably arrange for other whalers to deviate from their course in order to obtain information.

Dr. F. A. Cook, the ethnologist on Peary's former expedition, has issued a prospectus of a pleasure trip which he is to conduct up Baffin's Bay to Smith Sound, with the opportunity of a slight change of route should any of the passengers desire it. This would, if the state of the ice permitted, render it possible to call at Clarence Head and the Carey Islands, and make at least a hasty search for the missing party; but a pleasure trip scarcely lends itself to serious Arctic exploration.

Prophecy with regard to the results of geographical exploration is too uncertain to be indulged in by modern critics, and in Arctic exploration particularly the conditions are so difficult to predict that success may attend the most inexperienced and worst equipped, while experience and all the resources of wealth and science would struggle in vain against adverse conditions. There are certain remarkable features about the new expeditions which distinguish them from most of the earlier efforts. Each has been planned and is being carried out by a man who is thoroughly in earnest, and whose reputation rests on his success. This is widely different from the case of a commander "ordered" to carry out the plans of others. Each expedition is small; Nansen's, which is the largest, comprises only thirteen men. Two of those which have already faced the awful monotony of the Arctic night, have appliances for dissipating the darkness by the electric light, an advantage which can hardly be over-estimated in its effect on the spirits of the men. Provisions and equipments have been greatly improved, even since the time of the *Alert* and *Discovery* and of the *Jeannette*. Most important of all, three of the expeditions are free from the responsibility of a ship. In all these ways the four serious attempts of this year have elements of success never combined previously. Their results will not be known for some time. News of Mr. Peary will certainly be received this autumn by the vessel to be sent up to Inglefield Gulf to bring him home if he considers his work satisfactorily finished. It is probable that Mr. Wellman also will return; but unless he should by some scarcely credible good fortune meet the crew of the *Fram* at his farthest north, we cannot hope to hear of Nansen for another year at least; and Mr. Jackson's scheme provides for a possible absence on his part for four years, though progress should be reported before the end of next year.

HUGH ROBERT MILL.

THE CRINOIDEA OF GOTLAND.[1]

THIS is the first instalment of a memoir based on a revision of the specimens of crinoids in the Angelin collection at Stockholm. It is published in English, and is illustrated by Mr. G. Liljevall, who has produced 382 remarkably beautiful figures upon ten quarto plates. Their accuracy may be relied on by those who know Mr. Bather's own scrupulous carefulness as an artist.

The author commences by pointing out the need for a thorough re-examination of the Stockholm specimens, the drawings in Angelin's "Iconographia Crinoideorum" being so frequently misleading, and having been in many cases produced by a union of several distinct individuals. The older palæontologists certainly had not that reverence for type-specimens which now very justly prevails among curators; they brought out, as they thought, the salient points of their specimens, filled in a sort of fancy groundwork of rock around the drawing, and left students to search in vain in the collection for the exact object that had thus been honoured above the others.

The classification of the Crinoidea undergoes considerable changes with each new descriptive paper, and Mr. Bather's works are a healthy example of receptivity and indifference to precedent. We read each in the light of the glossary appended to it, ridding our minds as far as possible of the technicalities that we have previously learned. We must confess that such changes in nomenclature are based on observation and on additions to our knowledge, and we need only quarrel with the terminology when it is reduced to algebraic symbols.

The abolition of the Fistulata and the Larviformia as sub-orders of the Inadunata (p. 8), and the substitution—quite temporarily—of divisions based on the presence or absence of infrabasals, may be hailed as a simplification, allowing more latitude in the association of the several genera. But the value of such close and detailed work as that of the present memoir will depend in no way upon the stability of the classification utilised. Mr. Bather (p. 19) can thus treat even the Inadunata as a convenient portmanteau, soon to be worn out; and specialists will turn with pleasure to the critical descriptions of individual specimens in the collections.

A fine example of how the collation of specimens, year after year, will add profoundly to our knowledge of ancient life upon the earth, is to be found in the story of *Herpetocrinus* (pp. 36-45). The crown of this genus was detected in certain Dudley specimens by Mr. Bather himself, Salter's opinion being thus amply verified; and the coiled stem, often supposed to be an arm, is now shown to have had a permanent tendency (p. 45), by its very structure, to bend round in one direction, while it could probably be uncoiled "by the simple contraction of the large muscles on the outer part of the articular surface." With a quaintness of expression now familiar to us, our author proceeds: "It is very probable that the animals usually broke off any rooted attachment they may have formed, and that they clung to corals or other submarine objects by their cirri." It is further suggested that they could move from one spot to another.

[1] "The Crinoidea of Gotland." Part i. The *Crinoidea Inadunata*. By F. A. Bather, M.A., F.G.S. (Stockholm: Kongl. Svenska Vet.-Akad, Handl. Bt. 25. 1893.)

The extraordinary difficulties surrounding this genus are illustrated by the fact that Mr. Bather himself at one time described the arm of a *Streptocrinus* as the stem of *Herpetocrinus* p. 176).

Controversial matters are treated in this paper with the delicacy of the duellist rather than with the tactics of the football-field; and Mr. Bather may be congratulated on the position he has gained among the exponents of intricate research. We look forward with keen interest to the completion of this handsome memoir.

G. A. J. C.

A DEDICATORY NUMBER OF THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.

A SPECIAL complimentary number of *The Quarterly Journal of Microscopical Science* has been issued, dedicated by his colleagues to Prof. E. Ray Lankester, F.R.S., in celebration of the completion of twenty-five years of editorship. The *Journal* contains contributions by Dr. E. Klein, F.R.S., Prof. A. G. Bourne, Mr. Adam Sedgwick, F.R.S., Mr. W. C. McIntosh, and Prof. A. A. W. Hubrecht, of Utrecht University. It is prefaced by the subjoined historical sketch, signed by Mr. Sedgwick and Prof. Weldon.

It is now five-and-twenty years since Prof. Lankester first undertook the task of editing the *Quarterly Journal of Microscopical Science*, and by issuing the present number his colleagues desire to mark the occasion, and at the same time to take the opportunity of offering to him their hearty congratulations on the success which has attended this quarter of a century of effort on his part.

The *Journal* was founded in the year 1853 by the publisher, Mr. S. Highley, and was edited by Dr. Edwin Lankester and Mr. George Busk. In 1856 the publisher's business was transferred to Mr. John Churchill, with which firm it has remained ever since. Up to 1868 the *Journal* published the "Transactions of the Royal Microscopical Society of London," but in 1869 the Society started its own publication, and a new editorial arrangement of the *Journal* was made. Mr. George Busk retired, and Mr. Ray Lankester, who had lately taken his degree at Oxford, joined his father in the editorship.

Mr. Ray Lankester's connection with the *Journal* began in 1863 with the publication of a paper on "Our Present Knowledge of the Gregarinæ," followed in 1864–5 by a memoir, in three parts, on "The Anatomy of the Earthworm." In 1865 he suggested the publication of a quarterly chronicle of the progress of histology and microscopic investigation, and joined Mr. Busk in its preparation. Curiously enough, this feature has been abandoned since 1872, whilst the Royal Microscopical Society has taken the task in hand, and produces an admirable and extensive record.

In 1872 Ray Lankester's father ceased to take part in editing the *Journal*, and was succeeded by Dr. J. Frank Payne. Lankester and Payne added Mr. Thiselton Dyer (now Director of Kew Gardens), to their editorial body in 1873, and he was succeeded in 1876 by Mr. Archer, of Dublin, the Secretary of the Dublin Microscopical Club, and the author of so many interesting discoveries among freshwater Rhizopoda. In 1877 Dr. Payne retired, and Dr. Klein joined the editorial staff.

In 1878 a further change was made. Prof. Lankester became sole editor, with the co-operation of Archer, Francis Balfour, and E. Klein. This arrangement has continued ever since, with various changes in the list of those co-operating. Thiselton Dyer returned for a few years as one of those giving his co-operation; and Moseley and Milnes Marshall have in turn assisted in the conduct of the *Journal*, and have published in it many of their most important papers, inducing their pupils to adopt the same mode of publication.

The number of contributions which this energetic policy attracted to the *Journal* soon made it necessary to enlarge it; and the term of Lankester's editorship has been marked by a continuous increase in the amount of letterpress and in the number and excellence of the plates. This has of necessity been accompanied by a rise in price. The original price was four shillings per number—the numbers being issued quarterly. At that time the volume consisted of some eight-and-twenty demy octavo sheets and twenty plates, mostly also octavo. The last volume contained thirty-six royal octavo sheets and forty-two plates, many of which were coloured, while the majority were of quarto size. The change from demy to royal octavo was effected at the commencement of 1883, and in 1890 the strict quarterly publication of the *Journal* was abandoned, so that more than four numbers could be issued in the year. During the eleven years which have elapsed since 1883, sixty-one numbers, divided into fifteen volumes, have been issued; so that the increase in size and price has not only affected the magnitude of each number, but has been accompanied by an increased rapidity of publication.

Every reader will remember that Prof. Lankester's energy has by no means been exhausted in merely editing the *Journal*, for besides his many writings elsewhere, he has published more than sixty memoirs in the pages of this *Journal* alone; and we may, perhaps, be permitted to mention a few of the more prominent of these—such as that on "The Development of the Pond Snail" (1874), which marks the starting-point of his well-known investigation of the development of Mollusca; the "Notes on the Embryology and Classification of the Animal Kingdom" (1877), which exercised so great an influence upon the whole tendency of morphological speculation; the descriptions of Limnocodium (1880); the series of memoirs on Apus and Limulus (1881–1884), and on Rhabdopleura (1884); the first description of the atrio-cœlomic funnels in Amphioxus (1875), and the subsequent memoir on the anatomy of the same animal, together with the account, commenced in conjunction with his pupil, Mr. Willey, and continued by Mr. Willey alone, of the later history of its remarkable larva.

It would be useless to enumerate all the naturalists who have contributed to the *Journal* since Prof. Lankester's successful enterprise has made it the chief medium of publication for English morphological work; but it is interesting to notice that the contributors have constantly included foreign naturalists of distinction, including E. van Beneden, Bowditch, Carrière, Claparède, Dollo, Giard, Hubrecht, Iijima, Ischikawa, Kingsley, Mitsukuri, H. F. Osborn, Oudemans, Packard, Patten, Pelseneer, Pouchet, Ranvier, Whitman, and others. Some of these have taken the opportunity, by contributing to the present number, of joining in the hearty congratulation on his past achievement, and sincere good wishes for the future, which Prof. Lankester's associates now offer to their chief.

NOTES.

THE following fifteen candidates were selected on Thursday last by the Council of the Royal Society, to be recommended for election into the Society:—Mr. W. Bateson, Mr. G. A. Boulenger, Dr. J. R. Bradford, Mr. H. L. Callendar, Prof. W. W. Cheyne, Mr. R. E. Froude, Prof. M. J. M. Hill, Prof. J. V. Jones, Mr. A. E. H. Love, Mr. R. Lydekker, Mr. F. C. Penrose, Dr. D. H. Scott, Rev. F. J. Smith, Mr. J. W. Swan, and Mr. V. H. Veley. We print their qualifications in another column.

THE "Ladies' Conversazione" of the Royal Society is announced for Wednesday, June 13.

THE death is announced of Dr. E. H. Vinen, at the age of sixty-nine. He was a Fellow of the Linnean Society, and well known among botanists and geologists.

WE regret to learn of the following deaths among scientific men abroad:—Dr. Louis von Uslar, Professor of Pharmacy in the University of Göttingen; Dr. A. Schmidt, Professor of Physiology in the University of Dorpat (or Jurieff); and Prof. Thomas Morong, the well-known botanist.

THE Council of the British Medical Association are prepared to receive applications for grants in aid of researches for the advancement of medicine and the allied sciences. Applications for sums to be granted at the next annual meeting must be made on or before June 15 in writing, addressed to the General Secretary, at the office of the Association, 429, Strand, W.C. They must include details of the precise character and objects of the research which is proposed. Reports of work done by the assistance of Association grants belong to the Association. Instruments purchased by means of grants must be returned to the General Secretary on the conclusion of the research in furtherance of which the grant was made. The Council of the Association are also prepared to receive applications for one of the three Research Scholarships which is vacant, of the value of £150 per annum, tenable for one year, and subject to renewal by the Council for another year.

A LECTURE on "Recent Discoveries at Koptos," with illustrations, will be delivered by Prof. Flinders Petrie at University College, Gower Street, on Saturday, May 26, at 2 p.m. These discoveries include the long-sought rise of Egyptian art, and the prehistoric remains of the race on entering Egypt. The lecture will be free to the public without ticket.

AT the annual general meeting of the British Ornithologists' Union, held on Wednesday, the 9th inst., Lord Lilford was re-elected President, and Mr. F. D. Godman Secretary, for the ensuing year, and Lieut.-Colonel L. H. Irby and Mr. W. T. Blanford, F.R.S., were placed on the committee in lieu of two retiring members. It was agreed that a new (seventh) series of *The Ibis* should be commenced in 1895 with the thirty-seventh volume, and that Dr. P. L. Sclater, F.R.S., and Mr. Howard Saunders should be appointed as joint editors of it.

IT is impossible to speak too highly of the part taken by the Smithsonian Institution in diffusing knowledge. Not the least important of the methods adopted to make the works of men of science known unto the ends of the world, is the inclusion of miscellaneous reprints of memoirs in the annual reports of the Institution. A report just received shows the operations, expenditures, and condition of the Institution in 1892, and contains an appendix of the kind referred to. Therefore it is useful and interesting to all engaged in the promotion of knowledge. Of the thirty-three papers appended to the report, six have been reprinted from NATURE, and, we need scarcely say, proper acknowledgment of the source is given in each case. There are several translations of important papers, among them being Prof. J. A. Palmén's report on the migration of birds, presented to the second International Ornithological Congress in Budapest in 1891; and translated extracts from an ornithological essay on the flight of birds, by M. L. P. Mouillard, published in Paris in 1881 under the title "L'Empire de l'Air." Other contributions calling for special mention refer to the geological history of the Yellowstone Park, Mr. W. Woodville Rockhill's explorations in Mongolia and Thibet, and the progress of astronomy during 1891 and 1892.

THE recent publication of several important works has brought into prominence the subject of the theo y of functions. Those who are interested in this branch of mathematical science will therefore be glad to know that Messrs. Mayer and Müller, of Berlin, intend to publish, in about eight volumes, the collected papers of Herr Karl Weierstrass, who has been termed the creator of the modern theory of functions. The work will be issued under the auspices of the Königlich Preussischen Akademie der Wissenschaften, and it is with the sanction of Prof. Weierstrass himself that this edition of his collected mathematical works is allowed to see the light. Messrs. Mayer and Muller rightly ground the importance of this publication on the name of the author. The first part is to contain memoirs already published, or which are ready for publication, in three volumes, the papers being printed in chronological order. The series is to open with "the development of the modular functions" which was presented to the Prüfung's-Commission at Münster in 1841. This part also contains the Braunsberg School programme, the fundamental importance of which in the theory of the Abelian functions is well known. The second part is to consist of five volumes, and will include the greater part of the lectures delivered in the University of Berlin. In the first volume of this part is the lecture based on "the Theory of the Elliptic Functions," which was delivered for the first and only time in the Professor's sixtieth year (*cf.* Forsyth, cap. v.-vii.) The theory is here established on Euler's Addition-theorem. The lecture closes with an application to several geometrical and mechanical problems. A later volume contains "the general Elliptic Transcendents," as well as a detailed discussion on the transformation of elliptic functions. The theory of the Abelian functions occupies the remaining volumes, one of which is devoted to a special discussion of the theory of the so-called hyperelliptic functions. The lectures are to be edited by a former pupil of Prof. Weierstrass, who, however, will himself supervise the publication. The work is to come out in quarto volumes, and great care is to be bestowed on their production. It is expected that all the volumes will be issued in a few years.

PROF. W. C. MACKENZIE, of the College of Agriculture, Ghizeh, has sent us some interesting information with regard to the existence of nitrate of soda in Egypt. It appears that the natives of Upper Egypt, from Keneh to Esneh, are in the habit of carrying a substance called "tafl," from the hills on the east side of the river, to manure their fields, especially the maize crop. That this was done seems to have been well enough known to many people in the habit of spending some time there, but beyond a casual knowledge of the fact that the "tafl" was used as a manure, no further interest seems to have been taken. What the valuable ingredient was, does not seem to have been known, and the name "tafl" was used indiscriminately for clay for pottery and clay for manure. Analyses of several samples of this substance showed, however, that they contained nitrate of soda from 2 per cent. to 18·5, mixed with varying proportions of chloride and sulphate, as well as calcium carbonate and clay. Further examinations of other samples did not show such a high percentage, the richest containing only 4 per cent. Prof. Mackenzie visited the deposit in the hills east from Luxor, and some eight miles distant from the town across the desert, and there found the "tafl" right on the face of a limestone hill, apparently cropping out of the rock. Samples taken at different heights gave percentages varying from 2 to 9·5 of nitrate of soda. On sending in a report about this nitrate, Nubar Pasha, the present Prime Minister, arranged to send up Mr. E. A. Floyer and Prof. Sickenberger to investigate the whole question, and endeavour to estimate the quantity. The investigation will no doubt throw considerable light on the origin of this curious occurrence of nitrate. Prof. Mackenzie thinks that the idea that the clay has simply acted as an absorbent for nitrates got from accumulations of potsherds, &c., does not seem possible, for at Luxor there is no evidence of this whatever, the deposit of nitrate-bearing clay being at the foot of a limestone cliff, and no appearance of potsherds anywhere. He believes that more probably caves or swallow-holes in the limestone cliffs have collected clay and organic matter from the river, and the nitrification of this organic matter has produced the nitrate where it is now found. Messrs. Floyer and Sickenberger's report will, however, no doubt clear this point up.

AMONG the shorter contributions in the May number of the *Psychological Review* is one by Prof. W. O. Krohn on the relation of sensation-areas to movement. He had the opportunity of testing the sensitivity of the skin of a man who had had his left forearm encased in a plaster-of-paris case for a period of three months. During this entire period the forearm could not be moved either at the wrist or at the elbow. Prof. Krohn compared the sensitiveness of the skin of the uninjured right forearm with that of the left forearm of the same person, after the plaster case had been removed, by means of the usual æsthesiometric tests. He found that on the latter forearm the one so long unmovable, when the two points of a pair of dividers or compasses, touching the skin at a given locality, were separated by as much as fifty-five millimetres, they were felt as one instead of two; while on the right forearm they only had to be about twenty millimetres apart in order to be perceived as two. On the back of the left arm, at a different locality from that just mentioned, it was found that even when the two points of the dividers were seventy-five and eighty millimetres apart, they were felt as one; while at a corresponding locality on the right arm the skin was so sensitive that points but 17 mm. apart could be felt as two. It should be mentioned that the subject was practically ambidextrous before meeting with the accident which led to the casing of his arm in plaster. Prof. Krohn thinks, therefore, that the sensitivity of the skin over the injured forearm was lost simply because that member was for so long a time immovable. He points out that this has an important bearing upon the principle that "the localising power is delicate in proportion as the skin covers a movable part of the body."

An "Atlas of the French Lakes" has been in progress since 1886, under the auspices of the Ministry of Public Works in France. It is now completed, and published in ten sheets, with coloured contour-maps of the French lakes, great and small. Lake Geneva, partly done by Swiss surveyors, is drawn to scale 1 50,000, Lake d'Annecy to scale 1 20,000, and the others 1 10,000. Several results of general interest are obtained—for example, the regular spherical shape of old crater lakes in the Auvergne district, the shallowness and irregularity of lakes at the outflow of a glacier, such as Lake Sylans in the Ain Department; again, the filling-up of lakes at the inflow of the river, typically shown by Lake Brenets, in the course of the River Doubs. The work has been accomplished by M. André Delebecque, Civil Engineer of Bridges and Roads, assisted by his colleagues MM. Garcin and Magnin. The day has yet to come when our Government will authorise a similar special work on British lakes.

So little is known about the origin of many infectious diseases that an article by Dr. Keser, in the *Medical Magazine* for May, will be read with interest. The chief reason why the matter is in obscurity is that the descriptions of diseases found in the works of early writers do not afford the necessary means of identification. A noteworthy exception to this, however, is Thucydides' narrative of the plague of Athens. The author gives a graphic account of an acute well-marked epidemic disease which invaded Athens in the year 430 B.C., appearing unexpectedly amongst healthy people, and destroying the lives of many thousand inhabitants during the three years that it lasted. It has been supposed by some that the disease was small-pox, while others have considered it to have been a malignant form of scarlatina or typhus. A careful review of the facts and evidence, however, leads Dr. Keser to believe that the plague of Athens was probably a variety of the true Oriental plague, characterised chiefly by a varioliform exanthem with redness and lividity of the skin, by ulcers, and by the absence or rarity of buboes. The connecting links between this form of the plague and the typical *Pestis inguinaria* still remains a matter of conjecture.

The April number of *Das Wetter* contains an article on sun-spots and weather, by P. Polis, based on sixty-four years' observations at Aix-la-Chapelle (1830-93). The author has tabulated Wolf's relative sun-spot numbers, together with the yearly, winter, and summer mean temperature values, the number of thunderstorms and annual rainfall, and has also represented the values graphically. The curves show that down to the year 1878 the summer and annual mean temperatures decrease with greater sun-spot frequency, and that an increase of summer and yearly temperature occurs with a decrease of sun-spots. The winter temperature curve also agrees generally with the other two. From the year 1878 the temperature curves are reversed, a decrease of sun-spots corresponding with a fall of temperature, and *vice versâ*. The rainfall curve is irregular, but it appears, contrary to results obtained elsewhere, to take exactly an opposite course to that of the sun-spots. The number of thunderstorms increases generally with a decrease of sun-spots, and *vice versâ*.

For some years past, Prof. Klossovsky, Director of the Meteorological Observatory of Odessa, has been actively engaged in collecting and discussing observations bearing on the climate of south-west Russia, and the observers co-operating with him amounted in 1892 to 1900 in number. A valuable paper on the climate of Odessa has recently been published (in Russian), from which it appears that the mean annual rainfall for 1866-92 was about 17 inches; the wettest month during this period was June 1886, in which the rainfall was 6.6 inches, while in September 1892 no rain fell. The annual mean temperature was 50°.2; the maximum was 95°.4, and the minimum −18°.8, giving an annual range of 114°.2. Several papers have also been published, bearing upon the agriculture of the district, including phenological observations, and also the occurrence of sandstorms, which are frequent in that part of Russia.

A recent number of the *Comptes Rendus* contains a paper by M. R. Swyngedauw, on the ratio of the currents produced by the discharge of a condenser in two circuits placed in parallel, one containing a spark-gap and the other self-induction. The apparatus employed by the author consists of a battery of two Leyden jars charged by a Holtz machine. The conductor which joins the coatings of these jars contains (1) a spark gap I_1; (2) a coil T which is traversed by the whole discharge Q_T; (3) two branch circuits, one containing a coil D exactly similar to T, the other containing a spark-gap I_2. The two coils T and D are identical, and can be placed either simultaneously or separately on the cross-bar of a Wiedemann-d'Arsonval galvanometer. Thus, by placing first the coil T and then D on the galvanometer, the total quantity of electricity discharged, or the fraction which passes through the branch circuit containing the coil, can be measured. The author finds that if the sparking distance I_1 is left constant, that the quantity of electricity passing through the branch circuit containing the coil increases continuously as the spark interval I_2 is increased. When the spark interval I_2 passes a certain limiting value, the quantity of electricity passing through the branch coil is greater than that passing through the coil T. This anomalous increase might be considered to be due to a dissymmetry in the spark-gap I_2, so that oscillatory currents set up in the branch circuits would pass one way but not the other. The author finds, however, that if this spark-gap is changed, or the direction of the discharge changed, the increase is still observable.

An elaboration of the presidential address delivered by Dr. D. Christison in November 1892, before the Botanical Society of Edinburgh, has just been published in the Society's *Proceedings* (vol. xix. part 3). The subject of the address was the actual size of the largest trees of species, native or long-naturalised, in Britain, particularly in Scotland, with a discussion of the question of their probable age. At the end of the paper Dr. Christison dispels a few pleasing illusions with regard to some historic trees. It is chiefly the oak, among trees, that has been associated with historic deeds, and perhaps none has acquired such fame as the Boscobel oak, reputed to have concealed Charles II. after the battle of Worcester in 1651. Dr. Christison says that an inscription which was placed against the present tree in 1875 certifies:—"This tree, under the blessing of Almighty God, had the honour of sheltering from his foes King Charles II." But, it is pointed out, Mr. R. F. Collins (*Trans. North Staffordshire Field Club*, 1890) has shown that this tree, being only eleven feet ten inches in girth, could not have been the pollard oak of nearly two and a half centuries ago, and that a previous inscription in 1817 testified that "the present tree sprung, it is said, from the above tree" (meaning the Royal tree). Previous inscriptions were also referred to, from which it seems that the original tree disappeared soon after 1787. Indeed, Dr. Stukely recorded that in 1713 "the tree was in the middle almost cut away by people who came to see it." As to historic hawthorns, one is credited with having witnessed the death of Lord Maxwell at the Battle of Dryfe Sands, and several have been associated with Mary Queen of Scots; but Dr. Christison remarks that it is scarcely possible that any hawthorn could exist for three hundred years, as the species rarely exceeds a very moderate size, and his observations show that it grows at a fair average rate.

MR. THOMAS CARROLL'S general report on the Irish Agricultural Department during 1892, published a few weeks ago, contains the results of experiments carried out under his direction, having for their object (1) the determination of the mode by which the disease *Phytophthora infestans* reaches the tubers of the potato plant, and (2) the examination of measures for the prevention of, or for the lessening the effects of, the disease upon the crop. The point upon which information was especially desired was, whether the disease producing Mycelium reached the tubers of the potato plant through the aerial and underground stems, or by means of the disease-producing spores falling upon the ground, and being carried through it to the surface of the tubers. To test this, a portion of ground upon which potatoes were growing was covered beneath the potato stems and leaves with a layer of cotton wool. This cotton wool was carefully placed around the stems, and every means used to have the ground perfectly covered with it, with the view of filtering out the spores that might fall upon the ground. No diseased potatoes were found on plants protected in this manner, whereas many occurred on plants grown in ground not covered with cotton wool. These experiments, which were very carefully carried out, serve to indicate that the disease is carried to the tubers of the potato plant through the spores which cause the disease being taken through the earth to the tuber, and not by means of the Mycelium finding its way to the tubers through the stem of the plant. An experiment, having for its object the testing of the effect of removing the stalks of potatoes upon the appearance of disease, with the view of preventing the tubers from being affected, was carried out at the Ballacutranta School Farm, County Sligo. This system of removing the potato haulm upon the appearance of the disease has frequently been recommended as a preventive. To test it, two plots of ground bearing a crop of potatoes were marked out for experiment. On one the stalks were removed; on the other they were allowed to remain. A comparison of the weights of the crops in each case, and the amounts of diseased tubers, shows, however, that through the removal of the potato haulm, before the crop was matured, the yield of crop was lessened without commensurate benefit in freedom from disease.

MR. GEORGE S. PERRIN has sent us a paper on "Australian Timbers," read before the Royal Victorian Institute of Architects in September 1893, and having special reference to the ornamental and decorative woods of Australia.

Bulletins Nos. 48, 49, and 50 have been sent out from the Purdue University Agricultural Experiment Station. They contain the results of experiments with small fruits; a history of the attempts that have been made to establish the sugar-beet in America, with a statement of the conditions required for its successful cultivation; and the results of some field experiments, by Prof. W. C. Latta, with Indian corn and oats. The *Bulletins* are sent free to all agriculturists in Indiana who desire them, and their contents are found iovaluable.

ON April 18 the Geological Survey of Alabama attained its majority—twenty-one years—under the present management. It has been thought desirable to mark this occasion by some sort of permanent memorial, and to this end maps are in course of preparation showing the condition of knowledge of the geology of the State at the beginning and at the end of the period 1873–1894, and columns showing the relative amounts of raw materials and of finished products from Alabama mineral resources at the same times, are also in preparation. In the line of this design a sketch has been prepared by Mr. E. A. Smith, showing the origin and progress of the survey, the difficulties under which it has laboured, what it has accomplished, what it has cost, and what it yet hopes to accomplish.

A LIST of apparatus for the psychological laboratory designed by Prof. J. Jastrow, and made by the Garden City Model Works, Chicago, has been received. It comprises descriptions of æsthesiometers, for determining the distance upon the skin at which two points are just perceived as two; pressure attachments, for testing the pressure sense of the skin; apparatus for the sense of roughness and smoothness; apparatus for all kinds of reaction experiments; an arrangement for testing the appreciativeness of changes of temperature; others for recording involuntary movements; and for testing memory. The character of some of the apparatus shows that experimental psychology and physiology overlap to a large extent. Indeed, it is often difficult to define the limits of psychological and physiological research. Like many other branches of science, these two merge into one another, and their peculiar provinces of investigation are comparatively small.

The fourth volume of the *Proceedings* of the Chester Society of Natural Science and Literature, which has just been published, contains a number of very interesting articles by several well-known men of science. It is a matter for regret that the publication of some of the papers has been so long delayed. For instance, we note that a paper by Prof. T. McKenny Hughes, F.R.S., on the Silurian Rocks of North Wales, was read before the Society in January 1886, and another, on caves and cave deposits, in October of the same year. Mr. A. O. Walker contributes to the volume some notes on the natural history of the Chester district, from 1879 to 1893, a paper on the climate of Chester, and one on that of the North Coast of Wales. The Heron, and Heronries of Cheshire and North Wales, forms the subject of a contribution by Mr. R. Newstead, who also gives a preliminary list of the mammals of the same district. Another important list gives the results of observations on the occurrence and distribution of birds in different parts of West Cheshire, Denbighshire, and Flintshire. This list was drawn up by Mr. W. H. Dobie, and is accompanied by a map. From this brief description it will be seen that the Chester Society of Natural Science is doing something to promote the study of natural knowledge. We are glad to learn that the Society is in a very flourishing condition, the number of members being at present over six hundred.

THE Society for the Protection of Birds have added to their list of publications a pamphlet by Mr. W. H. Hudson, entitled "Lost British Birds." The species described as lost by Mr. Hudson are those of which the British race is extinct, or very nearly so. The list includes the Crane, White Spoonbill, Capercailzie, Avocet, Great Bustard, Blacktailed Godwit, Great Auk, Red Night reeler, Bittern, Marsh Harrier, Ruff and

Reeve, and Hen Harrier. Though it may be thought a little "previous" to refer to some of these species as lost, there are others, such as the Goshawk, Night Heron, Little Bittern, and Baillon's Crake, not included in the list, but which there is reason to believe were once summer residents and breeders in Great Britain. It is often remarked that the total disappearance of some species of birds, and the extreme rarity of others once common in this country, is due to the draining of marshes and similar changes on the face of the land. But the facts brought together by Mr. Hudson show that the disappearances have been mostly brought about by the direct action of those inveterate bird-destroyers, described as "The Cockney sportsman, who kills for killing's sake; the gamekeeper who has set down the five-and-twenty most interesting indigenous species as 'vermin' to be extirpated; or, third and last, the greedy collector, whose methods are as discreditable as his action is injurious." If these and others who have helped to degrade the character of our bird-population will read Mr. Hudson's little pamphlet, they will see the greatness of the change that has taken place.

Further interesting properties of sodium peroxide are described in the current *Berichte* by Prof. Poleck, of Breslau. It is shown that sodium peroxide rapidly reduces salts of gold, silver and mercury with separation of the metal and evolution of oxygen gas. Platinum, however, is not precipitated from chloroplatinic acid or chloroplatinates until they are decomposed with a silver salt, when reduction both of the resulting platinum chloride and of the silver chloride occurs, both metals being precipitated. Ferric hydroxide is precipitated, as might be expected, from both ferrous and ferric salts; from manganous salts manganese dioxide is precipitated, presumably hydrated, and from salts of cobalt the higher cobaltic oxide. Permanganates are reduced to manganese dioxide, but chromic oxide is oxidised to chromic acid. The separation and quantitative estimation of iron and chromium or manganese and chromium are easily achieved by utilising these reactions, for iron is precipitated as ferric hydroxide and manganese as peroxide, while chromium remains in solution as chromate of sodium. Sodium peroxide also produces the highly oxidised sodium peruranate, $Na_4U_2O_8 + 8H_2O$, directly from salts of uranium, and it may readily be isolated by addition of alcohol which precipitates it. It is also interesting that iodine is oxidised on warming directly to the difficultly soluble acid sodium periodate, and upon decomposition of this salt with silver nitrate the normal silver periodate is at once produced, and free periodic acid $HIO_4 + 2H_2O$ may be readily obtained from it in large crystals by decomposition with bromine and subsequent evaporation *in vacuo*. Potassium ferricyanide behaves towards sodium peroxide in a similar manner to its action with hydrogen peroxide, reducing it energetically to ferrocyanide, and the volumetric process of Kassner can be readily carried out by use of it. Sodium peroxide reacts with lead oxide in presence of water to produce a plumbate of sodium of the composition $Na_2PbO_3 + 4H_2O$. Organic compounds dissolved in alcohol are usually very rapidly oxidised by sodium peroxide, while the alcohol itself is not attacked. Ether, on the contrary, at once ignites when brought in contact with the peroxide. Prof. Poleck recommends its use likewise in the separation of arsenic, antimony and tin, for the sulphosalts of these elements are at once oxidised by sodium peroxide in presence of water to oxygen compounds, the whole of the sulphur being simultaneously converted into sulphuric acid. Hence in toxicological investigations it is only necessary to oxidise the sulphosalts with sodium peroxide before proceeding immediately to employ Marsh's test. The practical uses of sodium peroxide appear indeed to be very numerous, and the information now rapidly accumulating concerning it will doubtless prove of value both from the theoretical and the technical point of view.

In our note concerning the atomic weight of barium (vol. xlix. p. 562), the statement that "the highest and lowest individual values obtained among the whole fifty separate estimations were 137·42 and 137·45" should have read "the highest and lowest of the mean values obtained from the different series of estimations were 137·42 and 137·45."

The additions to the Zoological Society's Gardens during the past week include a Mozambique Monkey (*Cercopithecus pygerythrus*, ♀) from South-east Africa, presented by Mr. H. Tattenhall; two Laughing Kingfishers (*Dacelo giganteus*), two Berigora Hawks (*Hieracidea berigora*) from Australia, presented by Mr. A. E. Henniker; seven Spanish Blue Magpies (*Cyanopolius cooki*) from Spain, presented by H.R.H. the Comte de Paris; a Tuatera Lizard (*Sphenodon punctatus*) from New Zealand, presented by Dr. W. J. Mackie; an Egyptian Terrapin (*Trionyx ægypticus*) from West Africa, presented by Mr. F. W. Marshall; a Green Lizard (*Lacerta viridis*) European, presented by Miss S. Borgaes, a Yellow-billed Sheathbill (*Chionis alba*) from Antarctic America, a Red and Blue Macaw (*Ara macao*) from South America, a Black Iguana (*Metopoceros cornutus*) from San Domingo, a Geoffroy's Terrapin (*Hydraspis geoffroyana*) from Trinidad, seven Say's Snakes (*Coronella sayi*) from North America, deposited; a Derbian Wallaby (*Halmaturus derbianus*, ♂) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Finder-Circles for Equatorials.—A very ingenious and what may prove a most useful addition to an equatorial are the so-called star-dials or finding-circles, a brief account of which is contributed to the current number of the *Zeitschrift für Instrumentenkunde* (4 Heft, April 1894). Every worker with the equatorial will no doubt at some time have found out that the present mode of setting the instrument on some object, as, for instance, a star, is not always very convenient, and in addition employs comparatively far too much time. The object of these finding-circles is to reduce this time very considerably, and a use of three years has shown that its aim has been successfully attained. The instrument to which it has been applied is the 12-inch of Georgetown College Observatory, Washington. On the pillar of this instrument are the two hand-wheels, by means of which the telescope is moved in right ascension and declination, and also two microscopes for reading the R.A. circle. Both axes of the telescope carry the usual circles for orientation, each being graduated in fine divisions on silver and large white divisions on a dark background. The finding-circles are situated just above the hand-wheels mentioned above, and fixed to the pillar, looking like a pair of aneroid barometers or steam gauges; they are arranged as follows:—The circular divided disc, with the declination divisions arranged round its circumference, is fixed firm in its case, and the index is so geared to the telescope that any movement of the latter is recorded on the dial; this gives one directly the declination. In the case of the other dial, that for right ascension, the disc is divided into two circles of twelve hours each, and instead of being fixed is moved by clockwork, sidereal time being shown on its face by means of another index; this latter index responds also to the movement of the telescope, but is quite independent of the first one. It will at once be seen that with these two dials so conveniently placed the telescope can be at once oriented, while the question of hour-angle is entirely eliminated.

The Harvard Observatory in Peru.—An historical sketch of the establishment of the Peru branch of the Harvard College Observatory, and the investigations carried on there, is contributed to the *Harvard Graduates' Magazine* for March by Prof. W. H. Pickering. The Observatory is situated about two miles from Arequipa, and four hundred feet above it, on the slopes of Mount Chachani. It is furnished with a very complete instrumental outfit, the most important instrument being a 13-inch equatorial, capable of being used for either visual or photographic purposes, and an 8-inch photographic telescope. Five meteorological stations have been established by the Observatory. One is at Mollendo, on the sea-coast, 100 feet above sea-level. The second is at La Joya, in the desert, altitude 4140 feet. The third is at the Observatory itself, altitude 8060 feet. The fourth is upon the side of the Misti, at an altitude of about 16,000 feet, and the fifth is upon the summit of the Misti, altitude 19,200 feet. The discoveries made at the Observatory are enumerated by Prof. Pickering. They include double stars, the "lakes" on Mars and the rapid changes in some of the canals and dark markings on the planet at the time of the melting of the southern snow-cap, the observations of changes of shape of Jupiter's satellites, which led to the conclusion that the outer satellites are not solid bodies, but dense swarms of meteorites, and pointed to a modification of Laplace's nebular hypothesis, to explain some of the diffitulties inherent in it. Peculiar lunar formations have also been observed, and an explanation has been given of the bright streaks seen at the time of full moon. A new class of lunar rills has been found, winding and tapering like a terrestrial river bed, and various facts have been determined with regard to what are called "variable spots" on the moon, which darken as the sun rises upon them, and fade out as it sets. Finally, the remarkable photograph of the spectrum of Nova Normæ, showing the star's constitution to be the same as that of Nova Aurigæ, was obtained at Arequipa. But only a small portion of the work of the Observatory is devoted to original research, the greater part of the time being taken up by routine work. Few observatories, however, can show a better record than that made at Arequipa during the three years of the Observatory's existence.

THE DIAMETERS OF SOME MINOR PLANETS.—Various attempts have been made to measure micrometrically the diameters of some of the larger asteroids, and also to determine them by photometric means, but the values obtained have never been very trustworthy. Prof. E. E. Barnard has now taken up the work, using the 36-inch of the Lick Observatory, and has already obtained some new results (*Astronomy and Astro-Physics*, May). So far, he has succeeded in directly measuring Ceres, Pallas, and Vesta, to which he assigns the following diameters:—

Ceres	...	599 ± 29 miles.
Pallas	...	273 ± 12 ,,
Vesta	...	237 ± 15 ,,

It will be seen from this that, contrary to the general belief, Ceres is the largest of the minor planets, and not Vesta. The values obtained by Argelander from a consideration of the relative light of the three foregoing asteroids and Juno, and those determined by Mr. E. J. Stone in 1867 from measures made by Herschel and Lamont, are as follows:—

		Argelander.		Stone.
Ceres	...	230 miles	...	196 miles.
Pallas	...	162 ,,	..	171 ,,
Juno	...	108 ,,	...	124 ,,
Vesta	...	275 ,,	...	214 ,,

Juno will soon be in a favourable position for observation, and Prof. Barnard will then apply the filar micrometer to its disc.

RETURN OF TEMPEL'S COMET.—A telegram from the Cape Town Observatory to Prof. Krueger (*Astr. Nach.* 3228) announces that Tempel's periodical comet (1873 II), the return of which was expected this year, was observed by Mr. Finlay on May 8. Its position was then R.A. = 356° 20′ 16″·5. P.D. = 94° 51′ 11″. The object was circular, with a diameter of about one minute of arc and some central condensation, but no tail. Its brightness was about the eleventh magnitude, or fainter.

THE NEW ENGINEERING LABORATORY AT CAMBRIDGE.

THE new Engineering Laboratory was opened on Tuesday by Lord Kelvin, in the presence of a brilliant assemblage of University dignitaries. The building occupies the site of the old Perse Grammar School, and has been erected from the designs of Messrs. Marshall, Vicars, and Co. The exterior is of plain but not unattractive red brick, in the French *château* style. The main building is of three stories. The three chief rooms, one above the other, are on the left of the handsome entrance doorway, and overlook the grounds of Corpus Christi College. To the right of the doorway are offices, small class-rooms, and rooms for special researches. The electrical laboratory is on the ground-floor; above it is the drawing school, excellently lighted by large western windows; and at the top is the mechanical museum, lighted by dormer windows and a cupola. Behind, the fine old schoolroom has been altered by raising its floor, but the beautiful oaken-roof of sixteenth-century work has been preserved, and the room gains rather than loses by the slight change in its proportions. Here is the chief mechanical laboratory, and it is furnished with all needful apparatus for work on the strength of materials, mechanism, and applied mechanics. Beyond, in the old schoolyard an admirable steam and dynamo laboratory has been erected from Prof. Ewing's designs. Here are several types of experimental steam-engines, dynamos, and motors, and in another compartment the boilers and other heavy appliances. The laboratories are on one side contiguous to the Chemical Laboratory, and when some day the necessary extension of the Cavendish Laboratory takes place, they will also abut on the Physical department. The cost of the whole has been some £6000, of which about £5000 was contributed by friends of the University who desired to see engineering science properly established and equipped in Cambridge.

The Vice-Chancellor presided at the ceremony, and in a happy speech alluded to the doubts at first entertained by many worthy Cambridge men as to the wisdom of admitting purely professional studies among those fostered by the University. In medicine, however, in law, and lately in agriculture, the claims of applied and practical knowledge had been recognised, and the recognition had been amply vindicated. It was due to the enterprise and ability of Prof. Ewing that engineering had now overcome all opposition to its admission to rank as a scientific profession, the preliminary training for which might fitly be carried on within the academic precincts. Lord Kelvin, in declaring the Laboratory open, spoke of the direct evolutional connection between the theoretical mechanics and pure mathematics of his day at Cambridge, and the establishment of a department in which their principles found application and verification. The Laboratory was excellently furnished so far as it went, but £20,000 might well be spent, in the interest of the University as well as of engineering science, in extending and completing it. Prof. Kennedy spoke of the place of such laboratories in the training of the engineer. Engineering was taking its due rank as a liberal profession, and from Cambridge, the centre of mathematical and physical inquiry, future engineers would go out fitted for acquiring with sureness and rapidity the practical details of their work. Sir Frederick Bramwell told stories of his early experiences. Prof. Jebb, M.P., and Prof. Ewing, who was very warmly received, gave thanks to all who had wrought with the Engineering Laboratory Syndicate to bring about the result they were celebrating. The donors, past and future, the architect, builders, demonstrators and workmen received their meed of acknowledgment. After the ceremony a reception was held by Prof. and Mrs. Ewing, and nearly 800 of the members of the University and ladies inspected the rooms. The students acted as guides and demonstrators, and at the close it was on all hands acknowledged that the occasion had been one of the most successful of University functions in recent years.

SCIENCE IN THE MAGAZINES.

THOUGH articles on scientific subjects are sprinkled through this month's magazines, they contain little that is new or suggestive. In the *Quarterly Review* (No. 356) two interesting articles appear, one on "Shakespeare's Birds and Insects," and another on "Ocean Meadows." Much has been written concerning Shakespeare's natural history, but the conclusion to which an examination of the poet's writings inevitably leads is that he was not an observant student of animal and plant life. The *Quarterly* reviewer criticises Shakespeare's knowledge of these matters, pointing out that Chaucer wrote of what he saw and heard in the animal life about him with a sense of personal delight that convinces the reader of his familiarity with animate nature. So too with Spenser, and with Ben Jonson. But, says the reviewer, Shakespeare resembles neither of these. "He borrows from Gower and Chaucer and Spenser; from Drayton and Du Bartas and Lyle and William Browne; from Pliny, Ovid, Virgil, and the Bible; borrows, in fact, everywhere he can, but with a symmetry that makes his natural history harmonious as a whole, and a judgment that keeps it always moderate and passable." This indictment is supported by uncontrovertible evidence, and concludes with the remark that Shakespeare's natural history "is commonplace when it is correct, and 'Elizabethan' when it is wrong." His method of handling animated nature has had a momentous effect on all succeeding poetry, so that poetry has sung of nature on Shakespeare's lines with an extraordinary fidelity. Groups of creatures which he misrepresented have been held up to reproach by poets since his time, and many others deserving of notice have been neglected. It is remarked, however, that "there is no necessity for a poet to be a naturalist in order to be true to nature; but there is the most urgent necessity that he should be in sympathy with nature and ready to acknowledge the good and beautiful, even if it should reach him in such questionable shapes as 'the deadly owle' or 'a full-blown toad that venom spits.'" In fact, owing to the great influence of Shakespeare's writings, the peculiarities of his sympathies and antipathies have been followed by almost all succeeding poets. His natural history was largely at fault; indeed, the reviewer asserts that he was sadly unsympathetic and unobservant. We conclude with a quotation which will come as a revelation to many people: "But taking men all round, ordinarily intelligent men of a country life (a town life was in Shakespeare's day what we should now call country life), was Shakespeare, as compared with these average individuals, 'an observer of nature?' The question is one liable to shock whose who have followed blind guides so long. The answer to it is liable to shock them more severely. No. Shakespeare was curiously unobservant of animated nature. He seems to have seen very little. Our authority for this is his own works, which, while they abound with beauties of fancy and imagination, are most disappointing to lovers of nature by (their errors apart) their extraordinary omissions."

Four important works on marine fauna and flora form the basis of an article in the *Quarterly Review* on "Ocean Meadows." In the course of the article, the reviewer refers to the necessity for making scientific investigations in the sea round our coasts, and shows the improbability of such work being furthered when those who hold high offices cannot appreciate its importance. In his words:—

"The minute animal life in turn furnishes food for shoals of fishes, and the importance of an inquiry into the whole life-history and seasonal occurrences of such organisms—the basis of the nutrition of marine life, as green plants are of terrestrial life—can scarcely be overrated. No such inquiry has ever been conducted in a serious scientific spirit in our seas by other than private investigators, unequipped with adequate resources for the proper study of the subject in its economic aspect. Our Fishery Boards concern themselves as little with this vital matter as they possibly can. Nor is this apathy surprising, when it is remembered that the present Government have appointed to the chairmanship of the Scottish Fishery Board an estimable gentleman, who possibly understands the 'branding' of herrings, but whose chief qualification for the post was a safe constituency. Yet, at the moment when this appointment was made, they had the opportunity, pressed upon them by a large body of scientific men, of choosing an eminent naturalist, whose claims as a student of the ocean are admitted by men of all nations to be unrivalled."

Almost every great advance in the study of the ocean has been made by this country, and though other countries are now competing with us, an opportunity will soon arise for us again to forge ahead.

"The proposed Antarctic expedition, for which a convincing case has been made out, can add to its usefulness by taking such an investigation in hand, not only in the Southern Seas but on its way to them. There is probably no region so fertile in the forms of pelagic life as the Southern Ocean, and an expedition which should not make the study of its vegetation one of its main objects had better stay at home. There is little fear of the subject being neglected in its widest aspects, since it is one of the professed 'aims which the promoters have in view,' to use the language of a prospectus. Botanists will have themselves to blame, and the public will have them to blame, if through their supine indifference this great and rich harvest of the ocean be not gathered in. In another respect the times are favourable. For many years this country lost its once eminent position in the study of the coast vegetation of the sea; but during the last six or seven years so much good and honest work has been done by a young and energetic band of observers that this position has been in a great measure retrieved. There are not lacking among our younger botanists men of skill in the use of the most recent methods of research, capable of meeting the Germans on their own field. It will be their fault if the naturalists of another nation forestall them in taking possession of not the least honourable part of our empire over the sea."

In the *Fortnightly*, Mr. Grant Allen, in an article entitled "The Origin of Cultivation," attempts to answer the question as to how early savages found out that plants would grow from seeds. His views are as follows:—"Cultivation began with the accidental sowing of grains upon the tumuli of the dead. Gradually it was found that by extending the dug or tilled area and sowing it all over, a crop would grow upon it all, provided always a corpse was buried in the centre. In process of time corpses were annually provided for the purpose, and buried with great ceremony in each field. By-and-by it was found sufficient to offer up a single victim for a whole tribe or village, and to divide his body piecemeal among the fields of the community. But the crops that grew in such fields were still regarded as the direct gifts of the dead and deified victims, whose soul was supposed to animate and fertilise them. As cultivation spread, men became familiarised at last with the conception of the seed and the ploughing as the really essential elements in the process; but they still continued to attach to the victim a religious importance, and to believe in the necessity of his presence for good luck in the harvest. With the gradual mitigation of savagery an animal sacrifice was often substituted for a human one; but the fragments of the animal were still distributed through the fields with a mimic or symbolical burial, just as the fragments of the man-god had formerly been distributed. Finally, under the influence of Christianity and other civilised religions, an effigy was substituted for a human victim, though an animal sacrifice was often retained side by side with it, and a real human being was playfully killed in pantomime."

Another origin about which Mr. Grant Allen makes suggestions is that of language. His remarks on this subject appear in *Longman's Magazine*, under the title "The Beginnings of Speech." The *Sunday Magazine* contains an article on "The Stuff we are Made of," by Dr. J. M. Hobson, in which some facts concerning amœbæ are stated, and also a sketch of the life and environment of Richard Jefferies, by the Rev. B. G. Johns. "Moon-Man or Moon-Maid" is the title of a short article by Mr. William Canton in *Good Words*. One of Cassini's drawings of the Gulf of Rainbows on the moon shows the form of a girl's head emerging from the rocks of the promontory of Heraclides on one side of the Gulf. M. Flammarion reproduced this drawing in *L'Astronomie* some time ago, and lamented that he had been unable to find the figure in any other drawing, or observe it himself. A few months later, however, M. Quénesset made out the form of a man's face at the spot to which attention had been drawn, and two hours later on the same evening M. Mabire, observing at the Juvisy Observatory, depicted "without a single stroke of imagination" the head of a woman in the same place. Mr. Canton's remarks refer to these two drawings, reproductions of which are given. The illustrations are curious, but not very instructive; they appeal more to the poetical than the scientific mind.

Mr. Henniker Heaton writes on "Telephones: Past, Present, and Future," in the *New Review*, his point of view being chiefly commercial. Sir Herbert Maxwell espouses the cause of tree-planting in London, and enumerates some of the trees suitable for town adornment. "The Imitative Functions, and their Place in Human Nature," is the theme of Mr. J. Royce in the *Century*. *Chambers's Journal* has several quasi-scientific contributions, among them being articles on amber, breath-figures and dust-photographs, and trees of the genus *Adamsonia*—Cream-of-Tartar trees. In addition to the magazines named in the foregoing, we have received *Scribner's*, the *Contemporary*, and the *Humanitarian*; but none of these contain articles calling for comment here.

THE SCIENCE OF VULCANOLOGY.[1]

VULCANOLOGY, or the science which deals with volcanoes and related phenomena, is a very important branch of geology—the science which treats of the earth's crust in general. Geology is yet hardly a century old; for before that time it consisted of little else than a collection of romantic hypotheses

[1] Introductory Address to a Course of Lectures on Vulcanology, delivered in the R. Univ. of Naples, by Dr. H. J. Johnston-Lavis.

and incredible superstitions. This remark applies with still greater force to vulcanology, for the study of which it is necessary to possess an extensive knowledge of physics, chemistry, and a well-developed faculty of observation. For a century or two previous to the nineteenth, however, there were acute observers, and we in Naples well know such names as those of Sorrentino, Duca e Padre della Torre.

Towards the end of the last century the active and extinct volcanic regions of Italy attracted the attention of four great men of science, each of a different nationality. I allude to Spallanzani, Sir William Hamilton, Dolomieu, and Breislak. Although their nationality was different, they had two merits in common—that of scientific truth and that of Baconian methods of reasoning. In other words, they were pure men of science, since by that term we understand one who observes carefully, records neither more nor less than he observes, and draws from these facts, and those collected by others, his conclusions, without disregard to a clear knowledge of the principles involved, and without flights of imagination. It is, therefore, more to these four men that we owe the advance of human knowledge concerning volcanoes than to all the writers who preceded them.

In the first years of the nineteenth century, vulcanological literature was enriched by many workers, because, as the allied sciences were then making great strides, they were able to offer to vulcanologists much more powerful and accurate means of investigation. Thus we had Humboldt, Scrope, Daubeny, Pilla, and Gemmellaro.

Following these came a phalanx of illustrious students of geology, some of whom are still among us, while others, though dead in person, are living and immortal in the memory of man as heroes of science and of human knowledge. Amongst these we may enumerate Lyell, Dana, Scacchi, Palmieri, Silvestri, and Phillips, whilst at present many younger and gifted investigators are not wanting.

No other branch of science has been so heavily burdened by extravagant hypotheses, which have so much retarded its progress, as that of vulcanology. It is not only in the first half of the present century but even still that we find an extensive literature produced by men who advertised themselves as scientific investigators, when in truth they did little else but write memoirs and books to promulgate and sustain fantastic, extravagant, imaginary, and impossible hypotheses. Nevertheless, amongst this chaff we not only meet with grain, but very good grain.

As a subject of study, Vesuvius holds the first place in all vulcanological investigations of this and the last century. A few figures will make this fact more evident. Some four years since, my wife and myself collected the titles of books, memoirs, and other writings referring to the South Italian volcanoes, for the purpose of publishing a bibliographical list. We found the following numbers:—

Graham's Island, or Isola Ferdinandea ...	28
Roccamonfina	33
Lipari Islands	119
Alban Hills	210
Campi Phlegræi	539
Etna	880
Vesuvius	1552

From this table it will be seen how much has been written concerning Vesuvius; in fact, its literature constitutes nearly half of what has been written about all the volcanic regions south of Rome. If we add to these the titles referring to the Campi Phlegræi, we then find that in a total of 3361 not less than 2091 concerns the volcanic district around Naples. Let me, however, give you a still more striking fact. The Naples branch of the Italian Alpine Club possesses the richest vulcanological library in existence. The catalogue contains more than 7000 entries of papers, books, and manuscripts. In this number, however, are included books that not only treat of vulcanology, but in large part refer to seismology and, to a smaller extent, to geology. It will be seen, therefore, that the Neapolitan volcanic district represents more than a quarter of all vulcanological literature.

It is true that the history of Etna and the Æolian Islands reach farther back than that of Vesuvius, but on the other hand the history of this latter is by far the most complete. From a chronological point of view, Vesuvius and also the Campi Phlegræi hold a more important place in history than any of their rivals. Even if the Pompeians, the Herculaneans and the Stabians did lose all their property eighteen centuries since, the modern world has recovered it as archæological treasures, whose value represents, from the point of view of culture, many times the original and the compound interest on the same for the whole interval; and this we owe to our Vesuvius. The Phlegræn region around Naples is so enchained with the poetry of the heroic and classic periods, that without it the legends of Cuma, of Pithecusa, of Sparctacus, of Partenope, of Baja, and so many others, which fill pages and pages of ancient history, would not exist.

Sometimes poetic ecstacy attacks the mind of the scientist; for, contrary to what the general public believe, science rather than abolish poetic sentiment further develops it, but in a more serious and refined form.

When, as we wander around Naples, we reach the hill of Cuma, and we encounter a few ruined walls and a few potsherds that peep out through the rich vegetation of that spot, where now the only inhabitants are the goats and the lizards, our imaginations speed back for nearly three millenniums, when this same rock, almost as in its present state, was chosen by the daring Greek navigators as the site of their new colonial town. All of us know the history of Cuma, all of us know that this little bit of Italy for one half of historic time held a very important place. We are deeply impressed when we make an effort to conceive clearly what 3000 years really is, how many generations lived and died during that time and in that place; but far greater are we impressed when we think that 3000 years is but a fraction in the *geological* history of that hill, and finally our mind fails to grasp the value of time when we consider that the physical record of this hill is not more than a minute fraction of the geological chronology of our globe.

Without going very far back in the geological history of our region, I will ask you to follow me to the first part of the Pliocene epoch, an epoch, as all know, to be considered quite near our own time. All of us now admire the beauty of the Gulf of Naples, which has few rivals in the entire world, but at that time its conformation was very different to what it is now. It then formed a very much larger gulf, represented to-day by the plain we call the Campania Felice, with a large part of the Terra di Lavoro. We must figure to ourselves a broad gulf limited on the north by the promontory of Gaeta, where its confines were limited by high limestone cliffs. Its coast had roughly the following trend. From Gaeta it corresponded with the present provincial road to close under Castelforte, and from there was almost represented by the valley of the Garigliano as far as the gorge between Monte Faito and Monte Cammino, by which narrow strait it was in communication with the sea covering the plain of Cassino. Winding round the south of Monte Cammino it again extended northwards to Mignano. The eastern coast of this strait corresponded with the present line of railway from Mignano to Taverna St. Felice, which coast, turning eastwards, passed under Presenzano to extend into the mountains by the valley of the Volturno. From this point the coast, winding round several islands, represented to-day by hills and mountains separated from the main mass of the Appennines, it extended into these latter, forming so many fiords. The sea then covered all the plain, and its waves beat the foot of the mountains behind Pietramelara, Pignataro Maggiore, Capua, Caserta, Nola, Palma, Sarno, Angri, and Castellamare, and then corresponded roughly with the present coast of the peninsula of Sorrento. In the middle of this great gulf rose two important isles—Capri and Monte Massico, besides a quantity of small ones. Numerous fiords penetrated the Appennines, where to-day we have the Garigliano, the Volturno, Valle di Maddaloni, Valle Caudina, and the Valle di Avella. In fact, this part of the coast of Italy in those pliocene times was very similar in configuration to that of the Istrian coast of to-day.

The rivers bringing down to the sea sand and mud, which, settling at the bottom of the gulf, prepared an almost flat marine floor, which later was to form the foundation of the Campanian Plain. At that period the Campania Felice was only sea, and where to-day flourishes vines, oranges, lemons, and gardens of flowers, then only grew marine algæ.

The great fissure in the earth's crust which corresponds with the western coast of Italy, and along which were formed the Italian volcanoes, opened a way for the igneous magma to the bottom of this gulf. Numerous eruptive centres were formed, giving rise to the volcanoes of Ischia, Roccamonfina, Campi Phlegræi, and Vesuvius. The order in which these different groups were formed is still an unsolved enigma. Ischia, as has been long known, shows by the fossiliferous deposits clothing its flanks, to have undergone great elevation since its original formation, and as we have no such evidence in the other volcanoes, we must conclude for the greater antiquity of Ischia. I also believe that the volcanic group of Roccamonfina is very much older than that of the Phlegræan Fields and Vesuvius, because we find the *piperno* and the *piperno tuff*, very old volcanic deposits in these regions, forming a mantle over Roccamonfina when it was almost a complete mountain. It must not be forgotten, however, that in the "Museum Breccia," first described by me, we have evidence of the effusion in these regions of many varieties of rocks long anterior to the *piperno*.

Gradually the large quantity of lava and fragmentary materials that were ejected at the bottom of the gulf, greatly diminished its depth, and this, combined with general elevation, resulted in the emergence of a number of volcanic islands at Roccamonfina, Ischia, Naples; and probably Vesuvius was, at first, like the others an island. Constant general elevation soon drove back the sea, leaving high and dry all that region we so well know. This plain, with its volcanic hills and mountains, constitutes one of the most beautiful, the most fertile, and the healthiest regions of our earth, if man were more capable of appreciating, enjoying, and developing this *pezzo di cielo caduto in terra*.

So many are the advantages that Vesuvius offers to the student of vulcanology, that I think it advisable to pass them in review. This renowned volcano occupies a very central position in the civilised part of the globe, only a few kilometres from Naples with all the resources of a great city, and in communication by numerous lines of passenger vessels and railways with all parts of Europe and America. Means of visiting Vesuvius are numerous, whilst the volcano is now entirely surrounded by a network of railways, besides good roads. By road and railway the top of the mountain can be reached, and upon its flanks can be found hotels and accommodation of all kinds, besides a meteorological observatory, intended to be used for the daily study and record of its varying phases. The simple but interesting form of the mountain, the extraordinary and unrivalled variety of its productions, which surpass in number, beauty, and interest those of any other volcano yet studied, are also a matter of maximum importance to the student. Besides this, of equal importance we must reckon that continuous activity with variation within such limits as to permit detailed study on the spot, and still more fully in the University laboratories or elsewhere.

Scattered over Italy, and within a few hours' reach, are several other active volcanoes, each having its own special interest, besides a large number of extinct ones and subsidiary volcanic phenomena, all of which, beyond their scientific interest, have a very great importance to the inhabitants from an agricultural, industrial, and hygienic point of view. This is especially the case in the immediate vicinity of the active ones, so that it becomes the duty of the Government to maintain a system of observation and record, and to develop a school in which students may acquire a scientific knowledge of vulcanology.

At Naples we have a chair of terrestrial physics, but as under this name is included a vast amount of different groups of phenomena, it is impossible for its holder to give a fair share of vulcanology alone. So far, the only chair of vulcanology was that of Catania, which was so well occupied by the late Prof. O. Silvestri, and which, after his premature death, was abolished.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The following have been appointed Public Examiners in the Honour School of Natural Science:—Mr. James Walker, of Christ Church, in Physics, Dr. Henry F. Morley, in Chemistry, and Dr. George A. Buckmaster, of Magdalen College, in Physiology.

The list of the newly elected Fellows of the Royal Society includes three Oxford men—the Rev. F. J. Smith, Mr. V. H. Veley, and Prof. Viriamu Jones.

A conversazione will be given in the University Museum on Tuesday next, by the members of the Junior Scientific Club.

Cambridge.—The Board of Managers of the Arnold Gerstenberg Studentship give notice that a Studentship on this Foundation will be offered for competition in the Easter Term of 1895. Candidates will have the option of being examined either in Logic and Methodology, or in Psychology. The Examination will be held at the time of the Moral Sciences Tripos: that is, not earlier than the last Monday but one in May 1895. The exact date of the examination will be announced later. The schedule of the subjects of examination will be the same as the schedules in Psychology and in Logic and Methodology for Part I. of the Moral Sciences Tripos. The competition will be open to men and women who have obtained honours in Part I. or Part II. of the *Natural Sciences Tripos*, and whose first term of residence was not earlier than the Easter Term of 1889. Candidates must send in their names not later than April 19, 1895, to Dr. Sidgwick, Newnham College, Cambridge, and must declare their intention, if successful, of pursuing a course of philosophical study. The studentship, which will be of the annual value of nearly £90, will be tenable for two years, upon the condition that at the end of the first year the student's progress in philosophical study is deemed satisfactory by the Board of Managers.

Dr. W. S. Melsome, Fellow of Queen's College, and Mr. Hubert Higgins, of King's College, have been appointed Senior and Second Junior Demonstrators of Anatomy respectively.

There are vacancies at the University's tables in the Naples Zoological Station, and at the Plymouth Marine Biological Laboratory. Applications to occupy these are to be sent to Prof. Newton, Magdalene College, by May 24th.

Prof. Macalister announces a short course of lectures in Physical Anthropology for May 16th, 19th, and 21st. The subjects are "Methods of Anthropometry," "The Races of Ancient Egypt" (at this lecture a mummy will be unwrapped and examined), and "The Races of Western Europe."

The Council of the Senate have published a Report recommending that in future all appointments of Demonstrators, and of Assistants to Professors, shall be made for a specific period not exceeding five years. At the end of this period the Demonstrator or Assistant is to be eligible for reappointment. It is also proposed that in the case of the vacancy of a Professorship, the Demonstrators and Assistant are to cease to hold office within three months of the appointment of a new Professor.

The Master, Wardens, and Commonalty of the Society of Merchant Venturers of the City of Bristol have decided that their Technical School shall henceforth be known as the Merchant Venturers' Technical College. In this connection the following nominations have been made:—Principal and Professor of Chemistry, Mr. J. Wertheimer; Professor of Mechanical Engineering, Mr. J. Munro; Professor of Electrical Engineering and Applied Physics, Mr. W. Wilson.

SCIENTIFIC SERIALS.

The Mathematical Gazette, No. 1, April 1893, 8 pp. (London: Macmillan.)—It is now matter of ancient history that a correspondence in the columns of Nature resulted in the formation, in January 1871, of the Association for the Improvement of Geometrical Teaching. The original objects of the association were threefold: to collect and distribute information as to the prevailing methods of instruction in geometry practised in this and other countries, to use its influence to induce examining bodies to frame their questions in geometry without reference to any particular text-book, and to stamp with its approval some text-book already submitted, or to bring out a new one under its own auspices. Ten years later, viz. in January 1881, the association widened its basis, though after some discussion it retained its name. The objects it had in view were now sought to be carried out by the reading of papers and raising discussions, and by the appointment of committees to report on existing defects in the usual methods, order, range, &c., in teaching special subjects—all branches of elementary mathematics and mathematical physics being included in the widened basis. Now that the association has passed its majority, it is thought that it owes its continued existence to a "widespread desire on the part of teachers of mathematics to become acquainted with the methods of other teachers." The editor of the *Gazette*, Mr. E. M. Langley, to whose long-continued and enthusiastic advocacy of its aims the Association for the Improvement of Geometrical Teaching owes so much as late secretary, hopes, through the agency of its columns, to extract from experienced teachers MSS. which have long been lurking in desk or pigeon-hole for want of a suitable organ for making them known. This new venture, which has been started in consequence of a resolution passed at the association's annual meeting in January last, is proposed to be "a terminal journal for students and teachers." The editor has to feel his way: words of encouragement have come from the far East and West, as well as from many teachers in this country. The number before us opens with a short paper, by the editor, on the eccentric circle of Boscovich. We borrow from Dr. C. Taylor's classical book on Conics the following verdict on Boscovich's work:—It is "a clear and compact treatise, which for simplicity, depth, and suggestiveness will not readily be surpassed." Dr. J. S. Mackay abstracts the first book of Gino Loria's treatise on "the exact sciences in ancient Greece," viz. that on the Greek geometers before Euclid. In addition to the works cited by Dr. Mackay, we may call attention to three notes on the history of mathematics by the Danish mathematician, H. G. Zeuthen (which have recently been published in the *Bulletin de l'Académie Royale des Sciences de Danemark* (1893). Prof. A. Lodge gives some useful approximations and reductions. Then follow some elegant solutions of examination questions, and a select number of questions for solution. A commendation of the new French journal, *l'Intermédiare des Mathematiciens* closes this No. 1. The size of the page, the clear type, and the excellent paper, should secure for the *Gazette* far more than a mere *succès d'estime*. The figures are lithographed on a separate sheet. We note one little slip—*Adam's* property for *Adams'* (p. 8.)

American Journal of Mathematics, vol. xvi. 2. (Johns Hopkins University, April, 1894.)—W. H. Metzler in compound determinants (pp. 131–150) shows how to express certain minors of a compound determinant $\Delta_{(m)}$ in terms of the minors of various orders of Δ. The paper is divided into two parts, one relating to determinants, the other to matrices. A short note follows on the order of terms in a semi-convergent series, by H. P. Manning (pp. 151–155). Writing on the addition theorems of Jacobi and Weierstrass (pp. 156–163), E. Study gives a new presentation of results connected with an investigation of the addition theorems given in Hirzel's paper, "Sphärische Trigonometrie, orthogonale Substitutionen und Elliptische Functionen" (1893). Two articles follow by A. Chessin. The first is summation of logarithmic and exponential series (pp. 164–185), the second a note on the general solution of Bessel's equation (pp. 186–7). In an article on adjustable cycloidal and trochoidal curves (pp. 188–204) Prof. F. Morley gives many interesting results in connection with these curves. The text is illustrated with several carefully drawn figures. A two-page note on induced linear substitutions, by Prof. F. Franklin, closes the number.

SOCIETIES AND ACADEMIES.

London.

Royal Society, April 19.—"Electrical Interference Phenomena somewhat analogous to Newton's Rings, but exhibited by Waves along Wires." By Edwin H. Barton, B.Sc., late "1851 Exhibition" Science Scholar.

(1) The preliminary paper (Roy. Soc. Proc., vol. liv. pp. 85–96, 1893) on this subject gave the results of a single experiment, and approximately accounted for them by a mathematical theory of the phenomena involved.

(2) The present paper discusses the question of disturbances, and gives nine experiments. Two of these are similar to the first experiment, but were made under better conditions; the others were made either to lead to these improved conditions or in confirmation of the original fundamental conclusions.

(3) The disturbances alluded to arise from the fact that the electrical waves are not suddenly lost after their first incidence upon the abnormal part of the secondary, but course to and fro until they die out. A method of avoiding the greatest disturbance due to this cause is pointed out and adopted. A correction is also calculated and applied for another disturbance which still remains.

(4) The chief experiment (Expt. v. arts. 42–48) is on interference phenomena, somewhat analogous to Newton's rings, by transmission.

(5) The experiments conclude with two examples (Expts. viii. and ix. arts. 51–62) of modifications of the secondary which produce *no* reflexion. These consisted respectively of thinner wires near together, and of thicker wires further apart, than the normal spacing. In each case the capacity was practically unaltered by the change in the wires; hence, as anticipated from the theory, no reflexion occurred.

(6) The systematic comparison of theory and experiment, made (Arts. 63–77) near the end of the paper, does not exhibit an absolute quantitative agreement. Nevertheless, the two are so far concordant in all their general features as to be mutually confirmatory, and were approved by Prof. Hertz (under whose able guidance the work was carried out in Bonn, 1892–93) as close approximations.

"On Rocks and Minerals collected by Mr. W. M. Conway in the Karakoram-Himalayas." By Prof. T. G. Bonney, F.R.S., and Miss C. A. Raisin.

Physical Society, April 27.—Prof. A. W. Rücker, F.R.S., President, in the chair.—A paper on the mechanism of electrical conduction (Part I. Conduction in Metals) was read by C. V. Burton. Considering a body not at absolute zero of temperature, the author shows that electromagnetic radiation would result in heat being degraded into a lower form of energy, if any parts of finite electric conductivity were present, and from the fact that our planet is not devoid of heat, deduces the following Theorem I.:—"In a region containing matter there may be (and probably always are) some parts which are perfect insulators, and some parts which are perfect conductors, but there can be no parts whose conductivity is finite, unless every finitely conductive portion is enclosed by a perfectly conductive envelope." This conclusion is in accordance with Poisson's theory of dielectrics, and with Ampère's and Weber's theories of magnetism and diamagnetism respectively. Theorem II. is enunciated as follows:—"In metals, and in other non-electrolytes whose conductivity is finite, the transmission of currents must be affected by the intermittent contact of perfectly conductive particles"; and as a corollary, Theorem III. is given:—"If we suppose that in a substance at the absolute zero of temperature there is no relative motion amongst the molecules or amongst their appreciable parts, it follows that every substance at this temperature must have either infinite specific resistance (which does not imply infinite dielectric strength) or infinite conductivity." Fleming and Dewar's experiments on pure metals tend to confirm this. The author then shows why, on the intermittent contact hypothesis, a conductor is heated when a current flows through it. On the assumption that in ordinary conductors the relation between the electromotive intensity in the intermolecular spaces and electric displacement is a linear one, and that the electric forces are small in comparison with the ordinary intermolecular forces, Ohm's Law is deduced. A model is next described by means of which contact E.M.F. and the Peltier effect can be represented and explained, and in considering Volta E.M.F.'s, the author points out that it is doubtful whether experiments in a perfect vacuum could decide the questions at issue in the contact-force controversy. The fact that the transparency of metals is much greater than Maxwell's theory indicates might be explained without attributing any new properties to the electro magnetic field by supposing the dimensions of molecules not quite negligible in comparison with the wave-length of light. Prof. S. P. Thompson thought the paper had an important bearing on the kinetic theory of solids. He saw no reason why Ohm's Law should be proved, for he regarded it as a definition. The President said the author represented all actions as being due to collisions, thereby introducing the same difficulties as were felt in the kinetic theory of gases, viz. that collisions would give rise to mechanical oscillations in the molecules of shriller and shriller pitch. Prof. J. J. Thomson had recently given an explanation of electrical phenomena by vortex filaments. After some remarks on the visibility of molecules by Mr. Hovenden, Dr. Burton, in reply to Prof. Thompson, said Ohm's Law, when expressed as $\frac{E}{C}$ = *a constant*, was really a law, and not a mere definition.—A communication on the design and winding alternate-current electromagnets, by Silvanus P. Thompson, F.R.S., and Miles Walker, was read by the former. The paper describes experiments showing that when the magnetic induction does not exceed 4000 (C.G.S.), the pull exerted by a laminated electromagnet on its armature is the same, whether it be excited by a continuous or by an alternating current of equal strength. For higher inductions the continuous current gives slightly greater force. Another experiment made with solenoids and the U-shaped plunger of a Brush alternate current arc lamp, gave similar results. In considering the question of winding alternate current electromagnets so as to obtain a given excitation when the current is supplied at constant voltage, it is shown that the ampere-turns are inversely proportional to the number of turns, for the impedance varies nearly as the square of the number of turns. One important property of such electromagnets when supplied at constant voltage is that they give a fairly constant pull over a long range, for as the armature moves away from the magnet the current increases, thus counteracting to some extent the effect of distance. On the other hand, the alternating voltage required to obtain a given force is much greater than that needed with continuous currents. With the armature in contact with the core the ratio of the two voltages was found to be 170, whilst separating them by 9·2 mm. reduced the ratio to 21·5. Prof. Perry pointed out that the constant pull of the alternate current magnet followed immediately from the fundamental equation $e = rc + n\dot{I}$ when rc is small, for if e be constant then $\dot{I}$ and therefore I and I^2 are constant. He was interested to see that the pulls for equal ampere-turns were the same, and indicated how the problem could be worked out mathematically when hysteresis was taken into account. Mr. Blakesley thought it better to fill the space on a magnet full of copper, rather than use wire only just large enough to carry the current, for the loss of energy would be reduced. Some of the formulæ given might be put in simpler form. Mr. Swinburne said an alternate current magnet would only give constant pull in special cases. As another rule for winding alternate current magnets, he said, wind the magnets as for continuous currents, and put a condenser in to take the same current, thereby reducing the voltage required. Mr. Blakesley said it would require a capacity of 600 microfarads to suit the magnet mentioned in the paper. Dr. Thompson, in reply, agreed with Mr. Blakesley that the condenser was impracticable in many cases.—Major R. L. Hippisley, R.E., read a paper on a graphical method of constructing the curves of current in electromagnets and transformers, and exhibited a machine for drawing these curves. Taking the ordinary equation for a simple alternate current circuit $E \sin pt - \frac{dB}{dt} = Ri$, where B is the total magnetic flux, and i the current; the author writes it in the form

$$E \sin pt - m_k L \frac{di}{dt} = Ri,$$

where L is the coefficient of self-induction of the circuit with the iron withdrawn and m_k the tangent of the inclination of the BH curve at the point corresponding to the instant considered. This equation is integrated for a short part of the cycle during which m may be considered constant giving

$$i = \frac{E}{R} \cos \theta_k \sin (pt - \theta_k) + A_k e^{-\frac{Rt}{m_k L}}$$

Methods of finding the constants in the last equation are then described, and the method of drawing the current curves step by step explained. The machine for performing the process is illustrated in the paper, and the curve for an electromagnet fed with alternating current shown. The case of a transformer without magnetic leakage is worked out at some length, and the curves of primary and secondary current determined. Dr. Sumpner said the author had used great care in working out a difficult problem more completely than usual. In cases such as arise in practice the Rt term is small, and for this case Evershed showed how to determine the current curves of a transformer when the periodic state had been reached, some five or six years ago. He (Dr. Sumpner) had also shown how to graphically determine the current curves for circuits containing iron in 1888. The author's method was, however, of more general application. Mr. Trotter inquired if whether the machine could be used in practical alternate current problems, say, for example, to predetermine the E.M.F. curve of an alternator. Major Hippisley replied to the points raised.

Geological Society, April 25.—Dr. Henry Woodward, F.R.S., President, in the chair.—Mr. A. R. Sawyer, referring to specimens exhibited by him from the Transvaal, Orange Free State, Cape Colony, Mashonaland, and Matabeleland (the last mentioned collected during the recent war), remarked that gneisses and gneissose granites cover a large portion of Mashonaland, together with patches of schistose rocks and a few stratified rocks. He drew attention to the fantastic shapes assumed on weathering by the granitic gneiss, which he considered solely due to atmospheric agencies, and not to ice-action or to the effects of submersion. The schistose rocks are, for the most part, sheared and altered igneous masses. There are numerous examples of dolerites and epidiorites passing into hornblende-schists, and of more acid igneous rocks. Masses of magnetite occur in various parts of Mashonaland, and serpentinous rocks (which probably owe their origin to the alteration of peridotites) in the north-west corner of the Victoria gold-field. Extremely auriferous veins occur amongst the sheared acid igneous rocks of the Umhungwe Valley in the Manica district, and gold occurs in the kaolin produced by the disintegration of these rocks.—The following communications were read:—Further notes on some sections on the new railway from Romford to Upminster, and on the relations of the Thames Valley beds to the boulder clay, by T. V. Holmes. The author alluded to his discovery of boulder clay on this new railway at Hornchurch (*Quart. Journ. Geol. Soc.* August 1892), and described the finding of more boulder clay close to Romford during the deepening and widening of a cutting there. The boulder clay was on precisely the same level as that at Hornchurch, a mile and a half to the south-east, and, like it, was covered by gravel belonging to the highest, and presumably oldest, terrace of the Thames Valley system. A portion of the silted-up channel of an ancient stream-course was also found in this Romford cutting. Its relations to the boulder clay could not be seen, as they were not in contact, but they were alike covered by the oldest gravel belonging to the Thames Valley system. The author discussed the probable direction of the flow of this stream-course, and the way in which it was superseded by the ancient Thames. After noticing certain points brought forward during the discussion on his former paper, he concluded with a criticism on the views to which Dr. Hicks inclines in his paper on the sections in and near Endsleigh Street (*Quart. Journ. Geol. Soc.* vol. xlviii. 1892) as regards the age of those beds, asserting that they are, in all probability, simply river drift of the Thames Valley system, and consequently post-glacial, in the sense of being later in date than the boulder clay of Essex and Middlesex.—On the geology of the Pleistocene deposits in the valley of the Thames at Twickenham, with contributions to the flora and fauna of the period, by Dr. J. R. Leeson and G. B. Laffan. The section described in this paper was exposed during the construction of an effluent from the Twickenham sewage-works to the Thames. Its length was about one mile. The beds exposed were (1) coarse reddish-yellow gravels, coloured blue below, lying on an eroded surface of (2) dark blue loam, varying in thickness, the greatest thickness seen being three feet, at a place where the bottom was not reached; (3) dark sand; (4) coarse ballast gravel; (5) London clay. The loam (which is quite a local deposit) yielded eight species of mollusca and fourteen species of plants, all still living in the neighbourhood. A number of mammalian bones, referable to seven species, were lying just on the surface of the loam. Amongst the forms were bison and reindeer. The authors consider that the loam was deposited in a small lake, and they alluded to similarities between it and a deposit described by Dr. Hicks as occurring in the Endsleigh Street excavations. In the remarks on these two papers, the President congratulated the authors of the second paper on having succeeded in rescuing so interesting a collection of remains of Thames Valley mammalia. Sir John Evans expressed his pleasure at Mr. Holmes's further discovery of evidence as to the superposition of the old Thames Valley gravels upon the boulder clay, as these discoveries supported the view he had always held that these gravels, whether at a high or at a low level, were "post-glacial" in the sense indicated by the author. He also remarked that the finding of the mammalian remains by Dr. Leeson in the low-level gravels at Twickenham was of interest, as proving the existence of the reindeer and bison in the Thames at the time of the deposition of these beds. As to some of the remains of other animals, however, he entertained doubts whether, though found in the course of the excavation, they really belonged to the gravels. Mr. E. T. Newton, Mr. Lewis Abbott, Mr. G. B. Laffan, Prof. Hull, and Dr. Leeson also spoke, and Mr. T. V. Holmes briefly replied to the remarks made on his paper.—On a new goniatite from the lower coal measures, by Herbert Bolton. Sowerby in his "Mineral Conchology" figures two fossils under the name of *Goniatites Listeri*, of which the left-hand figure is clearly *G. Listeri*, whilst the right-hand one differs considerably from it. The author gave diagnoses of *Goniatites Listeri* and of a new species, which agrees with the form represented in Sowerby's right-hand figure. This species is limited to the shales forming the roof of the "Bullion" or upper foot seam of the lower coal measures, whilst *G. Listeri* ranges from the lower limestone shales to the "Bullion" seam.

Chemical Society, April 19.—Dr. Armstrong, President, in the chair.—The following papers were read:—The magnetic rotations of fatty acids containing halogens; of acetic and propionic acids, phosgene and ethylic carbonate, by W. H. Perkin. The molecular association investigated by Ramsay and Shields is apparently without influence on the magnetic rotations of acetic and propionic acids. In a number of cases where two similar atoms or groups of atoms enter a compound by substitution, the change in magnetic rotation caused by the entrance of the first group is different to that caused by the second; as the President pointed out, Thomsen has observed an analogous phenomenon in his thermochemical investigations. —The action of concentrated acids on certain metals when in contact with each other, by G. J. Burch and J. W. Dodgson. The authors are investigating the chemical and electrical behaviour of different pairs of metals in contact when placed in the strong mineral acids. Very slow action occurs when a piece of sodium impaled on a strip of platinum, iron, or carbon, is placed in concentrated sulphuric acid; the sodium of a sodium-carbon couple requires more than eight hours for its solution in sulphuric acid.—The action of light on oxalic acid, by A. Richardson. Oxalic acid, exposed to light, is slowly decomposed with formation of hydrogen peroxide and carbonic anhydride.—English jute fibre, by A. Pears, jun.—Natural oxycelluloses. I. Celluloses of the *Gramineæ*, by C. Smith.—Preliminary note on the volatilisation of salts during evaporation, by G. H. Bailey. During the evaporation of salt solutions a considerable amount of the salt is volatilised, although every precaution be taken to guard against mechanical loss. Cæsium chloride solution containing 286 grams to the litre lost 18·86 milligrams of salt per litre during evaporation.—Constitution of glycocine and its derivatives, by Joji Sakurai. The author considers that glycocine must be regarded as an internal ammonium salt of the constitution

$$\begin{array}{l} CH_2\text{—}NH_3 \\ |\qquad\ \ | \\ CO\text{—}O \end{array}.$$

Similar views of the constitutions of hippuric acid, aspartic acid, and asparagine are also expressed.—Note on the constitution of glycocine, by J. Walker. Reasoning by analogy, the evidence afforded by the electrical conductivity goes to show that glycocine has the ordinarily accepted constitution

$$NH_2 \,.\, CH_2 \,.\, COOH.$$

—On the oxidation of the alkali metals, by W. Holt and W. E. Sims. Potassium, sodium, and probably lithium may be distilled in perfectly dry oxygen without undergoing oxidation; potassium monoxide, K_2O, is not formed by the oxidation of the metal in any of the oxides of nitrogen, as is generally supposed, and there is no evidence of its existence in the pure state.—The action of iodine and of methyl iodide on aconitine, by W. R. Dunstan and H. A. D. Jowett.

Zoological Society, May 1.—Dr. A. Günther, F.R.S., Vice-President, in the chair.—The Secretary read a report on the additions that had been made to the Society's menagerie during the month of April 1894, and called special attention to a valuable collection of mammals presented to the Society by Dr. J. Anderson, F.R.S., being part of the proceeds of his recent expedition to Egypt.—Dr. Günther, F.R.S., exhibited and made remarks on specimens of a South African Hornbill (*Buceros melanoleucus*) and of a portion of the tree in which the nest was placed, and spoke of its mode of nesting and of its extraordinary habits during that season. The specimens had been transmitted to the British Museum by Dr. Schonland of Grahamstown.—Dr. H. E. Sauvage exhibited a vertebra of the earliest known Snake from the gault of Portugal.—Mr. W. Bateson exhibited a large number of specimens of *Gonioctena variabilis*, a Phytophagous Beetle from Spain, in illustration of discontinuous variation in colour.—Prof. F. Jeffrey Bell gave an account of the Echinoderms collected during the voyage of H.M.S. *Penguin* and by H.M.S. *Egeria*, when surveying Macclesfield Bank. The collection, which had been made by Mr. P. W. Bassett Smith, with the co-operation of Mr. J. J. Walker, was very extensive, and contained examples of many new species, some of which were of a very remarkable character. —Mr. Ernest W. Holt gave an account of some of the results of his recent studies in teleostean morphology made at the Marine Laboratory at Cleethorpe. Mr. Holt spoke first of some specimens of the Birkelänge (*Molva abyssorum*, Nilsson). The regular occurrence of this fish off the Faroe Islands and its occasional capture on the coast of Iceland were now recorded for the first time, the species having been previously observed only on the Scandinavian coasts. The specimens, six in number, all of considerable size, were described in detail, and the species was carefully compared with the allied form *M. vulgaris* (the Common Ling). Mr. Holt next proceeded to describe the "*recessus orbitalis*," an accessory visual organ of the Pleuronectid Fishes. The organ in question was stated to be a highly elastic saccular process of the membranous wall of the orbital cavity. It had been found to occur in all the flat-fishes examined, viz., the Halibut, Long Rough Dab, Brill, Plaice, Flounder, Lemon-Sole, Dab, and Common Sole, and was believed to occur in all flat-fishes with well-developed eyes. Finally, Mr. Holt spoke of an adult specimen of the Common Sole with symmetrical eyes, and discussed the bearing of this specimen on ambicoloration. The specimen in question, about fifteen inches long, was perfectly normal in external configuration, except that the left eye had retained its position on the left side of the head, and was nearly opposite to the right eye. Antero-ventrally it had been somewhat overgrown by the skin. The coloration was normal, the right side being brown and the left side white.—A communication was read from Mr. St. George Littledale, containing field-notes on the Wild Camel of Lob Nor, as observed during his recent journey across Central Asia.—Mr. Oldfield Thomas gave an account of a collection of mammals from Oman, S.E. Arabia, which had been transmitted to the British Museum by Dr. A. S. G. Jayakar, among which were examples of a new Hare (*Lepus omanensis*) and of a new Goat of the genus *Hemitragus*, proposed to be called *jayakari*, after its discoverer. Altogether seventeen species were represented in this collection, from a locality of which very little was previously known.

Linnean Society, May 3.—Prof. Stewart, President, in the chair.—Dr. Johann Mueller, of Aargan, and Prof. K. Mitsickuri, of the University of Tokio, were elected foreign members of the Society.—Prof. Poulton exhibited the larvæ of certain Lepidoptera to illustrate the results of experiments which he had made in regard to the influence of environment upon their colours. Variously coloured twigs and shoots, such as occur in nature, were shown to influence the appearance of many twig-like larvæ in such a manner as to aid their concealment.—Prof. G. B. Howes exhibited and made remarks upon the eggs and young of *Ceratodus Fosteri*, received from Prof. Semon, of Jena, who is engaged in working out the development of this fish.—Mr. James Saunders, of Luton, with the aid of the oxyhydrogen lantern, exhibited plasmodium in the act of forming sporangia; the species, which had been found on birch, was *Didymium squamulosum*.—On behalf of Dr. H. B. Guppy, the Secretary read a paper on the habits of three species of *Lemna*. In this paper, the author detailed the results of experiments made by him during a period of twenty months, and showed that *Lemna gibba* can pass the winter either in the gibbous form or with fronds which in appearance resemble those of *Lemna minor*. The flowering of *Lemna gibba* was observed in July, when it was found that the gibbous plants were producing their flat fronds, which were also in flower, and floating detached. In both cases the flowers were hermaphrodite, but they had the appearance of being unisexual, on account of the flowers of the gibbous plants protruding only the pistil, while those of the flat fronds only evolved the stamens. After describing the habits of the winter fronds of *Lemna polyrhiza*, and alluding to *Lemna minor*, the paper concluded with a table of temperatures relating to the germinating, budding, and flowering of these plants.—A paper was then read on the fertilisation of certain Malayan orchids, by Mr. H. N. Ridley.

Entomological Society, May 2.—Captain Henry J. Elwes, President, in the chair.—Mr. S. Stevens exhibited a specimen of *Argynnis aglaia* var. *charlotta*, taken by the late Rev. James Watson in the New Forest in 1870.—Mr. J. A. Clark exhibited a curious variety of *Chelonia caja*, having an extraordinary wedge-shaped marking extending from the outer margin to the base of the left hind wing, and also, on the same wing, a small spot, which was brown and white in colour, and had the appearance of having been taken from the fore wing and inserted in the hind wing. The specimen was taken at Abbotts Wood, Sussex, in July 1892.—Prof. E. B. Poulton, F.R.S., exhibited living specimens of the larvæ of *Gastropacha quercifolia*, surrounded respectively during the early stages of growth by black twigs and lichen-coloured twigs, the food being the same in both cases. All the larvæ were shown upon a white paper background, but examples of the surrounding twigs which produced the change of colour were shown beside each batch. Mr. Merrifield made some remarks on the subject.—Mr. E. Meyrick communicated a paper entitled "On *Pyralidina* from the Malay Archipelago."—Mr. C. J. Gahan read a paper entitled "A Supplemental List of the Longicorn Coleoptera obtained by Mr. J. J. Walker, R.N., during the voyage of H.M.S. *Penguin*."

PARIS.

Academy of Sciences, May 7.—On the spectra of oxygen at high temperatures, by M. J. Janssen.—Researches on the isomeric propylenes and their compounds with sulphuric acid, by M. Berthelot. Trimethylene is rapidly absorbed by pure sulphuric acid forming the normal ethereal salt $(C_3H_7)_2SO_4$. On addition of water it separates as a heavy oil which is only very slowly acted on by water and is decomposed by potash slowly in sealed tubes at 100°. Ordinary propylene combines with sulphuric acid in the same way to yield a much less stable derivative.—On *Flabellum anthophyllum* from the Gulf of Lyons, by M. de Lacaze-Duthiers.—Articular movements studied by means of photography, by M. Marey. Photographs are taken in successive positions of a bright wire attached to the moving part. The results of a study of human jaw movements are given.—Report of M. Darboux on a memoir on the triangle of sequences (presented by M. Désiré André).—Azimuth, latitude, and longitude, by equal heights without the aid of the chronometer, by M. E. Caspari. The method described is held to have many good characteristics, among which the fact of the same precision being obtained for all latitudes and all zenithal distances is noted.—Experiments on the contraction of liquid jets and on the distribution of velocities internally: abstract of a memoir by M. Bazin.—Mathematical theory of the Watt indicator: abstract of a memoir by M. L. Lecornu.—Observations of the comet Gale, made at Algiers Observatory, by MM. Rambaud and Sy. M. Tisserand gave details concerning a photograph of this comet obtained on May 5, at Paris. The photograph shows the comet with a tail 4° in length.—Emission of sounds, by M. Henri Gilbault.—Equality of the speeds of propagation of very short electric waves in free space and in long wire conductors, by M. M. Dufour. The author experimentally demonstrates the extension of MM. Sarasin and de la Rive's conclusions on the subject to the case of a wave-length of 8·5 cm.—Absorption spectra of cupric bromide, by M. Paul Sabatier. The spectral absorption of aqueous solutions varies with the concentration; alcoholic solutions give the same absorption spectrum as concentrated aqueous solutions, probably the salt here exists in the anhydrous condition.—On the variations of viscosity shown by melted sulphur, by MM. J. Brunhes and J. Dussy.—On the blue lakes obtained from dibromogallanilide and on some reactions yielding blue products of polyphenols, by M. P. Cazeneuve.—On a new carbon chloride, the dichloride of hexachlorobenzene, by M. Et. Barral. The properties are described of the substance C_6Cl_8 obtained from hexachlorophenol by action of PCl_5.—On the aldehyde from essence of lemon grass, by MM. Ph. Barbier and L. Bouveault.—On the industrial manufacture of products rich in nicotine, by M. Th. Schlœsing.—On the oxidation of beer worts, by M. L. Petit.—Researches on the chemical transformations of the fundamental substance of cartilage during normal ossification, by M. C. Chabrié.—On some points in the anatomy of Cryptoproctus from Madagascar, by M. H. Filhol.—The perfume glands of Viverridæ, by M. H. Beauregard.—The sexual reproduction of Ascomycetes, by M. P. A. Dangeard.—The lacustrine basin of Constantine and oligocene formations in Algeria, by M. E. Ficheur.—Examination of milks by pressure, by MM. R. Lezé and E. Hilsont.—On the *réclamation*, by M. Calmette, concerning the antitoxic blood of animals protected against the poison of serpents, by MM. C. Phisalix and G. Bertrand.

PRACTICAL PAPER MAKING.

Practical Paper Making. By George Clapperton. (London: Crosby Lockwood and Son, 1894.)

THE book before us is not without value. The chapters devoted to paper-making proper, that is, to the mechanical details of the art, contain a great deal of useful information; and although "experience" must be classed as of the "incommunicables," the notes and observations of an experienced man serve to concentrate the attention of the less experienced upon those points, the mastery of which constitutes technical skill. Technological handbooks, however, ought in our opinion to possess the higher *educational* value belonging only to those which preserve the perspective of the subject of which they treat. A book, like a lecture, must be diagrammatic to be effective educationally; and in this sense it must be an artistic production. We do not by any means imply that a certain level of literary style must be attained and maintained. In the "literature" of the industrial and physical sciences we must be content, it would seem, with the irreducible minimum of "Queen's English." What we do imply is the infusion of personality, in the clear grasp of principles, and in the consequent development of the subject-matter according to its natural perspective. Judged from this stand-point, "Practical Paper Making" must be labelled "found wanting." If we apply to the art or industry the crude criterion of money values, we find that in the production of paper the proportion of costs, for raw materials, and their chemical treatment, are in this, in comparison with many other industries, unusually high; this being "practically" interpreted, means that chemistry is of first importance in the mill. The author makes an oblique confession of his convictions in this direction in his opening sentence: "As the chemical and physical characteristics of the materials . . . . determine to a marked degree the qualities of the finished product, a thorough grasp of these characteristics is indispensable to all who aim at the production of the best possible results with the minimum of cost." We are quickly reminded, however, of the adage, "red dawning shepherd's warning," as the author plunges at once from the sunshine of first principles into a much less promising treatment of practical matters, opening with the following remarkable sentence:—

> "The percentage of cellulose—or to use a term more readily understood by paper-makers, the amount of available paper-making material—varies with the plants from which it is obtained, and the treatment to which it is subjected. . . . ."

Comment would be superfluous. He then proceeds to extract comfort from "the chemical formula of cellulose—$C_6H_{10}O_5$—which means that six equivalents of carbon, ten of hydrogen, and five of oxygen are united together to form the substance known by that name." This evidently has the effect upon the practical paper-maker which is recorded of the "blessed word Mesopotamia" in another sphere of experience. That is all as to cellulose proper! "Oxycellulose" is then alluded to, and described as possessing "an extraordinary affinity for *vanilline* compounds, uniting with them from solutions containing infinitesimal proportions." It would be thankless criticism to single out mere mistakes from what might be in other respects good matter; but the mistakes in this work are as slovenly as the matter—"vanilline" for "vanadium" (p. 2), and "hypochlorite," used on three successive occasions, for "hyposulphite" (pp. 29-30), are typical mistakes; and for looseness of construction, which characterises the matter throughout, we commend the following example:—"Sulphate of alumina is not a chemical compound of a definite composition, as the alumina varies between 2 and 3 per cent., though that purchased from reliable makers generally contains 15 or 16 per cent." (pp. 71-72). If the author's want of precision were an occasional lapse merely, with the effect of befogging a particular point, we should not have challenged the work upon the issue we have raised; but it extends to the entire ordering and treatment of the subject-matter. The sources from which the author has compiled his account of the chemical processes of the mill are familiar to us. He has probably aimed at reproducing what he may consider the essential and practical features of the originals. But the result is a second-hand and garbled version, and in many important places, more especially where effects are discussed in relation to causes, essentially wrong. Thus (p. 6) "jute fibres" are described as "strong but very difficult to bleach white, and if subjected to such treatment as will dissolve all the extraneous matter and reduce to ultimate fibres, their original strength is much impaired." The facts are that jute is easily bleached white, but then is no longer jute but jute-cellulose; and on the structural question the destruction of the *filament* by no means implies disintegration of the *ultimate fibre*. Then again (p. 7), "Straw fibres are very similar in appearance to esparto, but shorter and more highly polished, tending to make their filling power much less, and rendering paper made from them very brittle." In another place (p. 47), "Papers made from straw are, owing to the hard nature of the ultimate fibres, very hard and brittle." Any explanation appears to some minds better than none, even a re-statement of the fact to be explained, in somewhat varied terms. It does not occur to the author that straw "cellulose" differs constitutionally from esparto, and with these differences are correlated not only the relatively low yields of bleached straw pulp (which the author labours to explain on p. 40), but generally its relationships to oxygen and water (hydration), and these again with its paper-making qualities.

It would serve no useful purpose to continue our criticisms. The best we can say of the work is that it represents a good deal of thought on the part of a man skilled in his art, and struggling to compass the science upon which its successful practice primarily depends. It may be that in this endeavour the author has followed the classic maxim: "If you want to learn a subject, write a book upon it."

To those who will bear in mind that the chemical part of the work is a compilation, not well digested, and in some places unsound, we have no hesitation in recommending it.

E

THE THEORY OF OPTICAL INSTRUMENTS.

Theorie der Optischen Instrumente nach Abbe. Von Dr. Siegfried Czapski. Breslau: Eduard Trewendt, 1893.

HAPPENING not long ago to meet a German friend well posted up in physical literature, the present writer inquired whether any of the year's publications were specially worth getting and reading. The answer was a doubtful "No," and then "Oh, yes—Czapski's 'Theory of Optical Instruments.'" This was high praise, but not unmerited. For although the book will not appeal to a large circle of readers, it will soon become indispensable to all who are interested in the investigation of the merits and defects of optical systems, or who are concerned in turning out high-class optical work.

Although only a third of the book is devoted to the description of the microscope, telescope, and other instruments. there is no unnecessary rambling beforehand —either into the pleasant regions of developmental history or along the more dusty paths of the optical text-book proper. The author acknowledges the value of the undulatory theory as the ultimate test which must be applied when we wish to know how far the conclusions of geometrical optics are valid; and therewith dismisses it. He everywhere tries to be concise: and succeeds so far that the average student might complain of sometimes finding a day's work between one page and the next. But the condensation is not of that meaningless kind which so often irritates one in German school and college text-books. There are frequent (and valuable) bibliographical notes. The references to the works of Smith, Herschel, Lloyd, Airy, Rayleigh, Dallinger, and Pendlebury show that the English literature has not been neglected; indeed, Principal Heath's "Treatise on Geometrical Optics" (which is being translated into German) is recommended as the best of the modern text-books. But whereas these tend to treat optical instruments as convenient illustrations of optical theory or geometrical reasoning, the latter are here treated as strictly subservient to the former. The range is further limited by including among optical instruments only those which are strictly used for producing images of external objects—applications of reflecting mirrors in geodesy and astronomy, the stereoscope, &c., being included. Within these limits our author is at home and speaks with authority. As scientific adviser and technical director in the celebrated workshops of Carl Zeiss in Jena, he has daily opportunities of applying theory to practice with the aid of excellent glass, skilful workmen, and modern machinery; and has had the still greater advantage of continual intercourse with Prof. Abbe, to whose labours the perfection of high-power microscope objectives is so largely due. His debt in this direction is freely and gratefully acknowledged—most conveniently by stating what chapters are not directly or indirectly due to Abbe.

A short introductory chapter on geometrical optics is followed by three others on the geometrical theory of optical images, the fundamental properties of lenses and systems of lenses, and the theory of spherical aberration. In chapter v. (on chromatic aberration and the theory of achromatism) the author gives a simple method for calculating the magnitude of the secondary spectrum (the focus-difference) of a system of two infinitely thin lenses from the dispersion-constants. Assuming these to be achromatised for the lines F and C, he calculates the difference between the focus for light of a given wave-length (λ) and the light of the brightest part of the spectrum $\lambda = 0.55\ \mu$. (According to König the position of maximum brightness in the spectrum of sunlight varies, as the total intensity increases, from $\lambda = 0.53\ \mu$ to $\lambda = 0.61\ \mu$.) The values of the differences $f_\lambda - f_{0.55\,\mu}$ are given in thousands of $f_{0.55\,\mu}$ for various wave-lengths. In the case of a combination of a flint glass of medium density with an English silicate-crown glass the differences decrease from + 1.79 (for $\lambda = 0.77\ \mu$) and then gradually increase to 3.70 (for $\lambda = 0.41\ \mu$). But the researches of Prof. Abbe and Dr. Schott have resulted in the production of improved grades of optical glass, and especially of pairs of flint and crown glass in which the dispersion in various parts of the spectrum is much more nearly proportional. These glasses have been manufactured in the Jena works since 1884, and by their use the magnitude of the secondary spectrum is greatly diminished. Thus in the case of a combination of a heavy barium-phosphate-crown glass with a borate-flint glass the above differences begin at 0.04 (for $\lambda = 0.77\ \mu$) and the maximum value is 0.79 (for $\lambda = 0.41\ \mu$). Curves are given illustrating these results which have been confirmed by direct measurements of focus-differences of telescope-objectives made by Vogel, Hasselberg, and Wolf.

Chapter vi. contains an unusually complete and systematic treatment of prisms and systems of prisms, partly based upon Dr. Czapski's own investigations. The next chapter is devoted to stops and aperture, and the properties of an optical system which depend upon aperture, such as penetrating power and brightness. It is shown that in any instrument used for subjective observation the penetrating power (*i.e.* the total depth of vision) is exactly equal to the sum of the depth of focus of the objective and the accommodation-depth of the eye—a result which is of the greatest practical importance in microscopy. Next comes what is perhaps the most interesting and important chapter—that which deals with the principal types of optical instruments. The book closes with an account of the methods for determining the constants of optical instruments. Some of these will come as a revelation to students who are only familiar with the comparatively rough methods described in the ordinary text-books on practical physics.

Dr. Czapski appears to have at first intended to include in the book a tolerably full account of Abbe's theory of microscopical vision. One cannot help regretting that this intention was abandoned. A letter of his on "The Future of the Microscope," which is printed in van Heurck's sumptuous book ("The Microscope," English edition, pp. 357–364) shows his ability to present such a matter, not only with his usual accuracy, but in a fairly popular form. We understand that a separate volume on this subject may be expected from Prof. Abbe or Dr. Czapski, or both.

CHEMISTRY APPLIED TO AGRICULTURE.

Manures and the Principles of Manuring. By C. M. Aikman, B.Sc., F.R.S.E. Pp. xxx., 592. (Edinburgh and London: W. Blackwood and Sons, 1894.)

IT was rather more than fifty years ago, in the year 1840, that Liebig presented to the British Association his classical report on "Organic Chemistry in its Applications to Agriculture and Physiology." In tbis, among many bold and startling statements, we find such sentences as the following:—"As there is no profession which can be compared in importance with that of agriculture, so there is none in which the application of correct principle would be productive of more beneficial effects. Hence it appears quite unaccountable that we may vainly seek for a single leading principle relative to this subject in all the writings of agriculture and of vegetable physiologists." "Also, when we inquire in what manner manure acts, we are answered by the most intelligent men that its action is covered by the veil of Isis; and when we further demand what this means, we discover merely that the excrements of man and animals are supposed to contain an incomprehensible something which assists in the nutrition of plants and increases their size. This opinion is embraced without even an attempt being made to discover the component parts of manure, or to become acquainted with its nature." In this, as in other of Liebig's statements, there was much exaggeration. Sir Humphrey Davy, De Saussure, and other labourers in the field of scientific agriculture had not lived in vain. Liebig's writings, however, were productive of much good, and stirred up a great deal of interest in agricultural chemistry which led to many important results. Within a year or two before the date mentioned and five or six years after, not only were most of the more important artificial manures, now extensively used, brought into notice and experimented with, but several important writings on manures and manuring were published Suffice it to say that to this epoch is due the introduction of guano, of nitrate of soda, and of sulphate of ammonia as manures; and that Mr. Lawes (now Sir John Bennett Lawes) took out his patent for the manufacture of superphosphate in 1842; now nearly a million tons of this manure are made annually in this country alone. Two or three important manures, such as the potash salts of Stassfurt and Thomas' basic slag, are of later introduction. To illustrate the attention then given to the subject of manures and manuring generally, and to these new manures in particular, we may note that the second volume of the *Journal of the Royal Agricultural Society of England*, published in 1841, contains a paper by the Sibthorpian Professor of Rural Economy at Oxford, Dr. Charles Daubeney, "On the scientific principles by which the application of manures ought to be regulated," including results of many experiments; also an article by Prof. J. F. W. Johnston, "On Guano," and the results of experiments by numerous agriculturists with nitrate of soda, saltpetre, bones, and gypsum.

Within a very few years of this date Prof. Johnston published his Lectures, and Cuthbert W. Johnson published a very useful and interesting book "On the Fertilisers." It is almost needless to remark that the immortal experiments of Rothamsted were put on to a firm and systematic basis in 1843.

Since that time agricultural chemistry, including a knowledge of the principles of manuring, has steadily pursued its way, fostered by a host of workers, not only in this country but on the continent, and lately in the United States. The last few years have shown some revival of the public interest in the applications of science to agriculture. This has, we think, been brought about partly by the spread of technical education in the rural districts; but also partly byt he continued low prices of agricultural produce, which make it imperative on the farmer, if he would continue to survive, to use every good implement, mental or otherwise, he can in furthering his business.

Although many little books have been lately published in this country on the subject of manures, we may safely say that none of them are so satisfactory as that of Mr. Aikman. Though in some respects incomplete, it is a welcome addition to the literature of the more scientific side of agriculture. The first part of the book is a short historical introduction of 60 pp.; this is good, but too short. Part ii. is on the principles of manuring. It deals with the fertility of the soil, illustrated by and due to its physical, chemical, and biological properties; with the functions performed by manures, and the positions occupied by nitrogen, phosphoric acid, and potash in agriculture, and with nitrification in soils. The treatment of the biology of the soil is all too scanty. Part iii., more than half the book, treats of manures. The most important chapter is on the most important manure—farmyard manure—and this is well treated. Other chapters are on guano, nitrate of soda, sulphate of ammonia, bones, mineral phosphates, superphosphates, basic slag, potassic manures, indirect manures, which include lime, gypsum and salts, the application of manures, manuring of farm crops, the valuation and analysis of manures; and a final chapter giving the results of some of the Rothamsted experiments. There is a very short chapter on sewage, which is inadequately dealt with, and the minor manures are very scantily treated; seaweed is not even mentioned as a manure, and rape-cake and other oil-cakes are only casually alluded to. Generally, Mr. Aikman has done his work carefully and well, and presented the results in a clear and readable form, which will commend itself to his readers. As we confidently expect a new edition ere long, we may perhaps be pardoned for pointing out some of the minor defects of the book. More frequent references should be given to original papers; this might be done without unduly enlarging the volume. The explanation of "unit" values of manurial ingredients is hardly intelligible to one who first comes across it here. On p. 380, the last sentence is wrong; probably the word *only* is omitted. On p. 43, Beyerinck would hardly recognise his name in the way it is spelt; why should the words *glycin* and *glycocoll* be used on consecutive pages as though they denoted different substances; why should carnallite be sometimes spelt with a *c* and sometimes with a *k*, even in the index; also why are sylvine and kainite denied the final *e* usually accorded to minerals in this language?

The scheme of experimental plots, on p. 546, would be made more complete by including an eighth plot manured with phosphates, potash, and nitrogen. The valuation of unexhausted manurial residues, whether derived directly from manures or from foods, might well receive more attention.

The book is a genuine effort to treat the subject scientifically, and at the same time in a manner intelligible and interesting to the farmer of good education. We think it has succeeded. E. K.

LATITUDE BY EX-MERIDIAN ALTITUDE.

The "Ex-Meridian" treated as a Problem in Dynamics, &c. By H. B. Goodwin. (London: George Philip and Son, 1894.)

THE author of this brochure, with a tinge of satire, seems to apologise for its containing nothing about the already exhaustively developed Sumner method. In doing this he alludes to "the too just Aristides." This reminds us of a saying of that practical philosopher, that "the best way to appear just is to be so." The proverb may teach us that the way to obtain dependable results is to have a firm grasp of principles, that the most reliable navigator is one who understands the theory of his problems.

This remark is apposite, for we can conceive many a "simple sailor" being rather frightened at the title of this pamphlet which will first meet his eye, and we hear him say—"Cannot the seaman continue to navigate his ship without learning dynamics?" If he has courage to read a little further on, he finds that his belovedly simple "Sun Mer. Alt." connected with such words as "maximum" and "minimum." Hitherto he has banished the word "maximum" from his thoughts by avoiding the use of the moon and planets for finding the latitude at their culmination; considering that the problem—"To find the time when the moon and planets are at their maximum altitudes" to belong to "the gymnasium of the examination room" rather than to "the arena of every-day practical utility." But now he finds that modern ships require this problem to be considered with reference to all the celestial bodies, and that even the sun may be capricious enough not to "dip" at noon, that, in fact, instead of this phenomenon giving a meridian altitude it gives an ex-meridian altitude which has to be reduced to the meridian.

There is reason to be thankful for this new feature, because it will attract more attention to the hitherto shamefully neglected method of the ex-meridian among ordinary navigators. That this can be no longer thus relegated is exemplified by Mr. Goodwin, as follows:—

"In the *Standard* newspaper of October 23, 1893, it is stated that H.M.S. *Royal Sovereign*, flag ship of the Channel Squadron, had arrived at Gibraltar, having made the passage in less than seventy hours. Such a passage as this has ceased to be regarded as phenomenal, and is looked upon as quite an every-day occurrence. For a portion of the voyage a speed of over fifteen knots was maintained, and on board a ship steaming at this rate nearly due south, at that time of year, the sun would not appear to 'dip' until more than five minutes after noon, and a correction of nearly 45" would be necessary to reduce the maximum altitude to the meridian."

As the ship moves south a fresh horizon comes into view, and the sun will appear to rise until this shift of the horizon (the rate of which depends upon the rate of the ship towards the sun) is less than the rate of his motion in altitude.

There is another reason for being thankful for the sun having to be thus treated at the noon-day observation. It will lead to the moon and planets being no longer avoided for finding the latitude at the time of their culmination. No celestial bodies are more useful for such a purpose, especially at twilight, when a well-defined horizon is frequently available.

Every practical navigator daily uses the *Nautical Almanac*: it would be well if he devoted a short time also to study the "Explanation" at the end of the volume. In explaining "*Var. in* 1 *hour*" which occurs on every page I. of the book, it is stated that this "is the variation at *noon*, and requires to be reduced to midway between noon and the time at which the R.A., Dec., or Eq. of time is required"; in other words, the reduction of the quantities from apparent noon to any other time is a problem in dynamics. The moving body is subject to a uniform acceleration in the direction of its motion, and the space described in a given time is found by multiplying the *mean velocity* during the time by the given time. The same principle applied to the ex-meridian problem gives the result that the reduction is equal to the rate of change of altitude per half-minute of time, multiplied by the number of minutes of time from the meridian.

So far from decrying the rapid methods now so needful in practice, the author advocates their further use. He gives a "Method of solving the Ex-meridian Problem practically by the Azimuth Tables," which are, or should be, in the hands of every navigator, and also "Practical Rules for finding Time of Maximum Altitude," and ends with "Application of the Azimuth Tables to other Problems."

We can heartily recommend this short contribution to the science of nautical astronomy in its application to the practical requirements of modern navigation.

PERFUMERY.

Odorographia: a Natural History of Raw Materials and Drugs used in the Perfume Industry, including the Aromatics used in flavouring. Intended for the use of Growers, Manufacturers, and Consumers By J. Ch. Sawer, F.L.S. Second Series. (London: Gurney and Jackson, 1894.)

THIS book is a continuation of the subject of odour-yielding products treated of by Mr. Sawer in a volume bearing the same title and issued in 1892. Though the present book is a companion volume in every respect to its predecessor, and might well have been designated as the second volume, the author has preferred to call it the second series, thus implying, and indeed distinguishing, the former book as the first series—a little peculiarity which does not in itself affect the value of the work, but which tends to confusion lest the second series might be taken for an extended or enlarged edition of the first; whereas the term volume would have implied that it is an entirely new book, which is really what the author wishes his readers to understand, as he tells us in the preface to the new volume that the matter treated therein is a "continuation of the subjects already discussed."

It is true that many perfume-yielding plants treated of in the first volume are again referred to in the second. Mr. Sawer says that the matter published by him two years ago is now as far as possible brought up to date. This may be so, so far as the chemistry of the various substances is concerned; but we scarcely think, as an instance, that the paragraph on Ambrette (p. 402) indicates any new discovery since 1892, when *Hibiscus Abelmoschus* was briefly referred to and sufficiently described. The following is the paragraph to which we refer. It is placed in Section iv. under the head of "Addenda to Volume i.":—

"Ambrette, the seeds of *Hibiscus Abelmoschus* (Lin. Spec. 980).—'Hibiscus' is one of the names given by the Greeks to 'Mallow,' and is said to be derived from *Ibis*, a Stork, a bird which is said to chew some of the species. 'Abelmoschus' is derived from the Arabic *Kabb-el-Misk*, 'grain or seed of musk.' The 'Mallow' group consists of a very large genus of *Malvaceæ*, characterised by their large showy flowers being borne singly upon stalks towards the ends of the branches, by having an outer calyx or involucel composed of numerous leaves, and an inner or true calyx cut into five divisions at the top, which does not fall away after flowering; by having five petals broad at top and narrow towards the base, where they unite with the tube of the stamens; and by the latter forming a sheath round the five-branched style and emitting filaments bearing kidney-shaped anthers throughout the greater part of its length. The fruit is five-celled, with numerous seeds. *Hibiscus Abelmoschus* is a shrub of 6 to 8 feet in height, native of the East Indies and South America. Its leaves are somewhat peltate, cordate, 5 to 7-angled, acuminated, serrated, stem hispid; pedicels usually longer than the petioles; involucel 8 to 9-leaved. Flowers sulphur-coloured with a dark blue centre. Capsules conicle (*sic*) covered with bristles. The seeds are large and have a very musky odour. The seeds yield on distillation 0·1 to 0·25 per cent. of essential oil, which congeals at + 10° C. Its sp. gr. at 25° C. is 0·900 to 0·905."

It will scarcely be conceded that the bulk of this paragraph brings the information on Ambrette up to any more recent a date than might have been given in the book issued two years ago, for the botanical description is acknowledged as having been obtained from such works as Rumphius' "Herbarium Amboinense," Rheede's "Hortus Malabaricus," &c. The descriptions, indeed, of this and of most other plants referred to is of little or no value in a book of this character, and only helps to increase its bulk, a thing to be avoided in a work "intended for the use of growers, manufacturers, and consumers."

The range of plants over which Mr. Sawer travels is very extensive, and is indicated by the five and half pages of works consulted, as well as by a casual glance through the pages of the book. Many of these plants are new to us as perfume yielding.

The three species of *Barosma*, for instance, namely *B. crenulata*, *B. betulina* (which, by the way, is spelt Barasma), and *B. serratifolia*, the leaves of which are well known in pharmacy under the name of Buchu leaves, seem as much out of place in a work on perfumes as asafœtida or castor oil would be; and the fact that the leaves of the Barosmas "are used by the Hottentots as perfumes," is but a slight recommendation for their adoption in civilised life. Notwithstanding that Mr. Sawer summarises rather fully what has been done by such well-known chemists as Prof. Flückiger, Messrs. Schimmel, and others, in the examination of Buchu oil, he does not inform us whether the oil has been actually used in perfumery, or whether there is any prospect of its becoming an article of the perfumer's trade. All we gather on this point is that its odour agrees with that of peppermint.

Regarding the arrangement of the plants or products referred to in the book, we cannot discover that any systematic method has been attempted; the plants are not classed scientifically nor alphabetically, and if it were not for a fairly extensive index a good deal of difficulty would be experienced in finding any particular plant required. It cannot be denied that the book contains an immense amount of useful and interesting matter, and exhibits an enormous labour expended in its compilation. With a good deal of judicious pruning, a systematic classification of subjects, and much careful editing, the two books might be reduced into one good-sized volume, and made a standard work on all matters relating to perfumery.

That a careful revision has not been made of the proof sheets, is evident from the frequent mis-spelling both of scientific and common words. Thus we find *Melliaceæ* for *Meliaceæ*, String Bark for Stringy Bark, *Stellingia sabifera* for *Stillingia sebifera*, Madagasca for Madagascar, and such like errors that might with ordinary care have been avoided.

OUR BOOK SHELF.

Introduction to Elementary Practical Biology. By C. W. Dodge, Professor of Biology in the University of Rochester, U.S.A. (New York: Harper and Brothers, 1894.)

THIS volume of 422 pp. octavo is the first laboratory book on the established lines of Huxley and Martin's "Elementary Biology" which has reached us from the New World. It, however, excels that in scope, owing to the introduction of additional types of both plants and animals—the Starfish, Locust, Sponges, Rockweed (*Fucus*), Liverwort, and Water-silk (*Spirogyra*) being among those dealt with. The work embodies the results of seven years' experience in practical teaching; but, that notwithstanding, it bears at every turn the impress of the recognised English treatises of its kind, and to these the author, unlike certain writers nearer home, manfully acknowledges his indebtedness. The book opens with an introduction, dealing with instruction in manipulation and the use of instruments, and closes with an appendix, giving lists of and recipes for reagents, and there are added a bibliography of works of reference and a very good glossary-index. The bulk of the volume is subdivided into three parts dealing in succession with the Biology (1) of the Cell, (2) of the Animal, and (3) of the Plant, elementary experimental physiology and the study of habit receiving adequate attention. Such novelty as is claimed for the work is born of its author's conviction that "the methods of teaching now in vogue for elementary classes are methods of *instruction* rather than of *education*" (!) and he sets himself to overcome this imaginary defect of what he terms the "verification method" by the introduction of questions, as opposed to the more diadactic statement of facts customarily resorted to. Up to a certain point this may be all very well. For example, in dealing with the Protozoa, with which and the analysis of simple cell structure the author's course commences, the student, being told how to capture and mount his sample, is asked, "How many different shapes can you distinguish?" "What variations in size?" "In color?" and other questions of like order; but when there follow these (on p. 5 of the work), "How do these animals eat?" "Digest their food?" "Breathe?" (*sic*) we confess to a feeling of sympathy with the befuddled beginner. And when, further, after an altogether insufficient preamble and at the outset of his inquiry into the wide domain of biology, the tyro is asked, of the Amœba, "Is the process [of fission] preceded by sexual union?" "How is one sex distinguished from the other?" and, *à propos* of the cerebral hemispheres of the frog, "Why are they called hemispheres?" one's sympathy gives place to pity for the student thus led astray. We entirely disagree with the author's dictum that sooner or later the student will have to learn to use the microscope, and it matters little when he does so; and we further doubt the advisability of his interrogatory method, when "the questions usually apply equally well to several related forms," particular species being said to be "not required." A training in elementary biology is one in manipulation in a field beset with snares and pitfalls, rendering it a primary necessity to teach the beginner what to leave unconsidered. However, the experiment, while not altogether new, is an interesting one; the book is carefully compiled, and we await with interest the verdict of time upon the system which it advocates.

Notes on the Ventilation and Warming of Houses, Churches, Schools, and other Buildings. By the late Ernest H. Jacob, M.A., M.D. (London: S.P.C.K., 1894.)

A MELANCHOLY interest is attached to this little manual of health in the fact that its gifted author passed away on March 1. His posthumous work shows what a promising life was cut short, and will serve as a memorial to him. The idea that human beings confined in public buildings should have pure air at a suitable temperature supplied them, has only in recent years been taken seriously. It is notorious that in most churches there is no attempt at proper ventilation, and they are only excelled, as far as disregard for the laws of health go, by many Nonconformist chapels with galleries, and mission-rooms created by knocking two cottages into one. Dr. Jacob's manual should be consulted by those who are responsible for such buildings. Therein they will find described the general principles by which buildings are rendered healthy. The book should also be read by the householder, for he will learn from it how an ordinary dwelling-house ought to be ventilated and better, will find that it is an easy and not very costly business to make the average English house less stuffy and more healthy than it usually is. Indeed, all who desire in a popular form information on the subject of ventilation, should procure this book, while architects and builders would benefit the community by taking its lessons to mind.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Rotating Shafts.

In your account (NATURE, May 10, p. 43) of Dr. J. Hopkinson's "James Forrest" lecture at the Institution of Civil Engineers, appears the following statement: "Another example, having a certain degree of similarity with the case of struts, is that of a shaft running at a high number of revolutions per minute, and with a *substantial* distance between its bearings. . . . How will the shaft behave itself in regard to centrifrugal force as the speed increases? *In this case, so long as the shaft remains absolutely straight it will not tend to be in any way affected by the centrifugal force*, but suppose the shaft becomes slightly bent, it is obvious to anyone that if the speed be enormously high this bending will increase, and go on increasing until the shaft breaks. In this case also we may use mathematical treatment; we find that the condition of the shaft is expressed by a differential equation of the fourth order, and from consideration of the solution of this equation we can say that if the speed of any particular shaft be less than a certain critical speed, the shaft will tend to straighten itself if it be momentarily bent, but that, on the other hand, if the speed exceeds this critical value, the bending will tend to increase with the probable destruction of the shaft." (The italics are mine.)

The italicised statement seems to imply that a certain operating cause may have absolutely no effect, which cannot of course be the meaning Dr. Hopkinson intended to convey. Most engineers, it is to be hoped, are aware that the natural tendency of the material of the shaft is to retire from the axis of rotation, and that this is *necessarily* associated with a state of strain and stress throughout the shaft, whether straight or bent, for all speeds of rotation. Dr. Hopkinson must, I think, have had his mind so fully occupied with the idea of rupture through instability, worked out by Prof. Greenhill,[1] that he overlooked the fact that his language suggests the non-existence of the more commonplace and essential elastic phenomena.

So far even as rupture is concerned, Dr. Hopkinson's statements are, I believe, incomplete. The ordinary strain and stress developed by rotation in a shaft may, as I have shown elsewhere,[2] exceed the limits of safety before a velocity is attained at which, on the Greenhill theory, instability becomes possible. This is the more likely to happen the shorter the cylinder and the thinner its walls, if it be hollow; but even in a solid iron cylinder of length eight or nine times its diameter—a very substantial distance in a thick cylinder—the strain developed would be such as to merit an engineer's careful attention before a critical velocity was reached associated with instability.

I am somewhat doubtful whether Dr. Hopkinson's remarks on instability itself are altogether satisfactory. On the mathematical theory there appear in reality to be a series[3] of critical values, if any, at which instability *may* occur. Supposing the velocity gradually raised, it seems possible, *theoretically*, for the shaft to safely surmount the first crisis. It then would appear to remain unexposed to instability until the approach of the next higher critical velocity, and so on.

As Dr. Hopkinson says, Prof. Greenhill's instability theory leads to a differential equation of the fourth order. The solution of this equation is, however, dominated by the terminal conditions[4], at the ends or bearings of the shaft, and unless these be correctly assigned the numerical results deduced from the theory are untrustworthy. This is, I think, one of those points where the practical experience of the engineer is a most essential auxiliary to the analysis of the mathematician.

Kew Observatory, May 11. CHARLES CHREE.

IN order to shut out every possibility of ambiguity, I might have said, instead of "substantial distance between the bearings," "distance between the bearings very great in comparison with the diameter of the shaft," and in the next sentence quoted it would perhaps have been clearer if I had said "will not be broken by centrifugal force." But I do not think that in fact I could be misunderstood by anyone.

It was hardly desirable that I should touch upon the terminal conditions, or upon the possibility of stability between the critical values, in a paragraph introduced for illustration and not for detailed information.

But Mr. Chree's letter does remind me that I neglected to refer to Prof. Greenhill's name in this connection. This I should have done with the greatest pleasure, but, unfortunately, for the moment I forgot that it was he who had worked on the problem. I write this note in order to make the acknowledgment.

The North Sea Ice Sheet.

IN his letter in NATURE, May 3 (p. 5), my friend Prof. Hughes calls attention to a most important fact. In archæology it has long been known how necessary it is to make sure that not only the exact *provénance* of an object is ascertained, but also that when found it was *in situ*, and was not the result of a later disturbance of the ground. Thus Mr. Franks has a pricket candlestick, made at Limoges, which was found several feet deep in gravel at Calcutta, and this strange fact was only explained when it was discovered that the gravel in question was ballast, which had been dredged from the Thames, deposited in the hold of a vessel, and redeposited at Calcutta. The same caution is more especially needed in geology. Prof. Hughes describes the foreign ballast which he saw stranded on our east coast, and warns us of the very wrong inferences that may be deduced from it. I would add to his statement that it was the custom of the old Danish pirates to use blocks of stone as anchors, and thus no doubt some foreign boulders have found their way to the east coast of Britain.

Here we seem to have an explanation of the occurrence of so-called Norwegian boulders on the Yorkshire coast between Hull and Scarborough and at Cleethorpes, and which, oddly enough, are not found in Scotland, though so much nearer Scandinavia.

It must be remembered that the mother rocks from which these Scandinavian boulders are supposed to have been detached do not occur on the western flanks of the Norwegian mountains at all. In this behalf I will quote Mr. Carvell Williams, himself a believer in some ultra-glacial views. He describes these boulders as consisting of the "typical augite syenite, which occurs only at Langesund Fiord, near Breug, and also porphyry and granite from the same region. *All of these rocks*, he says, came out of the Skagar Rack, and were brought by a glacier going south from Christiania and then south-west. Other rocks came from Fredericksvorn on the same coast."

This is assuredly a very difficult journey to understand. If the North Sea, as we are told, was filled with ice, how could an ice stream force its way from the comparatively low country round the Christiania Fiord right round the Nose of Norway, and then across the deep ocean basin to Britain? Prof. Bonney has argued that any ice sheet would be embayed in the great trough which skirts the coasts of Norway, out of which it could not rise again. Apart from this, it must be remembered that if the elevation of this ice sheet was so slight at the point when it started its journey as to enable it to get a load of these Norwegian boulders on its back from the comparatively low ground where the mother rock occurs *in situ*, it could not have the necessary slope to move beyond a very short distance. Pettersen has shown very admirably that the glaciers from the high mountains of Northern Norway, far from traversing the North Sea, were not powerful enough even to reach the string of islands which line the western shores of Norway, *a fortiori* would this capacity be lacking in the case of the ice from Christiania Fiord. The existence of the serrated and peaked Lofoden islands in the route which a North Sea ice sheet must have traversed was long ago pointed out as a great impediment in the way of such a postulate. Again, if this vast ice sheet came from any part of Norway, how did it get the stones on to its back? for in that case all Norway must have been smothered with ice. Lastly, where is the terminal moraine, or anything like a moraine, left by this monster? A glacier is not like a river which deposits fewer and fewer stones from its head waters as it flows. On the contrary, a glacier deposits its greatest load at its furthest extremity. In the case in question we have a few sporadic stones only, whose origin may well have been such as that pointed out by Prof. Hughes. It seems to some of us, and I have argued the question in my "Glacial Nightmare," that the whole notion of a North Sea ice sheet is a product of some other form of reasoning than inductive science, and that we have no good reason to doubt that when the mountains of Scotland and Scandinavia were nursing large glaciers, the North Sea was free from ice, except perhaps some floating bergs, and was the home of a rich molluscan fauna. HENRY H. HOWORTH.

Festoon Cumulus or "Pocky" Cloud.

THE following observation of Dr. Clouston's "pocky" cloud, which I had an opportunity of making a few days ago during a sounding cruise on board H.M.S. *Jackal*, seems to throw some light on the conditions under which this somewhat rare phenomenon occurs in these islands.

At 9.30 a.m. on May 3, while sounding in lat. 59° 45' and long. 1° 20' W., wind west-south-west, force 3 to 5, very gusty, a heavy squall approached from windward and struck the ship; wind in the squall about north, maximum force 8 to 9. Similar squalls came up at intervals during the day, the weather remaining almost unchanged except for a slight veering of the wind in the afternoon and the appearance of a "mackerel sky" of unusually fine texture.

While sounding in lat. 59° 32' N., long. 1° 0' E., a squall similar to the others approached from windward (west), and reached the ship at 6.20 p.m. The wind again shifted some points to the northward, with a smart shower of rain and sleet. Ten minutes later the "pocky" cloud was observed, forming the rear of the squall cloud. The number of festoons or mammæ was eight, with a possible ninth, of which two were incomplete, looking as if the bottom had come out of the "poke." The appearance fully maintained its reputation as a prognostic. The wind shifted to north-west about 9 p.m., and at midnight it was blowing a whole gale from that direction.

Before the "pocky" cloud was observed my attention was specially drawn to the weather by the peculiar nature of the sea disturbance. A moderate swell from windward appeared to be complicated by a cross sea from about north-east, resulting in a kind of miniature of the pyramidal seas met with in the centre of tropical cyclones. When the gale broke out the sea produced in this way tried the *Jackal* to an extent out of all proportion to the violence of the wind. It would appear from the "Daily Weather Reports" that at the time the "pocky" cloud was seen the *Jackal* was slightly in advance and to the right of the centre of a depression which had shortly before begun to increase in depth. If the cloud was observed in a region where an ascending current was increasing in velocity, its indications are of obvious interest. In any case, Abercromby's statement ("Weather," p. 79), that the storm the festoons prognosticate belong to another cyclone following, requires modification.

Oxford, May 10. H. N. DICKSON.

Ouramœba.

THIS peculiar amœboid animal was first observed by the late Dr. Jos. Leidy in 1874. Though he recognised in it the essential characters of the genus *Amœba*, the permanent filamentous appendages with which the posterior end of the body is provided led him to consider it a distinct genus. His description, embodied in "Freshwater Rhizopods of North America," was published by the United States Government in 1879, a brief notice of the form having appeared previously in the *Proceedings* of the Academy of Natural Sciences of Philadelphia. Dr. Leidy cites two or more notices of the same animal by Mr. Archer, of Dublin, who, however, held it to be a form of Wallich's *Amœba villosa*.

In 1879 it was stated by Leidy to be rare, he having found it only in two localities on a single stream in Pennsylvania; but Dr. Stokes, of Trenton, N.J., informs me that it is somewhat common in that vicinity.

My own observations, made in February and March of the present year, upon the only specimens which I have met in this locality, convince me that a suspicion which Dr. Leidy expresses, but which he rejects, is, after all, well grounded, namely, that the filaments, which constitute the only peculiarity of the creature, are of the nature of a parasitic fungus growing upon the genus *Amœba*.

The citation by any reader of NATURE of published observations upon this singular form since Leidy's monograph would be prized by me. WM. L. POTEAT.

Wake Forest College, N.C.

An Intelligence of the Frog.

DR. ROMANES, in his "Animal Intelligence," p. 254, says that, "frogs seem to have definite ideas of locality." This matter appears to have been noticed of old by the Japanese and Chinese, inasmuch as we credit Ryōan Terashima's explanation of the names given to the frog by the two nations. In his "Illustrated Encyclopædia of Three Systems of Japan and China," completed in 1713 (new edition, Tokio, 1884, book liv. p. 553), he remarks:—"When frogs are 'removed far' (Chinese, *hia*), they always 'long' (Chinese, *má*) after the original locality; hence the Chinese name 'Hia-má.' For the similar reason the Japanese call them 'Kaeru' (meaning 'return')." Shisei Tagawa (1707–76), one of the most erudite lexicographers of Japan, holds to the same opinion in his "Dust from a Sawyer's Workshop" (Tokio, 1891, p. 8).

May 12. KUMAGUSU MINAKATA.

PERENNIAL IRRIGATION IN EGYPT.

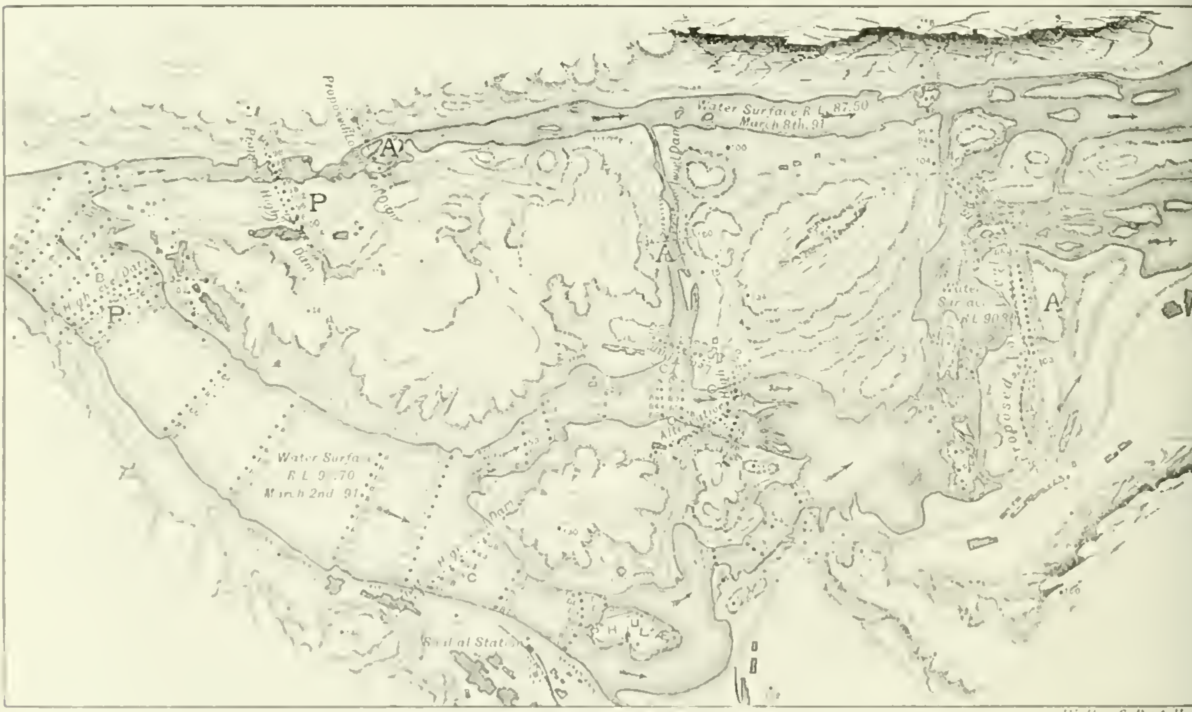
THE "Report on perennial irrigation and flood protection for Egypt," by Mr. Willcocks, brings us face to face with one of the most stupendous applications of science of modern times, and it is to be regretted that in consequence of the tardy arrival of the report and plans in this country, and of the general interest having been directed to a side issue, both the vastness of the scheme and the completeness and admirable method of the preliminary studies have received scant recognition.

Everybody is familiar with the saying of Herodotus that Egypt is the gift of the Nile, but only few are familiar with the conditions of the river, which are thus tersely stated in one of the appendices to the report. "The Nile drains nearly the whole of North-Eastern Africa, an area comprising 3,110,000 square kilometres. Its main tributary, the White Nile, has its sources to the south of Lake Victoria, and has traversed over 3500 kilometres before it is joined by the Blue Nile at Khartoum.

Taking the years since 1873 the mean of the minimums (which vary between May 14 and June 24) was −0·08 of the gauge; the mean of the maximums (which vary between August 20 and October 1) is 8·17. The Nile flood level at Assuân is then roughly 27 feet above average low water. The water therefore passing over the cataract varies enormously in quantity at low and high Nile; we have in an average of 20 years 440 cubic metres per second in May, 9170 in September.

Finally, of all this water which passes Assuân in such varying quantities at different times of the year, the total yearly average quantity being equal to 2990 cubic metres per second, 370 disappear before Cairo is reached, where the discharge is 2610 cubic metres per second; of this again 550 cubic metres are absorbed for the irrigation of Lower Egypt, so that 2060 cubic metres reach the sea each second, or 65,000,000,000 each year.

The rainfall as stated, treated as it is in Egypt at the present day, gives us the land area under cultivation, the number of crops per annum, and the quantity of produce



The Front Cataract at Assuân, showing the Dams proposed. P P, Philæ; A A A, Assuân.

From the junction onwards the river is known as the Nile, and after a further course of 3000 kilometres flows into the Mediterranean Sea by the Rosetta and Damietta mouths. The modulus of the Nile at Assuân is 2990 cubic metres per second, and at Cairo 2610 cubic metres per second."

The total mean annual rainfall in the Nile valley, including the desert north of Khartoum, amounts to 2,633,000,000,000 cubic metres. This water is brought to the main stream by the White Nile in a pretty constant quantity all the year round, but the river is liable to an annual flood which is due to the Saubat, the Blue Nile and the Atbara. Leaving out of consideration the accidents of the river above Assuân, we may state that at that place is the last of a series of cataracts, and also is a gauge by which the various heights of the river at different times of the year and in different years are recorded. The gauges are in metres, and are referred to mean low water level as zero. The zero at Assuân is 85 metres above the level of the Mediterranean.

on which the revenues of the country, and the food of the inhabitants, depend.

The question which has occupied the Egyptian engineers of late years has not been whether waste lands can be brought into cultivation and the agricultural yield increased if there were more water—that has long been obvious—but *how much* water was wanted in the worst years. Other questions were, whether the amount was available in the river, and at what period. First as to the amount wanted:—

		Area in feddans.[1]	Water wanted in cubic metres.
Upper Egypt	Assuân – Assyût	1,200,000	1,160,000,000
Middle Egypt	Assyût – Cairo	1,200,000	950,000,000
Lower Egypt	Cairo – Sea	2,810,000	1,551,500,000

[1] A feddan = $\frac{4200}{4047}$ of an acre.

The water requirement, then, is 3,661,000,000 cubic metres. We have already seen that 65,000,000,000 reach the sea each year. But it is not enough to know this yearly amount, we require to know the amount available *after the flood* each year. Taking the worst, Mr. Willcocks shows that the quantity available for storage in November, December, and January amounts to 6,100,000,000 cubic metres, practically twice the quantity wanted.

Next the water has to be stored *above* the place where it is wanted. Since the southern boundary of Egypt is below the second cataract that is out of the question; the only three possible sites for the dam are at Kalabsheh, Assuân, and Silsila. And now a very important question comes in: the slope of the Nile, except at the cataracts, is so gradual that holding up water to any height by a dam will flood a long reach of the river valley up stream of the dam. The dam must be high to store a sufficient amount of water, and naturally the higher the dam the longer will be the flooded region. Thus a dam at Silsila submerges the whole valley to the first cataract including the town of Assuân. A dam at Assuân floods the valley up to Korosko (199 kilometres); a dam at Kalabsheh floods the valley still further south.

It is to be gathered from Mr. Willcocks' report, and Mr. Garstin's (the Under-Secretary) note upon it, and the recommendation of the Technical Commission, the English and Italian members of which were Sir B. Baker and Signor Torricelli, that the Assuân site is the best. The foundations of the dam can be built in the dry and on hard igneous rock. The estimated cost of the dam is a little over £1,600,000.

The proposed dam is thus described by Mr. Willcocks: "The design for the work consists of a solid unsubmergible dam pierced with 100 undersluices 10 m. × 2 m., and constructed on solid rock. The piers between the undersluices are 3 metres wide, and every set of ten sluices is separated from the next by abutment piers 10 metres in width." The undersluices are regulated by Stoney's patent balanced roller gates.

The dam will be worked as follows: During the flood all the sluices will be open, and the flood waters, with all their contained fertilising mud, will be discharged through the undersluices. When the flood has passed, and the comparatively clear water supply has begun to flow, the lower undersluices will be gradually closed so that the water will begin to rise and flow through the higher sluices. When the water has risen to a height 3 or 4 metres above the floors of the higher sluices, or 10 or 11 above the floors of the lower ones, the latter will be entirely closed, and the river will discharge through the upper sluices, which will be gradually closed until the water gains its full level.

When the reservoir is emptied the reverse process will be followed; the higher sluices will be opened first, and then the lower ones, until the time is reached when the next annual flood is due.

It is next of importance to see how this stupendous scheme bears upon Egypt financially. It is pointed out that the value of the reclaimed lands may be estimated roughly at £46,000,000, the increase in the value of yearly rental at £3,700,000, and of the yearly produce £12,000,000.

It will be perfectly clear that if only half of these values are realised the scheme will work wonders for the prosperity of Egypt, and that it would be a crime not to go on with it.

Rests then the great drawback, that wherever the dam is erected a portion of the up-stream valley will be swamped. All the world has heard of the possible drowning of Philæ provided the dam be built at Assuân. But this cry could scarcely have been started by archæologists, for as a matter of fact Philæ is only one temple site out of very many lying between Assuân and Korosko. Since none of them have been completely explored, it is hazardous to state that it transcends the others in scientific importance, although certainly it is uneclipsed as a beautiful spot.

The ruins besides Philæ threatened with destruction have thus been stated by Mr. Somers Clarke in a letter to the Society of Antiquaries:—

"The dam will create a reservoir of enormous extent, not only drowning the island of Philæ, but extending southward into Nubia for nearly a hundred miles. When full the waters of the reservoir will rise several feet above the highest level of the pylon of the Temple of Isis at Philæ. The rocks surrounding the island are full of hieroglyphic inscription; these will spend many months under water, and there is yet much to be discovered in the immediate neighbourhood. At Debôt is a Ptolemaic temple, which retains its original girdle-wall, three great standing doorways, the first being the entrance through the girdle-wall, the second being the doorway in a ruined pylon, and the third standing more immediately before the temple. At Dimri are the remains of ancient structures still to be explored. At Kertassi there is, in fair preservation, a small hypæthral temple with Hathor-headed columns; a little south are extensive quarries, part of the surfaces covered with graffiti, chiefly Greek votive inscriptions. Surrounding the village of Kertassi is a great wall enclosure. At Tafeh a small temple, very perfect, is still standing in the middle of the village, and near it are some remarkably interesting specimens of Roman masonry, but built in the Egyptian manner. They are the lower parts of houses, rectangular structures with their internal subdivisions still to be traced. At Kalabsheh is the most magnificent structure in Lower Nubia. Overhanging the Nile are the remains of a grand quay pierced by two stairways leading on to a great platform. On this is a long terrace of approach from which we rise to another terrace, parallel with the course of the river and lying in front of the pylon. The walls of the temple are very perfect, the roofs only having fallen in. Surrounding the temple is a girdle-wall of masonry. The entrance court of the temple is full of graffiti of the greatest historic interest, and between the crannies of the fallen masonry can be seen many more now inaccessible. At Abu Hor are ancient remains and a quay standing by the river side; a place that needs careful exploration. At Dendûr are the remains of a temple dating from Roman times. The names of many native gods and princes are carved upon the walls. At Koshtemneh are the ruins of a great brick fort, and in one corner of it are the bases of the temple columns. At Dakkeh is a particularity interesting temple. Stones of an early building of Thothmes III. and Seti I. have been found, but the existing structure was begun under Ergamenes, a native king, and completed under a Roman emperor, presumably Augustus. The pylon is absolutely perfect. This building would be engulfed. At Kobban, opposite Dakkeh, are the remains of a very large rectangular fortress of Egyptian crude brick, some 370 by 350 feet. The remains of a temple of the middle empire can be traced, and outside are the remains of temples of the XIXth dynasty. At Mahārakah are the ruins of a very late temple. Its plan is unique. In addition to the places above mentioned there are traces of buried towns and of tombs in great abundance. The whole of these things will be submerged, and the inhabitants transported I know not where."

It has been stated by some that the destruction of these various memorials of antiquity has been regarded by the Egyptian engineers with absolute indifference. It is only just therefore to print the following extract from Mr. Garstin's note dated December 27, 1893, referring to the Assuân dam:—

"Unfortunately, with every advantage in its favour as to volume of water stored, soundness of foundation, and economy of construction, this site labours under the objection (which I fear may be found insuperable) of having Philæ temple on its up-stream side. No dam could be constructed on the cataract without inundating a great portion of this temple for several months every year. I agree with Colonel Ross that no project, which had this effect, should be admitted, unless it were impossible to find a reservoir site elsewhere. We cannot say that there are no other possible sites. There are Kalabsheh, Philæ, and Gebel Silsila, which are all available, and we cannot therefore claim that if a dam has to be built, it must necessarily be built at the head of the first cataract, and drown the temple of Philæ.

"Admitting this fact to the full, I still consider the Assuan site to be so superior to any other, that if any means could be found for obviating the difficulty which attaches to this temple, I think the subject well worth the consideration of the Egyptian Government, even although it involved additional cost to the project. On p. 36 of his report, Mr. Willcocks suggests the possibility of removing the temple of Philæ from its present site, taking it up stone by stone, and rebuilding it on the adjacent island of Bigeh, where it would be well above the highest water level of the reservoir. I cannot say whether it would be possible to do this without injury to the temple. If so doing would cause any injury, or alteration of any kind to it, I should recommend the abandonment of the Assuan dam altogether. Any work which caused either partial damage to, or the flooding of this beautiful temple, would be rightly considered by the whole civilised world as an act of barbarism. Moreover, it would be an act not absolutely necessitated by the circumstances, for I repeat that we have other possible, though somewhat inferior, sites upon which to construct dams.

"If the removal of Philæ temple is, however, only a question of expenditure, the subject at once commands attention. In this matter I turn naturally to Mr. T. de Morgan, the able Director of the Department of Antiquities in Egypt. If it is possible to remove the temple, and rebuild it upon the adjacent island exactly as it stands at present, we may rely on his ability to do so; and I ask that his opinion as to the removal and reconstruction of Philæ temple be obtained before the project for the Assuan dam be altogether rejected.

"Were the removal of the temple to be successfully carried out, I cannot myself see that it would be an act of vandalism, which, as I read it, is a term meaning the wanton destruction of interesting relics. In this case there would be no question of wanton destruction. The Government of Egypt would duly weigh on one side, the advantages to the country of the safest and most economical dam which could be constructed north of Wady Halfa, and, on the other, the sentiment which clusters round the site of the present temple, and objects to its removal even if it could be done without injury. Finding the advantages to the country to outweigh the sentiment, it would proceed to carry out the work with a religious regard for every detail, and through the agency of the competent staff of the Department of Antiquities.

"Removals somewhat similar to that now proposed have been successfully carried out. Mr. Willcocks mentions in his report having himself, when at Rome, been a witness to the dismantling and rebuilding of the most ancient existing bridge over the Tiber by Italian engineers. Civilised nations in recent times have removed from their original sites, and set up in other countries, interesting and valuable monuments. The Elgin marbles taken from the Acropolis and deposited in the British Museum, afford an example, and so also do the Luxor obelisk in the Place de la Concorde, and Cleopatra's needle on the Thames Embankment. These records of the past have been removed from their historical surroundings, and set up amongst others with which they are not in keeping. We, on the contrary, prompted by a desire to benefit the country, suggest the removal of an ancient building from one site on the Nile to another which is but a few hundred yards distant. We propose re-erecting it exactly as it stands to-day, and on an island in the middle of the great lake which we hope to create, where it would form a beautiful and appropriate object in the landscape."

To us it seems clear that with such a case as the Egyptian engineers have made out for the increased water supply, it is certain that a dam will be built somewhere, and, to be more precise, unless the frontiers of Egypt are enlarged, between Wady Halfa and Assuan. Assuan, Philæ, and Kalabsheh have each been suggested, and in either case the memorials of antiquity along a long reach of the river will be necessarily destroyed. This being so, there is room for an attempt to carry to a completion the work begun by the French Expedition of 1798 and continued by Lepsius in 1844, by making an English survey of the Nile between Philæ and Wady Halfa. Archæologists associated with engineers in such a work as this would certainly be a more pleasant sight to gods and men than when indulging in charges of "vandalism" and the like; and be it remembered no amount of money voted by Parliament, or by the Egyptian Government, no munificence of archæologists and others, with a view of dealing with the case of Philæ alone, will be of avail in final mitigation if a dam is to be built *anywhere*. To consider Philæ alone would convict us of a philistinism by the side of which the "vandalism" of the engineers were small indeed! On the other hand, when such a survey as that suggested has been completed; when what Maspero has called *l'histoire matérielle* of every temple has been investigated; every inscription copied, and every detail photographed, dam or no dam we shall be infinitely better off from the scientific point of view than we are now or should have been for the next century, if the question of the dam had not been raised.

J. NORMAN LOCKYER.

THE CENTENARY OF THE PARIS POLYTECHNIC SCHOOL.

THE hundredth anniversary of the foundation of the Polytechnic School of Paris was celebrated on the 17th, 18th, and 19th of May.

The 17th, consecrated to the memory of old comrades, comprised, in the morning at 10.30, a visit to the tomb of Monge. M. Mercadier, Director of studies at the Polytechnic School, pronounced Monge's eulogy, and deputations from the Institute, &c., assisted him. At 2.30 the President of the Republic visited the school and examined the pupils. M. Faye made a speech recalling different events of the school. Then a tablet was put up to the memory of the comrades killed by the enemy a century ago. The 18th was the "cérémonie des ombres." Lastly the *fête*, which took place on the 19th at the Palais de Trocadéro, constituted, independently of its programme, a special attraction, as *fêtes* had never previously been given at night in the immense and magnificent hall. From 10 o'clock to midnight more than 5000 people took part in the gala entertainment, which was followed by a ball.

The palace and Trocadéro Park were brilliantly illuminated. The entertainment consisted almost entirely of compositions by old pupils of the school. It ended with an apotheosis by M. A. Silvestre, during which a remarkable picture, consecrated by M. Dupain to the glory of the school, was uncovered.

The eulogy on Monge, pronounced by M. Mercadier, was of great eloquence. Monge was, as a child, very remarkable. When sixteen he made a plan of his native town, having invented an instrument for determining angles. At the age of twenty-two he had already invented many things. With the aid of an engineering officer he got into the Engineering School at Mézières, where in 1768 he succeeded Bossut as professor of mathematics, and two years later, Nollet in a course of physics.

He published his great works on "Les Surfaces considérées d'après leur mode de génération" in the Memoires de l'Academie de Turin. The illustrious Lagrange, after reading them, exclaimed "Avec son application de l'analyse à la représentation des surfaces, ce diable d'homme sera immortel!" "Ce diable d'homme" was but twenty-five, but—true to prophecy—made himself immortal.

In 1780 Monge was made professor of hydraulics; at the same time he entered the Academy of Sciences in the mechanical section. He lived six months in Paris, then six months at Mézières, but in 1783, on being made naval examiner, he returned to Paris for good.

He was an ardent revolutionist, and was made Minister of that department in 1792, during which time he unconsciously made a true friend of Buonaparte. In 1794 he helped to found the school in which he was a devoted professor.

In 1796 he and Berthollet and a few artists were ordered to Italy, to collect the numerous objects of art handed over to France by various Italian towns. It was at this time he became great friends with Buonaparte and Berthollet. Afterwards he took part in the Egyptian Expedition. He went with Berthollet, and Berthier in his report says of them: "ils s' occupent de tout et sont partout."

On his return to France, Monge again devoted himself to the Polytechnic School, his affection for the pupils and influence with them being unchanged and quite remarkable. After having worked steadily for forty-five years, he was obliged, on account of bad health, to retire.

The political disturbances, in which he was much engrossed, all tended to affect his health, but the disbanding of the school in 1816 was the final blow. He was never the same again, and died July 18, 1818.

M. Mercadier's address ended with a touching appeal to his auditors to imitate the patriotism and emulate the science of the great man whose useful life and work they had met to celebrate.

We may have to say something of the final *fête* next week.

NOTES.

WE learn with profound regret that Dr. Romanes died at Oxford at twelve o'clock yesterday.

THE first meeting of the International Meteorological Committee, as reconstituted at the Munich Conference of 1891, will be held at Upsala, and will commence on August 20. The programme, as will be seen, consists mainly of the various questions referred to the committee by the Conference. (1) Reports of the President and Secretary; (2) the question of the establishment of an International Meteorological Bureau; (3) Agricultural Meteorology; (4) the establishment of stations for the observation of the direction and velocity of movements of clouds; (5) the construction of a Cloud Atlas (reports from Dr. Hann, Dr. Hildebrandsson, Mr. Rotch, and M. L. Teisserenc de Bort); (6) the possible acceleration of weather telegrams; (7) the observation of the scintillation of stars (a proposal by M. Charles Dufour); (8) the organisation of the next Conference.

PROF. ROBERTS-AUSTEN is to be congratulated on having completed his responsibility for no less than one hundred millions sterling of gold coin. The twenty-fourth annual report of the Royal Mint, which has just been issued, shows that of the long series of holders of his office none could have claimed anything like such a record, as the largest amount of gold coin for which any individual King's Assay Master had previously been responsible was the fifty-nine millions coined during the tenure of office of Mr. Robert Bingley, King's Assay Master from 1798 to 1835. As showing the remarkable accuracy of the standard fineness of coins, the Mint Report states that of the hundred millions sterling of gold coin, seventy-one millions were sovereigns, and that their average fineness as indicated by successive trials of the Pyx proved to be 916·668. The exact legal standard is 916·666, and it must be remembered that the gold coins would be within the "remedy" allowed by law if the amount of precious metal they contained varied between 914·6 and 918·6 parts in one thousand.

THE preliminary programme of the fourteenth Congress of the Sanitary Institute, to be held in Liverpool in September, has now been issued. The meetings of the Congress will consist of three general addresses and lectures. The three sectional meetings, dealing with (1) Sanitary Science and Preventive Medicine, (2) Engineering and Architecture, (3) Chemistry, Meteorology, and Geology, will be presided over by Dr. E. Klein, F.R.S., Mr. G. F. Deacon, and Dr. Thomas Stevenson. Five special conferences will take place: the Sanitation of the Passenger and Mercantile Marine Service, presided over by Sir W. Bower Forwood; Medical Officers of Health, presided over by Mr. Charles E. Paget; Municipal and County Engineers, presided over by Mr. A. M. Fowler; Sanitary Inspectors, presided over by Mr. Francis Vacher; Domestic Hygiene, presided over by the Lady Mayoress of Liverpool. An exhibition of sanitary apparatus and appliances and articles of domestic use and economy will be held, and excursions to places of interest from the point of view of sanitation will be arranged for those attending the Congress. The local arrangements are in the hands of an influential local committee, presided over by the Lord Mayor of Liverpool, with the City Engineer (Mr. H. Percy Boulnois) and the Medical Officer of Health (Dr. E. W. Hope) as honorary secretaries. It appears from the programme that over 100 sanitary authorities, including several County Councils, have already appointed delegates to the Congress, and as there are 1500 members and associates in the Institute, a large attendance may be expected.

A COMMITTEE has been formed at Boulogne for the purpose of making arrangements for an international exhibition of hygiene and hydropathy, which it is proposed to hold there from July 15 to September 15.

A KNIGHTHOOD has been offered to Dr. J. C. Bucknill, F.R.S., not for his scientific work, but in recognition of his services to the volunteer movement, of which he was the originator. Dr. Bucknill was elected into the Royal Society in 1866, and is now in his seventy-eighth year.

THE thirty-ninth annual exhibition of the Photographic Society of Great Britain will be inaugurated by a conversazione on September 22, and will remain open from Monday, September 24, to November 14. Medals will be awarded for the artistic, scientific, and technical excellence of photographs, lantern slides, and transparencies, and also for apparatus. Foreign exhibitors are invited to contribute. The Society will pay the carriage of photographs on the return journey, and provide frames or portfolios during the exhibition for approved photographs. There will be no charge for space. Communications on all matters connected with the exhibition should be sent to the Secretary of the Society, 50 Great Russell Street, Bloomsbury, W.C.

ALL students of science know that a knowledge of German is essential in their work, and no better way of obtaining it can be found than by joining German students in study. Facilities for obtaining this desirable end are now offered in the shape of holiday courses at Jena, from August 1 to 23. The courses have been arranged by a committee representing some of our University Colleges and High Schools, Mr. J. J. Findlay (Rugby) being the secretary. There will be an elementary course for those who have little or no acquaintance with the spoken language. The subjects dealt with in this course include physiological psychology, the hygiene of schools, and pedagogy. Each will be conducted by an experienced teacher, who will speak very slowly and clearly, but will only employ the German language as the medium of instruction. A more advanced course, for those who can follow lectures delivered in German, will be held from August 1 to 16. During this period Dr. Straubel will lecture every day on the microscope, Prof. Detmer on the fertilisation of plants and microscopic botany, Prof. Schaffer on experimental physics, and Prof. Auerbach on modern physical demonstrations. Dr. Knopf will discourse on time and its determination, illustrating his lecture with practical work at the Observatory; Dr. Straubel will give demonstrations on electrical and magnetic measurements; Prof. Wolff will lecture on theoretical and practical chemistry; Prof. Ziehen on physiological psychology; Dr. Römer on zoology; and Dr. Gange on spectroscopic and polarising apparatus. This programme should be sufficient to tempt many students of science to Jena, and they may be assured that the German schoolmasters, who attend similar summer meetings every year, will offer a cordial welcome to their "englische Kollegen."

THE Friday evening discourse at the Royal Institution, on June 1, will be delivered by Prof. Oliver Lodge, F.R.S. The subject will be "The Work of Hertz." On Tuesday afternoon Dr. Dallinger began a course of three lectures on "The Modern Microscope, an Instrument for Recreation and Research," and to-day Prof. Flinders Petrie commences three Thursday afternoon discourses on "Egyptian Decorative Art."

IT has been decided to provide chambers in one of the light towers which will be erected on either arm at the entrance of Madras Harbour, when finished, for the purpose of a tidal observatory, the establishment of which has been approved of by the Government of India.

PROF. VINCENZ CZERNY, of Heidelberg University, has been elected to fill the chair of Surgery left vacant in Vienna University by the death of Prof. Billroth.

THE Midland Railway Naturalists' Society has been established at Derby. The first monthly meeting was held on Monday, 7th inst.

MISS NORTH'S Gallery of Flower Portraits in Kew Gardens has been reopened to the public, the pictures having undergone a thorough inspection and varnishing, under the advice of the President of the Royal Academy.

IT is reported from Auckland, by Dalziel's Agency, that two shocks of earthquake occurred at Wellington on Monday morning. They were preceded by loud concussions, and all the buildings in the town were violently shaken, the public library being considerably damaged. Lesser shocks were also felt at Nelson, Taranaki, and Christchurch.

DR. GILL, the Director of the Cape Observatory, has communicated to the *Times* some significant facts in connection with the recent earthquake at Thebes. He says that the observer on duty with the transit circle, on the evening of April 27, found that the surface of the mercury used in making observations for errors of level was disturbed by continuous and persistent undulations from 6h. 2m. to 6h. 32m. Greenwich mean time. It was not until 6h. 43m. that the undulations ceased sufficiently to permit good observations of nadir and level to be made. No general conclusion can be drawn from these observations, but Dr. Gill thinks it probable that the delicate disturbances of the mercury at the Cape of Good Hope had its origin in the disturbance which produced such disastrous results at Thebes.

A CONSIDERABLE retrocession of temperature has occurred over these islands during the past week, accompanied by strong northerly and easterly winds, and causing much injury to fruit and vegetable crops. Snow or hail fell over the whole of Scotland and a large part of England and Wales on Sunday, while the minimum shade temperature on Sunday and Monday nights fell several degrees below freezing point, and on the grass temperatures of 20° or less have been recorded. For several days the maximum shade temperature did not exceed 45° at places in Scotland, and was below 50° in many other parts. In the neighbourhood of London it was below 50° on Sunday, a value which is about equal to the average maximum temperature of the middle of March. The Greenwich temperatures show that so low a maximum in the second half of May is very rare, having occurred only twice in the last twenty years.

A "MONOCHROMATIC rainbow" is rare enough to deserve record. Mr. Charles Davison writes:—"On the 28th of last November rain was falling shortly before sunset, and a rainbow was formed, though little more than the nearly vertical portion of one limb was distinctly visible. In a few minutes the blue, green, and yellow parts gradually faded away, and only a dull red band remained."

WE have received several numbers of the *British Central Africa Gazette*, published at Zomba, containing interesting articles on the prevention of the coffee-disease, and on the export of india-rubber (*Landolphia*) from the West Shire, Lower Shire, and Ruo districts.

THE *Naturwissenschaftliche Wochenschrift* for May 13 contains an interesting article, with illustrations, on fossil-like structures produced by the action of running water. Some of them present a remarkable resemblance to algæ and to the leaves of ferns; and the author, Dr. T. Fuchs, questions the organic origin of many so-called fossil remains from the older formations.

IN the form of a rectorial address to the University of Basel, Dr. G. Klebs has published an interesting essay on the relationship of the two sexes in nature. The first development and gradual progress of sexual differentiation in the animal and vegetable kingdoms are traced, and the connection between sexual reproduction and the development of new forms of life is discussed. Dr. Klebs sums up strongly in favour of the theory of the inheritance of acquired characters.

AT a recent meeting of the Société Française de Physique, M. Curie read a paper on the magnetic properties of soft iron at temperatures between 20° and 1350°, and for magnetising forces of 25 to 1350 units. He has drawn a series of curves showing the connection between the magnetising force and the intensity of magnetisation at different temperatures. For magnetising forces up to 1300 units the different curves do not differ much, but for higher values of the magnetising force they separate to a more marked degree. For temperatures between 756° and 1375° the curves obtained are straight lines passing through the origin, showing that between these temperatures the susceptibility is a constant and independent of the magnetising force. The author has also plotted a series of curves connecting the intensity of magnetisation (I) and the temperature, the magnetising force being constant. The value of I is at first constant as the temperature rises, then it diminishes faster and faster till the change becomes most rapid at a temperature of about 745°. Above this temperature the rate of change of I diminishes. Between 950° and 1210° the value of I only diminishes slowly, while at a temperature of 1280° it increases suddenly, and then as the temperature goes on increasing it gradually diminishes. The author finds that at any given temperature the value of I obtained is independent of whether this temperature has been reached by warming the body or by cooling.

AN interesting paper by M. van Aubel, on the electrical resistance of some new alloys, was recently read before the Société Française de Physique. In the first place, the author gave some particulars about a form of steel called kruppine, manufactured by Herr Krupp, at Essen. This alloy has a specific resistance of 84·7 microhms $\left(\frac{cm}{cm^2}\right)$ at 18° C., or of 85·5 if the sample has been heated for several days. The mean coefficient of variation of the resistance with temperature decreases slightly with increase of temperature, but is always nearly equal to + 0·0007. This body, although it has a relatively high specific resistance (that of german silver being 20·76), can be heated to a temperature of 600° C. without change of structure, and can be obtained in the form of wire or sheet. The author also gave particulars of the experiments made on some nickel alloys manufactured by Messrs. Fleitmann, Witte, and Co., of Schwerte (Westphalia). One of these alloys (marked $I_a\ I_a$) has when hard a specific resistance at 20° C. of 50·2 microhms and a temperature co-efficient of − 0·000011, while when soft its specific resistance is 47·1 microhms and its temperature co-efficient + 0·000005. This alloy may prove of considerable practical utility, although if it is found that its thermoelectric power with reference to copper and brass is, as is generally the case with these alloys, at all great, this will in a great measure prohibit its use in cases where great accuracy is required. During the discussion on the above paper M. Guillaume mentioned that an alloy of 68·6 parts copper, 30 parts manganese, and 1·3 parts of iron has a specific resistance of 108 microhms, while its temperature co-efficient is very small, even passing from positive to negative as the temperature rises. He also mentioned that the difficulty of the high thermoelectric power with reference to copper could be overcome if the wires are soldered to plates of the same alloy, which are in turn soldered to the copper connectors of the resistance boxes or Wheatstone bridges.

PROFS. RICCÒ AND SAIJA have, after many laborious efforts, succeeded in obtaining a fairly accurate record of the diurnal and annual variations of temperature on the summit of Mount Etna. The results, as communicated to the *Accademia Gioenia di Catania*, form a valuable addition to meteorological thermometry. The impossibility of maintaining a staff at an elevation of 3000 m. above sea-level, at a place difficult to reach and without telegraphic communication, made the employment of automatic recording instruments indispensable. A Richard barograph and thermograph were installed at the Etna Observatory, capable of acting for forty days without further attention. Some interruptions occurred owing to the freezing of the lubricants and irregular unrolling of the register paper, but between August 27, 1891, and February 28, 1894, a total of 357 days were registered automatically, and 137 days by personal observation. With the slight diurnal variation, 3-hour intervals were found sufficient. The highest temperature observed was 16° C., on September 2, 1892; the lowest − 10°·3 C., on March 2, 1893. As a rule, the coldest month was January, and the warmest August. The mean diurnal variation was 1°·6 in winter, and 6°·8 in summer. The climate of the summit of Etna, with its mean annual temperature of + 1°·06 C., resembles that of the North Cape or the Brocken. The uniformity of temperature was to be expected after similar observations in the Alps, and the covering of snow, which usually lies from the middle of November till the end of March, serves to keep the diurnal oscillation in winter below 1°·6 C. The changes of temperature during the year are very similar to those observed at the foot of the volcano, but the daily maximum, instead of being several hours after midday, occurs just about noon at the summit, probably owing to the absence of vapour capable of absorbing and storing up the heat of the sun.

LITTLE is known of the interior of the great peninsula of Labrador, that vast territory estimated to contain two hundred and eighty-five thousand square miles. During the last six or seven years, however, several explorers have visited the region, and returned with interesting geographical results. Mr. H. G. Bryant is one of these, and his description of the journey through Labrador to the Grand Falls on the Grand, or Hamilton River, recently published in a *Bulletin* (vol. i. No. 2) of the Geographical Club of Philadelphia, is full of interest. The greater part of the paper, and all the excellent views that illustrate it, originally appeared in the *Century Magazine*. Mr. Bryant set out with Prof. C. A. Kenaston in June 1891, and they reached the Falls on September 2. A mile above the main leap the river is about four hundred yards wide. Four rapids intervene between this point and the Falls. At the first rapid the width of the stream does not exceed one hundred and seventy-five yards, and from thence it rapidly contracts until, just above the escarpment proper, the water rushes between banks not more than fifty yards apart. Below the Falls the river runs for twenty-five miles between vertical cliffs of gneissic rock, which rises in places to a height of four hundred feet. The water falls through a height of about three hundred and twenty feet, and under favourable conditions the roar of the cataract can be heard at a distance of twenty miles. Appended to the paper is a list of plants collected by Prof. Kenaston during the expedition, and also the results of meteorological observations made at various points. The further exploration of the region traversed by Messrs. Bryant and Kenaston would be of great value to geographical science, and might lead to geological discoveries of scientific and commercial importance.

IN order to satisfactorily identify any particular bacillus with that generally associated with cholera, it is necessary to have recourse to animal experiments. For this purpose it has been customary to use guinea-pigs; and Pfeiffer's method is to take about ·0015 grm. of the surface-growth of an agar-agar culture, distribute it in 1 c.c. of sterile broth, and inject it into the peritoneal cavity. The above quantity is usually fatal with characteristic symptoms to an animal of 300–350 grms. weight. This is, however, by no means a simple or easy operation, but so far no other method of proving the virulence of the cholera bacillus has superseded it. In a recent number of the *Centralblatt für Bakteriologie* (vol. xv. 1894, p. 150), Dr. Sabolotny describes some investigations which he has made on the susceptibility of the marmot to Koch's cholera bacillus. The experiments were carried out in the Bacteriological Institute at Odessa, and Sabolotny mentions that these animals are found in large numbers in the south of Russia. When 0·1–0·2 c.c. of a one-day old broth-cholera-culture grown at 37° C. is introduced into the peritoneal cavity of marmots, they die in from 12–18 hours. Of much interest is, however, the discovery that similar quantities of cholera cultures introduced *subcutaneously* also proved fatal to these animals, the bacilli being found in the blood, liver, spleen, and peritoneal fluid. It was also found that they could be infected *per os* without any preliminary treatment with soda and opium, for marmots fed with materials containing small quantities of cholera bacilli died, and the latter were always found in large numbers in the stomach, as well as frequently in the liver and spleen, and also occasionally in the blood. The identification of the cholera bacillus by animal experiment is thus greatly simplified.

THE Committee that controls the operations of the Kew Observatory, and which in February of last year became "The Incorporated Kew Committee of the Royal Society," have issued their report of the work done during 1893. Under experimental work we note that, to estimate the amount and density of fog and mist, the observation of a series of distant objects referred to in the last report were continued. A note is taken of the most distant of the selected objects visible at each observation hour. An analysis of the results for the period May 1892, to December 1893, is at present being carried out. During the thickest fog experienced in 1893, at one of the hours of observation the most distant object visible was only 12 feet off. Twelve watches, designated "non-magnetic watches," were examined during the year, both as to their ordinary time-keeping and also as to their non-magnetic properties, and although the trial to which they were submitted was severe—the movement being tested in an intense magnetic field, both in vertical and horizontal positions, and gradually approached to and removed from the poles, whilst its behaviour is critically watched—in the majority of cases the watches were found to perform very satisfactorily. Magnetic and meteorological observations were carried on as usual, and sketches of sun-spots were made on 155 days.

It occurred to us while glancing through the "Mémoires de la Société de Physique et d'Histoire Naturelle" of Geneva, of which the second part of vol. xxxi. was recently received, that the custom of inserting, at the commencement of the volume, the President's *résumé* of the communications to the Society during his year of office, is an admirable one. The present bulky tome contains an address by the late C. de Candolle, in which he surveyed the scientific advances of the Society during 1891, and also a similar retrospect in which M. E. Sarasin reviews the growth of knowledge during 1892. It has been said more than once that the abstracts of papers are frequently superior to the originals, inasmuch as they present in a concise form the tenor of an author's work. But however this may be, it is certain that the plan followed by the Presidents of the Physical Society of Geneva (and also by those of some of our own Societies), viz. that of giving terse descriptions of the investigations communicated to the Society during their respective years of office, considerably facilitates reference, and what is more, it enables a worker to know the gist of a paper without reading through and digesting the original. In addition to the two presidential addresses referred to, the "Mémoires" contain a paper by Prof. J. Brun, on a new species of marine diatoms, fossil and pelagic, illustrated by twelve plates, containing 120 of the author's drawings, 40 microphotographs by Prof. van Heurck, and 80 by M. Otto Müller. The volume also comprises the second part of Prof. Chodat's "Monographia Polygalacearum," illustrated by twenty-three plates, and the fifth of his "Contributions à la Flore des Paraguay." Both of these papers will excite the admiration of systematic botanists.

THE address delivered by Dr. Armstrong, in March last, at the annual general meeting of the Chemical Society, is contained in the May number of the Society's journal.

THE papers set at the examinations of the Royal University of Ireland during 1893 have just been published as a supplement to the University Calendar for that year.

MESSRS. R. FRIEDLANDER AND SON, of Berlin, have sent us Nos. 5–8 of "Naturæ Novitates," containing lists of scientific works recently published.

MESSRS. PERCY LUND AND CO. will shortly publish a work entitled "The Stereoscope and Stereoscopic Photography," translated from the French of F. Drouin.

AN excellent feature of the *American Naturalist* is the classified notes of recent work in all of the natural sciences. Dr. W. S. Bayley, of Colby University, edits the section devoted to mineralogy and petrography. His contributions to the journal under that head, during 1893, have now been collected and published separately, and the pamphlet thus created forms a useful summary of progress.

THE "Year-book of the Scientific and Learned Societies of Great Britain and Ireland," published by Messrs. C. Griffin and Co., first appeared in 1884, and has been issued annually since then. It is really an extremely useful and convenient handbook of reference. Lists of the papers read during the year are given under the descriptions of the societies to which they were presented, with the dates of the communications. These have been compiled from official sources, and therefore constitute a trustworthy record of the progress of various branches of science. All the papers read before almost every British society are included in the lists, so the "Year-Book" may claim to be recognised as an important assistant in the organisation of scientific literature.

THE advances made in the study of geology since 1878 have rendered the publication of a new edition of the late Sir Andrew Ramsay's well-known manual on "The Physical Geology and Geography of Great Britain" a necessity, if the book is to retain its place. We are glad, therefore, to learn that a new edition (the sixth) has been undertaken by Mr. Horace B. Woodward, of the Geological Survey. The edition, accompanied by a corrected form of the small coloured map which appeared in the fifth edition, will very shortly be issued by Mr. Edward Stanford.

WE have received the second yearly report of the Sonnblick Society, for the year 1893. The Society now numbers 423 ordinary members, and the report shows that the importance of keeping this mountain observatory in thorough efficiency is fully recognised. The height of the summit has been determined by trigonometrical measurement during the year, and was found to be 10,192 feet, which agrees very closely with that found by barometrical measurements by Dr. Hann. In addition to the regular meteorological observations, special attention is paid by the observer, P. Lechner, to observations of atmospherical electricity, and some interesting results have been already obtained. It is found that the electric condition of the earth at the summit remains nearly constant during clear days throughout the year, so that, owing to its height and configuration, it is free from the daily and yearly fluctuations of electricity which are observed on the earth's surface at lower levels. It would be interesting to know whether this has also been observed at other mountain stations. The observations of St. Elmo's Fire have shown the interesting fact that when snow falls in large flakes, the electricity is almost always positive, but when the snow consists of dust-like particles, negative electricity is developed.

A DIRECT method of preparing the methyl and ethyl derivatives of hydroxylamine of the type RHNOH is described by M. Lobry de Bruyn in the current issue of the *Receuil des travaux chimiques du Pays-Bas*. These so-called β-alkylhydroxylamines have only recently been isolated in the pure condition by Kjellin, by an indirect process, although their formation has been demonstrated by several workers. Goldschmidt and Kjellin some time ago showed that they were produced in the decomposition by hydrochloric acid of the esters of nitrobenzaldoxime. E. Hoffmann and Victor Meyer have also shown that when nitro-ethane is reduced by stannous chloride the hydrochloride of β-methylhydroxylamine, $CH_3 . NHOH . HCl$, is produced: and Kirpal has further proved that the reaction is general, that whenever nitroparaffins are reduced to amines intermediate products are formed which reduce Fehling's solution. Dr. Kjellin has more recently resumed the former work which he carried on in collaboration with Dr. Goldschmidt, and has succeeded in isolating the chlorides of the alkyl hydroxylamines from the products of the reaction above referred to. Moreover, by employing a similar process to that which proved so successful in the hands of M. de Bruyn for the isolation of free hydroxylamine, Dr. Kjellin eventually obtained the pure bases themselves. An account of his work was given in these columns at the time (vol. xlix. p. 38). M. de Bruyn now shows that these simple alkyl derivatives of hydroxylamine may be obtained in the pure state directly from the base itself. In his preliminary account of the isolation of the parent base, he stated that upon agitating a very concentrated aqueous solution of hydroxylamine with methyl iodide and a little methyl alcohol, considerable evolution of heat occurs and a crystalline mass separates. On repeating this experiment with 4·1 grams of a 52 per cent. solution of hydroxylamine, 10 grams of methyl iodide (the molecular proportion), and a smaller quantity of methyl alcohol, mixed together in a flask fitted with an upright condenser, the energy of the reaction was found to be sufficiently great to heat the liquid to the point of ebullition, and crystals soon commenced to deposit. Ethyl iodide reacted in a precisely similar manner. The crystals, after draining and washing with a mixture of alcohol and ether, proved to be those of the pure hydriodides of the β-alkyl hydroxylamines. Their aqueous solutions acidulated with nitric acid do not reduce silver nitrate, so that their analysis is easily effected. In this respect they differ from nitric acid solutions of hydroxylamine, which of course at once reduce silver nitrate. They reduce Fehling's solution, however, instantly at the ordinary temperature. It would appear from this mode of preparation that the action of alkyl iodides on hydroxylamine is similar to their action upon ammonia. The salts are perfectly stable up to beyond 200° C. M. de Bruyn shows finally that it is not essential to have at command such concentrated solutions of hydroxylamine as those obtained during the preparation of the solid base. The weak aqueous or alcoholic solutions obtained in the usual manner from hydroxylamine hydrochloride, may equally well be employed; it is only necessary to decompose the solution of the hydrochloride in tepid water with potash, add an equal bulk of methyl alcohol, filter from the precipitated potassium chloride, and at once proceed to agitate with methyl iodide. The only further point of difference is that the liquid should be finally boiled in the flask fitted with upright condenser in order to complete the reaction.

The additions to the Zoological Society's Gardens during the past week include a Black-eared Marmoset (*Hapale penicillata*) from South-east Brazil, presented by Mr. H. M. Dodington; a Common Peafowl (*Pavo cristatus*) from India, presented by Mrs. Tannenbaum; a Monteiro's Galago (*Galago monteiri*) from West Africa, two Pinche Monkeys (*Midas œdipus*) from New Granada, deposited; a Maholi Galago (*Galago maholi*), two Japanese Deer (*Cervus sika*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Recent Observations of Jupiter's Satellites.—In the May number of *Astronomy and Astro-Physics*, Dr. E. S. Holden calls attention to some important points in connection with Prof. Barnard's observations of Jupiter's satellites, recently published in that journal and in the *Monthly Notices*. In the first place, the results announced by Prof. W. H. Pickering in 1893 (see Nature, vol. xlvii. p. 519), with regard to the forms and rotations of these bodies, are not confirmed by Prof. Barnard's observations. Next, Prof. Barnard has found that all the Jovian satellites are spherical, whereas Profs. Schaeberle and Campbell announced in 1891 that Satellite I. was ellipsoidal, with its longest axis directed towards the centre of Jupiter. It was also concluded by these observers that the periods of rotation and revolution of the first satellite were equal; but Prof. Barnard says that his observations lead to a different result. Another point upon which Prof. Barnard's recent observations have thrown light, is the appearance of the first satellite when projected upon Jupiter. It will be remembered that the satellite was seen in transit as a double body in 1890, but Prof. Barnard has shown that the apparent duplicity was due to simple contrasts between bright regions on the planet and two extensive dusky polar caps on the satellite (see Nature, vol. xlix. p. 300). Other strange appearances of satellites during transit can be explained in a similar manner. Prof. W. H. Pickering has criticised the statement that the assumed belt on the first satellite is a permanent one (*Astr. Nach.* 3229), and says that it certainly did not exist at the time of the opposition of 1892, during the period covered by the Arequipa observations. He points out that, upon his meteoric hypothesis, it is not unlikely that belts should form and then disappear. It is a fairly common belief among astronomers that the satellites of Jupiter can be seen through the planet's limb during occultation. On this point, Prof. Barnard says: "In my mind this [the observation of the transparency of Jupiter's limb] has been due to poor seeing, a poor telescope, or an excited observer. For nearly fifteen years I have observed Jupiter and his satellites, and with telescopes all the way from five inches up to thirty-six inches have tried to see this phenomenon. I have often watched the satellites under first-class seeing with the 12-inch here [Mount Hamilton] at occultation, but have never seen one of them through the limb of Jupiter, though that phenomenon was specially looked for." It will be seen from these points that Jupiter and his satellites still offer a wide field for investigation.

The Mass of the Asteroids.—Mr. B. M. Roszel contributes to the Johns Hopkins *University Circular* for April a preliminary note on the probable mass of the asteroids. He has investigated the secular perturbations to which a ring of matter, such as the asteroids form round the sun, would give rise. The problem divides itself naturally into two parts—(1) to determine the combined mass of the asteroid belt; and (2) knowing the mass, to derive the secular perturbations of the elements of the orbits of certain of the major planets caused by this elliptic ring of matter. If the total number of the asteroids were known, it would only be necessary to determine the most probable mass of one member of the group to derive the combined mass of the whole group. But this is not the case, so Mr. Roszel has contented himself with determining the mass from a study of two hundred and sixteen of the minor planets at present known. The magnitudes of these bodies vary from magnitudes 6 to 15·5, the greater number lying between magnitudes 11 and 12. From photometric observations, Prof. Pickering derived for Vesta a diameter of 319 ± 10 miles. (Prof. Barnard's recent observations only assign the planet a diameter of 237 ± 15 miles). Now the ratio of the total quantities of light reflected by two planets at the same distance from the observer is equal to the ratio of the squares of their diameters. Utilising this fact, Mr. Roszel has been able to determine the volumes of the two hundred and sixteen asteroids referred to in terms of the volume of Vesta. Assuming Pickering's dimensions of Vesta to be correct, it appears that it would take roughly three hundred and ten asteroids of the sixth magnitude, or twelve hundred of the seventh, to equal our moon in volume. And in round numbers the combined volume of a ring of two hundred and sixteen would be only one two-hundredth part of that of our satellite. Assuming a mean density equal to that of Mars, the mass of the zone of asteroids comes out as about one one-hundred and seventieth part of the mass of the moon. From these considerations Mr. Roszel thinks that the probable mass of the entire asteroid belt is somewhere between one-fiftieth and one one-hundredth part of that of our moon.

Ephemeris of Gale's Comet.—The following ephemeris (for Berlin midnight) is abstracted from one given by Prof. Kreutz in *Astronomische Nachrichten*, Nos. 3227 and 3229:—

	R.A. h. m. s.	Decl. ° ′	Brightness.

The brightness on April 3 has been taken as unity.

The comet was photographed by the Brothers Henry, at Paris Observatory, on May 5. The photograph was obtained with an exposure of forty minutes, and showed a tail, about four degrees in length, divided, at a short distance from the head, into two branches separated by an angle of about three degrees. The mean direction of the two parts of the tail was very nearly perpendicular to the direction of the comet's motion.

SOME LONDON POLYTECHNIC INSTITUTES.

It is only in recent years that any attempt has been made to supply the demand for technical education in London. Not so very long ago the question as to whether such education was desirable for the working classes was gravely discussed; now the necessity is recognised by everyone, and the subject under consideration is the best method of carrying on the work. The commercial world has begun to realise the importance of training workmen on scientific lines; it has been led to see that the encouragement of science means the advance of industry and increase of trade. These lessons were difficult to learn, and, even at the present time, the connection between science and manufactures is not properly understood. But a beginning has been made. London, the city that prides itself upon being the largest and richest in the world, but which until recently ignored the need for technical instruction, has begun to foster the child it had done its best to kill by neglect. A comparison with the educational work carried on in Polytechnics on the continent has served to accentuate the deficiencies of London, and to create a desire to follow the lead there indicated. The awakening was rather abrupt, and it was thought by some that the time lost could be rapidly made up again. But this mistaken idea has now been given up, and it is seen that the only way to improve our arts and industries is by slowly educating the mind and training the hand of the mechanic.

Goldsmiths' Institute is specially fortunate in having a very strong Governing Body, containing as it does the names of Sir Frederick Abel, Sir Frederick Bramwell, Sir Richard Webster, Sir Walter Prideaux, Dr. Anderson, and Mr. G. Matthey. It will be seen from Fig. 1, which shows a view of the Institute from the back, that the building covers a considerable area. The structure is the old Royal Naval School building adapted and extended to the requirements of the Institute. Some people considered it a disadvantage to take an institute like that of the Goldsmiths' Company into an old building, but, on the whole, there are many advantages in so doing. In a new building, the architect provides everything he is told to provide, but he does not leave room for future exigencies. In an old building, however, there are usually facilities for extensions in the direction which experience shows to be necessary.

The buildings of the Goldsmiths' Institute are considerably larger than those of any of the other London Polytechnics. A technical museum is now being added, which will be a special feature of this Institute.

The Institute differs from most other Polytechnics in the conditions of membership. The Battersea Polytechnic and the

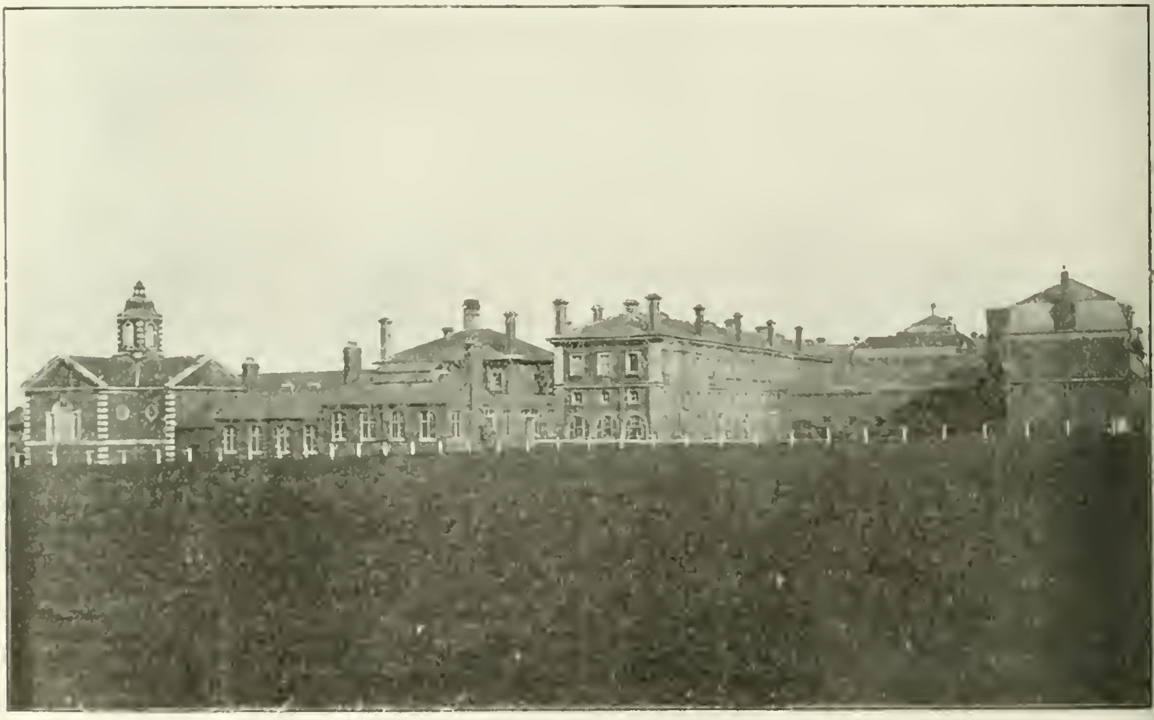

Fig. 1.—The Goldsmiths' Institute (from the back)

It is proposed in this article to give an account of three institutes in London which provide evening education and recreation for persons engaged in various trades and industries during the day. The institutes referred to are the Goldsmiths' Institute, the People's Palace, and the Battersea Polytechnic Institute. Other institutes, however, are referred to incidentally.

To begin with the technical and recreative Institute at New Cross, established and endowed by the Goldsmiths' Company. The expenditure of this Company upon their Institute has amounted to something like £80,000, and they have assigned it an endowment of £5000 per annum. Work was commenced in the Institute in October, 1891, Mr. J. S. Redmayne, of Merton College, Oxford the Secretary, having been appointed about eighteen months previously in order to draw up a scheme of work and get together a strong and efficient staff. His duties are generally to supervise the staff and work, under the direction of the Governors, and generally act as resident representative of the Governors. It is hardly necessary to remark that the success of Polytechnic Institutes from an educational point of view depends very largely upon the Governors. The

People's Palace exclude from membership of the institute, that is, from the social and recreative side, all except students. At the Regent Street Polytechnic, we believe, the rules are exactly the opposite way; those who care to pay for enjoying the social side can also, in virtue of so doing, get their education cheaper, that is to say, the class fees are reduced to members. We have no hesitation in saying that this plan is very bad. The first object of a Polytechnic should be the advancement of technical education. When this purpose is kept more or less in the background, the social and recreative side of the work tends to run rampant. In such cases the "House of Commons," where persons play at Parliament, is one of the most flourishing of the societies, and the "dreary drip of dilatory declamation" constitutes the pabulum of a large proportion of the members. The Governors of the Borough Institute have apparently found that too much attention to clubs and concerts is detrimental to educational work, for they have recently required that all new members should belong to one or more of the classes, and even now there seems to be room for improvement.

At the Goldsmiths' Institute there is one class fee for members and students alike, but a student can get his membership—that is, his social and recreative privileges—at a cheaper rate through being a student. At the same time, people are not excluded from the social side of the Institute, even if they are not students. To put the matter briefly: at the Regent Street Polytechnic studentship is of less account than membership. At Battersea, the People's Palace, and, to some extent, Borough Road, there is no membership without studentship, while at the Goldsmiths' Institute studentship is the main thing, but those who are not students are not excluded from membership—they are only made to pay a little more for their privileges because they are drones.

It must not be supposed that the social or recreative side of Polytechnic Institutes consists entirely of play, for some extremely useful societies belong to it. The mechanical engineering and the chemical societies of the Goldsmiths' Institute are really doing splendid work. At their meetings students read papers of really scientific merit, and important problems in mechanics and chemistry are discussed. Too much praise cannot be given to societies of this kind, and we are glad to find that most institutes recognise their usefulness. They create interest and stimulate research; they help students to realise that scientific attainments must not be gauged by certificates, but by contributions to knowledge. Many institutes put forward as an advertisement of their efficiency the fact that a larger proportion of their students passed certain examinations than those of any other Polytechnic; that their students carried off such and such medals, and so on. This is all very well, but we look to Polytechnics for further evidence of efficiency than that shown by examinational honours. If the mere obtaining of certificates is inculcated into students as the end and aim of their work, the useful results expected from technical education will never arrive. The test, indeed, of the work done in Polytechnics must not be rated according to the list of examinational successes, but by the number and quality of papers published, and inventions made, by its alumni. So far as we know, no London Polytechnic Institute is yet able to produce this evidence of the development of originality, though it is impossible to say what may be done in the future. We would suggest, however, that such institutes should begin to record the additions to knowledge made by their students, and publish the lists year by year in their prospectuses. There would then be no difficulty in determining which of them all had borne the best fruits.

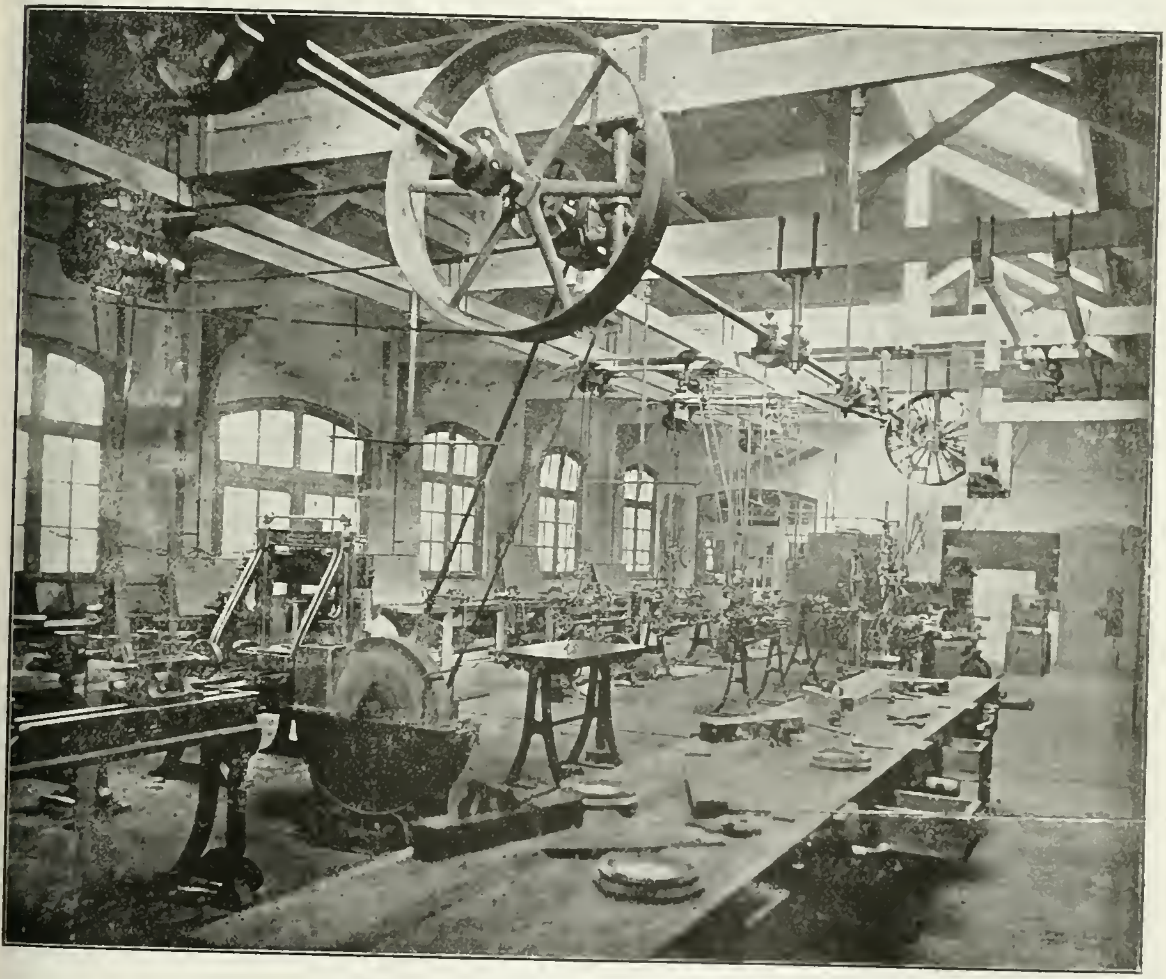

FIG. 2.—Engineering Workshop of the Goldsmiths' Institute.

The engineering department of the Goldsmiths' Institute is one of the best in London. Through the kindness of Mr. W. J. Lineham, the head of this section of work, we are able to give an illustration of the engineering workshop. It will be seen that the workshop is extremely well-fitted with useful machines—far better, indeed, than many of the shops in manufactories. Students who pass through workshop courses are made familiar with almost all the tools and appliances met with in ordinary practice. As for the courses themselves, we can suggest nothing to improve them. Each student is given a rough casting, and is expected to turn out from it a finished product. The first bit of work consists in grinding a cold chisel, both flat and cross cut, and in learning how to do simple marking off. For practice in chipping, filing, and scraping, a cast iron block is worked into a paper-weight. A scribing block is then made, the castings and forgings being provided. This serves as exercise in chipping, filing, drilling, turning, and screwing. The student has afterwards to turn out a surface plate, hexagonal pattern, with handles. This work serves as exercise in planing, turning, drilling and screwing, filing and scraping. During the second year a ratchet brace is made, and a lathe; and third-year students make a shaping and a slotting machine. The course of study for engineering students is worth reprinting, for in it theory and practice are excellently combined:—

First year.	Second year	Third year.	Fourth year.
Fitting and Machining (Shops)	Heat Engines, Advanced.	Smithing (Shops).	Smithing (Shops).
Engineering Lecture (Preliminary).	Mathematics (2nd stage).	Fitting and Erecting (Shops).	Pattern Making (Shops).
Applied Mechanics, Advanced	Fitting and Machining (Shops).	Machine Construction (Special).	Smithing (Shops).
Machine Drawing, Elementary.	Machine Drawing, Advanced	Engineering Lectures.	Engineering Lectures (Special).
Fitting and Machining (Shops)	Engineering Lecture.	Pattern Making (Shops).	Pattern Making (Shops)
The Steam Engine, Elementary.	Applied Mechanics, Advanced.	Finished Drawing and Design (Special).	Finished Drawing and Design (Special).
Mathematics (1st stage).	Fitting and Machining (Shops)		
Drawing Practice (Special).	Drawing Practice (Special).		

The course for building students is just as good. These courses are very popular, and they well deserve the success they have gained. Another successful class is one of carpentry for women; not merely Sloyd or woodwork, but real, practical carpentry. This is, we believe, the first class of the kind that has ever been held. The chemistry classes are specially good, and the laboratories the largest of all the Polytechnic Institutes.

Certain classes of the Goldsmiths' Institute are open to a limited number of *bonâ fide* artisans and handicraftsmen, on payment of half the ordinary fees. This is a rule well worth following in other institutes. Some of the trade classes are open to any one, irrespective of occupation. The clerk who has a taste for machine work may go through the same courses as fitters. If the clerk were allowed to waste his time in dabbling with the lathe and making pretty things, then he ought to be kept out; but when he is compelled to take up routine work, the case is different, for nothing but good can come of it. The young man who is willing to forego empty pleasures in order to obtain technical knowledge, is the one who will develop into an inventor. He works for the pure love of it, and something original may be confidently expected from him in time.

R. A. Gregory.

(*To be continued*).

EXPLORATION OF THE HADRAMUT.

AT the last meeting of the Royal Geographical Society Mr. J. Theodore Bent gave an account of the archæological tour recently made by him and Mrs. Bent in Southern Arabia. On account of the fanaticism of the people, only one European had previously been able to penetrate to the broad valley of the Hadramut, which runs for one hundred miles or more parallel to the south coast of Arabia, gathering in tributary valleys from north and south, and carrying their drainage to the sea at Saihut. Opposition to the expedition was offered, as in the case of Mr. Hirsch, by the British officials at Aden, but in spite of this the Bents, accompanied by the accomplished Indian surveyor, Imam Sharif, and by botanical and natural history collectors, travelled in safety without disguise, and, though there were some hostile appearances, without injury through a large tract of unmapped country.

The region they traversed consisted of three parts, the narrow coast strip or Sahil, backed by the high plateau or Akaba, and the Hadramut and other valleys on the north, which lies between the southern plateau and the high desert land farther north. The whole coast strip from Mokulla to Saihut was extremely arid, only fertilised in patches by occasional hot springs. No traces of antiquities were found along the coast. The plateau of Akaba was ascended by the Wadi Howari, one of numerous short valleys which diversify the southern slope. The plateau presented the appearance of an unbroken plain with only a few flat-topped indications of a previously greater height to break its surface. This district was waterless except for tanks preserving precarious supplies of rain water along the paths. The highest point was found to be Haibel-gabrein, near the southern edge, its elevation being 5300 feet. The plateau was wandered over by a few Bedouins, and on its northern slope considerable numbers of frankincense trees occur, their produce being gathered not by the Bedouins but by Somalis, who come across in the season for that purpose. Where the plateau was trenched by the Hadramut valley the tributary valleys were found remarkably short and steep, cut out of the edge of plateau-like slices from a cake. All these valleys have their floors nearly on the same level as the main valley, and terminate at their heads in steep cliffs 700 or 800 feet high. Their appearance did not seem to justify the theory of water erosion, and Mr. Bent is inclined to consider them as lateral fjords excavated when the Hadramut was an arm of the sea. The rocks were exposed in steep cliffs of horizontally stratified red sandstone. The valley-bottoms are richly cultivated, thronged with villages shaded by palm groves, in effective contrast with the shadeless sterility of the plateau and the desert on either side. In this valley many archæological finds were made, principally in the shape of Himyaritic monuments and inscriptions dating back, in some instances, to B.C. 300. The people of the part of Arabia visited formed four distinct classes. The wild tribes of Bedouins, scattered irregularly, living in isolated houses or caves, rear camels and do all the carrying work. Next are the Arabs proper, who dwell in towns, cultivate the surrounding lands, and engage in extensive trade, sometimes visiting India and the Straits Settlements. Thirdly, the Sayyids and Sherifs form a sort of aristocratic hierarchy, tracing their descent from the Prophet; they are the religious fanatics who object to the admission of foreigners. The last class is that of the slaves, all of African origin, acting as labourers, personal servants, and soldiers to the Sultans of the many independent tribes into which the other classes of the population are divided.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—In connection with the visit of the Royal Agricultural Society to Cambridge next month, the University will bestow honorary degrees on a number of the high officers of the Society and others who have distinguished themselves in promoting agricultural science. The Duke of Devonshire, Chancellor of the University, is President of the Society, and will probably himself confer the degrees. The list of names submitted to the Senate includes H.R.H. the Duke of York, the Duke of Richmond and Gordon, Lord Cathcart, Sir John Thorold, Sir Dighton Probyn, Sir Nigel Kingscote, Sir John B. Lawes, Sir Joseph H. Gilbert, Mr. A. Peckover, the Lord Lieutenant of Cambridgeshire, and Mr. Albert Pell. The Master and Fellows of Trinity College have issued invitations to a banquet in the College Hall for June 26, at which the Prince of Wales, the Chancellor, and the recipients of honorary degrees, will be entertained.

We learn from the *Scotsman* that two important draft ordinances were issued on May 14 by the Scottish Universities Commission. One of these deals with the matter of the regulations for the encouragement of special study in research and for the institution of Research Fellowships. The ordinance provides that the Senatus Academicus of each university may make regulations under which graduates of Scottish universities, or of other universities recognised for the purposes of the ordinance, or other persons who have given satisfactory proof of general education and of fitness to engage in some special study or scientific investigation, may be permitted such study or research in the university. The University Court in each university may establish Research Fellowships, which shall be open to research students only, and may set aside out of the General University Fund such sums as it may think fit to provide for stipends of Research Fellowships. The Court may also provide such sums as it may think fit in aid of the expenses of special research. Research students may be admitted to the degrees of Doctor of Science or of Doctor of Letters of the university in which they have studied as research students, under conditions prescribed in another ordinance of the Commission just issued dealing with the regulations for higher degrees in arts and science. In regard to the degree of Doctor of Science, it is provided that graduates who have taken the degree of Master of Arts with honours in mathematics and natural philosophy, may proceed to the degree of Doctor of Science in the same university after the expiry of five years from the date of their graduation in arts, under the same conditions as if they held the degree of Bachelor of Science. Research students within the meaning of the ordinance relating to the regulations for the encouragement of special study and research may offer themselves for the degree of Doctor of Science of the university in which they have pursued some special study under that ordinance, although they have not taken the degree of Bachelor of Science, or the degree of Master of Arts with honours in mathematics and natural philosophy in that University, under the following conditions:—

(1) That they hold the degree of Bachelor of Science or Bachelor of Medicine of a Scottish or any recognised university, or a degree of any such university, which the Senatus Academicus shall hold to be equivalent to the degree of Bachelor of Science or to the degree of Master of Arts with honours in mathematics and natural philosophy.

(2) That they have spent not less than two winter sessions or an equivalent period as research students in the university granting the degree, and that they produce evidence of satisfactory progress in the special study or research undertaken by them during that period.

(3) That a period of not less than five years shall have elapsed from the date of the graduation required in sub-section (1) of this section.

All candidates for the degree of Doctor of Science have to present a thesis or a published memoir or work, to be approved by the Senatus on the recommendation of the Faculty of Science; provided that, if required by the Senatus, the candidate shall also be bound to pass such an examination as may from time to time be determined. The thesis must be a record of original research undertaken by the candidate, and has to be accompanied by a declaration signed by him that the work has been done and the thesis composed by himself.

It will be noted with regret that no provision is made for the publication of the thesis. This is a serious omission, for scientific work, if worthy of a degree, is surely worthy of publication.

THE name of Dr. D. H. Scott should have been added last week to the list of Oxford men who are among the selected candidates for the Fellowship of the Royal Society.

SCIENTIFIC SERIALS.

American Journal of Science, May.—Observations on the derivation and homologies of some Articulates, by James D. Dana. It is probable that all Articulates are successional to the Rotifers. There is reason for believing further that the types of Annelids, Crustaceans, and probably that of Limuloids, had their independent Rotifer origin. The line to the lower and earlier Arachnoids, that is to the Scorpions, leads up from the early Pterygotus—like Limuloids. A line of succession from Worms to Myriapods and from these to Insects, although not proved geologically, is suggested by the fact that in low-grade insects there is no proper metamorphosis, while in the higher the larval stage is lower and lower in embryonic level. The larval stage would result from an attendant retrograde embryonic change to a line parallel with the Myriapod, and beyond to the memberless condition of a worm.—Notes on apparatus for the geological laboratory, by J. E. Wolff. This paper contains instructions for making diamond saws, for sawing thin sections of rock specimens, and for the management of the arc light for purposes of projection.—An elementary expression in thermoelectrics, by Carl Barus. Two metals are thermoelectrically identical when the sign and the number of available molecular paths which the current (or better, the elementary charge) is free to take, is the same in both metals.—Gases in Kilauea, by William Libbey. Observations of bluish-green flames bursting out from the lava, made with a pocket spectroscope, revealed what was probably carbonic oxide and some hydrocarbons, shown by a band in the green, and bands in the red and blue.—Transformations of mechanical into chemical energy, III. Action of shearing stress continued, by M. Carey Lea. The most instructive experiment was that with mercuric oxide. Half a gram was taken, and after trituration the unchanged oxide was dissolved out by repeated digestions with hydrochloric acid. The reduction products were dissolved out by a few drops of aqua regia, filtered, and precipitated by hydrogen sulphide. The amount of sulphide obtained correspond to the reduction of ·0329 gram of mercuric oxide. The amount of mechanical energy transformed into chemical was found to be 322 gram meters. Silver oxide, potassium ferricyanide, ferric ammonia, alum, silver carbonate and sulphite, and sodium chloroaurate were also successfully reduced by grinding, but not cupric chloride. A porcelain mortar was found much more efficient than one made of agate.

Bulletin of the New York Mathematical Society, vol. iii. No. 7, April 1894. (New York: Macmillan.) Prof. H. Maschke, in a thorough analysis of Harkness and Morley's "Theory of Functions"—it occupies pp. 155–167 of the present number—records the opinion that "the great merits of this valuable work will secure it a high rank in modern mathematical literature." Dr. G. A. Miller, in a note on substitution groups of eight letters (pp. 168–9), makes an important addition to Dr. Cole's list in vol. ii. which is suitably acknowledged by him. Prof. J. McMahon writes on the general term in the reversion of series (pp. 170–2). In the notes the Simson-Lines are printed Simpson's lines. Dr. J. S. Mackay's discovery that no such property has been found in R. Simson's published writings, has not yet "caught on." There is a long list of new publications.

L'Anthropologie, tome v. No. 2, March April, 1894.—M. Ed. Piette contributes some notes to be used for the history of primitive art. The bulk of the accumulations found in caves are composed of broken bones of animals eaten by man, and a cursory examination of the débris suffices to show that whilst the remains of Equidæ predominate in the lower strata, those of Cervidæ are more abundant in the upper strata. Hence, the Glyptic period, as M. Piette calls the age in which quaternary man was in the habit of ornamenting bone, horn, ivory, and stone with sculpture or engraving, has two primary divisions—the Equidian age and the Cervidian age. The former of these may be considered to have two subdivisions, namely the elephantine, or ivory epoch, and the epoch of the horse, called by M. Piette the Hippiquian epoch; two subdivisions are also comprised in the Cervidian age, viz. the epoch of the reindeer and that of the red-deer, or the Rangiferian epoch and the Elaphian epoch.—In a paper on the female deity and the sculptures of the Allée Couverte of Epone, M. Emile Cartailhac describes several blocks and menhirs from various parts of the country on which a female figure is sculptured with more or less detail. On the breast of one of these figures is the representation of an implement or weapon much like the ancient Egyptian boomerang. In a dolmen, excavated by Canon Greenwell at Folkestone, there were found two small cylindrical blocks of limestone, covered with geometrical designs, in the middle of which, in a prominent place, is seen a human face, confined to the forehead, nose and eyes, but, so far, identical with the French sculptures.—M. Maurice Delafosse gives an account of the Hamites of Eastern Africa, in a brief summary of the ethnographical parts of the most recent works that have appeared on the subject. He refers more particularly to the valuable monograph by Dr. Philipp Paulitschke, entitled "Ethnographie Nordost-Afrikas, die materielle Cultur der Danâkil, Galla und Somâl" (Berlin, 1893). The Danakil, Somal and Galla peoples, each comprising a large number of tribes, divide the eastern horn of Africa between them. The Danakil dwell along the coast of the Red Sea and to the east of Abyssinia, the Somal occupy the whole of that point of Africa which projects into the Indian Ocean, while the Galla tribes inhabit the country west of the Somal and to the south of the Danakil and Abyssinia. They are all of Hamitic origin, and differ as much from their neighbours, the Berbers and the Semites of the north, as they do from the negroes and the Bantu of the south. Their hair is not frizzly, but only woolly, and sometimes it attains to a considerable length, especially among the women. The nose is not flat; it is frequently broad and short, but it is sometimes even aquiline. The lips are rarely protuberant, though they are almost always thick. M. Salomon Reinach continues his account of sculpture in Europe prior to Greco-Roman influence; and M. E. Vouga discusses the probable age of the lacustrine stations in Switzerland. M. Vouga calculates that the layer of mud that overlies the bronze bed to the thickness of about 0·12 m. has required 3000 years for its accumulation, that the deposition of the bronze bed itself occupied one or more centuries, a layer of lacustrine mud between the bronze bed and the stone bed (0·12m. thick) took another 3000 years to accumulate, and that the stone bed probably took twice as long in its formation as the bronze bed did. The stations have been suddenly abandoned, with all the personal property of the inhabitants, several times, and completely deserted: once by the men of the pure stone age—the stone of the country; a second time perhaps, but very probably, by other men who possessed nephrite and jade implements, axes and polished hammers, and articles of copper; lastly, by the men of the bronze age. No satisfactory explanation of these facts has yet been offered, but perhaps the frequent change of level of the lake waters may be to some extent responsible for them.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, April 26.—"On the Specific Heats of Gases at Constant Volume. Part II. Carbon Dioxide." By Dr. J. Joly, F.R.S.

In the former experiments on this gas, recorded in the first part of this research,[1] the highest absolute density at which the specific heat was determined was 0·0378. In the present observations the determinations of specific heat have been carried to densities at which the substance was partly in the liquid state at the lower limit of temperature of the experiments. Observations dealing with true specific heat, uncomplicated by the presence of thermal effects due to the presence of liquid, are limited by the density 0·1444. At this density the mean specific heat over the range, 12° C. to 100° C., is 0·2035.

These observations, combined with those contained in Part I. (*loc. cit.*), afford a well defined line, which rises slowly at the higher densities, turning away from the axis of density.

According to an empirical equation to this line, the specific heat of carbon dioxide at constant volume is given in terms of its variation with density ρ, as follows:

$$Cv = 0{\cdot}1650 + 0{\cdot}2125\rho + 0{\cdot}3400\rho^2$$

"On the Specific Heats of Gases at Constant Volume. Part III. The Specific Heat of Carbon Dioxide as a Function of Temperature." By Dr. J. Joly, F.R.S.

In order to investigate the question of the variation of the specific heat of carbon dioxide with temperature, a steam calorimeter was constructed having double walls of thin brass, between which the vapour of a liquid boiling under atmospheric pressure could be circulated. The vessels used in the experiments were hung in the closed inner chamber. Into this chamber steam could be admitted after the temperature had become stationary and the same as that of the jacketting vapour. In this way the initial temperature could be varied.

Experiments at various densities and over four intervals of temperature were carried out. The densities chosen were 0·0456; 0·0800; 0·1240; 0·1800, and 0·1973. The intervals of temperature over which the gas at each density was investigated were: air temperature to 100°; 35° C. (boiling point of ether) to 100°; 56° (boiling point of acetone) to 100°, and 78° (boiling point of ethyl alcohol) to 100°.

The results are plotted on 5 equi-density lines, in which the precipitation due to the calorific capacity of the gas between t_1, and 100° is plotted against the initial temperature t_1 in each case. If the specific heat is invariable these are right lines. This proves to be sensibly the case for the lines $\rho = 0{\cdot}0456$ and $\rho = 0{\cdot}0800$; those of lowest density.

The next line, 0·124, is nearly rectilinear over the higher ranges, but pursued in the direction of decreasing temperature it rises markedly, thus indicating that the specific heat at constant volume falls in value with increasing temperature. The line $\rho = 0{\cdot}1800$ and the one close above it, $\rho = 0{\cdot}1973$, show this variation very markedly. Their variation below the critical temperature is complicated by the presence of liquid.

[1] "On the Specific Heats of Gases at Constant Volume," Part I. *Phil. Trans.* vol. clxxxii. 1891 (pp. 73-117).

The following empirical equation expresses the line $\rho = 0{\cdot}124$ calculated into a line of variation of specific heat with temperature:—

$$Cv = a\,(100 - t) + b\,(100 - t)^2 + c\,(100 - t)^3,$$

where t is the initial temperature of the experiment in centigrade degrees;

$$a = 0{\cdot}19020000,$$
$$b = -0{\cdot}00006750,$$
$$c = 0{\cdot}00000182.$$

Geological Society, May 9.—Dr. Henry Woodward, F.R.S., President, in the chair. The following communications were read:—Carrock Fell: a Study in the Variation of Igneous Rock-masses. Part I. The Gabbro. By Mr. Alfred Harker. The author opened with an account of the general relations of the intrusive rock-masses of the district, and proceeded to deal more particularly with the gabbro, which forms the earliest intrusion. A petrological description of the Carrock Fell gabbro followed a study of the variations observed in different parts of the mass. The rock becomes progressively more basic from the centre to the margin, passing from a quartz-gabbro with as much as 59½ per cent. of silica to an ultrabasic type with as little as 32½. The latter in extreme cases contains nearly 25 per cent. of iron-ores, partly titaniferous. This was compared with the igneous iron-ores described by Vogt in Scandinavia, &c., and the probable physical cause of the remarkable variation in the gabbro was discussed. Other modifications of the gabbro were briefly noticed, due on the one hand to metamorphism of the rock by a somewhat later intrusion of granophyre, on the other hand to the gabbro-magma having enclosed considerable masses of the basic lavas of the district, which are themselves highly metamorphosed. The paper was commented upon by Mr. Marr, Prof. Judd, Prof. Cole, and Mr. Rutley.—The Geology of Monte Chaberton, by Mr. A. M. Davies and Dr. J. W. Gregory. The importance of the Chaberton district, as affording a key to the general geology of the Cottians, was explained, and the opinions of previous observers referred to. The mountain was examined from three sides—that of the Grand Vallon; the approach from Mont Genèvre by the Col de Chaberton; and that of the Clos des Morts Valley. The following are the conclusions arrived at:—(1) The well-known Chaberton serpentine is intrusive into the calc-schists, and yields fragments to the *cargneules* of the Trias: it is therefore a *pre-Triassic* intrusion. (2) There are on the mountain other fairly basic schistose rocks (quartz-chlorite-schists) which cut the Trias, and are therefore *post-Triassic*. (3) The contorted beds in the Clos des Morts Valley are fossiliferous limestones, and it is from them that the fallen blocks previously recorded were derived. The only recognisable fossil is *Calamophyllia fenestrata*, Reuss, a characteristic coral of the Gosau Beds. In spite, therefore, of the doubts of Kilian and Diener, the opinion expressed by Neumayr as to the existence of Cretaceous rocks in this part of the Alps is confirmed. (4) The earth-movements of the mountain are described: they include ordinary folds, inversions, faults, and an important thrust-plane. (5) It is suggested that in addition to the two series of intrusive rocks above mentioned as pre- and post-Triassic, a third series of late Cretaceous or Tertiary date may be represented in the Mont Genèvre and Rocciavrè masses.—Cone in Cone. How it occurs in the Devonian (?) Series in Pennsylvania, U.S.A., with further details of its structure, varieties, &c., by Mr. W. S. Gresley. The author described cone in-cone structure occurring in the Portage Shales of Pennsylvania, and gave details concerning the nature of the structure as seen in these shales. He criticised the explanation of Mr. J. Young as to the origin of the structure, and concurred in a great measure with the views of those who have suggested that the formation was due to pressure acting on concretions.

Mathematical Society, May 10.—Prof. Greenhill, F.R.S., Vice-President, in the chair.—The following communications were made: On the kinematical discrimination of Euclidean and non-Euclidean geometries, by Mr. A. E. H. Love. The problem of Helmholtz, to lay down axioms concerning motion, by which the Euclidean, elliptic, and hyperbolic geometries shall be distinguished from all other imaginable geometries, has been recently solved by Sophus Lie in the third part of his "Theorie der Transformations-gruppen" (1893), and he adds the remark that the group of the Euclidean motions is distinguished from the two groups of non Euclidean motions by the possession of a real invariant sub-group. This remark obviously refers to translations, and in fact it appears to have been previously noticed that in the elliptic and hyperbolic geometries, the transformations that correspond to translations do not form a group. In the present communication a number of representations of elliptic and hyperbolic geometry are described and illustrated with the object of making this kinematical distinction between the Euclidean and the other geometries intuitively obvious.—Permutations on a regular polygon, by Major P. A. MacMahon, F.R.S.—The stability of a tube, by Prof. Greenhill (Dr. J. Larmor, F.R.S., *pro tem.* in the chair). The difficulties of constructing a theory for the stability of a tube, subject to external pressure and end thrust, have been discussed by Mr. A. B. Basset in the *Phil. Mag.* September 1892. Similar investigations have been undertaken by Mr. Love and Mr. Bryan in the *Proceedings* of the London Math. Society. The analytical difficulties due to the difference of pressure on the two sides of the plate, have not yet been overcome, so that the investigation of the present paper must be taken as provisional, as it proceeds on the old theory, as laid down in Thomson and Tait's "Natural Philosophy." The chief object is to determine the number of segments or waves into which the cross section of the tube will tend to break, as the supporting influence of the ends is made to operate at sections which are brought closer and closer together; the influence of the end thrust is also taken into account. A differential equation is obtained for w, the infinitesimal normal displacement of the tube, of the form

$$A\left(\frac{d^4w}{dx^4} + 2\frac{d^2w}{dx^2dy^2} + \frac{d^4w}{dy^4} + 2\frac{d^2w}{a^2dx^2} + \frac{w}{a^4}\right)$$
$$+ A\sigma\frac{d^2w}{dx^2} + X\frac{d^2w}{dx^2} + Za\left(\frac{d^2w}{dy^2} + \frac{w}{a^2}\right) = 0 \quad . \ . \ (A)$$

where x is measured parallel to the axis of the tube, and y circumferentially; a denotes the radius of the tube, b its thickness, A the flexural rigidity, σ Poisson's ratio, X the longitudinal thrust in the tube per unit length of cross section, and Z the external applied pressure; the inch and pound are taken as units of length, so that the theoretical results may be compared immediately with experimental values; to do this it is assumed provisionally that we may put $A = \frac{1}{12} Mb^3/(1 - \sigma^2)$, where M denotes Young's modules of elasticity. If the tube breaks circumferentially into n waves, we put

$$\frac{d^2w}{dy^2} = -\frac{n^2w}{a^2}, \quad \frac{d^4w}{dy^4} = \frac{n^4w}{a^4};$$

and equation (A) becomes

$$\frac{d^4w}{dx^4} - 2n^2\frac{d^2w}{a^2dx^2} + (n^2 - 1)^2\frac{w}{a^4}$$
$$+ \left(\sigma + \frac{Xa^2}{A}\right)\frac{d^2w}{a^2dx^2} - (n^2 - 1)\frac{Za^3}{A}\frac{w}{a^4} = 0 \quad . \ . \ (B)$$

For cylindrical collapse, when the supporting influence of the ends is left out of account, $\frac{d^2w}{dx^2}$ is zero, and therefore

$$\frac{Za^3}{A} = n^2 - 1, \; nZ = \frac{n^2 - 1}{12}\frac{M}{1 - \sigma^2}\left(\frac{b}{a}\right)^3.$$

But if the ends of the tube are supported or strengthened, the collapsing pressure is obviously increased, so that

$$\frac{Za^3}{A} - (n^2 - 1)$$

is positive. If the supporting influence is due to a series of equidistant strengthening rings, as is a caisson, l inches apart, preserving accurately the circular form at the corresponding section, while permitting slight changes of direction in the longitudinal seams, we put

$$\frac{d^2w}{dx^2} = -\frac{\pi^2w}{l^2}, \quad \frac{d^4w}{dx^4} = \frac{\pi^4w}{L^4};$$

so that (B) becomes

$$\left(\frac{\pi a}{L}\right)^4 + \left(2n^2 - \sigma - \frac{Xa^2}{A}\right)\left(\frac{\pi a}{L}\right)^2$$
$$+ (n^2 - 1)^2 - (n^2 - 1)\frac{Za^3}{A} = 0 \quad . \ . \quad . \ (C)$$

In practice X is proportional to Z, when it is not zero; and to determine the number n of segments into which the tube collapses, we may put $Za^3/A = y$, and $(\pi a/l)^2 = x$, and draw the hyperbolas represented by (C) for values of $n = 1, 2, 3, \ldots$; and the points of crossing of these hyperbolas will represent the separating states when an integral change in n is about to take place. The case of $n = 1$ would only occur when the tube was used as a long cylindrical column, on the point of buckling sideways, without crippling; we now find that the formula assigns a critical thrust which is only $\frac{2}{3}(b/a)^2$ of that given by the usual theory, due to Euler.—Researches in the calculus of variations, Part v., the discrimination of maxima and minima values of integrals with arbitrary values of the limiting variations; Part vi., the theory of discontinuous or compounded solutions, by Mr. E. P. Culverwell.

Physical Society, May 11.—Walter Baily, Vice-President, in the chair.—A mathematical communication on electromagnetic induction in plane, cylindrical, and spherical current sheets and its representation by moving trails of images, by G. H. Bryan (part 1, general equations), was read by Dr. C. V. Burton, who also explained some of the parts in greater detail. After mentioning that the magnetic field due to induced currents in thin conducting sheets placed near moving magnetic poles could be represented by moving trails of images of those poles, the author goes on to say that in the paper, the surface-conditions which hold at the surfaces of the sheets are deduced directly from the fundamental laws of electromagnetic induction. (1) The total current across any enclosed portion of a surface which always contains the same particles is equal to $1/4\pi$ of the line-integral of the magnetic force round the curve bounding the surface; and (2) the rate of decrease of the surface integral of magnetic induction across any enclosed surface which always contains the same particles to equal to the line-integral of electromotive force round the curve bounding the surface. By working with the scalar magnetic potential instead of vector-potential, the investigation is simplified. In addition to the above laws, the author makes the usual assumptions that displacement currents in the dielectric are so small as to be negligible, and that the induced currents are distributed uniformly through the thickness of the sheet. On these suppositions the surface conditions satisfied by the potentials at the two sides of plane, cylindrical, or spherical sheets are determined, and with an additional limitation as to the thickness of the sheet fulfilling certain conditions, extended to current sheets of other forms. In the latter part of the paper a synthetic determination of the images in a plane sheet is given and expressed in the form of a definite integral. In reading the paper to the meeting Dr. Burton pointed out several misprints in the proof.—Prof. Minchin showed that equation (1) of the paper ($\Omega_2 - \Omega_1 = 4\pi\phi$ + constant, where Ω_2 and Ω_1 are the magnetic potentials at the two sides of the sheet, and ϕ the current function), could be deduced by purely mathematical reasoning instead of being based on the laws of electromagnetic induction. Moreover, it was true for any function whatever and did not depend on ϕ being the current function. Equation (2) $\left(\frac{d\Omega_2}{dz} = \frac{d\Omega_1}{dz}\right)$ followed immediately from the fact that the magnetic force was continuous. The latter part of the paper might be simplified by integrating the linear partial differential equation (15)

$$\left(\frac{d^2\Omega'}{dz\,dt} - R\frac{d^2\Omega'}{dz^2} = -\frac{d^2\Omega_0}{dz\,dt}\right)$$

in the ordinary way, for the form was one for which the auxiliary equations are well known. Dr. Burton, in reply, said he thought Mr. Bryan's reason for developing the equations from the laws of electromagnetic induction was to give his work a physical rather than a mathematical basis.—A paper on dielectrics was read by Mr. Rollo Appleyard. In testing the insulation resistance of celluloid, by having a sheet pressed between two metal plates, the author noticed that the resistance, which was very high, *decreased* as the time the testing battery was left on increased. The "electrification" (using the word to indicate the rate of diminution of galvanometer deflection) was therefore *negative*. The resistance also diminished greatly with increase of battery power, and a considerable amount of hysteresis was observed, the resistance at any given voltage, after a minute's electrification, depending on the previous history of the specimen. On making contact with the surfaces of the celluloid by mercury instead of by solid metal, the abnormal results disappeared, little or no resistance-hysteresis or "electrification" being present, and only a small diminution of resistance with increase of voltage. For a sheet 6 mils thick the resistance between opposite faces 5½ inches diameter was of the order 30 megohms, and one specimen broke down at 1200 volts. The celluloid condensers used in the experiments were found to discharge slowly at first, and after a certain time the deflection of the galvanometer became reversed, and attained a steady negative value. This the author attributes to an E.M.F. of about 0·0026 volt between the mercury and celluloid. Similar experiments on gutta-percha tissue showed no such E.M.F., and the "electrification" was normal. The resistance usually attained a maximum for voltages between 600 and 800. Although the tissue had a thickness of only 2 mils (0·002"), it stood a pressure of 1200 volts, and offered a resistance between circular faces 5½ inches in diameter of about 3000 megohms. The opaque white spots seen in celluloid under the microscope, led the author to test the behaviour of mixtures of conducting and insulating materials. A strip of gutta-percha was warmed, and coarse brass filings scattered over it as thickly as possible. In spite of this the resistance was practically infinite even when tested with 750 volts. A number of rods were made from mixtures of brass and gutta-percha in various proportions, and on testing these it was found that if the weight of filings exceeded about twice that of the gutta-percha, the resistance of a rod 20 inches long, ¾ inch diameter, was small (sometimes a fraction of an ohm), whereas a slightly smaller proportion yielded rods having resistances measured in thousands of megohms. Such rods were found to be affected by oscillating discharges in a manner similar to Prof. Minchin's "impulsion" cells and M. Branly's tubes of filings. Experiments were also made on the behaviour of such rods when subjected to high alternating pressures. This caused small local arcs to form along the rods, but did not permanently destroy their high resistance.—In connection with Mr. Appleyard's paper, a note on the behaviour of certain bodies in presence of electromagnetic oscillations, by Prof. G. M. Minchin, was read by Mr. Elder. Referring to the employment of impulsion cells, metallic films, &c., for detecting the modes of electromagnetic vibrations, he says that so far the physical state of such bodies are too variable to be of service. Metallic surfaces formed by embedding fine metallic powders in films of gelatine, shellac, or sealing-wax, are, as described in a previous communication to the Society, found to act as insulators, but become conducting when subjected to strong electromagnetic disturbances. After a current has once passed through such a film its resistance is changed by very feeble impulses, whereas previously it failed to respond to strong ones. On breaking contact by removing the electrode from the surface, the film loses its conductivity, the time necessary to do this depending on the hardness of the matrix. The resistance of a film containing tin powder, measured between the rounded tips of two platinum wires, 1 c.m. apart, varied under the electromagnetic impulses from infinity to 130 ohms. In conclusion, the author points out that with films and tubes the whole phenomenon relates to charge of resistance, whereas impulsion cells may have currents from external sources passing through them whilst in either the sensitive or insensitive states.—Mr. Bright and Mr. Enright asked questions as to the electrification of gutta-percha, and the bridge connections in the resistance tests of the semi-conducting rods respectively, to which Mr. Appleyard replied.

Royal Meteorological Society, May 16.—Mr. R. Inwards, President, in the chair.—Mr. W. Ellis, F.R.S., read a paper on the relative frequency of different velocities of wind, in which he discussed the anemometer records of the Greenwich Observatory for the five years 1888–1892, with the view of ascertaining the number of hours during which the wind blew, with each of the different hourly velocities experienced during the period. The results of this discussion show that the wind blew for the greatest number of hours with the hourly velocities of ten and eleven miles.—Mr. W. Marriott gave an account of a series of observations on the audibility of "Big Ben" at West Norwood, which he had carried on for a period of five years. The clock tower at Westminster is five and a half miles distant from the point of observation in a north-by-west direction. The large bell "Big Ben" was designed by Lord Grimthorpe, and was cast in 1858; its weight is about fourteen tons. It is 9 ft. 5½ ins. in diameter, and 9½ ins. in thickness, its tone being E. The observations were 676 in number, and were made at the hours of 9 a.m. and 9 p.m. The bell could be heard more frequently in the evening than in the morning, and on Sundays it was more frequently audible than on week-days. The direction of the wind most favourable for hearing "Big Ben" was between west and north. The observations were also discussed in relation to temperature, moisture, cloud, and barometric pressure.—A paper by Mr. A. W. Moore was also read on earth temperatures at Cronkbourne, Isle of Man, 1880–1889.

Royal Microscopical Society, April 18.—Mr. A. D. Michael, president, in the chair.—Dr. W. H. Dallinger directed attention to a stereoscopic photomicrograph of Heliopelta, which had been presented to the Society by Dr. W. C. Borden, of New York.—Dr. Dallinger read a short paper from Dr. H. G. Piffard, in reference to a method which he had adopted for the examination of some of the old immersion objectives.—Mr. J. W. Brown exhibited a "home-made" microscope.—Prof. F. J. Bell read a letter from M. C. I. Pound, describing the laboratories of the Stock Institute of Queensland, which had recently been instituted for the purpose of investigating the nature and causes of animal diseases in that colony.—Mr. J. G. Grenfell read a paper on the tracks, threads, and films of oscillatoriæ and diatoms, illustrating his subject by diagrams and specimens. Mr. T. Comber and the President made some remarks on Mr. Grenfell's paper.

Paris.

Academy of Sciences, May 15.—M. Lœwy in the chair.—On the influence of bending in telescopes mounted as coudé equatorials, by MM. Lœwy and Puiseux.—Researches on the augmentation of crops by introduction into the soil of large quantities of carbon bisulphide, by M. Aimé Girard. The author shows that, for at least two years after treating soils with carbon bisulphide, wheat, oats, beetroot, potatoes, and clover yield much heavier crops than on soil not treated. He traces the increased production rather to the destruction of insect pests than to any action on parasites belonging to the vegetable kingdom.—Observation of Tempel's comet (1873 II.) made at Algiers Observatory. A telegraphic despatch transmitted by M. Tisserand.—On the periodic comet Tempel (1873 II.), by M. L. Schulhof.—Observations of comet Denning (1894, March 26) made at Toulouse Observatory, by M. E. Cosserat.—Observations of Gale's comet (1894, April 3) made at Lyons Observatory, by M. J. Guillaume.—Observations of the same comet made with the coudé equatorial at Lyons Observatory, by M. G. Le Cadet.—Graphic ephemerides giving the co-ordinates of the stars for the purposes of navigation, by M. Louis Favé.—On the equations of mechanics, by M. Wladimir de Tannenberg.—Determination of the relative intensity of gravity, made at Joal (Senegal) by the expedition sent out by the Bureau des Longitudes to observe the total eclipse of the sun on April 16, 1893, by M. G. Bigourdan. Taking g = 981 at Paris, at Joal the mean value of g, reduced to sea-level, is 978·437. This result confirms Defforge's law that g has a characteristic value for the littoral of the same sea, of which the variation follows exactly Clairaut's law of the sine squared of the latitude.—On the physical properties of pure nitrous oxide, by M. P. Villard. The author describes the preparation of the pure gas by a liquefaction method, and compares the densities of the liquid and its vapour from 0° to 30°·3. He finds the critical temperature of the pure gas to be 38°·8 as compared with Dewar's value, 35°·4, and Janssen's 36°·4. The critical volume, density, and pressure are respectively 0·00436, 0·454, and 77·5 atmospheres.—On the stability of dilute solutions of corrosive sublimate, by M. Léo Vignon. The stability depends on the absence of alkaline matter which may be present in the water used or derived from the air or the glass of the containing vessel.—On the chemical character and constitution of ethylic acetoacetate, by M. de Forcrand. From a consideration of thermal data, the author concludes that ethylic acetoacetate most nearly resembles phenols, that it is neither an acid nor a ketone, but a tertiary alcohol of a special type, and should be represented by the formula

$$CH_3.C(OH):CH.COOEt.$$

—Comparative study of the isomeric nitrobenzoic acids, by M. Oechsner de Coninck.—The Diptera parasitic on Acridians: viviparous Muscidæ, *à larves sarcophages*. Aptenia and parasitic castration, by M. J. Kunckel d'Herculais.—On the fixity of race in the cultivated mushroom, by MM. Costantin and L. Matruchot. The peculiarities distinguishing the varieties recognised by mushroom growers are hereditary.—Remark concerning a recent communication, by M. Issel, on the Zante earthquakes, by M. Stanislas Meunier.—M. d'Abbadie describes a new method of measuring a geodetic base-line in presenting volume li. of "Memoires de la Section topographique de l'État-Major-Général russe," on behalf of M. Vénukoff.

BERLIN.

Meteorological Society, April 3.—Prof. Hellmann, President, in the chair.—Dr. Rassner spoke concerning the measurements of the height of clouds at the Eiffel Tower, which had given 150 m. as the lowest value, and discussed the different methods of determining the height of clouds by means of artificial illuminants as proposed and used by La Cour, Cleveland Abbe, Jesse, Hasen, and others. The speaker himself on two occasions had the opportunity of measuring the height of clouds; the first, in the summer of last year, was a thunder cloud, whose height he determined, with the aid of an electric lamp, to be about 80 m.; on the second occasion, in January of this year, he was able by the use of an intermittent benzole light, to measure the height of the clouds to 750 m.—Dr. Schubert made a communication concerning the cyclone of February 12 last, which did very great damage in the forest of Freienwalde and Chorin, especially in the pine districts, where the trees were torn up by the roots, and blown down by the storm. A series of beautiful photographs illustrated the devastation produced by the storm.

Physiological Society, April 13.—Prof. du Bois Reymond, President, in the chair.—Dr. Krüger spoke concerning the determination of the uric acid and nuclein bases in urine by precipitation with copper sulphate and sodium bisulphide. With the help of these reagents one can determine exactly the nitrogen of the uric acid and of the nuclein bases. If the nitrogen of the uric acid be now determined by means of the Ludwig-Salkowsky method, one arrives at a quantitative determination of the nuclein bases. On the other hand, the uric acid in the urine may be changed into allantoin by manganese, in which case treatment with the copper sulphate-sodium bisulphide yields only the nitrogen of the nuclein bases. This is then deducted from the total nitrogen which had been found before, and so one obtains quantitative estimation of the uric acid. These reactions were verified in a great number of experiments.—Dr. Jacob reported on a case of leukæmia which he had investigated in conjunction with Dr. Kruger. They first showed that an increase in the nitrogen of the uric acid and nuclein bases of the urine is associated with the increase in the number of the leucocytes. After injection of an extract of spleen, there was observed first a decrease, and later an increase in the number of leucocytes. In proportion to the increase of the leucocytes there was an increase in the quantity of urine excreted and in the amount of uric acid and nuclein bases. When after some days the number of leucocytes decreased the quantity of urine, of uric acid, and of nuclein bases also diminished.—Dr. Lilienfeld communicated the results of experiments which he had made on the condensation of glycocol ether, and on the union of a diamine base derived from glycocol with leucine ether and tyrosine ether. The condensation of glycocol ether and tyrosine ether resulted in a body which gave the reactions of glutin, and resembled glue in appearance, while the union of the above-mentioned three substances gave a proteid-like body, which showed the biuret reaction, and was dissolved by pepsin. The conjectures as to the constitution of these three substances will be tested by further experiments.

April 27.—Prof. du Bois Reymond, President, in the chair. Dr. Ad. Loewy communicated the results of his experiments on the influence of rarefied and compressed air on the circulation. As he showed in earlier experiments a diminution of pressure to about 450 mm. of mercury was tolerated very well and did not lead to any real disturbance, and that the lowered oxygen tension, produced either by still greater rarefaction or by the addition of carbonic acid to the air breathed, is compensated for by deeper respirations. The speaker desired now to determine by experiment whether, with rarefaction of the air, compensating changes can be observed in the vascular system. In particular he determined the velocity of the blood flow by the method recently devised by Prof. Zuntz (NATURE, vol. xlix. p. 168) in animals which respired in rarefied air of about ½ atmosphere, and found that, at each systole of the heart the volume of the blood ejected exactly equals that which the same animal shows under normal pressure. Thus if the tension of the oxygen breathed is reduced one half the effect on the circulation is as slight as it is on the respiration. With still greater rarefaction the oxygen tension in the alveoli can, by deeper respiration, still be brought to the level where the hæmoglobin of the blood is saturated, and no distress appears. Dr. Loewy drew interesting conclusions from his experiments in relation to the meaning of mountain sickness.—Prof. A. Kossel, in his further researches on thymin, a decomposition product derived from nucleic acid extracted from the thymus, has obtained a substance which gave all the reactions of levulinic acid, and produced a salt with silver which possessed exactly the crystalline form of the silver salt of levulinic acid. As levulinic acid originates from levulose, and is viewed by many chemists as proof of the presence of levulose, so from the above reaction the presence of a carbohydrate in nucleic acid is to be deduced. The origin of the nucleic acid is indifferent for this reaction, since it was found with all nucleic acids, a very important fact in relation to the physiology of metabolism. The attempt to discover a carbohydrate in the atom complex of casein, closely related to nucleic acid, led to the discovery of a substance which gave all the reactions of levulinic acid, with the exception of the levulinic acid salts, so that a certain conclusion as to the presence of a carbohydrate complex in casein cannot be drawn.

Physical Society, April 20.—Prof. du Bois Reymond, President, in the chair.—Prof. Koenig reported on a form of colour-blindness lately examined by him, which had not been observed before. The typically colour-blind see yellow in the spectrum where the normal eye perceives red, and the yellow continues with increasing admixture of white until the middle of the spectrum, about $\lambda = 530\mu\mu$, where it commences to change to pale blue which becomes continuously deeper until, at the violet end of the normal spectrum, deeply saturated blue is perceived; in the totally colour-blind, as is well known, every colour sensation has vanished; they see in the entire spectrum only white, which attains its greatest intensity about where the normal eye sees green. The typically colour-blind fall into two groups, which differ only in the position of the greatest brilliancy of the spectrum, the maximum in the one lies where the normal eye sees orange, about $650\mu\mu$, in the other it lies at the yellow, near $580\mu\mu$. The newly investigated case of colour-blindness showed a condition intermediate between typical colour-blindness and total colour-blindness. In the entire spectrum only white was seen, but at the red end of the spectrum the white was mixed with a very weak yellow, and at the violet end with a very weak blue. These colours were first perceived when the two ends of the spectrum lay next one another, and were compared. The maximum brilliancy lay in this case where the second group of typically colour-blind show it—near $580\mu\mu$. The present theories of colour perception are unable to explain this new case. [In the report of the meeting of the Physical Society for March 2 (NATURE, vol. xlix. p. 595), for Roepsel read Koepsel, and for Hulske read Halske.]

SYDNEY.

Linnean Society of New South Wales, March 28.—The following papers were read:—Notes on Australian *Typhlopidæ*, by Edgar R. Waite. Two new species were described—*T. batillus*, from New South Wales, and *T. diversus* from Queensland. Some discrepancies in the published descriptions of *T. unguirostris*, Peters, and *T. affinis*, B'gr. were pointed out. Three aspects of the head of *T. wiedii*, Peters, the only species hitherto unfigured, were given in order to complete the series. The measurements of a gigantic example of *T. polygrammicus* were recorded, the total length being 717 mm. (28¼ inches).—On the fertilisation of *Clerodendron tomentosum*, R.Br., and *Candollea serrulata*, Labill, by Alex. G. Hamilton. The author showed that both plants possess contrivances for the purpose of ensuring cross-fertilisation. *Clerodendron* is proterandrous, and is fertilised by *Sphingidæ*, the pollen being deposited on the legs and underside of the thorax of the insects, a bending of the style keeping the immature stigma at this stage out of the way. After the pollen is shed the stamens curve downwards and the style straightens, bringing the now mature stigma into the position formerly occupied by the anthers. *Candollea serrulata* and its congeners have the anthers and stigma at the end of a sensitive column. This possesses a hinge, which if touched, causes the style to fly over. The anthers mature before the stigma, and at first conceal it. The flower is so constructed that when a bee thrusts in its proboscis, it inevitably touches the sensitive spot, and the style immediately flies over and clasps the bee, which then receives the pollen on its back. Later, when the pollen is all shed, the stigma, which is papillose, grows out, and a bee visiting a flower is struck by the stigma, when the papillæ being glutinous receive the pollen. The author also noted some experiments and observations on the action of the sensitive column.—Note on Bungwall (*Blechnum serrulatum*, Rich.), an aboriginal food, by Thos L. Bancroft. The rhizome of this fern formed, with the nuts of the Bunya Bunya (*Araucaria Bidwilli*), the most important food of the aborigines of Southern Queensland.—On the nests and habits of Australian *Vespidæ*, by Walter W. Froggatt.—Description of *Calliostoma purpureo cinctum*, a new Australian marine shell, by C. Hedley. A small Trochoid, ornamented with beaded sculpture, and coloured orange with a spiral lilac band, was added to the local fauna under the above title.—Note on the habitat of the Naked-eyed Cockatoo (*Cacatua gymnopis*, Sclater), by Alfred J. North. Living specimens caught near Burketown in North Queensland, now on view in Sydney, have been examined; and there are specimens in the Macleay Museum from the Gulf of Carpentaria and from Port Darwin, and in the Australian Museum from Cambridge Gulf. The note of interrogation in the record of the habitat for this species given in the British Museum Catalogue of Psittaci ["South Australia (and also Northern and North-west Australia?")] may therefore be dropped.—Oological notes, by Alfred J. North, (1) *Ptilotis analoga*; (2) *Lamprococcyx malayanus*.—Observations upon the anatomy of the "dumb-bell-shaped bone" in *Ornithorhynchus*, with a new view of its homology, by Prof. J. T. Wilson. The "dumb-bell-shaped" bone is not confined to the palatine region, but both dorsally and posteriorly it is in intimate relation to the nasal septum. From the dorsal part of its hinder extremity it sends backwards a distinct vomerine spur, about 3 mm. in length, which is bifurcated posteriorly and grooved along its dorsal border, forming a splint for the ventral edge of the cartilaginous nasal septum. The tips of this bifid spur are connected with those of the anteriorly bifid end of the true vomer by means of a strong "vomerine ligament," varying in length from about 2 mm. downwards. In coronal sections this ligament is seen to possess the same sectional shape as the vomerine spurs, and to be structurally and morphologically continuous with the bone at either end. The vomerine spur lies quite dorsal to the palatine plate formed by the maxillæ, and it extends backwards to a plane from 2–3 mm. behind the tip of the anterior median process of the latter, from which it is separated by an interval. This interval forms a wide passage of communication (1 mm. vertically), below the nasal septum, between the nasal cavities of opposite sides, and it is lined by columnar epithelium like the neighbouring parts of these cavities. The "dumb-bell-shaped bone" is a true "anterior vomer" formed by the fusion of bilaterally symmetrical halves; and both in its nasal and in its palatine relations it resembles the palatine lobe of the vomer in *Caiman niger*.

DIARY OF SOCIETIES.

London.

THURSDAY, May 24.

Royal Society, at 4.30.—On the Dynamical Theory of Incompressible Viscous Fluids, and the Determination of the Criterion: Prof. O. Reynolds, F.R.S.—Measurements of the Absolute Specific Resistance of Pure Electrolytic Copper: J. W. Swan and J. Rhodin.—On some Voltaic Combinations with a Fused Electrolyte and a Gaseous Depolariser: J. W. Swan.—On certain Functions connected with Tesseral Harmonics, with Applications: Prof. A. H. Leahy.—On the Measurement of the Magnetic Properties of Iron: Prof. T. Gray.—Researches on the Electrical Properties of Pure Substances—No. 1 The Electrical Properties of Pure Sulphur: Prof. Threlfall, J. H. D. Brearley, and J. B. Allen.—On the Influence of certain Natural Agents on the Virulence of the Tubercle Bacillus: Dr. A. Ransome, F.R.S., and Dr. Delépine.

MATHEMATICAL THEORIES OF ELASTICITY.

A History of the Elasticity and Strength of Materials. Vol. II. Parts I and II. By the late Isaac Todhunter, D.Sc., F.R.S. Edited and completed by Karl Pearson, M.A., Professor of Applied Mathematics, University College, London. (Cambridge: at the University Press, 1893.)

A Treatise on the Mathematical Theory of Elasticity. By A. E. H. Love, M.A., Fellow and Lecturer of St. John's College, Cambridge. Vol. II. (Cambridge: at the University Press, 1893.)

Introduction to the Mathematical Theory of the Stress and Strains of Elastic Solids. By Benjamin Williamson, D.Sc., D.C.L., F.R.S., Fellow and Senior Tutor of Trinity College, Dublin. (London: Longmans, Green, and Co., 1894.)

Theory of Structures and Strength of Materials. By Henry T. Bovey, M.A., D.C.L., F.R.S.C., Professor of Civil Engineering and Applied Mechanics, M'Gill University, Montreal. (New York: John Wiley and Sons. London: Kegan Paul, Trench, Trubner, and Co., 1893.)

PROFESSOR KARL PEARSON is to be congratulated on having brought his task, after nine years' hard work, to a conclusion; and the result would surprise Dr. Todhunter, the original projector of the treatise, could he see the three large volumes, of 2200 pages and 1800 articles, which have grown from the notes he made for a modest history of elasticity. The labour in the preparation of this history must have been enormous; it is the sort of work which is best left for a German to carry out; even the cutting of the pages is sufficient to give the reviewer a headache and mental indigestion.

The assistance of Mr. C. Chree is gratefully acknowledged in the preface, also of M. Flamant, Professor at the École des Ponts et Chaussées, Paris; and the Syndics of the Cambridge University Press are thanked for their financial assistance in the production of the book.

The part relating to St. Venant's writings, which forms the first half of part i, vol. ii., was issued separately some four years ago, and received notice in these columns in the number for March 20, 1890.

It is impossible within any reasonable limits to give an idea of the developments which the subject has received at the hands of the various mathematicians whose work is cited in the pages. A mere enumeration of the principal names—St. Venant, Rankine, Kupffer, Wertheim, Zöppritz, Neumann, Kirchhoff, Clebsch, Boussinesq, Thomson and Tait, &c.—and the list of chief elasticians given on p. xv., will show that the subject has attracted the attention of the principal analysts, who seek for the stimulus and directing influence of real physicial problems.

It must be allowed that the mode of attack of some of these problems is, by reason of their extreme difficulty, calculated to shock the mathematical prudery of certain pure analysts; and also that there is not yet complete accord among elasticians in the results they obtain; but then, to quote Rankine's eloquent words from his "Preliminary Dissertation on the Harmony of Theory and Practice in Mechanics": "The question in Practical Science is—*what are we to do?*—a question which involves the necessity for the immediate adoption of some rule of working. In doubtful cases we cannot allow our machines and our works of improvement to wait for the advancement of science; and if existing data are insufficient to give an exact solution of the question, that approximate solution must be acted upon which the best data attainable show to be the most probable."

"In Theoretical Science, the question is—*What are we to think?* and when a doubtful point arises for the solution of which either experimental data are wanting, or mathematical methods are not sufficiently advanced, it is the duty of philosophic minds not to dispute about the probability of conflicting suppositions, but to labour for the advancement of experimental inquiry and of mathematics, and to await patiently the time when these shall be adequate to solve the question."

So far as concerns the analyst who despises the stimulus that arises from the contemplation of the difficulties of an actual problem, the above advice in Theoretical Science amounts very much to what King Paramount says to the wise men of Utopia—"Go and play in the corner."

A distinguished biologist once said to the editor of the present work, that he had for many years given up endeavouring to ascertain what others had done or were doing in his subject. To follow the great mass of contemporary work meant to expend his time in historical investigations rather than in original research (p. 488). But the present volumes on the history of elasticity will save this expenditure of time, and enable the investigator to start where others have left off.

The curious spiral lines, crossing at 45° the circles concentric with a punched hole, called Lüder's curves, and shown in the frontispiece of part ii., vol. ii., are interesting in confirming W. Carus Wilson's theory, that plastic yielding of an elastic metal takes place chiefly by shearing in directions inclined at 45° to the principal tension. The subject has recently been discussed in the *Comptes Rendus*, by M. Hartman, who brings out these curves more clearly by biting into the steel with acid.

Mr. Love's vol. ii. of his treatise on the mathematical theory of elasticity also completes the work, of which the first volume was noticed in NATURE, April 6, 1893.

A valuable historical chapter begins the volume, but we are puzzled to see the authors of a well-known treatise on Natural Philosophy given as Kelvin and Tait; it might as well be said that the Duke of Wellington commanded the British Forces in the Peninsula.

We learn incidentally that the battle over the theory of the curved plate is still raging, and that the rival theories of Lord Rayleigh and Mr. Basset do not yet meet with the author's complete acceptance; the investigations of Mr. Bryan and of the author on the wrinkling of the plating of a ship, and on the collapse of boiler flues, discussed in chapter xxiii., will do much to bring into focus the real points at issue.

The problem of the spiral spring, with Kirchhoff's kinetic analogue of the steady motion of a gyrostat, is treated in an interesting manner; what is the modification and the kinetic analogue when a helical wire is pushed into a helical tube, of a different curve?

A search through Clebsch's article in Crelle, t. 57, would reveal the clue to the construction of pseudo-elliptic cases of the general tortuous elastica, and thus also of its kinetic analogue in the general motion of a Top. The spherical catenary forms another analogue, and the special pseudo-elliptic case, devised by Clebsch, has been constructed in the series of models of Brill of Darmstadt, so that a string of beads can be placed on a plaster sphere in the appropriate curve.

Mr. Love has devoted careful attention to the examination of different cases of elastic stability, familiar instances of which are to be seen around us, in the waving of the cornstalks in the field, the vibration of a fishing-rod or of the mast of a steamer, or the whirling vibrations of a rapidly rotating shaft; an examination of the period of vibration at once assigns the limits of stability, as the place where the period of vibration becomes infinite, and afterwards imaginary. Thus the farmer can tell by the speed of the waves seen over the cornfield the appropriate time for the harvest.

The treatment of the wire generally, in chapters xiii.–xviii., is complete, and the graphical method of Fig. 30 is very elegant; but the period equation for lateral vibrations,

$$\cos m \cosh m = \pm 1,$$

is improved by being thrown into the equivalent form,

$$\tanh \tfrac{1}{2}m = \pm \tan \tfrac{1}{2}m, \text{ or } \pm \cot \tfrac{1}{2}m,$$

of which the solution by a geometrical construction is readily effected.

We miss the theorems of the elasticity of cylindrical bodies required nowadays in the construction of built-up ordnance and in the wire gun; the practical results can be exhibited very simply by geometrical constructions, merely requiring the drawing of a few straight lines.

Prof. Williamson's treatise of 130 pages will serve as a very good introduction to the study of Mr. Love's work. Great attention has been paid to the notation and nomenclature, and a suggestion of Prof. Townsend has been adopted which seems clear and simple; however, we must not wander far from the system laid down in Prof. Karl Pearson's history.

The work concludes with a description of the models, devised by Profs. Alexander and Thomson, for illustrating Rankine's ellipse of stress. This model was exhibited at the Munich Mathematical Exhibition, where it attracted great interest.

Prof. Bovey's theory of structures will provide for Canadian and American engineers the information and exercises which our engineers derive from Rankine's treatises; but Rankine's very condensed method of reasoning has been expanded for the benefit of the average student, so that the present work runs to over 800 pages.

It would be impossible to give a complete account of all the subjects discussed in the treatise within reasonable limits; but many elegant and novel theorems in the treatment of the theory of the beam and cantilever are to be found, illustrated numerically by an appeal to existing structures of the largest scale; in this respect the American engineer is at an advantage, as more bridge work of great dimensions comes under his notice.

Incidentally, Prof. Bovey provides his engineering students with a complete treatment of statics and dynamics, treated episodically as required for a problem in hand; and each chapter concludes with a large collection of examples, by which the student can test the soundness of his knowledge: these examples are based in general upon existing realities, and form a great contrast to the old-fashioned Cambridge mechanical problems, which were generally geometrical or trigonometrical theorems, with only a slight flavour of mechanics. One or two of these problems, for instance, 47, on p. 220, and 60, on p. 221, will doubtless receive revision in a future edition; and Mr. Macfarlane Gray's elegant constructions for the points of maximum piston velocity may then well find a place in p. 205. As the author writes for engineers, the gravitation unit of force is used throughout, and expressions such as $\frac{Wv^2}{2g}$ and $\frac{Wv^2}{gr}$ abound in consequence.

The confusion introduced by writing M for $\frac{W}{g}$ has been carefully avoided, with all its attempted *a posteriori* explanations; and for this mercy the engineering student owes a great debt of gratitude to Prof. Bovey.

A. G. Greenhill.

LAW AND THEORY IN CHEMISTRY.

Law and Theory in Chemistry: a Companion Book for Students. By Douglas Carnegie, M.A. Pp. vi. 222. (London: Longmans, Green, and Co., 1894.)

THE object of this book is to help fairly advanced students "to recapitulate and co-ordinate the more important principles of chemistry before proceeding to more detailed and advanced works." The book makes no claim to be regarded as a text-book; it is intended to be read along with the text-book, which it is meant to supplement, especially in those parts of the subject that are sometimes overlooked, but are needed, in the opinion of the author, for "a liberal understanding of the science," and in some of those parts that are thought to present especial difficulties. In his preface, the author says that "the seven chapters are really short and independent essays on the subjects of which they severally treat"; he also adds that "the attempt has been made to indicate, with due appreciation of perspective, the trend of modern research in its relation to the science as a whole."

The first chapter, on "Alchemy and the birth of scientific chemistry," is evidently to be looked on as introductory to the study of law and theory in chemistry. The second chapter introduces the student to chemical laws and chemical theories by sketching the "Phlogistic period and the beginnings of chemical theory." The other parts of the science chosen for the display of the workings of law and theory are chemical classification, the atomic theory, isomerism, and chemical equilibrium.

The first and second chapters are chiefly historical; they present in a clear and interesting style the chief features in the development of the general conceptions regarding elements, and changes of properties, from the early days to the overthrow of the phlogistic theory by Lavoisier.

The distinguishing marks of this book are, in my opinion, clearness and suggestiveness. There are plenty of facts, and these are lucidly stated; but when the book has been read, the student is not left fact-stuffed to suffer from mental indigestion, but is incited to intellectual activity and imaginative action. Many works on chemistry convey stale truisms to the student; some preach the kind of truth that makes a man drunk when it is "stagnant inside him." This book suggests more than it asserts, and leaves the reader eager and hopeful. Take, for instance, the treatment of the well-worn subject of mixtures and compounds in chapter iii.: the many forms in which the differences between these classes of substances are stated, oblige the reader to think as he reads; and the admirable way in which illustrations of the differences are drawn from the processes of applied chemistry, give an air of reality to the matter, and withdraw it entirely from the sphere of mere academic discussion. The free use which is made of processes employed in manufactures to illustrate the laws and principles of the science, is much to be commended. The book deals for the most part with those portions of chemistry which require to be treated at once soberly and suggestively; and, on the whole, the author has succeeded in combining breadth of view with accuracy of detail. The chapter on "molecular architecture" well exemplifies the combination of these two qualities. But it seems to me that too much space is devoted in this chapter to Guye's views regarding optical activity. The reader is thrown somewhat off the main track, and he does not readily recover the path. The chapter on the classification of compounds is not, in my opinion, so happy as many of the others. The author seems to be too eagerly pursuing definitions, which Hunter said are the most accursed of all things on the face of the earth. Would chemistry be much better off were perfect definitions of acid, base, and salt to be found? I very much doubt it. Indeed, I think one of the great advantages of chemistry is its freedom from definitions. The last chapter, on chemical equilibrium, enables the careful student to grasp the bearings of the recent work in this department that has already profoundly changed the scope and aim of the science. It is just such an introduction to the study of chemical equilibrium as was wanted.

It would be easy to find fault; it is always easy to find fault. I have preferred to point out some of the excellencies of this work. It is exactly what the title-page describes it—a companion-book for students of chemistry. The want of an index, however, is a serious blemish in the book.

M. M. PATTISON MUIR.

CLIMATE AND LUNG DISEASE.

Aero-Therapeutics; or, the Treatment of Lung Diseases by Climate. By Charles Theodore Williams, M.A., M.D. Oxon., F.R.C.P. pp. 186. (London: Macmillan and Co., 1894.)

THIS work affords valuable information, not otherwise easily attainable, concerning distant health resorts. Modern facilities of locomotion have brought the Andes and the Karoo within easier access than Montpelier or Penzance at the beginning of the Victorian era. The world is now at the feet of the health-seeker, and our ocean steamers and trans-continental railways are day by day carrying an ever-increasing number of convalescents. It is not necessary to have a yacht of our own if we would take a trip to the Fiords of Norway, the Grecian Archipelago, the West Indian Islands, or even to Japan; perfectly appointed steamers, with the comforts of a good hotel and the reliableness of an express train, are ever ready to convey us wherever we may desire.

Dr. Williams, who, as President of the Royal Meteorological Society, might be expected to fill his pages with statistics and tabular statements, gives also his own experiences of travel, together with a sketchy outline of cases of disease distributed amongst the varied and world-separated havens of health. It cannot be doubted that, in chronic disease, the wise selection of health stations is often of vastly greater import than physic or even diet, and in these lectures we find a comprehensive epitome of the claims of the most valuable resorts within our reach.

The description of the Riviera, given as it is by one with ample personal and acquired experience, is a valuable part of the work, and is summarised thus:—"The winter climate of the Riviera is clear and bright, with a good deal of wind but devoid of fog or mist; with a mean temperature of 8° to 10° higher than that of England, with half the number of rainy days and four or five times the number of bright ones."

Should the Riviera prove too stimulating, Ajaccio and Corsica are recommended.

Algiers is too rainy in November, December, and January, though the neighbouring desert converts what would be a moist into a dry climate.

Tangiers combines the warmth of the Mediterranean with the equability of the Atlantic, and is regarded as of value in some forms of phthisis.

Among the many attractions of South California (visited by the author in 1892) are the fruits of South Europe and of the tropics, as well as the apples, pears, and apricots of old England, and strawberries all the year round. In the large towns, however, the noise of the cable and electric cars detracts from the comfort and repose so desirable for the invalid.

The Australian health resorts are hot and dry; in inland regions are suited for young men with agricultural tastes, and threatened consumption.

The value of sea voyages is clearly shown, but the author rightly places in a clear light the cruelty of allowing unsuitable cases to start off alone on a long voyage.

The statistics of sea voyages come out well. It must be borne in mind, however, that patients sent to sea by a discriminating physician, and deemed fit to bear the vicissitudes and uncertainties of the voyage, are, on an average, of a more sturdy and hopeful type than those sent to Madeira, Egypt, or the Riviera.

The voyage to the Cape is described as sedative, that from the Cape to Australia as bracing. The voyage through the tropics to the Cape, followed by residence in the South African highlands, is unquestionably great.

It does infinite credit to Dr. C. T. Williams to have kept notes of his cases so systematically as to be able to arrange them as he has done. Among the interesting conclusions at which he arrives is this: that, in cases of cavity in the lung, the saline atmosphere of the ocean promotes antiseptic changes, and so encourages the arrest of disease.

In chapter iii., "On Barometric Pressure in Relation to Health," an interesting account is given of "Caisson Disease" and "Divers' Disease," due to too sudden exposure to change of atmospheric pressure, when working under deep water, as in the construction of the Forth Bridge. The disease begins with pain and sickness; paralysis of the lower limbs sets in, and death may occur speedily. A pressure equal to that of four or even six atmospheres is thus sometimes borne, and, if gradually attained, is not necessarily injurious.

In the "Compressed air bath," at the Brompton Hospital, the pressure rarely exceeds an addition of 10 lb. to the square inch, or $\frac{2}{3}$ of an atmosphere. Half an hour is given to reach this pressure, it is maintained for an hour, and half an hour is occupied in reducing it to the natural pressure; thus all danger of sudden change is taken away, and it is found that, in asthmatic cases, marked benefit is often secured by the compressed air.

The value of rarefied air, as at Davos, St. Moritz, or Denver is great; the analysis of cases thus treated shows an improvement in $\frac{7}{8}$ of the cases.

"In general results, the English home counties yield the smallest percentage of 'improvement,' and the largest of 'worse.' Next comes the Riviera, not much better; then, with a rise of 12 per cent. 'improved,' are sea-voyages, the percentage of 'worse' being still large. 'High altitudes' win easily in all categories, with their 83 per cent. 'improved,' and only $14\frac{1}{2}$ per cent. 'worse.'"

It must be admitted there is strong evidence in favour of high altitude treatment. The value of such comparisons would be enhanced if we could be certain the patients pursuing different forms of climate treatment conformed to the same rules of hygiene and dietetics.

The concluding chapter of the book, "On the High Altitudes of Colorado," gives the results of Dr. Theodore Williams' recent visit to Denver, and is thus epitomised:

"The climate of Colorado is dry and sunny, with bracing and energising qualities, permitting outdoor exercise daily throughout the year. It has rescued many consumptives from a life of invalidism. Its exhilarating influence may be traced in the wonderful enterprise which the Colorado people have shown in developing their country. Thirty years ago Denver did not exist; it is now a well-built and well-organised city of 150,000 inhabitants."

This short survey must suffice to show that in the work before us facts are collected and arranged which cannot but prove of essential service to the public, and especially to the medical profession seeking the newest information concerning aero-therapeutics.

OUR BOOK SHELF.

Histories of American Schools for the Deaf, 1817–1893. Edited by Edward Allen Fay, Ph.D. In three volumes (Washington, D.C.: the Volta Bureau, 1893.)

Four hundred years ago the great double-continent of America was discovered, and almost contemporaneous with that event was a second discovery of, perhaps, less apparent but no less real importance. In the fifteenth century Rodolphus Agricola recorded the first instance of a deaf mute who learned to read and write, and not long afterwards Girolamo Cardano, a fellow-countryman of Columbus, insisted that the instruction of individuals thus afflicted was possible though difficult, and, going farther, stated clearly the principle on which such instruction depends.

Like many another beneficent discovery, that of Cardano was long in finding recognition, and, although there were isolated cases instructed in Spain, England, Holland, France, and Germany, it was but a century and a half ago that the theory began to be put into practice. Paris claims the merit of giving the first start to the work of benevolence, Abbe de L'Épée there establishing his school in 1760, similar institutions rising in Dresden and Edinburgh about the same time. From such a beginning has sprung a work which, though carried on for the most part in silence, stands foremost in the philanthropic labours of the world—a work that must have brought light and happiness to many thousands of our less fortunate brethren, and been the means of developing valuable intellects which might otherwise have been lost to the community. Some idea of its quiet but steady progress may be gained from the following facts:—In 1836 there were 134 schools for the deaf in the world, in 1883 there were 397, and in 1893 the number had risen to 435. In the United States fifty years ago there were but six schools, in Canada and Mexico none, while in the three volumes before us are the histories of 79 schools in the United States, seven in Canada, and one in Mexico, which instruct, respectively, 7,940, 682, and 34 pupils.

True charity works, as a rule, in the dark; the outside world knows little as to its achievements, and seems to care as much. Here, however, can be learned something of its labours in one direction and its untiring energy appreciated. We hear little about similar institutions in this country, although they certainly exist, and a volume compiled on similar lines to the one at present under review would be welcome to all who have to do with deaf persons. This book, prepared for the Volta Bureau in commemoration of the four-hundredth anniversary of the discovery of America, contains, as we have said, the histories of eighty-seven schools for the deaf and dumb. These histories, which fill three large volumes, were nearly all prepared by the heads of the schools, and, many of them being written by the deaf and dumb themselves, they form a lasting monument of the excellence of the work done. By the help of excellent portraits and photographs the information to be gained is made exhaustive, and the reader becomes acquainted not only with the work done, but with the lives of many of the workers, lives which are worthy of a place among those who truly follow in the footsteps of Him who "made the deaf to hear and the dumb to speak."

P. Macleod Yearsley.

Monograph of the Stalactites and Stalagmites of the Cleaves Cove, near Dalry, Ayrshire. By John Smith, Vice-President of the Geological Society of Glasgow. (London: Elliot Stock, 1894.)

The author has taken advantage of the opportunity afforded by the exploration of a cavern in the Lower Carboniferous Limestone, to study the various forms of deposit produced by the percolating waters. He appears, from his preface, to be under the impression that nothing has been previously written on the subject of stalagmitic deposits, and no references to any earlier literature occur in his pages. This is unfortunate, as a study of the writings of Cöhn, and others who have investigated the action of plants in promoting the deposition of calcium carbonate, would have helped him to solve some of the difficulties he has experienced.

The author classifies the different forms of deposit as "a stalactite" (when it is a pendent icicle-like mass), "a stalagmite" (when a similar mass, rising from the floor), "sheet stalagmite," "wall stalagmite," "tear-bands," "ribs" and "combs," all of which terms explain themselves. He would have done well to consult a botanist before applying the name *Gallionella* to the "confervoid filaments" found in the chalybeate water.

The 18 pages of text are illustrated by 36 plates, including 107 figures, roughly drawn, but characteristic. They show most of the common and seemingly capricious forms assumed by stalagmitic deposits. Certain of the observations are somewhat trivial, such as the reference to the "profile of Gladstone" in the centre of one stalactite, and the comparison with the "hind-quarters of an elephant" in another. The author has not availed himself of the assistance which would have been obtained by examining thin sections of the deposits under the microscope.

Botanical Charts and Definitions. By Miss A. E. Brooke and Miss A. C. Brooke. (London: G. Philip and Son, 1894.)

IT is notorious that examinations in elementary practical chemistry are frequently little more than tests of capacity for remembering analytical tables. This little book will serve the same purpose in botany that tables of analysis do in chemistry. In thirty-four pages the authors summarise the work required for the South Kensington (Elementary) and the Oxford and Cambridge Junior Local Examinations in Botany. Charts and definitions are given of sub-kingdoms, classes, orders, and floral whorls; of root, stem, leaf, inflorescence, and fruit. These, with definitions of terms of cohesion and adhesion, enable the student to classify a plant on the lines of the table of analysis with which the book concludes. We are afraid that the compilation will induce cramming for the examinations for which it is intended; but if this be avoided, and the charts are only used as supplementary to oral teaching and demonstration, they will help students to acquire a clear view of the relation and arrangement of the parts of a plant.

The Great Globe: First Lessons in Geography. By A. Seeley. (London: Seeley and Co., 1894.)

A SIMPLY worded and instructive primer of geography, printed in clear type, and illustrated with numerous cuts and diagrams. The book does not merely consist of lists of lengths of rivers, heights of mountains, populations of cities, and similar statistics, but is a compendium of facts calculated to interest the young reader, and, at the same time, to add considerably to his knowledge. There is a little too much of the goody-goody style of writing about missionary enterprises, but that is the only point we are inclined to criticise. Tales of the torturing of converts and murdering of missionaries are apt to create in children a morbid state not at all desirable, and they can very well be omitted without making a work on geography any the less interesting.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Trituberculy and Polybuny.

IN all the speculations on the original type of the mammalian molar, beginning from Rütimeyer (1863), we find that a simple cusp or cone is, with perfectly logical reasoning, considered to be the primitive form from which all others are derived. The error, fatal in its consequences, consisted in the fact that all the teeth possessing such a simple form, whether recent or fossil, high or low in the system, have for a long time likewise been considered to be primitive; so that the only problem remaining to be solved, seemed to be to trace back the intermediate stages between the more or less complicated molars of recent mammalia and the "simple reptilian cone."

The cretaceous deposits having long failed to throw light upon the obscure relations between the comparatively scanty mesozoic mammalian teeth and the tertiary and existing forms, we were reduced to make the best of the oldest tertiary faunas. It is from the discovery of the lower eocene Puerco beds that the establishment of the tritubercular theory dates, Cope having traced the superior molars of placentalia to a "tritubercular," and their inferior molars to a "tubercular sectorial" type, both of which he found to be of overwhelming preponderance in the Puerco beds, the oldest known deposits of tertiary mammalia.

I have elsewhere [1] raised objections to the inferences drawn from the Puerco fauna, and now one of the most strenuous defenders of trituberculy has, with his own hands, undermined the stronghold of the theory, by denying the Puerco fauna the claim to be in ancestral relation with later faunas, for he considers this old fauna to be merely "an independent radiation of placentals, like the Australian radiation of marsupials." [2]

Owing especially to the perseverance of Prof. Marsh, cretaceous mammalia were discovered in due time. The principal characters of their molars can be grasped at once by a single glance at the two beautiful and highly instructive plates published by Prof. Osborn, in December last. [3]

Whoever examines with an unbiassed mind the molars figured in the latter plate, must receive the impression that the term "trituberculate" applied to them can stand only upon the *lucus a non lucendo* principle. Speaking for myself, I cannot consider to be tritubercular, molars which consist of from five to ten tubercles; therefore the teeth represented on Pl. viii. in my opinion are polybunous (multitubercular), as well as those of Pl. vii., though in a different manner. Prof. Osborn informs us that the former "include a variety of forms *just emerging from the primitive tritubercular stage*" (the italics are mine), "lending overwhelming proof, if any more were needed, of the unity of origin of the molar types of the higher mammalia, from a tritubercular stem instead of from a multitubercular, as Forsyth Major has suggested." [4] I suppose that by "primitive tritubercular molar" we are intended to understand a molar which is in fact tritubercular *sensu strenuo*, namely, composed of no more and no less than three cusps arranged in a triangle; but I fail to discover in the pages which follow the above quotation, the proofs for the various assertions it contains.

In order to explain why for such complicated molars as those on the precited Pl. viii, the designation *tritubercular* is maintained, it must be recorded that this name is said to be meant to imply that the two outer cusps (paracone, metacone) and the single inner one (protocone) in upper molars, as well as the three anterior cusps (two inner and one outer) in lower molars, generally the best developed of all the cusps, are to be considered as typical, primitive; whilst the remainder, namely, the intermediate and all the others of superior molars supposed to play a subordinate part, as well as those composing the heel of inferior molars, are considered to be later additions to the crown.

It has not, however, been shown, and I deny, that the predominant cusps have always been such, and that the intermediate ones, as well as the inferior heel (talonid), are of later origin than the former, and have always been in a subordinate position with regard to them. Without searching farther than what is to be seen on Pl. viii., I state that the figures F are not in favour of the assumption that two of the supposed primitive cusps, the paracone and metacone, are always the best developed; externally to them, we have here two superadded cusps, the "parastyle" and "metastyle," [5] which are in a much better state of development than the reduced two "primitive" cusps. The latter, as the other figures of the plate suggest, may only gradually have acquired their predominance by supplanting the "styles," which in other patterns have become more or less obsolete. On the whole, the superior molars of these "tritubercular" cretaceous mammalia can best be compared with those of *Didelphyidæ*, as was done by Marsh, or to speak more guardedly, rather with the *Polyprotodontia* in general, the principal differences between the two consisting in the fact that the cretaceous forms are more complicated.

From the seemingly subordinate condition of the "heel" of lower molars, as compared with their anterior portion, it does not follow that the former is of later origin; the difference between the two in vertical extension obviously depends on one or more of the cusps of the so-called trigonid having secondarily become more elongated, for brachydonty and not hypsodonty is the original condition. If the heel were a later addition to the

[4] *l.c.* p. 32.

[5] Of their homologues, by the way, may be found traces in the molars of many existing mammals: see *e.g.* *H. Winge*, Om Pattedyrenes Tandskifte 1882, Table III

crown, we ought to find it in a more or less incipient stage in such remote forms as the cretaceous mammals, whereas the very reverse is the case, as admitted by Osborn himself;[1] in them the heel is mostly better developed than in such of later forms, marsupial or placental, which morphologically most closely approach them.

So that, in conclusion, the superior as well as the inferior molars, far from "just emerging from the primitive tritubercular stage," are more remote from it, both morphologically and chronologically speaking, than the tertiary and living forms.

According to the tritubercular theory, the so-called quadritubercular superior molars (composed of four principal cusps), were derived from the tritubercular pattern by the addition of a postero-internal cusp (hypocone). In order to test the value of this hypothesis, let us see what relation the cusps of the superior bear to those of the inferior molars. In a "quadritubercular" mammal, *e.g. Erinaceus*, the antero-internal cusp (protocone) of a superior molar works as a pestle in its mortar, below which is the posterior valley, formed chiefly by the talonid, whilst the hypocone functions in a similar manner in the hinder molar's anterior valley, formed by the trigonid. According to the theory, the superior "talon" (hypocone) and the inferior "talonid," are later additions to the crown: from this it would follow that the phylogenetically older of the two superior pestles, the protocone, was preformed before its mortar, and *vice versâ*, the posterior of the two mortars was in existence long before its pestle, the hypocone; so that the second pestle and the second mortar would make their appearance only in a distant future or never appear at all, the function of *their* respective mortar and pestle thus remaining for ages sinecures. The following reasoning, which appears to me more logical, may, however, be not unworthy of consideration. Starting from the assumption that the more complicated pattern, in our special case, the "quadritubercular" molar, is primitive as compared to the tritubercular, we had originally, viz. in the ancestral form of tritubercular molar, two superior pestles working in the two inferior mortars, as in the case of the recent *Erinaceus*. According to this view, the tritubercular type is derived from the quadritubercular, by the gradual suppression of the posterior pestle (hypocone), *pari passu* with the reduction or suppression of its mortar, the anterior valley, formed by the trigonid.

The impropriety of the term *tritubercular*, as applied to many patterns which in reality are multitubercular, is apt to create not a little confusion. Partially to this circumstance I ascribe some obviously contradictory statements to be met with in Mr. Goodrich's recent letter in this journal: *On the tritubercular theory*,[2] as well as in a previous paper by the same author,[3] to which he refers us for further information as to his views on the primitive mammalian molar.

On looking at the conclusions contained in the appendix ("On the primitive mammalian molar") to Mr. Goodrich's valuable paper on the mammalia from the Stonesfield slate, I felt gratified to find that he considers it extremely probable that the molars "of the ancestors of both Monotremes and Ditremes were of an indefinite multituberculate pattern," because I had for years advocated the view that the mammalian molar is derived from a polybunous form, a view in favour of which I have reopened the discussion on a recent occasion.[4] So, I naively believed at first that it was for this reason my paper was recorded in Mr. Goodrich's List of References. My gratification was, however, considerably abated on finding that I am merely alluded to in a footnote, where I am stated to have expressed views which are the very reverse of those which every attentive reader will find in my paper to which he refers.

In his letter on the tritubercular theory, Mr. Goodrich states:—"There is much evidence for the view that the upper molars of the pro-mammalian ancestors were of the tritubercular, and the lower molars of the tubercular-sectorial types; in fact, I think, we cannot do better than accept Prof. Cope's generalisation, if not as a definitely established theory, at all events as an excellent working hypothesis . . . that the superior molars of both ungulate and unguiculate mammalia have been derived from a tritubercular type; and that the inferior true molars of both have been derived from a tubercular-sectorial type."

[1] H. F. Osborn, "Fossil Mammals of the Upper Cretaceous Beds." (Bull. Am. Mus. Nat. Hist. v. [illegible], p. [illegible]
[2] NATURE, May 3, 1894, p. [illegible]

[4] P. Z. S., [illegible], pp. [illegible]

I would put the following questions:—(1) How does this last statement agree with the one above quoted from Mr. Goodrich's former paper, referring to "the ancestors of both Monotremes and Ditremes?" For these alone can be alluded to by the term "Pro-mammalia." (2) How does the acceptance of Cope's "generalisation," quoted by Mr. Goodrich, and which is the very quintessence of the tritubercular theory, agree with his criticism of this same theory in the beginning of his paper, where he exclaims, "Never before have its weaknesses been so obvious, its errors so plain"?

I leave Prof. Cope to reply to Mr. Goodrich's implication, that he extends the tritubercular and tubercular-sectorial types to the molars of the "Pro-mammalian ancestor."

C. I. FORSYTH MAJOR.

S.W., May 10.

The Determination of Latitude and Longitude by Photography.

LATITUDE and longitude may be determined on shore with considerable accuracy by means of an ordinary photographic camera; and this method will, I think, prove useful for several reasons. The observation part of the business, which consists in taking the photographs, is separated from the measuring and calculating part, and may be performed by different persons at different times and places. For taking the photographs no scientific apparatus is wanted besides the camera and a watch, the latter to measure intervals of not more than a few hours with an accuracy of a second or so. Anyone may easily be instructed to take the photographs, as no mathematics and very little astronomical knowledge are wanted, only the measuring of the plates and the calculation requiring some scientific training.

I will first describe the determination of latitude. The general plan is well known to astronomers; it is here only adapted to the use of an ordinary camera.

If the lens is directed to the zenith, and the stars are allowed to draw their trails over the plate, it will evidently be possible to determine the latitude from the plate, provided the point of the plate is known which corresponds to the zenith. Now this point may be found in the following manner:—Let the camera float and be turned while floating. It will turn exactly round a vertical axis. The zenith will then be the only point of the sky whose corresponding point on the plate will remain unaltered. The way I arranged the experiment was this:—I placed the camera in a rectangular tin box, lens upwards, fixing it firmly by wedges. The box was ballasted so as not to be capsized when floating. Photographic plates will do as ballast, but it is better to take a plate of lead, which brings the centre of gravity lower down, and thereby increases the stability. I then filled a second rectangular box, somewhat larger than the first, with so much water, that when the first box floated in it, the rims of both boxes were in the same plane. Two opposite points on the rim of the inner box were fastened to the rim of the outer one, each with two strings, forming an obtuse angle. This prevented the inner box from turning during an exposure. The strings need not be tight, as the forces they have to resist are small.

Having placed the whole apparatus on a firm table in the garden, I removed the cap from the lens. As the trails of brighter stars may generally be measured more accurately than those of faint ones, I exposed long enough for a star of the third magnitude to pass sufficiently near the zenith to appear on the plate. After replacing the cap, I turned the whole apparatus carefully through an angle of 180°. For this purpose I had pressed a row of flat nails into the board along one edge of the outer box, and having turned it, I let the same edge of the box touch the row of nails from the other side. Before again removing the cap, I waited about three minutes to allow the oscillations of the water and the inner box to subside. The second exposure I made long enough for the image of a star of about the third magnitude to be thrown on the plate during the star's culmination near the trail of the star of the first exposure. In order to see that it is possible to determine the latitude from this plate, imagine first the trails of the two stars to touch. That would be a proof that they had passed the meridian on different sides, but at the same distance from the zenith. The mean of their declinations, taken from the almanacks, would therefore be equal to the distance of the zenith from the equator that is equal to the geographical latitude. If, on the other hand, the trails of the two stars do not touch, their shortest distance may be measured. Now the distance of the trails of any other two stars, which appear during the same exposure, will, when their declinations are taken from the almanacks, enable us to calculate what angle approximately corresponds to a certain length, the approximation being close for small lengths. Thus we are enabled to calculate what the declination of the second star would have been, if its trail had touched the trail of the first star, and thus the latitude may be found.

Generally there will be the trails of several stars in both exposures available, so that one plate will allow of several determinations, and thereby of an elimination of errors. The results of seven plates, taken on different nights in my garden in Hannover, Germany, will give an idea of the accuracy.

	52° 22'·50
	52° 22'·56
	52° 22'·47
	52° 22'·78
	52° 22'·90
	52° 22'·93
	52° 22'·90
Mean:	52° 22'·72 (mean error of a single plate = 0'·2).

According to the *Preussische Landesaufnahme* the latitude should be—

52° 22'·84

The same plate may also serve to determine the deviation of a watch from local mean time, if the time of the watch is noted each time the cap is withdrawn and replaced. Imagine, first, that a star was photographed whose declination coincided with the geographical latitude, and imagine that the box could be turned infinitely quickly without any oscillations being started. If we then found that the two trails of the star corresponding to the two exposures touched each other at one end, the end corresponding to the moment the box was turned, we might conclude that the star at this moment was in the zenith. For there alone the image of the star would remain unaffected by the turning of the plate. Now, we can calculate from the almanack the local mean time of the moment when this particular star culminates, and this would give us the deviation of our watch from local mean time. Imagine now the box had not been turned at the moment the star culminated, but, say, ten minutes later. Then the two trails would not have one end in common. The ends corresponding to the moment when the box was turned, would be on opposite sides of the zenith at the same distance from it. Now we should be able by the length of the trails to determine what interval of time corresponds to a given length, and so the plate would show us that the culmination of the star took place ten minutes before the box was turned. If the box is not turned very quickly, the interval after replacing and before removing the cap must be taken into account. But it is evident that we can calculate where the ends of the trails would have been if the box had been turned infinitely quickly. If there is no star that passes exactly through the zenith, we must take one that passes near the zenith. This will also do. By the ends of the trails we find which point of the plate corresponds to the zenith, and at the same time we can, by the trails and their ends, find out the line representing the meridian. This gives us the necessary data for finding the deviation of our watch from local mean time. For a star near to the zenith a small error in the direction of the meridian will make very little difference. I have spoken of the ends of the trails as a means of determining local mean time only for the sake of simplicity. It is far preferable to proceed differently, and to interrupt the first and the second exposure a number of times, thus causing as many interruptions of each trail. Five seconds or less will do very well for the length of an interruption. These interruptions are preferable to the ends, because they are symmetrical, and their middle can with more accuracy be brought under the cross-hairs of a micrometer. My lens having a focus of about 24 cm. made one minute about equal to 0·6 mm. on the trails of stars that culminate near the zenith. With a micrometer it is not difficult to measure exact within 0·01 mm. which is equivalent to one second of time.

If by the help of a chronometer Greenwich mean time were known at the place where the photograph was taken, the longitude would thus also be determined. But a chronometer can be dispensed with if another photograph is taken of the moon and the stars. For this purpose the camera is taken out of its box, directed to the moon, and fixed as firmly as possible. A number of instantaneous photographs of the lunar disc are then taken, all on the same plate, at intervals of not less than two minutes, to prevent the images from overlapping. The camera must be touched as little and as gently as possible, so that it may remain in the same position. After a number of exposures, say six or eight, the camera is shut until the moon has quite gone out of the field. The cap is then again removed, and the stars draw their trails over the plate, interrupted here and there, the lens being now and then covered for five seconds. If the local mean time of the instantaneous exposures of the lunar disc and of all the interruptions is known, the Greenwich mean time may be found from the plate. One may apply three different methods. Either one can determine the right ascension of the moon or the declination, or one can measure lunar distances. I have tried all three, and prefer the second, provided the moon is not near the maximum or minimum of her declination. For the slower rate of change of declination is made up by the greater accuracy with which it can be measured, on account of the trails being lines of constant declination. Each image of the lunar disc allows a separate determination, so that the final value is the mean of a number of determinations. (For the details of measuring, see my article in the *Zeitschrift für Vermessungswesen*, August 1893.)

The results of one plate for the difference of Greenwich mean time and local mean time were by the three methods—

	39·1 minutes
	39·1 ,,
	38·6 ,,
Mean	38·93 ,,

while the true value is 38·943. This very close coincidence must be considered accidental. But I think one can well rely on the determination from one plate not differing more than 0·2 minute from the real value. When exposing for a longer time, the dew will sometimes condense on the lens, and render it opaque. To prevent this, I place a screen before the lens with a hole in it a little larger than the lens. The screen keeps the lens from cooling below the temperature of the surrounding air, and thus removes the cause for the condensation of dew. When determining the latitude the screen was arranged as a lid of the outer box, and served at the same time to protect the camera from gusts of wind. C. RUNGE.

Technische Hochschule, Hannover.

Sodium and Uranium Peroxides, &c.

IN your notes of May 17 you give an account of work done by Prof. Poleck on the action of sodium dioxide on the salts of various metals, from the *Berichte* of May 8.

Some of this work has been already recorded by other observers who used either sodium dioxide or hydrogen dioxide in alkaline solutions.

In the *Journal* of the Chemical Society, 1877, pp. 1-24, and pp. 125-143, I gave papers on the reactions of hydrogen dioxide, and described its action on uranium salts both in acid and in alkaline solutions. I do not wish, however, to say anything on a mere question of priority, but simply to point out inaccuracies in the formulæ given in NATURE from the *Berichte*.

Prof. Poleck gives for sodium peruranate the formula $Na_4U_2O_8 . 8H_2O$. This either involves the use of the old atomic weight of uranium, half of that now adopted, or it means that his salt is exactly like that prepared by me in every respect, excepting that it contains twice the proportion of uranium. Assuming the atomic weight at approximately 240, the correct formula of sodium peruranate is $Na_4UO_8 . 8H_2O$ (*Journal* of the Chemical Society, 1877, p. 139).

I also showed that hydrated sodium dioxide is readily obtained on adding alcohol to mixed sodium hydrate and hydrogen dioxide solutions (p. 125), so that the materials used by Prof. Poleck and myself are practically the same.

The uranium compounds are interesting as examples of a special highly oxidised type (see Mendeléeff's "Principles of Chemistry," vol. ii. p. 244), also as throwing light on the nature of certain analogous but unstable bodies, such as perchromic acid. (*Journal* of the Chemical Society, 1877, pp. 7-8). This was further confirmed by Dr. C. Haussermann last year, who has isolated a definite crystallised sodium perchromate, as described in the *Journal fur Praktische Chemie*, quoted in NATURE in the notes given July 27, 1893, p. 300. THOMAS FAIRLEY.

Cataloguing Scientific Papers.

THE recent circular issued by the Royal Society anent the indexing of scientific literature affords me a pretext for suggesting in your columns a reform which I have long thought to be urgently required. It is that henceforward all scientific publications should be issued in only one volume per annum—in parts, if necessary, but consecutively paged and with only one index—and that this volume should be primarily referred to by the year of its publication, *not* by its number since the first issue of the publication. Two advantages would accrue from this system. In the first place, the date of all quoted work would be fixed; in the second place, the finding of the abstracts of papers published elsewhere, printed in the journals of scientific societies, would be rendered more easy. A little reflection will show that these benefits are not trivial. For example, suppose an author refers to a paper by Smith published in NATURE, vol. xi. I have not (may I be pardoned for saying so!) the slightest idea when NATURE was first issued, nor do I remember whether one or two volumes of this periodical appear per annum. I am therefore totally in the dark as to whether Smith's work is one year old or twenty years old, and consequently I am ignorant whether he is likely to have used the most modern appliances in his research, and whether he is likely to have been contradicted by subsequent observers. Again, I am referred by an author to a paper by Schmidt, in the *Berichte* of the German Chemical Society, vol. xx. Not possessing this journal, I hope to be able to find an abstract of the paper in question in the *Journal* of the Chemical Society, to which I subscribe; but as I have no notion in what year vol. xx. of this *Berichte* was published, I have to search through numerous indexes in order to find the abstract. A search for previously published work is already sufficiently difficult to cause many to shrink from the task; ten years hence it may be expected to be the most laborious and thankless work which the investigator has to perform. A. G. BLOXAM.

May 19.

Clavatella Prolifera.

THIS hydrozoan may be added to the list of the Jersey marine fauna. It occurs in rock pools on the higher littoral between the Point des Pas and Gorey, and probably at other places round the coast. I often found three or four colonies in one small pool; but the number of polypites in a colony was very small—generally two or three, rarely four, and only in one case five. The stolon runs along in the chinks of the Melobesia that grows over so many of the pools, hence it is not an easy matter to obtain specimens there. The walking-buds, however, were fairly plentiful.

May I ask if any correspondent of NATURE has ever seen the walking-bud of *Eleutheria*, in which both extremities of the bifurcated arms are said to consist of a ball of thread-cells?

May 22. HENRY SCHERREN.

THE DESTRUCTIVE EFFECTS OF SMALL PROJECTILES.[1]

THE effects of small projectiles when driven at high velocity through the tissues of the brain have always excited the deepest interest, for very obvious reasons.

This interest must always be two-sided, namely: (1) Physical; (2) Pathological; and it is upon these two points of view that I propose to speak to you this evening.

Conceive a cylindrical bullet with a conical head flying through the air some ten or fifteen times faster than an express train.

We have now to study what it is doing in its aerial flight, and what will happen when that terminates by the projectile striking both hard and soft substances.

This embodies the matter for the purely physical side of the work.

But imagine, further, that the hard and soft substances just mentioned are the skull and brain respectively, what will happen then?

This is the pathological part of the question, and it is one of the greatest moment; for whereas it is true that a few persons do survive being shot in the head, the large majority die; and it is my object to show you how a combination of physical and pathological experiments has revealed the reason why the majority do die, and revealed it, fortunately, so distinctly as to suggest means for warding off the fatal result.

(1) *Physical Considerations.*—First take the case of a bullet flying through the atmosphere. Here in this extremely beautiful photograph, kindly lent me by Prof. Boys, you observe that the bullet drives before it a wave of compressed air. Now this compressed air-wave is what is popularly called the wind of the shot, and to it used to be ascribed by military surgeons a certain proportion of deaths. The origin of this theory is difficult to discover, as the only case I am aware of in which the *post mortem* examination did not reveal hæmorrhage, fracture, &c. indicating that the shot had actually struck the body (though without injuring the highly elastic skin) is the instance given by the great Russian military surgeon Pirogoff, in his interesting surgical experiences of the Crimean war. Even this instance finds *à priori* a more reasonable explanation in syncope, and we shall see directly that the wind of the shot not only cannot, under any circumstances, kill a man, but also that its energy is far too slight for it to have any destructive effect whatever. It is rather curious to find that but few attempts have been made directly to estimate the wind of the shot, and those by Pelikan and others are only for large shot and by too coarse methods to be applicable in the case of a bullet, as the following experiment shows.

An extremely light vane of paper carrying a delicate mirror is suspended to a cocoon fibre, and carefully protected from currents of air in the room. A very gentle puff causes the vane to fly out most vigorously, yet we shall find that the ·380 bullet moving a thousand feet a second may pass within eight inches of it without causing the least deviation of a ray of light reflected from the mirror. It is only when the bullet passes within an inch or two of the edge of the vane that there is some slight rotation. The ·303 magazine service rifle, with a velocity of twice that of the larger bullet, produces little more than the same result. It is therefore obvious in this case that the far higher velocity is more than compensated for by the lesser sectional area of the projectile displacing the air. Although there was no proof of much displacement of the air, it was pretty generally held that when the bullet entered any substance the compressed air driven before it exercised an explosive effect. This opinion was more particularly supported by the Belgian physicist Melsens, who actually described it by the term "projectile air." The matter was taken up from the point of view of pure physics, and Magnus demonstrated that if a body like a bullet entered water, *e.g.* in falling the funnel which the displaced water makes in the axis of the body as soon as that is fully immersed, entangles air, and that it is this air which is carried by the body into the fluid, rather than that any air is forced in in front of the bullet. In answer to Magnus, Laroque invented the following ingenious experiment. He allowed a long body, incapable of wholly sinking, to drop into the water, and then found that there was air driven in in front of it; while, by the nature of the experiment, he had, of course, excluded the possibility of any air following the base of the projectile. I have repeated all these experiments (employing in Laroque's a slender rod of wood) and found that while his contention that air is driven in front of the bullet is completely substantiated, yet Magnus' observation is so far correct that air is also

[1] A [illegible] at the Royal Institution [illegible], by Prof. Victor H[illegible], F.R.S.

driven in after it, the fact being that the two conditions are not opposed but simultaneous. Magnus' view was further supported by the adverse criticism of the theory of projectile air of the celebrated French artillerist Morin, which criticism amounted to this, that when a projectile was directed against a *solid* body it must necessarily follow that so elastic a substance as air should be completely reflected from the surface. I should like to draw your attention to this word *solid*, because I believe that in that we find the key to the difficulty, and the apparent paradoxes presented to us are to be explained by the fact that the results are wholly dependent upon the simple question of the relative viscosities of the substances entered. To solve this, I employed the same falling bodies, and examined their entanglement of air in water and glycerine respectively, and found that whereas in the case of water, Laroque's non-floating rod drove air in front of it as well as probably at the side, yet when the same rod was caused to fall into glycerine of high concentration there was no air in front, but air-bubbles could be seen clinging to the sides of the rod. Further, in glycerine the entanglement of air in the funnel formed by the base of the bullet, as described by Magnus, was very striking. It appeared to me that whatever air was driven in front of it was wholly reflected by the sufficiently viscous fluid, and hence it must be, *à fortiori*, still more completely reflected from the surfaces of hard and soft solids like the skull and brain respectively.

To sum up, the so-called projectile air can have no real bursting effect, since, as I have demonstrated, in the first place it exerts very feeble pressure, as tested on a delicate vane, and in the second place it is certainly easily reflected from surfaces of but moderate density.

The Influence of Rotation produced by Rifling.—It is commonly thought that the spin of the bullet communicated to it by the rifling of the barrel, and which is very great, causes a considerable amount of the disturbance created in the interior of moist substances, which is usually spoken of as the bursting or explosive effect. Kocher thought that this would not be appreciable, and that the rotatory movement would only cause the displaced particles to take a course tangential to the surface of the bullet rather than perpendicular. Although the smooth surface of the bullet of course adds force to the idea that its rotation is not very effective, it is obviously a matter of both interest and importance that the matter should be more closely studied. Colonel Henrad made plaster casts of the tracks of shots, and obtained distinct spiral markings indicative of the rotation in question. Acting on this suggestion, it was easy to institute a series of experiments of the following kind. Pure modelling clay of firm consistence (for the influence of the water present *vide infra*) was rendered homogeneous by kneading, shaped into square blocks of varying length, and supported in a hard flat surface or in a box, the ends being open. The cavity made by the bullet in entering and traversing the mass was then filled with liquid plaster-of-paris, and a cast obtained. Examples of such casts are before you, and they completely display the rotation in question.

The first point which has to be borne in mind is the relation of the rotation to the projection or forward movement of the bullet. In passing through a body of little resistance like the air, it is clear that for every given unit of distance travelled, the displacement evoked by the rotation must be something very small, because although the bullet turns one and a half times in traversing the barrel, that is nearly a yard in length consequently, so far as the rotation is concerned, that for a unit, say one inch, of the flight of the bullet would be extremely small, namely about one-twentieth of the circumference of the bullet, which, roughly speaking, would be (for the ·380 bullet) about one-twentieth of an inch, the insignificance of which is obvious. The matter, however, assumes a somewhat different aspect when a bullet is engaged in a solid substance through which it is forcing its way with rapidly diminishing velocity. In such a case, where the projection journey of the projectile is quickly coming to an end, it becomes of special importance to see what is becoming of the factor of rotation. The plaster casts obtained in the manner indicated show clearly enough the interesting fact that the rotation persists to the end, when the bullet has simply taken its course through the atmosphere, and then entered the soft clay. Further, the casts also show what is a necessary deduction from our earlier considerations on this matter, namely, that as the rotation is preserved till the end of the trajectory, the twist is proportionately more pronounced as the forward movement is lost.

It is for our present purpose important to see whether the rotation is well marked when the projectile is completely deformed. To examine this point a new series of experiments were undertaken, in which the bullet was first caused to penetrate a flat bone before entering the clay. It is very clear that the rotation is still present. In discussing this question I have left unnoticed the fact that owing to the resistance of a body like clay, the cohesiveness of which of necessity varies slightly from point to point, there will be a great tendency for the bullet to change its direction, more especially as the base is heavier than the apex, and to this change of direction must be attributed in part the change of surface simulating the rotation effects due to the rifling. The two conditions, however, can be distinguished readily on careful examination.

So far as destructive effects in the brain are concerned, it is therefore clear that relatively little is to be ascribed to rotation.

Projection Destructive Effects.—The destruction by the bullet moving forward through a solid body is the most important matter for us to consider. There are two sets of factors determining the degree of destruction in any given substance.

(1) Factors due to the bullet.

(2) Factors due to the *physical constitution* of the solid.

(1) Factors due to the bullet. So far as the projectile is concerned, the chief considerations are (*a*) its momentum; (*b*) its sectional area; (*c*) its becoming heated.

(*a*) *Momentum.*—Although it will of course be generally understood that the greater the velocity the greater the damage for the same weight of shot, still, in connection with the small-bore service rifles of the present day, some seem to think that the small bullet, by virtue of its travelling at a great pace, would pierce the tissues without causing much general damage. The fallacy involved in this belief we shall see directly; but a single glance at the casts arranged in order of the velocities of the bullets, shows immediately the unreality of the notion. In every case the particles of the substance are hurried forward (particularly evident in the casts before mentioned) in front of the bullet, and thus by increasing the size of the moving mass such particles practically constitute a larger projectile. Much destruction is due to this, as Delorme has more particularly demonstrated in the well-known case of firing a bullet into a book, wherein one may see the laceration of the pages successively increased, although the momentum of the bullet is steadily diminishing and in proportion to the increasing laceration, so discs of increasing diameter are found in the cavity, having been cut from the preceding pages. The hurrying forward of the particles is very beautifully shown by Prof. Boys in his photographs of the débris of glass plates after a bullet has passed through them. In one case a large fragment of glass is shown to be moving parallel to the bullet, *i.e.* with the same velocity. This question of accessory damage is of much importance to the pathological problem how much damage is effected in the brain. I have found discs of bone forced through the brain, such discs (as will appear directly being larger than the projectile itself. Small fragments are also hurried forward with the same velocity as the bullet, as these casts show, the plaster method thus confirming Prof. Boys' photographic record.

(*b*) *Sectional Area.*—From what has just been said, it is plain that the crushing effect of the bullet will be greatly increased if its diameter is enlarged: and it is understood that this was the reason why the Duke of Wellington opposed the introduction of the smaller bore weapon for the old musket called "Brown Bess." But few words, therefore, are requisite in dealing with this point. I wish, however, to draw attention to an extremely common result of the employment of leaden bullets, and a result which is wholly dependent on the principle just enunciated. In a photograph of the penetration of an iron plate by the magazine rifle bullet, it will be noticed that the diameter of the holes is almost twice that of the bullet as it leaves the muzzle of the rifle. When the bullet is picked up, however, after it has passed through the plate, the reason of this seeming absurdity is at once recognised, for the bullet is compressed into a hard mass of lead and nickel by its first impact on the front of the plate, of the size of the hole shown. It is important, therefore, for the military surgeon to consider what proportion of the damage is due to deformation of the projectile on its striking the body, but the sectional area demands very little attention when compared to the velocity as a source of destruction.

(*c*) *Heating.*—The notion that a bullet produced some of its destructive effects in consequence of its being raised in temperature, as a natural result of some of its momentum being converted into heat, has always been before scientists ever since the invention of fire-arms, and endless have been the suggestions put forward to support this idea. I am not going to waste your time on the matter because, in spite of the plausible papers of Hagenbach and Socin, there are certain facts plain and simple enough which, to my mind, completely dispose of the notion put forward by those authors, namely that the bullet undergoing deformation on striking a hard substance like bone becomes heated so intensely that it partly fuses. The simplest observation of all is that, I think, made by von Beck, and which I have often confirmed, namely that a bullet, though completely deformed by impact, may enclose a hair or piece of wood without these being in the least degree altered by heat; while as for its being heated in the barrel, &c., that cannot amount to 40 C., for Messner has shown that a bullet traversing dirty clothing carries with it living microbes, and deposits them in the object it strikes, still in a living state, so that they grow therein if the soil is a suitable one; and these observations have been fully confirmed by Delorme and Laveran. It is to be hoped that we have heard the last of this unquestionably exaggerated idea of the heating of a bullet.

(2) Factors due to the physical constitution of the solid.

We now enter upon the discussion of the most interesting of all the physical considerations determining the well-known bursting effect which a bullet produces on certain substances, *e.g.* clay, brain, &c., while simply perforating others, *e.g.* wood, iron, &c. The reason why a bullet behaves apparently quite differently when it is forcing its way through solids of different kinds, has been, as a matter of fact, answered ever since 1848, when Huguier made some remarkable, but little known, researches of the effects of bullets on soft tissues, after he had observed the results of the wounds inflicted in the fighting in Paris in 1848. It will be remembered that in that struggle, as in others, the appearance of bursting within the tissues was very noteworthy, and gave rise to the notion of explosive bullets having been employed by the combatants contrary to the received opinions of international comity. The whole question is a perfectly simple matter, and resolves itself merely into the proposition that destructive effects vary in direct proportion to the cohesiveness, *i.e.* the fluidity of the particles composing the body. Ever since the observations of Tresca, Roberts-Austen, and others, we have been made familiar with the phenomenon of the flow of metals when these are subjected to powerful pressure, and the mode of the displacement of the particles has always been compared to the displacement observed in viscous fluids. The extreme case in which fluidity is least present is that of the substances which we term brittle. In these, while much pulverisation occurs, the displacement of particles laterally is very slightly marked. Contrast the penetration of an example of this class, namely a flat, thin bone, with the effect produced on a more or less plastic solid like brain, and a striking difference presents itself, for whereas the bone is simply penetrated in the long axis of the bullet, the brain is thrown aside in every direction. Huguier made observations on certain dead organs, *e.g.* lung, liver, &c., and suggested that the reason why there was so much lateral disturbance was that the tissues contained water in large quantity, and that the energy of the moving projectile being imparted to the particles of water, caused the dispersion of these in a hydrodynamic fashion. Kocher, in 1874 to 1876, was the first who thoroughly dealt with this question in the manner shadowed forth by Huguier, and he proved, in a series of interesting experiments, which Dr. Kramer and myself have fully confirmed, that the effect is really a hydrodynamic one. One of the simplest of his observations you see before you, and is made as follows:—Two tin canisters are taken of precisely the same size and strength, and are filled with equal quantities of lint; but in the one case the lint is dry, in the other saturated with water. When a bullet of moderate velocity is fired through these canisters, it simply perforates the dry one, but causes the wet one to burst explosively. It is, however, not a simple question in dealing with these artificial schemata merely to provide a porous substance the cavities of which are filled with water, for I have found that if the intervening septa are strong, as, for instance, in the case of sponge, that the bursting effect is not so great. In fact, the water must be thoroughly incorporated with the substance, or, to speak more correctly, the substance must be more perfectly fluid. This can be easily demonstrated by taking dough containing different percentages of water, and since dough is a substance in which the incorporation of the water is very complete, it affords a particularly good example to employ. By firing bullets of precisely the same velocity through these samples, you see that the destruction is effected strictly proportionally to the fluidity of each specimen. This is the reason why it is really of no absolute value to make experiments on dead tissues, for the brain in a state of *rigor mortis* is practically a solid, since both its living protoplasm and blood in the blood-vessels has coagulated, whereas in the living condition the first is semi-fluid, and the second quite fluid. It was to investigate this point, as well as the previous questions, that I have paid more especial attention to the proportionate relation existing between the velocity and the explosive effect. The results are very obvious in the casts before you. This work has been immensely facilitated by the kindness of Sir Andrew Noble, who caused to be constructed at my request a modification of a 22-calibre rifle, whereby I can fire a 40-grain bullet with any velocity I wish from a few hundred feet per second to over 3500 feet per second.

The casts show that the effect in the clay is proportional to (1) the velocity of the bullet, (2) the wetness of the clay.

The method of proof is so convincing I need not detain you further in this discussion.

Since the question is, we now see, all-important, it becomes a matter of no small moment to study the effect exerted by bullets entering fluid (for example, water). In the first place, as may be seen by these experiments, the effect of the perforation of a skull, filled with water, by a bullet, as was first done by Kocher, is to cause the burst of the sutures. I would draw your attention to the fact that the separation of the bones is most marked on the side of the entry of the bullet. It was the observation of this latter point which led me to think that it might be possible to automatically record the disturbance of the fluid, and this was effected in the following way.

A long trough having been prepared, with one end closed with rubber one-eighth of an inch thick, and a tall, white, flat surface lowered vertically into the trough, the latter is filled with a solution of methylene blue. A small bullet of low velocity (600 feet per sec.) is fired in the long axis of the trough, 1 cm. below the surface of the water. As a result, a wave is thrown up against the white screen, which is consequently marked with a blue splash, the same describing a curve, indicating, firstly, that the disturbance is greatest where the velocity and resistance, increased by compression, are both at their highest, *i.e.* soon after the bullet enters the fluid; and, secondly, that the displacement diminishes gradually as the momentum lessens.

Complete confirmation of the parallelism between soft solids and fluids in their behaviour to the rapidly-moving bullet is seen in comparing the cast of the track made by a bullet moving through clay, with the curves obtained by the water record.

In both, the maximal displacement occurs shortly after the bullet has entered the substance, and in both the diminution of disturbance is much more gradual than its development, and is evidently proportional in the main to the loss of momentum. A final proof is afforded by suspending columns of methylene blue in clear water, or salt solution, and then firing through the whole. With the ·380 bullet and three grains of smokeless powder the last column in the 4-foot trough was not disturbed.

This doubtless is a result which would be generally foreseen, but it was worth while to test it experimentally, and it certainly very strikingly demonstrates how localised the bursting disturbance is, which completely explains the limitation of the explosive effect on the skull on the side of entry. Sundry interesting subordinate points arose in the course of these experiments, and have served to afford the necessary control of the method, *e.g.* the peculiar splash of the bullet striking the rubber end of the trough alone, *i.e.* not penetrating; and, again, the tracing made by a bullet which, being fired a little too superficially, records the elevation of successive waves as it ricochets along the surface; and, finally, the record of a bullet deflected by the resistance of the water (as well as by want of horizontality), showing a long, oblique splash where it has carried up the fluid into the air.

From all these experiments on the pure physics of this subject we are justified in believing that when a bullet is fired against the head (whether that of a man or any other warm-blooded animal), so as to penetrate the cerebral hemispheres in a transverse direction, the following series of phenomena occurs. The impact of the bullet on the bone causes depression of that bone over an area larger than the diameter of the uninjured bullet, this causing a slight rise of tension in the skull, since that cavity is completely filled with fluid, *e.g.* the cerebrospinal fluid and blood in the blood-vessels, together with the living brain, which, as has already been stated, is a semi-viscous substance. In the next instant the bullet enters the cavity, and the slight rise of tension is instantly converted by the universal displacement (explosive effect) of the contents, into a very severe rise of pressure, most marked on the side of entry. The lines of force which this pressure takes is shown in this diagram, and it will be obvious to you that these forces will on meeting the rigid skull tend, as I have already shown, to burst it, and if they fail in that, then they will certainly be reflected on to the brain, a matter, as we shall presently see, of special pathological significance. As you see from the diagram, the brain substance must be driven against the internal surface of the globular cranium. This driving of the brain against the hard bone is exemplified in every post-mortem examination. A good instance is seen in the accompanying specimen, in which, although the bullet traversed the extreme tips of the frontal lobe and the olfactory bulbs, numerous bruises are seen on the hinder portions, where they have been crushed against the bone. Similarly evidences of the direct transmission of the pressures are to be found at the base of the brain in the longitudinal fissure, &c., wherever, in short, the brain can be pressed against an unyielding substance. The final proof of the correctness of this interpretation is to be referred to directly, in which the vault of the cranium is removed before the shot, so that the energy of the pressure is expended in ejecting portions of the brain into the air, and not so much on the basal regions, as just described. So, too, the energy of the bullet is communicated in the same way to the fluid in the ventricular cavities (Duret's "choc cephalo-rachidien"), which tunnel the brain down to the medulla oblongata. The medulla oblongata is thus subjected to pressure from two sources: (1) the hydrodynamic displacement of the brain *en masse*; (2) the direct crushing effect due to the movement of the cerebrospinal fluid in the ventricles.

We are now brought to the aim and object of these preliminary considerations, namely, the reason why these disturbances within the skull cause death, and how the fatal issue is produced; in short, we must pass from the questions of pure physics to the more complex problems of pathology.

(2) *Pathological Considerations.*—The experiments, the results of which I now wish to lay before you, constitute a long series which was carried out last year by Dr. Kramer and myself. We arranged the experiments as follows: A dog was placed under ether, and one femoral artery connected with a mercurial manometer to give record of the heart beats and pressure of the blood in the trunk arteries of the circulatory system. Another similar manometer was connected with the peripheral end of an artery so as to record the changes of pressure in the small capillary vessels, changes which I may remark incidentally are usually due to those disturbances in the central nervous system which we call vaso-motor. Thirdly, the movements of respiration are traced on the recording surface by means of rubber tambours known as Bert's and Marey's, respectively. If the pressure within the skull was also to be recorded, then a steel tube was fixed into a trephine opening filled with the salt solution, and connected by a rubber air-tube also with a Marey's tambour. Occasionally we put on the same paper a record of the contraction of the rectus femoris muscle, this latter being directly connected with a Fick's spring myograph. At the bottom of the tracing is given, firstly, the record of the movements of an electro-magnet signal (Smith's) interrupted by a metronome beating seconds. The last line traced is that from a Smith's signal in the circuit of a single cell, and one of the wires from which is made of very slender brass, and fixed across the muzzle of the pistol or rifle, so that when the shot leaves the muzzle it cuts it and breaks the contact (Woolwich method).

When a bullet of low velocity (600 f.p.s.) strikes the skull in a glancing fashion, there is only a trifling disturbance of respiration, but when the bullet enters the cranial cavity and sets up the powerful hydrodynamic pressure before referred to, a very severe effect is produced, namely, complete arrest of the respiration and a slight fall of the central blood pressure, this causing a similar feeble fall in the peripheral blood pressure. A little later (5–10 secs.) than the arrest of respiration a remarkable rise in the blood pressure occurs, this rise continuing until the normal tension is exceeded. These observations prove beyond doubt that the first cause of death is not what it is usually supposed to be, and as taught in the text-books, namely arrest of the heart and syncope, since, as you see, the heart goes on beating although the respiration has completely stopped. Furthermore, if we quickly perform artificial respiration we obtain recovery from the otherwise fatal arrest.

This suggests very strongly that the police and persons who are trained in giving the first aid to the wounded should be taught that with a gunshot wound of the cerebral hemispheres, the proper thing to do is to employ artificial respiration rather than the giving of stimulants, &c. But, as you may well expect, the matter does not stop here, nor is it so very simple, because we find that there are certain conditions under which the secondary rise of blood pressure does not occur.

It is now quite evident that the fatal phenomena of the gunshot wound of the cerebral hemisphere is in the first instance cessation of the breathing, and I have now to indicate in detail how this is produced by the hydrodynamic disturbance evoked within the skull cavity by the energy of the bullet. It is perhaps necessary to first remind you that the upper part of the spinal cord or medulla oblongata contains the chief centre for the movements of respiration. I would also draw your attention to the fact that therein is also the centre of origin of the vagus nerve, which nerve has the power of slowing the heart. Thus there are two important centres in the medulla which are liable to be affected by changes of tension around them induced, as above stated, when the bullet traverses the cerebral hemispheres in a transverse direction. It may be that the centres are principally affected by the mechanical pressure of the explosive effect, but this latter of necessity produces a certain amount of anæmia of the nerve centres; some of the effect may also be produced by that condition too. Supposing that the artificial respiration has been properly carried out, and the respiratory centre is revived into activity, there is yet another condition to be overcome, without which the animal or person dies, and for a long recognised reason, namely, that the bullet having in its passage cut through various blood-vessels, blood is poured out within the skull, and consequently raises very severely the intra-cranial tension. This constitutes, as a matter of fact, a second cause of death, for under these circumstances the accumulated blood causes such severe compression, that it not only again paralyses the respiratory centre but also irritates the vagus centre, causing a marked slowing of the heart. The proof of the truth of this statement is given at once the moment we cut the vagi nerves, for if these are divided the heart immediately resumes its former rhythm. The next curves are to exhibit the increase in the intra-cranial tension, which occurs the moment the bullet enters the skull. The line drawn by the Marey's tambour shows a violent increase of pressure at the moment of shot (first or explosive effect) and a certain recoil therefrom, this recoil being directly changed for a steady increase in tension brought about by the secondary cause of death, namely, the hæmorrhage, of which I have already spoken. To treat such hæmorrhage only ordinary surgical measures are requisite, but these will be impossible if the activity of the respiratory centre has not previously been restored in the manner already indicated.

To sum up, the basis of scientific discussion of the nature and causation of the phenomena evoked by bullet wounds of the cerebral hemispheres must rest on two principal factors—the velocity of the projectile and the development of hydrodynamic movement in the wet living tissues.

I am glad to have had the opportunity of laying before you the facts on a subject which combines the pleasure of pure physical research with the interest inseparable from the resolution of pathological problems.

GEORGE JOHN ROMANES.

ANOTHER of our not too numerous band of English biological investigators has been taken from us in the prime of life. The list is a heart-rending one, and its full share of sadness surrounds the fate of this last dear friend and companion. Garrod, Frank Balfour, Moseley, Herbert Carpenter, Milnes Marshall—all were younger at death than Romanes, and he only reached the age of forty-six just three days before he died. For some two years his friends have watched with anguish the progress of the disease—a condition of the arteries resulting in apoplexy—which has now ended his pain. Marvellous was the activity of mind and the eagerness with which he pursued his favourite discussions even to the day of his death. Nothing, perhaps, more touching was ever witnessed by those who knew and loved his kindly earnest nature than the calm conviction with which he realised that the hand of Death was laid on him, the pathetic smile with which he would say, as he puffed his cigarette, "Of course my life is only hanging by a thread, and I shall never be able to finish the experiments which would, I think, convince you."

George John Romanes was the son of the Rev. Prof. Romanes, and was born in Kingston, Canada, on May 20, 1848. He studied at Caius College, Cambridge, took honours in the Natural Sciences Tripos (1870), and was Burney Prize essayist in 1873. Having private means, he determined to devote himself to the study of psychology, which he proceeded to attack from two sides—that of physiology, and that of the doctrine of evolution. He further equipped himself for his task by mastering the teachings of modern writers on "philosophy." To contribute to a knowledge of the evolution of Mind was the ultimate aim of his numerous researches and discussions. He was fortunate as a young man in forming an intimate friendship with Mr. Darwin; and it was his ambition not merely to carry the application of Mr. Darwin's methods and principles into the great field of mental evolution, but also to strengthen and, where possible, supplement the Darwinian theory itself. Mr. Darwin assisted Romanes in this enterprise by leaving to him unpublished work of his own on "instinct" and similar subjects.

Romanes first became known to the larger public as a gifted and capable exponent of scientific doctrine by the lecture on "Animal Intelligence" which he gave in Dublin during the meeting of the British Association in that city in 1878. He was subsequently appointed Fullerian Professor in the Royal Institution, and gave numerous lectures both there and at the London Institution. He contributed a series of papers describing his researches on the nervous system of the Medusæ to the *Philosophical Transactions*, and was elected a Fellow of the Royal Society fifteen years ago. His literary activity was very great, and resulted in the publication of several large and well-known books, as well as in numerous essays and short articles of a controversial character published in the reviews and in this journal. His chief books are "Animal Intelligence," "Mental Evolution in Animals," "Mental Evolution in Man," "Jelly-fish, Star-fish, and Sea-urchins," "Darwin and after Darwin," and "An Examination of Weismannism." He had a keen love of public discussion and a native skill in dialectic, which may sometimes have led him to seek too eagerly an argumentative triumph. But his writings bear evidence of the most extensive knowledge and of a conscientious examination of all sources of information, combined with independence of judgment and much subtlety of analysis. The high estimation in which his work is held may be judged of from the fact that all his books have been translated into French and German, and that the book on which he was engaged when the first symptoms of his fatal illness appeared—namely, that entitled "Darwin and after Darwin"—was published simultaneously in the United States and in this country under special conditions highly satisfactory to him.

Four years ago, in order to enjoy greater quietude and the facilities of the newly erected physiological laboratory of the University, Romanes removed from London and took up his residence with his wife and family in a fine old house in Oxford, facing the cathedral house of Christchurch. Here he has left his name and memory not only to be cherished by the numberless friends who mourn his early death, but to be carried forward to all future generations of Oxford scholars by the lectureship founded by him three years ago. Gladstone, Huxley, and Weismann have been the first three "Romanes lecturers" nominated successively by the founder. Hereafter it will be the duty of the University to elect annually a lecturer worthy to follow them.

Whilst it would be premature to claim for Romanes the merit of a great discoverer or originator in psychology or in the philosophy of evolution, it is nevertheless true that by his keen criticism, careful mastery of details, and great literary fertility, he has exercised a most important influence stimulating the thought and research of others by his example and enthusiasm, and by those contests in the arena of the "reviews" with Wallace, Spencer, and Weismann, which have made his name so widely known.

It is not generally known, though a fact, that Romanes produced, in addition to his numerous scientific writings, a considerable volume of verse, which was printed for private distribution, as well as occasional poems. These poems deal with philosophic and emotional subjects, and are often of great beauty. It should be mentioned (although it is not possible here to record every fact of importance in his life) that Romanes was for some years honorary secretary of the Linnean Society of London, and a member of the Council of University College, London; he was Rede lecturer in the University of Cambridge, an honorary LL.D. of the University of Aberdeen, twice Croonian lecturer of the Royal Society of London, and Rosebery lecturer in the University of Edinburgh, when the courses delivered by him formed the substance of his book, "Darwin and after Darwin."

One word before this too hasty notice is concluded as to his personality. His unaffected good-nature, and almost boyish simplicity and gaiety of character, endeared him to every man and woman with whom he came into contact. He has left behind him numberless friends, not one enemy.

E. RAY LANKESTER.

NOTES.

THE fourth volume of that very useful work of reference, the "Minerva Jahrbuch," which goes to press in July next, is to contain an engraved portrait of Lord Kelvin. If the portrait is as good as that of L. Pasteur, which adorned the third volume, it will be well worth having.

WE regret to note the death of Dr. B. H. Hodgson, at the advanced age of ninety-five. He was elected into the Royal Society in 1877.

DR. S. J. HICKSON, Fellow of Downing College, Cambridge, has been appointed Professor of Zoology in the Owens College, Manchester.

COLONEL LAUSSEDAT has been elected an "Académicien libre" of the Paris Academy of Sciences, in succession to the late General Favé.

THE Société des Arts de Geneve have opened a subscription list for the purpose of raising a fund to erect a bronze bust of the late M. Colladon somewhere in Geneva.

THE gold medal of the Linnean Society has this year been awarded to Prof. Haeckel, of Jena, for his important contributions to zoological science.

THE new buildings of St. Thomas's Hospital Medical School will be opened on Saturday, June 9, at 4 p.m., by the President, H.R.H. the Duke of Connaught.

A GENERAL meeting of the Federated Institution of Mining Engineers will be held in the rooms of the Institution of Civil Engineers on Thursday and Friday, June 7 and 8. Arrangements have been made for a visit to Messrs. Siemens Brothers and Co.'s works at Woolwich on Saturday, June 9.

AN international photographic exhibition will be held in Arnhem, Holland, from July 14 to 29. The exhibits will be divided into six classes, one of which will include scientific photographs. Mr. G. S. de Veer is the Secretary of the Exhibition Committee; his address is Velperwege 94, Arnhem, Holland.

THE annual meeting of the Photographic Convention of the United Kingdom will be held in Dublin in July. The President for the year will be Sir Howard Grubb, and the committee of reception includes, among others, the Earl of Rosse, Viscount Powerscourt, the Lord Mayor, and the Astronomer Royal of Ireland. The proceedings will open on Monday, July 9, with a reception and conversazione in the Museum of Science and Art.

IN these columns on March 8 and May 10, we noted the gigantic landslip that had occurred in the Gurhwal district in India, and blocked up the valley of the Bihri Ganga river. The disaster that was expected to result from this has happened. A Reuter's telegram reports that the dam has burst, and the immense volume of water that had been kept back has flooded the district, sweeping away villages, and causing the loss of about two hundred lives.

LAST year was a critical one in the history of the Zoologica Society of Philadelphia. We learn from the twenty-second annual report that an effort was made early in the summer to raise a fund by private subscription for the purpose of meeting a large financial deficit. This, however, met with little success, and all hopes of saving the Garden of the Society had been given up, when the Commissioners, who hold the ground upon which the Garden is situated, asked from the City Councils a sum of 10,000 dollars for purposes of maintenance, in addition to the 5000 dollars which had for several years been granted. This sum was promptly voted, the Zoological Society placing in the hands of the Board of Education fifty thousand tickets for free admission of pupils of the public schools to the Garden. This liberal and broad-minded action has prevented the closing of the Garden and the dispersal of the collection.

IN the House of Commons, on Thursday last, Mr. Strachey asked the President of the Board of Agriculture whether it was proposed to repeat the experiment of transmitting the weather forecasts to telegraph offices in rural districts, for exhibition during the time of harvest; and, if so, what were the arrangements to be made for the purpose. In reply, Mr. Gardner said it was proposed to repeat the experiment of last year, and that the counties of Cambridge, Somerset, Carnarvon, the East Riding of Yorkshire, Haddington, and Ayr had been selected for the purpose. The forecasts will be despatched to rural telegraph offices at such periods as will suit the agricultural conditions of hay and corn harvest in the respective counties, and Mr. Gardner hoped that those interested in the matter would supply information as to the results of the experiment, so that it could be determined whether the system was of sufficient utility to justify its continuance and extension. The forecasts are, of course, prepared at the Meteorological Office, which has for many years issued hay harvest forecasts to a limited number of stations, and has had them properly checked by the recipients. The results of these forecasts are regularly published in the Reports of the Meteorological Council, and they show that the percentage of success has been remarkably good in nearly all the districts.

The weather over these islands has continued very unseasonable during most of the past week; the maximum shade temperature readings have been as low as 55° in many parts, and below 50° at some of the northern stations, while on Tuesday morning, the 29th inst., the minimum shade temperature fell below freezing point in the Midland counties. On the 26th a deep depression was situated over Germany, and caused very stormy weather over the south of England; in London the wind blew from the north-north-west with great force during Saturday night, the pressure amounting to 11½ lbs. on the square foot at Greenwich. The fall of rain which accompanied this disturbance was very great. On the Kentish coast it amounted to over 2 inches, and more than 3 inches fell at the Helder. Slight thunderstorms occurred in the Midland counties and southern parts of England in the early part of this week.

The influence of ancient village communities on the map of England is made the subject of an interesting paper by Mr. H. T. Crofton in the last number of the *Journal* of the Manchester Geographical Society. Mr. Crofton reproduces a portion of the six-inch ordnance survey map with the parishes coloured, and thus brings out the curiously complicated manner in which the boundaries are drawn, and the frequency with which portions of one parish are scattered in isolated patches through the neighbouring parishes. In order to explain these curious forms he points out that the ancient village communities of the primitive Celtic people, with their complicated adjustment of arable and pasture land, were not wiped out by the Roman conquerors, but gradually assimilated to the new distribution of property. Thus, acquiring a recognised character, the lands of separate tribes or families retained their ancient names and groupings, and to the present day the parishes of Manchester and its neighbourhood bear witness in their irregular boundaries to the primitive customs of the pre-Roman inhabitants of the land. The question of county and parish boundaries is one so full of interest for the student of primitive populations, that he must be grateful to the proverbial conservativeness of parochial authorities. Still, intending students in this interesting field would do well to set to their task speedily before the changing of the old order destroys landmarks which can never be restored.

The report of the Hydrographer to the Admiralty, published a few days ago, describes the work performed under the direction of the Lords Commissioners of the Admiralty during last year, in the examination and charting of seas and coasts in various parts of the globe. The necessity for accurate surveys on a large scale is strikingly illustrated by the number of rocks and dangers to navigation annually discovered, this number being steadily on the increase, no less than 201, which it has been deemed necessary to notify by notices to mariners, having been reported during the year 1893. Of these, 26 rocks were reported by H.M. surveying vessels; 35 by others of H.M. ships; 22 by various British and foreign vessels; 13 were discovered by vessels striking on them; and 105 were reported by colonial and foreign Governments. Ten vessels were employed in the surveys during the year covered by the report—four on home and six on foreign stations. The English stations were Plymouth Sound, the south coast, east coast, west coast, and the east coast of Ireland. On the west coast of Newfoundland the portion surveyed comprises from Cape St. George to a point 16 miles eastward of Cape Anguille, nearly 100 miles of coastline. An area of about 500 square miles was closely sounded. Of this locality there is at present no chart in which the navigator can place any confidence, and the new work will be especially useful. As might have been expected, a certain number of uncharted dangers were discovered, and no fewer than nine rocks with a less depth of water than five fathoms over them were found round the shores of the bay. A plan of Isthmus Bay, on a scale of 6 inches to the mile, was also completed. Dr. Bassett-Smith accompanied H.M.S. *Egeria*, and during the sounding of the Macclesfield coral bank in the China Sea was enabled to obtain a very valuable collection of corals from the deeper slopes of the bank, special attention being paid to the zone lying between the depths of 30 to 40 fathoms, from which he was able to prepare a highly interesting report on his investigations. The collections have been sent to the British Museum. The Solomon Islands, Queensland, Tasmania and the New Hebrides, and the Mediterranean were also the centres of marine surveys during 1893. The marine survey of India was carried out under the direction of officers of the *Investigator*.

An ethnographic expedition to the islands of Inishbofin and Inishshark, County Galway, was made by Dr. C. R. Browne in the autumn of last year, and the results of his observations, communicated to the Royal Irish Academy in November, have now been published. A similar expedition was made to the Aran Islands in 1892, and both were undertaken in connection with the Dublin Anthropometric Committee. These local investigations in selected parts of Ireland are as important as the results are interesting. The people visited, on the whole, much resemble the inhabitants on the opposite coast of Connemara, and their appearance testifies to a mixed origin. The average height is 5 ft. 6½ in., which falls short of the Irish mean stature as found by Gould, and the Anthropometric Committee of the British Association, by about two inches. Sight and hearing are very acute, and Dr. Browne says that the distance at which the islanders can make out a sail or a bird on the wing is amazing. The proportional measurements of the face and upper limb with reference to the stature differ in some respects, not only from those of the Aran islanders, but also from the accepted canons, and form the proportions obtained by Quetelet, Gould, and others, in their investigations on several European peoples. Though a large proportion of the marriages are consanguineous unions, the uniformity of strain does not appear to have produced any effect except a great similarity of appearance; no cases of malformation or congenital diseases are ascribed to it. Marriages are arranged by the parents from considerations of suitability of families, not, as in many other places, by money bargains. If the bridegroom be the eldest son, who usually inherits the parent's house, &c., the bride goes to live with his family. Sometimes, on the occasion of a wedding, "strawboys" go round with long straw masks on, and if they do not get either money or liquor will threaten to break the windows and furniture of the house. Many other customs are described by Dr. Browne, and his notes on the legendary lore of the islands will be read with interest. The Dublin Anthropological Laboratory is to be commended for extending its work by these local investigations.

THE description of the external anatomy of the brain of a Chinaman, contributed to the current number (part lxv.) of *Brain*, by Mr. C. H. Bond, is noteworthy, for only seven Chinese brains had previously been reported upon. Several decided differences from what is looked upon as the normal are pointed out as existing in the Chinese brains. First of these stands out a greater prominence given to furrows running transversely as compared to those in the antero-posterior direction. As to convolutional complexity, the Chinese brains were up to the normal standard, and in the frontal lobes rather beyond the average. The weight of the brain studied by Mr. Bond was 1182 grammes, that is, 176 grammes less than the weight of an average male adult brain. The proportion of the cerebral hemispheres to the cerebellum was as 5 is to 1. In the case of the average man the proportion is $8\frac{1}{2}$ to 1, and for the chimpanzee it is $5\frac{3}{4}$ to 1. It is pointed out that if the brain investigated was at all typical of the race to which it belonged, then the small size and weight of the cerebrum as compared to the cerebellum is a point worthy of special emphasis. The number which includes Mr. Bond's description also contains the presidential address to the Neurological Society, delivered by Dr. D. Ferrier, F.R.S., last January, his subject being "Recent Work on the Cerebellum and its Relations."

THE current number of the *Journal de Physique* contains a discussion of the metals suitable for the manufacture of standards of length, from the pen of M. C. E. Guillaume. Those of iridio-platinum, originally proposed by M. H. Sainte-Claire Deville, have fulfilled all expectations as regards durability, but the price of the metals brings the cost of a metre rule up to about £400. The conditions to be fulfilled are a comparatively low price, hardness and good polish, constancy of length at a certain temperature, power of resisting moisture and ordinary laboratory chemicals, and, for large rules, a high modulus of elasticity. The condition of constancy excludes all alloys containing zinc. The metals studied by M. Guillaume were nickel, white bronze, aluminium bronze, and phosphor bronze. Ferro-nickel, although much less oxidisable than steel, and harder and twice as rigid as bronze, could not be used owing to its feeble resistance to the action of water. Bars of the above four metals were submitted to repeated heating in steam and cooling. A comparison with standard No. 17 of the Conservatoire gave a shortening of $0{\cdot}3\,\mu$ (thousandths of a mm.) in the case of nickel, the amounts for the bronzes being 2, 5, and $-0{\cdot}3\,\mu$ respectively. The nickel was lengthened to the same amount by magnetisation. Phosphor and aluminium bronze were blackened by the steam, and are therefore not suitable. White bronze (consisting of 35 parts nickel to 65 parts copper) was found suitable for engraving a scale on, though it might be attacked by traces of sulphur or chlorine. Contact with mercury only leads to amalgamation after several hours, thus showing a great superiority to silver. Nickel is, on the whole, the most suitable metal. But it is difficult to obtain bars of the commercial metal free from numerous small punctures. Until this difficulty is surmounted, an alloy of equal parts of nickel and copper may render good service at moderate cost.

"THE DANGERS OF MILK" is the title of a useful little article in the April number of *Modern Medicine and Bacteriological Review*. Whilst the boiling or Pasteurisation of milk is advocated, it is pointed out that too much reliance must not be placed on this treatment as regards the entire removal of germs enabling the milk to be kept for any considerable time before use. Spores of bacilli may still be present, which, after some hours, may develop to such an extent that the bacilli may become so numerous as to render it acid and unfit for consumption. It is suggested that people entrusted with the feeding of infants on cow's milk should be supplied with litmus paper, by which the acidity of the milk should be tested before use. An interesting account will also be found in this number of a paper by Dr. Ledoux-Lebard, on the action of light on the diphtheria bacillus. Amongst the conclusions arrived at by the author, we read that whilst the direct rays of the sun arrest the development of these germs, and sterilise the culture medium in a few days, diffused light has no bactericidal action on diphtheria bacilli in *neutralised bouillon*, but has a markedly deleterious action on them when immersed in *distilled water*. Hitherto it has been found that micro-organisms are less sensitive to light in water than in culture media, but possibly Dr. Lebard's results may be explained by the fact that he used *distilled* water, which is well known to act prejudicially in itself on many bacteria.

ON the occasion of the celebration, last May, of the 150th anniversary of the foundation of the American Philosophical Society, Mr. S. H. Scudder presented a paper entitled "Tertiary Tipulidæ, with special reference to those of Florissant, Colorado." This important memoir has now been issued separately, and it will direct attention to the remarkably well preserved and numerous remains of insects, found at Florissant, in a lake deposit supposed to be of Oligocene age. Several hundred specimens of the family of "Crane-flies" or "Daddy Long-legs" have been collected there, and the nine finely drawn plates which accompany the paper completely represent many species. It is remarked that previous illustrations of fossil Tipulidæ rarely represent more than the wings, so that, merely as illustrations of fossil remains, Mr. Scudder's plates far surpass all that have gone before. The new forms described in the memoir number twenty-nine species of ten genera of Limnobinæ, and twenty-two species of five genera of Tipulidæ. No such extensive addition to tertiary Tipulidæ has been made since Loew first indicated the riches of the amber fauna of Europe. A careful study of the remains leads the author to several conclusions, some of which can be expressed as follows: (1) The general facies of the Tipulid fauna of the western territory is American, and agrees best with the fauna of about the same latitude in America. (2) All the species are extinct, and though the Gosinte Lake and the ancient lacustrine basin of Florissant were but little removed from each other, and the deposits of both are presumably of Oligocene age, not a single instance is known of the occurrence of the same species in the two basins. (3) No species are identical with any of the few European tertiary Tipulidæ. (4) Of the fifteen genera described, eight are not yet recognised among the living, these genera including about one-third of the species. (5) With one exception all the existing genera which are represented in the American tertiaries are genera common to the north temperate zone of Europe and America, and are generally confined to these regions.

THE second part of "The Natural History of Plants," from the German of Prof. Kerner, by Dr. F. W. Oliver, has just been published by Messrs. Blackie and Son.

THE report of the Trustees of the South African Museum for the year 1893 has been distributed. The accessions to the collection during the year included 367 new species, of which two were mammals, eight reptiles, three fishes, six molluscs, and 348 insects.

THE paper on "The Genesis of the Chalk," read by Dr. W. F. Hume before the Geologists' Association in January last, appears in the May number of the Association's *Proceedings*, together with the presidential address on "Geology in the Field and in the Study," delivered by Mr. H. B. Woodward.

The late Prof. Milnes Marshall's little book on "The Frog," known to be a most concise introduction to anatomy, histology, and embryology, has reached a fifth edition. A note by Dr. Hurst informs us that the preparation of this edition for the printer was Prof. Marshall's last professional act, and was completed only a week before his death.

The Marlborough College Natural History Society, founded just thirty years ago, has issued its report for 1893. The report chronicles the work of the sections of astronomy, botany, entomology, geology, microscopy, zoology, and meteorology during the year. It also includes an anthropometrical report containing the statistics of weights and measurements of members of the school. This is a feature that other societies in our schools and colleges would do well to take up, for the anthropological information thus collected is very useful.

It is well known that many amateur photographers send their negatives to professionals to be printed. The Indian amateur, however, has usually to make his own prints, as there are few professional photographers in the far East who undertake the work. To make up for this dearth of available assistance, the *Journal of the Photographic Society of India* reports that the society of which it is the official organ have established a printing department for its members. Though such a departure might be adversely criticised in the case of a British society, it may be pardonable in India.

Volumes viii. and ix. of the *Annalen der k. k. Universitäts-Sternwarte in Wien*, edited by Prof. E. Weiss, have recently been issued. The former volume contains the results of meridian observations made at Vienna Observatory during 1886 and 1887, of comet observations made between 1890 and 1892, and of observations for positions of planets, comets, and comparison stars. In vol. ix. are given the zone observations made by Dr. Palisa during 1884 in connection with the Vienna star catalogue. This volume also includes the results of observations of planets during 1890, and meteorological observations made in 1887 and 1888.

Messrs. J. and A. Churchill have published a new edition of "Materia Medica, Pharmacology, and Therapeutics," by Dr. C. D. F. Phillips. The work originally appeared in 1882, but was out of print for some years. Dr. Phillips has made numerous emendations and additions in order to bring his book in touch with the present state of knowledge of the physiological and therapeutical actions of remedies. More than usual space has also been devoted to pharmacy. The present volume deals with the actions of inorganic substances, and a new edition of its companion volume on the vegetable, animal, and organic compounds will be published to supplement it.

The tidal streams round the Isle of Wight can be found at any hour on any day by means of an arrangement devised by Mr. F. Howard Collins, and published by Mr. J. D. Potter. A plan of the island, with arrows showing the directions of tidal currents, is drawn in each of twelve sections of a cardboard circle pivoted at the centre. This circle is capable of being moved round inside another, upon which the hours from one to twelve are marked. When the inner circle has been set to the time on the outer one at which high water occurs at Portsmouth, the directions of the arrows opposite any hour on the latter show the direction of the tide at that hour. Yachtsmen in the Solent and round the Isle of Wight should find the chart useful.

In the June number of *Natural Science* Dr. A. R. Wallace compares the Palæarctic and Nearctic regions, as regards the families and genera of their mammalia and birds. It has been suggested by several zoologists that these two regions should be united so as to form one new region—the Holarctic—coextensive with the extra-tropical northern hemisphere. Dr. Wallace finds, however, that the two regions, instead of being so much alike that they should be united to form a single region, are really exceptionally distinct, and that their union would not be an improvement upon Dr. Sclater's system of zoological regions. The journal also contains articles on the distinguishing of sex in ammonites, by Messrs. S. S. Buckman and F. A. Bather; problems in experimental psychology, by Prof. E. B. Titchener; the mode of formation of ground ice, by Mr. R. D. Oldham; the significance of the bird's foot, by Mr. F. Finn; and cell-division, by Mr. M. D. Hill.

The new series of *Science Gossip* is really an improvement upon the old one. Each month pages are specially devoted to astronomy, notes and queries, science abroad, zoology, geology, botany, and transactions of scientific societies. The articles in the June number include one by Mr. A. T. Tait, on the beautiful dendritic crystals sometimes found on the pages of books. The author remarks that he has never seen a specimen of these arborescent crystals in a book older than 1835 or younger than 1882, and that rather more than twenty years are usually required for their fullest development. He has examined a large number of volumes of foreign origin, but has never discovered any of the crystals upon their pages. The crystals are supposed to owe their formation to chemical action set up by the accidental deposition of minute fragments of copper upon the surfaces of paper during the processes of manufacture or printing, so it is suggested that differences between British methods of paper-making and printing, and those in vogue in America and on the continent, may account for the absence of the crystals.

In a communication to the Société Chimique, M. Girard explains the interesting fact that when wood charcoal is heated with sulphuric acid, for the purpose of preparing sulphur dioxide, colourless crystals are frequently observed to form. M. Terreil has previously pointed out the occurrence, but without offering any evidence as to its nature. M. Girard now finds that if excess of carbon is used, and the operation is continued until the complete cessation of the evolution of gas, so large a sublimate of the crystals is obtained as to cover the sides and neck of the flask, and to almost obstruct the delivery tube. In order to purify the substance it is only necessary to dissolve it in water, boil until sulphur dioxide is expelled, precipitate any sulphuric acid by the necessary quantity of barium chloride, evaporate to dryness, and recrystallise from alcohol. The well-formed colourless crystals obtained are found to consist of pyromellitic acid, $C_6H_2(COOH)_4$, one of the isomeric tetrabasic acids of the benzene series, and the acid whose anhydride is produced when mellitic acid is heated. Mellitic acid is a substance well known from the fact of its occurrence in combination with alumina in honey-stone. The crystals of pyromellitic acid obtained in the interesting manner above indicated are soluble without decomposition both in boiling sulphuric and boiling nitric acids. Their aqueous solution reacts like an ordinary dilute acid, decomposing carbonates with effervescence. The crystals themselves are efflorescent in the air, and upon heating they volatilise with production of a sublimate of long needles, melting about 280°, and which prove to be pyromellitic anhydride. M. Girard further shows that when sulphuric acid reacts upon wood charcoal which has previously been well calcined at a white heat, or upon coke, no production of pyromellitic acid is observed. On the other hand, substances richer in hydrogen and oxygen than wood arcoal, such as the denser varieties of cellulose, yield it in atively large quantities. It appears, therefore, to be proiced by the action of sulphuric acid upon that portion of the od charcoal which is least carbonised and retains a larger poortion of hydrogen and oxygen. Now it is well known ıt pyromellitic acid may be obtained by the action of sul-uric acid upon mellitic acid. M. Verneuil has recently own, while these experiments of M. Girard were in progress, t when sulphuric acid acts upon wood charcoal a certain iount of mellitic acid is produced. It is therefore practically tain that by the action of sulphuric acid upon wood charcoal, addition to the production of the gaseous dioxides of sulphur l carbon, mellitic acid is produced which in turn is converted a further quantity of sulphuric acid into pyromellitic acid, l the latter is deposited in crystals in the cooler portion of the k in which the reaction occurs.

THE additions to the Zoological Society's Gardens during the t week include two Brown Capuchins (*Cebus fatuellus*, ♂ ♂) m Guiana, presented respectively by Mr. Charles Gordon zer and Miss Florence Marryat; two Four-horned telopes (*Tetraceros quadricornis*, ♂ ♂), from India, pre-ted by Mr. W. F. Sinclair; four common Swans (*Cygnus r*), British, presented by Lord Braybrooke; two Jameson's lls (*Larus novæ-hollandiæ*), from Australia, presented by Ferdinand von Mueller, K.C.M.G.; two Hoary Snakes (*ronella cana*), a Crossed Snake (*Psammophis crucifer*), Infernal Snake (*Boodon infernalis*), from South Africa, sented by Mr. J. E. Matcham; two Natterjack Toads (*ufo calamita*), British, presented by Miss Peckham; ee Stock Doves (*Columba ænas*), British, presented by Mr. nel A. Williams; a yellow-cheeked Amazon (*Chrysotis umnalis*), from Honduras, two Alligator Terrapins (*Chelydra pentina*), from North America, deposited; a White-bellied Eagle (*Haliætus leucogaster*), two Wonga-Wonga Pigeons (*ucosarcia picata*), from Australia, purchased; a Reindeer (*angifer tarandus*, ♀), a Japanese Deer (*Cervus sika*, ♀), n in the Gardens.

OUR ASTRONOMICAL COLUMN.

SUN-SPOTS AND WEATHER.—The first part of vol. vi. of ndian Meteorological Memoirs" (Calcutta, 1894) contains aper by Mr. W. L. Dallas, Assistant Meteorological Reporter the Government of India, on the relation between sun-spots l weather, as shown by meteorological observations made on rd ships in the Bay of Bengal during the years 1856 to 1879. e region selected offered peculiar advantages for such uiry. The annual periodic changes in it are small, and the riodic changes are very slight. There is also comparatively le horizontal air motion, and, being a sea surface, the area is liable to the sudden changes which affect a land observatory, l result from irregularities in the elevation of the land sur-nding an observatory. The discussion of the pressure servations shows that there are certain points of similarity ween barometer readings and the number of spots on the . The number of years during which the number of sun-ts exceeded the normal average coincides with the number years during which the pressure was below the average, *vice versâ*, while the maximum pressure differences, whether ove or below the average, occur one year after the maximum -spot variations in both directions. The same general agree-nt is disclosed by the discussion of temperature observations, here again there is the same want of exact relation. In the e of pressure the curves show that a defect of pressure pre-led during the years in which the relative number of spots s excessive; and an excess of pressure during the time they re at or about their minimum. So in temperature, it appears m Mr. Dallas' investigation, that there exists a general defect en the number of spots is low, and a general excess when number of spots is high. The indications are, therefore, t years of maxima and minima in a solar cycle are also years maximum and minimum solar radiation.

Another paper on sun-spots and weather has also recently been received (*Bulletin de la Société les Amis des Sciences et Arts de Rochechouart*, 1894), the author being Prof. J. P. O'Reilly. By extracts from the annals of Ireland (*Annala Proghacta Eireann*) and those of Ulster (*Annala Uladh*), it is shown that remarkable years of dryness and of cold in Ireland and in Europe are connected with the cycle of solar activity.

EPHEMERIS FOR TEMPEL'S COMET.—The following positions are extracted from the search ephemeris for Tempel's comet, given by M. Schulhof in *Astr. Nach.* No. 3219:—

Ephemeris for Paris Midnight.

1894.	R.A.	Decl.
	h. m. s.	° ′
June 2	1 0 16	S. 0 22·8
4	5 58	S. 0 3·9
6	11 37	N. 0 14·5
8	17 11	0 32·3
10	22 41	0 49·6
12	28 8	1 6·3
14	33 31	1 22·4
16	38 49	1 37·9

The comet is not in a good position for observation, but it may possibly be picked up in the east shortly before sunrise.

JUPITER'S SATELLITES IN 1664.—Under this head we reprinted, on February 1, a letter from the New York *Nation* upon a supposed observation of five satellites of Jupiter, made by John Winthrop in 1664. The note led Mr. Frank H. Clutz to determine whether there was any "fixt starre with which Jupiter might at that tyme be in neare conjunction" (*Johns Hopkins University Circular*, May). He finds that the date of observation in our present reckoning was August 16, 1664, and on that date the star B.A.C. 6448 (R.A. 18h. 46m. 55·6s. Decl. – 23° 21′ 33″·04) was at a distance from Jupiter of about 10′·5, which is approximately the distance that the outer satellite may reach. In brightness the star is about the same as the three smaller satellites—between the sixth and seventh magnitudes. Mr. Clutz thinks, therefore, that this star was the object which Winthrop took for a fifth satellite.

ANNIVERSARY MEETING OF THE ROYAL GEOGRAPHICAL SOCIETY.

THE report of the Council of the Royal Geographical Society was presented at the annual meeting on May 28. The total number of Fellows at May 1 was 3775, a net increase of 29 during the year.

The President and Council for the ensuing year were ballotted for and elected. The principal changes are the retirement of the honorary secretary, Mr. D. W. Freshfield, and the retirement from the Council by rotation of Mr. Francis Galton, Generals Sir W. D. Jervois, J. T. Walker, and Sir Charles Wilson, and Mr. Delmar Morgan. Mr. Clements R. Markham was re-elected as President, the Hon. G. N. Curzon was added to the list of Vice-Presidents, Sir John Kirk was elected Foreign Secretary, and Major Leonard Darwin to co-operate with Mr. H. Seebohm as Secretary. The following new Councillors were elected:—Dr. Robert Brown, Right Hon. Hugh Childers, General Goodenough, Lord Lamington, Admiral A. H. Markham, Admiral E. H. Seymour, and Colonel J. K. Trotter.

The Society's medals were presented in the absence of their recipients, Captain Bower and M. Reclus; the minor awards, already announced in NATURE, were also given, and a series of educational prizes to students from the training colleges.

The President then delivered his annual address, reverting from the recent custom of dealing with the progress of geography during the year to the earlier practice of devoting special attention to some prominent features of exploration.

The greater part of the address was devoted to the polar expeditions of the present year, the facts regarding which have already appeared in NATURE. Mr. Markham is a high authority on Arctic travel, and his views will carry much weight. He professes a strong preference for large expeditions organised by government, and commanded by naval officers, believing that men combining high scientific attainments, great experience of ice-navigation, and the rare qualities of a leader of men, all of which are necessary for a great polar explorer, are seldom to be found except in the service of a government with a wide range of selection. Still he would encourage all enterprise and every carefully planned expedition, on however small a scale. Without expressing any confidence in the correctness of Nansen's theories, he felt no doubt as to the great scientific results which must accompany his journey. With regard to Mr. Jackson's projected exploration in Franz-Josef Land, Mr. Markham did not favour Austria Sound as the best approach to Petermann Land, and he pointed out the drawback of the winter quarters of the expedition being so far south as Eira Harbour, between which and the point where really new ground can be broken, there intervenes a space of nearly 200 miles to be traversed each season; but with wise management and favourable conditions of ice and weather, a good measure of success appeared quite possible. In his scheme for retracing Parry's footsteps north of Spitzbergen, Mr. Wellman transgresses the best established canon of Arctic travel, which is never to enter the drifting pack away from land; but as he has started early, Mr. Wellman may possibly enough beat the record of the farthest north, a motive which was deprecated by the Austrian explorer, Weyprecht, as the bane of good Arctic work. Little service to geography is to be looked for from this expedition, unless there are islands north of Spitzbergen which may be explored. In speaking of Mr. Peary's journeys in the north of Greenland, Mr. Markham said: "For my own part, I look upon Peary as an ideal explorer. He chose one of the greatest and oldest of the geographical problems that remain to be solved, and he set to work as if he really intended to find the solution. Every detail of equipment was thoughtfully considered, gear was tried and tested before being used, a brilliant preliminary journey over the inland ice was made. All was done in the workmanlike style of a true discoverer. I therefore believe that Peary will succeed. I am sure that he deserves success." There is, in Mr. Markham's opinion, ground to hope that Bjorling and Kalstenius may be still alive; "the two Swedish lads are the stuff of which heroes are made, and every civilised people must be interested in their rescue." Want of funds has prevented a search expedition from being sent out, and the two Swedes who have left for Ellesmereland trust to be landed there by the good offices of whalers. No efforts on the part of the Council were spared to inaugurate a great Antarctic expedition, the promotion of which is now under consideration by the Royal Society.

In the evening the anniversary dinner of the Royal Geographical Society was held in the Whitehall rooms of the Hôtel Métropole.

THE MAGNETIC DEFLECTION OF CATHODE RAYS.

THE current number of the *Electrician* contains a translation of a very interesting paper by Herr P. Lenard, on the deflection of the cathode rays by a magnet. It is well known that when the cathode rays traverse a magnetic field they are deflected from their otherwise rectilineal path, and in the form of tube ordinarily employed this deflection increases with an increase in the pressure of the residual gas in the tube. In this particular the cathode rays behave just like a current of negatively charged particles projected from the cathode. The paths of such particles would be curved in a magnetic field, and the curvature would increase with a decrease in the speed with which the particles travel, *i.e.* they would be more curved in a denser and more resisting medium. The above explanation is not in accord with the results of the experiments the author has made, and which have led him to consider the cathode rays as phenomena in the ether. In fact, the author finds that when the observation tube and the tube in which the rays are generated, are separated by a gas-proof aluminium partition, so that the gaseous pressure can be varied in the two tubes independently, that the above explanation entirely fails, and that everything confirms his previous view that these rays are phenomena in the ether, and not electrically charged particles. For instance, if the pressure of the gas in the discharge-tube be kept constant, while that in the observing tube be lowered from 33 m.m. to 0·021 m.m. it is found that the deflection produced remains constant. Higher pressures than 33 m.m. could not be employed, as under these circumstances the medium became so turbid to these rays as to entirely destroy all definition in the phosphorescent spot. If, however, the pressure of the gas in the observing tube be kept constant, while that in the discharge tube is varied, a marked influence on the position of the deflected spot is at once observable. Thus, if the pressure is altered so that the sparking distance in the discharge tube changes from 2 cm. to 4 cm. there is an alteration in the deflection of from 12·2 m.m. to 8·5 m.m. Thus it would appear that the difference in the deflection observed with varying gas pressures in the ordinary form of tube is not caused by difference of the medium in which the deflection is observed, but in the difference of the rays themselves, which are produced with varying pressures of gas. A curious deformation in the shape of the deflected phosphorescent spot was observed, for while the undeflected spot was always circular in form, the distribution of light being dependent on the turbidity (*i.e.* density) of the gas in the tube, in very turbid gases the edge of the spot is undefined. If the gas becomes rarer there appears in the centre of the spot a more or less sharply defined kernel, surrounded by a less bright penumbra. After deflection the spots become elliptical in shape, which may be due to the fact that the rays no longer met the screen at right angles, but when the gas was so rarefied that there was a central bright spot and a penumbra, the appearance of the spot was subject to sudden changes. While the position and shape of the central spot remained constant, the penumbra changed both in shape and position, sometimes even being quite separate from the bright spot. The penumbra was in every case more deflected than the bright spot, thus showing that the penumbra contains rays of greater deflectibility than the core, but never of less. This is borne out by previous experiments, which had shown that it is the rays that are most easily diffused that are most deflected.

SOME LONDON POLYTECHNIC INSTITUTES.[1]

II.

ON account of a mistaken idea as to the true end of education, the object of technical instruction is often defeated. Many young operatives take up courses of study in order that they may become clerks in manufactories where technical knowledge is desirable. This notion causes the ranks of the mechanic class to lose many of their brightest men, while the supply of clerks increases. What has to be impressed upon the minds of students in trade classes is that the object of the instruction is to enable them to perform their duties in a more efficient manner, not to remove them from one sphere of life to another. This point was very well expressed by Sir Benjamin Baker at the beginning of this year, in presenting the prizes and certificates to students at the People's Palace. "It is necessary," he said, "for teachers and students alike to remember that a certain amount of scientific or theoretical knowledge in the future, still more than in the present, must be considered as an indispensable element of success in the great battle of life, but not as a thing having necessarily any more market value in itself than a knowledge of reading and writing, nor must the facilities in acquiring knowledge now enjoyed by students be carried to such an extent as to incapacitate them from acting in an emergency promptly and reliantly without help from books or professors, or the benefits of scientific and technical education would be too dearly bought, and the self-education system of our predecessors would turn out the better men."

The People's Palace owes its existence almost entirely to the Drapers' Company. In the year 1890 this company took the entire management of the educational work, which was carried on under the supervision of Mr. William Phillips Sawyer, the clerk to the Company. Two years later, on the Drapers' Company having offered an annual contribution of £7000 to the Palace, a new scheme was drawn up by the Charity Commissioners, which provided for an annual grant of £3500 from the City and Parochial Charities' Funds, in addition to the Drapers' Company's contribution, and a new body of Governors was formed, of which the Master of the Drapers' Company acts as chairman. This body, besides representatives of the Drapers' Company, consists of members appointed by the London University, the London County Council, the London School Board, the Trustees of the City and Parochial Charities' Funds, and the Lord President of the Council.

The educational work consists of (1) the day technical

[1] Continued from p. [illegible]

chool, under the management of Mr. D. A. Low, head master, vhich is largely recruited from the public elementary schools, .nd to which the Drapers' Company have contributed yearly £1000 to be expended in scholarships. (2) The evening classes, ınder the management of Mr. J. L. S. Hatton, Director of Evening Classes.

The evening classes are conducted with a view to giving tudents a practical and theoretical knowledge of the arts and ciences, and to prepare them for the examinations of the)epartment of Science and Art, the City and Guilds of London nstitute, and of the Society of Arts. It will be concluded, herefore, that instruction is given in a large number of subjects; n fact, the time-table includes more than fifty classes in pure and .pplied sciences, and further, the Governors offer to consider he formation of classes in any similar subjects provided a ufficient number of students offer themselves for admission. Thus the subjects taught at the institution are those for which here is a demand. It would hardly be expected that purely cientific subjects would be in favour in the East End of London. The object of the majority of the students in such a district must e a desire to command better wages as workmen rather than he simple pursuit of knowledge. Some, however, are actuated y a higher spirit. Among the classes conducted by Mr. Hatton is one on the differential and integral calculus, another n analytical conic sections, and a third on the theory of deterninants. And many, if not most, of the students of these ubjects are not pupil teachers merely aiming at the obtaining f a certificate and nothing more, but young men who after assing their days in grimy workshops find recreation in mathematical exercises of no mean order. It is such ardent spirits as hese that bring credit upon the institutions assisting in their evelopment, not the mercenary "pot-hunter."

Strange as it may appear, there are numbers of young men in London who are unable to pay the small entrance fees to classes t these institutes. While at the People's Palace a short time go, the writer had pointed out to him a young mechanic who, hough he had been a student, found himself in circumstances o low that he could not pay the entrance fees for the classes in vhich he desired to continue his studies. He pleaded with the Director of studies for free admission, and, it need hardly be aid, his request was granted. That young man is now in his eventh heaven of delight, for he attends classes six nights a veek, and revels in the privilege that has been extended to him. To all who are desirous of democratising knowledge, this case —and it is not an isolated one—must appeal very strongly. The nan who wishes to work but finds his labour unwanted is an object of everyone's sympathy. But his claims for assistance are no tronger than those of the man who craves for knowledge and as not the means of attaining his desire. The London Polytechnics are doing an excellent work by reducing the tolls that or many years barred the ways of wisdom. But though the ees to classes represent only a small part of the income of these nstitutions, it is doubtful whether any very great educational dvantages would accrue from their abolition. "That which is asily gained is lightly prized," is an old saying and a true one, nd if all students were admitted free to Polytechnic classes, they vould possibly not appreciate the instruction so highly as they o at present. Perhaps the best way to meet the case of poor tudents would be for private benefactors to bestow a small sum pon Polytechnics for the purpose of paying their fees. It is ot suggested that these free studentships should be competed or, but that they should be obtainable by any who desired to oin classes, and were prevented by the inability to pay the fees; rovided only that the Director of studies satisfied himself as to he poor circumstances of the applicant.

The engineering department at the People's Palace is nder the control of Mr. Robert Holt. Students are ermitted to enter any of the classes in engineering subjects, but are always strongly advised to take up theoretical courses at the same time. For the first year the ubjects thus recommended are mathematics, geometry, and nachine construction; for the second year, more advanced nathematics, geometry, and machine construction, with heoretical and applied mechanics and steam; while thirdear students take still higher developments of mathenatics, machine construction, steam, and applied mechanics, nd also mechanical engineering. It will be seen, herefore, that by following this line of study a theoretical raining is obtained which must be of the greatest advantage in the engineering workshop. Only when a knowledge of theoretical principles is regarded as an essential qualification for entrance into the workshop, can the teaching be sound, and when this is more generally recognised among engineering students we may expect to see some results of technical education.

For some time Prof. Holt had in his mind a scheme for the erection of a machine shop, a pattern-making shop, a smithy, and an experimental workshop, but the necessary funds were not available. It has just been announced, however, that the Drapers' Company, supplementing their former benefactions, have voted the sum of £4000 for the erection of a new engineering laboratory with workshops.

The creation and extension of workshops such as exist at the People's Palace for various trades will do much to bring the workmen to a higher degree of efficiency. But in order to discover if the teaching is suitable for the students, and whether they make satisfactory progress, it is necessary from time to time to hold examinations which completely cover the work done. At present, however, there is only one general examination in technical subjects, namely, that of the City and Guilds of London Institute, which covers only a small range of the subjects usually taught, classes of such importance as those in practical engineering and practical carpentry finding no place in this examination. To remedy this defect, the educational committee of the People's Palace have taken steps to form a joint examination board of the London Technical Institutes. It is proposed that the examination consist of three parts:—(1) An inspection of practical work certified to be the unaided work of

FIG. 3.—Engineering Workshop of the People's Palace.

the student; (2) a *viva voce* examination; (3) a written examination. The intention of the committee is to make the examination more a mechanical qualifying one than one of general technical theoretical character, as will be gathered from the subjoined extract:—

"It is proposed to lay more stress on the *viva voce* part of the examination than is usually done, for the following reasons. It has been found that one of the great difficulties in conducting an examination on the above basis is to place the workman—unaccustomed to express himself in writing—on an equality with the clerk, who has not the same practical knowledge and experience. On paper, the workman frequently finds himself defeated by the clerk, and consequently looks with suspicion on such examinations as the City and Guilds, the results of which he, with justice, considers to be no just criterion of the merits of the candidates. In our Universities, in olden days, *viva voce* and written examinations were held concurrently, so as to afford those who had no facility for expressing themselves in writing an opportunity of showing the extent of their knowledge. With the advance of learning and the ever-increasing opportunity for expressing oneself in writing, the need of the *viva voce* examination at the University has died away, and it is at present little more than a useless formality. In the case of the workman, however, who has the greatest difficulty in expressing himself on paper, it is eminently desirable to revive the old system."

Examinations conducted in this manner have already been carried out at the People's Palace with some success, and it certainly seems desirable to extend them. After all, the majority of the students in Polytechnics desire certificates which guarantee that the holder, when applying for work, is a thoroughly competent workman. By enlisting employers of labour, and representatives of various trades, as examiners, the work done is truly tested from a practical point of view, and the certificates awarded by them is of use in obtaining employment. In all probability there will be a difficulty in arranging a joint examination board on the lines suggested by the People's Palace committee, but however this may be, it seems desirable that some provision should be made for determining the amount of directly useful knowledge obtained in the Polytechnic workshops.

Before passing to another Polytechnic, a few words must be said with regard to the extent of the work carried on at the People's Palace. The number of class tickets issued for the current session is 7408. Such subjects as light, sound, physiology, botany, and physiography attract comparatively few students, the reason evidently being that they do not directly bear upon industries. Though we cannot but regret this lack of interest in subjects most of which are necessary for a proper scientific education, it is not strange that in the East End, where the battle of life is so keen, people should only be interested in matters which they think may assist them to earn a living. Engineering subjects are greatly favoured, as many as 300 students attending the class in machine construction and drawing. The average attendance each evening at classes in all subjects is about nine hundred.

Dr. Macnair, who until recently was the head of the chemistry department, made that branch of science very popular among students, and Dr. Hewitt, who has succeeded him, will doubtless sustain the character of the work. The research laboratory, which it is proposed to arrange, will help to this end.

We come now to the Battersea Polytechnic Institute, formally opened last February. The Institute has been built and equipped at a cost of nearly £53,000, the greater part of which was raised by voluntary subscriptions. It is at present in possession of a fixed endowment of £1500 per year, but this will be raised to £2500 when the sum of £60,000 has been collected. As only £2200 is now wanted to complete this figure, the Institute will probably soon be in possession of the further endowment. The London County Council will also eventually contribute to the Institute an annual sum estimated to amount to about £1500. The Institute contains workshops for various trades, physical and chemical laboratories, and numerous rooms for classes and lectures. Instruction is provided in technological subjects, in general science; art, including wood-carving and metal chasing; music; and in commercial and general education. The principal is Mr. Sidney H. Wells, and Dr. W. E. Sumpner is the head of the electrical engineering department. Mr. S. H. Davies has charge of the chemistry department, and Mr. W. E. Walker carries on the engineering work in conjunction with Mr. Wells.

For the first time in the history of London Polytechnics, the Governors appointed a Principal, and by selecting for the post a man in whom theoretical and practical knowledge are happily combined, they did their best to secure a well-balanced scheme of instruction. Without expressing an opinion upon the advisability of putting each Polytechnic under the control of a Principal, we would point out that an educational head who teaches is bound to be prejudiced in the direction of his special branch of study to the detriment of other branches. By placing at the head of affairs a man who is not a specialist, and properly arranging each department of the educational work under a competent head, each branch is sure of its right share of attention. At the Goldsmiths' Institute there are ten departments, each under a head who, with Mr. Redmayne, arranges the details of work. The system has been proved to work well, and there is no friction between the departmental heads and the head of the Institute, owing doubtless to the fact that they feel that he is not unduly prejudiced in favour of any one department. The system of putting the whole Institute under a Principal is being tried at Battersea. Time will show whether this manner of control, or that adopted at New Cross, best furthers the interests of all branches of an Institute's work.

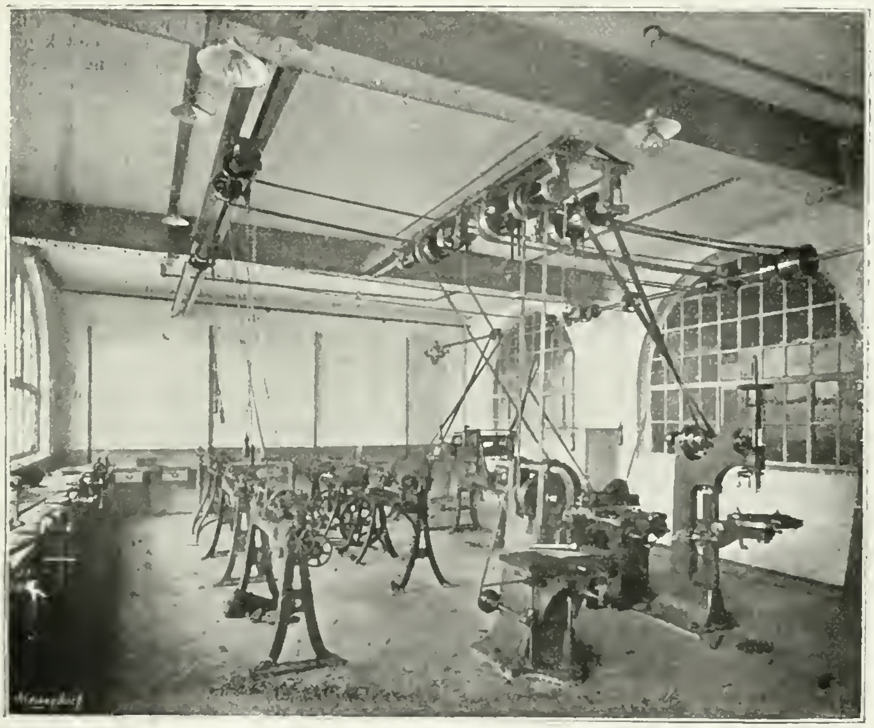
A few remarks with regard to the lines adopted at Battersea should be of interest. The Battersea Institute is open to persons

FIG. 4.—The Battersea Polytechnic Institute.

of either sex, without limit of age, who are students of any class in it. Persons who wish to join a trade class are required to satisfy certain conditions before permission is granted them. There is a reason for this stipulation. By attending a course in a trade subject, it is possible for men to become dexterous enough to do jobbing work without serving an apprenticeship in that trade. This is not only detrimental to the interests of the skilled workman, but it also encourages inefficient labour, for though the way to do a thing may be picked up in a workshop course, the way to do it well can only come by practice. In order to prevent this rapid manufacture of workmen, many Polytechnics in the provinces make each trade class a close preserve for the instruction of apprentices and workmen belonging to that trade. Thus, a carpenter would not be permitted to join a class in bookbinding. Something can be said both for and against this preservation. There is the possibility that the smattering of knowledge obtained in a Polytechnic workshop may be thought by some sufficient to qualify as a workman, but this is very doubtful. On the other hand, if a person wishes to learn it seems a pity to place any barrier in his way. Many young men are apprenticed to trades for which they have no taste whatever, and an institute which enables them to follow their inclination is doing a good work.

Membership of the Institute is open to any student between sixteen and twenty-five years of age, upon the payment of a nominal fee. Among the privileges to which members are entitled are: admission to ordinary evening classes, lectures, and entertainments at reduced fees, use of reading-room, and facilities for joining clubs and societies. This system of membership is calculated to develop an *esprit de corps* among the students, which will do much to make the Institute a success. Only by such means can a Polytechnic earn the title of a People's University. The establishment of these institutes has certainly put an end to many small science classes, and objections have been raised to this concentration of work. Teachers who for years have shown the "young idea" how to pass South Kensington examinations, have found their occupation gone when such an educational and social centre as now exists at Battersea has been started. But while everyone condoles with the teachers upon their misfortune, we must point out that the mode in which most sporadic classes under the Department of Science and Art are carried on is capable of improvement. Usually a teacher rushes to his class-room, gives an hour's instruction, and then leaves the students until the following week. A Polytechnic Institute, however, is looked upon by the students in it as their *alma mater*. The teachers are generally in the building ready and willing to help the inquiring mind, instead of being merely periodic visitors.

The classes at the Battersea Institute are chiefly intended for persons engaged in earning their own livelihood. Special courses at reduced fees are arranged applicable to various trades and industries, and students are strongly urged to take these courses in preference to single classes; indeed, everything is done to give the students a thorough and scientific education. In order to encourage students to take up mathematics, the fees in that subject are lower than for any other science or trade class. Some inducement of this kind is necessary, for very few workmen recognise that mathematics is a subject of immense importance, and forms the groundwork of all applied sciences. An excellent departure from stock subjects is the formation of a class in technical mensuration, in which the needs of students attending the trade classes are met, and engineers, builders, plumbers, bricklayers, masons, carpenters, joiners, and other operatives are taught the application of mensuration to the practical problems which occur in their work. Another class worthy of special mention is one in graphic statics, designed to teach the application of graphics to architectural, building, and engineering construction. A course of experimental work is carried on in a fine mechanical laboratory, only those who possess a knowledge of elementary mathematics, mechanics, and drawing being admitted to it. The electrical department, under Dr. Sumpner, is provided with a well-equipped laboratory, and the electric lighting plant of the Institute is available for experimental purposes. The chemical laboratory is also well-equipped and arranged. Altogether, we are of opinion that the Battersea Institute has started well. Its sphere of usefulness is limited for want of a larger endowment than it at present possesses, but doubtless further funds will be received when the important work it is doing for the quarter of a million inhabitants of south-west London is more widely known.



From a Photograph by Russell & Sons, 17, Baker Street, W.

FIG. 5.—Engineering Workshop of the Battersea Polytechnic Institute.

This survey would not be complete without a few words on the admirable day schools in connection with these institutes. Until recent years there were no facilites for the education of boys who had passed through public elementary schools, and desired further training in preparation for the workshop and manufactory. Continuation schools, such as those at Battersea Polytechnic, the People's Palace, and the Goldsmiths' Institute, supply the needful knowledge of science and technology, and, at the same time, carry on the subjects of general education. They represent a most important rung in the educational ladder, and every encouragement should be given to them.

At Battersea the same teachers conduct the day and the evening classes. The Institute thus possesses a permanent staff, all the members of which give the whole of their time to the work. There can be no doubt that this system of organisation is far preferable to that in which visiting masters are employed.

It may be well to briefly state the conclusions to be drawn from an examination of the work of London Polytechnics. In the first place, the funds at the disposal of the Institutes are usually not sufficient to permit the educational needs to be properly supplied. In order to supplement the sum arising from endowment, grant-earning classes have to be held, which means that subjects come to be considered for what they will bring to the Institute's exchequer rather than for what they are worth. The Technical Education Board of the London County Council have taken steps to remedy this evil by contributing maintenance grants, and capital grants for equipment, apparatus, &c., the former being allotted according to a scale calculated to promote educational efficiency, and regularity of attendance. The Department of Science and Art, and other Examining Bodies, should consider the advisability of treating Polytechnic Institutes in a similar manner, instead of regarding them as mere collections of classes. The less an institute of this kind depends upon payment by results, the more likely is it to develop in the proper direction.

Very little provision is made in the institutes for really advanced work or research, but this will probably come, for in London, technical education is only in its experimental stage. Many years of work will have to be done before any London institute will be able to find students for instruction of such an advanced character as that given in continental Polytechnics. Mr Ll. Smith recommended, in his report to the London County Council, that a grant should be made "towards the maintenance of an advanced department of applied science, bearing on some local industry, under the control of a well-qualified instructor who gives all his time to the work of the institute." The Technical Education Board have promised a contribution for this purpose when a Polytechnic desiring it shall have drawn up a detailed scheme of work, and the Board is satisfied that the proposed class will be of value to the industries of the district.

As to the recreative side of the institutes, little need be said. The desire for physical exercise is so much stronger than that for mental development, that there is a possibility of recreation swamping education in one or two cases. Generally, however, the two sides are very well balanced, and admirably assist one another in the development of men of thought as well as men of muscle.

For the rest, Polytechnic Institutes have aroused the interest of the working class, and men now realise the necessity of a scientific grounding for every trade. To have done this in so short a time promises well. In a few years, perhaps, London Polytechnics will be able to compare favourably with those in other European capitals, and when that day arrives a generation of workmen will have sprung up which, for aptitude and efficiency, should be able to hold its own against the world.

R. A. GREGORY.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Mr. V. H. Veley and Mr. G. C. Bourne have been appointed Examiners for the Burdett-Coutts Scholarship.

The sixth annual report of the Curators of the Botanic Garden shows a deficit of nearly £200 on the close of the financial year. This is due principally to the decrease of income derived from rents and profits of estates. The Curators report that the existing endowment is inadequate to maintain the Garden, and that it will be necessary to call on the University at no distant date, to consider whether a moderate annual subvention should not be made to place the Garden on a satisfactory basis. The deficit would have been greater but that the Professor of Botany has made, *proprio motu*, a contribution of £50 towards the funds of the Garden. The new range of glass-houses, including the palm house and the succulent house, has been completed and proves satisfactory.

Elections to Scholarships in Natural Science will be held at the following Colleges:—Balliol College, examination to begin on November 20, a scholarship in Natural Science worth £80 a year, on the foundation of Miss Hannah Brakenbury. Balliol, Christ Church and Trinity College. At Balliol two Scholarships of the value of £80 a year and one Exhibition of the value of £40 a year. Christ Church, one Scholarship of the value of £80 a year and one Exhibition of the value of £85 a year. Trinity College, one Scholarship of the value of £80 a year. The examinations for these Scholarships will begin on Tuesday, November 20.

CAMBRIDGE.—Dr. Bradbury, the Downing Professor of Medicine, has appointed as his assistant in Pharmacology Mr. C. R. Marshall, Research Fellow of Owens College, Manchester.

The Rede Lecture will be given in the Anatomy School by Mr. J. W. Clark, Registrary, on June 13 at noon. The subject is "Libraries during the Middle Ages and the Renaissance."

A considerable number of courses in scientific subjects, including Chemistry, Mineralogy, Geology, Anatomy, and Pathology are announced for the ensuing Long Vacation, which is more and more assuming the character of a regular term.

No less than twenty-three women are announced as having "deserved Mathematical Honours" in Part I. of the Mathematical Tripos.

By the election of Dr. Hickson to the Professorship of Zoology at Owens College, Manchester, a vacancy is created for a University Lecturer in Invertebrate Morphology.

SCIENTIFIC SERIALS.

Wiedemann's Annalen der Physik und Chemie, No. 5.—On the measurement of surface tension of water and mercury in capillary tubes, by G. Quincke. In accurate measurements of the surface tension of water by elevation in capillary tubes the marginal angle must be taken into account. It is different from zero, and generally increases with the age of the tubes. For the same kind of glass the surface tension of water at 18° is generally found to increase with the diameter of the capillary tube. For wide tubes of normal Jena glass or English flint glass the surface tension at 18° was 7·846 and 7·776 mgr.—On the magnetic deflection of cathode rays, by Philipp Lenard. The magnetic deflection is not affected by the medium in which the rays are observed, but remains the same for a given species of cathode rays, whatever may be the gas, the intensity, and the pressure. But at different pressures within the generating apparatus different cathode rays are produced, showing varying amounts of deflection.—On a sodium-nitrogen compound, by L. Zehnder. Sodium mirrors deposited electrolytically in vacuum tubes gave rise to strong absorption and rapid fall of pressure, accompanied by the formation of a brown mirror during the glow discharge. A detailed investigation showed that this action takes place as soon as metallic sodium has been transferred to the cathode. The compound formed, probably NNa_3, is not deposited on the cathode, but on the glass walls near the anode.—On the elliptic polarisation of reflected light, by K. E. F. Schmidt. In the case of glasses of equal refractive indices and different dispersive powers the glass with the higher dispersion shows the wider range of angle at which ellipticity is observed.—On the spectra of tin, lead, arsenic, antimony and bismuth, by H. Kayser and C. Runge. The authors have continued their efforts to find uniformities in the structure of the metallic line spectra through the periodic series of the elements. The above metals were taken as convenient representatives of the fourth and fifth rows. The spectrum of tin may be reconstructed by superimposing three equal spectra differing by a constant oscillation frequency. The same law applies to the spectra of lead and arsenic. In the case of antimony, six such spectra are superposed, and in bismuth four.—Line spectra, by J. R. Rydberg. This is a comparison of the spectra of calcium and strontium.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 10.—"Preliminary Report on the Results obtained with the Prismatic Camera during the Total Eclipse of the Sun, April 16, 1893." By J. Norman Lockyer, C.B., F.R.S.

During the total eclipse of 1871 observations were made by Respighi and the author with a spectroscope deprived of its collimator, and a series of rings was seen corresponding to the different rays emitted by the corona and prominences. A similar instrument, arranged for photography, was employed during several succeeding eclipses, but the photographs were on so small a scale that none of the results came up to the expectations raised by the observations of 1871. As the Solar Physics Committee is now in possession of a prismatic camera of 6 inches aperture, the prism having a refracting angle of 45°, it was determined to employ it during the eclipse of 1893. The instrument was placed at the disposal of the Eclipse

Committee by the Solar Physics Committee, and was entrusted to Mr. Fowler, who took the photographs at the African station.

It also seemed desirable that a series of similar photographs should be taken at another point on the line of totality, even though an equally efficient instrument were not available. A spectroscope with two 3-inch prisms of 60°, used in conjunction with a siderostat, accordingly formed part of the equipment of the expedition to Brazil, and was placed in charge of Mr. Shackleton.

The present preliminary report is intended to indicate the kind of results obtained, and some of the photographs are reproduced for the information of those specially interested, as it will be some time before the complete reductions are ready for publication.

The most conspicuous lines, or rather portions of circles, seen in the photographs taken during totality, are the H and K lines of calcium, and in these rays the images of the various prominences are very clearly outlined.

The lines of hydrogen, extending far into the ultra violet, are also very prominent, and numerous other lines are seen in addition.

Isochromatic plates were used for some of the exposures, and on some of these the ring formed by the characteristic line of the coronal spectrum (1474 K) is clearly depicted, especially in the Brazilian photographs. A comparison with the photographic records of the corona shows that the prismatic camera has picked out the brightest parts of the corona in this way. All the photographs show a bright continuous spectrum from the inner corona.

"On the Leicester Earthquake of August 4, 1893." By C. Davison, M.A., King Edward's High School, Birmingham.

On August 4, 1893, at 6.41 P.M., an earthquake of intensity nearly equal to 6 (according to the Rossi-Forel scale) was felt over the whole of Leicestershire and Rutland and in parts of all the adjoining counties. The disturbed area was 58 miles long, 46 miles broad, and contained an area of about 2066 square miles. The direction of the longer axis (about W. 40° N. and E. 40° S.) and the relative position of the isoseismal lines show that the originating fault, if the earthquake were due to fault-slipping, must run in about the direction indicated, passing between Woodhouse Eaves and Markfield, and hading towards the north-east. The anticlinal fault of Charnwood Forest, so far as known, satisfies these conditions, and it is highly probable that the earthquake was caused by a slip of this fault; greatest in the neighbourhood of Woodhouse Eaves, and gradually diminishing in amount in either direction, rather rapidly towards the north-west and much more slowly towards the south-east. The total length of the fault-slip may have been as much as twelve miles or even more, and there can be little doubt that it was continued for some distance under the Triassic rocks on which Leicester is built.

Royal Society, May 10.—"The Stresses and Strains in Isotropic Elastic Solid Ellipsoids in Equilibrium under Bodily Forces derivable from a Potential of the Second Degree." By C. Chree, Superintendent of Kew Observatory.

The problem solved in the present memoir, viz. that of an isotropic elastic solid ellipsoid under the action of bodily forces derived from a potential

$$\tfrac{1}{2}(Px^2 + Qy^2 + Rz^2),$$

is the most general case of equilibrium under forces derived from a potential of the second degree. The above potential covers forces arising from mutual gravitation or from rotation about a principal axis in an ellipsoid of any shape.

The solution obtained satisfies without limitation or assumption of any kind all the elastic solid equations. It enables the variation in the effects of gravitation and rotation with the change of shape of the ellipsoid to be completely traced.

The results obtained for the very oblate and very oblong forms seem to show that in many cases of bodily forces the assumptions usually made in the treatment of thin plates and long rods would not be justified.

By comparison with the author's previous researches, a close similarity is shown to exist between the phenomena in rotating flat ellipsoids and thin elliptic discs on the one hand, and rotating elongated ellipsoids and long elliptic cylinders on the other.

Royal Society, May 24.—"On certain Functions connected with Tesseral Harmonics, with Applications." By A. H. Leahy, late Fellow of Pembroke College, Cambridge, Professor of Mathematics at Firth College, Sheffield.

Royal Society.—*Correction*.—In the abstract of the paper "On the Specific Heats of Gases" (Part III.), by J. Joly, F.R.S., read (in place of the formula given):—

$$Cv = a + 2b(100 - t) + 3e(100 - t)^2.$$

Royal Microscopical Society, May 16.—Mr. A. D. Michael, President, in the chair.—Mr. C. Lees Curties exhibited and described a microscope which had been specially made for photographic purposes. The leading feature of the instrument is that the nose-piece is removable, so that an ordinary photographic lens can be substituted for the objective if required. He also exhibited a new form of apparatus for obtaining instantaneous photographs of objects under the microscope; as examples of what could be done with this apparatus, he showed photo-micrographs of blood-corpuscles taken with powers × 306 and 600 diameters, and also some low-power photos of living specimens of *Lophopus* with tentacles extended. Dr. W. H. Dallinger thought the photomicrographs were extremely good. He noted in the immediate vicinity of the *Lophopus*, there were some vorticellæ, and this suggested that it might be possible to take them in the act of closing, so as to get an idea how the movement was performed.—Mr. Shrubsole said he had brought to the meeting a few living specimens of *Gromia*, which were shown under the microscopes on the table. One peculiarity of these specimens was that instead of possessing but one aperture, there was a zone of small apertures round a central one. This he thought was a good reason why this object should be removed from the Monostomia. After describing a naked rhizopod closely allied to *Lieberkuhnia*, and an organism resembling *Shepheardella*, Mr. Shrubsole said he had on the previous day obtained from the water off Sheerness some masses of a dirty-looking substance containing all sorts of forms of gelatinous objects, in which were imbedded a number of granules; they were the cause of what the fishermen called "foul water," or "May water." They were only seen for certain seasons and for a short time, and it would be an interesting inquiry to find out what became of them.—Prof. Jeffrey Bell said that he had just been present at the annual inspection of the Marine Biological Laboratory at Plymouth, and he found that one of the greatest troubles there had been the condition of the water. Only two fish had died during the last twelve months, but the Director was desirous of obtaining information as to the diatomaceous and desmidaceous condition of the water in the tanks. Inquiries naturally suggesting themselves would be what the organisms really were which caused this "foul water"; was the "foul water" due to their presence, and were they a great number of larva undergoing transformation?—Prof. Bell called attention to the three frames of photo-micrographs which formed the Society's exhibit at the Chicago Exhibition, and which had just been returned. The Fellows would have now the opportunity of seeing them and determining whether they were worthy of the medal which they were told had been awarded the Society.

Quekett Microscopical Club, May 18.—Mr. A. D. Michael, Vice-President, in the chair.—Mr. C. L. Curties exhibited a new instantaneous photo-micrographic apparatus, and explained the method of using it. Some excellent pictures of pond-life, and fresh human blood corpuscles, &c., taken by this apparatus, were handed round for inspection, and one group of *Lophopus*, fully extended, surrounded by vorticellæ, was particularly admirable and life-like. The Chairman thought this apparatus would be especially valuable for obtaining representations of quickly-moving organisms, which were almost impossible to draw in a natural way because of their rapid volutions, and they might get composite pictures which would throw some light on this difficult subject of locomotion in minute animals, such as had been done by Muybridge and others with the horse, for instance. Mr. G. Western read some interesting notes of foreign rotifers which had since been found in Britain, amongst them being *Notholca heptodon*, *Bipalpus vesiculosus*, *Chromogaster testudo*, *Æcistes mucicola*, and *Æ. Socialis*, *Brachionus dorcas*, and others, which were accompanied by beautifully executed drawings by Mr. Dixon-Nuttall. Mr. Western pointed out the uncertainty and variability of many of the characters relied upon for specific, and in some cases for generic, value, such as the presence or absence of setæ, antennal appendages, or even of the eyes. Mr. Michael said with regard to the eye he had frequently found the same peculiarity among the Hydrachnea or water-mites; in the same gathering would perhaps be met with specimens otherwise identical, some with and some without eyes, or the eye present on one side only. The pigment greatly varied in amount, or was entirely wanting, but without sections it was difficult to say whether that was the case with the true nervous part of the visual organ, which, from its transparency, was easily overlooked in merely surface views.

PARIS.

Academy of Sciences, May 21.—M. Lœwy in the chair.—Researches on trimethylene and propylene, and on a new class of hydrocarbons: dynamical isomerism, by M. Berthelot. Trimethylene and propylene have, respectively, − 17·1 Cal. and − 9·4 Cal. for heats of formation from their elements. The corresponding dibromides, sulphates, and alcohols have nearly the same heats of formation; just as trimethylene and propylene differ by − 7·7 Cal. in heat of formation, so the formation of bromides, sulphates, and alcohols from these substances liberates more heat in the case of trimethylene, the excess being + 9·4, + 8·8, and + 10·2 Cal. in the respective cases. The dibromides liberate heat on the further addition of bromine as follows:—

	$+Br.$	$+Br_2.$	$+2Br_2.$	$+3Br_2.$
Propylene dibromide	+0·522,	+0·872,	+1·397,	+1·661 cal.
Trimethylene dibromide	+0·592,	+1·010,	+1·567,	+2·052 ,,

The heat of formation of terebenthene is +4·2 Cal., of citrene is + 21·7 cal., and of liquid camphene is about 24 Cal. The corresponding hydrochlorides have nearly the same heats of formation. From these data it is argued that trimethylene and terebenthene belong to a new class of hydrocarbons, and are dynamical isomerides of propylene and camphene respectively.—A note by M. Lœwy accompanying the presentation of a volume of the "Annales de l'Observatoire de Bordeaux."—On the formation of urea in the liver after death, by M. Charles Richet. The formation of urea is analogous to the production of sugar. Urea continues to be formed in the liver after removal from the body and cleansing from blood, &c., by washing, probably by hydrolysis due to the action of a soluble diastase.—The insects of the carboniferous period, by M. Charles Brongniart.—On the superficial tension of saline solutions, by M. H. Sentis. If F be the superficial tension of the saline solution, f that of water at the same temperature, u the volume of 100 molecules of water, and v that of a mixture of n molecules of the salt with 100 − n molecules of water, we have

$$\Phi = F - \frac{100-n}{100} \cdot \frac{f}{\sqrt[3]{\frac{v}{u}}},$$

where Φ is the action per unit of length between the molecules of the salt and the molecules of water. With regard to Φ—(1) This action is independent of the temperature between 0° and 25°; (2) it is proportional to n up to the most concentrated solutions; (3) it is independent of the nature of the salt and approximately equal to 0·78 dyne per centimetre for each radical equivalent (*e.g.* $\frac{\Phi}{n}$ for NaBr, KCy, $MgSO_4$, $CaCl_2$, and K_2CrO_4 is respectively 1·6; 1·5; 1·6; 2·3; and 2·4).—Properties of magnetic substances at various temperatures, by M. P. Curie. Oxygen, manganese chloride, ferrous sulphate, and palladium follow the law expressed by $k = \frac{A}{T}$ where k is the specific coefficient of magnetisation, A is a constant, and T is the absolute temperature. The temperature of magnetic transformation of nickel is near 340°. Its coefficient between 373° and 806° is independent of the intensity of the field, and decreases regularly and very rapidly as the temperature rises. The temperature of magnetic transformation of magnetite is about 535°. From 550° to 850° it behaves like nickel, from 850° to 1370° it obeys the same law as oxygen. Iron exhibits very complex phenomena. Between 860° and 1280° there appears to be another modification of iron formed; before 860° and beyond 1280°, iron behaves like nickel.—On a system of new scales, by M. Alexandre de Bertha.—Apparent death produced by alternating currents. Restoration to life by means of artificial respiration, by M. A. d'Arsonval. In the cases where death has apparently been caused by direct action of the current on the nerve centres, without lesion or destruction of the tissues, it is found possible to revive the patient by the treatment adopted with apparently drowned persons.—On a method permitting the measurement of the mental intensity of vision and the longitudinal aberration of the eye, by M. Charles Henry.—Absorption spectra of hydrobromic solutions of cupric bromide, by M. Paul Sabatier. The absorption between $\lambda = 660\,\mu\mu$ and $\lambda = 440\,\mu\mu$ is far more intense than in the cases of the alcoholic solution of the anhydrous salt or the aqueous solutions of the green and blue hydrates.—On the molecular transformations of some chromic compounds, by M. A. Recoura.—On some combinations of ammonia with various silver salts, by MM. Joannis and Croizier. The compounds $AgBr.3NH_3$, $AgBr.1\frac{1}{2}NH_3$, $AgBr.NH_3$, $AgI.NH_3$, $AgI.\frac{1}{2}NH_3$, $AgCy.NH_3$, $AgNO_3.3NH_3$, $AgNO_3.2NH_3$, $AgNO_3.NH_3$ have been studied, and their temperatures of dissociation, as also their characteristic formulæ for the pressures of dissociation at any temperature, are given.—On the detection of hydrochloric acid, by MM. A. Villiers and M. Fayolle.—On geraniol from the essence of *Andropogon Schœnanthus*.—Does digestion of proteid matters without digestive ferments exist? by M. A. Béchamp.—Essay on a theory of the temporal (bone), by M. S. Jourdain.—On the increase of temperature of earth-layers with the depth in the low Algerian Sahara, by M. Georges Rolland. In many parts of the low Algerian Sahara, between 30° and 35° Lat., the temperature increases with the depth at least 1° for 20 metres, and often much more rapidly.—Agronomic map of the canton of Ferté-sous-Jouarre, by M. Gatellier.

HAGEN'S SYNOPSIS OF HIGHER MATHEMATICS.

Synopsis der Höheren Mathematik. Von Johann G. Hagen, S.J., Director der Sternwarte des Georgetown College, Washington, D.C. Erster Band: Arithmetische und algebraische Analyse. (Berlin: Felix L. Dames, 1891.)

THE author's object has been to give a bird's-eye view, or synopsis, of the whole range of higher mathematics; and this handsome volume of 398 pages is a first instalment. The work is not intended as a treatise, or to be merely a book of reference to which the mathematician may turn for his formulæ. It has a much more ambitious scope, and aims at presenting a general view of all branches of mathematics, methodically arranged and separated into a great number of sections, each of which contains a notice of the history of the subject to which it relates, followed by a series of numbered paragraphs giving the principal formulæ, with full references to the books and writings from which they are taken, and to which the reader must have recourse for further information.

The branches of mathematics treated of in the present volume may be classed under the four heads of Theory of Numbers, Theory of Series, Theory of Functions, and Theory of Equations. In this classification, however, an extended meaning must be given to these titles, for the functional branch includes determinants, invariants, and groups. Altogether there are twelve subject headings divided into 102 sections, each of which is further subdivided into separate articles when required. As an example of the mode of arrangement, we may take the Partition of Numbers. We first find a general sketch of the algebraical methods of Euler, Cayley, and Sylvester, with many of Euler's most interesting results; then we pass to partitions into figurate numbers and to quadratic forms, both treated in a similar manner.

It is evident that any near approach to absolute completeness could not be attained in such a comprehensive undertaking. No single person could read and digest the whole of mathematics as it exists in our day, and arrange and systematise it in a series of volumes. It might even be regarded as open to question whether so bold an enterprise could meet with any measure of success. But no one can look at this volume without admitting that the attempt has been well justified, and that, whatever its imperfections, we are indebted to the author for a most interesting and valuable work.

The critical reader naturally turns first to the subjects—or, rather, the portions of subjects—with which he is himself best acquainted, and it is not surprising if he should here find omissions; but, even in this extreme case, the sections in question can scarcely be read without advantage as well as interest. The true test of the utility of the work is afforded by an inspection of the sections relating to subjects which lie adjacent to, but not upon, the direct line of the reader's own studies; here he cannot fail to be impressed by the new matter which he will find set out before him.

The history, theorems, and references are grouped together in an attractive manner; a mathematician could not turn over the pages, even in the most casual manner, without being tempted to stop here and there and pore over some of the paragraphs. The historical introduction is always remarkably clear, and the formulæ are sufficiently explained to render them intelligible as they stand. Although the book is to some extent a cyclopædia, it is not unduly concise, nor is any attempt made to save space by the introduction of special abbreviations in the explanations or references.

As an illustration of the contents of the sections, we may take the paragraphs which relate to the number of prime numbers. We first find references to the proofs of the theorems that the number of primes is unlimited, and that every arithmetical progression, whose first term and difference have no common factor, must contain a prime. The next paragraph gives an account of Gauss's, Encke's, and Legendre's approximate formulæ for the numbers of primes between given limits, with references. Then we come to a *résumé* of Tchebicheff's memoir of 1851, with Sylvester's additions (1881), followed by a similar statement of Riemann's results (1859) and a reference to Meissel's methods of calculating the exact number of primes up to a given limit (1871). As another illustration, we may take the section relating to the harmonic series. First we find references to works or memoirs where special cases of harmonic series are treated at some length; then we come to the general summation by means of the semi-convergent series with Eulerian numbers as coefficients; and the section closes with an account of the history of Euler's constant. From this description it will be seen that the work, covering as it does all higher mathematics, is unique in its character. No other writer has attempted to deal systematically with any large field of mathematical research so fully and completely.

It seems to us that Mr. Hagen has very skilfully combined statements of results with references. It is difficult to avoid being too diffuse when formulæ have to be selected from an elaborate memoir; and it is difficult to render a mere body of references attractive. But in both these respects the author has been successful. The references are always accompanied by enough explanatory matter to render them interesting; in fact, unlike most mathematical quartos, every page of the book is "readable" in the ordinary sense of the word. The subdivision of the subjects into so many sections, though convenient for the user, must have added considerably to the labour of preparation, and increased the difficulty of arranging the references so as to avoid repetition.

A list of sixty-six treatises and twenty-one periodicals, which are referred to in the volume, is given at the end. This list, long as it is, might have been considerably extended, had more complete libraries been accessible to the author. As it is, the works consulted form a most excellent nucleus, which may be supplemented at some future time by the author or a successor. Had many more been included, we think the author's attempt must have failed, no matter what ability and perseverance he might have brought to his task. It is to be remembered that for such a compilation it is necessary to study the memoirs with some care in order to decide upon the results to be selected. No one who has not had experience of this kind of work can appreciate the labour involved; it is comparatively easy when the abstractor can confine himself to his own line of study, but when he has to get up fresh subjects for the purpose, the difficulty is enormously increased. It would be manifestly unfair to criticise a work of this kind on account of its deficiencies, or even its errors. Any competent mathematician who carries out such an undertaking is entitled to the thanks of his fellows for whatever he puts before them; and when he does his work well, as Mr. Hagen has done, he may be heartily congratulated upon a real service rendered to mathematical science.

The difficulty of dealing with the ever-increasing volume of journal literature is one which is common to all the sciences, but it is perhaps felt most acutely in mathematics, where the lines of research are so very numerous, and the workers in each are but few. The want of treatises has to some extent been supplied by the republication in a collected form of the scattered papers of many eminent mathematicians. The value of these complete editions cannot be exaggerated; but they necessarily aggravate the tendency to accumulate all discoveries upon the greatest names, and throw still further into the background the productions of the less distinguished writers. The paramount merit of classified indexes and books of an encyclopædic character is that they treat all papers with the same impartiality; and probably there are no works which do more for the advance of science than those which, like the present, have for their sole object to make available for general use the stores of more or less inaccessible knowledge which have been laboriously acquired and put on record. Perhaps, too, when Mr. Hagen has mapped out the whole territory of mathematics, there may be found some who will be willing to fill in certain regions on a larger scale than so comprehensive a plan has permitted to him.

A few words should be added with respect to the book itself. It is beautifully printed, the pages are large and handsome, and it is well indexed. The formulæ are so numerous, and the text is so conveniently divided into short and clear paragraphs, that the language will present no obstacle to anyone possessing the least acquaintance with German. It is intended that the complete work shall consist of four volumes, the second relating to geometry. If carried out in its entirety with the same care that has been bestowed upon the first volume, the whole work will form a splendid contribution to the history and progress of mathematics.

J. W. L. Glaisher.

MICRO-CHEMISTRY.

A Manual of Micro-chemical Analysis. By Prof. H. Behrens. With an introductory chapter by Prof. John W. Judd. (London: Macmillan and Co., 1894.)

THE necessity of supplementing the microscopical examination of rocks and minerals by chemical tests led Dr. Boricky in 1877 to devise his method of micro chemical analysis. He decomposed extremely minute particles of the substance to be examined on a glass slide, protected by a coating of Canada balsam, and examined the fluosilicates formed by the aid of the microscope. Since his time Prof. Streng, Dr. Haushofer, the author of the present manual, and others have devoted themselves to improving and extending micro-chemical methods. Although originally introduced for the purpose of enabling chemical tests to be applied to extremely small particles, it has been found that these methods have another and perhaps equally important claim to recognition. They often shorten the time required for a qualitative chemical examination. Thus Prof. Behrens tells us that a solution containing calcium, magnesium, zinc, manganese, cobalt, and nickel has been examined in forty minutes; and one containing silver, mercury, lead, bismuth, tin, antimony, and arsenic in an hour.

Up to the present time no general work on micro-chemical analysis has appeared in the English language, so that the manual before us fills a definite gap in our scientific literature. It is divided into three parts. The first treats of the general method and of the reactions at present employed in the identification of the different elements; the second, of the application of the method to the analytical examination of mixed compounds.

The apparatus required is of the simplest character. A microscope with magnifying powers of 50 and 200, a few microscopic slides, some capillary tubes, one or two platinum spoons, some platinum wire and foil, a burner giving a flame 5 mm. high, and a box of reagents, are almost all that is absolutely necessary. An idea of the scale on which the operations are conducted may be obtained from the fact that, in establishing the limits of the applicability of the several tests, the author worked with drops having a volume of one cubic millimeter. The conditions which determine the suitability of any particular reaction for micro-chemical work are obviously very different from those which govern ordinary qualitative analysis. It is much more important that the compounds formed should be easily recognisable, than that complete precipitation should be effected. The compounds by which elements are recognised under the microscope are therefore, as a rule, those which possess an appreciable though not very great solubility; for such compounds most readily form well characterised crystals.

It is in the selection of suitable reactions that Prof. Behrens has done so much to facilitate the application of micro-chemical methods. In describing these reactions he gives in each case the limit of sensibility in micro-milligrams, the precautions necessary to secure the result, and the circumstances under which the particular reaction is applicable. The work is illustrated with numerous figures representing the compounds relied upon for diagnostic purposes; but, as the author points out, the only way of acquiring facility in the identification of these compounds, as well as confidence in the method, is to go through the reactions and observe the results under the microscope.

The second part of the work treats of a systematic scheme of examination, and of the micro-chemical analysis of water, ores, rocks, alloys, and some combinations of rare elements. It must be admitted that it is at present quite impossible to formulate any general scheme at all comparable with those in use in ordinary analysis; and the chemist, unacquainted with what has been done by the aid of micro-chemical methods, would undoubtedly carry away a very unfavourable impression of them if he confined his attention to this part of the book. The following portions, which treat of the application of the method to ores, alloys, rocks, &c., are much more satisfactory, and contain information of great value to the metallurgist, petrologist, and others.

After all, micro-chemical analysis is only in its infancy, and, as the author points out, the present work will doubtless prove to be a mere outline compared with the manuals which will be published twenty years hence, "when the advantages of micro-chemical analysis will be understood everywhere, when its appliances will be fully developed, when difficulties have been surmounted, and obscurities have been cleared up." Meanwhile it is to be hoped that the publication of this small but extremely valuable little volume will have the effect of largely increasing the number of those who use micro-chemical methods in this country.

OUR BOOK SHELF.

Practical Botany for Beginners. By F. O. Bower. (Macmillan and Co., 1894.)

PROF. BOWER'S well-known "Practical Botany" has won for itself universal recognition as forming an indispensable adjunct to the botanical laboratory. But with its increasing popularity the size and scope of the volume also advanced, and at the present time, though it is invaluable to the student with sufficient time at his command, it is somewhat bulky for the large class of persons who, from various circumstances, require a more elementary acquaintance with the types they investigate.

It is for these that the "Practical Botany for Beginners" has been designed, and it will certainly prove of great service. Although the book is of smaller dimensions than the larger work just referred to, it is still conducted on the same lines. The text, so far as it goes, is for the most part similar, and the reduction in size is provided for by the use of smaller type, and by the omission of many subsidiary descriptions which had been introduced for purposes of comparison.

Like all good introductory books, it assumes no previous knowledge in the department to which it relates, and thus the student is enabled to begin really at the beginning. It will, however, be his own fault if he is not in possession of a very creditable amount of sound knowledge by the time he has worked through the volume. For those who are unable to go through the more extended course, a better book than the present one could not be recommended.

Simple Experiments for Science Teaching. By John A. Bower. (London: Society for Promoting Christian Knowledge, 1894.)

TEACHERS of science in elementary schools now live in halcyon days. Time was when books containing courses of experiments suitable for teaching the young idea the science of common things were hard to find, and they who desired to impart such instruction had to prepare their own sequence of lessons. But the examinations of the Science and Art Department and similar bodies have changed all that. There are now numerous primers for all branches of elementary science, some good, many indifferent, and a few bad. Teachers are no longer under the necessity of exercising the faculty of originality in devising experiments for class-demonstration, for the work is done for them, and frequently done well, by the much-maligned text-book writer. Possibly the mental atrophy thus brought about is not desirable, but there is little doubt that the teaching has been benefited. Few of the courses of elementary science in our schools and colleges were truly scientific in character, and it is chiefly the text-book that has improved the old state of things by giving law and order to the chaos of experiments.

Mr. Bower's book deserves classification with those that help on the work of science. It consists of two hundred experiments fully illustrating the elementary "Physics and Chemistry" division in the code for evening continuation schools. The experiments are well graded, they are simple, they illustrate phenomena of every-day life, and most of them can be performed with the homeliest things. The pupil who sees the experiments will learn much; he who does them will obtain an excellent foundation in physical science. The book is nicely printed and sufficiently illustrated, and would be a very acceptable present for a boy fond of finding out some of the ways of nature.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Teeth and Civilisation.

IN a letter to NATURE for May 17, on "The Teeth and Civilisation," the writer advances a theory to account for the great prevalence of decay of the teeth at the present day, and concludes that Dr. Wilberforce Smith's investigations show that "the ancients enjoyed a perfect set of teeth till advanced years, and modern savages enjoy the same blessing."

I have not had the opportunity of seeing Dr. Wilberforce Smith's communication, but the number of cases examined in this particular instance (ten Sioux Indians) would hardly be sufficient to draw any conclusions from; and even in these ten cases *all* the teeth were not examined. I think, however, it has been sufficiently proved by several careful investigations that caries of the teeth is not a purely modern disease, and is not entirely confined to civilised races. My father, in a communication to the Odontological Society in 1870, brought together the results of an inquiry extending over more than ten years, in which he examined over 2000 skulls, including all the available collections in Great Britain, and his conclusions as to the prevalence of dental caries differ very considerably from those of the writer of this letter.

Among thirty-six skulls of ancient Egyptians he found caries in fifteen (41·66 per cent.), in seventy-six Anglo-Saxon skulls he found twelve cases (15·78 per cent.), among 143 skulls of Romano Britons there were 41 cases of caries (28·67 per cent.), while among 44 miscellaneous skulls of ancient Britons 20·45 per cent. showed carious teeth. Several other collections gave similar results.

Again, with regard to savage races—among the Tasmanians 27·7 per cent. of caries was found, among native Australians 20·45 per cent., among East African skulls 24·24 per cent, and among those of West African natives 27·96.

Similar results were obtained on the examination of skulls of many other races, but I think I have quoted figures sufficient to prove that caries is not confined to civilised races or to modern times.

It is quite comprehensible that excessive nerve strain, especially by affecting vascular supply, may lead to imperfect nutrition during the *development* of the teeth, and we know that the diseases of early childhood have a very marked effect upon tooth structure, indicated by the ridged and defective teeth so frequently seen, and it seems quite possible that too early stimulus of the brain in childhood may have a similar effect on forming teeth. It is very difficult, however, to understand how nerve strain can have any *direct* effect upon fully formed teeth, and we should, I think, look for the explanation of the cases referred to in some vitiated condition of the fluids of the mouth, caused by the depressed condition of health so common amongst hospital nurses.

There is little doubt that an open-air life and healthy surroundings encourage the formation of sound teeth in a sound body: but I cannot but think that the principal cause of caries must be looked for in the food. It is plainly shown by many investigators, and in the paper above referred to, that caries is rare among peoples who subsist principally upon animal food; the Esquimaux showed, among sixty-nine skulls, only two cases of caries, and the largest amount of disease was found among those races who lived upon a mixed or exclusively vegetable diet. These results are, of course, easily understood under the more accurate knowledge which we now possess of the immediate causes of dental caries.

As to the relative frequency with which different teeth are affected, I think statistics plainly show that it is the first molar tooth of the *lower* jaw which is most prone to decay of any tooth in the series, and most authorities consider the second lower molar as the next in order; with these two exceptions the upper are more frequently diseased than the lower teeth. This would, however, not affect the argument, as the lower molars are of course also supplied by the fifth nerve.

Structural defects, due to inherited weakness or imperfect nutrition *during the development of the teeth*, combined with the use of soft cooked food, which is long retained in contact with them, and is of a nature eminently suitable for fermentation, give us, I think, the principal factors of decay among civilised races.

While allowing the influence of nerve strain in early childhood, and as a factor in hereditary transmission of defective structure, I fail to see how it can influence teeth already formed. J. Howard Mummery.

May 27.

Centipedes and their Young.

Referring to Mr. Urich's letter in your issue of April 5, I send the following remarks, which no doubt will interest some of your readers. During my eight years' residence in Guiana, I have frequently had brought to the museum, centipedes of from 5 8 inches in length, carrying their young clasped by means of their legs to all parts of the under-side of the body, though generally the young have been clustered in dense masses rather than scattered. In their very early stages the young are closely clustered, and seem quite unable to clasp their parent in turn, but later they become very restless, and will be seen moving about independently, and when clustered by the action of the parent they are incessantly changing their position in the cluster. When the young are thus bunched together, the body of the parent is coiled upon itself at that part; and the contrast between a centipede in this position, and a scorpion carrying her young upon her back, just as a small opossum does, is a very marked one.

I had imagined that this habit of the centipedes was widely and generally known; and indeed Packard ("Guide to the Study of Insects," p. 674) remarks that "Wood also states that the female guards her young by lying on her side, and then coiling her body passes them along by a rapid cilia-like action of her feet, thus arranging them satisfactorily to herself." This is but a very terse description of what will be observed when one disturbs a centipede and the arrangement of her young about her body.

As remarked by Dalton ("History of British Guiana," vol. ii. p. 267), the centipedes "lay their eggs in clusters like little berries on the ground, and the female chooses an obscure place for this purpose, as under flower-pots, where she can remain until the eggs are hatched." Centipedes are not seldom met with in such obscure and uniformly moist places as under flower-pots and tubs, or boards and shingles, with their eggs clustered as described.

With regard to the disappearance of the young ones from the box forwarded from Trinidad to London, the most likely explanation is that they were eaten by the parent. If the parent centipede be kept with the young ones, and left unfed for a day or two, it will be observed to feed quite leisurely and greedily at times on its young. This I have witnessed directly in three separate cases where they had been kept unfed in a long glass jar in the museum. The most desirable food for centipedes in the tropics, I may incidentally remark, is the cockroach. J. J. Quelch.

The Museum, British Guiana, May 10.

The Penetrative Power of Bullets.

I have been stimulated by the recent trials of the bullet-proof cuirass, to try a few experiments on the subject. I will only mention one experiment, which I made this morning, assisted by several members of the junior scientific club here. It occurred to me that if the energy of the bullet could be made to act at rather a large angle to its line of flight, its penetrative power would be diminished. To effect this, I arranged a number of soft iron rods ¼-inch in diameter and 5 inches long, side by side and touching a piece of deal board; on these another layer was placed, so that one of the upper rods touched two of the under ones. A sheet of thin rubber $\frac{1}{16}$-inch thick, placed on this, separated it from a similar combination attached to it at right angles; and the whole formed the target. The rifle used was a Winchester, 22 bore, carrying a long bullet. At a distance of 20 feet the bullet penetrated 5 inches of hard pine with certainty; but when the bullet fired at the same distance hit my rod target, it failed to penetrate even the first layer, but only drove the upper rods aside nearly at right angles to the line of flight. The next experiments will be made with heavier materials and larger shot. Possibly a similar arrangement, but of large steel cylinders, might make a satisfactory barrier to the shot of big guns. Frederick J. Smith.

Millard Engineering Laboratory, Oxford, June 1.

The Garhwal Landslip.

Let me point out that the paragraph on p. 109 of Nature for May 21, stating that the landslip that had occurred in the Garhwal district in the Himalaya, blocking up the Bireh Ganga river, had burst, causing the loss of many lives, is erroneous. The catastrophe reported from India had reference to a locality in Kulu, and not to Garhwal, the two being several hundred miles apart.

An accurate description of the Garhwal landslip will, I hope, be shortly published in the Royal Geographical Society's journal. The obstruction is being carefully watched, and the water has not yet topped it. There is, I think, considerable reason to anticipate that no great destruction will be caused at this place, as the landslip is of such vast dimensions as to make it almost impossible that it should be carried away in a manner to give rise to a great and sudden flood. It is upwards of a mile in length and two-thirds of a mile wide, rising about 900 feet above the original level of the valley, and being largely composed of enormous masses of rock.

June 1. R. Strachey.

Research Work.

May I be allowed to suggest that it would be a great help to many interested in science if an authorised body, such as the British Association, were occasionally to indicate paths of research work in different branches of science, especially in physics and chemistry, which would offer a reasonable prospect of leading to useful results? Many, especially among those engaged in educational work away from London, have not the advantage of continued intercourse with the leaders of scientific thought which would give them the opportunity of forming a judgment themselves, and the fear of having been forestalled by others makes them hesitate to devote the time required for a sustained course of experimental research. Within the writer's experience, men whose judgment carries great weight do not individually feel inclined to give advice which they consider ought primarily to be devoted to the advancement of their own students. The advantages of a laboratory, of leisure time, and of a desire to add their quota to the stock of knowledge are not, by the wise, thrown away, but a great deal of energy, at present more or less dissipated, might be diverted into more useful channels if the above suggestion were carried out—offering each one the opportunity of choosing that particular line of research which most nearly satisfies the conditions in which he is placed. The idea might be still further developed by associating workers together for a common end, even at the risk of not being able to eliminate the personal factor. W. G. Woollcombe.

Birmingham, May 31.

A Daylight Meteor.

The following account of a meteor, seen by me in full daylight, may be of interest to readers of Nature. It was written a few hours after the meteor appeared.

While practising at cricket to-night (May 18), in splendid light, I observed at 7.58 (railway time) a very brilliant meteor cross the sky obliquely from a point considerably north of the zenith to the south-east. Its movement was very slow, and it shone with a brilliant intense white light, which was concentrated in itself, and did not leave a train behind it like the meteor of March 18, 1893, which I had also the good fortune to see.

It got gradually smaller and smaller, and just before disappearing broke up into three or four pear-shaped portions. During its course, although the massy head was always brilliantly white, the little tail varied in hue, crimson and a rich ultramarine blue being most noticeable.

I immediately timed it, and found that it was about 13 seconds in view, which I thought a very long time indeed.

From diagrams made on the same evening, it seems that the meteor moved from a point 40° from the zenith, and some 15° west of north to a point about 30° east of south at an altitude of 30°. JAS. G. RICHMOND.

Muirkirk, Ayrshire, May 30.

P.S.—The *head* when first seen had an apparent diameter about ⅔ that of the sun, and when last seen ⅜ sun's diameter. It rolled across like a ball with a very short tail, until it broke up, when the distance from the head to the tail of the last pear-shaped portion was about 3½ sun's diameter.

Iron Crows' Nests.

REFERRING to the note by Mr. McMillan, in your issue of May 3, it may be of interest to some of your readers to know that we have in this museum a crow's nest from Rangoon entirely made of iron wire such as is used in fastening the corks of aerated water bottles. The donor, Mr. Joseph Dawson, of the Public Works Department, Rangoon, stated in his letter at the time that "wire nests are hardly a novelty in this country, as they can always be obtained from high trees in the vicinity of aerated water factories." The nest in question has a piece of hoop-iron about three or four inches long woven into it; but with that exception it is entirely composed of the small wire, and is about a foot in diameter. J. MACNAUGHT CAMPBELL.

Kelvingrove Museum, Glasgow, May 28.

THE REPORT OF THE COMMITTEE ON ARMY EXAMINATIONS.

IN the *Times* of Wednesday, 23rd ult., there was a brief account of the report lately presented to Parliament by the committee appointed in 1893 "to enquire into the entrance examinations (in non-military subjects) of candidates for commissions in the Army, and to advise whether any modification of the existing arrangements is desirable."

The syllabus of subjects and marks recommended by the committee is as follows:—

CLASS I. (*All may be taken up.*)

	Marks.
1. Mathematics ...	3000
2. Geometrical Drawing...	1000
3. French or German ...	2000
4. English...	1000
5. Freehand Drawing ...	500

CLASS II.—(*Any three subjects may be taken up, but for Woolwich one of the three must be Chemistry and Heat.*)

	Marks.
1. Pure Mathematics ...	2000
2. Applied Mathematics...	2000
3. German or French, as alternating with the same group in Class I. ...	2000
4. Latin ...	2000
5. Greek ...	2000
6. English History ...	2000
7. Chemistry (inorganic) and Heat ...	2000
8. Electricity and Magnetism and Light ...	2000
9. Geography, Political and Physical, and Geology ...	2000
10. Biology...	2000

Certain recommendations as to the fusion of the Woolwich and Sandhurst examinations, the admission to the Army of Queen's cadets, Militia candidates, and University candidates are also made.

In regard to the question of marking for physical exercises and development, which has lately been strongly advocated, it is advised that these subjects should not be marked in these competitions. It seems to be thought, however, that though the physique of our officers has been *well maintained* under the competitive system, yet a small proportion of cadets have been admitted who were not quite up to the necessary standard, and it is recommended that the medical examination should be made somewhat more stringent.

The two changes of greatest importance which have been advised by the committee are, briefly, as follows—

(1) That an elementary knowledge of chemistry and heat shall be made practically obligatory for Woolwich.

(2) That Latin shall be transferred from Class I. to Class II.

There is also a minority report on certain points, viz., on the suggestion of a complete fusion of the competitions for Woolwich and Sandhurst, and on the proposal to transfer Latin to Class II. This is signed by three of the nine members of the committee, and one of these three also signs a separate note in which he dissents from the addition of geography to No. 9 of Class II., and of biology to Class II. as a new subject, and makes certain proposals to meet the special needs of Woolwich (which he admits) that would certainly fail to effect their proposed purpose.

On May 29, this report, and especially the two recommendations relating to science for Woolwich, and to Latin, were vehemently attacked by the *Times* in an article in which the report was denounced as such an one as "might have been framed by a committee of crammers," so far as their probable effect is concerned, rather than by a committee which is unanimous in subscribing to the principle laid down in 1869–70, that the examinations should be designed "with special reference to the curriculum adapted at the most advanced of our public schools, and with the express intention of enabling the competitors to come straight from one of those establishments to the examination-hall without having occasion to resort to any intermediate place of study." And again in a later paragraph, as a mere attempt by a portion of the committee to show themselves modern and advanced at all hazards by replacing the dead languages by the new sciences—Latin by chemistry—which latter subject is pronounced to be the most easy of all to cram in face of the statistics, produced by the Civil Service Commissioners and printed with the report, which show the subject to be above the average in discriminating power—that is to say, one in which teachers have not succeeded, by cramming or in any other way, in raising the marks of the least apt to or near the level of those of the more apt.

The *Times* has not hesitated to accuse the majority of the committee of disregarding the evidence before them, but has itself committed this fault. Its case is indeed mainly founded on such disregard of the facts. By coupling together two changes which stand upon entirely different footings it creates the impression, and is itself apparently under the impression, that the committee was divided on both the above proposals. Nothing is plainer in the reports than that this was not the case.

From the same cause, a reader would gather from the *Times* that science is recommended as an obligatory subject for all Army candidates, whereas nothing of the sort has been proposed.

Then it ignores the fact that the opinions of head masters as expressed to the committee were almost entirely in favour of giving more weight to science in the case of Woolwich candidates. And finally, it seeks to give weight to the opinions of the minority of the committee by putting aside the opinion of the present Director-General of Military Education as that of a person of little present importance on this question, by ignoring the high classical acquirements of Mr. Roby, who is a distinguished scholar and the author of a standard Latin grammar, and by dismissing Sir Henry Roscoe, with his great educational experience on the Scotch University Commission and on other occasions, as though he were an ordinary Member of Parliament with no special experience or weight on a question of this kind. All these facts combine to make it important that we should place the matter fully and in a true light before our readers.

In order to form a just judgment on the recommendations of the committee, it is necessary to do just that which the *Times* has not done. Each of the proposed changes must be considered on its own merits, in relation to the other subjects, to the needs of the various branches of the Service, and to the present teaching powers of the most advanced public schools.

We must first point out that the recommendation that chemistry and heat shall be required in future from all Woolwich candidates stands upon a footing which is in many respects different, and altogether independent of that upon which the other recommendation stands.

In the first place, this recommendation is adopted by every member of the committee except one. And even he, in his dissent, admits that for Woolwich some degree of further specialising is necessary, and makes a recommendation for the purpose of effecting it. Unfortunately his proposal would pretty certainly fail of its purpose; it is quite unsound, and was, we think rightly, not adopted by the rest of the committee.

Secondly, it is not advised that science should be made a compulsory subject for the Army in the same sense as that in which Latin has of late years been compulsory. It is not proposed to require it of all candidates, but only of those who are admitted to the scientific branches.

These, we need hardly point out, form only a minority of the whole. No one need be kept out of the Army through ignorance of science, and those who are really strong in other subjects will not even be kept out of the Artillery and Engineers by this regulation if it be adopted.

Thirdly, as what follows will show, science for Woolwich was strongly supported by most of the head masters who assisted the committee with their opinions. Thus, Dr. Percival, of Rugby, included obligatory science in a scheme of examination which he offered for consideration, and said that he thought any school which is worth considering would bring its candidates up to a very fair level in science before they entered Woolwich or Sandhurst; and explained that he meant not only the larger, but almost all schools.

The Rev. J. E. C. Welldon, of Harrow, included a branch of science in a list of obligatory subjects which he considered should enter into the education of every English gentleman.

Mr. Phillpotts, of Bedford, did not advise compulsory science, but he expressed a wish that the chemistry marks should be raised to 2500, which experience has shown in effect almost make this subject an obligatory one.

The head master of St. Paul's suggested in a letter that a branch of experimental science should be raised to Class I. with 2000 marks for Woolwich candidates.

The head master of Westward Ho wrote that he believed that nothing short of the inclusion of a science among "obligatory subjects" will bring about satisfactory results.

The head master of Loretto placed science on his optional list; but said that but for geography he is not sure if some power of practical work should not be placed among the necessary subjects, and stated that he longs to see practical chemistry introduced into the regular curriculum of schools.

Only two head masters said nothing in support of science subjects for Woolwich. And finally, Prof. Jebb has lately expressed to the Secretary of State for War his opinion that the scientific study and the linguistic studies should be put on an equal footing in respect to these examinations.

With this evidence before them, with complaints alike from schools and on the part of the Professor of Experimental Science at Woolwich, of a waste of time and power there in regard to science teaching, which makes itself felt even in Class I., and which is inevitable under the present system, and with ample testimony to the increasing importance of science to the scientific branches, could any impartial body of advisers have made a more reasonable and more modest recommendation than that which the Army Examinations Committee has made to Parliament?

As regards the influence this change would have upon the curriculum of our "most advanced public schools," and the possibility that it may drive boys from the schools to the crammer, which our contemporary seems greatly to fear, what we wonder would be said by Rugby, Cheltenham, Clifton, Marlborough, St. Paul's, or by Westward Ho, Malvern, Dover, and a score of other schools, if it were suggested to them that their appliances for and power of teaching science were inferior to those of the private tutors? It is notorious that the contrary is the case, that for long past the schools have held more than their own in these respects, and that the school of moderate size that is not now able to give good elementary instruction in chemistry and heat, is so far from being amongst our most advanced schools that it must be pronounced to be one that is unmistakably behind the times.

Finally, the selection of subjects made by the committee is not only a good one, but under the circumstances seems the best that could be made. It will not discourage either chemistry or physics entirely in the schools, and there are schools which prefer each of these branches; it is within the scope of the resources of all thoroughly efficient schools, which some other selections might not have been; and, above all, since it corresponds well with the elementary courses of instruction that have been in force at Woolwich, it will best avoid the loss of time there, which has been already alluded to, and will permit the cadets at once to proceed to those sciences of which they will need a technical and advanced knowledge, such as electricity and the chemistry of explosives, and for which more time and a better state of preparedness at entrance is said to be greatly wanted.

The recommendation to place Latin in Class II., as we have said, needs separate consideration. It must be admitted that there was a considerable body of evidence against it, and a division of opinion on the subject among the members of the committee. The question is one of great difficulty. It would have been impossible to retain compulsory Latin for Sandhurst without practically compelling it for Woolwich also. All who are experienced in these examinations will admit this. But to have retained it for Woolwich would have tended very greatly to limit the range of subjects taken by these cadets. It cannot be said that Latin is professionally an essential subject for Army candidates, as a few others are; and even the *Times* admits that possibly its study may not be "an ideal whetstone of the mind," whilst it is certain that a good many youths do not appear to gain much from it after boyhood is past. Its early introduction into education, and its retention up to a certain point, are, on the other hand, widely thought to be among the best features of the public school system. There is also a feeling that it serves as an excellent introduction to the study of languages, and doubtless it does so when well taught. But these facts, though they afford a strong reason for avoiding any step which would really be likely to prevent the teaching of Latin in the lower forms of public schools, seem to be an insufficient reason for compelling those who do not get on with the subject to continue to study it up to the age of eighteen or nineteen years, when by dropping it in reasonable time they might turn to some, for them, more profitable study. It is often forgotten that when all boys learnt Latin and Greek and little else, but few of them stayed at school so late as great numbers do at present, and that therefore there is less reason for resisting a change in this direction now than there would have been in the days mentioned by General Sir G. T. Chesney, when cadets might enter Woolwich at the age of fourteen or fifteen years.

On the whole, therefore, our feeling is that the recommendation of the majority on this point goes in the right direction. The general position of Latin in the schools will surely be sufficiently protected by the action of the universities, and hence its serious discouragement need not be greatly feared. We would ask, however, whether the objections of the dissentient members of the committee could not be met by a requirement that all candidates should take for one of their subjects from Class II. a language. This would distinctly protect linguistic studies in the schools, and so act distinctly in favour of Latin, without compelling all candidates to offer Latin, or handicapping any school which may prefer not to teach it in all its divisions. It has been said that the difficulty of Latin will prevent its being much adopted as a voluntary subject. Surely this must mean that too high a standard has been adopted for the circumstances of these candidates who cannot of course reach to the level of the higher classical forms. The Civil Service Commissioners should and could prevent any such unfairness as this from occurring, and therefore could prevent the subject from being killed, which surely all would regret.

RECENT ADDITIONS TO THE ZOOLOGICAL SOCIETY'S MENAGERIE.

ALTHOUGH it becomes more difficult year by year for the Zoological Society to add new objects to their collection of living animals, yet, as is shown by the annual reports read at the anniversary meetings, examples of a certain number of species which have not been "previously exhibited" are acquired every year. In 1892, as we are told in last year's report, specimens of 11 mammals, 20 birds, 14 reptiles, and one batrachian "referable to species not included in the last (eighth) edition of the 'List of Animals,'" were added to the series. In 1893, the numbers of novelties in the respective classes were hardly less numerous.

FIG. 1.—The Ounce or Snow-Leopard.

Some of the more noticeable among the recent additions we now propose to bring before the readers of this journal by illustrations drawn from the life by Mr. J. Smit, the principal artist employed by the Zoological Society.

(1) The Ounce or Snow-Leopard (*Felis uncia*).—The Society's lion-house always contains a good representative series of the larger species of cats (*Felis*), such as lions, tigers, pumas, leopards, and cheetahs. All do well in confinement, and probably live much longer in their cages in the Regent's Park than they would do in their native wilds, subject "to the struggle for existence." The jaguar is certainly less easy to obtain, and perhaps less suited to captivity than those already mentioned, but has always a place in the series. But the ounce, or "snow-leopard," as the Indian sportsmen call *Felis uncia*, is a much more difficult subject to deal with. In the first place, the snowy interior of Central Asia, where it lives, is by no means easy of access. In the second place, the animal when captured must "pass through the fire" of an Indian sea-port on its way home, and is not unlikely to succumb to such an ordeal. It was consequently, in spite of the exertions of their many Indian friends and

Fig. —The Cunning Bassaris.

correspondents, not until 1891 that the Zoological Society acquired their first specimen of the ounce. This, however, was a mere kitten, in feeble condition, and, notwithstanding the care lavished on it, did not live many weeks. But in the spring of the present year the Society were more fortunate, having received a fine young male of this animal from the Western Himalayas. It was originally captured, when quite small, by the retainers of Thakur Debi Chand, a native chieftain of Gundla, in Lahaul, in the Western Himalayas, and was sent as a present to Mrs. Mackay, of Dunbar House, Kullu. Mrs. Mackay made a complete pet of it, and brought it up most carefully by hand. It is now nearly full-grown, measuring upwards of six feet in length, and is in splendid health and condition.

In its native state the ounce is said to live amongst the rocks at an elevation of 9000 feet and upwards, on the borders of the snows in the Himalayas and Thibet. It preys upon the wild sheep and goats, and probably also upon the rodents that inhabit these inhospitable regions. In similar situations the ounce is said to be found throughout the higher districts of Central Asia, extending northwards to the Altai and to Amoor-land, and even, it is said by Schrenck, into the Island of Saghalin. But the story of the occurrence of the ounce in Asia Minor, credited by Mr. D. G. Elliot, who has figured this species in his "Monograph of the *Felidæ*," is, as has been subsequently shown, altogether apocryphal, the animal mistaken for the ounce in this district being simply a pale variety of the leopard (*Felis pardus*).

(2) The Cunning Bassaris (*Bassaris astuta*).—The racoons and their allies form a peculiar family of carnivora restricted to the New World with one special exception, *Ælurus* of the Himalayas. One of the most singular and interesting genera of this group is *Bassaris*, of Central America, of which two species are known, *B.*

Fig. —The Grey Coly-strike.

astuta of Texas, California, and Northern Mexico, and its southern representative, *B. sumichrasti* of Southern Mexico, Guatemala, and Costa Rica. It is the former of these two species of which an example has recently been acquired by the Zoological Society after a period of forty years, during which, so far as it is known, no bassaris has reached Europe alive.

The cunning bassaris is of about the size of a small domestic cat, but more slender in form, and provided with a long cylindrical white tail, which is crossed by seven or eight distinct black rings, rendering it the most conspicuous feature of the animal. In a state of nature the bassaris lives among wooded rocks, but often takes up its abode close to houses, and proceeds to ravage the pigeons and poultry. The genus *Bassaris* was originally referred by systematists to the *Viverridæ*, but Sir William Flower's account of its anatomy, published in 1869 (*P.Z.S.* 1869, p. 31), has placed its correct systematic position among the *Procyonidæ* beyond question.

(3) The Grey Coly-strike (*Hypocolius ampelinus*).—For their living specimens of this rare and beautiful passerine bird, which will be found lodged in one of the large cages in the parrot-house, the Society are indebted to their excellent correspondent Mr. W. D. Cumming, of Fao, on the Persian Gulf. The coly-strike has obtained its name, together with its scientific appellation *Hypocolius*, from some fancied resemblance to the African colies (*Colius*), with which, however, it has really nothing to do, though the tints of its plumage exhibit some slight similarity to the above-mentioned form. But *Hypocolius* is a true passerine bird, probably belonging to the caterpillar-hunters (*Campophagidæ*), though this is by no means certain. It was first discovered by the French collector Botta, on the coast of Abyssinia, and described from his specimens by Bonaparte. The German naturalist Heuglin obtained examples of it in 1850 from Massowah,

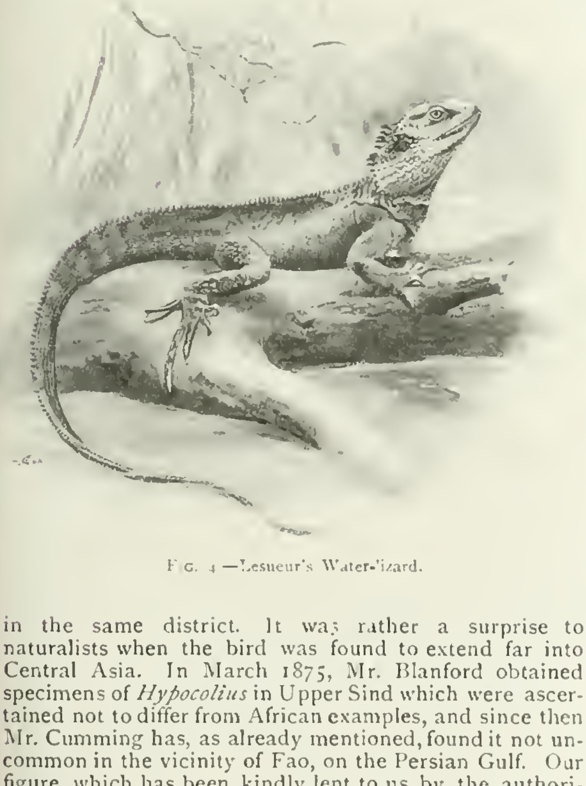

FIG. 4.—Lesueur's Water-lizard.

in the same district. It was rather a surprise to naturalists when the bird was found to extend far into Central Asia. In March 1875, Mr. Blanford obtained specimens of *Hypocolius* in Upper Sind which were ascertained not to differ from African examples, and since then Mr. Cumming has, as already mentioned, found it not uncommon in the vicinity of Fao, on the Persian Gulf. Our figure, which has been kindly lent to us by the authorities of the Zoological Society of London, represents both sexes of this bird during their attempts at nest-making in the Zoological Society's aviary.

(4) Lesueur's Water-lizard (*Physignathus lesueuri*).—Some very strange forms of Agamoid lizards are found in Australia, such as *Chlamydosaurus kingi* with its conspicuous frill, and *Moloch horridus* with its coat of spikes, pronounced by an American writer to be "one of the most repulsive creatures in nature"! The lizard which we now figure, though belonging to the same family, is, however, rather elegant in shape, and bright in colour. It is a member of the Agamoid genus *Physignathus*, of which seven species are recognised by Mr. Boulenger in his "Catalogue of Lizards." Of these four are inhabitants of Australia, whilst one comes from Timor Lant, and the remaining two are found in Cochin China and Siam. The name is taken from the bladder-like expansion of the lower angle of the jaw, which is very striking in these lizards.

In habits the *Physignathi* are said to be aquatic, inhabiting the trees on the margins of rivers, and swimming well with the aid furnished by the wide expansion of the horizontal fringes of scales on the sides of their long stout toes.

The Zoological Society's specimen of this lizard—so far as is known the first that has reached Europe alive—was received, along with other Australian reptiles, in exchange from the Australian Museum, Sydney.

NOTES.

PROF. ROBERTS AUSTEN has been awarded, by the Société d'encouragement pour l'industrie Nationale of Paris, a prize of 2000 frs. for his recent researches on alloys, and more particularly for those which relate to the behaviour of metals and alloys at high temperatures and to their mechanical properties as influenced by small quantities of added elements.

AT the last general meeting of the Zoological Society, it was announced by the Council that they had resolved to bestow the silver medal of the Society on Mr. Henry Hamilton Johnson, C.B., H.B.M. Commissioner and Consul-General for British Central Africa, in acknowledgment of the efforts he had made to increase our knowledge of the zoology of British Central Africa.

WE regret to learn that the American journal *Science* has been discontinued owing to insufficiency of support. The first number appeared on February 9, 1883, and though the circulation, after fluctuating, has steadily increased during the last two years, the paper has never paid expenses.

THE Salters' Company have recently established in connection with the medical school of St. Thomas's Hospital a Research Fellowship in Experimental Pharmacology of the annual value of £100. The Fellow elected, who may hold the office for three years, will be required to devote himself to the study of the physiological action of drugs. The Salters' Company have also endowed a similar Research Fellowship in Chemistry in connection with the research laboratory of the Pharmaceutical Society, in order to provide for investigations on the chemical side of pharmacology.

THE Prince Jablonowski Society of Leipzig has just issued the subject for the mathematical competition of 1897. It is well known that the methods of integrating partial differential equations of the second and higher orders, due to Monge, Ampère, and Darboux, can only be applied to equations which have solutions in common with other equations, which solutions are not entirely dependent upon arbitrary constants. On the other hand, it follows from Lie's investigations of infinite groups that equations admitting of an infinite group of contact transformations have in general this relation of involution to other equations. The problem proposed by the Society is that of developing the methods of integration indicated, and to illustrate them by the most instructive and completely worked-out examples. The prize offered consists of 1000 marks (about £50). Full particulars are given in the annual report of the Society, 1894.

A LARGE number of pupils, friends, and colleagues of Prof. Bertrand, the Permanent Secretary of the Paris Academy of Sciences, met at the École Polytechnique on May 27, and presented him with a medal struck in commemoration of the jubilee of his service on the staff of the school. M. Maurice Lœwy, the President of the Academy of Sciences, presided over the meeting, and among those who assembled to do honour to Prof. Bertrand were General André, MM. Faye, Darboux, and Cornu, M. Gaston Boissier (the Administrator of the Collége de France), G. Perrot (the Director of the École Normale), M. Poincaré, and M. Mercadier (the Director of Studies at the École Polytechnique). "Un pays s'honore en honorant ses grands citoyens," says the *Revue Scientifique* in its report of the ceremony. This aphorism is borne in mind in France more than anywhere else. Bertrand has now been honoured by receiving the homage of his admirers and pupils, like Pasteur and Hermite before him. It is right that this regard should be expressed in the manner it has, for the mathematical sciences do not appeal to the generality: and the only recompense a student of them can hope for is a recognition of the scientific importance of his labours by fellow-workers. The meeting at the Polytechnic School, and the speeches that were made at it, must have made Prof. Bertrand feel that the consecration of his life to the search for truth has brought a reward worth working for.

THE death is announced of Geheimrath A. Kundt, Professor of Physics in Berlin University, and of Dr. K. W. Baur, Professor of Mathematics in the Stuttgart Technische Hochschule.

THE *British Medical Journal* states that Prof. Czerny has declined the offer of the Chair of Surgery in the University of Vienna, made to him by the Austrian Government. It is believed that the reason for his refusal to accept the succession of his old master, Billroth, is the inadequacy of the laboratory and teaching equipment in the Allgemeines Krankenhaus.

WE learn from *La Nature* that a company, formed some time ago for the purpose of constructing an electric railway on the Jungfrau, have asked permission to devote a sum of one hundred thousand francs to the erection of a geophysical observatory, and five thousand francs annually for its maintenance. The observatory would have an altitude of 4200 metres, and the projected line would put it into direct communication with the valley below.

ACCORDING to the *Zoologist* for June, a committee of English sportsmen and naturalists has been formed for the purpose of devising some scheme for the protection of South African mammals, chiefly giraffe, zebra, gland, gnu, koodoo, and other antelopes, several of which, owing to indiscriminate slaughter, are on the verge of extinction. To attain this desirable end it is proposed to enclose a suitable tract of country, of about one hundred thousand acres, with a wire fencing, strengthened by a strong live fence of thorn on the outside. It is hoped that the British South African Chartered Company may allow such an enclosure to be made in the district near Fort Salisbury, which has already been reserved for game by the Company. That such a scheme is feasible is shown by the success which has attended Mr. Austin Corbin's efforts to establish in New Hampshire, U.S.A., a similar game park to that suggested, covering an area of twenty-eight thousand acres. The description of the enclosing and stocking of this park, which follows the proposals of the new preservation society in the *Zoologist*, will do much to combat adverse criticism.

The aim of the National Home-Reading Union may be summed up in a short sentence—to render study attractive. A happy experience of four successive summers has proved to the council of the society that there is no other means by which this can be accomplished so effectively as by taking the student to the locality which most abundantly illustrates his work. We all know that geology can only be learned in the field: and, in like manner, the beginnings of history acquire an objective reality as one stands within the circle at Stonehenge. Botany, also is irresistibly interesting when the teacher accompanies his pupils through a wood or over a moor. The summer assemblies of the Union, which are open to all, whether members of the Union or not, will be held this year at Buxton, in Derbyshire, during the last week in June, and at Salisbury during the first week in July. The character of the scientific side of the meetings may be gathered from the following abridged list of lecturers and subjects. At Buxton the inaugural address will be given by the Ven. Archdeacon Farrar, and lectures will be delivered by the Rev. R. Harley, F.R.S., and others. The geological excursions will be conducted by Mr. J. C. Marr, F.R.S., who will lecture on "The Building of the Pennine Chain." Conferences upon various social and educational subjects have also been organised. The object of the meeting at Salisbury will be the study of the monuments with which the district abounds, illustrative of the archæology, art, and history of Early England—"from Stonehenge to Salisbury Cathedral." Among the lecturers are Professor Jebb, General Pitt Rivers, F.R.S., and Sir Robert Ball, F.R.S. Archæology and geology will be in the charge of Dr. Humphry Blackmore, Professor T. McKenny Hughes, F.R.S., and Baron Anatole von Hugel. Mr. A. C. Seward will lecture on Botany, and accompany the excursions as botanical guide. The Marquis of Bath will preside at the Salisbury assembly, and the Right Hon. W. Woodall, M.P., at the Buxton meeting. Full programmes can be obtained from the Secretary to the Union, Surrey House, Victoria Embankment, London, W.C.

THE current number of *Himmel und Erde* contains a valuable article by Dr. J. Hann, entitled "Ebb and Flow of the Earth's Atmosphere." The paper deals entirely with the diurnal and annual range of the barometer, and Dr. Hann's laborious investigations of these phenomena have frequently been referred to in our columns. It is more than 200 years ago since the regular variation of the barometer by day-time was first observed, and the first person who investigated the regular variation during the night-time, and fixed the morning minimum at about 3h. or 4h. a.m. was the celebrated botanist Colestino Mutis, at Bogota, who commenced his observations in 1761. Blanford and F. Chambers first explained the characteristic difference between the daily range on the sea-coast and at inland stations, and showed the connection of this difference with land and sea breezes. Dr. Hann points out that while there is a large number of theories as to the cause of the double daily oscillation of the barometer, none of them satisfactorily explains the whole of the phenomena. With regard to the yearly range he shows that when the values for the northern and southern hemispheres are separately considered, it is found that the smallest quantities occur in both hemispheres in July, so that we obtain the important result that the values of the double daily oscillation depend more upon the position of the earth with respect to the sun than upon the seasons. He agrees with Lord Kelvin and others that the only means of eventually obtaining a satisfactory explanation of the subject will be by harmonic analysis, and by comparison of the variations at a large number of stations.

THE sixth annual report of the trustees of the Marine Biological Laboratory at Wood's Holl, Massachusetts, informs us that not only has the past season been very successful as far as the number of students and investigators and the quality of their work are concerned, but also that the condition of the finances is more satisfactory than at any time since the foundation of the laboratory. The fact that eighteen different colleges and universities now contribute annually to the support of tables in the laboratory is very encouraging, as showing a wide-spread interest in the laboratory as the summer working-place of both instructors and students interested in biology. It is the aid thus obtained from colleges and universities which, for the first time since its establishment, has rendered the laboratory self-supporting during the past season. The number of students and investigators occupying work-tables last summer was one hundred and eleven, this being the extreme limit of accommodation. There is every reason to believe that the number of applicants for places during the coming summer will considerably exceed the present capacity of the laboratory, and, unless the present building is enlarged, it will be impossible to accommodate them. The trustees hope that provision will be made for the increasing number of students. Further, they have to consider the question of the extension of the field of usefulness by the introduction of departments of biology not yet represented, and the development of those recently introduced into the institution. Such an extension implies an increase of working room, as well as an increase in the laboratory equipment. For the first time, the laboratory numbered last summer among its workers investigators in comparative pathology, and it is thought that, in the near future, this branch of biology should be included among the lines of investigation to be carried on in the laboratory, as are zoology, botany, and physiology at the present time.

A RECENT number of *Science* contains a short article on the employment of disease-causing microbes for the destruction of field mice and similar vermin, in which attention is called to a paper on this subject recently presented to the French Academy by M. Jean Danysz. The microbe employed in producing artificially a destructive epidemic amongst these troublesome vermin, is stated by the author to be very similar to the bacillus of duck cholera, but is not identical, for it is not pathogenic either to these birds or other fowls. Both Löffler and Lasar have discovered similar microbial enemies to field mice which have been used with marked success for the suppression of plagues of these animals, but so far in the United States they have been content to use poisoned grain or carbon bisulphide for this purpose; but Mr. Gerald M'Carthy's interesting little article will no doubt attract attention to this more novel method of dealing with such vermin. Another article in this number is on the self-purification of rivers, a subject upon which so much difference of opinion exists, that it invariably affords ample material for discussion. The aëration of the water of rivers in falling over dams and natural obstructions, has been regarded by some as exerting an important influence in purification, but according to the experiment made by Prof. Leeds upon the water above and below Niagara Falls, where natural aëration is carried on to the utmost extent possible, no chemical purification is effected during the process. The bacterial aspect of the subject is also discussed, and the writer closes his article with the observation that "a river which receives sewage should be considered unfit to serve as a public water supply." Fortunately in this country we are alive to this objection, but many of the largest cities in America invariably use sewage polluted river-water unpurified, resulting in severe epidemics of typhoid fever.

A PORT BLAIR correspondent of the Allahabad *Pioneer* announces the discovery of the remains of an elephant on South Sentinel, an islet about twenty miles from any other land. The remains were buried about nine inches below the surface, and since the yearly deposit of soil on the island must be very small, it is supposed that they are of very considerable age. It is, moreover, interesting to learn that the volcano on Barren Island is apparently entering upon a period of renewed activity.

THE Washington letter in the last number of the *Bulletin* of the American Geographical Society announces that the recent study of the observations on mountain summits in the neighbourhood of Mount St. Elias, shows that Mount Logan is the loftiest peak in North America with a height of 19,500 feet, thus being 1200 feet higher than Orizaba, and 1500 feet higher than Mount St. Elias itself.

THE June number of the *Geographical Journal* completes the third volume of the new form of the monthly publication of the Royal Geographical Society. It contains an exceptional range of geographical news, including the text of Mr. Littledale's paper on his recent journey across Central Asia, with a series of original maps and illustrations. Mr. Dolby Tyler contributes an account of his journey up the river Napo, perhaps the least known of all the tributaries of the Amazon. There is an excellent account of the primitive "Indians" of the region. Mr. Ravenstein, in a lightly written article on recent African books, incidentally calls attention to the immense flood of literature on that continent now appearing, his list including twenty-one works, all published within the last few months. Mr. H. Yule Oldham has a most readable account of the Manchester ship-canal, showing its peculiar geographical importance, and Mr. A. Montefiore gives a note on the geography of Franz-Josef Land.

THE *Scottish Geographical Magazine* for June contains the first part of an extremely valuable paper by Prof. Otto Pettersson, of Stockholm, on Swedish hydrographical work on the Baltic and North Seas. He uses *hydrographical* not in the ordinary English sense of a mere survey by soundings, but with the wider meaning of a physical and chemical examination of the water. This first part, indeed, is mainly chemical, detailing the processes employed for analysing the dissolved gases and determining the salinity and density of sea-water. The author's opinion that the use of hydrometers in marine research is nearly past, and that only determinations of density by weighing with apparatus similar to Sprengel's pyknometer can be held as sufficiently accurate, is not corroborated by the experience of most British oceanographers in whose hands the *Challenger*-type hydrometer has given most excellent results. The Edinburgh magazine sustains by this article the high reputation it has long held as the first English authority on oceanography, and it is to be congratulated on securing the first publication in any language usually read by scientific men outside Scandinavia of so original and able a treatise.

THE current number of *Wiedemann's Annalen* contains a paper on the similarity between the after-glow of a Geissler tube and the first glow of solid bodies, by Carl Kirn. Herr H. F. Weber has shown that the first light which becomes visible when a solid body is heated, is not, as was supposed by Draper, dark red but grey, which shows itself spectroscopically as a band in the yellow-green. The researches of Stenger and Ebert on the limits of the visible light have shown that the phenomenon was caused by the different sensitiveness of the eye to the different colours, this sensitiveness being a maximum for that part of the spectrum where the band of grey light is first seen. The Geissler tube employed by the author exhibited, after an electric discharge had been passed through it, all the phenomena observed by Riess and Morren; the yellowish-white after-glow of the bulbs being visible for more than half a minute in a completely dark room. The light being observed with a spectroscope, it was found that, while the discharge was actually passing, the tube gave a line spectrum, the brightest lines coinciding with those of nitrogen and carbonic oxide. The feeble spectrum of the after-glow, however, is continuous, and at first occupies the entire space covered by the previously mentioned line spectrum, but it shrinks fairly quickly on either side into a band lying between wave-lengths of 555 and 495 $\mu\mu$, and this band vanishes more slowly, diminishing in breadth as it does so. The colour of this band does not appear to the eye to be the characteristic colour of this part of the spectrum, but a pale yellowish-grey, which becomes darker as extinction approaches. The position of the final glow corresponds almost exactly with the line E of the solar spectrum, and coincides closely with the region of greatest brightness in the ordinary solar spectrum. The whole phenomenon is thus seen to be the exact reverse of what is observed to take place when solid bodies begin to glow. Opinion is still divided as to the cause of the after-glow in Geissler tubes, but the author considers that the results of various researches seem to show that the phenomenon must be considered to be the result of chemical modification of the contents of the tube.

The following excerpts from the Report for 1892 of the U.S. National Museum have lately been distributed by the Smithsonian Institution. "Japanese Wood-cutting and Wood-cut Printing," by Mr. T. Tokuno, edited and annotated by Mr. S. R. Koehler. Mr. Tokuno is the chief of the Bureau of Engraving and Printing Department at Tokio, and the information which he has given to the National Museum will be welcomed by all who are interested in the art of the wood-cutter and in the arts of Japan, more especially as his communication is believed to be the first authoritative statement on this subject made by a native of Japan thoroughly qualified for the task. "The Crump Burial Cave," discovered on the southern branch of the Warrior River, Alabama, is the subject of a paper by Mr. Frank Burns. The cave is about four hundred feet above the river, and in it were found a number of wooden coffins, indicating that the aborigines used it as a burial cave. In a note to the paper, Mr. T. Wilson, the curator of pre-historic anthropology in the Smithsonian Institution, points out that while this method of coffin burial was unusual, if not previously unknown in the United States, yet there are several instances of similar burials among the prehistoric peoples of other countries. Mr. Wilson has a paper on an extensive series of minute stone implements collected by Mr. A. C. Carlyle in the Vindhya bills or mountains in central and north-western India, and now in the National Museum. The implements are said to belong to the neolithic period, but Mr. Carlyle has also found others belonging to the palæolithic period in the same locality, and he believes that the evidence of the archæology of the district shows that there was no hiatus between the palæolithic and neolithic periods, and that the series of implements run from one period to another, their differences being accounted for by the general progress from the lower to the higher civilisation. "The Comparative Oology of North American Birds" is the subject of another excerpt. In this Dr. R. W. Schufeldt brings together a large amount of information of interest to ornithologists, and presents it in a manner which will greatly facilitate the study of the variations in the matter of form and colouration of the eggs of birds of different countries.

Messrs. Cassell and Co. have commenced a new issue, in monthly parts, of Mr. W. F. Kirby's admirable and comprehensive work on "European Butterflies and Moths."

Mr. C. F. Juritz's report on work done in the Analytical Laboratory and Mineralogical Museum at the Cape of Good Hope, during 1893, has just been issued.

It was a happy inspiration that led to the publication of the series of little books on "The Country Month by Month," by Mrs. J. A. Owen and Prof. G. S. Boulger. The June number of the series points out the beauties of nature in the same attractive style that distinguished previous volumes. Messrs. Bliss, Sands, and Foster are the publishers.

Mr. A. F. Calvert, the author of several works on Australia and its resources, has collected a number of facts and fancies with regard to "The Coolgardie Goldfield" in Western Australia, and his compilation has been published by Messrs. Simpkin, Marshall, and Co. The evidence adduced goes to show that the Coolgardie district is richly auriferous, and that the only great drawback to its development is the scarcity of water.

Following the lead of other London Polytechnic Institutes, that at Battersea has started a journal—the *Battersea Polytechnic Review*. We hope that the new journal will not become merely a medium for recording cricket matches and social gatherings. Schemes of courses of study in various branches of science, art, and technology might be profitably included in its pages; and also lists of good books to read, and notes on recent work; while brief descriptions of the Polytechnics on the continent would create a spirit of emulation that would certainly help to develop the work of the Institute in the proper direction.

Each of the papers in *Science Progress* is an important addition to scientific literature. The contributors to this monthly review of current investigations are always men in thorough touch with their subjects, and the result is that they summarise all that is worth knowing on the matters treated by them. The contents of the June number are as follows:—"Pure Yeast and its Relations to Brewing Operations," by Dr. A. K. Miller; "Electrosynthesis," by Dr. James Walker; "Glycogen," by Prof. W. D. Halliburton, F.R.S.; "Mesozoic and Kainozoic Geology in Europe," by Mr. Philip Lake; "The Localisation of Enzymes in Plants," by Prof. J. R. Green; and "Recent Additions to our Knowledge of the Ancient Sediments," by Mr. J. E. Marr, F.R.S.

The additions to the Zoological Society's Gardens during the past week include a Two-Spotted Paradoxure (*Nandinia binotata*) from West Africa, presented by Mr. Joseph Wills; a Raccoon (*Procyon lotor*) from North America, presented by Mr. H. Burgess; a Grey Parrot (*Psittacus erithacus*) from West Africa, presented by Mrs. Lemming; two Goliath Beetles (*Goliathus druryi*) from West Africa, presented by Captain A. S. Mitchell; a White-handed Gibbon (*Hylobates lar*) from the Malay Peninsula; two Gazelles (*Gazella dorcas*, ♂ ♀) from Suakin, deposited; a Beech Marten (*Mustela foina*), a Pine Marten (*Mustela martes*), European, a Silky Bower Bird (*Ptilonorhynchus violaceus*), a Garrulous Honey-eater (*Myzanthe garrula*) from Australia, four Vinaceous Turtle Doves (*Turtur vinaceus*), four Cape Doves (*Œna capensis*) from Africa, a Timneh Parrot (*Psittacus timneh*) from Sierre Leone, two Stanley Cranes (*Tetrapteryx paradisea*) from South Africa, purchased; two Hamadryads (*Ophiophagus elaps*) from India, received in exchange.

OUR ASTRONOMICAL COLUMN.

Astronomical Congresses at Utrecht and Vienna.—An astronomical congress will be held at Utrecht on Friday, the 10th, Saturday, the 11th, and Monday, the 13th of August. Notices of motion and other communications should be addressed to one of the committee before August 7. Dr. H. Gyldén, of Stockholm, will preside. Herren H. Seeliger, of Munich, and R. Lehmann-Filhés, of Berlin, are acting as secretaries.

The preparations for Section 2 (Astronomy) of the meeting of German men of science and physicians, to be held this year at Vienna, from Sept. 24 to 30, are under the direction of Prof. E. Weiss, Dr. J. Palisa, and Dr. J. Holetschek. Papers and subjects for demonstration should be announced to them at once, so as to form part of the provisional programme to be issued early in July. Intending exhibitors at the scientific exhibition, to be held in connection with the meeting, should write to the "Ausstellungs Comité der Naturforscher-versammlung, Wien., Universitat."

PROPOSED ASTRONOMICAL CONGRESS IN 1896.—At the end of a paper read at the last meeting of the Royal Astronomical Society, Dr. Gill propounded the following questions, which we reprint from the *Observatory*. (1) Whether, in the opinion of astronomers generally, steps should be taken for a more complete and harmonious organisation and partition of the astronomical world from the year 1900? (2) Are astronomers prepared to enter upon a preliminary study, discussion, and experiment on the practical methods by which the art of observation may be raised to a higher level of accuracy, and its results be derived and published in a more systematic and homogeneous system? (3) If these questions are answered in the affirmative, would it be desirable to hold an international astronomical congress, say in 1896, to discuss and make the necessary preliminary arrangements, and then let the definitive programme and partition of work be made at another general congress to be held in the year 1899?

THE LAW AND GREENWICH TIME.—Is there any legal authority for the use of Greenwich Time throughout Great Britain? The editors of the *Observatory* point out that in the Statutes (Definition of Time) Act 1880, 43 and 44 Vic. cap. 9, it is enacted that whenever any expression of time occurs in any Act of Parliament, deed, or any other legal instrument, the time referred to shall, unless it is otherwise specifically stated, be held in the case of Great Britain to be Greenwich Time, and in the case of Ireland, Dublin Time. It is remarked, however, that Sir James Stephen says, in the Larceny Act, "Criminal Law Digest," p. 247, sec. 3, in referring to the expression "of the clock":—"It may be worth while to observe that the expression 'nine of the clock,' 'six of the clock,' indicates *mean* as opposed to *solar* time; but a question might arise as to whether they mean local mean time or the mean time commonly observed at any given place. London time, or, as it is called, railway time, is now very generally observed, and there is a difference of more than twenty minutes between London and Cornwall. Local mean time is the natural meaning." In the case which led our contemporary to look up the matter, a defendant arrived at a court at the local (Carlisle) time appointed by the court to sit, but found that the court had met by Greenwich Time, and had decided against him. The difference of interpretation of the time appointed led to the granting of a new trial.

THE WORK OF HERTZ.[1]

THE untimely end of a young and brilliant career cannot fail to strike a note of sadness and awaken a chord of sympathy in the hearts of his friends and fellow-workers. Of men thus cut down in the early prime of their powers there will occur to us here the names of Fresnel, of Carnot, of Clifford, and now of Hertz. His was a strenuous and favoured youth; he was surrounded from his birth with all the influences that go to make an accomplished man of science—accomplished both on the experimental and on the mathematical side. The front rank of scientific workers is weaker by his death, which occurred on January 1 of the present year, the thirty-sixth of his life. Yet did he not go till he had effected an achievement which will hand his name down to posterity as the founder of an epoch in experimental physics.

In mathematical and speculative physics others had sown the seed. It was sown by Faraday, it was sown by Thomson and by Stokes, by Weber also doubtless, and by Helmholtz, but in this particular department it was sowed by none more fruitfully and plentifully than by Clerk Maxwell. Of the seed thus sown Hertz reaped the fruits. Through his experimental discovery, Germany awoke to the truth of Clerk Maxwell's theory of light, of light and electricity combined, and the able army of workers in that country (not forgetting some in Switzerland and France and Ireland) have done most of the gleaning after Hertz.

This is the work of Hertz which is best known; the work which brought him immediate fame. It is not always that public notice is so well justified. The popular instinct is generous and trustful, and it is apt to be misled. The scientific eminence accorded to a few energetic persons by the popular estimate is more or less amusing to those working in the same lines. In the case of Hertz no such mistake has been made. His name is not over well known, and his work is immensely greater in every way than that of several who have made more noise.

His best known discovery is by no means his only one. I have here a list of eighteen papers[1] contributed to German periodicals by him, in addition to the papers incorporated in his now well-known book on electric waves. I would like to suggest that it would be an act of tribute, useful to students in this country, if the Physical Society of London saw their way to translate and publish a collection of, at any rate, some of these papers.

Portrait Slide.

The portrait which I show is not a specially pleasing one. It is from a photograph taken by Mr. Yule, one of the band of foreign students who flocked to Hertz's laboratory at Bonn. It is excellent as a photograph, though it fails to represent Hertz at his best; perhaps because it was not taken till after the pharyngeal trouble had set in, which ultimately carried him off.

In closing these introductory and personal remarks, I should like to say that the enthusiastic admiration for Hertz's spirit and character, felt and expressed by students and workers who came into contact with him, is not easily to be exaggerated. Never was a man more painfully anxious to avoid wounding the susceptibilities of others; and he was accustomed to deprecate the prominence given to him by speakers and writers in this country, lest it might seem to exalt him unduly above other and elder workers among his own sensitive countrymen.

Speaking of the other great workers in physics in Germany, it is not out of place to record the sorrow with which we have heard of the recent death of Dr. August Kundt, Professor in the University of Berlin, successor of von Helmholtz in that capacity.

When I consented to discourse on the work of Hertz, my intention was to repeat some of his actual experiments, and especially to demonstrate his less known discoveries and observations. But the fascination exerted upon me by electric oscillation experiments, when I, too, was independently working at them in the spring of 1888,[2] resumed its hold; and my lecture will accordingly consist of experimental demonstrations of the outcome of Hertz's work rather than any precise repetition of portions of that work itself.

In case a minority of my audience are in the predicament of not knowing anything about the subject, a five minutes' explanatory prelude may be permitted, though time at present is very far from being "infinitely long."

[1] A Lecture delivered at the Royal Institution on Friday, June 1, by Prof. Oliver Lodge F.R.S., ably assisted during both preparation and performance by Mr. Edward E. Robinson.

The simplest way will be for me hastily to summarise our knowledge of the subject before the era of Hertz.

Just as a pebble thrown into a pond excites surface ripples, which can heave up and down floating straws under which they pass, so a struck bell or tuning-fork emits energy into the air in the form of what are called sound waves; and this radiant energy is able to set up vibrations in other suitable elastic bodies.

If the body receiving them has its natural or free vibrations violently damped, so that when left to itself it speedily returns to rest, then it can respond feebly to notes of almost any pitch. This is the case with your ears and the tones of my voice. Tones must be exceedingly shrill before they cease to excite the ear at all.

If, on the other hand, the receiving body has a persistent period of vibration, continuing in motion long after it is left to itself, like another tuning-fork or bell for instance, then far more facility of response exists, but great accuracy of tuning is necessary if it is to be fully called out; for if the receiver is not thus accurately syntonised with the source, it fails more or less completely to resound.

Conversely, if the *source* is a persistent vibrator, correct tuning is essential, or it will destroy at one moment motion which it originated the previous moment. Whereas if it is a dead beat or strongly-damped excitor, almost anything will respond equally well or equally ill to it.

What I have said of sounding bodies is true of all vibrators in a medium competent to transmit waves. Now a sending telephone or a microphone, when spoken to, emits waves into the ether, and this radiant energy is likewise able to set up vibration in suitable bodies. But we have no delicate means of directly detecting these electrical or etherial waves, and if they are to produce a perceptible effect at a distance they must be confined, as by a speaking tube, prevented from spreading, and concentrated on the distant receiver.

This is the function of the telegraph wire; it is to the ether what a speaking-tube is to air. A metal wire in air (*in function*, not in details of analogy) is like a long hollow cavity surrounded by nearly rigid but slightly elastic walls.

Sphere charged from Electrophorus.

Furthermore, any conductor electrically charged or discharged with sufficient suddenness must emit electrical waves into the ether, because the charge given to it will not settle down instantly, but will surge to and fro several times first; and these surgings or electric oscillations must, according to Maxwell, start waves in the ether, because at the end of each half swing they cause electrostatic, and at the middle of each half swing they cause electromagnetic effects, and the rapid alternation from one of these modes of energy to the other constitutes etherial waves.[1] If a wire is handy they will run along it, and may be felt a long way off. If no wire exists they will spread out like sound from a bell, or light from a spark, and their intensity will decrease according to the inverse square of the distance.

Maxwell and his followers well knew that there would be such waves; they knew the rate at which they would go, they knew that they would go slower in glass and water than in air, they knew that they would curl round sharp edges, that they would be partly absorbed but mainly reflected by conductors, that if turned back upon themselves they would produce the phenomena of stationary waves, or interference, or nodes and loops; it was known how to calculate the length of such waves, and even how to produce them of any required or predetermined wave-length from 1000 miles to a foot. Other things were known about them which would take too long to enumerate: any homogeneous insulator would transmit them, would refract or concentrate them if it were of suitable shape, would reflect none of a particular mode of vibration at a certain angle, and so on, and so on.

All this was "known," I say, known with varying degrees of confidence, but by some known with as great confidence as, perhaps even more confidence than, is legitimate before the actuality of experimental verification.

Hertz supplied the verification. He inserted suitable conductors in the path of such waves, conductors adapted for the occurrence in them of induced electric oscillations, and to the surprise of everyone, himself doubtless included, he found that the secondary electric surgings thus excited were strong enough to display themselves by minute electric sparks.

Syntonic Leyden Jars.

I shall show this in a form which requires great precision of tuning or syntony, both emitter and receiver being persistently vibrating things giving some thirty or forty swings before damping has a serious effect. I take two Leyden jars with circuits about a yard in diameter, and situated about two yards apart. I charge and discharge one jar, and observe that the surgings set up in the other can cause it to overflow if it is syntonised with the first.[1]

A closed circuit such as this is a feeble radiator and a feeble absorber, so it is not adapted for action at a distance. In fact, I doubt whether it will visibly act at a range beyond the $\frac{1}{4}\lambda$ at which true radiation of broken off energy occurs. If the coatings of the jar are separated to a greater distance, so that the dielectric is more exposed, it radiates better; because in true radiation the electrostatic and the magnetic energies are equal, whereas in a ring circuit the magnetic energy greatly predominates. By separating the coats of the jar as far as possible we get a typical Hertz oscillator, whose dielectric extends out into the room, and this radiates very powerfully.

Ordinary size Hertz Vibrator.

In consequence of its radiation of energy its vibrations are rapidly damped, and it only gives some three or four good strong swings. Hence it follows that it has a wide range of excitation, *i.e.* it can excite sparks in conductors barely at all in tune with it.

The two conditions, conspicuous energy of radiation and persistent vibration electrically produced, are at present incompatible. Whenever these two conditions coexist, considerable power or activity will of course be necessary in the source of energy. At present they only coexist in the sun and other stars, in the electric arc, and in furnaces.

Two Circular Vibrators sparking in sympathy.

The receiver Hertz used was chiefly a circular resonator, not a good absorber but a persistent vibrator, well adapted for picking up disturbances of precise and measurable wave-length. I find that the circular resonators can act as senders too; here is one exciting quite long sparks in a second one.

Electric Syntony—that was his discovery, but he did not stop there. He at once proceeded to apply his discovery to the verification of what had already been predicted about the waves, and by laborious and difficult interference experiments he ascertained that the previously calculated length of the waves was thoroughly borne out by fact. These interference experiments in free space are his greatest achievement.

He worked out every detail of the theory splendidly, separately analysing the electric and the magnetic oscillation—using language not always such as we should use now, but himself growing in theoretic insight through the medium of what would have been to most physicists a confusing maze of troublesome facts, and disentangling all their main relations most harmoniously.

Holtz Machine, A and B Sparks; Glass and Quartz Panes in Screen.

While Hertz was observing sparks such as these, the primary or exciting spark and the secondary or excited one, he observed as a bye issue that the secondary spark occurred more easily if the light from the primary fell upon its knobs. He examined this new influence of light in many ways, and showed that although spark light and electric brush light were peculiarly effective, any source of light that gave very ultra-violet rays produced the same result.[2]

Wiedemann and Ebert, and a number of experimenters, have repeated and extended this discovery, proving that it is the cathode knob on which illumination takes effect; and Hall-

[1] [illegible] in the waves themselves there is no lag or difference of phase between the electric and the magnetic vibrations, the difference exists in emitter or receiver, but not in the transmitting medium. True radiation of energy does not begin till about a quarter wave-length from the source, and within that distance the initial quarter period difference of phase is obliterated.

[1] See NATURE, vol. 41, p. 36[illegible]; or J. J. Thomson, "Recent Researches," p. [illegible]95.

[2] The experiment shown in the lecture was on the lines of those described in my book, "Lightning Conductors," pp. [illegible]14 and [illegible]; the connections being much as on p. 2[illegible]5, or as depicted in *Proc. Roy. Soc.*, vol. [illegible], p. 4.

wachs made the important observation, which Righi, Stoletow, Branly, and others have extended, that a freshly-polished zinc or other oxidisable surface, if charged negatively, is gradually discharged by ultra-violet light.

It is easy to fail in reproducing this experimental result if the right conditions are not satisfied; but if they are, it is absurdly easy, and the thing might have been observed nearly a century ago.

Zinc discharging Negative Electricity in Light; Gold Leaf Electroscope; Glass and Quartz Panes; Quartz Prism.

Take a piece of zinc, clean it with emery paper, connect it to a gold leaf electroscope, and expose it to an arc lamp. If charged positively nothing appears to happen, the action is very slow, but a negative charge leaks away in a few seconds if the light is bright. Any source of light rich in ultra-violet rays will do; the light from a spark is perhaps most powerful of all. A pane of glass cuts off all the action; so does atmospheric air in sufficient thickness (at any rate, town air), hence sunlight is not powerful. A pane of quartz transmits the action almost undiminished, but fluor-spar may be more transparent still. Condensing the arc rays with a quartz lens and analysing them with a quartz prism or reflexion grating, we find that the most effective part of the light is high up in the ultra-violet, surprisingly far beyond the limits of the visible spectrum.[1]

This is rather a digression, but I have taken some pains to show it properly because of the interest betrayed by Lord Kelvin in this matter, and the caution which he felt about accepting the results of the Continental experimenters too hastily.

It is clearly a chemical phenomenon, and I am disposed to express it as a modification of the Volta contact effect[2] with illumination.

Return now to the Hertz vibrator, or Leyden jar with its coatings well separated so that we can get into its electric as well as its magnetic field. Here is a great one, giving waves 30 metres long, radiating while it lasts with an activity of a hundred horse-power, and making ten million complete electric vibrations per second.

Large Hertz Vibrator in action; Abel's Fuse; Vacuum Tube: Strike an Arc.

Its great radiating power damps it down very rapidly, so that it does not make above two or three swings; but, nevertheless, each time it is excited, sparks can be drawn from most of the reasonably elongated conductors in this theatre.

A suitably situated gas-leak can be ignited by these induced sparks. An Abel's fuse connecting the water-pipes with the gas-pipes will blow off; vacuum tubes connected to nothing will glow (this fact has been familiar to all who have worked with Hertz waves since 1889); electric leads, if anywhere near each other, as they are in some incandescent lamp-holders, may spark across to each other, thus striking an arc and blowing their fuses.

This blowing of fuses by electric radiation frequently happened at Liverpool till the suspensions of the theatre lamps were altered.

[1] While preparing for the lecture it occurred to me to try, if possible, during the lecture itself, some new experiments on the effect of light on negatively charged bits of rock and ice, because if the effect is not limited to metals it must be important in connection with atmospheric electricity. When Mr. Branly coated an aluminium plate with an insulating varnish, he found that its charge was able to soak in and out of the varnish during illumination (*Comptes Rendus*, vol. 110, p. 898, 1890). Now, the mountain tops of a negatively charged earth are exposed to very ultra-violet rays, and the air is a dielectric in which quiet up-carrying and sudden downpour of electricity could go on in a manner not very unlike the well-known behaviour of water vapour; and this perhaps may be the reason, or one of the reasons, why it is not unusual to experience a thunderstorm after a few fine days. I have now tried these experiments on such geological fragments as were handy, and find that many of them discharge negative electricity under the action of a naked arc, especially from the side of the specimens which was somewhat dusty, but that when wet they discharge much less rapidly, and when positively charged hardly at all. Ice and garden soil discharge negative electrification too, under ultra-violet illumination, but not so quickly as limestone, mica schist, ferruginous quartz, clay, and some other specimens. Granite barely acts; it seems to insulate too well. The ice and soil were tried in their usual moist condition, but, even when thoroughly dry, soil discharges quite rapidly.

No rock tested was found to discharge as quickly as does a surface of perfectly bright metal such as iron, but many discharged much more quickly than ordinary dull iron, and rather more quickly than when the bright iron surface was thinly oiled or wetted with water.

To-day (June 5) I find that the leaves of a geranium discharge positive electrification five times as quickly as negative, under the action of an arc-light, and that glass cuts the effect off while quartz transmits it.

[2] See Brit. Assoc. Report, 1884, pp. 502, 519; or *Phil. Mag.* vol. 19, pp. 267, 352.

The striking of an arc by the little reverberating sparks between two carbon points connected with the 100 volt mains I incidentally now demonstrate.

There are some who think that lightning flashes can do none of these secondary things. They are mistaken.

Specimens and Diagrams.

On the table are specimens of various emitters and receivers such as have been used by different people. The orthodox Hertz radiator of the dumb-bell type, and the orthodox Hertz receivers—a circular ring for interference experiments, because it is but little damped; and a straight wire for receiving at a distance, because it is a much better absorber. Beside these are the spheres and ellipsoids (or elliptical plates) which I have mainly used, because they are powerful radiators and absorbers, and because their theory has been worked out by Horace Lamb and J. J. Thomson. Also dumb-bells without air-gap, and many other shapes, the most recent of mine being the inside of a hollow cylinder with sparks at ends of a diameter; this last being a feeble radiator but a very persistent vibrator,[1] and therefore well adapted for interference and diffraction experiments. But indeed spheres can be made to vibrate longer than usual by putting them into copper hats or enclosures, in which an aperture of varying size can be made to let the waves out.

Many of these senders will do for receivers too, giving off sparks to other insulated bodies or to earth; but besides the Hertz type of receiver, many other detectors of radiation have been employed. Vacuum tubes can be used, either directly, or on the trigger principle, as by Zehnder,[2] the resonator spark precipitating a discharge from some other auxiliary battery or source of energy, and so making a feeble disturbance very visible. Explosives may be used for the same purpose, either in the form of mixed water-gases or in the form of an Abel's fuse. Fitzgerald found that a tremendously sensitive galvanometer could indicate that a feeble spark had passed, by reason of the consequent disturbance of electrical equilibrium which settled down again through the galvanometer.[3] This was the method he used in this theatre two years ago. Blyth used a one-sided electrometer, and young Bjerkness has greatly developed this method, abolishing the need for a spark, and making the electrometer metrical, integrating, and satisfactory.[4] With this detector many measurements have been made at Bonn, by Bjerkness, Yule, Barton, and others, on waves concentrated and kept from space-dissipation by guiding wires.

Mr. Boys has experimented on the mechanical force exerted by electrical surgings, and Hertz also made observations of the same kind.

Going back to older methods of detecting electrical radiation, we have, most important of all, a discovery made long before man existed, by a creature that developed a sensitive cavity on its skin; a creature which never so much as had a name to be remembered by (though perhaps we now call it trilobite). Then, in recent times, we recall the photographic plate and the thermopile, with its modification the radio-micrometer; also the so-called bolometer, or otherwise known Siemens' pyrometer, applied to astronomy by Langley; applied to the detection of electric waves in wires by Rubens and Ritter and Paalzow and Arons. The thermal junction was applied to the same purpose by D. E. Jones and others.

And, before all these, the late Mr. Gregory, of Cooper's Hill, made his singularly sensitive expansion meter, whereby waves in free space could be detected by the minute rise of temperature they caused in a platinum wire: a kind of early and sensitive form of Cardew voltmeter.

Going back to the physiological method of detecting surgings, Hertz tried the frog's-leg nerve and muscle preparation, which to the steadier types of electrical stimulus is so surpassingly sensitive, and to which we owe the discovery of current electricity. But he failed to get any result. Ritter has succeeded; but, in my experience, failure is the normal and proper result. Working with my colleague Prof. Gotch, at Liverpool, I too have tried the nerve muscle preparation of the frog, and we find that an excessively violent stimulus of a rapidly alternating character, if pure and unaccompanied by secondary actions,

[4] *Wied. Ann.* 44, p. 74.

produces no effect,—no stimulating effect, that is, even though the voltage is so high that sparks are ready to jump between the needles in direct contact with the nerve.

All that such oscillations do, if continued, is to produce a temporary paralysis or fatigue of the nerve, so that it is unable to transmit the nerve impulses evoked by other stimuli, from which paralysis it recovers readily enough in course of time.

Experiment of Gotch and Lodge on the physiological effect of rapid pure electric alternations. Nerve and muscle preparation, with four needles or else non-polarisable electrodes applied to the nerve. C and D are the terminals of a rapidly alternating electric current from a conductor at zero potential, while A and B are the terminals of an ordinary very weak galvanic or induction coil stimulus only just sufficient to make the muscle twitch.

This has been expected from experiments on human beings; such experiments as Tesla's and those of d'Arsonval. But an entire animal is not at all a satisfactory instrument wherewith to attack the question; its nerves are so embedded in conducting tissues that it may easily be doubted whether the alternating type of stimulus ever reaches them at all. By dissecting out a nerve and muscle from a deceased frog, after the historic manner of physiologists, and applying the stimulus direct to the nerve, at the same time as some other well-known 1/100th of a volt stimulus is applied to another part of the same nerve further from the muscle, it can be shown that rapid electric alternations, if entirely unaccompanied by static charge or by resultant algebraic electric transmission, evoke no excitatory response until they are so violent as to give rise to secondary effects such as heat or mechanical shock. Yet, notwithstanding this inaction, they gradually and slowly exert a paralysing or obstructive action on the portion of the nerve to which they are applied, so that the nerve impulse excited by the feeble just perceptible 1/100th volt stimulus above is gradually throttled on its way down to the muscle, and remains so throttled for a time varying from a few minutes to an hour after the cessation of the violence.

I had intended to exhibit this effect, which is very marked and definite, but it is impossible to show everything in the time at my disposal.

Air Gap and Electroscope, charged by Glass Rod and discharged by moderately distant Sphere excited by Coil.

Among trigger methods of detecting electric radiation, I have spoken of the Zehnder vacuum tubes; another method is one used by Boltzmann.[1] A pile of several hundred volts is on the verge of charging an electroscope through an air-gap just too wide to break down. Very slight electric surgings precipitate the discharge across the gap, and the leaves diverge. I show this in a modified and very simple form. On the cap of an electroscope is placed a highly-polished knob or rounded end, connected to the sole, and just not touching the cap. Such an electroscope overflows suddenly and completely with any gentle rise of potential. Bring excited glass near it, the leaves diverge gradually and then suddenly collapse, because the air space snaps; remove the glass, and they rediverge with negative electricity; the knob above the cap being then charged positively, and to the verge of sparking. In this condition any electrical waves, collected if weak by a foot or so of wire projecting from the cap, will discharge the electroscope by exciting surgings in the wire, and so breaking down the air-gap. The chief interest about this experiment seems to me the extremely definite dielectric strength of so infinitesimal an air space. Moreover, it is a detector for Hertz waves that might have been used last century; it might have been used by Benjamin Franklin.

For to excite them, no coil or anything complicated is necessary; it is sufficient to flick a metal sphere or cylinder with a silk handkerchief, and then discharge it with a well-polished knob. If it is not well-polished the discharge is comparatively gradual, and the vibrations are weak; the more polished are the sides of an air-gap the more sudden is the collapse, and the more vigorous the consequent radiation, especially the radiation of high frequency, the higher harmonics of the disturbance.

For delicate experiments it is sometimes well to repolish the knobs every hour or so. For metrical experiments it is often better to let the knobs get into a less efficient but more permanent state. This is true of all senders or radiators. For the generation of the, so to speak, "infra-red" Hertz waves any knobs will do, but to generate the "ultra-violet" high polish is essential.

Microphonic Detectors.

Receivers or detectors which for the present I temporarily call microphonic are liable to respond best to the more rapid vibrations. Their sensitiveness is to me surprising, though of course it does not approach the sensitiveness of the eye; at the same time, I am by no means sure that the eye differs from them in kind. It is these detectors that I wish specially to bring to your notice.

Prof. Minchin, whose long and patient work in connection with photoelectricity is now becoming known, and who has devised an instrument more sensitive to radiation than even Boys' radio-micrometer, in that it responds to the radiation of a star while the radio-micrometer does not, found some years ago that some of his light excitable cells lost their sensitiveness capriciously on tapping; and later he found that they frequently regained it again while Mr. Gregory's Hertz wave experiments were going on in the same room.

These "impulsion-cells," as he terms them, are troublesome things for ordinary persons to make and work with—at least I have never presumed to try—but in Mr. Minchin's hands they are surprisingly sensitive to electric waves.[1]

The sensitiveness of selenium to light is known to everyone, and Mr. Shelford Bidwell has made experiments on the variations of conductivity exhibited by a mixture of sulphur and carbon.

Nearly four years ago, M. Edouard Branly found that a burnished coat of porphyrised copper spread on glass diminished its resistance enormously, from some millions to some hundreds of ohms, when it was exposed to the neighbourhood, even the distant neighbourhood, of Leyden jar or coil sparks. He likewise found that a tube of metallic filings behaved similarly, but that this recovered its original resistance on shaking. Mr. Croft exhibited this fact recently at the Physical Society. Branly also made pastes and solid rods of filings in Canada balsam and in sulphur, and found them likewise sensitive.[2]

With me the matter arose somewhat differently, as an outcome of the air-gap detector employed with an electroscope by Boltzmann. For I had observed in 1889 that two knobs sufficiently close together, far too close to stand any voltage such as an electroscope can show, could, when a spark passed between them, actually cohere; conducting an ordinary bell-ringing current if a single voltaic cell was in circuit; and, if there was no such cell, exhibiting an electromotive force of their own sufficient to disturb a low resistance galvanometer vigorously, and sometimes requiring a faintly perceptible amount of force to detach them. The experiment was described to the Institution of Electrical Engineers,[3] and Prof. Hughes said he had observed the same thing.

Coherer in open, responding to Feeble Stimuli; Small Sphere, Gas-lighter, Distant Sphere, Electrophorus.

Well this arrangement, which I call a coherer, is the most astonishingly sensitive detector of Hertz waves. It differs from the actual air-gap in that the insulating film is not really insulating; the film breaks down not only much more easily, but also in a less discontinuous and more permanent manner than an air gap. A tube of filings, being a series of bad contacts, clearly works on the same plan; and though a tube of filings is by no means so sensitive, yet it is in many respects easier to work with, and, except for very feeble stimuli, is more metrical. If the filings used are coarse, say turnings or borings, the tube approximates to a single coherer; if they are fine, it has a larger range of sensibility. In every case what these receivers feel are sudden jerks of current; smooth sinuous vibrations are ineffective. They seem to me to respond best to waves a few inches long, but doubtless that is determined chiefly by the dimensions of some conductor with which they happen to be associated.

Filings in open, responding to Sphere, to Electrophorus, to Spark from Gold-leaf Electroscope.

I picture to myself the action as follows. Suppose two fairly clean pieces of metal in light contact—say two pieces of

[1] *Wied. Ann.* 4 , p. [illegible]

[1] *Phil. Mag.* vol. 31, p. 223.

[2] E. Branly, *Comptes Rendus* vol. 111, p. 785; and vol. 112, p. 90.

[3] *Journal Inst. E. E.*, 1890, vol. 19, pp. 352-4; or "Lightning Conductors and Lightning Guards" (Whittaker), pp. 382-4.

iron—connected to a single voltaic cell; a film of what may be called oxide intervenes between the surfaces, so that only an insignificant current is allowed to pass, because a volt or two is insufficient to break down the insulating film except perhaps at one or two atoms. If the film is not permitted to conduct at all, it is not very sensitive; the most sensitive condition is attained when an infinitesimal current passes, strong enough just to show on a moderate galvanometer.

Now let the slightest surging occur, say by reason of a sphere being charged and discharged at a distance of forty yards, the film at once breaks down—perhaps not completely, that is a question of intensity—but permanently. As I imagine, more molecules get within each other's range, incipient cohesion sets in, and the momentary electric quiver acts as it were as a flux. It is a singular variety of electric welding. A stronger stimulus enables more molecules to hold on, the process is surprisingly metrical: and as far as I roughly know at present, the change of resistance is proportional to the energy of the electric radiation from a source of given frequency.

It is to be specially noted that the battery current is not needed to effect the cohesion, only to demonstrate it. The battery can be applied after the spark has occurred, and the resistance will be found changed as much as if the battery had been on all the time.

The incipient cohesion electrically caused can be mechanically destroyed. Sound vibrations, or any other feeble mechanical disturbances, such as scratches or taps, are well adapted to restore the contact to its original high-resistance sensitive condition. The more feeble the electrical disturbance the slighter is the corresponding mechanical stimulus needed for restoration. When working with the radiating sphere at a distance of forty yards out of window, I could not for this reason shout to my assistant, in order to cause him to press the key of the coil and make a spark, but I showed him a duster instead, this being a silent signal which had no disturbing effect on the coherer or tube of filings. I mention forty yards, because that was one of the first outdoor experiments; but I should think that something more like half a mile was nearer the limit of sensitiveness. However, this is a rash statement not at present verified. At forty yards the exciting spark could be distinctly heard, and it was interesting to watch the spot of light begin its long excursion and actually travel a distance of two or three inches before the sound arrived. This experiment proved definitely enough that the efficient cause travelled quicker than sound, and disposed completely of any sceptical doubts as to the sound-waves being perhaps the real cause of the phenomenon.

Invariably, when the receiver is in good condition, sound or other mechanical disturbance acts one way, viz. in the direction of increasing resistance, while electrical radiation or jerks act the other way, decreasing it. While getting the receiver into condition, or when it is getting out of order, vibrations and sometimes electric discharges act irregularly, and an occasional good shaking does the filings good.

I have taken rough measurements of the resistance, by the simple process of restoring the original galvanometer deflection by adding or removing resistance coils. A half-inch tube, eight inches long, of selected iron turnings, had a resistance of 2500 ohms in the sensitive state. A feeble stimulus, caused by a distant electrophorous spark, brought it down 400 ohms. A rather stronger one reduced it by 500 and 600, while a trace of spark given to a point of the circuit itself, ran it down 1400 ohms.

This is only to give an idea of the quantities. I have not yet done any seriously metrical experiments.

From the wall diagram which summarises the various detectors, and which was prepared a month or so ago, I see I have omitted selenium, a substance which in certain states is well known to behave to visible light as these other microphonic detectors behave to Hertz waves.

And I want to suggest that quite possibly the sensitiveness of the eye is of the same kind. As I am not a physiologist I cannot be seriously blamed for making wild and hazardous speculations in that region. I therefore wish to guess that some part of the retina is an electrical organ, say like that of some fishes, maintaining an electromotive force which is prevented from stimulating the nerves solely by an intervening layer of badly conducting material, or of conducting material with gaps in it; but that when light falls upon the retina these gaps become more or less conducting, and the nerves are stimulated.

I do not feel clear which part is taken by the rods and cones, and which part by the pigment cells; I must not try to make the hypothesis too definite at present.

If I had to make a demonstration model of the eye on these lines, I should arrange a little battery to excite a frog's nerve and muscle preparation through a circuit completed all except a layer of filings or a single bad contact. Such an arrangement would respond to Hertz waves. Or if I wanted actual light to act instead of grosser waves, I would use a layer of selenium.

But the bad contact and the Hertz waves are the most instructive, because we do not at present really know what the selenium is doing, any more than what the retina is doing.

And observe that (to my surprise I confess) the rough outline of a theory of vision thus suggested is in accordance with some of the principal views of the physiologist Hering. The sensation of light is due to the electrical stimulus; the sensation of black is due to the mechanical or tapping-back stimulus. Darkness is physiologically not the mere cessation of light. Both are positive sensations, and both stimuli are necessary; for until the filings are tapped back vision is persistent. In the eye model the period of mechanical tremor should be say $\frac{1}{10}$th second, so as to give the right amount of persistence of impression.

Eye Model with Electric Bell on Board.

No doubt in the eye the tapping back is done automatically by the tissues, so that it is always ready for a new impression, until fatigued. And by mounting an electric bell or other vibrator on the same board as a tube of filings, it is possible to arrange so that a feeble electric stimulus shall produce a feeble steady effect, a stronger stimulus a stronger effect, and so on, the tremor asserting its predominance and bringing the spot back whenever the electric stimulus ceases.

An electric bell thus close to the tube is, perhaps, not the best vibrator; clockwork might do better, because the bell contains in itself a jerky current, which produces one effect, and a mechanical vibration, which produces an opposite effect; hence the spot of light can hardly keep still. By lessening the vibration—say by detaching the bell from actual contact with the board, the electric jerks of the intermittent current drive the spot violently up the scale; mechanical tremor brings it down again.

You observe that the eye on this hypothesis is, in electrometer language, heterostatic. The energy of vision is supplied by the organism, the light only pulls a trigger. Whereas the organ of hearing is idiostatic. I might draw further analogies, about the effect of blows or disorder causing irregular conduction and stimulation, of the galvanometer in the one instrument, of the brain cells in the other.

A handy portable exciter of electric waves is one of the ordinary hand electric gas-lighters, containing a small revolving doubler—*i.e.*, an inductive or replenishing machine. A coherer can feel a gas-lighter across a lecture theatre. Minchin often used them for stimulating his impulsion cells. I find that, when held near, they act a little before the spark occurs, plainly because of the little incipient sparks at the brushes or tinfoil contacts inside. A Voss machine acts similarly, giving a small deflection while working up before it sparks.

And notice here that our model eye has a well-defined range of vision. It cannot see waves too long for it.

Holtz Sparks not exciting Tube: except by help of a polished knob.

The powerful disturbance caused by the violent flashes of a Wimshurst or Voss machine it is blind to. If the knobs of the machine are well polished, it will respond to some high harmonics, due to the vibrations in the terminal rods; and these are the vibrations to which it responds when excited by a coil. The coil should have knobs instead of points. Sparks from points or dirty knobs hardly excite the coherer at all. But hold a well-polished sphere or third knob between even the dirty knobs of a Voss machine, and the coherer responds at once to the surgings got up in it.

Electrophorous Lid and insulated Sphere.

Feeble short sparks again are often more powerful exciters than are strong long ones. I suppose because they are more sudden.

This is instructively shown with an electrophorous lid. Spark it to a knuckle, and it does very little. Spark it to a knob, and it works well. But now spark it to an insulated sphere, there is some effect. Discharge the sphere, and take a second spark, without recharging the lid. Do this several times; and at last, when the spark is inaudible, invisible, and otherwise imperceptible, the coherer some yards away responds more violently than ever, and the spot of light rushes from the scale.

If a coherer be attached by a side wire to the gas-pipes, and an electrophorous spark be given to either the gas pipes or the water-pipes, or even to the hot-water system, in another room of the building, the coherer responds.

In fact when thus connected to gas-pipes, one day when I tried it, the spot of light could hardly keep five seconds still. Whether there was a distant thunderstorm, or whether it was only picking up telegraphic jerks, I do not know. The jerk of turning on or off an extra Swan lamp can affect it when sensitive. I hope to try for long-wave radiation from the sun, filtering out the ordinary well-known waves by a black-board or other sufficiently opaque substance.

We can easily see the detector respond to a distant source of radiation now, viz. to a 6-inch sphere placed in the library between coil knobs.

Portable Detector.

Also I exhibit a small complete detector made by my assistant Mr. Davies, which is quite portable and easily set up. The essentials are all in a copper cylinder three inches by two. A bit of wire a few inches long, pegged into it, helps it to collect waves. It is just conceivable that at some distant date, say by dint of inserting gold wires or powder in the retina, we may be enabled to see waves which at present we are blind to.

Observe how simple the production and detection of Hertz waves are now. An electrophorous or a frictional machine serves to excite them: a voltaic cell, a rough galvanometer, and a bad contact, serve to detect them. Indeed they might have been observed at the beginning of the century, before galvanometers were known. A frog's leg or an iodide of starch paper would do almost as well.

A bad contact was at one time regarded as a simple nuisance, because of the singularly uncertain and capricious character of the current transmitted by it. Hughes observed its sensitiveness to sound-waves, and it became the microphone. Now it turns out to be sensitive to electric waves, if it be made of any oxidisable metal (not of carbon), and we have an instrument which might be called a micro-something, but which, as it appears to act by cohesion, I call at present a coherer. Perhaps some of the capriciousness of an anathematised bad contact was sometimes due to the fact that it was responding to stray electric radiation.

The breaking down of cohesion by mechanical tremor is an ancient process, observed on a large scale by engineers in railway axles and girders; indeed, the cutting of small girders by persistent blows of hammer and chisel reminded me the other day of the tapping back of our cohering surfaces after they have been exposed to the welding effect of the electric jerk.

Put Copper Hat over Tube. Shut up everything in Box completely.

If a coherer is shut up in a complete metal enclosure, waves cannot get at it, but if wires are led from it to an outside ordinary galvanometer, it remains nearly as sensitive as it was before (nearly, not quite), for the circuit picks up the waves, and they run along the insulated wires into the closed box. To screen it effectively it is necessary to enclose battery and galvanometer and every bit of wire connection; the only thing that may be left outside is the needle of the galvanometer. Accordingly here we have a compact arrangement of battery and coil and coherer, all shut up in a copper box. The coil is fixed against the side of the box at such height that it can act conveniently on an outside suspended compass needle. The slow action of the coil has no difficulty in getting through copper, as everyone knows; only a perfect conductor could screen off that, but the Hertz waves are effectively kept out by sheet copper.

Chink, Round Hole; Protruding Wire.

It must be said, however, that the box must be exceedingly well closed for the screening to be perfect. The very narrowest chink permits their entrance, and at one time I thought I should have to solder a lid on before they could be kept entirely out. Clamping a copper lid on to a flange in six places was not enough. But by the use of pads of tinfoil, chinks can be avoided, and the inside of the box becomes then electrically dark.

If even an inch of the circuit protrudes, it at once becomes slightly sensitive again; and if a single branch wire protrudes through the box, provided it is insulated where it passes through, the waves will utilise it as a speaking tube, and run blithely in. And this whether the wire be connected to anything inside or not, though it acts more strongly when connected.

Receiver Hat and Metal Tube for Connecting Wires.

If wires are to be taken out of the box to a coherer in some other enclosure, they must be enclosed in a metal tube, and this tube must be well connected with the metal of both enclosures, if nothing is to get in but what is wanted.

Similarly, when definite radiation is desired, it is well to put the radiator in a copper hat, open in only one direction. And in order to guard against reflected and collateral surgings running along the wires which pass outside to the coil and battery, as they are liable to do, I am accustomed to put all these things in a packing case lined with tinfoil, to the outside of which the sending hat is fixed, and to pull the key of the primary exciting circuit by a string from outside.

Sender in Hat and Box, with Lid (adjustable) clamped on.

Even then, with the lid of the hat well clamped on, something gets out, but it is not enough to cause serious disturbance of qualitative results. The sender must evidently be thought of as emitting a momentary blaze of light which escapes through every chink. Or, indeed, since the waves are some inches long, the difficulty of keeping them out of an enclosure may be likened to the difficulty of excluding sound; though the difficulty is not quite so great as that, since a reasonable thickness of metal is really opaque. I fancied once or twice I detected a trace of transparency in such metal sheets as ordinary tinplate, but unnoticed chinks elsewhere may have deceived me. It is a thing easy to make sure of as soon as I have more time.

One thing in this connection is noticeable, and that is how little radiation gets either in or out of a small round hole. A narrow long chink in the receiver box lets in a lot; a round hole the size of a shilling lets in hardly any, unless indeed a bit of insulated wire protrudes through it like a collecting ear-trumpet.

Gas-lighter with Tinfoil.

It may be asked how the waves get out of the metal tube of an electric gas-lighter. But they do not; they get out through the handle, which being of ebonite is transparent. Wrap up the handle tightly in tinfoil, and a gas-lighter is powerless.

Optical Experiments.

And now in conclusion I will show some of the ordinary optical experiments with Hertz waves, using as source either one of two devices: either a 6-inch sphere with sparks to ends of a diameter, an arrangement which emits 9-inch waves, but of so dead-beat a character that it is wise to enclose it in a copper hat to prolong them, and send them out in the desired direction; or else a 2-inch hollow cylinder with spark knobs at ends of an internal diameter. This last emits 3-inch waves of a very fairly persistent character, but with nothing like the intensity of one of the outside radiators.

As receiver there is no need to use anything sensitive, so I employ a glass tube full of coarse iron filings, put at the back of a copper hat with its mouth turned well askew to the source, which is put outside the door at a distance of some yards, so that only a little direct radiation can reach the tube. Sometimes the tube is put lengthways in the hat instead of crossways, which makes it less sensitive, and has also the advantage of doing away with the polarising or rather analysing power of a crossway tube.

Various Apertures in Lid.

The radiation from the sphere is still too strong, but it can be stopped down by a diaphragm plate with holes in it of varying size clamped on the sending hat.

Reflecting Plate, Wet Cloth, Glass Plate.

Having thus reduced the excursion of the spot of light to a foot or so, a metal plate is held as reflector, and at once the spot travels a couple of yards. A wet cloth reflects something, but a thin glass plate, if dry, reflects next to nothing, being, as is well known, too thin to give anything but "the black spot." I have fancied that it reflects something of the 3-inch waves.

Refracting Prism and Lens.

A block of paraffin about a cubic foot in volume is cast into the shape of a prism with angles 75°, 60°, and 45°. Using the large angle, the rays are refracted into the receiving hat, and produce an effect much larger than when the prism is removed.

An ordinary 9-inch glass lens is next placed near the source, and by means of the light of a taper it is focussed between source and receiver. The lens is seen to increase the effect.

Arago Disk, Grating and Zone-plate.

The lens helps us to set correctly an 18-inch circular copper disk in position for showing the bright diffraction spot. Removing the disk, the effect is much the same as when it was present. Add the lens, and the effect is greater. With a diffraction grating of copper strips two inches broad and two inches apart, I have not yet succeeded in getting good results. It is difficult to get sharp nodes and interference effects with these sensitive detectors in a room. I expect to do better when I can try out-of-doors, away from so many reflecting surfaces; indoors it is like trying delicate optical experiments in a small whitewashed chamber well supplied with looking-glasses; nor have I ever succeeded in getting clear concentration with this zone-plate having Newton rings fixed to it in tinfoil. But really there is nothing of much interest now in diffraction effects except the demonstration of the waves and the measure of their length. There was immense interest in Hertz's time, because then the wave character of the radiation had to be proved; but every possible kind of wave must give interference and diffraction effects, and their theory is, so to say, worked out. More interest attaches to polarisation, double refraction, and dispersion experiments.

Polarising and Analysing Grids.

Polarisation experiments are easy enough. Radiation from a sphere is already strongly polarised, and the tube acts as a partial analyser, responding much more vigorously when its length is parallel to the line of sparks than when they are crossed; but a convenient extra polariser is a grid of wires something like what was used by Hertz, only on a much smaller scale; say an 18-inch octagonal frame of copper strip with a harp of parallel copper wires. The spark-line of the radiator being set at 45°, a vertical grid placed over receiver reduces the deflection to about one-half, and a crossed grid over the source reduces it to nearly nothing.

Rotating either grid a little rapidly increases the effect, which becomes a maximum when they are parallel. The interposition of a third grid, with its wires at 45° between two crossed grids, restores some of the obliterated effect.

Radiation reflected from a grid is strongly polarised, in a plane normal of course to that of the radiation which gets through it. They are thus analogous in their effect to Nicols, or to a pile of plates.

The electric vibrations which get through these grids are at right angles to the wires. Vibrations parallel to the wires are reflected or absorbed.

Reflecting Prism.

To demonstrate that the so-called plane of polarisation of the transmitted radiation is at right angle to the electric vibration,[1] *i.e.* that the wires of the grid are parallel to it, I use the same paraffin prism as before, but this time I use its largest face as a reflector, and set it at something near the polarising angle. When the line of wires is parallel to the plane of incidence, in which case the electric vibrations are perpendicular to the plane of incidence, plenty of radiation is reflected by the paraffin face. Turning the grid so that the electric vibrations are in the plane of incidence, we find that the paraffin surface set at the proper angle is able to reflect hardly anything. In other words, the vibrations contemplated by Fresnel are the electric vibrations; those dealt with by McCullagh are the magnetic ones.

Thus are some of the surmises of genius verified and made obvious to the wayfaring man.

[1] *c.f.* Trouton, in NATURE, vol. 39. p. 393; and many other optical experiments by Mr. Trouton, vol. 40, p. 398.

THE REPORT OF THE ASTRONOMER ROYAL.

AT the annual visitation of the Royal Observatory, Greenwich, on Saturday last, the Astronomer Royal presented his report of the progress made from May 11, 1893, to May 10 of this year. We take from it the following information:—

It appears that the average number of transits observed was no less than 31 each day, or if Sundays are excluded, 36. As an instance of the number of observations which were made under very favourable conditions, it may be mentioned that on three consecutive days in February no fewer than 458 transits and 460 zenith distances were observed.

A new universal transit-circle or altazimuth is being constructed by Messrs. Troughton and Simms, and satisfactory progress has been made towards completion. All the heavy portions of the instrument, including the rotating and reversing gear, are made, and have been put together, the object glasses for the instrument and collimators are practically finished, as well as the eye end with its micrometers, and the circles, microscopes, &c., are in hand.

As previously noted in our astronomical column, a valuable gift has been made to the Observatory by Sir Henry Thompson, who has generously offered a sum of £5000 to provide a large photographic telescope with accessories, which would serve as the complement of the 28 inch visual telescope just completed. This munificent offer was readily accepted by the Admiralty, and after careful consideration and discussion, a photographic telescope of 26 inches aperture and 22 feet 6 inches focal length, equatorially mounted, was ordered of Sir H. Grubb on May 5, the instrument to be completed in eighteen months. This telescope will be of exactly double the dimensions (aperture and focal length) of the astrographic equatorial which has proved so successful, and it will be mounted on a very firm stand which will allow of complete circumpolar motion without the necessity for reversal on the meridian, which has been felt as a drawback in the astrographic equatorial. It will be erected on the central tower of the new Physical Observatory, under the 30 feet dome which is shortly to be placed there, and will carry the 12¾-inch Merz refractor as a guiding telescope and the Thompson 9-inch photoheliograph. It will thus be mounted under very favourable conditions for work, and will be in every respect a most effective instrument.

The new 28 inch refractor has been brought into working order after much time spent in the erection of the instrument, in the adjustment of the object glass, and in the provision of various fittings at the eye end. The adjustments were finished by October 1, when, under good atmospheric conditions, the definition was found to be very fine. Since then the object glass has been tested on various objects with very satisfactory results. A sketch of Jupiter and some measures of double stars have been made, and the colour correction of the object glass has been determined on stars by readings for focus at different parts of the spectrum.

The object glass has also been tried in the photographic position, with the crown lens reversed and the lenses separated on the plan proposed by Sir G. G. Stokes. The determination of the best distance between the lenses and the exact adjustment of the crown lens for tilt and centering relatively to the flint has necessarily taken a long time, as small modifications were required in the cells and special contrivances had to be devised for the delicate adjustment of the heavy crown cell and lens. A large number of photographs have been taken at different distances inside and outside of the focus corresponding to different positions of the crown lens, and affording interesting information which will be useful in connection with the Thompson 26-inch photographic telescope.

With the astrographic equatorial, 923 plates, with a total of 2143 exposures, were taken on 183 nights in the year ending May 10. Of these 181 were rejected, owing to photographic defects, mechanical injury, mistakes in setting, the plate being wrongly placed in the carrier, failure in clock driving, and interference by cloud. The following statement shows the progress made with the photographic mapping of the heavens in the year covered by the report:—

	No. of Photos taken.	Successful Plates.
Astrographic chart (exposure 40m.) ...	280	220
Plates for catalogue (exposures 6m., 3 m. and 20s.)	508	387
Number of fields photographed for the chart		200
Number of fields photographed for the catalogue		367
Total number of fields photographed since the commencement of the work for the chart		333
Total number of fields photographed since the commencement of the work for the catalogue		610

To test the optical photographic distortion up to considerable distances from the centre, seven plates with the Pleiades photographed in the four corners have been measured. It appears that the distortion is practically insensible up to 60′ from the centre, and is still small up to 80′, but is not quite the same in the four corners of the plate. On examination, the character of the images in the four corners was also found to vary slightly, the coma being slightly inwards in one corner and outwards in another. The perpendicularity of the plate and object glass to the optic axis were examined and found to be satisfactory.

Solar Observations.

Observations of the sun have shown that the solar activity was fully maintained throughout the whole of 1893, the mean daily spotted area for the year being considerably in excess of that for 1892. The great spot of 1892 February still remains the largest hitherto seen in the present cycle, but in 1893 August a very fine group attained dimensions but little inferior, and the groups of 1893 November and 1894 February were very large. The characteristic of the year was, however, rather the great number of groups visible at the same time than the extent of any one of them. Thus in August and December 1893 as many as 16 or 18 distinct groups of spots were seen on the disk at the same time.

Magnetic Observations.

The variations of magnetic declination, horizontal force and vertical force, and of earth currents were registered photographically, and accompanying eye observations of absolute declination, horizontal force and dip were made as in former years. The period was one of much less magnetic activity than last year, but there was a large increase occurring in 1894 February, at the time of the great sun-spot. Copies of the magnetic and earth current registers during the disturbances of February 20–March 1 and March 30–April 1, have been supplied to Mr. Preece for discussion in connection with disturbances on the telegraph lines.

Meteorological Observations.

Meteorological observations have been made as usual. The reductions show that the mean temperature of the year 1893 was 51°·1, being 1°·6 above the average for the 50 years 1841–1890.

During the twelve months ending 1894 April 30, the highest air temperature in the shade exceeded 80° on 28 days. It was 91°·0 on June 19, 93°·0 on August 16, 94°·2 on August 17, and 95°·1 on August 18. In the 53 years since 1841 higher temperatures have been recorded only twice previously (on both occasions in July). The lowest was 12°·8 on January 5, the maximum on that day being only 19°·0 and the mean daily temperature 15°·9. The mean temperature on August 18 was 79°·6, being the highest mean value recorded in August since 1841. The mean temperature of January 5 was lower than any previously recorded since 1841, with two exceptions. The mean monthly temperature was above the average in all months excepting September, November, and January 1894. In May it was 4°·6, in August 3°·9, in March 2°·7, and in April 3°·8, above the average. In November it was 1°·5 below the average.

The number of hours of bright sunshine recorded during 1893 by the Campbell-Stokes sunshine instrument was 1454, the greatest number on record since the commencement of the registration in 1877. This is 171 hours above the average of the preceding 16 years, after allowance is made for the small difference of indication of the Campbell and Campbell-Stokes instruments. The aggregate number of hours during which the sun was above the horizon was 4454, so that the mean proportion of sunshine for the year was 0·326, constant sunshine being represented by 1.

The rainfall for 1893 was 20·1 inches, being 4·4 inches below the average of the 50 years 1841–1890. From March 1 to September 30 (the period of the great drought) the rainfall amounted to only 7·77 inches, while the average for the 50 years 1841–90 for those months is 14·22 inches.

The mean amount of cloud for the year on the scale 0–10 was 5·75. The average amount as determined by Mr. Ellis (*Quarterly Journal Royal Meteorological Society*, vol. xiv.) from 70 years' observations is 6·75.

The outlook as regards instruments and accommodation for them is stated to be fairly satisfactory; but the fact that four vacancies in a staff of twelve persons have occurred during the fiscal year has necessarily caused serious disorganisation of the work, and greatly handicaps progress.

SCIENCE IN THE MAGAZINES.

THERE are few articles of scientific import in the magazines received by us. By this we do not mean to say that science is unrepresented in magazine literature for June, but that the articles, while affording an excellent pabulum for the omnivorous reader, lack originality of thought. They are, in fact, more descriptive than suggestive. "In the year 1887" (writes Mr. Edison, as an introductory note to an article by Antonia and W. K. L. Dickson in the *Century*) "the idea occurred to me that it was possible to devise an instrument which should do for the eye what the phonograph does for the ear, and that by a combination of the two all motion and sound could be recorded and reproduced simultaneously." The development of this idea, and its practical realisation, are well described by the authors of the article on Edison's kineto-phonograph—this being the comprehensive term given to the invention that is able to record and give back the impressions to the eye as well as to the ear. Muybridge, Marey, Boys, and others have shown what can be done in the way of instantaneous photography, but the plan used by Edison to obtain pictures of movable objects appears to differ from any previously used. After many trials, a highly sensitised strip of celluloid one and a-half inches wide has been adopted for the production of negatives, each strip being perforated on the outer edge. "These perforations occur at close and regular intervals, in order to enable the teeth of a locking-device to hold the film steady in the nine-tenths of the one forty-sixth part of a second, when a shutter opens rapidly and admits a beam of light, causing an image of phase in the movement of the subject. The film is then jerked forward in the remaining one-tenth of the forty-sixth part of a second, and held at rest while the shutter has again made its round, admitting another circle of light, and so on until forty-six impressions are taken a second, or 2760 a minute. This speed yields 165,600 pictures in an hour, an amount amply sufficient for an evening's entertainment, when unreeled before the eye. . . . The advantage of this system over a continuous band, and of a slotted shutter forging widely ahead of the film, would be this, that in one case only the fractional degree of light comprised in the 1720th part of a second is allowed to penetrate to the film, at a complete sacrifice of all detail, whereas in the present system of stopping and starting, each picture gets one-hundredth part of a second's exposure with a lens but slightly stopped down—time amply sufficient, as any photograper knows, for the attainment of excellent detail even in an ordinarily good light." The perforations in the film, referred to in the foregoing, are of assistance in establishing harmonious relations between the kinetoscope and phonograph, in making the action recorded by the one suit the word imprinted upon the other. Several reproductions of series of pictures obtained by the kinetograph accompany the article. In order that the subjects leaving their "passing moods" upon the kinetograph film may be brilliantly illuminated, a new kind of studio has been constructed. The building is pivoted at the centre, and is capable of being rotated so as to present any desired aspect to the sun. Another article in the *Century*, entitled "Field Notes," by Mr. John Burroughs, contains some interesting notes on the habits of a few common animals. This kind of contribution is very common in the magazines. "The Dog," by Mr. N. S. Shaler, and "American Game Fishes," by Mr. L. M. Yale, both in *Scribner*, belong to this anecdotal class.

Cassell's Family Magazine contains an article by Mr. J. Munro on "How I discovered the North Pole." The story is, of course, purely imaginary, but the idea upon which it is based might be developed for preliminary geographical exploration. A number of balloons are supposed to have been set free in high north latitudes, each provided with magazine cameras stocked with plates and having long-distance lenses of various focal lengths. Exposures were automatically made at regular intervals by means of clockwork, so that when the balloons were captured, they contained photographs of the tracks above which they had passed. Each balloon also carried a gyroscope mounted in such a manner that when its axis of rotation became vertical—that is, when the balloon containing it was exactly over the North Pole, cameras were brought into action and photographs taken of the earth below.

"The Spring of the Year," in *Longman's*, is an inspiring article written by Richard Jefferies, and found by Mrs. Jefferies among the MSS. left by him. Mr. A. Morgan retails some second-hand information on "Celestial Photography" in the same magazine. In *Good Words* Sir Robert Ball gives the second of a series of articles on "The Great Astronomers," the subject of his biographical sketch being Kepler. E. M. Caillard founds an excellent article on "Matter," and manages to impart clear and accurate notions on the universal properties of extension, inertia, unity, indestructibility and structure.

We note in *Chambers's Journal* "The Science of Colouring in Animals," "The Sargasso Sea," "Spiders and their Habits," and "The Identification of Habitual Criminals." Mr. A. Binet's "Mechanism of Thought," in the *Fortnightly*, is chiefly concerned with psychology and hypnotism. Honour is done to the late Prof. Robertson Smith by Mr. J. G. Frazer in the same magazine. Prof. Victor Horsley replies in the *Humanitarian* to the paper on vivisection contributed by Bishop Barry to the April number. The seventh of Mr. Phil Robinson's articles on "The Zoo Revisited," in the *English Illustrated*, deals with the animals in the "Small Cats' House." In the same magazine, Mr. W. B. Tegetmeier briefly describes the scope of his forthcoming book on horses, asses, and zebras. The May number of the *Nautical Magazine* contains an article in which Capt. Wilson Barker points to the study of "Natural History" (a term used to cover the ground of physiography) as a recreation for sailors.

In addition to the magazines mentioned in the foregoing, we have received the *Contemporary* and *National* reviews.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Provost of King's, Mr. A. Austen Leigh, has been re-elected Vice-Chancellor for the ensuing year.

St. John's College has carried off both the Smith's prizes this year; the winners are Mr. S. S. Hough and Mr. H. C. Pocklington, third and bracketed fourth Wranglers respectively in 1892, and first class in Part II. of the Mathematical Tripos, 1893.

Candidates for the University Lectureship in Invertebrate Morphology, vacated by Prof. Hickson, are requested to send their names to the Vice-Chancellor by June 9. The stipend is £50 a year.

Prof. Foster has been re-appointed a Manager of the Balfour Studentship Fund for the ensuing five years.

Mr. J. J. Lister, of St. John's, is to occupy the University's table at the Plymouth Biological Laboratory this summer.

The first examination for Diplomas in Agricultural Science will be held on July 2. Candidates are to send their names and fees to the Registrary by June 13.

The next examination for Diplomas in Public Health will begin on October 2. The names of candidates, with their certificates, are to be sent to the Registrary by September 18.

Sir G. G. Stokes, Dr. Sandys, and Prof. Robinson, are to represent the University at the Bi-centenary Festival of the University of Halle, to be held next August.

The following Examiners have been nominated by the Special Board for Medicine:—In Medicine, Dr. W. H. Dickinson, Dr. J. K. Fowler, Dr. L. Humphry, Dr. J. F. Payne; in Midwifery, Dr. W. S. A. Griffith, Dr. J. Phillips; in Surgery, Mr. H. H. Clutton, Mr. F. Treves, Mr. H. Marsh, Mr. W. H. Bennett.

Mr. H. Woods, of St. John's College, has been appointed an Elector to the Harkness Scholarship in Geology and Palæontology.

SCIENTIFIC SERIALS.

American Meteorological Journal, May.—The principal article is "Meteorology and Geodesy," by Prof. C. Abbe. It contains tables showing the variations in the force of gravity over the North American continent and the Atlantic ocean and their effect on the mercurial barometer. The author points out that there is a local attraction of gravitation that is less over the continents than over the oceans, and probably, on the average, less in the northern than in the southern atmosphere; these differences must be allowed for, in combination with the effects due to the density of the atmosphere and to centrifugal force. The principal resistance to the motion of the atmosphere originates in the connective processes that force stagnant air to mix with air in motion; this convective friction is quite independent of viscosity, which has been generally introduced into the formulæ for atmospheric motion, and it is much more effective. The most important subject for the meteorologist to study is these convective mixtures and the resistances or accelerations that result therefrom. The author considers it unnecessary to take up the minute irregularities treated of in this paper, until after the study above referred to has explained the larger part of the irregularities of atmospheric motions. The same journal contains some very useful suggestions by Prof. Abbe, on the various meteorological problems that might be taken up by mathematical students.

Bulletin de la Société des Naturalistes de Moscou, 1893, Nos. 2 and 3.—On the copulation organs of the males of the genera *Crosica*, *Melecta*, *Pseudomelecta*, &c., by General O. Radoczkowsky (in French, with four plates).—Contribution to the pathologic evolution of the nervous system, by Mme. O. V. Leonova, being a description of a complicated case of total anencephaly in a human embryo.—A case of seeming hermaphroditism with *Perca fluviatilis*, by N. Iwanzoff.—The Tithonian deposits of Theodosia, Crimea, by O. Retowski (in German, with six plates). This elaborate monograph contains the description of sixty-five fossil species from those little-known beds—no less than thirty-one species and one genus being new.—Palæontological data for the vertical subdivision of the Sarmathian deposits of South Russia, by A. P. Ivanoff (in Russian, summed up in French). The following five zones are distinguished:—(1) Zone of *Cerithium mitrale*, *mediterraneum*, and *rubiginosum*; (2) *C. disjunctum* and *mitrale*; (3) *C. nodosoplicatum*, *disjunctum*, and *mitrale*; (4) *C. rubiginosum*, *nodosoplicatum*, *disjunctum*, *mitrale*, var. *bicostata*, and *nympha*; (5) *C. mitrale*, var. *bijuga*; and (6) *C. disjunctum*. The beds overlying the above are characterised by the absence of *Cerithes*, and the appearance, for the first time, of *Trochus podolicus*, and a great development of *Mactra ponderosa*. The uppermost layers of the series contain no *Trochus podolicus*, while other species of *Trochus* and *Turbo* appear in great numbers. The birds of Moscow, by Th. Lorenz, continued.—Note on J. D. Chersky, with a complete list of his works, by A. Iwanowski.—On a new species, *Parus transcaspius*, by N. Zaroudnoi (in French).

Memoirs of the Kazan Society of Naturalists, vol. xxvi. Nos. 4, 5, and 6.—On the theory of the root-force in the plant, by Dr. Alexis Horvath. The manometric measurements of the author prove the existence of a rarefaction within the plant, and he therefore considers the vessel of a plant as a tube, in which we should have a succession of drops of a liquid, separated from each other by bulbs of air. The heating of the gas and its expansion acts in the tube as the piston of an aspirating pump.—On the consequences of the decapitation of the plant on some of its organs, by W. Rothert.—On the supply of water to Kazan, by Prof. Stscherbakoff.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, April 19.—"On Variations observed in the Spectra of Carbon Electrodes, and on the Influence of one Substance on the Spectrum of Another." By W. N. Hartley, F.R.S.

Certain "lines" in Hartley and Adeney's spectrum of carbon are attributed to cyanogen in a recent paper by Eder and Valenta.[1] These lines are not produced by cyanides such as potassium cyanide or mercuric cyanide. Graphite electrodes immersed in solutions show beautiful groups of lines which coincide with the edges of certain bands in spectra of the flame of burning cyanogen. These bands can be recognised in the groups iii. and iv. on the spectra photographed by Kayser and Runge.

The origin of these coincident portions of spectra, namely, from the combustion of cyanogen and from carbon electrodes in saline solutions, taken in conjunction with the fact that they are not rendered by cyanides, makes it doubtful whether the cyanogen spectrum is not due to elementary carbon, as first advocated by Marshall Watts. There are other facts and circumstances which somewhat support this doubt. First, variations have been observed in the spectrum of carbon which cannot be easily accounted for. Secondly, the effect of one substance on

[1] "Line Spectrum of Elementary Carbon and the Ultra-violet Spark Spectrum of Wet and Dry Wood Charcoal" (Vienna: "Akad Wiss. Denkschriften," vol. 60, 1893).

the spectrum of another, which I have recently observed, not only strengthens weak lines, but in certain cases brings a new series of lines into view. Thirdly, the spectra of mixed vapours have been shown to be different from the spectra of the substances by themselves (Liveing and Dewar, "Roy. Soc. Proc.," vol. xxxiv. p. 428); and, fourthly, the influence of the strong lines of an element on adjacent weaker lines of another substance is to strengthen the weaker lines in some cases, but almost to obliterate them in others.

Variations in the spectrum of carbon as observed in different circumstances have been carefully examined and described. In order to test the probability of the carbon and nitrogen spectra being subject to variations when the two elements are together in the spark or flame, it is necessary to consider the effect of one spectrum on another when the two are produced simultaneously from quite different materials.

In the oxyhydrogen flame the water-vapour lines are prominent, but only two groups are visible in the spectrum under normal conditions, and with an exposure of half an hour. If, however, some sulphur be burnt in the flame, the conditions being otherwise unchanged, then the spectrum, in addition to a band of continuous rays and flutings characteristic of sulphur vapour, shows the water-vapour lines wonderfully strong, with groups extending beyond those portions of the spectrum usually photographed, and not only are the lines distinct, but dense, as if their radiating power or the chemical action of their radiations was greatly increased. This does not arise from the continuous spectrum merely overlapping and apparently strengthening the water-vapour lines, since new groups of lines came into view which were too feeble to be visible on the other photographs. Sulphur is not the only substance which affects this spectrum; for instance, the banded spectrum of magnesia and the spectrum of lime also appear to intensify it.

It is probable that something similar takes place with regard to carbon; we know that the spectrum is modified by the surrounding nitrogen of the atmosphere, and the rays of carbon increase the intensity of the nitrogen rays adjacent to the carbon lines, the effect being increased in the case of the spark by a saturated solution of zinc or calcium chloride.

The facts here set forth certainly favour the view that the lines in Hartley and Adeney's spectrum of carbon are the lines of the element and not merely the edges of cyanogen bands. Finally, the carbon spectra of Eder and Valenta differs from that published in the *Journal* of the Chemical Society, vol. xli. p. 91; the graphite spectrum, No. 10, on plate ii., yields neither the group III. nor group IV. of cyanogen as depicted in spectrum No. 4 of the photogravure plate illustrating Eder and Valenta's paper.

"Experimental Determination of Poisson's Ratio." By C. E. Stromeyer.

The experiments with which this paper deals were carried out between the years 1883 and 1886 by Prof. Kennedy and the author, with an instrument which the latter had originally designed for measuring local strains in metal structures, but which proved itself to be so exceedingly sensitive that it was capable of being applied to the measuring of the cross contraction of test pieces while these were subjected to a longitudinal pull, thus providing the means for measuring Poisson's ratio direct.

The conclusions drawn from the experiments with nineteen samples are:—

(1) That Poisson's ratio is not a constant value for all materials.

(2) That mechanical treatment (cold rolling and annealing) of the metal alter it.

(3) That Poisson's ratio is sometimes a function of the stress.

(4) That Poisson's ratio, as found by direct measurement, is not the same as that found by comparing torsion and tension experiments.

May 24.—"Some Voltaic Combinations with Fused Electrolytes and Gaseous Depolariser." By. J. W. Swan.

In this paper are described several voltaic combinations in which fused electrolytes and a gaseous depolariser were used. The electrodes were the same in all the experiments, viz. lead in a fused state as the positive, and carbon as the negative. The electrolyte used in the first experiments was a fused mixture of KCl,NaCl, but this was changed for one of $PbCl_2$. The depolarising gas used in all the experiments was chlorine, and was so applied as to chemically act on the electrolytic product formed at the carbon pole. Several methods of applying the gas were employed: by forcing the gas through porous carbon, by making the carbon pole tubular and feeding the chlorine through it, and by nearly wholly surrounding the carbon pole by an atmosphere of chlorine.

The condition found to be most necessary for successful depolarisation was *to alternately expose the carbon pole to the action of the gas and electrolyte in rapid succession.* During the electrolytic action, the lead dissolves as chloride of lead, and lead is deposited on the carbon pole, but is immediately reconverted to chloride by the action of the chlorine gas. The theoretical E.M.F. corresponding to the union of Pb and Cl_2 is 1·7942 volts, the highest obtained was 1·40 volts, this lower E.M.F. was probably due to the incomplete solution of the lead at the carbon electrode.

A noticeable feature of this kind of cell is the very low internal resistance, which makes it possible to obtain a large current density with comparatively small electrodes. In one of the experiments a current of 1·0 ampère was given with an area of the carbon of 10 to 12 sq. cm. It was also observed that the internal resistance, and at the same time the polarisation, *decrease*, when the electrical output *increases*, and that the cell gave an almost constant effect. The best results were obtained with small cells, the action of the chlorine being then more effective than when larger cells were employed. Experiments were also made with oxygen as a depolariser, but a description of them is left for a future paper.

Physical Society, May 25.—Prof. A. W. Rücker, F.R.S., President, in the chair.—Prof. W. Ramsay, F.R.S., read a paper on the passage of hydrogen through a palladium septum, and the pressure which it produces. After referring to the analogy between osmotic pressure of solutions, and the behaviour of hydrogen and palladium, the author described the apparatus he had used in his experiments, and showed it in operation. A vertical platinum tube provided with a palladium cap is enclosed within a glass vessel through which hydrogen or other gases may be passed, and outside the glass vessel is a vapour jacket, by means of which a constant temperature can be maintained. The lower end of the platinum tube communicates through a graduated capillary tube, with adjustable manometer, which enables the volume of the enclosed gas to be kept constant. Great precautions were taken for ensuring purity and dryness of the gases used. After filling the palladium and platinum tube with dry nitrogen at atmospheric pressure and the desired temperature, hydrogen was passed through the glass vessel. Some of the hydrogen permeated the palladium walls, thus increasing the pressure inside. After some time (usually an hour or so) the pressure attained a steady value, and the total increase was then observed. Experiments were made with air, nitrogen, nitric oxide, nitrous oxide, carbon dioxide, carbon monoxide, and cyanogen in the palladium tube, and in some cases the hydrogen was diluted with nitrogen. In all cases the maximum pressure of the hydrogen within the tube was less than that of the hydrogen outside the tube, as will be seen from the following table, which shows the ratio of these pressures under various conditions:—

Gas originally inside tube.	Gas passed outside tube.	Temp.	Ratio $\frac{\text{Internal hydrogen pressure}}{\text{External hydrogen pressure}}$
Nitrogen	Hydrogen	280 C.	0·9053
,,	,,	335	0·8984
,,	,, 50 % (rest N)	,,	0·9362
,,	,, 25 ,, ,,	,,	0·9344
Carbon Dioxide	Hydrogen	280	0·9621
,, Monoxide	,,	,,	0·9545
Cyanogen	,,	,,	0·9693

After the palladium had been used once or twice it became coated with mercury (vapourised from the manometer), and lost its permeable properties. It was found necessary to heat the tube to remove the mercury, and then dissolve off the oxide of palladium thus produced, after each experiment. The permeable nature of palladium was found to depend greatly on the temperature, for at 232° C. the passage of hydrogen was so slow that the internal pressure was still rising after ten days; at 330 the passage was very rapid. An attempt to use the apparatus for giving a continuous indication of the amount of hydrogen in coal gas failed because the palladium did not retain its activity sufficiently long. Other experiments showed that nickel is impervious to carbon monoxide. In the latter portion of the paper the author discusses the various "so-called" explanations which have been given of the phenomena, but finds none satisfactory. Experiments on the absorption of gases by platinum and other metals are in progress with a view to the further elucidation of the subject. Mr. Mond thought the fact that rise of temperature accelerates diffusion, tended to confirm Graham's view that the gases pass through openings in the solid, for increase of temperature would widen any pores which might exist in the metal. The President inquired whether the author's argument against the possibility of palladium hydride condensing in the pores of the metal, because of its being unstable at the temperatures employed, would be affected by the fact of water being capable of existing in contact with glass at temperatures much above boiling point. In reply Prof. Ramsay said the President's suggestion might be true, but if so another condition must be fulfilled, viz. that the hydrogen molecules must be split up into the atomic or *nascent* state.—A paper on the relations of pressure, volume, and temperature of rarefied gases, by Prof. W. Ramsay, F.R.S., and Mr. E. C. C. Baly, was read by the latter. In the first part of the paper a historical summary of previous researches on the subject is given, and the chief sources of error pointed out. The method employed by the authors was to have two McLeod gauges connected with a pump, and arranged so that both could be trapped under exactly the same pressure. One of the gauges was surrounded by a vapour jacket at about 130 C., whilst the other was cold at about 13° C. After both were trapped, the hot gauge was allowed to cool and the readings of both taken. From these observations the coefficient of expansion of the gas used could be calculated. The experiments also served as tests of the reliability of the McLeod gauge under different conditions. For air and carbon dioxide the gauges proved quite unreliable, whilst for hydrogen they were very satisfactory. With carbon dioxide the surface condensation was so large as to make the observations worthless, but hydrogen suffered no condensation between pressures of 650 mm. and 0·000076 mm. Great difficulty was experienced in filling the gauges with pure hydrogen, but when accomplished the expansion was found to be normal ($\frac{1}{273}$) down to 0·4 mm. pressure, and diminished to $\frac{1}{300}$ at 0·07 mm. Oxygen, however, gave a coefficient of $\frac{1}{261}$ at 5 mm. pressure, $\frac{1}{250}$ at 2·5 mm., and $\frac{1}{233}$ at 1·4 mm. At 0·7 mm. its behaviour was most erratic, there being as much as fifteen times the amount of gas trapped in the gauge at one time as at another. This confirms C. Bohr's observations on the anomalous behaviour of oxygen about this pressure. For nitrogen the values of the coefficients found were $\frac{1}{300}$ at 5 mm., $\frac{1}{304}$ at 1·1 mm., and $\frac{1}{342}$ at 0·6 mm. At small pressures the elasticities of hydrogen, nitrogen, carbon dioxide and air increase with decrease of pressure, but in oxygen the reverse holds. Examining the consequences of this increase of elasticity in the light of the kinetic theory of gases the authors point out that it means an increase of internal energy, and suggest that this may be the the cause of phosphorescence in high vacua. The President announced that the discussion on the last paper would be taken at the next meeting, after proofs had been distributed to members.

Chemical Society, May 3.—Dr. Armstrong, President, in the chair.—The following papers were read.—The structure and chemistry of the cyanogen flame, by A. Smithells and F. Dent. The flame of cyanogen burning in air consists of an inner cone of a peach-blossom tint surrounded by a blue-grey mantle. With a small air-supply the only products of combustion in the intercenal gases are carbon monoxide and nitrogen with small proportions of nitrogen oxides and carbonic anhydride; the quantity of the latter constituent increases as the air-supply increases. On igniting dry cyanogen—the flame being fed with dry air—and separating the two cones in the usual way, the outer cone becomes extinguished; this agrees with Dixon's observation that a mixture of dry carbon monoxide and air is not explosive.—The results of measurements of the freezing points of dilute solutions, by H. C. Jones. The author defends his work from Pickering's recent criticisms, and attacks Pickering's method of plotting the results of freezing point determinations.—The conditions in which carbon exists in steel, by J. O. Arnold and A. A. Read. The authors confirm the existence in steel of a carbide having the composition Fe_3C; it is isolated as a greyish-black powder from normal steel, and as bright silvery plates from well-annealed steel. A highly manganiferous steel contained a double carbide of the composition Fe-Mn C_3.—The "cis" and "trans" modifications of tetramethylenedicarboxylic acid (1 : 2) and pentamethylenedicarboxylic acid (1 : 2), by W. H. Perkin, junr.—Hexamethylenedibromide, $BrCH_2 . CH_2 . CH_2 . CH_2 . CH_2 . CH_2 Br$, by E. Haworth and W. H. Perkin, junr. The authors have prepared chloromethoxypropane, $Cl (CH_2)_3 OMe$; this, when treated with potassium in benzene solution, yields a substance of the composition $MeO (CH_2)_6 OMe$, which is converted into hexamethylenedibromide on heating with hydrobromic acid.—α-Hydrindone and its derivatives, by F. S. Kipping.

Linnean Society, May 24.—Anniversary meeting.—Prof. Stewart, President, in the chair.—The Treasurer presented his annual report duly audited, and the Secretary having announced the elections and deaths during the past twelve months, the usual ballot took place for new members of Council, when the following were elected in the place of those retiring:—Dr. John Anderson, F.R.S., C. B. Clarke, F.R.S., Prof. J. Reynolds Green, Arthur Lister, and Albert D. Michael. On a ballot taking place for the elections of President and officers, Mr. Charles Baron Clarke, F.R.S., was elected President, and the officers were re-elected. The Librarian's report having been read, and certain formal business disposed of, the retiring President delivered his annual address, taking for his subject "The Locomotion of Animals, with special reference to the Crustacea." On the motion of Dr. D. H. Scott, seconded by Mr. Howard Saunders, a unanimous vote of thanks was accorded to the President for his able address, with a request that he would allow it to be printed.—The Society's gold medal was then formally awarded to Prof. Ernst Haeckel, of Jena, and was received on his behalf by Mr. W. Percy Sladen, who read a long and excellent letter of acknowledgment and thanks, which was prefaced by an expression of the writer's regret at his inability to come to England to receive the medal in person.

CAMBRIDGE.

Philosophical Society, May 14.—The Master of Downing College, Vice-President, in the chair.—Mr. S. J. Hickson exhibited a specimen of *Chelifer* from Celebes, showing a remarkable sense-organ on the coxæ of the last legs.—Mr. A. E. Shipley read a note on *Filaria immitis*.—On variations in the larva of *Asterina gibbosa*, by Mr. E. W. MacBride. The larva of *Asterina gibbosa* when fully developed possesses five cœlomic cavities, a median anterior and two pairs of posterior cavities, which suggest a comparison with the similarly arranged spaces in the *Balanoglossus* larva, a suggestion which derives further support from the fact that in both cases the anterior cavity opens to the exterior by a pore situated on the left side, called the madreporic pore, in the *Asterina* larva. Two cases of a similar pore on the right side were recorded, but the variations described chiefly concern the more anteriorly situated of the paired cavities. The left of these forms the water vascular system of the adult. In one instance a pore was observed leading from it directly to the exterior, recalling the collar pore of *Balanoglossus*. The right usually remains rudimentary, but several instances are described of its presenting in greater or less degree the features normally exhibited by its fellow on the left. These variations are to be interpreted, taking into consideration the bilateral symmetry of Echinoderm larvæ, as atavisms.—On a new method of preparing culture media, by Dr. Lorrain Smith. The author described a method for preparing media suitable for the cultivation of bacteria. The principle of the method consists in the addition of a small percentage of alkali to fluids which contain proteid such as egg-white and serum of blood. The fluid is then heated to the boiling-point or over it in the autoclave. By this means it is converted into a clear transparent jelly. It is then a medium suitable for the growth of a large variety of germs.

PARIS.

Academy of Sciences, May 28.—M. Lœwy in the chair.—Observations of Brooks' comet, 1893, 6 (October 16, 1893), and of Wolf's planet (AX, 1894), made with the great equatorial of Bordeaux Observatory, by MM. G. Rayet, L. Picart, and F. Courty. Note by M. G. Rayet.—On solar faculæ, by Prof. George E. Hale. A rejoinder to some remarks by M. Deslandres on a paper published by the author in *Knowledge*.—Observations of the sun made at Lyons Observatory during the first quarter of 1894, by M. J. Guillaume. From the observations quoted, March shows a decided minimum of spot surface more marked than the minimum of November 1893; the maximum for spots was in August 1893, and for faculæ in May of the same year.—On four related solutions of the problem of the transformation relative to the elliptic function of the second order, by M. F. de Salvert.—On the limitation of degree for the algebraical integrals of the differential equation of the first order, by M. Autonne.—On the properties of groups of substitutions of which the order is equal to a given number, by M. E. Maillet.—On the integration of partial equations of the second order with two independent variables, by M. J. Beudon.—On uniform integrals of partial differential equations of the first order and *genre zéro*, by M. Petrovitch.—Variation of the surface tension with the temperature, by M. H. Pellatt. A mathematical paper leading to the conclusion that the surface tension is a linear function of the absolute temperature.—On the capacity of the capillary electrometer, and on the initial capacity of mercury, by M. E. Bouty.—Method for the direct measurement of electromotive forces in absolute value, by M. C. Limb. The method depends on the direct comparison of the unknown electromotive force with an induced electromotive force in a case where the latter may be calculated.—*Résumé* of meteorological observations made at Joal (Senegal) by the mission sent by the Bureau des Longitudes to observe the total eclipse of the sun on April 16, 1893. A note by M. G. Bigourdan.—On the detection of hydrochloric acid, by MM. A. Villiers and M. Fayolle.—A comparative study of the nitrobenzoic acids, by M. Oechsner de Coninck. The reactions of these acids with aqua regia, dilute chromic acid, dilute hydrochloric acid, dilute nitric acid, dilute alcohol, and acetone have been further studied. Just as was found for their physical properties, two of these acids yield similar reactions, and differ from the third.—On the constitution of licareol, by MM. Ph. Barbier and L. Bouveault. The formula adopted now for licareol is the following:—

$$CH_3 . C(CH_3) : CH . CH_2 . CH(CH_2OH) . C(CH_3) : CH_2.$$

Athough licareol has given nearly the same products of oxidation as geraniol, the corresponding aldehydes appear to be different, as they give compounds with para-amidophenol having different melting points. Licareol is active, geraniol is inactive, and may possibly be a racemic form of the alcohol.—On the melting points of some phenols and their benzoates, by MM. A. Béhal and E. Choay. A tabular statement.—On the rectification of alcohol, by M. E. Sorel.—On the latex of the lacquer-tree, by M. G. Bertrand. The mechanism of the production of lacquer from the exudation from trees of the *Rhus* genus is demonstrated. It is shown that the oxidation of the substance *laccol* only produces the characteristic black insoluble lacquer in the presence of a diastase termed by the author *laccase*.—On parthenogenesis in the Sarcoptidæ. A note by M. E. Trouessart.—On the development of excretory organs in *Amphiuma*, by M. Herbert Haviland Field.—Utilisation of vintage *marcs*, by M. A. Muntz. The wine retained by the *marc* is displaced mechanically by water in special cylindrical vessels, and yields a good quality wine practically undiluted. The residual *marc* after treatment is utilised as cattle food.

AMSTERDAM.

Royal Academy of Sciences, April 21.—Prof. van de Sande Bakhuyzen in the chair.—Prof. Schoute made a communication on the regular sections and projections of the hekatonkosædroid (Z^{120}) and the hexakosiœdroid (Z^{600}). The chief results can be gathered from the following table:—

Projections of							Sections of
Z^{120}	v	42	52	56	44	f	Z^{120}
	e	120	130	150	120	e	
	f	80	80	96	78	v	
Z^{600}	v	158	180	160	80		
	e	240	282	250	120	e	Z^{600}
	f	84	104	92	42	v	

The four columns of the above represent at the same time the number of vertices, edges and faces of the projections of Z^{600} and Z^{120}, and the number of faces, edges and vertices of the sections of Z^{120} and Z^{600}.—Prof. Kamerlingh Onnes communicated the results of measurements made by Dr. Zeeman in the Leyden laboratory, of the reflection of polarised light on the pole of a magnetised nickel mirror. The so-called null rotation changes its sign at the incidence of 26°, in accordance with Goldhammer's theory. Drude's theory gives a value of 60°.

BOOKS AND SERIALS RECEIVED.

BOOKS.—The Frog: Prof. A. Milnes Marshall, 5th edition (Manchester, Cornish).—Walks in Belgium—the Old Flemish Towns and the Ardennes: edited by P. Lindley (30 Fleet Street).—A Handbook to the Marsupialia and Monotremata: R. Lydekker (W. H. Allen).—A Handbook to the Birds of Great Britain: Dr. R. B. Sharpe, vol. 1 (W. H. Allen).—Flore de France: A. Acloque (Paris, Baillière).—The Camel, its Uses and Management: Major A. G. Leonard (Longmans).—The Country Month by Month: J. A. Owen and Prof. Boulger, June (Bliss).—Elementi di Fiscia: Prof. A. Roiti, vol. 2 (Firenze, Monnier).—An Introduction to the Study of Metallurgy: Prof. W. C. Roberts-Austen, 3rd edition (Griffin).—Électricité Appliquée a la Marine: P. Minel (Paris, Gauthier-Villars).—Étude Expérimentale Dynamique d'une Machine a Vapeur: V. Dwelshauvers-Dery (Paris, Gauthier-Villars).

MINING BOOKS.

Economic Geology of the United States, with briefer mention of Foreign Mineral Products. By Ralph S. Tarr, B.S., F.G.S.A., Assistant Professor of Geology at Cornell University. (London: Macmillan and Co., 1894.)

The Ore Deposits of the United States. By James F. Kemp, A.B., E.M., Professor of Geology in the School of Mines, Columbia College. (New York: Scientific Publishing Company, 1893.)

Mining; an Elementary Treatise on the Getting of Minerals. By Arnold Lupton, M.I.C.E., F.G.S., &c. (London: Longmans, 1893.)

The Miner's Handbook. Compiled by John Milne, F.R.S., Professor of Mining in the Imperial University of Japan. (London: Lockwood, 1893.)

THE mining student of to-day has no reason to complain that his interests are being neglected, for text-books relating to his art are being showered upon him. Prof. Tarr states in his preface that there is no recent text-book on economic geology of any value. Surely the well-known library of his University must possess the big treatise of Fuchs and De Launay, published last year. The first part of Prof. Tarr's work, which deals with the mineralogical aspect of the question, might well have been omitted, for the student gains nothing in the end by being taught mineralogy in a loose and vague fashion. Objection must be taken to the word "mineralizer," which is used throughout the book to denote a non-metallic element, such as sulphur or chlorine, combined with a metal. In mining and metallurgy the author perpetrates a series of blunders, for which even junior students would be upbraided by an examiner. In speaking of the extraction of metals, he says there are three methods of treating ores: "Amalgamation, smelting (the dry way), and metallurgy (the wet way)." A treatise upon metallurgy would be strangely imperfect if Prof. Tarr's definition of the term were adopted. On the next page is the remarkable statement: "Before smelting some ores it is necessary to either calcine them—that is, to allow them to decompose in the air at ordinary temperatures—or to roast them." A moment's reflection upon the derivation of the word "calcine" would have prevented the mistake. It is evident that the author has not even turned over the pages of "De re Metallicâ," for otherwise we should not have the curious piece of historical information: "During the reign of Agricola, Portugal produced stream tin." Though sadly marred by careless writing of this description, the book contains much useful information compiled from various sources; but it is singularly deficient in figures.

Prof. Kemp in his introduction gives a valuable *résumé* of various schemes for classifying ore-deposits, a subject upon which there is much difference of opinion, for mining geologists are not yet agreed whether the basis of the classification should be form or origin. The author casts his vote in favour of the latter, and brings forward an elaborate scheme of his own, which will be of service to teachers and to students in reminding them of the very various causes which may have contributed to the production of ore-deposits. But is it not a mistake for a Professor to limit his classification to deposits worked for metals? Surely it is better to make the student take a wider view of the subject, and adopt some scheme which includes all kinds of mineral deposits. In the second part of the work will be found concise and useful descriptions of the modes of occurrence of the various metallic ores, with references to numerous original memoirs. The illustrations are far too few to do justice to the importance of the subject, and many of them are valueless. Reproductions of photographs of mining buildings and mining camps serve no useful purpose in a work of this description. There is a strange lack of geological feeling in the section of the Eureka Mine; judging by the illustration, the surrounding strata are horizontal, whilst Mr. Curtis' original plates show that they are highly inclined. Several of the woodcuts are rendered useless from the absence of any explanatory legend.

Prof. Lupton has brought into comparatively small compass the results of a long experience among mines; but it is not good taste in an author to blow his own trumpet so loudly in his preface. The arrangement of the book is not all that one would desire, for it shows a decided want of method. Like many of his predecessors, the author devotes one of the early chapters to "sinking," with the result of confusing the student, who is introduced suddenly to processes of excavation, supporting, winding, pumping and ventilation, all of which are described at length in other parts of the book. The gases found in mines are dealt with in the chapter upon ventilation; it would have been more logical to have discussed the nature of the polluting agents before describing the means of getting rid of them. Due importance is very rightly given to the dangers arising from coal dust; but why separate this chapter by 200 pages from the part of the book treating of accidents generally? The student will be grateful to the author for the lavish manner in which he inserts woodcuts, though some are far from satisfactory, and a few utterly useless. Reduction by photography may be carried too far, and the figure of the Rio Tinto drill is practically incomprehensible.

In the remarks about coal-cutters the author is not up to date, for he says "electrical coal-cutters have made but small progress," and supposes that no Winstanley machines are in use at the present time.

Mistakes are more frequent than they should be in the case of an author who has travelled much at home and abroad. It might almost be supposed that he had never looked inside a smith's shop at a mine, when one reads that the edge of a drill cannot be sharpened sufficiently by hammering. It will be news to most miners that lead ore is jigged upon a bed of *felspar*, and that gold quartz, after a preliminary crushing, is passed through rolls before going to the stamps. The description of the concentration of gold ores by endless belts is strangely confused. The author is weak in physics, for he seems to consider the density and the specific gravity of a gas to be two different things. The passage of gases through porous diaphragms is spoken of as "Eudiometry," and the repetition of the word in the index proves that it is not a mere slip of the pen.

The same inexactness pervades his mineralogy and geology; he looks upon tungsten ore and wolfram as two different minerals, and he puts down cadmium and phosphorus in his list as if they occurred native. If he had taken the trouble to consult the details of the official statistics, which he quotes, he would have been spared the erroneous statements that all the British tin comes from Cornwall, and that only small quantities of zinc ore are obtained in Great Britain.

When dealing with coal-mining Prof. Lupton is standing upon firmer ground, and he has brought together much general information and many useful details, which will render the book acceptable to students. Considering the amount of matter and the number of illustrations, the treatise is remarkably cheap.

During his long stay in Japan, Prof. Milne seems to have acquired the deftness of a native in packing, for it is difficult to conceive how more information could have been crammed into a book no bigger than a cigar-case, and weighing only six and a half ounces. It is a veritable miniature compendium of mining, which is likely to find a place not only on the shelves, but also in the luggage of most mining engineers.

A NEW STANDARD DICTIONARY.

A Standard Dictionary of the English Language. Vol. i. (New York: Funk and Wagnall's Company, 1893).

IT has been said that "a dictionary of language should contain all the words which may be reasonably looked for in it, so arranged as to be readily and surely found, and so explained as to make their meaning, and if possible their use, clear to those who have a competent knowledge of the language or languages in which the explanations are given." In other words, a dictionary should be an "inventory of language," and this being so, it constitutes an index to the state of knowledge at any epoch. Not so very many years ago it was held that words belonging to sciences and the arts should be omitted from dictionaries. The French Academy at first went so far as to reject all technical terms from their dictionary, though they afterwards decided to admit them, and, when the Philological Society projected their dictionary in 1856, they resolved to accept all English words except "such as are devoted to purely scientific subjects, as treatises on electricity, mathematics, &c." But time has changed all that. No man is now considered well-informed if he is not familiar with common scientific words, and therefore no work in which such a sin of omission is committed deserves the name of a dictionary.

In the dictionary before us, special attention has been paid to science, and words have in all cases been submitted to specialists. As a guarantee of the trustworthy character of the definitions, it is sufficient to mention the names of some of the eminent scientific men upon the editorial staff. Among those responsible for words pertaining to astronomy, physics, and mathematics, are Prof. Simon Newcomb, Prof. Frank H. Bigelow, Dr. A. E. Bostwick, and Prof. A. J. Kimball. Meteorological definitions have been edited by Prof. Mark W. Harrington, and zoological ones have been controlled by Prof. T. N. Gill, Mr. L. O. Howard, and Mr. Ernest Ingersoll. Special biological terms have been referred to Prof. F. Starr and C. S. Dolley. The editors of botanical definitions are Prof. Frank H. Knowlton, with Mr. E. F. Smith (mycology), Mr. David White and Mr. W. T. Swingle (Palæozoic flora), and Mr. A. A. Crozier (pomological terms). Anatomy was under the editorship of Prof. Frank Baker; bacteriology, of Dr. T. M. Prudden; medicine, of Dr. F. P. Foster; chemistry, of Prof. R. O. Doremus and Dr. M. Benjamin. Dr. W. Hallock and Mr. R. Gordon are responsible for the formulæ of colours; Prof. N. S. Shaler and W. R. Dwight for geological words; Dr. G. H. Williams and Dr. W. G. Brown for mineralogy and crystallography; and Mr. G. F. Kunz for gems and precious stones. Dr. G. P. Merrill has been the referee for words relating to building-stones; Mr. R. W. Pope for words used in electricity; Prof. W. H. Pettee for those belonging to metallurgy; Prof. Huxley has had evolution under his care; Dr. P. T. Mason, anthropology, and Mr. E. Muybridge, animal locomotion. These are only a few of the names of men of science who have helped in the production of the dictionary. One has only to read through the complete list to come to the conclusion that the projectors of the dictionary have done everything possible to render the work authoritative and uniformly accurate.

It is for us to point out the special features of the dictionary as regards science. Beginning with chemistry, we find that the rules adopted for the spelling and pronunciation of chemical terms are those recommended in a resolution passed by the Chemical Section of the American Association for the Advancement of Science, at the Rochester meeting, in 1892. The following changes have, therefore, been introduced. In the case of terminations in *ide* the final *e* has been dropped, thus giving chlorid, iodid, hydrid, oxid, hydroxid, sulfid, amid, &c. In names of chemical elements and compounds terminating in *ine* (except doubly unsaturated hydrocarbons) the final *e* is also dropped, and the syllable pronounced *in*, as, for instance, chlorin, bromin, &c.; amin, anilin, morphin, quinin, vanillin, emulsin, caffein, and cocain. The termination *ine* is retained, however, in the case of the hydrocarbons referred to. Preference is given to the use of *f* in the place of *ph* in sulphur and all of its derivatives, as sulfate, sulfite, sulfuric, &c. But though this system of spelling has been accepted by most American chemists, there is little possibility of its being generally adopted in our own chemical literature.

Handicraft terms are given with great completeness and grouped under the different trades. By a new system of grouping applied to the names of fruits, flowers, coins, weights, measures, stars, &c., the facts concerning this class of words are very fully given. Thus, in *constellation* Prof. Newcomb gives the names of all the constellations; under *apple* are found the names of 368 varieties, under *dog* the names and characteristics of all the different kinds of dogs, under *coin* a complete list of coins, under *element* a list of chemical elements, with their atomic weight, specific gravity, melting points, valency, date of discovery, name of discoverer, and condition of occurrence in nature.

The volume under review is full of illustrations, and the fine plates in it are marvellous specimens of colour-printing. Among the full-page coloured plates is one of gems and precious stones, and another of birds. A third plate of special interest is a splendid monochrome in which a number of ancient coins are grouped. When the work is completed it will contain nearly five thousand illustrations, all especially drawn for it. Each picture has been drawn so as to help to define a word, and the object of the plates is to facilitate comparison.

Whether the dictionary will, in course of time, "be accepted as the standard by all who use the English language," may be doubted. Many years will pass before we spell honour without the *u*, and sulphur has evolved into sulfur. But, putting these differences of spelling aside, we have no hesitation in saying that, in point of accuracy, the dictionary will compare favourably with any similar compilation extant, while for comprehensiveness combined with handiness, it is as good a work as could be desired. Everything has been done to facilitate the finding of words and to make the definitions trustworthy when found. It passes the wit of man to suggest anything which ought to have been done that has not been done to make the dictionary a success.

OUR BOOK SHELF.

An Introduction to the Study of Metallurgy. By Prof. W. C. Roberts-Austen, C.B., F.R.S. Third edition. (London: Charles Griffin and Co., 1894.)

THE part metallurgy has played in the industrial progress and material prosperity of our country is so great, that we hail with pleasure the appearance of this enlarged edition of Prof. Roberts-Austen's book, in which all that is important for a sound knowledge of the principles on which metallurgy is based is set forth with remarkable lucidity and ability.

The issue of this edition marks, in fact, an epoch in metallurgical teaching.

Its especial value lies, not in mere descriptions of the processes and appliances of metallurgy, but in the admirable systematic course of study laid down for the student in the fundamental scientific principles on which the appliances used in metallurgy are constructed, its processes based, and the character of their products determined. Without a clear understanding of these principles, it is needless to say, no knowledge of mere practical details, however extensive, can be of any value in enabling the metallurgist to cope successfully with the difficult problems which often confront him both in furnace and laboratory operations.

The elaborate researches of the author in the "thermal treatment of metals" and "thermal measurements" is a sufficient guarantee that these subjects will be treated in a manner worthy of their importance. (Chaps. iv. and v.)

Chapter ix., a special feature of this edition of the book, is a masterly compendium of the facts, principles, theories and laws of thermo-chemistry, and the importance of a correct application of these to the practical work of metallurgy is wisely insisted on. In other text-books and treatises the laws of stoichiometry have been chiefly relied on for the guidance of the metallurgist in interpreting and controlling the reactions which take place under the complex conditions which present themselves in furnace operations, and it has long been felt that the results of many of these operations could only be imperfectly explained or predicted by these laws. In this chapter metallurgists are clearly shown that they "have no longer merely to deal with atoms and molecules, but with the influence of mass," and that if they are to advance their industrial practice "they must think in calorics, and not merely employ the ordinary atomic tools of thought." They will then be able to suggest what reactions can take place under given conditions, to indicate those which will be completed, and to avoid those which are impracticable.

Thus far we have mainly considered those chapters of the book which deal with the fundamental principles of scientific metallurgy, but the whole work is of the greatest interest, and deserves the careful and earnest study of all who are interested in the scientific advances which have been made in metallurgy during recent times. It is, in fact, indispensable not only to students, but to all metallurgists. W. GOWLAND.

Structural Botany (Flowering Plants). By Dukinfield Henry Scott, M.A., Ph.D., F.L.S., F.G.S. With 113 Figures. (London: A. and C. Black, 1894.)

AN introduction to the study of structural botany has long been a desideratum in this country, where we have hitherto been compelled to refer the beginner either to works in foreign languages, or to such help as he may glean from lecture courses. Dr. Scott's little book supplies this need in a most admirable manner, and he has thoroughly earned the gratitude both of teacher and student alike for the freshness and clearness with which he has presented his subject. We notice with satisfaction that, amongst many other good points, there is an intelligible account given of the transition of the structure of the root to that of the stem, a matter concerning which there exists a great deal of needless ignorance and misapprehension in the minds of many students. Another excellent character of the work lies in the large number of new figures which it contains, an example which might with advantage be followed by other writers, for it is really not easy to see why the older illustrations should be regarded with such superstitious (or is it indolent ?) veneration, especially when this practice leads to the exclusion of new figures, as is not unfrequently the case.

We can only hope that Dr. Scott will speedily fulfil the promise hinted at in his preface, and provide, before long, a second volume dealing with the cryptogams.

The Lowell Lectures on the Ascent of Man. By Henry Drummond. (London: Hodder and Stoughton, 1894.)

MR. DRUMMOND is well known as a brilliant and enthusiastic writer, and his latest book will be welcomed by a wide circle of admirers. He approaches the study of nature and evolution with the sympathetic eye of a moral teacher who is possessed by a praiseworthy desire to find wholesome and ennobling lessons therein. In this he is successful. He has, however, a further purpose, that of setting biologists right in matters of biology. In this he is scarcely so successful. "Evolution," he tells us in his preface, "was given to the modern world out of focus, was first seen by it out of focus, and has remained out of focus to the present hour." The focus is adjusted in "The Ascent of Man." We must, however, leave those of our readers who can spare an hour or two for the perusal of the well-printed volume, to see how far Mr. Drummond aids them in acquiring a more definite and accurate conception of evolution. They will, we feel sure, be impressed with his eloquence and earnestness.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Tribute to Hertz.

[We have received the following two communications. In accordance with the wish expressed in the first letter, the writer's name is not given.—Ed.]:—

On page 133 of this week's number of NATURE, Prof. Oliver J. Lodge suggests "an act of tribute" to the memory of Hertz, "useful to students in this country," to which I desire to contribute *anonymously*; and I enclose my cheque for £200.

To this distinguished man the world is more indebted than has, as yet, been made known. His broad mind enabled him to conform to what Herbert Spencer has said to be the first condition of success in scientific research, viz. "an honest receptivity, and willingness to abandon all preconceived notions, however cherished, if they be found to contradict the truth."

When invited, in 1889, to witness demonstrations, declared by men of science to "demonstrate the discovery of a force previously unknown to them," he did not excuse himself on the ground of his own occupations, nor yet because he believed the man to be a charlatan. He gave over five hours to the examination of photographs of the discoverer's researching instruments; at the end of which he said that were he to go to America to witness the production of the energy, he could render no assistance; that the man must work out his system alone; and that, in order to work it out, he should not attempt to apply it to mechanics until he had obtained full knowledge of the laws of nature governing its operation.

This advice, within a period of four years, followed faithfully as it was after nearly twenty years of work on engines), has now led to the completion of a system of vibrating physics, with entire mechanical success (it is for the assistance thus rendered that I give my tribute of gratitude); and will, in the not distant future, give to the world "the crowning achievement of an age of scientific progress," opening "the unseen highways of the air" to ships of thousands of tons burden, by the neutralising of gravity.

June 9.

Since writing my letter Prof. Dewar has been here, and some remarks made by him have caused me to think I can better serve the end that I have in view by another appropriation of the £200 which I offered to you for the publication of Hertz's works, although he made no suggestions, nor does he know that I have sent it.

Will you kindly hold the cheque until I gain further information, or return it to me, as you may think best?

June 10.

[The cheque has been returned to the writer.—Ed.]

Bullet-Proof Shields.

I am induced by the sight of the letter from Mr. Frederick J. Smith, in NATURE for June 7, to suggest an idea for armour-plating which occurred to me a few weeks ago, and which seems to me to offer certain advantages over Mr. Smith's proposal.

If a space were filled closely with balls of approximately the same size as the expected missile, would not the resistance be greater than that offered by either a solid plate or by Mr. Smith's cylinders, while there would be a considerable diminution of weight as compared with either?

Each ball, except those at the surface of the receptacle, would be surrounded by twelve balls, to the three of which furthest from the missile the force of the impact would pass, radiating from the ball struck at an angle of 180°. The direction thus deflected would be passed on, again at an angle of 180°, to 3 × 3 balls, each of which would again forward it to its three hindermost balls.

These balls, of which there should perhaps be six layers, should be of the hardest metal available; perhaps of aluminium steel or aluminium bronze. Possibly they should be set in some soft and elastic medium that would prevent their leaking out at the hole made by the missile in the rigid covering; and, if this be not done, then a sheet of india-rubber of sufficient thickness to close after the entry of a bullet should be placed outside the frame holding the balls.

This method seems to me to have 50 per cent. more deflecting power than that of Mr. Smith, as the cylinders would only divide the direction of the missile into two, while the spheres would divide it into three.

Whether the missile would behave like Achilles when he so unwarrantably passed the tortoise, or whether its initial line would be curled round hexagonally in every direction, as it theoretically should be, might, I think, be very simply proved by experiment.

Emma Hubbard.

Kew, June 10.

The Teeth and Civilisation.

In reply to Mr. Arthur Ebbels, I can state some facts about several thousand people in the north isles of Scotland. We find here side by side old people with strong teeth free from decay, though possibly worn down like those of an old horse, and several later generations among whom dental caries is quite general, and including many girls in their teens who are almost edentulous.

No increased wear and tear of the nervous system, nor overstrain of the fifth nerve, nor increased privation can explain this extraordinary contrast. Work is if anything less arduous, clothing and other comforts more.

The habits of the older and younger generations form an equally striking contrast. The former, even as children, were thinly dressed, and did well on three meals daily. Both men and women gathered seaweed for kelp in all weathers, and worked until the tough bere bannock in their pockets became a tempting meal. It was then torn and masticated with incisors and molars doing their proper work. A drink of milk at the nearest farm completed the repast. Oatcake or oatmeal as brose or porridge served for breakfast and dinner, and home-brewed ale was a frequent beverage. Four distinctive facts can be pointed out. (1) They did not eat till they were hungry and at long intervals; (2) plenty of exercise for teeth and jaws; (3) no hot drinks; (4) they could eat without drinking. In all these points the younger generation differs. White bread is preferred, washed down with tea at 150 to 160° F. (tested with thermometer). The eat-and-swill method of eating is universal, the bolus being swept into the œsophagus without even the pretence of mastication. It is considered that not even a child can eat without a hot drink ready to its hand, and children of eighteen months may be seen drinking strong concoctions of theine and tannic acid, and refusing other food. And this usually for every meal. As school children they exist but do not thrive on this diet, but at twenty commences a divergence in the habits of the sexes. The woman, unless engaged in outdoor work, eats and swills more; the hungry ploughboy eats and masticates more, and swills less. As regards the teeth, two results are observed.

Either decay and disintegration takes place, or else the alveoli shorten until the teeth hang loose by their exposed fangs and drop out. This pseudo-senile change may happen before thirty. The incisors hardly ever suffer so much from inertia; biting is essential, but on the other hand the first impact of the semi-boiling tea is borne by them, and they often share the general ruin. Neuralgias of the fifth nerve and stomachic catarrh are exceedingly common. Oatmeal is of course almost banished from the diet of the people.

The only fallacy seems to be this: May not the old people in question be the exceptionally hardy survivors of a race equally prone to dental decay? Others must judge; but the old folk say, "I never heard much of toothache when I was young."

Sanday, May 26. Ed. Jas. Wenyon.

It may be mentioned, in reply to a letter on the "Teeth and Civilisation," that this agent probably affects the health of the human teeth by the injurious nature of the food and diet she introduces in her wake. The worn-down crowns of the molar teeth of the native will correspond with the use of *grain food* and vegetable diet, mostly cold, when the silex in their constituents triturates the teeth down by degrees. But the use of *meat diets* by the civilised peoples will not affect the crown of the teeth, but tend to induce rheumatic or gouty disorders and affections of their periosteum. The most likely medium of *teeth caries*, however, being induced is the use of hot drinks, soups, tea and coffee, which primarily may cause a fissure in the enamel by unequal contraction and expansion of the structures of the teeth. Into this fissure, on it cooling down, will be kneaded by mastication articles of irritating food and drink, which will lead to caries round it. The progress of this may *erode* a segment of the tooth, or at last penetrate into the cavity and the pulp, and lead to inflammation and abscess; and none is a more virulent agent in doing this than hot tea. The simmering kettle may be seen on the hobs of the kitchen fires in the houses of the working classes in Yorkshire and Lancashire, who are much subject to caries of the teeth and dyspepsia, in consequence of the frequent imbibition of its hot contents all day. W. G. BLACK.

Edinburgh, May 17.

The Lowell Observatory, Arizona.

I LEARN—although I have not myself yet seen the note—that NATURE has been unwittingly led into the error of stating that Lowell Observatory, at Flagstaff, Arizona, is a branch of Harvard College Observatory. This impression had its origin in a press dispatch, and I am, with the approval of Mr. Lowell, correcting these wrong impressions when possible.

Mr. Percival Lowell—whose father is trustee of the Lowell Fund from which the cost of the Lowell Institute Lectures is defrayed—is himself an author ("Japanese Art and Customs") and a man of scientific training. He has himself worked out the plan for his observatory work, and will personally supervise and direct the investigations. His institution is one of magnitude, having 18 in. and 12 in. telescopes, and he is justly entitled to the credit. The misunderstanding seems to have arisen from the fact that he has employed two of the Harvard College Observatory assistants for the season, they having been granted leave of absence. I enclose Mr. Lowell's own statement, published yesterday, being his paper before the Boston Scientific Society, and really the first public official statement.

May 26. JOHN RITCHIE, JUN.

[The following description is from the enclosure referred to by Mr. Ritchie. We are glad to render Mr. Lowell the credit due to him.—ED.]

The Lowell Observatory, the construction of which is now almost completed, is situated in the territory of Arizona, near the town of Flagstaff, in longitude 112° west, latitude 35° north, at an elevation of 7300 feet above the sea. Its site is thus the highest of any large observatory in the northern hemisphere, the next in point of elevation being the observatory at Denver, 5400 feet. In latitude it is furthermore the most southerly of those north of the equator. But the chief advantage hoped for from its position is in the way of atmospheric conditions, the singularly dry and clear climate of Arizona commending itself to astronomical purposes.

The observatory buildings stand upon the eastern end of a spur of high land, which rises just to the west of the town and is connected at the back some fifteen miles away with the San Francisco Mountains that reach to a height of 12,500 feet. The buildings are thus protected from the north. To the east and south they overlook the town and the plain beyond, being about 300 feet above Flagstaff and a mile away from it in an air line. The hill and the surrounding country are covered in part by a sparse growth of timber. Trees about an observatory are usually considered an advantage, as such vegetation reduces the radiation from the ground and tends to equalise the daily extremes of temperature, thus giving steadier seeing. The land for the site has very generously been given by the town, and a road to the observatory is being built by the town at its own expense.

The buildings consist of the equatorial building and of the study, placed at a short distance away from it to leeward of the prevailing winds. This disposition of the buildings is in order to minimise the risk from fire, a serious matter in so isolated a situation.

The dome of the equatorial building is constructed on a system of parallel arches, after a design by Prof. W. H. Pickering, who has made a study of domes here and abroad. It is built of a framework upon which rests a cage of wire-netting, and over this is stretched a covering of canvas. One of the chief features of the dome is its lightness. Although it is thirty-four feet in diameter, the whole revolving hemisphere weighs but two tons. Some idea of its lightness and of the ease of moving it in consequence may be got by comparing it with the dome of the large equatorial at Harvard, which, though four feet smaller, weighs fourteen tons, or seven times as much. The whole revolves on the wheels of a live-ring. The dome was built here and, together with the pier, shipped out in pieces to Arizona. The study building will contain a general or reception room, two sleeping rooms, a photographic room and a tool-room.

The telescopic equipment consists of three telescopes of 18 inches, 12 inches and 6 inches aperture, respectively. The 18-inch glass is by Brashear, and is the largest objective Mr. Brashear has yet finished. Its focal length is 26 feet 4 inches. This is an unusually long focus, and length of focus is an advantage in an objective. It and the 12-inch one of Clark's are mounted in twin. The 18-inch will be used for usual and spectroscopic purposes, while the 12-inch will be chiefly employed photographically. The third glass, the 6-inch, is also by Clark, and is a fine objective. It has already done good work at Flagstaff by being the first of those in the northern hemisphere to catch the Gale comet the other day. Incidentally, it is a far travelled telescope, having been safely half round the world and back again before ever it started for Arizona. It is of the same size and quality as the one with which Burnham made himself the first of double-star observers. By the ingenuity of Mr. Clark it is mounted portably in equatorial, being thus rendered the largest of small telescopes, or the smallest of large ones, at pleasure.

The 18-inch has been carefully fitted by Mr. Brashear with various ingenious contrivances by Prof. Pickering for photometric and spectroscopic work. For micrometrical purposes, in addition to the micrometer proper, he has also had prepared plates minutely ruled, dotted and designed and then diminished by photography, to be introduced beside the image in the telescope, for direct comparison with the canals and lakes of Mars and other similar purposes, thus furnishing a second method for micrometrical measurement of such detail.

The Berthollet-Proust Controversy and the Law of Definite Proportions.

IN his able address at the annual meeting of the Chemical Society, the President spoke of chemical text-books somewhat scornfully. While I confess that I am not prepared to regard these books as "soul-destroying," one and all, I have long felt at least that the dogmatic exposition of the elementary laws of chemistry to which they have accustomed us is most unsatisfactory, and that a critical re-statement of first principles is much needed. To deal with the subject fully, would carry me far beyond the limits of a letter to NATURE; but it is proposed in the following communication to draw attention to certain serious misconceptions which have crept into modern text-books with regard to the Berthollet-Proust controversy and the Law of Definite Proportions, and to attempt to re-define somewhat more accurately the points which were at issue.

Berthollet, it is said in the text-books, held that the composition of a compound was not rigidly constant, while Proust showed that "the same chemical compound always consists of the same elements combined in the same proportions by weight," (a statement to be referred to later, as statement A); and this statement is regarded as an enunciation of the Law of Definite Proportions, against the acceptance of which Berthollet strove so hard. As a matter of fact it seems unlikely that Berthollet would have felt in the least inclined to contradict the statement quoted. He did not suppose for a moment that it *was* possible for two substances to exist which should be sufficiently alike in properties for them to be called the same chemical compound, and yet for these to differ sensibly in their quantitative chemical composition; yet this is what a denial of statement A amounts to. On the contrary, Berthollet, like Proust, held the opposite view, namely, that the physical properties of substances are necessarily correlated with their chemical composition, and therefore that two substances differing in their chemical composition have in general different properties and are not called by the same name. We find Berthollet making use of this view, for instance, in the course of an argument given in the "Essai de Statique Chimique," vol. i. p. 346. For he says in effect that if in certain cases we only find compounds of which the constituents are united in ratios, such as $x : y$ or $x : y_1$, among the infinite number of compounds of these constituents capable of existing, it is just because these combination-ratios correspond precisely to some physical property (*e.g.* insolubility) which renders the resulting substance easy of isolation, and takes it (to use the terminology of the time) beyond the reach of the chemical forces which caused its formation.

We see then that statement A in no wise discriminates between the views of Proust and Berthollet, and cannot be regarded as an enunciation of the Law of Definite Proportions. That such misrepresentation should have arisen, shows how hard it is to find in Proust's writings any sufficiently clear account of his views. I think the following may perhaps be accepted as a correct statement of his position:—

"If two substances unite chemically, they will do so either in a single ratio or in a series of ratios which are separated by intervals of finite magnitude." Berthollet thought, on the contrary, that in most cases two substances could combine chemically in an infinite number of ratios varying continuously between certain limits.

As Berthollet himself pointed out, the whole question turns on our definition of the term *chemical union*, and of *compound*, which latter we may regard as a substance formed by the chemical union of its constituents.

The joint efforts—or rather the divided efforts—of Berthollet and Proust made clear what neither chemist was willing to recognise frankly, namely, that there exist two distinct classes of homogeneous chemical substances which might fairly have been called compounds:—

Class I.—The substances belonging to this class are formed by the union of their constituents either in a single ratio or in a series of ratios separated by a definite interval. By the addition of a small quantity of any one of its constituents to a portion of a substance of this class we shall in general obtain a heterogeneous body.

Class II.—The substances belonging to this class are formed by the union of their constituents in an infinite number of ratios which vary continuously between certain limits. By the addition of a small quantity of any one of its constituents to a portion of a substance belonging to this class, we shall in general be able to obtain a new homogeneous substance.

Berthollet, on the one hand, regarded the substances belonging to Class I. as exceptions to the normal rule; Proust, on the other, wished to restrict the name of compound entirely to these. But for such a restriction Proust had certainly no sufficient reason to give. His point, however, as is well known, was carried by the weight of Dalton's discoveries of the Law of Equivalents and the Law of Multiple Proportions, which only applied to Class I. and therefore drew special attention to it, and by the weight of Dalton's atomic hypothesis, which allowed a sharp theoretical distinction to be drawn between the constitution of substances belonging to Class I. and that of substances belonging to Class II.[1]

To enter into a more complete discussion of this distinction as understood by Dalton, and of the modifications of the theory necessitated by our modern ideas on dissociation, would be beyond the scope of the present letter; but it should be pointed out that the controversy at present raging on the theory of solutions is, after a long interval, the continuation and development of the controversy between Berthollet and Proust.

With the facts clearly set before us, we may now inquire into the origin of the error of the text-books, an error which seems to me to be not a merely verbal one, but one due to a misunderstanding of the real points at issue.

I have not found this error in any book before Davy's "Elements of Chemical Philosophy," first published in 1812,[2] and it appeared but in comparatively few text-books until attention had been re-directed to the Law of Definite Proportions by Marignac and Stas in the "sixties."[3] It has since that time been reproduced in most of the books under one form or another. It is often stated, for instance, that Stas showed that "however we prepare ammonium chloride, it always has the same composition." The real problem attacked by that great chemist was this:—"Is what we have called 'chloride of ammonium' a single chloride of ammonium or a series of chlorides of ammonium resembling one another closely, and of which the combination ratios only vary between certain narrow limits?" Or, to state the matter more generally, "Ought the substances which we have supposed to be members of Class I. (*supra*) to be really considered as members of Class II., with the reservation that the limits of the combination-ratios are in these cases close together?"

Stas's own language is, it must be admitted, not perfectly unambiguous on this point.

If Davy's treatise be possibly the historical source of the error, to trace its intellectual origin, or at any rate to offer some plausible explanation of this origin, we must go back further, and consider a time when a nomenclature founded on the exact chemical composition of substances, and the accurate measurement of their properties, was not so much impossible as uncontemplated.

In those days a common name was given to specimens of homogeneous substances, which might (excluding the case of the elements) prove to be either

(1) As in the case of liver of sulphur, a *series* of substances belonging to Class II.; or

(2) As in the case of water, a *single* substance belonging to Class I.; or

(3) As in the case of, say, some *particular* gun-metal, a *single* substance belonging to Class II.

I have chosen the order of these alternatives in this somewhat arbitrary manner in order to bring out more clearly the point where I believe misconception to have arisen. For I think that what the writers have done is to have considered only alternatives (1) and (2), and to have neglected (3).

After the rise of modern chemistry a closer examination of specimens of "liver of sulphur" and of "water" enabled chemists to say:

(B) The specimens labelled "liver of sulphur" do not always contain the same elements united in the same proportion. (C) The specimens labelled "water" do always contain the same elements united in the same proportion.

And these statements were contracted very naturally into the following:—

(D) "Liver of sulphur" does not always contain the same elements united in the same proportion; (E) "water" does always contain the same elements united in the same proportion.

Now the contracted statement (D) has misled the writers into forgetting that "liver of sulphur" is a collective noun, and that the contrast of the two statements is not a contrast between *a* mixture[1] and *a* compound, to which it is of course inapplicable; but a contrast between a *series* of mixtures and a *single* compound.[2]

They then proceed to substitute for "liver of sulphur" the general term, *a mixture*, and for water the general term, *a compound*, and so we obtain statement (F): *A mixture* does not always contain the same elements united in the same proportion; which is absurd; and our old friend (A): A *compound* does always contain the same elements united in the same proportion; which bears a very different meaning to that which its authors intend to convey by it, and which will be further considered immediately.

With statements F and A before them it appeared quite natural to the writers to suggest that "ammonium chloride" prepared in different ways might vary in composition, without their realising that they had returned to the careless days when "liver of sulphur" appeared an eminently satisfactory term.[3]

Perhaps from their error it may be possible to extract some good after all. For would it not be well to state more clearly in our books the postulate to which enunciation A reduces itself when interpreted rationally, viz. "Two portions of matter in other respects alike possess the same quantitative composition."[3] This postulate has been tacitly accepted by chemists, and it is made use of every day in the laboratory.

In conclusion I may be allowed to reply to a criticism which I foresee, namely, that no serious misunderstanding has followed from the errors to which I have drawn attention. That may be so, but accuracy of expression has a value of its own, and my object will have been attained, at any rate partially, if I have succeeded in removing (what should have been) a serious stumbling-block from the path of the student.

PHILIP J. HARTOG.

Owens College, Manchester, June 4.

[1] Kopp in his contribution to the much transformed Lehrbuch of Graham-Otto, and Mendeléef in his treatise, depart very wisely from usual custom in calling both these classes of homogeneous bodies compounds.

[2] See "Davy's Collected Works," vol. iv., p. 479 (1840). This reference I owe to my friend Dr. Harden.

[3] It must be noted that the Law of Multiple Proportions includes the Law of Definite Proportions, and the latter has on that account often been omitted entirely from text-books.

[1] I use the word "mixture" for "homogeneous mixture," or "solution" in the sense of Van't Hoff.

[2] They have neglected alternative (3), which would have reminded them that E applies quite as well to any *single* homogeneous mixture as to any single compound.

[3] The accurate statement of the problem dealt with by Stas has been given previously.

[4] This interpretation may seem to some of my readers to need a fuller explanation, for which I have not space here.

THE OXFORD MEETING OF THE BRITISH ASSOCIATION.

THERE are already signs that the meeting of the British Association, to be held this year at Oxford, will be a success. It is unfortunate, perhaps, that the city of Oxford is this year destitute of municipal buildings, the old buildings having been pulled down, while the new have scarcely their walls raised to the level of the first floor. But this deficiency is amply compensated by the numerous University and College buildings which have been placed at the disposal of the Local Executive Committee. The reception room will be in the entrance hall of the new Examination Schools in High Street, and the rooms for the meetings of Council, of the General Committee, and of Sections E and F will be held in the same building, the large south and east writing schools lending themselves particularly well for the departments of Geography and Economics and Statistics. The meeting rooms of the remaining sections will be distributed among the University Museum and among Colleges which are on the direct road between the Schools and the Museum. Section A (Mathematical and Physical Science) will meet in the Lecture Theatre of the Clarendon Laboratory, and the allied Section G (Mechanical Science) will meet in close contiguity in Keble College Hall. Section B (Chemistry) will meet in the Chemical Theatre, and for larger meetings will have the use of the large Lecture Theatre in the Museum. Section C (Geology) will meet in Hertford College Hall; Section D (Biology) in the Anatomical Theatre. Section H (Anthropology) will be accommodated in Prof. Arthur Thomson's new Hall of Anatomy, and will have the advantage of being in close proximity to the Pitt-Rivers Museum. The new Section I (Physiology) will perhaps be better off than any, as the whole of the new Physiological Laboratories will be at its disposal.

The proceedings will begin on the evening of Wednesday, August 8, when Prof. Burdon Sanderson will resign the presidency, and the new President, the Most Hon. the Marquis of Salisbury, K.G., Chancellor of the University, will deliver the opening address. On the Thursday evening there will be a conversazione in the University Museum. On the Friday evening Mr. W. H. White, C.B., will give an evening lecture in the Sheldonian Theatre, on "Steam Navigation at High Speeds." The Saturday evening lecture to working men will be given by Prof. Sollas. On Monday evening Prof. J. Shields Nicholson will lecture in the Sheldonian Theatre, on "Historical Progress and Ideal Socialism," and the Tuesday evening will be occupied by a conversazione, which will probably be given in the new Examination Schools. Invitations to foreign investigators have been issued by the Local Executive Committee, and nearly eighty have already signified their intention to attend the meeting, amongst them being Prof. Quincke, Prof. Oskar Schlömilch, Prof. Moritz Cantor, Prof. Kohlrausch, Prof. Strasburger, Prince Roland Bonaparte, Prof. Anoutchine, M. Cartailhac, Dr. Mojsisovics von Mojsvar, Prof. Maxime Kovalevskij, Prof. Victor Carus, Prof. E. van Beneden, Prof. Dames, Prof. F. von Sandberger, Prof. F. Schmidt, Prof. Taussig, Prof. Ostwald, Prof. Beilstein, and many other notabilities in every branch of science. Nearly every prominent English man of science has already expressed his intention of being present, and there can be little doubt that the Oxford meeting of 1894 will equal in interest the last Oxford meeting of 1860, which was made celebrated by Prof. Huxley's spirited defence of the then novel doctrine of Darwinism.

The Local Secretaries for the Oxford meeting are Messrs. G. C. Bourne, G. Claridge Druce, and D. H. Nagel, and any communications respecting the meeting should be addressed to them at the University Museum, Oxford.

EXHIBITIONS OF PHYSICAL APPARATUS.

IN the days when *a priori* reasoning reigned supreme, when all observations which were not found in the works of early writers were regarded with suspicion, and all facts had to stand or fall according to their relation to metaphysics, there was no demand for scientific instruments and apparatus. A cause or a principle was then stated like a proposition in mathematics, and the effects which follow upon it were deduced; nowadays the scientific method is to observe the effects, and afterwards formulate a law which embraces them. To carry out this method of experiment and induction, apparatus is needed, and hence the state of physical science at any epoch can be estimated by the character of the instruments at the disposal of investigators. Judged by this criterion, physics and astronomy must have attained a marvellous degree of accuracy. The intricate nature of some physical instruments, and the complicated accessories with which all large astronomical telescopes are now equipped, not only testify to the skill of the instrument-maker, but also represent engines of research whereby new fields are explored. These instruments thus afford tangible evidence of advance, and it is for this reason that their exhibition is to be commended. Such an exhibition of physical instruments was lately held at Paris by the Société Française de Physique, and it is well worthy of imitation on this side of the Channel.

The apparatus of physics falls naturally into two classes—that used for lectures, and that belonging more especially to the laboratory. The apparatus employed in teaching elementary science cannot be too simple and the experiments performed with it should be so clearly shown that the facts they exemplify become evident to the most obtuse student. In many cases this tenet of experimental philosophy is disregarded, the lecturer aiming at producing brilliant effects—stage fireworks, as they have been appropriately called—rather than the illustration of a physical law. In fact, there is a tendency to push lecture-room experimentation too far, to use the lecture-assistant's skill as a make-up for lack of eloquence. The popular mind looks in awe upon the abundance of instruments arranged for this end, but it may be doubted whether, under such circumstances, the points of the discourse are not often obscured.

As to laboratory experiments for students, each should constitute a little investigation in itself. An experiment consists in changing the conditions and arrangements of natural bodies in order to examine their behaviour. The student should, therefore, be given the apparatus required to demonstrate a principle, and should be told what to do with it, but the inference to be drawn from his observations should be left entirely to him. If it is necessary to tell him what the experiment proves, then the object of his work has not been attained. By following this method, and properly grading the experiments, the student not only derives considerable educational benefit in learning to think for himself, but the instinct for research is also stimulated. In many colleges and institutions where the aim is to rush the student through as much experimental work as possible in a short time, the apparatus is all arranged for the student, who merely presses a knob and sees a galvanometer needle wriggle, or something of the kind. There can be no independent thinking in such cases, and, except for examinational purposes, the experiments might just as well be left undone. Most physicists agree with these opinions, and, by arranging an exhibition of apparatus, the Physical Society would help to impress their importance upon teachers. Sets of apparatus suitable for lectures and for practical work in various branches of physics might be arranged for exhibition by a committee, and these, with the instruments of precision, would make an extremely interesting, as well as useful, collection.

The exhibition of physical apparatus at Paris comprised numerous ingenious instruments, but there was no attempt at arranging educational sets. Lord Kelvin's voltmeters and ammeters were shown, and various instruments for measuring electric energy and resistance. A binocular photometer attracted some attention, and also a new kind of ophthalometer and a monochromatoscope. M. V. Chabaud showed a form of electrometer devised by M. Lippmann, several pieces of apparatus made from dielectrine, tolueine thermometers for the measurement of low temperatures, Villard manometers, Varenne's apparatus for fractional distillation, and Bichat's hygrometers. M. J. Carpentier's exhibit included mica condensors, and an instrument invented by General Sebert for determining the rapidity of photographic plates. M. J. Richard showed a meteorograph constructed for the observatory on Mont Blanc, an electric anemometer, Favé sounding-line, and numerous recording voltmeters and ammeters. His exhibit also comprised, among other things, several of Bonetti's electrical machines, Berlemont's mercury pump, and various sterilisers. The photographs of interference fringes obtained by M. Meslin call for special mention, and also a pendulum devised by Captain Colson for measuring short exposures in photography, and a theodolite adapted to photographic work by M. Echassoux. The French Photographic Society exhibited sets of photographic apparatus, and M. G. Raymond some fine cloud photographs. The apparatus used by M. Marey for photographing objects in motion, naturally found a place in the exhibition. Photographs in colours, obtained by the Lippmann method, were seen by projection, and were greatly admired. Many other results of scientific research were shown, together with the instruments by means of which they were obtained, but no useful purpose would be served by enumerating them. It is proposed to hold a similar exhibition next year, and if instrument-makers co-operate with investigators as they did in the one just closed, there can be no doubt as to its value to workers in all branches of physics.

There should be little difficulty in arranging an annual exhibition of a similar kind in London. Scientific instrument-makers would compete with one another in showing work of a high quality; and if the exhibits were organised by a competent committee, the venture would be successful from every point of view. R. A. G.

AUGUST KUNDT.

PHYSICAL science, which within the lapse of six years has witnessed the death of Kirchhoff, Clausius, and Hertz, has suffered another severe loss; on May 21, August Kundt, who was but fifty-four years of age, suddenly died at his country place near Lübeck.

Kundt was born at Schwerin, on November 18, 1839, and began his studies at Leipzig in 1860, under Hankel, Neumann, Bruhns, and others. Thence he went to Berlin, where Encke, Forster, Dove, and Kummer were his principal teachers. He began by giving special attention to astronomy, and indeed intended to devote himself to that branch of science. While yet undecided, however, he entered the private physical laboratory that Gustav Magnus had fitted out in the Prussian capital, and in which students with a decided taste for experimental investigation were allowed to work. From the beginning he displayed extraordinary experimental ability, combined with rare energy in the pursuit of the work he had once taken in hand, qualities which were characteristic of him during his whole scientific career. He also attended the physical "colloquia" which Magnus had introduced, and under the influence of the latter was definitely enrolled in the lists of experimental physicists.

He graduated at Berlin in April 1864, with an investigation on the depolarisation of light. The first and last of the theses appended to his dissertation (dedicated to Magnus) are characteristic of the state of his mind at that time. They run as follows:—

(1) Vires animæ non minus metiri possumus, quam vires physicas. . . .

(4) Theoriam a Cl. Fresnel de torsione planitiei polarisationis promulgatam si adoptamus, omnia ea corpora quæ planitiem polarisationis torquent, sub aptis conditionibus birefractionem demonstratura esse, negare non possumus.

He never himself followed up the psychological lines of research hinted at in the first thesis; the last proposition is known to be entirely borne out by modern research on circular double refraction.

In 1867 he became "Privatdocent" in the University of Berlin, but was appointed to a professorship in the Swiss federal polytechnic school at Zurich, in the following year. There he remained but two years, removing to Würzburg in 1870, where his stay was of no longer duration, the then newly organised University of Strasburg having called him to represent his science on a brilliant staff of young and enterprising men, who within a few years brought their "alma mater" to a high level of excellence. In this work of organisation Kundt was one of the most actively engaged, holding the office of rector in the year 1877, when but 38 years of age. Quite apart from his purely scientific reputation, this alone is sufficient to mark his name with golden letters in the annals of Strasburg University, for which he also erected an imperishable monument, the Physical Institute, well known throughout the scientific world as one of the best laboratories existing.

In 1888, when Prof. von Helmholtz became president of the "Reichsanstalt," Kundt succeeded him as professor of experimental physics, and director of the Berlin Physical Institute. A prolonged period of scientific activity from a man of but fifty years of age with a world-wide reputation might still have been expected; but these hopes have proved vain. A few years ago the symptoms of a disease began to appear, which could not be subdued. Kundt fought for life to the last; and notwithstanding the slow but unceasing strides his ailment made, which would have entirely prostrated most other men, he continued his lectures and other pressing duties during the whole of last winter, thus setting an example of sacrifice to the cause of science even in the face of death. When, at the urgent instance of his medical advisers and friends, he stopped work and left Berlin, it proved of no avail; in fact, he may be said to have died as he had lived, in the midst of scientific work.

As an investigator Kundt was many-sided; his discoveries are so generally known, that it is hardly necessary to describe them in detail. He first turned his attention to acoustics; his start in scientific life being the invention of the well-known "Kundt's sound tubes," or "Kundt's dust figures," which he himself and others turned to account in many different ways. The application of that purely acoustic method led to the determination of the ratio of specific heats of mercury vapour. In collaboration with Warburg (1884), Kundt found this to be 5/3, as predicted by the kinetic theory for a monatomic gas. He also conducted researches on thermal conductivity and inter-diffusion of gases or vapours and on the influence of pressure on the surface tension of liquids; and developed his well-known red and yellow dust-spray method for investigating the pyro-electric and piezo-electric properties of crystals.

But in glancing over his life-work as it now lies before us, it appears as if the palm ought to be assigned to his optical and magneto-optic discoveries. He began with a brilliant series of papers on anomalous dispersion, which placed this important subject on a sound footing. He described the doubly refractive properties of vibrating solids, of metallic films obtained by disintegration of cathodes and of certain liquids in motion, and investigated the optical properties of electrified quartz. With Röntgen he was able to show a slight magneto-optic rotation in several vapours and compressed gases, which even Faraday had not been able to detect, and, on the other hand, its enormous value in iron, cobalt, and nickel. The latter will be known to coming generations as "Kundt's phenomenon." Last, but not least, he succeeded in determining the refractive indices of metals, which he was able to obtain in the shape of extremely thin prisms.

His experimental work, of which the above gives but an incomplete summary, is throughout characterised by the greatest ingenuity in the selection of means to attain definite ends, by the rare quality of ever-watchful self-criticism, which prevented his running away with himself. He possessed that instinctive and immediate power of discriminating the broad way of progress into the unknown from the stray paths leading into tangled wilderness, a faculty which he used to call the pioneering scent of the experimenter.

Space forbids an adequate account of what Kundt personally was to his family, his friends, and his pupils. The latter, a great number of whom are scattered throughout the civilised world, were attached to him by the strongest ties of a scientific and private character, and lost no chance of showing the high esteem they felt for him. They owe a life-long debt of gratitude to the great experimenter, who to most of them was not only a teacher but also a personal friend, ever ready to render help and advice based on his varied experience of scientific life.

H. du Bois.

NOTES.

The annual meeting for the election of Fellows into the Royal Society was held on Thursday last, when the following gentlemen were elected:—Mr. William Bateson, Mr. G. A. Boulenger, Dr. J. R. Bradford, Prof. H. L. Callendar, Prof. W. W. Cheyne, Mr. R. E. Froude, Prof. M. J. M. Hill, Prof. J. V. Jones, Mr. E. H. Love, Mr. Richard Lydekker, Mr. F. C. Penrose, Mr. D. H. Scott, Rev. F. J. Smith, Mr. J. W. Swan, Mr. V. H. Veley.

Prof. Percy Frankland, F.R.S., has been elected to the chair of chemistry and metallurgy in Mason's College, Birmingham, rendered vacant by the resignation of Dr. Tilden.

We regret to announce the death, at the age of sixty-seven, of Prof. W. D. Whitney, well known for his philological researches.

We are requested to state that a British Committee, of which Sir Douglas Galton, K.C.B., F.R.S., is the chairman, and Prof. W. H. Corfield is the treasurer, has been formed to further the interests in this country of the Eighth International Congress of Hygiene and Demography, which is to be held in Budapest, from September 1 to 8 of this year. Any information may be obtained about the Congress from the Hon. Secretary, Dr. Paul F. Moline, 42 Walton Street, Chelsea, S.W.

The University of Halle will celebrate its second centenary on August 2nd, 3rd, and 4th of this year.

Sir Spencer Wells has been elected a Fellow of the Hungarian Academy of Sciences.

M. d'Arsonval has been elected a member of the Section de Médecine et Chirurgie of the Paris Academy of Sciences, in succession to the late Dr. Brown-Sequard.

The death is announced of Dr. E. Sperk, Director of the Imperial Institute of Experimental Medicine, St. Petersburg, and of Prof. Fischer, Chief of the Royal Prussian Geodetic Institute.

Dr. H. Molisch has been appointed Director of the Institute of Vegetable Physiology at Prague, in the place of the late Prof. G. A. Weiss.

M. P. Sinteins has just started on a journey of botanical exploration in Eastern Armenia.

Dr. C. V. Riley has resigned the post of entomologist to the U.S. Department of Agriculture, on account of failing health.

It is reported by the Eastern Extension, Australasia and China Telegraph Company, that a plague has broken out at Hong Kong. No particulars as to the epidemic have been received, but its serious nature may be gathered from the report that fifteen hundred deaths have already occurred, and that this list is increased by nearly one hundred every day. It is said that half the native population, numbering about one hundred thousand, have left the colony, and thousands are following them daily.

A violent hailstorm visited Vienna on Thursday last, shortly before seven o'clock in the morning. The hail was preceded by a heavy fall of rain, and accompanied by slight displays of sheet lightning. In the course of a few minutes the streets were covered with a thickness of several inches of hailstones. It is said that upwards of one hundred thousand windows were smashed by the hail; numerous trees were entirely stripped of their foliage, and most outdoor plants within the area of fall were destroyed. The hailstones were, on the average, about the size of hazel-nuts. During the storm the temperature dropped to 10° Réaumur (54° Fahr.), but shortly afterwards the thermometer rose a few degrees. Similar storms are reported from various districts in Hungary and Croatia.

The New York members of the London Society of Chemical Industry have drawn up a petition requesting permission from the Council to form a local section. This is a step towards the realisation of the scheme suggested by Dr. Armstrong in his recent address to the Chemical Society.

The Iron and Steel Institute has issued its provisional programme for the Brussels meeting, which is to be held August 20 to 24. There will be a reception by the Local Committee on the 20th, reading and discussion of papers on the mornings of 21st and 22nd, a visit to the Antwerp International Exhibition on the afternoon of 21st, a visit to the Mariemont Collieries and Couillet Steel-works at Charleroi on the 23rd, and a visit to the works of the Cockerill Company, at Seraing, and the Angleur Steel-works, at Liége, on the 24th.

In connection with the recent foundation of a Research Fellowship in Chemical Pharmacology by the Court of the Salters' Company, the Research Committee of the Pharmaceutical Society announces that the selection of the Salters' Company's Research Fellow will take place on July 3 next. Written applications for the Fellowship must be received by the Director of the Research Laboratory, 17, Bloomsbury Square, before June 30.

At the meeting of the American Academy, on May 8, the following officers were elected to serve during the coming year: President, Prof. Josiah P. Cooke; Vice-President, Mr. Augustus Lowell; Corresponding Secretary, Prof. Charles L. Jackson; Recording Secretary, Mr. William Watson; Treasurer, Mr. Eliot C. Clarke; Librarian, Mr. Henry W. Haynes; Councillors, Messrs. William R. Livermore, Benjamin O. Peirce, Benjamin A. Gould, Henry P. Walcott, Benjamin L. Robinson, Henry W. Williams, J. R. Thayer, T. W. Higginson, and Andrew M. Davis.

The preliminary programme of the forty-third meeting of the American Association for the Advancement of Science, to be held in Brooklyn, from August 15 to 24, under the presidency of Dr. D. G. Brinton, has been issued. The officers of the various sections are as follows:—Section A (Mathematics and Astronomy): Vice-President, Prof. George C. Comstock; Secretary, Prof. Wooster C. Beman. Section B (Physics): Vice-President, Mr. William A. Rogers; Secretary, Mr. Benj. W. Snow. Section C (Chemistry): Vice-President, Mr. Thomas H. Norton; Secretary, Prof. S. M. Babcock. Section D (Mechanical Science and Engineering): Vice-President, Mr. Mansfield Merriam; Secretary, Mr. John H. Kinelay. Section E (Geology and Geography) Vice-President, Mr. Samuel Calvin; Secretary (vacancy to be filled). Section F (Zoology): Vice-President (vacancy to be filled); Secretary, Prof. William Libbey. Section G (Botany): Vice-President, Mr. Lucien M. Underwood; Secretary, Prof. Charles R. Barnes. Section H (Anthropology): Vice-President, Mr. Franz Boaz; Secretary, Mr. Alex. F. Chamberlain. Section I (Economic Science and Statistics): Vice-President, Mr. Henry Farquhar; Secretary, Mr. Manly Miles. The following subjects of addresses by the Vice-Presidents are announced:—Physics: "Obscure Heat as an Agent in producing Expansion and Contraction in Metals." Anthropology: "Human Faculty as determined by Race." Geology and Geography: "Some Points in Geological History illustrated in North-Eastern Iowa." Economic Science and Statistics: "A Stable Monetary Standard." Mathematics and Astronomy: "Binary Stars." Botany: "The Evolution of the Hepaticæ." Chemistry: "The Battle with Fire." Mechanical Science and Engineering: "Paradoxes in the Resistance of Materials."

The affiliated societies holding meetings during the meeting of the Association are:—The Geological Society of America (President, Prof. T. C. Chamberlain; Secretary, Prof. H. L. Fairchild); Society for Promotion of Agricultural Science (President, Mr. L. O. Howard; Secretary, Mr. William Frear); Association of Economic Entomologists (President, Mr. L. O. Howard; Secretary, Mr. C. P. Gillette); Association of State Weather Service (Secretary, Mr. Robert E. Kerkham); Society for Promoting Engineering Education (President, Prof. De Volson Wood; Secretary, Prof. J. B. Johnson); American Microscopical Society (President, Dr. Lester Curtis; Secretary, Dr. W. H. Seaman); American Chemical Society (President, Prof. H. W. Wiley; Secretary, Prof. Albert C. Hale); American Forestry Association (President, Prof. B. E. Fernow; Secretary, Mr. J. D. W. French); the Botanical Club (President, Prof. William P. Wilson; Secretary, Mr. Thomas H. McBride); the Entomological Club (President, Mr. C. J. S. Bethune; Secretary, Mr. C. L. Marlett). Geological, mineralogical, botanical, zoological, and engineering excursions have been organised, and arrangements are being made by the American Forestry Association to enable members to proceed from Brooklyn at the close of the session to the White Mountains to attend a Forestry Congress. Special invitations have been extended to distinguished European men of science, and it is announced that properly-accredited members of all National Associations for the Advancement of Science attending a meeting of the American Association are entitled to register without fee as members for the coming meeting. There is every prospect that the meeting will be a very successful one. Information relating to membership and papers can be obtained from Mr. F. W. Putnam, Permanent Secretary, Salem, Mass. All matters relating to local arrangements are managed by Prof. George W. Plympton, Local Secretary, 502 Fulton Street, Brooklyn, N.Y.

The revival of exploration by Frenchmen has led to the establishment of a series of lectures on scientific subjects to intending travellers at the Natural History Museum in Paris, of which the most recent, a discourse on comparative anatomy, by M. H. Beauregard, appears in the current number of the *Revue Scientifique*. This lecture was originally undertaken by Prof. Georges Pouchet, whose untimely death deprives the French scientific world of one of their most laborious and successful travelling naturalists. The lecturer attributed the lack of attention to comparative anatomy on the part of most travellers to the fact that in making collections they aimed rather to supply museums with attractive specimens than to provide specialists with the material for study and research.

A plan of Timbuktu, sent by an officer of the French expedition, was presented to a recent meeting of the Paris Geographical Society, and is reproduced in the last number of the *Comptes Rendus* of that Society. The town has about 12,000 inhabitants, but its commercial prosperity has been destroyed by recent Tuareg raids, many of the buildings being in ruins, although from a distance its large pyramidal mosques give it an imposing appearance. The town is surrounded outside the walls by mounds of dried filth and putrefying animal remains. The desert lies all round, but on the west side there is an extensive pond gradually undergoing desiccation, and several small pools whence the water-supply is obtained.

The Ethnological Museum at Berlin has just published the second part of Mr. Hrolf Vaughan Stevens' great study of the people of the Malay Peninsula, under the title "Materialen zur Kenntniss der wilden Stämme auf der Halbinsel Malaka," edited by Albert Grünwedel. This part contains a short account of the Negritoes of the Malay peninsula, and a full discussion of the mythology and religion of the Orang Panggang, illustrated by numerous drawings of ceremonial accessories, and particularly the curiously inscribed bamboo-rods called *penitah*, which are buried with the dead to serve as passports in the other world. A long glossary of the Orang-hutan dialects is given in conclusion, being compiled from the records of all travellers who have studied the Malay languages. The value of this glossary is enhanced by the actual renderings of the various authorities being preserved in the different European languages in which they wrote.

The Weather Bureau of the United States has published its first volume of results of meteorological observations for the years 1891 and 1892, continuing the series formerly published by the Signal Service, together with other climatological tables and special reports of general interest. The work contains 528 large quarto pages, with illustrations and plates, and includes hourly means for 28 stations, with comprehensive and plainly printed monthly and annual summaries at about 170 stations. Prof. C. F. Marvin gives a very full description of the various instruments in use, and Prof. C. Abbe contributes a paper on instrumental corrections and methods of reduction. Both these reports supply much valuable information which will be found very useful to the general public. The work will be widely distributed, as we see that no less than 9000 copies have been printed.

We believe it is generally known that the Central Observatory of Moncalieri has for many years published a *Bollettino Mensuale*, which is the recognised organ of the Italian Meteorological Society. The bulletin contains the monthly results of a large number of meteorological stations in the Alps, the Appennines, and other parts of Italy, summaries of the proceedings of the Italian and other meteorological societies, and bibliographical notices. In addition to the above, there are articles by members of the Italian Meteorological Society and others on various subjects of scientific interest. The number for May contains a note by Prof. G. Buti on Dr. von Bezold's thermodynamics of the atmosphere, and attention is drawn to two phenomena which up to the present time have been but little studied, viz. the supersaturation and the over-cooling of the air in relation to the formation of thunderstorms and variations of barometric pressure; also a note, by Prof. L. Descroix, on the diurnal oscillations of the barometer at Paris, based on twenty years' observations. Prof. Descroix is of opinion that the differences in the variations of the maxima and minima from day to night, in passing from the warm to the cold season, are explained by the changes of conditions of dryness in the lower strata of the atmosphere, in so far as it is due to their expansion and contraction.

THOUGH the destruction of books by insects is not so great here as in India, it is sufficient to give general interest in the result of an inquiry into the means of preservation adopted in Indian museums (*Indian Museum Notes*, vol. iii. No. 3). In the library of the Revenue and Agricultural Department of the Government of India the books are disinfected by pouring a few teaspoonfuls of refined mineral naphtha, or what is known as benzine collas, into the crevices of the binding, and then shutting up the volume for a few days in a close-fitting box to prevent the escape of the fumes. Books so treated have to be afterwards sponged over lightly with a very little of the finest kerosine oil, which should be rubbed off with a cloth before it has time to penetrate into the binding. Dr. George King reports very favourably upon a system adopted for preserving books in the Royal Botanical Gardens, Sibpore. It consists in brushing the books over with a saturated solution of corrosive sublimate made by constantly keeping a few lumps of the poison at the bottom of a jar of alcohol, so that the maximum amount may be absorbed. In the Indian Museum Library the books are kept in close-fitting glass cases with a few ounces of naphthaline upon each shelf, with the result that little or no damage is caused by insects. It appears that the paste used in binding the Indian Museum books is poisoned by adding about half an ounce of sulphate of copper to each pound of paste, while books already infested are disinfected by shutting them up for four or five days in a close-fitting box of loose naphthaline with as much of this substance as possible between the leaves.

ANOTHER new method for determining the pitches of high tuning-forks is described by Herr F. Melde in the current number of *Wiedemann's Annalen*. It is, like the vibroscopic method previously described, independent of the ear, and is based upon the resonance of a rod clamped at one end and vibrating transversely. The laws of vibration of such clamped rods have already been so carefully studied that calculations of pitch, based upon their dimensions and the properties of the material of which they are made, are very reliable. The rods used consisted of hard brass, cast steel, or iron. They were 32 cm. long, 1 cm. broad, and 1·5 or 2 mm. thick. They were firmly clamped in an iron clamp let into a piece of sandstone, care being taken that the jaws of the clamp were strictly in the same plane at right angles to the length of the rod. The tuning-fork tested was mounted in a wooden block, and placed with one prong lightly touching the end of the rod, so that a vibration of the tuning-fork when bowed produced a transverse vibration of the rod. Fine sand was dusted on to the rod. If on bowing the tuning-fork the sand did not arrange itself in straight lines at right angles to the length of the rod, the clamp was shifted until it did. The mode of vibration, and consequently the pitch, was then calculated from the number of such nodal lines produced. An interesting application of the method was the testing of Appunn's tuning-fork apparatus for the determination of the upper limit of audibility. One fork marked 16,384, as determined by the method of beats, gave really only 11,717 vibrations per second. On the other hand, a standard fork by Dr. König, of Paris, of pitch 16,383, was found to give 16,480 by the new method—a good testimony to the accuracy of both determinations. In each case, the results were confirmed by the vibroscopic method.

THE current number of *L'Elettricista* (Rome) contains an interesting description, by Signor Riccardo Arnò, of a new experiment he has performed. As is well known, Prof. Crookes has shown that when an electric discharge is passed through an exhausted tube, and a small windmill is suitably placed in the path of the discharge, a continuous rotation is obtained. This phenomenon suggested to the author to try if he could obtain a similar rotation by placing an exhausted bulb containing a small windmill in a rotating electrostatic field. The rotating electrostatic field was obtained by connecting four upright brass plates to fixed points in the secondary of a large Ruhmkorff coil, through the primary of which an alternating current was passed. In order to try the experiment it was impossible to use an ordinary radiometer with mica vanes, since the author in a previous series of experiments had shown that when a dialectric is placed in a rotating electrostatic field it experiences a force tending to rotate it, in the same sense as the direction of rotation of the field. Hence the author had a special radiometer constructed with thin brass vanes, since it was only by using a windmill made entirely of a metal that he could be sure he had entirely eliminated the direct action of the rotating field on the vanes, and be sure the effect observed was due to the gas remaining in the tube. When the electrostatic field was sufficiently strong, and the surface of the glass vessel containing the vanes well dried, a rotation was obtained in the same direction as that of the field. In order to show that the rotation is not due to direct action on the vanes, the author suspended a similar set of brass vanes, by means of a long silk fibre, in air at the ordinary pressure in the same rotating field, and found that no rotation was produced. When the radiometer is under the influence of the rotating electrostatic field the bulb is uniformly lighted up, so that the number of turns of the vanes could be counted in the dark. The author considers the effect must be due to some action of the rotating field on the molecules of the gas, which tends to increase their velocity in the direction of rotation of the field, and thus in the case when the gas is much rarefied, so that the free path of the molecules is relatively long, the impact of the molecules on the metallic vanes cause the latter to rotate in the same sense as the field.

THE current number of the *Annali dell Istituto d'Igiene di Roma* contains a paper by Dr. Palermo, on the action of sunshine on the virulence of the cholera bacillus suspended in broth and water respectively. The pathogenic property of all the infected solutions was in each case determined by inoculation into guinea-pigs, so that the difference in the toxic character of the contents of the insolated and darkened tubes could be compared with that possessed by the cholera-infected broth or water solutions treated in the ordinary manner. In order to ascertain what was the effect of sunshine on the *number* of cholera bacilli present, agar dish cultures were made of the insolated and darkened tubes respectively; in no single instance, however, could any numerical difference be detected in either set of experiments. That the sunshine had modified the biological character of the bacilli, was shown very strikingly in drop-cultures, for when examined from insolated broth tubes they were found to have been deprived of all power of motility, whilst the characteristic activity was still apparent in such cultures prepared from the darkened tubes. As regards the degree of virulence possessed by the broth cultures, those exposed to sunshine for *less* than three hours invariably killed the animals, whilst when insolation was prolonged for three and a half, four, and four and a half hours respectively, not a single guinea-pig succumbed. The interesting discovery was, moreover, made that those animals which had survived inoculation with the insolated cholera cultures were protected from cholera, for when eight days later they were inoculated with virulent cholera cultures they did not succumb to this disease. The pathogenic properties of the cholera bacillus were removed more quickly by insolation when immersed in water than in broth. It will be remembered that Arloing stated, as far back as 1885, that he had succeeded in reducing virulent anthrax cultures to the condition of vaccine by insolation; but so far as we are aware, Dr Palermo is the only other investigator who has been able to render animals immune to a disease by the inoculation of insolated pathogenic cultures.

A PAMPHLET on "Dry Methods of Sanitation," by Mr. G. V. Poore, the author of "Essays on Rural Hygiene," has been published by Mr. Edward Stanford.

IN connection with an exhibition of beautiful and curious British and foreign species of butterflies and moths, at his Piccadilly establishment, Mr. William Watkins has issued a descriptive guide to the specimens on view.

THE address on "The Rise of the Mammalia in North America," delivered by Prof. H. F. Osborn at the last meeting of the American Association for the Advancement of Science, and partly reprinted in these columns (vol. xlix. pp. 235, 257, 1893), has been published separately, and can be obtained from Messrs. W. Wesley and Son.

A PRELIMINARY list of the vertebrate animals of Kentucky is contributed by Mr. H. Garman to the *Bulletin* of the Essex Institute, Massachusetts (vol. xxvi. Nos. 1–3). The list is based upon collections and observations made in various parts of Kentucky from points near the eastern limits of the State to Hickman on the Mississippi River.

A VOLUME by Prof. Dwelshauvers-Dery, entitled "Étude Expérimentale Dynamique d'une Machine a Vapeur," has lately been added to the Aide-Mémoire series published at Paris by Gauthier-Villars and by Masson. Two other volumes recently received are "Électricité Appliquée a la Marine," by M. P. Minel, and "La Rectification de L'Alcool," by M. Ernest Sorel.

THE Agent-General for New South Wales has sent us the report of the Department of Public Works for the year 1892. A considerable amount of work was carried out during the year in connection with harbours and rivers and water supply, water conservation and irrigation, roads and bridges and sewerage. The report contains twenty-seven plates illustrating the state of the work in hand and the machinery employed.

THE difficult genera *Rosa* and *Rubus* are the subject of careful study by French botanists. A Rhodological Society has been founded for the purpose of publishing a herbarium of the Roses of France, named by the Belgian rhodologist M. Crépin. Those intending to subscribe are invited to correspond with Dr. Pons, Ille-sur-Tet, Pyrénées Orientales. A publication is also announced with the title *Rubi praesertim Gallici exsiccati*, under the editorship of Prof. Bourlay, Rue de Toul, Lille, and M. Bouly de Lesdain, 16, Rue Emmery, Dunkerque. We note also the publication of the first fascicle of Messrs. E. F. and W. R. Linton's "Set of British Willows."

FOUR new volumes of the series of reprints published by Engelmann, of Leipzig, viz. Ostwald's "Klassiker der Exakten Wissenschaften," have just appeared. Nos. 46 and 47 deal with the calculus of variation, and contain papers by Joh Bernoulli (1696), Jac Bernoulli (1697), Euler (1744), Lagrange (1762, 1770), Legendre (1786), and Jacobi (1837). Electricians will be interested in No. 52, which contains Galvani's observations on the action of electricity on the muscles of frogs. The twenty-one quaint figures in the text give this volume additional value. Gauss' researches on the intensity of terrestrial magnetism, communicated to the Gottingen Gesellschaft der Wissenschaften in 1832, are reprinted in No. 53 of this very useful series.

AMONG numerous papers recently distributed by the Smithsonian Institution are Prof. S. P. Langley's memoir on "The Internal Work of the Wind" (see NATURE, vol. xlix. p. 273, 1893), and several contributions by Prof. H. F. Osborn to the *Bulletin* of the American Museum of Natural History. One of these is concerned with the fossil mammals of the Upper Cretaceous beds of America, and the conclusions arrived at from a discussion of the upper and lower dentition are the reverse of those expressed by Prof. Marsh on the same fauna. Other recently-issued excerpts from the *Bulletin* referred to are "Artionyx, a new Genus of Ancylopoda," by Prof. Osborn and Dr. J. L. Wortman; "On the Divisions of the White River or Lower Miocene of Dakota," by Dr. Wortman; and "Ancestors of the Tapir from the Lower Miocene of Dakota," by Dr. Wortman and Mr. C. Earle.

MM. J. B. BAILLIÈRE ET FILS, Paris, have published a "Flore de France," by M. A. Acloque, containing the description of all the indigenous species, and illustrated by 2165 small figures representing the characteristic types of genera and sub-genera. The book has been designed to assist in the identification of plants. It appeals, therefore, to those who, when they see a plant, want to know its place in the flora of France. By means of it, local botanists will be able to determine easily the species of plants in their districts, and thus a large amount of useful material with regard to geographical distribution may be got together. Another flora lately published is that of "Nordwestdeutchen Tiefebene" (Engelmann, Leipzig), by Prof. F. Buchenau. This, however, is not so much a work to assist amateur botanists as a work of reference in which all the plants in the region covered are systematically arranged and described.

THREE iodo-sulphides of phosphorus have been prepared by M. Ouvrard, and are described in the June issue of the *Annales de Chimie et de Physique*. The iodide of phosphorus P_2I_4 is not attacked by sulphuretted hydrogen at the ordinary temperature, but at a temperature slightly higher than the melting point of the iodide, about 115°, hydriodic acid is slowly produced, and after a couple of days' heating at this temperature the reaction is usually complete. The product is readily soluble in carbon bisulphide, and the solution deposits crystals of an iodo-sulphide of the composition $P_4S_3I_2$. The reaction proceeds in accordance with the equation, $2P_2I_4 + 3H_2S = P_4S_3I_2 + 6HI$. This new substance forms very well-developed yellow crystals of high refractive power. They are permanent in dry air, but slowly attacked by moisture with elimination of sulphuretted hydrogen. They melt about 106° to a viscous liquid, and about 300° they inflame with evolution of iodine vapour and white fumes of phosphoric anhydride. Cold water only slowly attacks them, but they are rapidly decomposed by hot water. Fuming nitric acid at once induces an explosion accompanied by incandescence. The compound may more easily be prepared by dissolving the constituents in the correct proportions in carbon bisulphide, evaporating and heating to 120° in a current of inert gas, and again dissolving in carbon bisulphide; the solution deposits crystals of the new substance upon evaporation. It may also be at once obtained by dissolving iodine in a solution of sesquisulphide of phosphorus in carbon bisulphide and evaporating. The second iodo-sulphide of phosphorus has the composition PSI or $P_2S_2I_2$, and was obtained by the action of sulphuretted hydrogen upon the tri-iodide of phosphorus, PI_3. A lower temperature than that required for the formation of the compound just described is advisable at first; it should not be much higher than 55°, the melting point of the tri-iodide; before the conclusion of the reaction, however, it may safely be raised to 120°. The solution of the product in carbon bisulphide deposits red crystals of the new compound PSI. These crystals are much more rapidly attacked by moist air than those of the first iodo-sulphide, and the reaction is accompanied by the liberation of fumes of hydriodic acid. They take fire upon warming in the air, disseminating the odour of sulphur dioxide and the violet vapour of iodine. Water dissolves them rapidly, producing trisulphide of phosphorus and hydriodic and phosphorous acids, and sulphuretted hydrogen is subsequently evolved owing to the decomposition of the trisulsphide. The third iodo-sulphide was obtained by reacting with excess of tri-iodide of phosphorus upon the trisulphide. It is deposited from carbon bisulphide in deep red crystals, very rapidly decomposed by moist air, and its composition is P_2SI_4. It thus appears that iodine is capable of replacing more or less of the sulphur contained in the sulphides of phosphorus, although it does not succeed in totally eliminating sulphur from its combination with phosphorus. M. Ouvrard has also obtained several new halogen derivatives of the sulphides of arsenic and antimony. English readers of the original paper cannot but be sorry, however, that M. Ouvrard employs the old notation, which renders it difficult at first sight to follow the equations representing the reactions. The formulæ above given are translated into the modern notation now universally employed in this country and Germany.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♀) from India, a White-throated Capuchin (*Cebus hypoleucus*) from Central America, presented by Mr. F. Erskine Paton; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Miss Florence Marryat; two Common Peafowl (*Pavo cristatus*, ♂ ♀) from India, presented by Mr. A. Tannenbaum; a Puff Adder (*Vipera arietans*) from South Africa, presented by Mr. J. E. Matcham; four Common Snakes (*Tropidonotus natrix*), a Common Viper (*Vipera berus*), British, presented by Mr. Harold Attewell; a Smooth Snake (*Coronella lævis*) British, presented by Mr. Harry Furniss; a Natterjack Toad (*Bufo calamita*), British, presented by Mr. F. Wallace; a Raven (*Corvus corax*), British, presented by Mr. Robert O. Callaghan; two Cape Crowned Cranes (*Balearica chrysopelargus*) from South Africa, four Yellow-bellied Liothrix (*Liothrix luteus*), two Hamadryads (*Ophiophagus elaps*) from India, deposited; an Ashy-black Macaque (*Macacus ocreatus*, ♂) from the East Indies, a Beech Marten (*Mustela foina*) from Russia, a Red and Yellow Macaw (*Ara chloroptera*) from South America, a Yellow-headed Vulture (*Cathartes urubitinga*) from Brazil, a Turkey Vulture (*Cathartes aura*) from America, a Guianan Crested Eagle (*Morphnus guianensis*) from the Amazons, purchased; an English Wild Cow (*Bos taurus*, var.), three Varied Rats (*Isomys variegatus*), a Bennetts Wallaby (*Halmaturus bennetti*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

REPORT OF THE ASTRONOMER-ROYAL FOR SCOTLAND.—The fourth annual report of Prof. Copeland on the Royal Observatory, Edinburgh, informs us that great progress has been made in the construction of the new Observatory. The masonry of all the buildings is complete, and some parts are ready for the internal fittings.

A comparison of the earlier Edinburgh star places with the catalogue of the *Astronomische Gesellschaft* has shown the necessity of a complete new reduction of the observations, in order to bring them into line with modern practice in this kind of work. For this purpose considerable progress has been made in an investigation of the errors of the transit instrument.

At the request of M. d'Abbadie, of the Paris Academy of Sciences, a bifilar pendulum was temporarily erected on the rock at Calton Hill on March 24. This extremely sensitive instrument, constructed by Mr. Horace Darwin on a principle suggested by Lord Kelvin, indicates the minutest change of level in the foundation to which it is attached. Prof. Copeland hopes shortly to commence a series of systematic observations in conjunction with allied observations made by M. d'Abbadie nearly on the same meridian in the south of France. These investigations will probably show if any considerable tilt takes place at the same time at both stations. It is thought that the bifilar pendulum may serve to detect the occurrence of sudden displacements in the foundations of observatories.

AWARD OF THE WATSON MEDAL.—At Washington a few weeks ago Mr. S. C. Chandler was awarded the Watson medal by the National Academy of Sciences. A description of the founding of the award and the work of previous recipients, given by Mr. John Ritchie, jun., in the *Boston Commonwealth*, recalls a few facts of interest. Prof. J. C. Watson, the founder of the award, was for many years professor of astronomy and physics in the Universities of Michigan and Wisconsin, and for some time previous to his decease was director of the Washburn Observatory at Madison. His treatise on theoretical astronomy is known to every computing astronomer. During the later years of his life he devoted his attention to the minor planets, of which he discovered twelve. It is common knowledge that, at the eclipse of July 29, 1878, he and Dr. Swift reported observations of an intra-mercurial planet, and he believed in the existence of such a body up to his death in 1880. At his death he left his estate, some family legacies excepted, in trust to the National Academy of Sciences, the fund having since been designated the Watson Fund. The amount of money realised was in all some twenty or thirty thousand dollars. The income of this is to be expended for the promotion of astronomical science, specific provision being made for the presentation of a gold medal and a gratuity of one hundred dollars in gold coin, from time to time, to an astronomer who shall have accomplished work of high merit. He nominated as trustees of his fund his friends Hilgard, Coffin and Newcomb, with provision for the appointment of their successors. The high quality of the trust has been continued by the selection of Dr. B. A. Gould and Prof. Asaph Hall as successors to Hilgard and Coffin, who passed away some three years ago. Four medals only have been given: the first to Dr. B. A. Gould in 1887; the second to Prof. Edward Schönfeld, Director of the University of Bonn, in 1888; the third to Dr. Arthur Auwers, of Berlin, in 1891; and the fourth to Mr. Chandler. It need hardly be said that the award was chiefly given to Mr. Chandler for his brilliant investigations on the variations of latitude.

TWO NEW CATALOGUES.—*Astronomische Nachrichten* No. 3232 contains a long list of stars with remarkable spectra, observed by the Rev. T. E. Espin. The catalogue comprises 167 stars, most of which have not had their spectra previously recorded, 206 stars found to have spectra belonging to Type III., and a list of 136 stars, of which it is doubtful whether they belong to Type II. or III. Nos. 3233–34 of the same publication contain a catalogue of 187 new double stars discovered with the 18½ inch refractor of the Deerhorn Observatory, U.S.A., and measures of 152 double stars, by Prof. G. W. Hough.

THE DENSITY OF NITROGEN GAS.[1]

IN a former communication[2] I have described how nitrogen, prepared by Lupton's method, proved to be lighter by about 1/1000 part than that derived from air in the usual manner.

[1] "On an Anomaly encountered in Determinations of the Density of Nitrogen Gas." A paper read before the Royal Society on April 19, by Lord Rayleigh, Sec. R.S.

[2] "On the Densities of the Principal Gases," *Roy. Soc. Proc.* vol. liii. p. 146, 1893.

In both cases a red hot tube containing copper is employed, but with this difference. In the latter method the atmospheric oxygen is removed by oxidation of the copper itself, while in Lupton's method it combines with the hydrogen of ammonia, through which the air is caused to pass on its way to the furnace, the copper remaining unaltered. In order to exaggerate the effect, the air was subsequently replaced by oxygen. Under these conditions the whole, instead of only about one-seventh part of the nitrogen is derived from ammonia, and the discrepancy was found to be exalted to about one half per cent.

Upon the assumption that similar gas should be obtained by both methods, we may explain the discrepancy by supposing either that the atmospheric nitrogen was too heavy on account of imperfect removal of oxygen, or that the ammonia nitrogen was too light on account of contamination with gases lighter than pure nitrogen. Independently of the fact that the action of the copper in the first case was pushed to great lengths, there are two arguments which appeared to exclude the supposition that oxygen was still present in the prepared gas. One of these depends upon the large quantity of oxygen that would be required in view of the small difference between the weights of the two gases. As much as 1/30th part of oxygen would be necessary to raise the density by 1/200, or about one-sixth of all the oxygen originally present. This seemed to be out of the question. But even if so high a degree of imperfection in the action of the copper could be admitted, the large alteration caused by the substitution of oxygen for air in Lupton's process would remain unexplained. Moreover, as has been described in the former paper, the introduction of hydrogen into the gas made no difference, such hydrogen being removed by the hot oxide of copper subsequently traversed. It is surely impossible that the supposed residual oxygen could have survived such treatment.

Another argument may be founded upon more recent results, presently to be given, from which it appears that almost exactly the same density is found when the oxygen of air is removed by hot iron reduced with hydrogen, instead of by copper, or in the cold by ferrous hydrate.

But the difficulties in the way of accepting the second alternative are hardly less formidable. For the question at once arises, of what gas, lighter than nitrogen, does the contamination consist? In order that the reader may the better judge, it may be well to specify more fully what were the arrangements adopted. The gas, whether air or oxygen, after passing through potash was charged with ammonia as it traversed a small wash-bottle, and thence proceeded to the furnace. The first passage through the furnace was in a tube packed with metallic copper, in the form of fine wire. Then followed a wash-bottle of sulphuric acid by which the greater part of the excess of ammonia would be arrested, and a second passage through the furnace in a tube containing copper oxide. The gas then traversed a long length of pumice charged with sulphuric acid, and a small wash-bottle containing Nessler solution. On the other side of the regulating tap the arrangements were always as formerly described, and included tubes of finely divided potash and of phosphoric anhydride. The rate of passage was usually about half a litre per hour.

Of the possible impurities, lighter than nitrogen, those most demanding consideration are hydrogen, ammonia, and water vapour. The last may be dismissed at once, and the absence of ammonia is almost equally certain. The question of hydrogen appears the most important. But this gas, and hydrocarbons, such as CH_4, could they be present, should be burnt by the copper oxide; and the experiments already referred to, in which hydrogen was purposely introduced into atmospheric nitrogen, seem to prove conclusively that the burning would really take place. Some further experiments of the same kind will presently be given.

The gas from ammonia and oxygen was sometimes odourless, but at other times smelt strongly of nitrous fumes, and, after mixture with moist air, reddened litmus paper. On one occasion the oxidation of the nitrogen went so far that the gas showed colour in the blow-off tube of the Toppler, although the thickness of the layer was only about half an inch. But the presence of nitric oxide is, of course, no explanation of the abnormal lightness. The conditions under which the oxidation takes place proved to be difficult of control, and it was thought desirable to examine nitrogen derived by *reduction* from nitric and nitrous oxides.

The former source was the first experimented upon. The gas was evolved from copper and diluted nitric acid in the usual way, and, after passing through potash, was reduced by *iron*, copper not being sufficiently active, at least without a very high temperature. The iron was prepared from blacksmith's scale. In order to get quit of carbon, it was first treated with a current of oxygen at a red heat, and afterwards reduced by hydrogen, the reduction being repeated after each employment. The greater part of the work of reducing the gas was performed outside the furnace in a tube heated locally with a Bunsen flame. In the passage through the furnace in a tube containing similar iron, the work would be completed, if necessary. Next followed washing with sulphuric acid (as required in the ammonia process), a second passage through the furnace over copper oxide, and further washing with sulphuric acid. In order to obtain an indication of any unreduced nitric oxide, a wash-bottle containing ferrous sulphate was introduced, after which followed the Nessler test and drying tubes, as already described. As thus arranged, the apparatus could be employed without alteration, whether the nitrogen to be collected was derived from air, from ammonia, from nitric oxide, from nitrous oxide, or from ammonium nitrite.

The numbers which follow are the weights of the gas contained by the globe at zero, at the pressure defined by the manometer when the temperature is 15°. They are corrected for the errors in the weights, but not for the shrinkage of the globe when exhausted, and thus correspond to the number 2·31026, as formerly given for nitrogen.

Nitrogen from NO by Hot Iron.

November 29, 1893	2·30143	Mean, 2·30008
December 2, 1893	2·29890	
December 5, 1893	2·29816	
December 6, 1893	2·30182	

Nitrogen from N_2O by Hot Iron.[1]

December 26, 1893	2·29869	Mean, 2·29904
December 28, 1893	2·29940	

Nitrogen from Ammonium Nitrite passed over Hot Iron.

January 9, 1894	2·29849	Mean, 2·29869
January 13, 1894	2·29889	

With these are to be compared the weights of nitrogen derived from the atmosphere.

Nitrogen from Air by Hot Iron.

December 12, 1893	2·31017	Mean, 2·31003
December 14, 1893	2·30986 (H)	
December 19, 1893	2·31003 (H)	
December 22, 1893	2·31007	

Nitrogen from Air by Ferrous Hydrate.

January 27, 1894	2·31024	Mean, 2·31020
January 30, 1894	2·31010	
February 1, 1894	2·31028	

In the last case a large volume of air was confined for several hours in a glass reservoir with a mixture of slaked lime and ferrous sulphate. The gas was displaced by deoxygenated water, and further purified by passage through a tube packed with a similar mixture. The hot tubes were not used.

If we bring together the means for atmospheric nitrogen obtained by various methods, the agreement is seen to be good, and may be regarded as inconsistent with the supposition of residual oxygen in quantity sufficient to influence the weights.

Atmospheric Nitrogen.

By hot copper, 1892	2·31026
By hot iron, 1893	2·31003
By ferrous hydrate, 1894	2·31020

Two of the results relating to hot iron, those of December 14 and December 19, were obtained from nitrogen, into which hydrogen had been purposely introduced. An electrolytic generator was inserted between the two tubes containing hot iron, as formerly described. The generator worked under its own electromotive force, and the current was measured by a tangent galvanometer. Thus, on December 19, the deflection throughout the time of filling was 3°, representing about 1/15

[1] The N_2O was prepared from zinc and very dilute nitric acid.

ampère. In two hours and a half the hydrogen introduced into the gas would be about 70 c.c., sufficient, if retained, to reduce the weight by about 4 per cent. The fact that there was no sensible reduction proves that the hydrogen was effectively removed by the copper oxide.

The nitrogen, obtained altogether in four ways from chemical compounds, is materially lighter than the above, the difference amounting to about 11 mg., or about 1/200 part of the whole. It is also to be observed that the agreement of individual results is less close in the case of chemical nitrogen than of atmospheric nitrogen.

I have made some experiments to try whether the densities were influenced by exposing the gas to the silent electric discharge. A Siemens tube, as used for generating ozone, was inserted in the path of the gas after desiccation with phosphoric anhydride. The following were the results:—

Nitrogen from Air by Hot Iron, Electrified.

January 1, 1894 ...	... 2·31163	Mean, 2·31059
January 4, 1894 ...	... 2·30956	

Nitrogen from N_2O by Hot Iron, Electrified.

January 2, 1894 ...	... 2·30074	Mean, 2·30064
January 5, 1894 ...	... 2·30054	

The somewhat anomalous result of January 1 is partly explained by the failure to obtain a subsequent weighing of the globe empty, and there is no indication that any effect was produced by the electrification.

One more observation I will bring forward in conclusion. Nitrogen prepared from oxygen and ammonia, and about one-half per cent. lighter than ordinary atmospheric nitrogen, was stored in the globe for eight months. The globe was then connected to the apparatus, and the pressure was readjusted in the usual manner to the standard conditions. On reweighing no change was observed, so that the abnormally light nitrogen did not become dense by keeping.

DR. ARMSTRONG ON THE PUBLICATION OF SCIENTIFIC LITERATURE.

THE presidential address delivered by Dr. Armstrong at the last annual meeting of the Chemical Society, and published in the May number of the Society's *Journal*, contains numerous suggestive remarks on questions affecting all branches of science. A subject that has lately been attracting some attention is the publication of the proceedings of societies. On this Dr. Armstrong has much to say, and as he has had abundant opportunity of proving the value of the system followed by the Chemical Society, and comparing it with those of other societies, his opinions carry weight. Our space will not permit us to reprint the address, but the following extracts will suffice to show its character.

"Chemical literature is fast becoming unmanageable and uncontrollable from its very vastness. Not only is the number of papers increasing from year to year, but new journals are constantly being established. Something must be done in order to assist chemists to remain in touch with their subject and to retain their hold on the literature generally. This object would be best attained if chemists could agree to publish everything in one journal; but for many reasons, and until the world has recognised one language, such an idea must remain but a dream. This being the case, we must endeavour to have as few journals as possible, which is desirable even from the point of view of our pockets and of the dimensions of our book-shelves and houses, none of which are infinitely elastic. It is clear that in the British Isles but one journal is necessary; a large majority of the papers by workers in British laboratories, containing matter new to chemical science, are at present communicated to us, and I see no reason why all should not be. I do not mean that all should be read before the Chemical Society, because the mere reading is frequently but a formal proceeding, or, in some cases, may take place with advantage elsewhere. The Society of Chemical Industry has set us a good example in this respect by publishing in one journal the papers read at various places in the country; it matters little that the papers are read before affiliated sections of the Society, as these sections are practically independent organisations. . . .

"It seems to me, that eventually one of two courses must be adopted in this country—either the societies engaged in doing similar work must become affiliated, or our Society must return to the practice of early days and publish lengthy abstracts of papers communicated to societies such as the Royal Societies of London and Edinburgh, in order to bring these papers properly under the notice of chemists generally. The former course would involve an agreement amongst us to print in some uniform manner, less expensive, magnificent and stately than that adopted by the Royal Societies; a somewhat larger octavo than that of our present journal would probably suffice, such as is adopted for the *Annals of Botany*. If such an agreement were arrived at, a paper read and discussed before the Royal Society of London or Edinburgh, for example, might be printed off, and the necessary number of copies supplied to the society; while, if the paper interested chemists, we might at the same time take an appropriate number, and issue the paper as part of our Transactions. . . .

"The policy thus advocated with reference to English chemical papers is already being elsewhere adopted. The *Monatshefte für Chemie*, for example, is advisedly a collection of the papers of Austrian chemists, although, unfortunately, this does not yet include the whole of the work done in Austria-Hungary. The *Gazzetta chimica italiana* appears to contain very nearly all the Italian work. All that is done in Holland is brought together in the *Recueil des travaux chimique des Pays-Bas*. France and Germany, however, each have a variety of journals. In France the prestige of the Academy is such that for some time to come it will probably be difficult to consolidate the interests of French chemists. In Germany, however, the *Deutsche chemische Gesellschaft* is no longer hampered by the words *zu Berlin*, which it has boldly dropped, while we still remain the Chemical Society *of London* in name; it is to be hoped that in the interests of the scientific world it will ere long acquire and quash the private interests by which other journals are supported. I see no good reason even why journals devoted to special branches of our subject should exist, and I regard the appearance, for example, of a special journal of inorganic chemistry as an unmitigated evil. Political colouring and a tendency to adopt methods akin to those of the newspaper editor, of which we have had evidence in one of these journals, are most undesirable features in science. Moreover, we cannot afford to buy everything; and no effort should be spared to prevent our being split up into factions and becoming narrow-minded specialists: the more the student of chemistry—and every original worker must be and remain a student throughout his life—is brought directly into contact with the work which is being done in the several departments of his science, the better it will be for him; he cannot and need not read everything, but do not let us deprive him of the opportunity of easily indulging in a mixed diet, and of exercising his mental faculties generally, while devoting himself specially to some one section of the vast subject which it is the privilege of the chemist to command.

"To complete my scheme—which I trust is not altogether visionary, for so great is the toleration and sympathy between all true-minded scientific workers that if union be possible in any field of human activity it is possible in the field of science—it will be necessary that the Scandinavian and Danish chemists, say, should unite; and also that the Russian chemists should give us a 'recueil des travaux chimiques' in *French*, so that the world may no longer be deprived of the knowledge of their labours, which we know, from experience, are of high value. As to America, it would be a great achievement if the political separation of our two nations could be disregarded and we were to unite with our cousins in establishing one journal for the publication of the work of chemists speaking English. There would be no real difficulty in doing this in these days of type-written manuscript, the proof of which need but be revised by the printers' reader. But if motives of expediency render such union impracticable, then it is to be hoped that steps may be taken to make the title *American Chemical Journal* truly and completely significant. I hope that we shall be successful in arranging to co-operate with all chemists in our own colonies and India. . . .

"There has been much discussion during the past few months, especially in the columns of NATURE, on the question of the publication of physical papers, which, strange to say, is in a very inchoate condition. I feel sure that the problem will soon be successfully solved by the Physical Society boldly coming forward and undertaking to do for physics what we have proved can be done for chemistry; there is no other solution possible, and the needs of physics are so great that no time should be lost. We, in this Society, can never be too grateful to Professor Williamson for having led the storming party to victory which established our system of abstracts; he foresaw that when such a scheme was successfully launched it was bound to become self-supporting, and such has long since proved to be the case. Let us hope that the physicists have at their disposal some one equally bold and far-sighted, who will overcome the fears of the timid, and initiate a thoroughly comprehensive scheme. Chemists are directly interested in the work, as we are bound to take notice of the progress of physics, and the want of an English record is much felt by us. We had no society with cognate aims to help us, so that the physicists are in a far stronger position than we were, as the Institution of Electrical Engineers should be prepared to forward such a cause. I believe it will be found to be of the utmost importance to them to do so. Indeed, the electrical engineer of the present day, I fear, is fast becoming a specialist of the deepest dye: having had experience of several hundreds, I know that when a student he is most difficult to deal with, as he will only pay attention, even in physics, to what he believes to be of immediate importance to him; as to chemistry, he will scarce notice it, forgetting, or not realising, that the whole field of electro-chemistry is yet untilled. It is, therefore, very necessary that no effort should be spared to make the electrical engineer better informed regarding physics generally. . . .

"The Royal Society of London has recently issued to the scientific world a circular having reference to the preparation of complete catalogues of science by *international co-operation*, which raises questions of such importance that I do not hesitate to reproduce it.

"'Sir,—The Royal Society of London, as you are probably aware, has published nine quarto volumes of *The Catalogue of Scientific Papers*, the first volume of the decade—1874-83—having been issued last year.

"'This catalogue is limited to *periodical* scientific literature, *i.e.* to papers published in the transactions, &c., of societies, and in journals; it takes no account whatever of monographs and independent books, however important. The titles, moreover, are arranged solely according to author's names; and though the Society has long had under consideration the preparation of—and is hoped may eventually issue as—a key to the volumes already published, a list in which the titles are arranged according to subject-matter, the catalogue is still being prepared according to author's names. Further, though the Society has endeavoured to include the titles of all the scientific papers published in periodicals of acknowledged standing, the catalogue is—even as regards periodical literature—confessedly incomplete, owing to the omission of the titles of papers published in periodicals of little importance or not easy of access.

"'Owing to the great development of scientific literature the task of the Society in continuing the catalogue, even in its present form, is rapidly increasing in difficulty. At the same time it is clear that the progress of science would be greatly helped by—indeed, almost demands—the compilation of a catalogue which should aim at completeness, and should contain the titles of scientific publications, whether appearing in periodicals or independently. In such a catalogue the title should be arranged not only according to authors' names, but also according to subject-matter, the text of each paper and not the title only being consulted for the latter purpose. And the value of the catalogue would be greatly enhanced by a rapid periodical issue, and by publication in such a form that the portion which pertains to any particular branch of science might be obtained separately.

"'It is needless to say that the preparation and publication of such a complete catalogue is far beyond the power and means of any single society.

"'Led by the above considerations, the President and Council of the Royal Society have appointed a committee to inquire into and report upon *the feasibility of such a catalogue being compiled through international co-operation.*

"'The Committee are not as yet in a position to formulate any distinct plan by which such international co-operation might be brought about; but it may be useful, even at the outset, to make the following preliminary suggestions:—

"'The catalogue should commence with papers published on or after January 1, 1900.

"'A central office, or bureau, should be established in some place, to be hereafter chosen, and should be maintained by international contributions—either directly, that is, by annual or other subsidies—or indirectly, that is, by the guarantee to purchase a certain number of copies of the catalogue.

"'This office should be regularly supplied with all the information necessary for the construction of the catalogue. This might be done either by all periodicals, monographs, &c., being sent direct to the office to be catalogued there, or by various institutions undertaking to send in portions of the catalogue already prepared, or by both methods combined.

"'At such an office, arrangements might be made by which, in addition to preparing the catalogue, scientific data might be tabulated as they came to hand in the papers supplied.

"'The first step, however, is to ascertain whether any scheme of international co-operation is feasible and desirable. The Committee, accordingly, is desirous of learning the views upon this subject of scientific bodies and of scientific men.

"'We, therefore, venture to express the hope that you will be so good as, at some early opportunity, to make known to us, for the use of the Committee, your own views on the matter.

"'Should the decision you report be in any way favourable to the scheme, may we further ask you to communicate to us, for the use of the Committee, any suggestions which you may think it desirable to make, as to the best methods of inaugurating such a scheme, as to the constitution and means of maintenance of the Central Office, as to the exact character of the work to be carried on there, as to the language or languages in which the catalogue should be published, and the like?

"'We are,

"'Your obedient servants,

"'M. Foster, *Secretary R.S.*

"'Rayleigh, *Secretary R.S.*

"'J. Lister, *Foreign Sec. R.S.*'

"If any such scheme as is here foreshadowed could be carried out, it would obviously be of the greatest value to the world and productive of much saving, both of time and treasure. But the subject is full of difficulty, owing to the very numerous interests concerned. I trust, however, that when the time comes to deal with the chemical section—and, indeed, in the case of any future catalogue of chemical work, that we shall not be satisfied with a mere alphabetical arrangement, but that we shall classify the subject-matter alphabetically in sections, so as to lighten the labour of ascertaining the state of knowledge in any particular group. Already we do not know very many of the names recorded in our indexes, and, in the future, we shall be ignorant of a still larger proportion, unless our system of nomenclature be made so significant that each name will explain itself; and in the case of an alphabetical arrangement, substances belonging to the same group, having names with different initial letters, occur interspersed throughout the index: so that it is a matter of the greatest difficulty, if not impossible, by consulting such an index, to ascertain the references to all the members of the group. An alphabetical index also affords no indication of the extent to which knowledge of any particular group has increased during the interval covered by it; and, in fact, it only becomes of real use when provided with a key, such as Beilstein affords, in which the names of the known members of any particular group may be first looked up before consulting the alphabetical index. Also, in using a lengthy alphabetical index it is very easy to miss entries, and it is necessary to pay far more attention when consulting it than is the case when one of limited extent is used.

"I do not believe that there would be any real difficulty in arriving at a system of classification which, at all events, would limit a reference to comparatively few pages. We are told that by the Bertillon system, dealing with the card records of 90,000 convicts, it is possible—when the necessary measurements have been taken—to ascertain whether a prisoner has been before convicted, as it may be said, with considerable, if not absolute, confidence, that, in that case, his card will be found in a drawer containing only about 400. Surely, we ought to be able to devise a system which would equally limit our search."

THE WORK OF HERTZ.

Additions and Corrections to the Lecture reported last week, by Dr. Oliver Lodge.

On page 135, middle of first column, the word "clearly" ought to have been *probably*; for I am by no means clear that the gradual discharge of negative electrification from the clean surface of metals under the action of light is really a chemical phenomenon. It had been asserted by some experimenters that the most oxidisable metals acted most powerfully, but my own experience renders this doubtful; I now find that gold platinum and carbon discharge with very fair rapidity, and that nearly all substances have some discharging power. A few materials, cobalt among metals, discharge positive electrification more rapidly than negative. The whole matter is therefore now under investigation.

In the foot-note to same column, end of first paragraph, the word "even" should be deleted. The assertion intended is that dried soil discharges rapidly, while damp soil discharges only slowly.

Same page, middle of second column, "two years ago" should be *four years ago*; since Fitzgerald's Royal Institution Lecture was delivered in March 1890, and reported in NATURE of June 19 the same year.

Lower down, the name Kolaček, preceding that of D. E. Jones, has been omitted.

Page 138, second column, with reference to the reflecting power of different substances it may be interesting to give the following numbers, showing the motion of the spot of light when 8-inch waves were reflected into the copper hat, the angle of incidence being about 45°, by the following mirrors:—

Sheet of window glass	0, or at most 1, division.
Human body	7 divisions.
Drawing board	12 ,,
Towel soaked with tap-water ...	12 ,,
Tea-paper (lead?)...	40 ,,
Dutch metal paper	70 ,,
Tinfoil	80 ,,
Sheet copper	100 and up against stops.

Page 139. It would have been clearer if the penultimate paragraph, beginning "To demonstrate," had run thus:—

To demonstrate that the so-called plane of polarisation of the radiation transmitted by a grid is at right angles to the electric vibration, *i.e.* that when light is reflected from the boundary of a transparent substance at the polarising angle the electric vibrations of the reflected beam are perpendicular to the plane of reflection, I use, &c.

The following is a copy of one of the wall-diagrams; it is interesting as showing how numerous the now-known detectors of radiation are:—

DETECTORS OF RADIATION.

Physiological	Chemical	Thermal	Electrical	Mechanical	Microphonic
					Selenium (?)
Eye	Photographic Plate	Thermopile	Spark (Hertz)	Electrometer (Blyth and Bjerknes)	Impulsion Cell (Minchin)
× Frog's leg (Hertz and Ritter)	Explosive Gases	Bolometer (Rubens and Ritter)	Telephone, Air-gap and Arc (Lodge)	Suspended Wires (Hertz and Boys)	Filings (Branly)
	Photo-electric cell	Expanding Wire (Gregory)	Vacuum Tube (Dragoumis)		Coherer (Hughes and Lodge)
		Thermal Junction (Klemencic)	Galvanometer (Fitzgerald)		
			Air-gap and Electroscope (Boltzmann)		
			Trigger Tube (Warburg and Zehnder)		

× The cross against the frog's leg indicates that it does not appear really to respond to radiation, unless stimulated in some secondary manner. The names against the other things are unimportant, but suggest the persons who applied the detector to electric radiation. The query against Selenium is placed there because of uncertainty as to its most appropriate column.

STUDY OF FLUID MOTION BY MEANS OF COLOURED BANDS.[1]

IN his charming story of "The Purloined Letter," Edgar Allan Poe tells how all the efforts and artifices of the Paris police to obtain possession of a certain letter, known to be in a particular room, were completely baffled for months by the simple plan of leaving the letter in an unsealed envelope in a letter-rack, and so destroying all *curiosity* as to its contents; and how the letter was at last found there by a young man who was not a professional member of the force. Closely analogous to this is the story I have to set before you to-night—how certain mysteries of fluid motion, which have resisted all attempts to penetrate them, are at last explained by the simplest means and in the most obvious manner.

This indeed is no new story in science. The method adopted by the minister, *D.*, to secrete his letter appears to be the favourite of nature in keeping her secrets, and the history of science teems with instances in which keys, after being long sought amongst the grander phenomena, have been found at last not hidden with care, but scattered about, almost openly, in the most commonplace incidents of everyday life which have excited no curiosity.

[1] A lecture delivered at the Royal Institution of Great Britain by Prof. Osborne Reynolds, F.R.S.

This was the case in physical astronomy—to which I shall return after having reminded you that the motion of matter in the universe naturally divides itself into three classes.

(1) The motion of bodies as a whole—as a grand illustration of which we have the heavenly bodies, or more humble, but not less effective, the motion of a pendulum, or a falling body.

(2) The relative motion of the different parts of the same fluid or elastic body—for the illustration of which we may go to the grand phenomena presented by the tide, the whirlwind, or the transmission of sound, but which is equally well illustrated by the oscillatory motion of the wave, as shown by the motion of its surface and by the motion of this jelly, which, although the most homely illustration, affords by far the best illustration of the properties of an elastic solid.

(3) The inter-motions of a number of bodies amongst each other —to which class belong the motions of the molecules of matter resulting from heat, as the motions of the molecules of a gas, in illustration of which I may mention the motions of individuals in a crowd, and illustrate by the motion of the grains in this bottle when it is shaken, during which the white grains at the top gradually mingle with the black ones at the bottom—which inter-diffusion takes an important part in the method of coloured bands.

Now of these three classes of motion that of the individual body is incomparably the simplest. Yet, as presented in the phenomena of the heavens, which have ever excited the greatest curiosity of mankind, it defied the attempts of all philosophers for thousands of years, until Galileo discovered the laws of motion of mundane matter. It was not until he had done this and applied these laws to the heavenly bodies that their motions received a rational explanation. Then Newton, taking up Galileo's parable and completing it, found that its strict application to the heavenly bodies revealed the law of gravitation, and developed the theory of dynamics.

Next to the motions of the heavenly bodies, the wave, the whirlwinds, and the motions of clouds, had excited the philosophical curiosity of mankind from the earliest time. Both Galileo and Newton, as well as their followers, attempted to explain these by the laws of motion, but, although the results so obtained have been of the utmost importance in the development of the theory of dynamics, it was not till this century that any considerable advance was made in the application of this theory to the explanation of fluid phenomena; and although during the last fifty years splendid work has been done, work which, in respect of the mental effort involved, or the scientific importance of the results, goes beyond that which resulted in the discovery of Neptune, yet the circumstances of fluid motion are so obscure and complex that the theory has yet been interpreted only in the simplest cases.

To illustrate the difference between the interpretation of the theory of heavenly bodies and that of fluid motion, I would call your attention to the fact that solid bodies, on the behaviour of which the theory of the motion of the planets is founded, move as one piece, so that their motion is exactly represented by the motion of their surfaces; that they are not affected with any internal disorder which may affect their general motion. So surely is this the case that even those who have never heard of dynamics can predict with certainty how any ordinary body will behave under any ordinary circumstances, so much so that any departure is a matter of surprise. Thus I have here a cube of wood, to one side of which a string is attached. Now hold it on one side, and you naturally suppose that when I let go holding the string it will turn down so as to hang with the string vertical; that it does not do so is a matter of surprise. I place it on the other side, and it still remains as I place it. If I swing it as a pendulum it does not behave like one.

Would Galileo have discovered the laws of motion had his pendulum behaved like this? Why is its motion peculiar? There is internal motion. Of what sort? Well, I think my illustration may carry more weight if I do not tell you; you can all, I have no doubt, form a good idea. It is not fluid motion, or I should feel bound to explain it. You have here an ordinary-looking object which behaves in an extraordinary manner, which is yet very decided and clear, to judge by the motion of its surface, and from the manner of the motion I wish you to judge of the cause of the observed motion.

This is the problem presented by fluids, in which there may be internal motion which has to be taken into account before the motion of the surface can be explained. You can see no more of what the motion is within a homogeneous fluid, however opaque or clear, than you can see what is going on within the box. Thus without colour bands the only visual clue to what is going on within the fluids is the motion of their bounding surfaces. Nor is this all; in most cases the surfaces which bound the fluid are immovable.

In the case of the wave on water the motion of the surface shows that there is motion, but because the surface shows no wave it does not do to infer that the fluid is at rest.

The only surfaces of the air within this room are the surfaces of the floor, walls, and objects within it. By moving the objects we move the air, but how far the air is at rest you cannot tell unless it is something familiar to you.

Now I will ask you to look at these balloons. They are familiar objects enough, and yet they are most sensitive anemometers, more sensitive than anything else in the room; but even they do not show any motion; each of them forms an internal bounding surface of the air. I send an *aerial messenger* to them, and a small but energetic motion is seen by which it acknowledges the message, and the same message travels through the rest, as if a *ghost* touched them. It is a wave that moves them. You do not feel it, and, but for the surfaces of the air formed by the balloons, would have no notion of its existence.

In this tank of beautifully clear distilled water, I project a heavy ball in from the end, and it shows the existence of the water by stopping almost dead within two feet. The fact that it is stopped by the water, being familiar, does not raise the question, Why does it stop?—a question to which, even at the present day, a complete answer is not forthcoming. The question is, however, suggested, and forcibly suggested, when it appears that with no greater or other evidence of its existence, I can project a disturbance through the water which will drive this small disc the whole length of the tank.

I have now shown instances of fluid motion of which the manner is in no way evident without colour bands, and were revealed by colour bands, as I showed in this room sixteen years ago. At that time I was occupied in setting before you the manners of motion revealed, and I could only incidentally notice the means by which this revelation was accomplished.

Amongst the ordinary phenomena of motion there are many which render evident the internal motion of fluids. Small objects suspended in the fluid are important, and that their importance has long been recognised is shown by the proverb—straws show which way the wind blows. Bubbles in water, smoke and clouds, afford the most striking phenomena, and it is doubtless these that have furnished philosophers with such clues as they have had. But the indications furnished by these phenomena are imperfect, and, what is more important, they only occur casually, and in general only under circumstances of such extreme complexity that any deduction as to the elementary motions involved is impossible. They afford indication of commotion, and perhaps of the general direction in which the commotion is tending, but this is about all.

For example, the different types of clouds; these have always been noticed, and are all named. And it is certain that each type of clouds is an indication of a particular type of motion in the air; but no deductions as to what definite manner of motion is indicated by each type of cloud have ever been published.

Before this can be done it is necessary to reverse the problem and find to what particular type of cloud a particular manner of motion would give rise. Now a cloud, as we see it, does not directly indicate the internal motion of which it is the result. As we look at clouds, it is not in general their motion that we notice, but their figure. It is hard to see that this figure changes while we are watching a cloud, though such a change is continually going on, but is apparently very slow on account of the great distance of the cloud and its great size. However, types of clouds are determined by their figure, not by their motion. Now what their figure shows is not motion, but it is the history or result of the motion of the particular strata of the air in and through surrounding strata. Hence, to interpret the figures of the clouds we must study the changes in shape of fluid masses, surrounded by fluid, which result from particular motions.

The ideal in the method of colour bands is to render streaks or lines in definite position in the fluid visible, without in any way otherwise interfering with these properties as part of the homogeneous fluid. If we could by a wish create coloured lines in the water, these would be ideal colour bands. We cannot do this, nor can we exactly paint lines in the air or water.

I take this ladle full of highly coloured water, lower it slowly into the surface of the surrounding water till that within is level with that without; then turn the ladle carefully round the coloured water; the mass of coloured water will remain where placed.

I distribute the colour slowly. It does not mix with the clear water, and although the lines are irregular they stand out very beautifully. Their edges are sharp here. But in this large sphere, which was coloured before the lecture, although the coloured lines have generally kept their places, they have, as it were, swollen out and become merged in the surrounding water in consequence of molecular motion. The sphere shows, however, one of the rarest phenomena in nature—the internal state in almost absolute internal rest. The forms resemble nothing so much as stratus clouds, as seen on a summer day, though the continuity of the colour bands is more marked. A mass of coloured water once introduced is never broken. The discontinuity of clouds is thus seen to be due to other causes than mere motion.

Now, having called our attention to the rarity of water at rest, I will call your attention to what is apt to be a very striking phenomena, namely that when water is contained, like this, in a spherical vessel of which you cannot alter the shape, it is impossible by moving the vessel suddenly to set up relative motion in the interior of the water. I may swing this vessel about and turn it, but the colour band in the middle remains as it was, and when I stop shows the water to be at rest.

This is not so if the water has a free surface, or if the fluid is of unequal density. Then a motion of the vessel sets up waves, and the colour band shows at once the beautifully lawful character of the internal motion. The colour bands move backwards and forwards, showing how the water is distorted like a jelly, and as the wave dies out the colour bands remain as they were to begin with.

This illustrates one of the two classes of internal motion of water or fluid. Wherever fluid is not in contact with surfaces over which it has to glide, or which surfaces fold on themselves, the internal motions are of this purely wave character. The colour bands, however much they may be distorted, cannot be relatively displaced, twisted, or curled up, and in this case motion in water once set up continues almost without resistance. That wave motion in water with a free surface, is one of the most difficult things to stop is directly connected with the difficulty of setting still water in motion; in either case the influence must come through the surfaces. Thus it is that waves once set up will traverse thousands of miles, establishing communication between the shores of Europe and America. Wave motion in water is subject to enormously less resistance than any other form of material motion.

In wave motion, if the colour bands are across the wave they show the motion of the water; nevertheless, their chief indication is of the change of shape while the fluid is in motion.

This is illustrated in this long bottle, with the coloured water less heavy than the clear water. If I lay it down in order to establish equilibrium, the blue water has to leave the upper end of the bottle and spread itself over the clear water, while the clear water runs under the coloured. This sets up wave motion, which continues after the bottle has come to rest. But as the colour bands are parallel with the direction of motion of the waves, the motion only becomes evident in thickening and bending of the colour bands.

The waves are entirely between the two fluids, there being no motion in the outer surfaces of the bottle, which is everywhere glass. They are owing to the slight differences in the density of the fluids, as is indicated by the extreme slowness of the motion. Of such kind are the waves in the air, that cause the clouds which make the mackerel sky, the vapour in the tops of the waves being condensed and evaporated again as it descends showing the results of the motion.

The distortional motions, such as alone occur in simple wave motion, or where the surfaces of the fluid do not fold in on themselves, or wind in, are the same as occur in any homogeneous continuous material which completely fills the space between the surfaces.

If plastic material is homogeneous in colour it shows nothing as to the internal motion; but if I take a lump built of plates, blue and white, say a square, then I can change the surfaces to any shape without folding or turning the lump, and the coloured bands which extend throughout the lump show the internal changes. Now the first point to illustrate is that, however I change its shape, if I bring it back to the original shape the colour bands will all come back to their original positions, and there is no limit to the extent of the change that may thus be effected. I may roll this out to any length, or draw it out, and the diminution in thickness of the colour bands shows the extent of the distortion. This is the first and simplest class of motion to which fluids are susceptible. By this motion alone elements of the fluid may be, and are, drawn out to indefinitely fine lines, or spread out in indefinitely thin sheets, but they will remain of the same general figures.

By reversing the process they change back again to the original form. No colour band can ever be broken, even if the outer surface be punched in till the punch head comes down on the table; still all the colour bands are continuous under the punch, and there is no folding or lapping of the colour bands unless the external surface is folded.

The general idea of mixture is so familiar to us that the vast generalisation to which these ideas afford the key, remains unnoticed. That continued mixing results in uniformity, and that uniformity is only to be obtained by mixing, will be generally acknowledged, but how deeply and universally this enters into all the arts can but rarely have been apprehended. Does it ever occur to any one that the beautiful uniformity of our textile fabrics has only been obtained by the development of processes of mixing the fibres? Or, again, the uniformity in our construction of metals; has it ever occurred to any one that the inventions of Arkwright and Cort were but the application of the long-known processes by which mixing is effected in culinary operations? Arkwright applied the draw-rollers to uniformly extend the length of the cotton sliver at the expense of the thickness; Cort applied the rolling-mill to extend the length of the iron bloom at the expense of its breadth; but who invented the rolling-pin by which the pastrycook extends the length at the expense of the thickness of the dough for the pie-crust?

In all these processes the object, too, is the same throughout—to obtain some particular shape, but chiefly to obtain a uniform texture. To obtain this nicety of texture it is necessary to mix up the material, and to accomplish this it is necessary to attenuate the material, so that the different parts may be brought together.

The readiness with which fluids are mixed and uniformity obtained is a byword; but it is only when we come to see the colour bands that we realise that the process by which this is attained is essentially the same as that so laboriously discovered for the arts—as depending first on the attenuation of each element of the fluid—as I have illustrated by distortion.

In fluids, no less than in cooking, spinning and rolling—this attenuation is only the first step in the process of mixing—all involve the second process, that of folding, piling, or wrapping, by which the attenuated layers are brought together. This does not occur in the pure wave motion of water, and constitutes the second of the two classes of motion. If a wave on water is driven beyond a certain height it leaps or breaks, folding in its surface. Or, if I but move a solid surface through the water it introduces tangential motion, which enables the fluid to wind its elements round an axis. In these ways, and only in these ways, we are released from the restriction of not turning or lapping. And in our illustration, we may fold up our dough, or lap it—roll it out again and lap it again; cut up our iron bar, pile it, and roll it out again, or bring as many as we please of the attenuated fibres of cotton together to be further drawn. It may be thought that this attenuation and wrapping will never make perfect admixture, for however thin each element will preserve its characteristic, the coloured layers will be there, however often I double and roll out the dough. This is true. But in the case of some fluids, and only in the case of some fluids, the physical process of diffusion completes the admixture. These colour bands have remained in this water, swelling but still distinct; this shows the slowness of diffusion. Yet such is the facility with which the fluid will go through the process of attenuating its elements and enfolding them, that by simply stirring them with a spoon these colour bands can be drawn and folded so fine that the diffusion will be instantaneous, and the fluid become uniformly tinted. All internal fluid motion other than simple distortion, as in wave motion, is a process of mixing, and it is thus from the arts we get the clue to the elementary forms and processes of fluid motion.

When I put the spoon in and mixed the fluid you could not see what went on—it was too quick. To make this clear, it is necessary that the motion should be very slow. The motion should also be in planes, at right angles to the direction in which you are looking. Such is the instability of fluid that to accomplish this at first appeared to be difficult. At last, however, as the result of much thought, I found a simple process which I will now show you, in what I think is a novel experiment, and you will see, what I think has never been seen before by any one but Mr. Foster and myself, namely, the complete process of the formation of a cylindrical vortex sheet resulting from the motion of a solid surface. To make it visible to all I am obliged to limit the colour band to one section of the sheet, otherwise only those immediately in front would be able to see between the convolution of the spiral. But you will understand that what is seen is a section, a similar state of motion extending right across the tank. From the surface you see the plane vane extending halfway down right across the tank; this is attached to a float.

I now institute a colour band on the right of the vane out of the tube. There is no motion in the water, and the colour descends slowly from the tube. I now give a small impulse to the float to move it to the right, and at once the spiral form is seen from the tube. Similar spirals would be formed all across the tank if there were colours. The float has moved out of the way, leaving the revolving spiral with its centre stationary, showing the horizontal axis of the spiral is half-way between the bottom and surface of the tank, in which the water is now simply revolving round this axis.

This is the vortex in its simplest and rarest form (for a vortex cannot exist with its ends exposed). Like an army it must have its flanks protected; hence a straight vortex can only exist where it has two surfaces to cover its flanks, and parallel vertical surfaces are not common in nature. The vortex can bend, and, with a horse shoe axis, can rest both its flanks on the same surface, as this piece of clay, or unite its ends with a ring axis, which is its commonest form, as in the smoke ring. In both these cases the vortex will be in motion through the fluid, and less easy to observe.

These vortices have no motion beyond the rotation because they are half-way down the tank. If the vane were shorter they would follow the vane; if it were longer they would leave it.

In the same way, if instead of one vortex there were two vortices, with their axis parallel, extending right across, the one above another, they would move together along the tank.

I replace the float by another which has a vane suspended from it, so that the water can pass both above and below the vane extending right across the middle portion of the tank. In this case I institute two colour bands, one to pass over the top, the other underneath the vane, which colour bands will render visible a section of each vortex just as in the last case. I now set the float in motion, and the two vortices turn towards each other in opposite directions. They are formed by the water moving over the surface of the vane, downwards to get under it, upwards to get over it, so that the rotation in the upper vortex is opposite to that in the lower. All this is just the same as before, but instead of these vortices standing still as before, they follow at a definite distance from the vane, which continues its motion along the tank without resistance.

Now this experiment shows, in the simplest form, the *modus operandi* by which internal waves can exist in fluid without any motion in the external boundary. Not only is this plate moving flatwise through the water, but it is followed by all the water, coloured and uncoloured, enclosed in these cylindrical vortices. Now, although there is no absolute surface visible, yet there is a definite surface which encloses these moving vortices, and separates them from the water which moves out of their way. This surface will be rendered visible in another experiment I shall show you. Thus, the water which has only wave motion is bounded by a definite surface, the motion of which corresponds to the wave; but inside this closed surface there is also water, so that we cannot see the surface, and this water inside is moving round and round, but so that its motion at the bounding surface is everywhere the same as that of the outside water.

The two masses of water do not mix. That outside moves out of the way of and past the vortices over the bounding surface, while the vortices move round and round inside the surface in such a way that it is moving in exactly the same manner at the surface as the wave surface outside.

This is the key to the internal motion of water. You cannot have a pure wave motion inside a mass of fluid with its boundaries at rest, but you have a compound motion, a wave motion outside, and a vortex within, which fulfils the condition that there shall be no sliding of the fluid over fluid at the boundary.

A means which I hope may make the essential conditions of this motion clearer occurred to me while preparing this lecture, and to this I will now ask your attention. I have here a number of layers of cotton-wool (wadding). Now I can force any body along between these layers of wadding. They yield, as by a wave, and let it go through; but the wadding must slide over the surface of the body so moving through it. And this it must *not* do if it illustrate the conditions of fluid motion. Now, there is one way, and only one way, in which material can be got through between the sheets of wadding without slipping. It must roll through; but this is not enough, because if it rolls on the under surface it will be slipping on the upper. But if we have two rollers, one on the top of the other, between the sheets, then the lower roller rolls on the bottom sheet, the upper roller rolls against the upper sheet, so that there is no slipping between the rollers or the wadding, and, equally important, there is no slipping between the rollers as they roll on each other. I have only to place a sheet of canvas between the rollers and draw it through; both the flannel rollers roll on the canvas and on the wadding, which they pass through without slipping, causing the wadding to move in a wave outside them, and affording a complete parable of the vortex motion.

I will now show by colour bands some of the more striking phenomena of internal motion, as presented by nature's favourite form of vortex, the vortex ring, which may be described as two horse-shoe vortices with their ends founded on each other.

To show the surface separating the water moving with the vortex from that which gives way outside, I discharge from this orifice a mass of coloured water, which has a vortex ring in it formed by the surface, as already described. You see the beautifully-defined mass moving on slowly through the fluid, with the proper vortex ring motion, but very slow. It will not go far before a change takes place, owing to the diffusion of the vortex motion across the bounding surface; then the coloured surface will be wound into the ring which will appear. The mass approaches the disc in front. It cannot pass, but will come up and carry the disc forward; but the disc, although it does not destroy the ring, disturbs the motion.

If I send a more energetic ring, it will explain the phenomenon I showed you at the beginning of this lecture; it carries the disc forward as if struck with a hammer. This blow is not simply the weight of the coloured ring, but of the whole moving mass and the wave outside. The ring cannot pass the disc without destruction with the attendant wave.

Not only can a ring follow a disc, but, as with the plane vane, so with the disc; if we start a disc, we must start a ring behind it.

I will now fulfil my promise to reveal the silent messenger I sent to those balloons. The messenger appears in the form of a large smoke ring, which is a vortex ring in air rendered visible by smoke instead of colour. The origination of these rings has been carefully set so that the balloons are beyond the surface which separates the moving mass of water from the wave, so that they are subject to the wave motion only. If they are within this surface they will disturb the direction of the ring, if they do not break it up.

These are, if I may say so, the phenomenal instances of internal motion of fluids. Phenomenal in their simplicity, they are of intense interest, like the pendulum, as furnishing the clue to the more complex. It is by the light we gather from their study that we can hope to interpret the parable of the vortex wrapped up in the wave, as applied to the wind of heaven, and the grand phenomenon of the clouds, as well as those things which directly concern us, such as the resistance of our ships.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The Curators of the University Chest have been authorised by Congregation to pay the following sums.

To the Delegates of the Museum, a sum of £140 for each of the years 1894, 1895, for the general expenses of the Museum.

To the Curators of the Botanic Garden a sum not exceeding £200, to provide for expenses incurred in connection with the erection of new houses in the garden.

The Curators of the University Chest have been authorised to expend a sum not exceeding £700 in making the rooms in the south corridor in the Museum, and the lofts over them, available for the use of the Hope Professor of Zoology, and to pay to the Hope Professor of Zoology, in addition to the statutable grant, the sum of £100 for each of the years 1894–1898, to provide for the salary of the attendant and other expenses of the Department.

The Delegates of Local Examinations have approved of the introduction of a new examination in the course for junior candidates in elementary physiology and hygiene.

Amongst those on whom it is proposed to confer the honorary degree of D.C.L. at the Encænia, is the name of Mr. Francis Galton, F.R.S.

One or more Natural Science Demyships, and Natural Science Exhibitions will be awarded by Magdalen College in October this year, the examination to commence on Tuesday, October 9.

At Wadham College, in the Scholarship examinations which will begin on Thursday, November 29, no papers in natural science will be set, but in the election to one of the Exhibitions preference will be given to any candidate who shall undertake to read for honours in natural science, and to proceed to a degree in medicine in the University of Oxford.

At Keble College an election will be held to one Scholarship in natural science of the value of £60 per annum, with laboratory fees not exceeding £20 per annum, on December 11 next. The examination will consist of papers in biology and chemistry, and all inquiries respecting the examination should be addressed to Mr. W. Hatchett Jackson, Keble College. The examination will begin on Thursday, December 6.

Mr. R. Warington, F.R.S., has been elected to the Sibthorpian Chair of Rural Economy, in succession to Sir John Gilbert.

CAMBRIDGE.—This year, for the first time on record, there is a bracket of two for the Senior Wranglership. In 1887 four names were bracketed for the highest place. These are the only instances in which the Senior Wrangler of the year has not stood "alone in his glory." Messrs. W. S. Adie and W. F. Sedgwick, both of Trinity College, share the honour. There is one lady wrangler, Miss E. H. Cooke, of Girton, who is bracketed twenty-eighth. In the second part of the Mathematical Tripos, a lady of Newnham, Miss A. M. J. E. Johnson, who was between fifth and sixth in the first part last year, heads the list, as she is placed alone in the first division of the first class. The Tyson Medal, for astronomy, offered this year for the first time, is not awarded.

Seven names appear in the first list of the Mechanical Sciences Tripo, all three of those in the first class having already taken the B.A. degree on some other examinination.

The Harkness Studentship in Geology has failed of award, in the absence of candidates.

The degree of Sc.D. is to be conferred on Professor Demetri Ivanovitch Mendeléef, of St. Petersburg, who was not able to accept the honour when it was offered him in 1889.

The following are appointed examiners for the new diploma in Agricultural Science: W. F. Darwin, Mr. W. G. P. Ellis, Professor Liveing, Mr. T. B. Wood, Professor Foster, Mr. A. Eichholz, Mr. A. E. Shipley, Mr. C. Warburton, Professor Hughes, Mr. P. Lake, Mr. O. P. Fisher, Mr. E. Clarke, and Mr. R. Menzies.

THE Scottish Association for the Promotion of Technical and Secondary Education have presented a memorial to Mr. Acland asking that the yearly examinations of the Department of Science and Art shall be held in the day as well as in the evening. It is pointed out that originally arranged, as they were, to suit the convenience of artisan pupils who could not be expected to attend during the day, these evening examinations are now taken by large and increasing numbers of pupils of secondary and higher grade schools. While, therefore, fully recognising the necessity which exists for examinations in all stages of art and science subjects being continued in the evening as heretofore, the memorialists urge the desirability of provision being made by the Department for the examination, within school hours, of pupils attending day schools.

SIR PHILIP MAGNUS has been appointed to represent the University of London at the bicentenary celebration of Halle University, to be held in August next.

SCIENTIFIC SERIALS.

Bulletin de l'Académie Royale de Belgique, No. 3.—Experimental demonstration of the purely accidental character of the critical state, by P. de Heen. A small quantity of amylene was introduced into the bottom of a tube, and surmounted by mercury, the tube being so thin that the mercury remained at the top. The tube was placed inside a box with glass windows, which was then heated to temperatures ranging from 201° C., the critical temperature of amylene, to about 350°. The tube was connected at the top with a Cailletet compression apparatus. It was found that even under pressures less than 5 atmospheres the amylene could be heated to 350° without evaporating. The critical state, characterised by turbulent movements, was never exhibited, but if by some accident a small quantity of vapour was formed the critical state set in at once. The author concludes that the critical state consists of a non-homogeneous mixture of "liquidogenic" and "gazogenic" molecules. At a certain high temperature, estimated for most liquids at 800° or 900°, the former are completely dissociated, and the pressure-volume curve becomes a simple isothermal. But the state of a fluid is not defined by pressure and temperature alone, since at the critical temperature, and at zero pressure, the volume can vary from unity to infinity.—Facts relating to the properties of carbon bisulphide, by H. Arctowski. The boiling point of pure carbon bisulphide is 46°·27, but this rises steadily during the process of determining it. The bisulphide is partially decomposed by the sun's rays, by moist air, and by a slight elevation of temperature continued for some time.—On the solubilities of the haloid salts of mercury in carbon bisulphide, by the same author. These salts show different solubilities, the iodide being the most, and the chloride the least soluble. The solubilities show a point of upward inflection at about 15° C. From 15° to −10° the lines of solubility converge in such a manner that if produced they would meet the axis of solubilities at a point corresponding to −25°.—Some experiments in experimental pathological embryology, by P. Francotte. Some ova of *Leptoplana tremellaris* were opened with a find steel point to admit schizomycetes. The microbes were either digested or excreted. The author concludes that microbian diseases cannot be transmitted by either ova or spermatozoa.

THE *Meteorologische Zeitschrift* for May contains a discussion of the results of meteorological observations on the Pic du Midi, by Dr. F. Klengel. The observations dealt with are those made during the years 1874-81 (excepting 1877), at the Plantade station, situated at a Pass, at an elevation of 7760 feet, and they furnish important materials respecting the climatic peculiarities of the high Pyrenees. The mean temperature was 34°·2; the absolute minimum was −11°·2 in January 1878, and the maximum 77°·4, in August 1881. Frost was observed on an average on 224 days in the year; the absolute maxima in all months were above 32°, and the minima mostly below 32°, even in July and August. The rainfall was exceedingly copious, amounting in the year to no less than 93·5 inches, a quantity which is only equalled at a few other places in Europe. The wettest month was April, with 18 inches, and the dryest July, with 2·7 inches. The distribution of rainfall throughout the year was extremely irregular; the number of wet days in the year amounted to 184. The most prevalent winds were from northwest, 25 per cent., and from south-west, 23 per cent. The French Meteorological Office has published in its *Annales* the observations made at the summit of the mountain since October 1881, at a still greater altitude; these will, no doubt, be dealt with in a subsequent paper.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 24.—"Measurements of the Absolute Specific Resistance of pure Electrolytic Copper." By J. W. Swan and J. Rhodin.

This paper is a record of measurements of the absolute specific resistance and temperature coefficient of pure electrolytic copper. The authors compared a large number of different specimens of electrolytic copper. Several of the specimens were at first roughly examined, and the best chosen for further investigation. The best of these was then electrolytically refined. This, without previous fusion, was drawn through sapphire dies to the requisite diameter, and the resulting wire subjected to careful measurements. The first specimen, "A," was measured both when hard and also after annealing at a red heat in an atmosphere of carbon dioxide gas; the second sample, "B," was only examined after annealing. The authors took extreme care in finding the dimensions of the wires and the temperatures at which they were measured.

The values of the two specimens in C.G.S. units were as follows, the density being 8·9587 at 15° C.

	Absolute specific resistance. C.G.S. units.	Temp. coefficient. Δt.
Sample A. Hard, as drawn......	1603	0·00408
,, A. Soft, as annealed....	1566	0·00418
,, B. Soft, as annealed....	1559	0·00415

May 31.—"On Rapid Changes of Atmospheric Temperature, especially during Föhn, and the Methods of observing them." By J. Y. Buchanan, F.R.S.

In July 1893, on the west coast of Scotland, föhn of a well-defined type prevailed. It was characterised by puffs of very hot air occurring every two or three minutes in the midst of the abnormally warm air of the day. On July 7 and 8 these hot puffs were felt very strongly, and especially on the water. Attempts to measure their temperature with a thermometer proved unavailing, as their temperature was so high and their duration so short that the thermometer had only begun to rise when the heating cause had passed. Between August 18 and 23 exactly the same character of weather was observed in the valleys around Pontresina in the Engadine. The hot puffs were very remarkable. The weather was recognised by the people as "föhn." Here the inadequacy of the thermometer as usually employed was again apparent. Observations were made on the exchange of heat taking place between the hot föhn wind and the Morteratsch glacier over which it was blowing. The temperature of the air was observed at a station on the glacier, and at a station at the same altitude on the mountain at its side. The temperature of the air at the land station was found very variable, altering as much as 2° C. in five minutes. By making a number of observations during quarter of an hour a mean value was obtained for comparison with the temperature over the ice. On land the average temperature of the air in the afternoon was 16·5 C.; over the ice, and at a height of one metre above it the temperature was 10° C., and when the thermometer was laid horizontally with its bulb at distances between two centimetres and two millimetres from the ice, the lowest temperature of the air in that position was 5°·5 and the highest 7°·5. The wind blew over the glacier at a speed of eight to ten kilometres per hour, and was a fresh breeze, which might have been expected to thoroughly mix the air, yet the result of repeated observations showed that well-defined temperature gradients were produced and maintained in the air between the ice and a height of a metre above it. Between one metre and one millimetre above the ice the gradient is moderate, averaging 3°·5 per metre. In the thin layer next the ice the gradient is precipitous. The occurrence of the highly-heated puffs of air due to the föhn directed attention to the measurement of rapid variations of temperature generally. An approximation was made to their estimation by noting the rate at which the thermometer began to rise in one of these puffs, and then determining experimentally the excess of temperature of the air required to produce this effect. This could not be satisfactorily done at the time, but attention was paid to it later.

This method seemed to be the only one by which ordinary thermometers can be made to indicate truthfully changes of temperature which are not extremely slow. The method was applied in the case of a series of temperatures observed at very close intervals during the first two hours after sunrise on several days in February at St. Moritz. The temperature of a thermometer freely exposed to the north was observed at intervals of twenty seconds. These are summarised in a table. The temperature exhibited generally two falls for every three to four rises; the largest rise or fall in twenty seconds was 0°·5 C. From careful experiments on the rate of cooling of the thermometer, both in a room and in the open air when the air was still, it resulted that to produce a rise of temperature of 0°·5 in twenty seconds, the temperature of the air at the beginning of the interval must have been at least 2°·25 C. higher than that of the thermometer at the same instant. If there had been a fall of the same amount, then the temperature of the air must have been as much lower than that of the thermometer at the beginning of the interval. So that if, in any two consecutive intervals of twenty seconds, the thermometer showed a rise of 0°·5 and a fall of the same amount, the apparent temperature of the air at the beginning and the end of the interval is the same, whereas the true temperatures differ by 2 × 2·25 − 0·5 or 4°·0 C. A table is given in the paper of the temperatures observed at intervals of twenty seconds during a few minutes on February 26, when the variations were considerable. The differences of temperatures required to produce the observed changes are given, and from them the amended or true temperatures are deduced and tabulated. The true variations of temperature are naturally much more abrupt than the apparent ones.

The concluding part of the paper deals with the employment of the thermometer as a calorimeter. For this purpose it is necessary, besides the rate of cooling, to know the "thermal mass" or water value of the bulb. A method is indicated by which this can be ascertained with very considerable accuracy by the measurement of the volume of the bulb. The circumference of the bulb is best determined by winding fine thread round it in a close spiral for a certain number of turns, then measuring the length of the unrolled thread. When the specific heat of mercury and that of ordinary glass are expressed in terms of unit volume they are very nearly identical; namely, 0·449 for mercury, and 0·466 for glass. It is clear that if the mean of the two is taken to represent the specific heat of the bulb, an error of not more than two per cent. is made in the extreme case when the bulb consists of all mercury or all glass. When the thermal mass and the rate of cooling of a thermometer have been determined, its usefulness as a metereological instrument is increased manifold.

Chemical Society, May 17.—Dr. Armstrong, President, in the chair.—The following papers were read:—The influence of moisture on chemical change, by H. B. Baker. Highly purified lime and carefully dried copper oxide do not combine with sulphur trioxide; dry ammonium chloride may be sublimed from a mixture with lime without the liberation of ammonia. Pure dry nitric oxide gives no brown fumes with dry oxygen, although the addition of a trace of moist air causes immediate interaction. Carefully dried ammonium chloride does not dissociate on volatilisation, the vapour having the density 28·7.—New volatile compounds of lead sulphide, by J. B. Hannay. The observed volatility of lead sulphide in water vapour may be explained by assuming the existence of gaseous compounds of lead sulphide and water; the author concludes that a definite compound of the composition PbS,H_2O exists. Evidence in support of the existence of a compound of the composition PbS,SO_2 is also brought forward; both these substances are colourless gases at a red heat, but decompose below 800°.—Notes on the cupellation of bismuth-silver alloys, by E. A. Smith.—Azo-*p*-cresol derivatives, by R. Meldola and F. Southerden. The authors have endeavoured to determine the constitution of several ortho-azo-derivatives of paracresol by treating their acetyl derivatives with nitric acid or bromine.—Effect of heat on iodates and bromates, by E. H. Cook. During the fusion of potassium bromate and iodate, bromine and iodine are respectively evolved; no halogen is given off after melting is complete, and after continued heating to drive off all the oxygen, only potassium bromide or iodide remains.

Geological Society, May 23.—Dr. Henry Woodward, F.R.S., President, in the chair.—On the stratigraphy and physiography of the Libyan Desert of Egypt, by Captain H. G. Lyons, R.E. The Nubian sandstone, wherever seen, rests unconformably on the old rocks called by Sir J. W. Dawson Archæan, and the author found no case of alteration of sandstone by these rocks, though in one case it is altered by an intrusive dolerite. The author considered the Nubian sandstone to be an estuarine deposit which was formed on an area afterwards gradually invaded by the Cretaceous sea. He considered the whole of the sandstone in the region which he had examined to be of Cretaceous age. He described a series of anticlinals, one set running W.N.W.-E.S.E., and the other N. by E. and S. by W. Many springs of the oases seem to occur along these anticlinals, owing to the beds which contain the water being brought nearer to the surface. Historical evidence was discussed which points to the Nile having reached a higher level in Nubia than it does at present, and it was suggested that variations in the level of the river were caused by earth-movement opposing obstructions to the river's flow. The sandstone of Jebel Ahmar near Cairo was described, and its occurrence over a wide area west of Cairo recorded. The author considered its age to be later Miocene. He believed that, with the exception of some erosion after the deposition of the Eocene beds, the greatest erosion, including the cutting-out of the Nile Valley, took place in Miocene times, while a certain amount, bringing the area to its present condition, was done in Quaternary times. This agrees with the observations of the French geologists in Algeria. The origin of the silicification of the fossil trees of the sandstone-deposits was discussed, and the action of water containing sodium carbonate suggested as a cause. The President, Mr. Hudleston, and the Rev. G. Henslow having made remarks upon the paper, Prof. Hull said he concurred with the view of the author that the course of the Nile above Cairo had been determined by the line of fault, which follows the valley for many miles upward. As regards the age of the Nile in Egypt, he considered it as referable to the Miocene stage rather than to the Pliocene. The Miocene period in that part of the world was one in which the main features of the present land-areas received their general contours. Referring to an observation by Mr. Hudleston regarding the absence of carboniferous beds in the Nile Valley, he reminded the Society that deposits of this age had been discovered by Dr. Schweinfurth in the Wady-el-Arabah between the Nile and the Gulf of Suez. Dr. Irving, remarking on the silicification of wood, said he wished again to emphasise the difference in the action of carbonic acid in petrological changes, according as it existed as a free acid or in combination with a base, as in sodium carbonate. The extent of the "Natron" deposits pointed to the supply of alkaline waters over large areas in former times, holding the mineral in solution. The reaction of such waters upon the potash-felspar of the sands, furnished by the disintegration of the crystalline rocks, would not lead to the deposition of free silica (as in the ordinary process of kaolinisation), because, while the potassium was taken up as a carbonate and carried away, the silica was also removed in solution, through combination with the sodium, to form sodium silicate. This last-named salt in solution would be readily decomposed by the organic acids and the carbonic acid furnished by decaying vegetable tissue, the silica being then deposited as a colloid *in situ*, and thus retaining the structural forms of the original tissue. The author briefly replied.—Notes on the geology of South Africa, by Mr. D. Draper. The district considered includes Natal, Zululand, Swaziland, the south-east part of the Transvaal, and the eastern part of the Orange Free State and of Basutoland. Physically it comprehends:—(1) The Drakensberg Range; divided into (*a*) mountain portion; (*b*) hill-covered plateau; (*c*) Highveld plateau; (2) the terrace along its foot; (3) the coast-belt. Their main features and characteristics were described. The geological formations are:—

Karoo Beds.	Upper.	1. Volcanic Beds.
		2. Cave Sandstone.
		3. Red Beds.
		4. Molteno Beds.
	Lower.	5. Beaufort Beds.
		6. Ecca Beds.
		7. Dwyka (Ecca) Conglomerate.
		[Bokkeveld Beds, wanting,]
Palæozoic.		8. Gats Rand (Zuurberg) Quartzite.
		9. Dolomitic Limestone.
		10. Table-mountain Sandstone.
		11. Malmesbury Schists.
		12. Gneiss and Granite.

—On the occurrence of dolomite in South Africa, by the same author. A peculiar calcareo-siliceous rock, near Lydenburg, described by Messrs. Penning and Crutwell as "Chalcedolite," and a similar rock mentioned by Mr. Penning as overlying the "Blackreef Series" of the Megaliesberg formation, have been recognised as a dolomite. Mr. C. Alford has described a "calcareous quartzite" as passing into dolomite and ultimately into chert, and known as the "Elephant-rock" in Transvaal, sometimes cavernous with underground waters. From his own experience Mr. Draper has recognised the "Elephant-rock" in the Potschefstroom, Lichtenburg, Malmani, and Lydenburg districts as a real dolomite, with interstratified siliceous bands, weathering into a brown earth like manganese oxide and superficial siliceous débris. It has its place between the Table-mountain sandstone and the quartzite of the Gats Rand (= Zuurberg quartzite of the Cape). It has auriferous veins in Malmani and Lydenburg. Dr. Schrenck has noticed a similar dark-blue dolomitic limestone in Great Namaqualand. The deep water-holes in it in Malmani are comparable with those found by F. Galton in West Central Africa. The great caves in Mashonaland may belong to it. The extensive tufaceous deposits in Griqualand-West, the Transvaal, and Orange Free State were probably derived from this extensive dolomite. Mr. Rutley, Mr. Nicol Brown, and Prof. T. Rupert Jones took part in the discussion that followed.—Contributions to the geology of British East Africa, by Dr. J. W. Gregory. The author described moraines, striæ, glacial lake-basins, perched blocks, and *roches moutonnées* below the present limits of the glaciers of Mount Kenya, which he maintained to indicate the existence of a "calotte" or ice-cap extending at least 5400 feet farther down the mountain than the termination of the present glaciers, and possibly farther, for in the belt of forest detailed observations could not be made. He agreed that this more extensive glaciation was produced by a greater elevation of Mount Kenya, and that any theory of universal glaciation is unnecessary, and indeed opposed by many facts in African geology. He discussed the probable influence of this former glaciation on the meteorological conditions of the surrounding area and the distribution of its flora and fauna.

PARIS.

Academy of Sciences, June 4.—M. Lœwy in the chair.—On the composition of apophyllite, by M. C. Friedel. No positive evidence of the presence of fluorine in this mineral could be obtained with specimens from Bou Serdoun (Algeria). Instead of an acid reaction, the water evolved possessed an alkaline reaction in the cases of specimens from Bou Serdoun, Andreasberg, Guanajuato (Mexico), Greenland, Nova Scotia, and Utö (Sweden). There is no fluorine in the samples examined; that reported by previous observers is probably due to the imperfect methods of analysis employed; on the other hand, they contain ammonia in quantity varying from 0·03 to 0·5 per cent., possibly replacing a part of the potassium. The evidence available is insufficient to settle the formula expressing the composition of apophyllite.—Report on a memoir by M. Bazin on experiments on the contraction of liquid jets and the distribution of velocities in their interior, by MM. Resal, Maurice Levy, Sarrau, and Boussinesq.—Transmission of sounds, by M. Henri Gilbault. The amplitudes of vibration being represented by y, and distances by x, it is shown that the law xy = a constant is not verified in practice for small values of x.—On the value of the theoretical ohm, by M. A. Leduc. The author shows that a part of a correction, considered unimportant by M. Wuilleumier, must be applied to the results obtained by the latter according to M. Lippmann's method. These results then give for the length of a column of mercury at 0° C. and of 1 sq. mm. section representing the theoretical ohm, the value 106·32 cm. in place of 106·267 cm. The revised value is in close accord with the mean of the best determinations made by other methods.—On the method of transformation of work into electric energy, by M. Vaschy.—On alternating currents and Wheatstone's bridge, by M. H. Abraham. A method is described for obtaining the frequency of the alternations by bridge measurements.—The *skiascope-optomètre*, by M. H. Sureau. A description of the use and parts of an instrument for the examination of the eye by opticians.—New researches on the chloroboracites, by MM. G. Rousseau and H. Allaire. The author describes the production and properties of compounds of zinc, cadmium, nickel, cobalt, and manganese having the general formula $6MO . 8B_2O_3 . MCl_2$.—On the *rôle* of the transformations of iron and carbon in the hardening of steel, by M. Georges Charpy. The following conclusions are drawn from the experimental results given. Hardening produces, among other modifications, a transformation of the iron (characterised by the breaking strain) and a transformation of the carbon (characterised by the variation of the results by the Eggertz test). The transformation of the iron appears to have but a feeble influence on the breaking strain, whereas the transformation of the carbon appears to be correlative with the augmentation of hardness.—On a hydrobromide of cupric bromide and on a red bromide of copper and potassium, by M. Paul Sabatier. The formula $CuBr_2 . HBr . 2H_2O$ is attributed to the substance obtained in black *chatoyant* crystals by cooling a concentrated solution of cupric bromide into which hydrogen bromide has been passed. The double compound with potassium is $CuBr_2 . KBr$. It forms fine, deliquescent, rhombic plates, which are very opaque and apparently black, but are seen to be red in thin sections.—On the analytical separation of chlorine and bromine, by M. R. Engel. The bromine is separated by oxidation with ammonium persulphate, and distilled off into a sulphurous acid solution, from which it is precipitated as silver bromide. Under the conditions given, the chlorine is not affected.—On the detection of hydrobromic acid, by MM. A. Villiers and M. Fayolle.—New derivatives of cyanacetic and cyanosuccinic esters, by M. L. Barthe.—Combinations of pyridine with the permanganates, by M. T. Klobb. A series of compounds parallel with the ammonia derivatives previously described and of the general formula $MMnO_4 . 2C_5H_5N$ or $MMn_2O_8 . 4C_5H_5N$ are given.—On the emetics, by M. Paul Adam. The conclusion is drawn that substances of the emetic type should be considered as ether salts and not double salts.—On monoethylphosphoric acid, by M. J. Cavalier. This acid exhibits, thermally, two clearly distinct functions and gives two series of definite salts, corresponding with the formulæ PO_4EtMH and PO_4EtM_2.—Action of trioxymethylene on alcohols in presence of ferric chloride, and on the new methylene derivatives which result, by MM. A. Trillat and R. Cambier. Mechanism of the action of chlorine on isobutylic alcohol, by M. A. Brochet.—Researches on the red pigmentary matter of *Pyrrhocoris apterus* (L.), by M. C. Phisalix.—On the relations between the dorsal cord and the hypophysis in birds, by M. G. Saint-Remy.—On a new *grégarine* of the family of the Dactylophorides, parasitic on Geophiles, by M. Louis Léger.—On a *Ustilaginée* parasitic on the beet-root (*Entyloma leproideum*), by M. L. Trabut.—On a vine disease caused by *Botrytis cinerea*, by M. L. Ravaz.—Contribution to the study of *géclases conjuguées*, by M. Stanislas Meunier.—Variations of the latent period of coagulation of milk soured by rennet, by M. C. Pagès.

DIARY OF SOCIETIES.

LONDON.

THURSDAY, JUNE 14.

ROYAL SOCIETY, at 4.30.—Flame Spectra at High Temperatures—Part II. The Spectrum of Metallic Manganese, of Alloys of Manganese, and of Compounds containing that Element. Part III. THE BROTHERS WILLIAM AND JOHN HUNTER.

Two Great Scotsmen: the Brothers William and John Hunter. By George E. Mather, M.D., F.F.P. and S. (Glasgow: James Maclehose and Sons, 1893.)

IF too long a time may seem to have passed away before we review this handsomely illustrated volume, we excuse ourselves by saying that before we determined to undertake the task we would read the work through conscientiously and thoughtfully from its alpha to its omega, and compare it with the sources of information from which it is compiled. We saw by the general tone of the press that the volume was being rather roughly treated, and hoped that some prejudice or carelessness had been at work, which might be corrected. It too often happens that treatises on science and on the labours and works of men of science are merely glanced at and spoken of from hastily gathered impressions bearing mainly on style and manner, not on actual matter of fact relating to the work and the mind that produced them. It happens also, not unfrequently, that in a work, difficult of comprehension at its first reading, one or two reviews set the tone for praise or dispraise to all others; so that a good work may, as it were, be, by accident, doomed to light or to darkness without just cause.

Let us say first then of this volume that as a work it is admirably got up and illustrated. The plates, whether they relate to men, buildings, or scenery, are simply perfect, and the volume altogether is just such an one as every scholar would be tempted to take down from the shelves and read at leisure. Let us say further, that through the narrative the author balances fairly between the two brothers, William and John Hunter. He discriminates wisely in regard to their characters, and shows how largely John Hunter was dependent for his success on his elder brother. But in his descriptions he has, too often, adduced sayings and thoughts which he has gathered from reading, and, with little alteration, has transferred to his own pages as if they were his own property. Thus, in comparing the two brothers, he makes use of a paragraph with which the life of William Hunter, by another author, is brought, in capital type, to a close.

"The brothers Hunter were twins in science, and William was the first-born."

A sentence which reads as follows, speaking also of the two brothers.

"Verily they were twin stars of the first magnitude, and William was the elder-born."

Such variations as these give to the volume the character of a compilation rather than a history, the whole appearing tinged also with a sense of weariness, as if its author were endeavouring to make old matter appear new, only too anxious to fill up his pages. To this must be added the introduction of matters almost altogether irrelevant. For example, at pages 40, 41, 42, we find a discussion, or colloquy, between Thomas Carlyle and Edmund Irving, with a long quotation from Carlyle, interesting enough in itself, but having not the slightest reference to the subject in hand. In like manner there is dragged in, at page 46, a description of the Manse at Mearns, where Christopher North received his early education, with a somewhat similar diversion on North Moorhouse, where Robert Pollok, the author of "The Course of Time," was born, together with a specimen of the poetry of the same poet, and a final digression containing snatches from the Ettrick Shepherd, Joanna Baillie, Prof. Wilson, and a rather long account of the famous Dr. Cullen, who, although a kind of master of William Hunter in his early life, is so much in evidence here, as to be made subject-matter for a third short biography, rather an intrusion when so much more admitted of being spoken of in reference to the two particular heroes of the book.

In noticing the labours of William Hunter, Dr. Mather is most at home in his description of the Hunterian Museum in Glasgow. With this palace of science he is evidently well acquainted. He remembers it in its old days, when it rose like an ancient temple in the grounds of that memorable old college which is now a railway station, and he knows it as it now stands, a part of the splendid new college which, as he says, "crowns the heights of Gilmorehill." The museum, he tells us, was begun for the purpose of illustrating the lectures of William Hunter, and at first its chief value consisted in the preparations showing the changes of the gravid uterus. "The Museum was not, however, confined," as he very properly explains, "to anatomical preparations, human and comparative, nor to specimens of disease merely, although the collection of these was wonderful, and thanks to hints from Albinus, all are in beautiful preservation. "Dr. Hunter was a man of very refined taste, and had a great desire to educate the members of his own profession, as well as the public, in this respect, and to afford opportunity to all of acquiring a rich and varied culture. William Hunter was a great teacher, and it was his ambition that his works, his bequests, should live and speak after him; it is not too much to say that there never has been gathered under one roof by one man a collection so vast and varied, and so well calculated to advance the wider culture of the members of the profession whose interests he had so greatly at heart.' And then he adds, copying word for word from a previous author, whom he immediately names, but not in connection with the passage: "Whether we turn to the Art Department, to the books, to the coins, to the natural history, or to the anatomy, there is to be discovered treasure upon treasure."

In the life and works of John Hunter presented in this volume, we find the same kind of faults as those which mark the life of William Hunter. There is compilation simply as the basis of all that is written, intermixed with a kind of philosophy which is also often the reflex of previous authorities, with more or less of acknowledgments. Much that might have been introduced and descanted upon is omitted, or so lightly touched as neither to be criticism nor narrative. Thus the great quarrel between the two brothers, which kept them practically apart for a long period, receives no new elucidation, and the life of John Hunter, at Earl's

Court, in the house recently pulled down and replaced by so many houses and streets that its site is now lost, receives the most scanty attention. Here, too, illustration fails us, which is much to be pitied, because illustration in the former part of the book has afforded its chief value.

There is nothing more painful to a reviewer than to find himself forced to discover faults and deficiencies in a work under his observation, and we have felt severely the task of pointing out the defects and deficiencies of the volume before us. But it would be false, even to the author of the work, if we did not notice its failures, for there is evidently an ardent desire on his part to be not only a faithful, but an enthusiastic biographer. What is wanted in his essay is work! work! work! expurgation of all that is irrelevant, introduction of all that can be added beyond what has been told by predecessors on the subject, with avoidance of the pitfalls of mere memory.

In a new edition, if it should appear, we will hope that the improvements suggested, in a perfectly friendly spirit, will be carried out. The volume as it now stands is a groundwork of a good treatise, which, under the influence of industry, learning, spontaneity, and art, might yet secure a good place in the literature of the century.

GOLD.

The Metallurgy of Gold. By T. Kirke Rose, B.Sc. (London: Charles Griffin and Co., 1894.)

A Handbook of Gold Milling. By Henry Louis. (London and New York: Macmillan and Co., 1894.)

THESE two books, which have been issued almost simultaneously, constitute important additions to the metallurgy of gold. They are both written by Associates of the Royal School of Mines, and it is singular that although the students of this great national institution have taken their full share in conducting mining and metallurgical operations in all parts of the world, and have gained wide experience, no treatise claiming to give a general account of the metallurgy of gold could hitherto have been attributed to a student of the School of Mines. No work on this subject of equal importance has appeared in English since Dr. Percy issued his volume on "Silver and Gold," in 1880, but his book, although unrivalled in accuracy of detail, is only a splendid fragment, and gold is alone dealt with in the sections devoted to the refining of bullion and to assaying.

Mr. Rose, who it appears gained his experience of gold and silver extraction in the Western States of America, is one of the able band of young men of whom Prof. Roberts-Austen is forming, in this country, a new school of metallurgists which is doing so much physical work in connection with metals and alloys. In the present volume Mr. Rose has made a successful effort to supply a succinct summary of the existing conditions of the metallurgy of gold for the use of students and others who are interested in the industries connected with the precious metals. In the second volume under review, Mr. Louis turns, it is true, more directly to an industrial application of the metallurgy of gold, and addresses the mill-man rather than the student; but Mr. Rose's volume is far from being only a student's manual, as he keeps steadily in view the needs of the managers of the gold mine and smelting works, a class who have hitherto considered that they had "little to learn from books."

The whole of the ground indicated by the title "metallurgy of gold" has been covered by Mr. Rose with equal care, and the space is carefully apportioned to the various branches of the subject according to their relative importance. Mr. Rose is probably at his best in dealing with the chemistry of the subject, as, for instance, in describing the MacArthur-Forrest process, which is now, for the first time, fully dealt with in a manual. Its importance may be gathered from the fact that nearly one-tenth of the world's annual production of gold is now being extracted by its aid. Among other processes which have not hitherto been described in a book, three deserve special mention. These are the process for separating gold from silver by the new Gutzkow process; the electrolytic process; and the modern barrel chlorination process, which is practised with great success in Dakota, where the Black Hills district is being rapidly developed by its aid. These processes are of special interest, but none which have stood the test of experience have been omitted. The four chapters devoted to chlorination, written from the point of view alike of the practical man and the chemist, teem with considerations hitherto unrecognised, and constitute an addition to the literature of metallurgy, which will prove to be of classical value.

The author has evidently taken great pains to secure details of gold-working from all parts of the world, and his descriptions range from Colorado to New Zealand and thence to South Africa, and as a result he has furnished practical men with details of working which should be of much service to them.

No less than eleven pages are devoted to an elaborate bibliography that is certainly more complete than any earlier ones, the latest of which—in Lock's work on the occurrence of gold—only brought us to the year 1882.

The illustrations are simple but effective; they are sufficiently accurate, and are characterised by much freshness, there being no time honoured diagrams from other metallurgical manuals. The same may be said of the illustrations in Mr. Louis' work.

Mr. Louis, in his book on "Gold Milling," has mainly limited his attention to the treatment of gold ores in stamp mills, and has, as the result of much personal experience, written a treatise of great practical value. He gives details of machinery with great fidelity, as a worthy pupil of the late Dr. Percy would be sure to do. While Mr. Louis clearly sets forth the general methods of working adopted in stamp mills, he reserves for full description those which he considers to be the best, instead of giving details of all methods, good, bad, and indifferent, that are to be met with in various parts of the world.

In a future edition the author would do well to devote additional space to considerations relating to the mill site, its building, modes of construction, and installation of machinery. These are of more importance to the mill manager, for whom the work is intended, than the shape of the cam-curve, and other points to which the maker of machinery should attend. The experience gained in the South African gold-fields, where the number of stamps at work is greater than in any other country, has led to great developments of practice, which it would be well to consider when the time comes for revising the work. If, however, the book be considered as a whole, Mr. Louis has undoubtedly offered the best account of gold milling that has yet appeared.

In concluding this review of both books, it may be well to remind the reader that, of all the phases of metallurgic art, that which leads to the consideration of gold is the most interesting. It is certain that modern chemistry had its dawn in the study of the properties of gold, while from the fourth to the fifteenth century chemists thought of little else than transmuting base metals into precious ones. The protest of the metallurgist against such wasted labour was, however, felt as early as the middle of the sixteenth century, and a book, "Rechter Gebrauch d'Alchemei," was published (1531), which by its title showed that the "right use of alchemy" was to bring chemical knowledge to bear upon industry. Hence it is that the modern metallurgist makes strenuous efforts not to transmute base metals into gold, but to extract it economically from a mass of material of which fifteen million parts may only contain one part of gold. It would be most interesting to know at what cost this is done, but upon this point Mr. Rose is unable to give us very definite information, though it is evident he considers that the ounce of fine gold which sells for about £4, should be produced for about £3, if it is to yield a profit to the miner and metallurgist.

Both books under review have each their special value. Mr. Rose has adopted a broad treatment of a very interesting subject, while Mr. Louis has shown how important a single branch of the metallurgy of gold can be.

OUR BOOK SHELF.

Geology. By Charles Bird, B.A., F.G.S. Pp. viii., 430. (London: Longmans, Green, and Co., 1894.)

LIKE the previous volumes in the series of Advanced Science Manuals published by Messrs. Longmans, this satisfies the requirements of the advanced stage of the Department of Science and Art. A sub-title informs us that the book is "a manual for students in advanced classes and for general readers." But while we believe the work to be well suited for use among students learning geology on South Kensington lines, we should be sorry to recommend it to the general reader, that is to say, to the person who reads geology for the pleasure it affords, and not with the idea of eventually exercising the acquired knowledge in an examination room. The author has collected together an abundance of facts, but the student who has to digest them all deserves our sympathy. There are, however, several good points about the book. One of these is the chapter on the industrial uses of rocks, in which numerous buildings, monuments, and other structures in London and elsewhere are noted as examples of various kinds of building materials. References to the practical application of geology to water supply, agriculture, and mining are also frequently made, and will doubtless endear the book to the man who measures the value of a science by its direct use in commercial life.

Mr. Bird has taken advantage of the splendid collection of photographs of geological formations published by Messrs. Wilson, of Aberdeen. The illustrations obtained from this source are among the best in the book, and many of them have not previously appeared in any work on geology or physiography. Another excellent feature in the pictorial part of the book is that a number of the figures of fossils, rocks, and minerals are from photographs of objects in the Jermyn Street Museum. The illustrations of some of the minerals are, however, not very instructive. The only use of a figure is to assist the student to distinguish the characteristics described in the text. It is doubtful, however, whether the figures of hornblende, heavy spar, fluor spar, iron pyrites, galena, and sulphur, given on pp. 24-30, are any help to identification, though one or two of them may serve to illustrate crystalline habit.

Scarcely any attention is paid to the microscopical examination of rocks, and we have vainly consulted the index for references to the use of the seismograph, earth-tremors, the permanence of ocean basins, secular movements of the sea, and several other subjects of recent work. Even if these matters are not specially mentioned in the syllabus which the book has been designed to meet, they might have been included with advantage. We note that Eozoon is still referred to as "the most ancient fossil known," though its mineral formation has been clearly made out. But taken altogether the book is trustworthy, and the student who assimilates its contents need not fear to present himself for the examination in Advanced Geology held by the Department of Science and Art.

The New Technical Educator. Vol. III. (London, Paris, and Melbourne: Cassell and Company, 1894.)

THE previous volumes of this series have been duly noticed in these columns, where it was pointed out that they very adequately fulfilled a useful purpose. The present volume is up to the level of its predecessors, treating as it does of every-day general engineering and other matters in their broadest sense. The information given is certainly of very recent date, and this is as it should be, from every point of view. There are, however, a few statements made that are not quite accurate: for instance, on p. 102 we are told that among other things wrought iron is supplied commercially in the form of rails. What railways now-a-days use iron rails? They are things of the past, steel having years ago taken their place. Further on we read that steel plates may now be obtained up to 70 square feet in area. Surely double this area would be nearer the mark? On page 105 we are told that fullering a rivetted joint means to caulk it with a narrow edge tool (as at C, Fig. 3). This is certainly not the case: to fuller a joint means to "set up" the plate edge with a tool at least the thickness of the plate, whereas the method shown in the figure is generally known as "narrow edge caulking." Further on it is stated that looseness at the rivets is sometimes guarded against by caulking the rivet-heads. This is all very well, but loose rivets should be cut out and replaced by sound ones.

Under the heading of "various types of steam boilers" we find much useful information, the locomotive type being represented by the standard boiler used on the Lancashire and Yorkshire Railway; it is, however, stated that in some cases the water spaces are carried down and across the bottom, thus constituting an ash-pan and called a wet bottom. This no doubt is true of a few boilers built at Crewe, but in the majority of cases the wet bottom is unknown to modern railway practice. In this chapter George Stephenson is said to have introduced the blast pipe in locomotives. Surely this invention is due to Richard Trevithick?

The marine type of boiler is represented by one made by the Central Marine Engine Company, West Hartlepool; it is of the single-ended type, and fitted with Fox's corrugated flues. Of water tube boilers there are two standard examples, viz. the Babcock and Wilcox for stationary engines, and the Thorneycroft for marine and other purposes. Considering the present rage for this type of boiler, other examples might have been given with advantage.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Hodgkins Fund Prizes.

THE time within which papers may be submitted to competition for the Hodgkins Fund Prizes of the Smithsonian Institution, for essays in regard to the nature or properties of atmospheric air, has been extended from July 1 to December 31, 1894. This action has been taken for the reason that many of the circulars announcing these prizes seem to have failed to reach the persons for whom they were intended.

Numerous inquiries have been received, which render it desirable to announce that while it is preferred that the name and address of each competitor should be attached to the manuscript, any one who desires it, is permitted to send his name and address in such a form that they can be detached from the manuscript, which he may identify by means of a motto. The manuscripts of unsuccessful competitors will be returned wherever they have been accompanied with the proper address; but the proprietorship of papers which have been awarded one of the named prizes, will rest with the Institution, which only desires to give them a wide publicity; and no copyright privileges are, in this case, to be expected by the author.

Papers which have been already published will not be accepted in competition for the prizes, but may be eligible for the medal. This medal will be awarded in the same way that medals are usually awarded by the principal scientific societies, the medallists being chosen from all investigators known to the Committee of Award, and not necessarily from among those who have submitted papers.

Information regarding the Hodgkins Prizes and the Smithsonian Institution may be obtained from the Secretary of the Institution, S. P. Langley, Washington, D.C., or from the Agents of the Institution, Messrs. William Wesley and Son, 28 Essex Street, Strand, London. S. P. LANGLEY.

Washington, June 6.

Electrical Theory of Vision.

IN reference to the hypothesis concerning vision which I suggested at the Royal Institution on June 1, Dr. Obach has favoured me with the enclosed letter detailing an observation of his on his own eyes, which may be worth placing on record. I therefore send it on to you. OLIVER J. LODGE.

University College, Liverpool.

IN your very interesting discourse at the Royal Institution on Hertz's work, which is reproduced in NATURE of June 7, you suggested that the susceptibility of the eye to light-waves might be analogous to that of your "coherer" to Hertzian waves, and that the light merely causes a diminution of electric resistance of some badly-conducting material interposed between a source of electricity and the sensitive nerves of the eye. The sensation of darkness you explain by the return of the interposed body to its original state, produced by an automatic tapping back on the part of the tissues.

In reference to this matter, I should like to bring to your notice an observation, made some three years ago, which seems to me to support your views as to the *modus operandi* of the eye. One evening, after having watched the famous Rhine Falls, near Schaffhausen, for a considerable time in the full glare of the sun, which produced a dazzling whiteness of the spray, I felt intense pains in the head and eyes, which did not diminish much even after I retired to bed in a perfectly dark room. I thereupon resorted to a remedy, which had given me relief on previous occasions with pains in the eyes caused by overstrain, *i.e.*, I placed the thumb and forefinger on the eyes over the closed eye-lids and imparted gentle vibrations to the eye-balls. After two or three vibrations I was compelled to stop, as the remedy was not only very painful, but also produced the sensation of a bluish-white light of dazzling brightness (like an electric arc) being brought almost into contact with the eyes. After the lapse of a few minutes the luminous phenomenon subsided, and I again commenced the vibrations of the eye-balls, which now I could do a little longer than before ere it became unbearable. This operation I repeated, with intervals of rest, perhaps eight or ten times, till finally the vibrations were almost painless and produced no longer any luminosity; the pains in the eyes and head had then nearly disappeared, and I slept soundly the whole of the night.

The explanation of this curious observation seems to me the following:—The intense brightness of the light reflected from the spray had not only reduced the resistance of the intercepting medium to a minimum, but at the same time overtaxed the elastic tissues whose duty it would have been to shake the material back into its normal condition, after the cessation of the light. The energy thus lost by the tissues was then suppressed from without by the vibrating fingers.

For what reason the return of the intercepting substance to its original insulating condition should also be attended by the sensation of light is difficult to conjecture, unless it be directly due to the physiological effect produced on breaking the circuit.

Similar effects, only not so pronounced, can be observed on vibrating the eye-balls after any ordinary overstrain of the eyes.

Old Charlton, Kent, June 10. E. OBACH.

Ophiophagus.

THE family of the venomous snakes called Elapidæ is divided into two sections, the Najidæ, or snakes with hoods, and the Elapidæ, without hoods. The Najidæ is represented by the Cobras and Ophiophagus; it has two genera, Naja and Ophiophagus.

The genus Ophiophagus has but one species, the *Ophiophagus elaps*, or *Hamadrayas ophiophagus*. This is probably the largest and most formidable venomous snake known. In size and deadliness it rivals the Crotaline snake, *Lachesis mutus*, the Bushmaster, found in South America. The Ophiophagus grows to the length of 12 or 14 feet, or even more. It is hooded like the cobra, and resembles it in configuration and character. The colour varies according to age and locality, being some shade of olive-green or brown; young specimens have a different colouring, and might easily be mistaken for another genus.

This deadly snake, though widely distributed, is fortunately not very common, and consequently its bite, though fatal, does not contribute largely to the 20,000 deaths that occur annually from snake-bite in India. It is found on the Indian Continent and Burmah, in the Andaman and Philippine Islands, in Java, Sumatra, Borneo, and perhaps in New Guinea. It is not known much, if at all, in North-Western and Central India; it is more common in the damp climates of Bengal, Burmah, Assam, and Southern India.

The Ophiophagus, like other snakes, takes readily to the water. It is found in the forest and grass jungle and in hollow trees; it climbs readily, being frequently found in the branches. As its name implies, it feeds upon other snakes, but probably, when its usual food is not forthcoming, it will take small mammals, birds, fish, or frogs.

It resembles the cobra, except that it is longer in proportion to its size, and that the hood is relatively narrower. The poison is of a golden yellow colour. It is even more graceful in its movements than the cobra, and turns more rapidly. The snake-charmers in India prize it highly, but they say it is exceedingly dangerous to catch and difficult to handle before its fangs are removed. It is said by the Rev. Dr. Mason, who knew it in Burmah, to be very aggressive, and Cantor describes it as being very fierce, and ready, not only to attack, but to pursue when opposed. Its Bengali name is Sunkerchor.

Three remarkably fine specimens of this rare snake have been received at the Zoological Society's Gardens. A few years ago a specimen died, which had lived for a long time in the Gardens and excited great interest. That and the individuals under notice are probably the only specimens that have been brought alive to this country.

It will be of interest to numbers of naturalists and others to know that this rare snake is now alive in the Society's Gardens, Regent's Park, where it can be seen to great advantage in the large and well arranged reptile-house. J. FAYRER.

London, June 12.

Mohl's "Primordial Utricle."

I SHOULD like to inquire, through the medium of NATURE, whether the way in which botanists now use Mohl's term "primordial utricle" is strictly accurate? In Sachs' "Lehrbuch," and in the English translation, it is applied to the *parietal layer of protoplasm* found in plant cells which are old enough to have a large central vacuole, and this practice is now generally followed by English botanists.

Now, in Henfrey's translation of Mohl's "Principles of the Anatomy and Physiology of the Vegetable Cell," it appears to be used in a different sense. On pp. 36–37 we have a description of *the young cells* of plants, in which the "primordial utricle" is spoken of as "a *very thin granular membrane*," which by appropriate methods becomes "*detached from the inside of the wall*," . . . "and consequently removes all the contents of the cell, *which are enclosed in this vesicle*, from the wall of the cell." (The italics are mine.) After this Mohl briefly refers to the nucleus, and then goes on to say that "the remainder of the cell is more or less densely filled with an opake, viscid fluid of a white colour, having granules intermingled with it, which fluid I call protoplasm."

Thus even in *young cells*, Mohl recognises not only the protoplasm and the nucleus, but a "primordial utricle" also, and save that he says it is granular, one might take it as the equivalent of what we now speak of as the ectoplasm.

Proceeding with his description, Mohl describes, on p. 38, how as plant cells become older, a large vacuole is gradually formed in the interior of the protoplasm, which then becomes differently distributed. In the result he tells us, "the protoplasm is then accumulated at one side in the vicinity of the nucleus; on the other side *it coats the inside of the primordial utricle*." (Italics again mine.)

Thus in the older cells, as well as the younger, we have a clear distinction drawn between the protoplasm and the "primordial utricle," a distinction which recent writers seem to ignore.

It is possible, though scarcely likely, I think, that Henfrey has not faithfully reproduced Mohl's conception of the "primordial utricle," or it may be that my interpretation of the above passages is at fault. In any case, it would be an advantage to have the opinions of our leading botanists on this point, as it is one which, to my own knowledge, brings some perplexity to students.

THOMAS HICK.

Owens College, June 14.

Hailstones at Cleveland, Ohio.

A REMARKABLE hailstorm occurred at Cleveland, Ohio, on the afternoon of Thursday, May 17, of a character to be remembered but probably not repeated during the present generation. Larger hailstones are rarely seen than fell on that day, and very likely few, if any, people living in this part of the country have ever witnessed a more severe bombardment.

The air was intensely sultry up to twenty eight minutes past three o'clock in the afternoon (sun-time), when it commenced to rain. Hailstones of moderate size rattled down in profusion, and it soon appeared that an ordinary thunderstorm had begun. At the east end of the city the wind increased rapidly in force, and it grew very dark. Presently the hail became violent, and for about twenty minutes the streets and lawns presented a most animated appearance. The impact of the icy bullets against the roofs of houses sounded like the rattle of musketry. The snow-white balls glistened upon the close-cropped lawns, where they kept up a lively dance, and in the street were shattered against the flags and paving stones.

The stones, many of which were as large as billiard balls, and some of the size of goose eggs, weighed from one to five or six ounces, and probably many that fell were much heavier than this. Their shape was very various, some being spheroidal, others discoidal or exceedingly irregular. The accompanying figures represent to some extent the forms of two stones which fell on the Adelbert College lawn, and were picked up by some of our students.

A hailstone was found by Prof. F. P. Whitman to weigh nearly an ounce and a half after it had melted considerably. Its measurements were $2\frac{3}{4} \times 2\frac{1}{2} \times 1\frac{1}{4}$ inches. The surface was fissured and raised into tubercles, while many others had an exaggerated mulberry appearance, suggesting a composite structure. Sections of such stones showed, however, that they were as a rule formed about a single nucleus, and were not the result of the regelation of a number of separate pellets.

The specimen represented in Fig. 1 measured three inches in length, two in breadth, and about one in thickness. There were two opaque central masses, the larger of which contained the original nucleus, while the smaller spot probably represents a stone which became welded to the larger and older one.

A somewhat flattened, or discoidal form, which was very common, presented a beautiful agate-like core, embedded in a clear mass. A section of one of the stones, which was sawn in two, is shown in Fig. 2. There is a central ball of snow-ice,

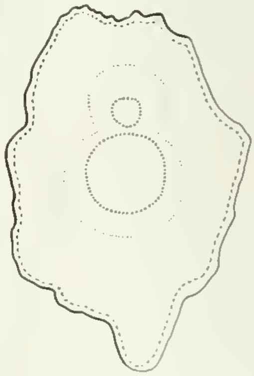

Fig. 1.—Outline of hailstone two-thirds natural size. Dimensions $3 \times 2 \times 1$ inch.

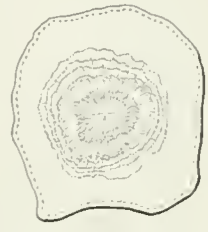

Fig 2.—Section of hailstone, two-thirds natural size.

and this is surrounded by alternating light and dark layers of varying density, and by a very much thicker clear, outer envelope, unshaded in the drawing, showing that the stone had passed through at least two distinct regions of condensation. There were also usually one or two thin superficial strata.

A stone which was examined by one of the observers at the United States Signal Office, was $3\frac{1}{2}$ inches long, 3 inches wide, 2 inches thick, and measured $10\frac{1}{2}$ inches in circumference. Another, which fell near Board of Education Building on Euclid Avenue, was weighed and measured by Principal Theo. H. Johnston. It was oval in shape and measured $3 \times 2{\cdot}5 \times 2{\cdot}75$ inches, and weighed, after some melting, $4\frac{1}{2}$ ounces. The surface of this stone was deeply pitted as by impact of warm raindrops. A second, brought in by one of Mr. Johnston's pupils, weighed 5·5 ounces. It had a large pear-shaped snow-iced centre.

The hailstorm was restricted to a belt a few miles in length, and formed a part of a general westerly storm, which was felt in this region for four or five days. During the thunder and hailstorm of May 17, the air-pressure remained nearly constant, the temperature fell from 84° to about 64° F. At the beginning of the storm the wind was south, and blowing at a rate of ten miles an hour, and increased to a rate of only 24 miles an hour. On the same day a destructive cyclone accurred at Kunkle in the north-western part of the State, in which a number of people lost their lives.

Everything in glass exposed to the brunt of the storm, when not of the strongest kind, was destroyed. Electric light globes, photograph galleries, and greenhouses suffered most. Canvas awnings were riddled. Flowers were cut down, and fruit and shade trees badly injured in many places. Horses and other animals, often too terrified to stir, winced under the stinging shot which they could not avoid. A few cases occurred of persons who were cut or stunned by the falling stones or glass. A man at the Winton Bicycle Factory was struck in the head as he stooped to pick up an unusually large stone, and was brought into the workshop in an unconscious condition. The stone went through his straw hat, and cut into his scalp.

Finder Circles for Equatorials.

ON p. 64 of the current volume of NATURE, I find a paragraph on "Finder Circles for Equatorials," which demands notice on my part because it impugns not only the verbal statements made to many astronomers who have inspected the instruments of the U.S. Naval Observatory, but also the correctness of an official report made by me to the Superintendent of the Naval Observatory, and appended by him to his report for the year 1893, printed copies of which have been distributed to nearly all the observatories in the world.

The paragraph in question is based upon an illustrated article in the *Zeitschrift für Instrumentenkunde*, 1894, 14 Jahrgang, pp. 125–130, which purports to be a description of the 12-inch equatorial telescope of the Georgetown College Observatory, and in which it is asserted (1) that the instrument was constructed *nearly three years ago* by Mr. Geo. N. Saegmuller, of Washington, D.C.; (2) that its principal novelty is a pair of star dials, or finding circles; and (3) that similar instruments have been constructed by Mr. Saegmuller for the U.S. Naval Observatory at Washington, and for other institutions which are named. From these statements the writer of the "Astronomical Column" very naturally inferred that Mr. Saegmuller constructed these dials, or finding circles, three years ago, when in reality he did nothing of the kind. The facts are as follows:—The idea of these finding circles first occurred to me while the question of building a 12-inch equatorial mounting for the U.S. Naval Observatory was under consideration, and in the specifications for that instrument, which were dated May 20, 1891, I embodied it in these words: "Connected with them (the quick motions) and arranged so as always to face a person operating them, suitable indicators shall be provided for showing automatically the right ascension and declination of the point to which the telescope is directed." Mr. Saegmuller got the contract for building that mounting, and the details of these indicators were arranged between us. The erection of the mounting at the Naval Observatory was completed in November 1892, and almost immediately thereafter Mr. Saegmuller put an exact copy of its indicators upon the Georgetown College telescope, *which had been erected some time previously*. Finally, the two woodcuts which illustrate the *Zeitschrift* article are not pictures of the Georgetown College telescope, but of the Naval Observatory telescope, which differs from the Georgetown instrument in many details.

On the Use of Quartz Fibres in Telescopes.

Perhaps it may interest some of your readers to know that the quartz fibres of Prof. Boys affords an excellent material for providing the eye-lens of telescopes, and specially the instruments used in combination with reflecting galvanometers and electrometers, with threads required for their adjustment on the divisions of the scale. I thought at first that as the fibres appear, when examined with the microscope, to be semi-transparent and have a silver-grey colour, they would, when seen behind the ocular lens, not present themselves as distinct and clear lines, but as a matter of fact, when they were put at the proper distance, they showed an intense black colour, even darker than the divisions made with ink on the scale on which the instruments were focussed. I used threads of 20 microns diameters, and they can be fixed on the diaphragm without much difficulty by means of a mixture of resin and mastic applied with a heated wire, and this mixture answers better than brittle shellac. It is obvious that the threads, when laid down in the diaphragm, are at once stretched, and remain in good condition, as they are not affected in any appreciable degree by the influence of heat and atmospheric moisture.

The Hague, June 18.

Bullet-Proof Shields.

In reply to a letter on bullet proof shields, in the last number of Nature, I wish to state that some preliminary experiments with spheres show that the energy of the shot is transmitted to the spheres nearly in line with the direction of the blow, to such a degree that great damage is done to the board to which the spheres are attached. This is not the case when rods are used. I hope shortly to give the details of my experiments on the subject.

Frederick J. Smith.

Oxford, June 10.

THE HORN EXPEDITION FOR THE SCIENTIFIC EXPLORATION OF CENTRAL AUSTRALIA.

Information has been received of the organization and despatch from Adelaide of a new and well-equipped expedition for the scientific exploration of the Macdonnell Ranges which lie about eleven hundred miles to the northward of that capital and nearly in the centre of the Australian continent. The expense of this expedition is borne by a wealthy and public-spirited colonist of South Australia, Mr. William Austin Horn, who thirty years ago carried out on his own account some explorations in the Gawler Ranges, and has since taken a very active part in the development of the mineral resources of the country, besides being a prominent member of the colonial legislature and of the Council of the University of Adelaide. Mr. Horn himself is the leader of the present Expedition, but has wisely associated with him some scientific gentlemen of great experience in Australian travel. Among them are Mr. Charles Winnecke, of the Trigonometrical Survey of South Australia, who in the performance of his duties has repeatedly traversed some of the most arid country of the continent, and has mapped out some thirty thousand square miles of its surface. With him also goes as medical officer, Dr. E. C. Stirling, C.M.G., F.R.S., of the University of Adelaide, the well-known discoverer, a few years since, of *Notoryctes*, and latterly the investigator of the *Diprotodon*-deposits, the results of which so many are impatiently expecting, though now it is clear that for them they will have to await his return from this new undertaking, the charms of which he found it impossible to resist. Besides these there are of the party, Prof. Ralph Tate, also of the University of Adelaide, and President of the last meeting of the Australasian Association for the Advancement of Science, eminent as a palæontologist, and especially as a palæobotanist, as well as Prof. Baldwin Spencer, whose name, from his connection with Owens College and Oxford, will be at once recognised by all; while there is also Mr. J. Alexander Watt, of the Geological Survey of New South Wales, to pay special attention to mineralogy and petrology. In the capacity of collecting naturalists, Mr. F. W. Belt, of Adelaide, and Mr. G. A. Keartland, of Melbourne, complete the staff of the expedition, which will be accompanied by three camel-drivers, a cook, and two prospectors sent by the Government. The Expedition was to leave Adelaide on May 3rd for Oodnadatta, and thence proceed along the telegraph line as far as Lilia Creek, where it will turn to the westward towards the Ayers Range and Goyder's Springs, after which it will make for the Palmer River, and then, deviating again to the westward towards Petermann Creek, will return to the upper valley of the Finke River, and then push on to Glen Helen at the foot of the Macdonnell Ranges. It will of course be understood that circumstances may cause this plan to be modified more or less extensively; but from the previous experience of those who have laid down the route to be taken it will probably be carried out pretty much as is intended, though some of the country to be traversed is absolutely unexplored, and much of it very imperfectly known. Wherever a prospect of doing work is found, a longer or shorter halt will be made, and as the Expedition is to be well furnished with camels—no fewer than twenty-three being taken with it—the difficulties that attend the needful supply of water will be reduced to a minimum, while it is said that owing to recent good rains in the latitudes to be passed through everything looks promising for a successful journey.

The importance of this undertaking is not easily to be over-rated. Expeditions of one kind or another to the interior of the continent have been numerous, and productive of results that we should be the last to impugn; but this we believe is the first attempt at a purely scientific investigation of Central Australia, while the names of the distinguished men whom Mr. Horn has been so fortunate as to engage in it, are a guarantee of the serious way in which it will be conducted. We doubt not that he and his companions will find plenty of rough work before them, and possibly some risk; but if good wishes can help them they may rely on those of all our readers, together with their high and hearty appreciation of the spirit which has prompted that gentleman not only to defray the cost of the Expedition, but to put himself at the head of it at a time of life when most men think of retiring upon the fruits of their labours.

THE ENRICHMENT OF COAL-GAS.

IT is almost impossible to over-estimate the importance of the influence which coal-gas has exercised upon the advancement of civilisation during the past fifty years, and at the present time it has reached a phase in its existence upon which its future career and utility is very largely dependent.

Up to the middle of the century but little attention was paid to the quality of the gas supplied for illuminating purposes; the gas manager made the best gas he could with the coals at his disposal, and the consumer was content as long as he obtained a reasonable amount of light.

In 1850 a Bill was passed which enacted that the light emitted by a brass argand burner with 15 holes, consuming five cubic feet of gas per hour, should be equal to the light of 12 wax candles of the size known as "sixes." These wax candles were, however, only equal in illuminating power to 10·3 of the sperm candles at present used for testing purposes. In 1860 an Act changed the illuminating power to 12 sperm candles, and in 1868 this was again raised to 14 candles, and by the Act of 1876 this was increased to 16 candles, and remains so to the present time.

In 1864 the 15-hole brass argand was discarded as a standard testing burner, and was replaced by a 15-hole steatite burner, which by increasing the temperature of the flame developed more light, whilst in 1869 the "London argand" 24-hole burner was introduced, and gave a still further increase in the light obtained from the gas, so that when we speak of London being supplied with 16 candle-power coal-gas, it means that the light emitted by the gas when burning at the rate of 5 cubic feet per hour from a London argand shall be equal to the light of 16 sperm candles of the size known as sixes consuming 120 grains of sperm each per hour.

When we come to consider what this in reality amounts to, we find that by one of those subtle strokes of humour in which our legislative body occasionally indulges, it means to the consumer almost anything except a light equal to 16 candles. The illumination which can be obtained by the consumption of coal-gas is entirely dependent upon the method by which the gas is burned. From a so-called 16-candle coal-gas the consumer rarely obtains a value of more than 12 candles per 5 cubic feet of gas consumed; whilst by using burners of rational construction, upwards of 40-candle illuminating power could be obtained for the same consumption of gas.

The light emitted by a coal-gas flame is dependent upon its temperature, and flat flame burners, exposing a thin sheet of flame to the cooling action of the air, give the worst results. Argand burners are better, as the cooling is not so great, whilst the regenerative burners lately introduced, by utilising the heat of the products of combustion for raising the temperature of the gas and air supplied to the flame, give an enormous increase in the light emitted.

If the gas companies could only get an Act passed authorising the use of the regenerative burner as the standard, there is no reason why they should not call the gas at present supplied 40-candle gas; the consumer, however, using the flat-flame burner would still be only obtaining the same light as at present. Incandescent mantle burners, which act on a totally different principle, also yield a high illuminating value.

On carefully testing the burners in ordinary use we find that for an equal consumption of gas the results at once show the enormous advantage to be obtained by regeneration, and also how serious is the loss which attends the employment of ordinary burners.

Light obtained per cubic foot of 16-candle gas consumed.

Burner.	Candle units.
Regenerative and incandescent	7 to 10·00
Standard argand	3·20
Ordinary ,, ...	2·90
Flat-flame No. 7	2·44
,, ,, 6	2·15
,, ,, 5	1·87
,, ,, 4	1·74
,, ,, 3	1·63
,, ,, 2	1·22
,, ,, 1	0·85
,, ,, 0	0·59

These burners were by well-known makers; but there are plenty of cheap German nipples in the market which will give even worse results. In the above table No. 7 is the largest flat-flame burner given, as any larger size would never be used for indoor illumination; but with some of the big flat-flame burners employed for outdoor work as much as three candle power per cubic foot of gas is developed by the best make, while it is also quite possible to find cheap imitations of them, which can scarcely be distinguished by their appearance, only developing a little more than one candle per cubic foot. It seems probable that 10-candle units represent the maximum light to be obtained in practice per cubic foot from the so-called 16-candle coal-gas, as, although greater regeneration will increase it as high as sixteen units, the heat is so intense that the burner is quickly destroyed. Taking 10-candle units as being the maximum amount of light for a consumption of one cubic foot of gas per hour, an approximate idea of the waste of illumination which attends the ordinary methods of burning the gas can be formed.

If the burners most commonly in use in houses be examined they will be found to consist chiefly of No. 4 and No. 5 flat-flame nipples, and it would not be over-estimating the number in use to put them at 85 per cent. of the total. The remaining 15 per cent. is made up of larger flat-flame burners, argands, and regenerative lamps, which give a higher service: but it will be found that the total value obtained will not exceed 2·5 candles per cubic foot. This means that 75 per cent. of the total value obtainable from the gas is wasted, and that for our present expenditure in coal-gas we could obtain four times as much light.

Mr. George Livesey some time ago proposed that unenriched coal-gas should be supplied to the consumer at a lower rate than is at present charged for the enriched 16-candle gas, and this question is of such interest and importance to both consumer and gas company that it deserves the gravest consideration.

In large towns like London, where the gas companies have to supply a gas of specific illuminating power, and where the gas is continually subjected to photometric tests at stations spread over the whole area supplied (any deficiency in the lighting value of the gas being visited with rigorously enforced penalties), enrichment in some form or other becomes a practical necessity. In London the gas has to have an illuminating power of sixteen candles; and in order to ensure this over so enormous an area, the gas must be sent from the works testing up to from 16·5 to 17 candles. With seaborne Durham coals of the character most largely used in the metropolis for gas-making, the illuminating value of the gas will be about fifteen candles, and the gas manager has to enrich the gas by from 1½ to 2 candles before he can with safety send it out for distribution. This enrichment is done in several ways: (*a*) by the admixture of a certain percentage of cannel coal with the original gas coal; (*b*) by carburetting the coal-gas with the vapours of volatile hydrocarbons; (*c*) by mixing the gas with carburetted water-gas: (*d*) by admixture with rich oil-gas.

Up to four years ago the admixture of a certain percentage of cannel coal with the Durham coal was the only method of enrichment employed by the metropolitan companies, and was perfectly satisfactory, as the coal being mixed, the gases came off together under the same conditions in the retorts, and a uniform gas was the result. During the past few years, however, the increase in price of cannel has forced the gas companies to find some other process which should take its place, and the Gas Light and Coke Company tried experiments which led to their largely adopting carburetted water-gas for this purpose.

When steam acts upon carbon at a high temperature, the resulting action may be looked upon as giving a mixture of equal volumes of hydrogen and carbon monoxide, both of which are inflammable but non-luminous gases. The water-gas is then carburetted, *i.e.* rendered luminous by passing it through chambers in which oils are decomposed by heat, and the mixture of oil-gas diluted with water-gas is made of such "richness" as to give an illuminating value of 24 or 25 candles, and this, mixed with the poor coal-gas, brings up its illuminating value to the required limit. During the winter months the gas supplied by the Gas Light and Coke Company has mostly contained about 10 per cent. of the carburetted water-gas.

This form of enrichment has several serious drawbacks: it increases the percentage of the highly-poisonous carbon monoxide in the gas, and so makes leakage more dangerous, whilst carburetted water-gas burns with a short but very brilliant flame, far shorter than coal-gas, a 22 candle water-gas flame burning from a London argand at the rate of 5 cubic feet an hour, with a flame only 2½ inches in height; whilst a 16-candle flame of the gas supplied up to three years ago gave a flame three inches in height; and the gas now supplied and enriched with the carburetted water-gas only gives a flame 2·6 inches in height, in order to emit a light of 16 candles.

When a householder lights his gas-burners, he invariably turns on the gas until he gets the largest possible flame without roaring or smoking, and from the alteration in the composition of the gas which has taken place, this means using far larger quantities of gas than heretofore, so that although an increase in illuminating power is obtained, a substantial increase in the quarter's gas bill is also found.

Another objection to this form of enrichment applies even still more to the admixture of rich oil-gas with the poor coal-gas, and is that although gases of different gravities mix perfectly well in small vessels, yet when you come to deal with the huge gas-holders used in the modern gas works, stratification of the gas takes place, and even if the enriching gas be mixed with the ordinary gas in the foul mains, so that they may pass through the scrubbers and purifiers together, uniformity in illuminating power is never obtained, and with the London coal gas variations of from 16 to 18 candles in value are found at the testing stations.

A burner which is giving its best duty with a 16 candle gas, will be very apt to smoke when burning a gas of higher quality, and under these conditions the products of combustion become more injurious to health from the presence in them of a larger proportion of the products evolved during incomplete combustion.

Enriching gas by the vapours of volatile hydrocarbons enables the manager to bring his gas up to the legal requirements as regards the illuminating value at the testing stations, which are mostly fixed where the great trunk mains deliver the gas to the districts to be supplied, and it is only under exceptional circumstances that the illuminating value of the gas is ever found to be below the required limit at these points. The consumers, however, reap but little benefit from it, as the loss of illuminating value during distribution is very great where this method of enrichment is employed.

No matter how enriched, change of temperature, and other troubles incidental to distribution generally reduce the illuminating power of the gas to a considerable extent before it reaches the consumers' burners, so that its actual value is far more often fifteen candles, although it may have been tested over sixteen at the station.

In the big mains the gas is continually flowing at a fairly steady rate, and is neither exposed to any great alteration in temperature, nor from the size of the mains to any very great amount of "skin friction," *i.e.* rubbing of the gases against the sides of the pipes; but as soon as distribution commences, both these factors come into play, and as some of the chief illuminants of the gas are vapours and not permanent gases, lowering of temperature causes condensation of some of them, whilst the power which friction against the sides of the main service pipes, coated with deposited hydrocarbons, has of withdrawing the illuminants from the gas, still further decreases its light-giving value, and anywhere near the dead end of a service, stagnation of the gas during a large portion of the twenty-four hours when gas is not being consumed, adds still further to the trouble, so that even at the testing stations, the influence of the small consumption of gas on Sundays, and consequent stoppage in the manufacture on that day, can be traced in the illuminating value found on Monday morning.

Coal-gas, as made from Durham coal at the temperature employed in the Metropolitan Gas Works, has an illuminating value of about fifteen candles, and the enrichment of this gas up to the required value costs far more *pro rata* than the amount of light obtained from the unenriched gas.

This cost has entirely to be borne by the consumers, and the whole practical question to be decided resolves itself into—"Is the game worth the extra candle and a half?"

If coal-gas were used for illuminating purposes only, the consumer would be a considerable gainer by having the unenriched gas supplied at a lower price; and when we consider the amount of gas used as a fuel, and that the quantity so employed is daily increasing, the cost of the enriched gas becomes of the greatest importance.

The value of one candle in illuminating power in the gas supplied in London at 1½*d.* per candle is £180,000, and if this calculation be correct, consumers in the metropolis would be saved about £270,000 a year by using unenriched coal gas, and probably not one of them would notice the slightest difference in the light emitted by the gas in the burners ordinarily in use.

In the regenerative burner the increase in illuminating value is almost entirely due to the rise in temperature causing methane, which forms about 34 per cent. of the coal-gas by volume to become a very valuable illuminant, and as there is just as much or more methane in the unenriched gas, it is manifest that this increase will still be found.

In the incandescent burner the coal-gas is burnt in an atmospheric burner, and the non-luminous flame is made to heat a mantle of refractory material up to incandescence, and for this purpose the 15-candle gas will do as well as the 16.

One argument which has been raised against the lowering of the standard is that if a 16-candle gas is reduced to 15 candles during distribution, a 15-candle gas will be lowered to 14. This I think is a mistake. An enriched gas is lowered in illuminating value because certain vapours are condensed from it; but it will be found that with an unenriched gas, made at a high temperature, this action is decreased to a minimum, on account of the small proportion of vapours present.

One of the most important experiments ever tried on a large scale has been made this year, the London County Council having given permission to the South Metropolitan Company to supply unenriched gas to South London for the space of a fortnight, in order to practically ascertain the result during distribution and the loss of light to the consumer.

At the testing stations the gas for the fortnight showed the average value of about 15 candles, ranging from 14 to 16 according to the coal used at the various works, whilst tests made with portable photometers on the consumers' premises gave identical results, before, during, and after this period, clearly showing that the whole value of the enrichment consisted in satisfying the legal requirements, whilst the consumer gained absolutely nothing but the privilege of paying for it.

It is to the interest of the gas consumer and gas company alike that the price of gas should be reduced to the lowest possible figure, and the possibility of reduction in price is entirely dependent upon the discarding of the costly enrichment.

Under the present legal conditions the companies gain nothing by supplying a gas a candle better than the standard, and if they fall a candle below have to pay the absurd fine of 40*s.*, a state of things which if the London companies did not show the greatest anxiety to fulfil all their obligations might lead to a considerable reduction in the value of the gas distributed, as to pay a daily fine and to send out gas of a value of 15·1 candles would save the companies many thousands a year.

This is all manifestly wrong, and if the consumers are to get the full benefit of coal-gas, and if coal-gas is to take its proper place as a fuel as well as an illuminant, its sale must be placed on a sound commercial basis. Enrichment should be entirely given up, and the gas that can be made direct from the coal supplied to the consumer.

A minimum of illuminating value should be fixed for each town based upon the coal used, and any fall below this should be visited by a fine of £50 for the first half-candle, and an increment of £100 for each half-candle below that, whilst the price charged for the gas should be governed by its illuminating value for the quarter as averaged from the testing station returns, a low initial price, say 2*s.* 2*d.* per thousand, being charged for 14-candle gas, and 1½*d.* a candle for each candle above it, with a maximum price of 2*s.* 5*d.* If some such scheme as this could be adopted, not only would the consumer obtain the full value for his money, but the gas companies would reap the benefit of an enormously increased consumption for fuel purposes, and the atmosphere of our big cities would gain in proportion.

Vivian B. Lewes.

NOTES.

The Council of the Society of Arts have, with the approval and sanction of the President, H.R.H. the Prince of Wales, awarded the Albert Medal to Sir Joseph Lister, Bart., F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries, by which not only has the art of surgery been greatly promoted and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

We are requested to state that before long a memoir of the late Dr. James Croll, F.R.S., will be ready for publication. Persons having letters from Dr. Croll, or information likely to be of interest, are requested to forward such to J. C. Blackwell, 10, Royal Terrace, Edinburgh. The letters will be returned when their contents have been noted.

A Pasteur Institute was opened at Tunis on Tuesday by Dr. Loir, a nephew of M. Pasteur.

The death is announced from Paris of M. Ed. Lefèvre, known for his work in entomology and botany.

Prof. Cannizzaro has been elected a correspondent of the Paris Academy of Sciences, in the place of the late M. de Marignac.

We learn from *La Nature* that a department of agricultural entomology has recently been formed at the Institut National Agronomique, and placed under the direction of Prof. Brocchi. The work of the department will be to identify insects sent for that purpose by agriculturists, and to point out the means of destroying insect pests or diminishing their ravages.

The *Cape Times* says that among the latest accessions to the South African Museum are an old imperfect skull and other bones of a white rhinoceros, presented by Mr. W. G. Schmidt. These remains of the now all but extinct "white" or Burchell's rhinoceros were found at a depth of about 8 feet, in black turfy soil, at about twelve miles from the Vaal River.

A complete statement has been issued of the different sections of the Mining and Metallurgical Exhibition to be opened at Santiago in September next. The classification is as follows:—(1) Motive Power; (2) Electricity; (3) Mining Machinery; (4) Mechanical Preparation of Minerals; (5) Metallurgy; (6) Chemical Industries; (7) Statistics and Plans; (8) Mining and Metallurgical Products.

The Paris correspondent of the *Times* reports that, at the first meeting of the 1900 Exhibition Commission, the following scheme of classification was read:—The first group of exhibits is entitled "Education," and contains six classes. Group II. comprises "Works of Art," containing paintings, drawings, engraving, lithography, sculpture, the cutting of precious stones, and architecture. Group III. is called "Instruments and General Processes of Literature, Sciences and Arts," including typography, photography, binding, newspapers, maps, instruments of precision, coins and medals, medicine and surgery, musical instruments, and the theatrical art. The IVth Group is "The *Matériel* and General Processes of Mechanics," including steam engines, motors, divers apparatus of general mechanics, and implements. The Vth Group deals with electricity, including the production and mechanical application of electricity, electro-chemistry, electric lighting, telegraph, and telephone. Then come locomotion, agriculture, horticulture, forestry, alimentation, mines, furniture, textiles, chemicals, social economy, and military weapons.

It is reported by the *British Medical Journal* that a committee of the Calcutta municipality have resolved to recommend that a sum of money be voted for two years in order to test thoroughly M. Haffkine's system of cholera inoculation. This method, worked out by M. Haffkine in the Pasteur Institute in Paris, and applied extensively in India by the investigator himself, was recently put to the test of actual experience near Calcutta. Dr. Simpson, the health officer, took special steps to make the inoculations in the neighbourhood of Calcutta serve as tests, as severely scientific as possible, of the efficacy of the method in man. Of the 200 inhabitants of a native hamlet, 116 were inoculated with the protective vaccine. Not long afterwards, an outbreak of the disease occurred in the hamlet: ten persons were affected, none of whom had been inoculated, and seven died, whereas all those who had been inoculated remained free. If the results of future experiments are favourable, a permanent department will probably be established to carry on the inoculations.

THE Hong Kong correspondent of the *British Medical Journal* gives the following particulars with regard to the epidemic noted in our last issue:—"The plague commenced here on May 5; it presents all the symptoms of the true bubonic pest which devastated Europe in the Middle Ages, and produced the terrible ravages described by Defoe during the great plague in London. This bubonic pest, although extinct in Europe, has never ceased to prevail in China from time to time, and has also spread from there to Persia and Asiatic Russia. The present outbreak is characterised by intense symptoms corresponding to those of typhus, and by the bubonic boils characteristic of the disease. The deaths up to to-day have amounted to 1708, but I am glad to say that the Europeans here are unaffected except in the case of ten of the military employed by the authorities in carrying out disinfecting work in the native quarter where the plague is located; one of them has unhappily died." It is pointed out by our contemporary that this bubonic pest is extremely contagious from person to person, and though aerial infection is not unknown in connection with it, it is so probably only to a slight extent. Like typhus, the plague is mainly diffused by personal contact, and its diffusion is one of the results of overcrowding and dirt.

The U.S. National Academy of Sciences is in a quandary. According to the *American Naturalist*, it has been in a state of paralysis for two years as regards the election of members, owing to the impossibility of concentrating a sufficient number of votes on any one candidate to elect him. At present fifty-eight members are devoted to the physical sciences, and thirty-one represent the natural sciences. Members of the latter class desire to destroy this disproportion, but they cannot procure enough votes to elect an additional member on their side, and the result is a deadlock. It has been proposed by a committee that the Academy be divided into classes, each having a fixed membership, such as exists, for instance, in the Paris Academy of Sciences. Three of these classes were to embrace the physical sciences; two, natural science; and one, the sciences that could not be well classified under either of these heads. This, however, has been objected to, and Prof. E. D. Cope has submitted the following division to the consideration of the committee. Class I. (35 members).—Physical Science (Sciences of Energy), to include Physics, Astronomy, Chemistry, Physiology, and Dynamical and Chemical Geology. Class II. (35 members).—Natural Science (Sciences of Morphology); Structural Geology, Mineralogy (apart from Chemistry), Biology including Embryology and Palæontology. Class III. (15 members).—Anthropological Science (Sciences treating of phenomena determined by psychic conditions); Anthropology, Statistics, Philology, Psychology. Class IV. (15 members).—Applied Science. Applications in the Arts of any of the Sciences previously enumerated), including Hygiene, Engineering, &c.

SUESS' famous work, "Das Antlitz der Erde" (the Face of the Earth), is to be translated into French by M. de Margerie. Abroad, the book is almost as well known to the general public as to geologists, but there seems to be no immediate prospect of an English translation.

WE are reminded of what we lose in this respect by a current article in the German "Weekly Magazine of Science" (*Naturw. Wochenschrift*, May 27 and June 3), on "the Flood and the Ice Age Question." The writer, Richard Hennig, discusses the views so amply stated by Suess in the aforesaid work, also those of Neumayr in the "Erdgeschichte" (History of the Earth). Suess and Neumayr may be said to have proved that the Mosaic account of the flood was copied, with but little alteration, from the original Assyrian version, and that the actual events took place in the plains of the Euphrates and Tigris, and not on the banks of the Jordan. Suess suggested a comparison with the occasional calamities caused in the lower parts of the rivers of India when a cyclonic storm whirls the sea inland, and the rivers overflow wide reaches of town and country. In Suess' opinion the Mosaic flood was of local nature:—"The traditions of other peoples do not in the least justify the assertion that the flood extended beyond the lower course of the Euphrates." Science went with Suess, and the true tale of the flood, while it remained picturesque, lost its magnificence.

NOW, however, Hennig brings forward persuasive arguments in favour of the independent origin of the flood Saga found among so many peoples. He associates it with some of the striking facts which indicate a general increase of rainfall and lowering of the temperature over the whole earth during the Quaternary period—*e.g.*, the presence of enormous lakes in the west of North America, whose water-level rose 1000 feet above the present Salt Lake of Utah, the Ice age and glaciation in North America and in Northern and Central Europe (without which geology would have lost a pet hobby), the floods which accompanied the retreat of the glaciers, the moist climate of Siberia, and the fertility and forest-growth in the now arid Sahara. Hennig concludes that the flood was contemporaneous with the Ice age, and was produced by the unknown causes which then lowered the temperature of the globe. The period was a prolonged one, during which the countries in milder latitudes were converted into swamp and sea, or underwent higher floods of local character under special meteorological conditions. Isolated lands remained free from inundation, Egypt for example, owing to their distance from any region of ice and dry climatic conditions.

THE German Saga tells how "the floods of the north came far from their home and were turned into ice, and the ice stood still, and the mist which hung over it froze . . . . till the hot sun-glow from the south met the hoar, and the frost fell in drops. The sun was strong and his heat gave life to the drops, so that a great frost-giant in the form of a man arose—Ymir of the Hrimthursen. But Bors killed the giant Ymir, and when he fell there ran so much blood from his wounds that the race of the Hrimthursen was drowned, all except him they called Bergelmir. In a boat he saved himself and his wife, and from them sprung the new race of Hrimthursen." The German Saga is scarcely less dramatic than the Eastern. After reading it we feel willing to believe that the Germanic Ossian was *bona fide*.

IN the *Programm des Gymnasium Ernestinum* (Gotha 1894), Dr. A. Schmidt has published an essay on the employment of a trigonometrical series in meteorology, which will be very useful to students of the mathematical branches of that science. It is divided into four sections, the first two of which are devoted to the history of the subject, from their earliest use by Euler, in 1748. Their first application to meteorology is attributed to T. Mayer, whose investigations were published after his death, by Lichtenberg, in 1775, although the principal merit for their employment in meteorology is undoubtedly due to Bessel, who explained their use in a treatise published in 1814. The last two sections deal with the means of deducing the harmonic constants from the usual formulæ, and the need of further investigations by this method. The *Programm* will probably not be generally accessible, but a careful summary of it, by Dr. Grossmann, will be found in the *Meteorologische Zeitschrift* for May of this year.

THE results of meteorological observations lose much of their interest when published four years late. Such is the report of the meteorological service of the Dominion of Canada for 1889, a copy of which has just reached us. We note in glancing through the volume that meteorological instruments are supplied to the experimental farms established in different provinces of the Dominion. There were 1126 warnings of approaching storms made during the year, 82·2 per cent. of which were verified. The railway companies in Canada give assistance in many ways to the meteorological service. One of these is by permitting trains to carry discs showing the weather forecasts for the districts through which they travel. A few weeks ago we noted that our Board of Agriculture intended to distribute in rural districts during harvest time, weather forecasts prepared at the Meteorological Office. It may be worth consideration whether such a system could not be usefully extended by displaying the predictions on trains running through agricultural districts.

THE earthquake in Baluchistan, described in NATURE of August 10, 1893, was also felt in South Russia and in Germany, and a comparison of the records at Nikolaiev and Strassburg is given by Herr E. von Rebeur-Paschwitz in the *Astronomische Nachrichten*, No. 3234. The epicentre of the earthquake was a spot fifty miles to the N.N.W. of Quetta. The main shock occurred at 12h. 19m. G.M.T. on December 19, 1892. The distances from Strassburg and Nikolaiev are 5290 and 3480 km. respectively. The first waves from the disturbance reached Strassburg in 16 min. with a velocity of 5·51 km. per second, this being about the same velocity as that observed in the case of the Wjernoje earthquake of July 11, 1889. The first maxima took 18 mins. and 30 mins. respectively to traverse the distances. It is very evident that the wave motion at some distance from the epicentre is very complicated. For several hours before and after the earthquake earth tremors, were recorded by the instruments, the two kinds of disturbances appearing to proceed independently of each other.

SOME interesting experiments with a rectangular glass prism are described by W. C. Röntgen in *Wiedemann's Annalen*. Those who have tried looking at themselves as reflected by two mirrors, placed at right angles to each other, will remember the amusing effect created by the image, contrary to the usual reflection in a mirror, not being reversed right and left. We can see ourselves "as others see us," also, by looking straight at the surface subtending the right angle of a rectangular prism. Herr Röntgen observes that in no case is the pupil divided into two equal parts by the faintly visible edge of the prism. This is an illustration of the angle between the line of vision and the axis of the eye, which is different in different people. Rectangular prisms can be easily tested for correctness of the angle by observing whether the two images of the cross-wires in a telescope, as seen in the two surfaces, coincide. The same test would tell us whether two mirrors are exactly at right angles—a fact which might be usefully applied for testing instruments like Gauss's heliotrope. Such a pair of mirrors, or a rectangular glass prism, give rise to another peculiar phenomenon. If they are rotated about the axis of vision, the image rotates in the same direction with twice the speed. If, therefore, the object, say a cardboard disc with writing on it, rotates twice as quickly as the mirrors or prism, it will appear to stand still. This might be applied to investigate the effects produced upon bodies by rapid rotation. Another peculiarity is that such an instrument will reflect rays falling upon the hypotenuse at any angle up to 45° to the same spot. By rotating such a prism about a line at right angles to its edge and to its hypotenuse the author was enabled to reflect the light from an electric lamp through a distance of 1 km. with ease and certainty.

IN a communication to the *Electrician*, Prof. Fitzgerald criticises Herr Lenard's last paper, a short abstract of which appeared in NATURE for May 31, 1894, p. 114. In a former note on Herr Lenard's previous paper, Prof. Fitzgerald had pointed out that the experiments so far would be consistent with the supposition that the cathode rays were rays of light of very high frequency, except for the fact that they were deflected by magnetic force, a phenomenon of which we have no other evidence, and which makes it practically impossible at present to suppose that cathode rays are of this nature. It was further pointed out that if this deflection were an action on the emitting surface, and not on the ray, it might be again possible to explain these cathode rays by the supposition that they are rays of light. Herr Lenard's more recent experiments seem entirely at variance with any such supposition, while Prof. Fitzgerald considers that there is nothing in them that, in the same conclusive way, proves that they are not streams of electrified molecules or atoms. From Herr Lenard's observation that the deflection of the ray depends on the pressure of the gas in the tube in which the rays are generated originally, and not on the nature and pressure of the gas in the tube in which deflection takes place, it follows that, if the rays are paths of projectiles, they must either pass through the window, or else be projected from it, by some action which behaves like a blow given to it from the other side. A study of the spectrum of the cathode light might settle whether any of the molecules actually traversed the partition. The fact that there is no increase in the pressure within the tube only shows that as many molecules traverse the partition in one direction as in the other. Blows delivered on one side of a plate would project molecules from the other side, with different velocities depending on the nature of the blow and on the mass of the molecule, so that a hypothesis of this kind would be quite in accord with Herr Lenard's observations. The fact that the magnetic effect is independent of the mass of the molecule struck is explicable by supposing the electrical charge to be the same for all molecules. Even though sufficient reasons were forthcoming for rejecting the theory that these rays are due to projected molecules, Prof. Fitzgerald considers that there are other possible suggestions which are worthy of consideration, such that they are straight Grotthüs chains of molecules which bend under magnetic force. This might account for a velocity of propagation of actions along them, comparable with the velocity of light, without requiring the component matter to move with this velocity. In fact, until the residual matter within the tube has been reduced very much beyond what has been attained, and it has been shown that these phenomena increase instead of diminish, and that there is no very slow projection of the material of the plates, such as darkens the glass in glow-lamps, it will be very difficult to prove that any of the phenomena hitherto observed are due to the ether, and not to the matter present. So far the phenomena described are quite like those that would be due to moving electrified matter, and the actions are quite unlike anything we know of the properties of the ether.

THE anomalies which are constantly observed in culture for bacteriological researches have, up to the present, been generally ascribed to abnormal conditions or to involution. Although the existence of polymorphism among bacteria may be inferred from the records of Metschnikoff, Weibel, Cornil and Babes, Kiessling, Karlinski, and especially those of Guignard and Charrin, as yet no absolute proof had been adduced to make it a fact. The *Weekblad v. h. Tydschrift v. Genesk* of April 28 contains an article in which the writers contend that among pleomorphic bacteria there are some species which, under different conditions, present different forms. Last year, when testing the water from the waterworks of Groningen, Ali Cohen and Uffelie, of the Hygienic Laboratory of that city, succeeded in cultivating in pepton Na Cl, fluid, spirilla which possessed all the morphological and biological properties generally ascribed to this species of organism. These spirilla, transplanted in nutritive gelatine, speedily developed colonies, but exclusively consisting of bacilli. These bacilli, replaced in a solution of pepton, Na Cl, reproduced again spirilla, not all identical, however, but consisting of commas, S forms, and short spirella. They repeated their experiments for several consecutive months, always with the same result. During these investigations another curious fact came under their notice. An organism which for several months, in alternate solid and fluid nutriment, had produced the alternate form of spirillum and bacillus, although the conditions of culture had not been altered in any way, lost at last the power of reproducing spirilla. The organism had retained all its individual characteristic properties, but it was impossible to revive this power. These observations led the writers to the conclusion that the present state of bacteriological science does not admit of ignoring the signs of polymorphy in bacteria, and that it is inaccurate to speak of normal and abnormal conditions, or to recommend as appropiate only those nutrients in which bacteria most speedily develop and accurately retain the form under which they are described in the text-books. The fact that most species of bacteria cultivated under glass gradually lose their power of multiplication, their loss of pathological and other biological properties, make this apparent. Even increased power of growth does not necessarily prove the exterior conditions to be favourable. It is well known that the bacillus of diphtheria loses its virulence in proportion as its power of development increases. In their opinion, therefore, it will henceforth be unsafe to deny, on morphological basis only, that the cholera spirillum may have developed from a certain form of bacillus, and that it is not invariably produced from an individual whom it morphologically resembles.

The first volume has been issued of Dr. Bowdler Sharpe's "Handbook to the Birds of Great Britain." The book belongs to the new edition of Allen's Naturalist's Library, of which Dr. Sharpe is the editor, and Messrs. W. H. Allen and Co. are the publishers.

We have received an excerpt from the Transactions of the Academy of Science of St. Louis (vol. vi. p. 481). Mr. Milton Updegraff is the author of the extracted paper, the subject of which is the determinations of the latitude, longitude, and height above sea-level of the Laws Observatory of the University of the State of Missouri, and the Observatory building and instruments.

The *Bulletin* of the Royal Gardens, Kew, Appendix ii. for 1894, is entirely occupied by a list of new garden plants brought into cultivation for the first time in the year 1893, including botanical varieties and hybrids, as well as the most noteworthy of those which have been reintroduced after being lost from cultivation, and others now for the first time described or published with authenticated names.

Part ii. No. 4, of vol. lxii. of the "Journal of the Asiatic Society of Bengal" contains two papers by Dr. G. King, the Superintendent of the Royal Botanic Garden, Calcutta: "On some Indian Species of *Canarium*," and a continuation of his "Materials for a Flora of the Malayan Peninsula"; also an account of the Deep Sea Collection made during the season of 1892-93 in H.M. Indian Marine Survey steamer *Investigator*, by Dr. A. Alcock, Superintendent of the Indian Museum.

We have received two important reprints from the "Sixth Annual Report of the Missouri Botanical Garden": North American species of *Sagittaria* and *Lophotocarpus*, by Jared G Smith, illustrated by twenty-nine beautifully executed plates; and a description, by W. Trelease, of *Leitneria Floridana*, a Floridan tree now for the first time discovered in south-eastern Missouri. The systematic position of this monotypic genus is still uncertain; the author being doubtful whether to place it near the Platanacea among Apetalæ, or near the Dipterocarpeæ or Balsamifluæ among Polypetalæ. This paper is also illustrated by fifteen excellent plates.

The first edition of Dr. J. E. V. Boas' "Lehrbuch der Zoologie für Studirende und Lehrer" (Gustav Fischer, Jena) was reviewed in these columns at the beginning of 1891 (vol. xliii. p. 268). A second edition of the manual has now been published. No alterations have been made in the plan of the book, but emendations and numerous additions have been inserted here and there, so as to bring the matter in line with recent work. Nearly fifty illustrations have also been added.

The tenth edition of "Quain's Elements of Anatomy" edited by Profs. E. A. Schäfer, F.R.S., and G. D. Thane, is slowly approaching completion. Messrs. Longmans, Green, and Co., the publishers of the work, have just issued the third part of vol. iii., dealing with the Organs of the Senses, and it is announced that the second part of this volume (Peripheral Nerves) will be published shortly. The fourth part (Visceral Anatomy) is in preparation, and will complete the work.

So long ago as 1883 we reviewed (vol. xxviii. p. 195) the first part of "Field and Garden Crops of the North-Western Provinces of Oudh," by Mr. J. F. Duthie, the Director of the Botanical Department of Northern India. The second part was published a year after the first, but the third and concluding part, dealing almost entirely with garden crops, has only just reached us. All important plants of this kind, grown in India on comparatively small plots, are described and excellently illustrated. Mr. Duthie has added to the usefulness of his work by giving at the end of the part just received a general index to all the parts.

In the Report of the U.S. National Museum for the fiscal year ending June 30, 1891, there are several papers describing and illustrating collections in the Museum, in addition to the reports of the various curators. Dr. G. Brown Goode describes the genesis of the Museum in an article full of information. The ethnological collections in the Museum from Kilima Njaro, East Africa, are enumerated by Dr. W. L. Abbott, and the Korean collections by Mr. Walter Hough, both papers being well illustrated. Mr. Romyn Hitchcock contributes three papers to the volume, one on Shinto, or the mythology of the Japanese, another on the ancient burial mounds of Japan, and a third on some ancient relics found in Japan. Finally, Mr. George H. Boehmer's exhaustive history of the prehistoric naval architecture of the North of Europe is included. This paper should be referred to by all who are interested in the development of the art of shipbuilding.

Scarcely a week passes without our receiving several voluminous reports on scientific work carried out under the auspices of the United States Government. One of the last volumes to come to hand is the Report of the U.S. Commissioner of Fish and Fisheries for 1889 91. The Commissioner's report alone is a valuable summary of work, but this covers less than one hundred pages, and the remaining 550 pages consist of papers upon various branches of inquiry. The subjects of these investigations are food-fishes and fishing-grounds, methods and statistics of the U.S. fisheries, the work of the U.S. Fish Commission steamer *Albatross*, the oyster resources and oyster fishery of the Pacific Coast of the United States, the coast fisheries of Texas, a review of the sparoid fishes of America and Europe, fish Entozoa from the Yellowstone National Park, and last, but not the least important, a translation of Prof. Haeckel's "Plankton-Studien," being "a comparative investigation of the importance and constitution of the marine fauna and flora." All these papers will be read with interest by students of marine biology.

SINCE 1844, Müller-Pouillet's "Lehrbuch der Physik und Meteorologie" (Vieweg und Sohn, Braunschweig) has passed through eight editions, and the ninth edition, edited by Dr. L. Pfaundler, only wants the second part of the second volume to complete it. There are three volumes altogether. Vol. i. treats of Mechanics and Acoustics, and vol. iii. of Magnetism and Electricity. The former appeared in 1886, and the latter in 1890. The publication of the second volume, dealing with Light and Heat, has been delayed owing to the removal of the editor to Graz University. Dr. Otto Lummer has, however, taken up the work where it was left, and the publishers have been able to issue the first part of the second volume, containing four chapters on Light. It is hoped that the remainder of the volume will be published at no very distant date. The whole edition has been thoroughly revised and greatly enlarged, the work, so far as yet published, running into more than 2200 pages. It is unfortunate that so many years should have elapsed between the publication of vols. i. and iii. and that the issue of vol. ii. should have been so long delayed. Owing to these differences of dates, the edition cannot be said to represent, as a whole, the state of physical science at any particular epoch. Like Jamin's and Ganot's and Deschanel's works on physics, that of Müller-Pouillet is amply illustrated. All experimental apparatus is fully described, and the objects accomplished with it explained in detail without the use of advanced mathematics. In a prefatory announcement the work is commended to those "welche nicht Gelegenheit finden, akademische Vorträge mit Experimenten zu besuchen." From this one could be led to believe that the manual was suitable for reading by a public debarred from seeing physical experiments performed. This, however, is not the case. The place of the work is among books of reference suitable for elementary students of natural philosophy, not with those designed for general readers.

THE additions to the Zoological Society's Gardens during the past week include a Bornean Ape (*Macacus inornatus*, ♀) from Borneo, presented by Mrs. Florence Firman; a Puma (*Felis concolor*, ♀) from South America, presented by Miss Florence Dickinson; a Leopard (*Felis pardus*, ♂), a Cheetah (*Cynælurus jubatus*) from East Africa, presented by Major Owen; an Isabelline Bear (*Ursus isabellinus*, ♂) from Cashmere, presented by Mr. E. Haag; a Sloth Bear (*Melursus ursinus*) from the Hills of Orrissa, Bengal, presented by Mr. J. W. Currie; a Downy Owl (*Pulsatrix torquatus*) from Brazil, presented by Dr. E. A. Goeldi; an Eroded Cinixys (*Cinixys erosa*) from Cape Lopez, Gaboon, presented by Commander J. L. Marx, R.N.; a Greek Tortoise (*Testudo græca*) from Greece, presented by Mr. H. K. Bartlett; a Hoolock Gibbon (*Hylobates hoolock*) from Assam, a Black-handed Teetee (*Callithrix melanochir*) from Brazil, a Black-winged Peafowl (♂) from Cochin China, five Helodermas (*Heloderma suspectum*) from Arizona, deposited; a Great Anteater (*Myrmecophaga jubata*) from South America, a Black Stork (*Ciconia nigra*), European, two Japanese Teal (*Querquedula formosa*) from North-East Asia, purchased; a Wapiti Deer (*Cervus Canadensis*, ♂), a Mouflon (*Ovis musimon*, ♀), a Yellow-footed Rock Kangaroo (*Petrogale xanthopus*, ♂), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

BRIGHT-LINE STARS.—Exact information about stars with bright lines in their spectra is appreciated by all who have the advance of celestial science at heart. In a paper in the June number of *Astronomy and Astro-Physics*, Prof. W. W. Campbell brings together all that is known with regard to objects of this spectroscopic character, and adds to the literature a number of important observations made by himself. Since 1867, when MM. Wolf and Rayet discovered three bright-line stars in Cygnus, fifty-two objects of the same type have been found, forty-two of this number being placed to the credit of the Harvard College Observatory. Prof. Campbell has made visual determinations of the positions of the lines in the spectra of thirty-two of these stars, and has also photographed the spectra in juxtaposition with a hydrogen comparison spectrum. One of the most noteworthy facts brought out by the observations is that the hydrogen lines in the spectra present a variety of forms and intensities. In many of the stars they are dark; in others, they are dark with bright borders. The bright hydrogen lines vary from faint to very bright, from monochromatic lines to very broad bands, and from those clearly single to those apparently multiple. Like many lines in the spectra of nebulæ, those of bright-line stars are difficult to identify with terrestial substances. The ubiquitous lines of hydrogen are certainly present, and Prof. Campbell finds that prominent lines of iron and other elements appear to coincide with a few of the star lines, while a line at wave-length 4480 suggests to him a magnesium origin, but the identifications are not sufficient to lead him to make any definite conclusions. Much more can be learnt from his comparison, in tabular form, of lines in stars of the Wolf-Rayet type with those found in the solar chromosphere, in Nova Aurigæ, and nebulæ; also with dark lines in Orion stars, and in β Lyræ. The hydrogen lines are shown to be prominent in all the six spectra. With the exception of the lines of hydrogen, D_3, and that at λ 4472, lines in the chromosphere do not furnish any striking coincidences with lines in Wolf-Rayet stars. The parallel columns of lines also fail to indicate any connection between these stars and Novæ, the only point of similarity being that the lines in both these classes of celestial objects are broad. As is well known, the nebular spectrum and that of bright-line stars are much alike. A close examination, however, has led Prof. Campbell to think that nine prominent star-lines do not occur in nebulæ; while, on the other hand, five nebular lines were unsuccessfully looked for in the stars. His deductions from the whole of the observations are summed up as follows:—"In conclusion, I think we can say that the spectra of the Wolf Rayet stars are not closely related to any other known type. They appear to have several points in common with the nebular and Orion type spectra; but the last two appear to be much more closely related to each other than to the Wolf-Rayet spectra. It is therefore difficult to place these stars between the nebulæ and Orion stars. They certainly do not come *after* the Orion stars, and one does not like to place them *before* the nebulæ. We can probably say that the bright lines are chromospheric, owing their origin to very extensive and highly heated atmospheres, but showing very little relation, in constitution and physical condition, to that of our own sun. For the present, at least, this type of spectrum must be considered as distinct from every other known type, just as the nebular spectrum is distinct, and like the nebular spectrum containing lines whose origin cannot now be assigned."

EPHEMERIS FOR GALE'S COMET.—The following positions for Gale's comet are from the ephemeris given by Prof. Kreutz in *Astronomische Nachrichten*, No. 3229:—

Ephemeris for Berlin Midnight.

THE ROYAL SOCIETY CONVERSAZIONE.

THE rooms of the Royal Society were crowded with a distinguished gathering on Wednesday evening, the 13th inst., the occasion being the annual Ladies' Conversazione of the Society. In accordance with our usual custom, we give descriptions of the most important exhibits not previously mentioned in these columns.

Prof. McKenny Hughes, F.R.S., exhibited specimens illustrating the evolution of the breeds of English oxen. The earliest breed, *Bison priscus*, belongs exclusively to the Palæolithic age. The next, *Bos primigenius*, commenced with *Bison priscus*, but outlived that species, and is characteristic of the Neolithic age. Both the above forms had disappeared before the arrival of the Romans in Britain. *Bos longifrons* appeared with *Bos primigenius*, but survived to Roman times. The Romans improved *Bos longifrons* by crossing it with some larger breed having straighter and more upturned horns. As there was no large native breed surviving, and, moreover, the characters of *Bos primigenius* do not appear in the cross, the Romans must have imported the breed with which *Bos longifrons* was crossed. The type of the Roman breed is still seen in the tawny Highland cattle (a larger variety of which is still common in Italy), in the black Welsh and Highland (such as were killed for funeral feasts); and in the Chillingham cattle (the descendants of the white sacrificial bull). All these are whole-coloured: the parti-coloured cattle are a much later introduction. After the withdrawal of the legionaries, there was soon no care of selection of stock, and the cattle, except those preserved in enclosures or isolated in the far West and North, reverted to the type of *Bos longifrons* as seen in specimens from the mediæval ditches round Cambridge.

Mr. Shelford Bidwell, F.R.S., exhibited illustrations of recurrent vision and retinal oscillations. For recurrent vision a moving patch of light, white or coloured, projected upon a screen, was followed at a short distance by a "ghost" or recurrent image, generally of a violet hue. To show retinal oscillations a modified form of Charpentier's experiment was used, demonstrating the brief period of insensibility to luminous impression which follows the impact of light upon the eye.

The shell musical instruments (trumpets and flutes), exhibited by Dr. George Harley, F.R.S., included: (1) Shell fog-horn used by fishermen on the banks of Newfoundland (*Strombus gigas*). (2) Welsh shell trumpet used as a dinner [illegible] (small *Strombus gigas*). (3) Miner's blasting signal horn, used in the Guernsey granite quarries (*Strombus gigas*). (4) Conch trumpet, blown at funerals and religious festivals in Southern India (*Turbinella rapa*—peeled and decorated with brass [illegible]). (5) Triton shell flute from New Guinea (*Triton* [illegible]). (6) Helmet shell trumpet from New Guinea (*Cassis cornuta*). (7) Figure-ornamented triton trumpet from Japan. (8) Triton shell flute from Solomon Islands. The exhibitor expressed the opinion that shells were the first forms of trumpets and flutes ever employed.

Sketches of clouds, by Luke Howard, F.R.S., were exhibited by his granddaughter, Lady Fry. These sketches were lately found, unmounted, amongst the family papers of the late Luke Howard. In many cases they bear his initials, or remarks in his handwriting. They appear to have been drawn by him from instances which came under his own observation, during the time that he was conducting those studies which resulted in his work on "The Modifications of Clouds," and in his well-known nomenclature and classification. Some of them were copied for, and appeared in, his work. See also the "Einleitung" to Prof. G. Hellmann's recent reprint of Howard's work. (Berlin: A. Asher and Co., 1894.)

Original drawings of the "Milky Way," made at Birr Castle Observatory, were exhibited by Lord Rosse. These drawings, comprising one general view and three sections of same on an enlarged scale, represent the "Milky Way," as seen with the naked eye as far as 2[illegible] South Declination. They were reproduced by lithography on half the original scale by Mr. W. H. Wesley and published by Messrs. Longmans.

The Postmaster-General exhibited (1) Wheatstone's automatic transmitter, running up to 600 words per minute, driven by Willmot's air motor. The air motor in this instrument dispenses with the 132 lb. weight which, when the instrument is running at 600 words per minute, requires rewinding by the operator every few seconds. And since the motor is applied directly to the [illegible] axle, it dispenses with the whole of the train of wheel-work, the friction regulator and complicated fly-wheel. The speed of the instrument is regulated by opening or contracting the nozzle regulating the supply of air. The power required is so small that the instrument can be driven at a moderate speed by simply blowing into it with the mouth. (2) Prof. Hughes' type printing telegraph, driven by Willmot's air motor. The air motor in this instrument takes the place of the 132 lb. weight previously used, and dispenses with the whole of the winding gear, and nearly all the train of wheel-work, the motor being applied directly to the printing shaft. The motor is self-starting in any position, and will run continuously without any aid from the operator.

Messrs. John I. Thornycroft and Co. had on view a case containing models of torpedo boats, light-draft patrol steamer, and the "Thornycroft" water-tube boiler.

A sonometer for measuring the relative and comparative perception of hearing was exhibited by Mr. T. P. Hawksley. The instrument consists of two primary coils of unequal winding; between them slides a secondary coil, two dry cells, or a thermopile supply current, which is made intermittent by an adjustable rheotome. The secondary coil is connected to a deep note telephone, from which proceeds a tube to be applied to the ear. A condenser may be used. At one point on the scale the interruptions of the rheotome are not heard in the telephone, but on approaching the secondary coil to one of the primary coils, the interruptions gradually increase in loudness until they become unbearable to the ear.

Mr. J. Wimshurst exhibited models showing an improved method of communication between shore stations and light-ships, or other like purposes. The method consists in arranging suitably wound coils of insulated wire upon the swivel pin of the moorings, the one coil being in communication with the shore station and the second coil in communication with the ship. Signals, or sound, are transmitted by induction, or by electromagnetic induction.

Mr. Charles Bradbury's exhibit was the "Brunsviga" calculating machine, for plain figures or decimals. The "Brunsviga" is an arithmometer constructed on an entirely new system, and will add, multiply, subtract or divide with absolute accuracy, giving products up to 13 figures (ordinary size) or 18 figures (large size). The handle is turned in one direction for addition or multiplication, and in the reverse direction for subtraction or division. This machine is used at the Royal College of Science, the City and Guilds Technical College, the Millard Laboratory at Oxford, the Postal Telegraphs Department, &c.

Mr. Charles Baker showed apparatus for obtaining instantaneous photo-micrographs, and viewing the image until exposure is made. The apparatus consists of a case containing a metal shutter, carrying a prism, and connected with a pneumatic release. When this shutter is set the image in the microscope is projected, by means of a prism, on to a screen, which is fixed in an adjustable tube at right angles to the optic axis, and can be viewed and focussed up to the moment of exposure. To ensure accurate focus, the screen in the adjusting tube should be placed the same distance from the microscope as the plane of the sensitised plate. A slit in the shutter can be opened or closed to regulate the exposure.

The exhibit of the Marine Biological Association included: (1) Living pelagic larvæ, &c., from Plymouth. (2) Examples of the echinoderm fauna of Plymouth. (3) Hybrid between brill and turbot (North Sea). (4) Sole with an eye on each side of the body. The usual distortion, due to the shifting of the left eye to the right side, had not occurred (North Sea). (5) Plaice larvæ, up to 28 days' old, reared from eggs hatched in the Plymouth Laboratory. The organisms exhibited were either of economic or of scientific interest.

A method of heating by electricity for hospital purposes was shown by Mr. C. F. Snelckor. By means of this electrical mode of generating heat it is possible to obtain and maintain uniform any required degree of temperature. The apparatus is enclosed in an elastic and flexible case, with a silk or woollen covering, so that it can be applied to and envelope any part of the body as a fomentation. It can also be used for a domestic Turkish bath, or used as a footwarmer, and generally for warming purposes in the bedroom or carriage.

Prof. Oliver Lodge, F.R.S., exhibited a compact and sensitive detector for electric radiation, and a spherical radiator of short Hertz waves. The apparatus consisted of a small copper cylinder containing a piece of zinc and sponge, forming a battery, a coil and suspended needle-mirror, forming a galvanometer, and a ball contact or ' coherer," or else a tube of filings, in circuit with the other two. Electric surgings in the air, or in a scrap of wire pegged into the lid, increased the conductance of the circuit. A light tap on the cylinder reduced it again. A handy lamp and scale enabled the deflexion of the needle to be seen. The surgings could be excited by giving sparks to an insulated sphere not far off, especially if the knobs supplying the sparks are well polished.

The exhibit of Dr. E. C. Stirling, C.M.G., F.R.S., was a series of fourteen photographs, with two maps and a geological section illustrating the researches carried on at Lake Callabonna, in South Australia, for remains of Diprotodon and other extinct animals, in 1893. A description of the work to which these photographs refer is given in another part of this number.

Gold leaf made by electro-deposition was exhibited by Mr. J. W. Swan, F.R.S. This exhibit illustrated an attempt to produce gold leaf by electro-chemical instead of mechanical means. The leaves were prepared by depositing a thin film of gold on a highly polished and extremely thin electro copper deposit. The copper was then dissolved by perchloride of iron, leaving the gold in a very attenuated condition. The leaves were approximately four millionths of an inch thick, and some of them mounted on glass showed the transparency of gold very perfectly when a lighted lamp was looked at through them.

Miss Edna Walter and Mr. H. B. Bourne had on view a projective goniometer. By means of this instrument, devised and constructed by the exhibitors, the projection of a crystal on a sphere is actually accomplished, realising in practice the fundamental assumption of the theory of crystallography: the instrument is thus of value in demonstrating the axioms of the science. If necessary, angular measurements could be made from the image, but these only attain an accuracy of about 40' in 60° = one per cent., which is inferior to that attained with a goniometer.

Lord Kelvin showed a model illustrating the molecular tactics of a quartz crystal. The crystalline molecule was represented by a regular hexagonal prism of wood, the long diagonal of the hexagon being ·95 of the length of the prism. This gave in the assemblage representing a quartz crystal of regular form, the correct angle (38° 13' between the faces of the prism and the faces of the terminal six sided pyramid. Each crystalline molecule was marked on alternate sides with slips of blue and red paper, to show the orientational difference between the alternate sides of the prism and the absolute difference between the alternate faces of the pyramid. The coloured slips were placed obliquely to give the chiral quality of the crystalline molecule and of the assemblage. Right-handed and left-handed molecules were shown. All the piezo-electric and pyro-electric properties of the crystal (including the chiral piezo-electric property discovered by Voigt) would be actually produced in the model, if copper and zinc were substituted for the red and blue paper, and the individual prisms separated by elastic insulating material. The model showed the well-known orientational macling on two faces of the prisms, and the contiguous pair of faces of the terminal pyramid.

Dr. Isaac Roberts, F.R.S., showed original negatives and enlarged photographs of the spiral nebulæ Messier 74 Piscium, Messier 101 Ursæ Majoris, Messier 65 and 66 Leonis, Herschel I. 168 Ursæ Majoris, Herschel I. 56 and 57 Leonis. These photographs revealed the forms and structures of the spiral nebulæ with much greater detail and accuracy than had previously been known. They also clearly showed that the spirals were almost perfect geometrical figures, but broken up into numerous stars, or star-like condensations of the nebulosity, or of the meteoric matter, of which they are probably composed, and thus furnish strong evidence of the truth of the nebular or of the meteoric hypotheses.

A number of specimens illustrating locomotion phases in decapod crustacea were exhibited by Prof. Stewart, who also showed mummy cloth, of not later than 4000 B.C., compared with finest Irish linen of to-day. The piece of mummy cloth, made not later than 6000 years ago (IVth Egyptian Dynasty), was shown by the side of a piece of finest Irish linen 140 · 140 of to-day. The strands of the mummy cloth were 300 150 per inch.

Specimens of metallic chromium, manganese, tungsten iron, &c., free from carbon, also fused alumina, obtained during reduction of the metallic samples, were exhibited by Mr. Claude Vautin. The specimens of metallic chromium, manganese, &c., had been reduced from their oxides by means of metallic aluminium. The oxide of the metal to be reduced was intimately mixed with finely divided aluminium, and heated in magnesia-lined crucibles. The heat produced by the oxidation of aluminium during the operation was sufficient to fuse alumina, specimen of which was exhibited.

Prof. A. M. Worthington, F.R.S., and Mr. R. S. Cole exhibited photographs of a splashing drop. The photographs shown were obtained by allowing a drop to fall in absolute darkness, and illuminating it at any desired stage of its splash by a suitably timed Leyden jar discharge taking place between magnesium terminals. The exhibit comprised (1) shadow photographs obtained when a drop of mercury fell on the sensitive plate itself, which was laid horizontally and illuminated from above; (2) objective photographs, showing much more detail than has usually been obtained in such instantaneous work, and illustrating the exquisite sensitiveness of the very rapid modern plates. To obtain these photographs the spark was produced at the focus of a deep, silvered watch glass subtending an angle of nearly 180°, and was brought very near to the place of impact. A single quartz spectacle lens was substituted for the usual lens of the camera, and thus the absorption of photographic rays by glass was avoided.

Mr. W. Kurtz (New York) exhibited photographic prints in the natural colours, obtained by printing in the three primary colours only (Dr. Vogel's process). The prints shown were all of them printed in *three* colours only, some by surface-printing, the others by lithography; but in all cases the printing blocks were produced by photography. The process employed is as follows:—By the intervention of suitable media, three photographs are obtained, severally appropriate to the three primary colours composing the original picture or view required to be reproduced. From these three photographs, respectively due to the chemical action of the red, yellow, and blue rays of the spectrum, printing blocks are prepared, which being printed from in red, yellow, and blue ink, give the multi-coloured effects shown by the specimens.

Prof. Elisha Gray exhibited the telautograph, an instrument for transmitting intelligence by electricity. The writer at one station using a lead-pencil, attached mechanically to the apparatus, and writing upon ordinary paper, transmits to the distant station a facsimile of his handwriting, at his ordinary writing speed. Sketches, sketch-portraits, diagrams, plans, trade-marks, and the like, as well as the characters of hieroglyphic alphabets may also be transmitted.

The following exhibits, with demonstrations by means of the electric lantern, took place in the meeting room of the Society:—

The magic mirror, by Mr. J. W. Kearton. It was shown that the English magic mirror owes its peculiar properties to curved elevations and depressions in the polished metallic face, the elevations producing figures in shade by scattering of light, and the depressions, figures in light by condensing rays reflected from the mirror on to a screen. The figures in relief and intaglio are first produced by the action of any suitable acid on the metal plate, and are then polished down until they disappear to direct vision The figures of the Japanese type of mirror are by-products in the process of manufacture, and arise from local yieldings of the face and back during polishing: the more rigid parts of the face, which correspond to raised metallic figures on the back, suffer a somewhat greater reduction from opposing greater resistance to the polishing tool.

As at the previous conversazione, Prof. E. B. Poulton gave illustrations of recent work upon the influence of environment upon the colours of certain lepidopterous larvæ.

Mr. D. Morris, C.M.G., exhibited and described a series of views illustrating the leading features of tropical vegetation.

A CHEMICAL METHOD OF ISOLATING FLUORINE.

A NEW salt of exceptional interest, the first member of a series of fluorplumbates, is described by Dr. Brauner, of Prague, in the June issue of the *Journal* of the Chemical Society. Dr. Brauner is well known in this country, having been Berkeley Fellow of the Owens College, Manchester, previous to his appointment to the chair of chemistry in the Bohemian University. Twelve years ago he described two compounds very rich in fluorine, $CeF_4 . H_2O$ and $3KF . 2CeF_4 . 2H_2O$, and showed that when heated they first gave up their water and subsequently evolved a gas which possessed an odour similar to that of hypochlorous acid, and which exhibited the chemical properties expected of free fluorine. The compound now described is a fluorplumbate of the composition $3KF \cdot HF \cdot PbF_4$. It may be obtained by three methods. The first consists in treating the freshly precipitated hydrated oxide of lead, $Pb_3O_4 \cdot 3H_2O$, a substance described by Dr. Brauner in the year 1885, with a mixture of hydrogen potassium fluoride and hydrofluoric acid. The fluorplumbate is separated from the lead difluoride simultaneously formed by crystallisation from hydrofluoric acid. The second method consists in substituting fluorine for oxygen in the plumbates of Fremy. Peroxide of lead and caustic potash, in the proportions of the compound $3KOH \cdot PbO_2$, are fused in a silver crucible; the product is moistened with water, and then added gradually to excess of pure hydrofluoric acid. The filtered solution is evaporated to the crystallising point in a current of air, and as soon as crystals commence to form is placed in a vacuum desiccator. Crystals of the salt are then deposited. The third method consists in displacing the acetic acid in lead tetracetate by fluorine. One molecular equivalent of lead tetracetate is added to three equivalents of hydrogen potassium fluoride, $HF \cdot KF$, dissolved in hydrofluoric acid; crystals of potassium fluorplumbate are formed upon evaporation, either in the air or *in vacuo*. Analyses of the crystals prepared by all three methods indicate the composition $3KF \cdot HF \cdot PbF_4$.

The needle-shaped crystals, which frequently attain the length of a centimetre, and are grouped radially, have been found to be in all probability monoclinic in symmetry, and isomorphous with the analogous fluorstannate described by Marignac.

Potassium fluorplumate is permanent in dry air, but becomes brown in moist air, being decomposed by water, with formation of hydrated peroxide of lead, hydrogen potassium fluoride, and free hydrofluoric acid The effect of heat upon the salt is most interesting and important. The experiments should be carried out in a platinum tube. At 100°–110° the crystals remain unaltered. At 200 hydrogen fluoride commences to be evolved in small quantity. When subjected to a much higher temperature, after previous heating for several hours at 230°–250°, a gas commences to be evolved endowed with the odour ascribed by Moissan to fluorine. This occurs much below a red heat. The gas liberates iodine in such large quantities from iodised starch paper as to cause it to be deposited in crystals, and small crystals of silicon held in the open end of the tube not only burn with a vivid incandescence, but even with explosive violence. There can, therefore, be no question that the gas is free fluorine, and it would thus appear that Dr. Brauner has discovered a trustworthy purely chemical process of isolating the element. Potassium fluorplumbate loses its hydrogen fluoride almost completely at 230°, without losing more than a trace of fluorine from the lead tetrafluoride. Any small traces of hydrogen fluoride subsequently evolved along with the fluorine at the higher temperature may be readily removed by Moissan's method of passing the gas over potassium fluoride.

Dr. Brauner has already obtained evidence of the existence of a whole series of fluorplumbates, analogous to Marignac's fluorstannates, and is now engaged in studying the sodium salt.

A. E. TUTTON.

A SURVEY OF THE ENGLISH LAKES.

AT the last meeting of the Royal Geographical Society a paper was read by Dr. Hugh Robert Mill, on the Lake District of North-western England, of which the following is an abstract The lake district is a remarkably definite and symmetrical geographical unit. It may be roughly described as a circular mass of elevated land, highest in the centre, and furrowed by a series of valleys running from the centre toward the circumference like the spokes of a wheel. Most of these valleys contain long narrow lakes of considerable size, and of a different type from the small round mountain tarns which also occur in the district.

An account was given in the paper of the methods employed for ascertaining the depth and fixing the position of each sounding, and for mapping the resulting information. The lakes considered were Windermere, Ullswater, Coniston Water, Wastwater, Ennerdale Water, Buttermere and Crummock Water, Derwentwater, Bassenthwaite Lake, and Haweswater, each of which was found to have certain special characteristics which distinguished it from all the others. The soundings were carried out by the author, assisted by Mr. E. Heawood, Mr. Shields, and others.

There are two main types amongst these lakes, the shallow and the deep. The former, including only Derwentwater and Bassenthwaite, are the broadest of all the lakes; they average 18 feet in depth, their mean depth being only 25 per cent. of the maximum depth, a smaller ratio than for any other lakes. The bed of these lakes may be roughly described as an undulating plain, grooved and ridged into shallow hollows, and low shoals running parallel to the long axis of the lake. The configuration suggests that they may have been shallowed by glacial accumulations.

The second, or deep type, the shallowest of which has an average depth of 40 feet, and in which the average depth varies from 36 to 61 per cent. of the maximum depth, comprises all the other lakes except, possibly, Ennerdale, which combines the characteristics of both types. They are long, narrow, sometimes winding like Ullswater, or slightly curved in outline like Wastwater and Haweswater. The most characteristic lie in long narrow valleys with steeply sloping sides, and the slopes are continued under water with almost equal steepness, in some cases with greater steepness, and terminate in a nearly flat floor. The typical form of this class of lake is thus a steep-sided flat-bottomed trough, diversified along the slopes by the still steeper conical mounds of débris thrown down at the mouths of streams. In Haweswater the largest example of a delta occurs, nearly cutting the lake in two; while Buttermere and Crummock, lying in one uniform valley, are entirely separated, probably by the same action, and Derwentwater is also divided from Bassenthwaite by a broad alluvial plain. Although most of the lakes show only one clearly defined trough, the two largest are divided into distinct basins. In Windermere, the shoal on which Belle-isle and the other islands off Bowness, rise separates the deep and wide upper basin from the less deep and much narrower lower basin. In Ullswater each of the three reaches of the lake contains a definite basin separated from the others by broad or narrow bars. From one of these the island of House-holm rises, a mass of strongly glaciated rock; but while the position of the basin to the south of it seems to confirm the glacial theory of the excavation of the hollow, the hollow to the north of the island is so situated as to make its origin by glaciation somewhat difficult to understand.

Three of the lakes have depths which descend below sea-level. In Wastwater 217 acres lie beneath sea-level, so that if drained to that extent it would present the appearance of a lake still 58 feet in depth at one point. Windermere, if similarly drained, would show a northern lake 3¼ miles long with a maximum depth of 90 feet, and 3 miles further south a narrower lake 1 mile in length and only 14 feet deep at its deepest, while south of this there would be a still shallower lagoon half a mile long. In Coniston reduced to sea-level there would probably appear one narrow lake 2½ miles long and 42 feet in maximum depths. All the other lakes are situated at such elevations that they do not approach sea-level in their greatest depths.

Altogether, the lakes which have been sounded and mapped cover an area of 20 square miles of unexplored territory. Contoured maps of the ten lake basins under consideration have been supplied to the Ordnance Survey for incorporation on the official maps of the country.

THE RECENT DISCOVERY OF FOSSIL REMAINS AT LAKE CALABONNA, SOUTH AUSTRALIA.[1]

I.

FROM time to time notices have appeared of a remarkable discovery of fossil bones at Lake Mulligan in the interior of South Australia, but so far there has been no connected statement of what has been done in the way of developing the discovery. For reasons which will be evident, it is not yet possible to announce the results with anything more than a rough approximation, which leaves many interesting questions unsolved, or even untouched. Still, in view of its palæontological importance, it seems desirable that any available information should be given without further delay.

Necessarily a fragmentary and imperfect record, I trust the following account will, at least, afford evidence that the authorities of the South Australian Museum are fully alive to the interest of the issues involved, and that, so far as their not

[1] By Dr. E. C. Stirling, F.R.S., C.M.G., Hon. Director, South Australian Museum.

too ample means will allow, they are doing their best to prosecute successfully a work of some magnitude and difficulty.

One other preliminary statement seems necessary. Though the so called lake in which the fossils were found has been hitherto spoken of as Lake Mulligan, that name has never been officially conferred or recognised, and indeed it will not be found on any of the maps of South Australia. There prevails a very proper sentiment, unfortunately not always carried into action, that the native names of localities should, so far as possible, be retained. In this particular instance the euphonious native name Callabonna, which applies to a large water-course leading into the lake and to an adjoining sheep-run seemed appropriate in all respects, save that the association of sound and idea might erroneously suggest the possession of the scenic beauties of an Italian lake by an area which is not only waterless, but also almost unsurpassable for barrenness and utter desolation. The name, however, has been approved by the Executive, and in future the locality will be known as Lake Callabonna, and will be so called in the following notes:—

PHYSICAL FEATURES OF THE LAKE EYRE BASIN.

As has often been observed, those who might form their estimate of the physical geography of South Australia from an inspection of its maps alone, would come to very erroneous conclusions. The numerous, and often immense, areas marked as lakes, and the plentiful streams which appear to supply them, deserve their names on rare occasions only. Ordinarily the lakes are only shallow, mud-bottomed, or salt-encrusted clay-pans, and the rivers dry water-courses, or it may even be that a definite channel is unrecognisable. Only after the heavy tropical rains, which at too rare intervals descend to these latitudes, do the rivers run for a brief period and the lakes contain water, though for some time afterwards the deeper parts of the water-courses may remain as water-holes, or chains of water-holes of greater or less size and permanence. Those, however, who have only seen the river channels dry, can have little idea of what torrents they may become under such circumstances. The flood waters of the Barcoo or Cooper, some few years ago, spread over a breadth of from forty to fifty miles on its way to reach Lake Eyre. Lake Eyre itself has occasionally been filled, and is then a vast inland sea over a hundred miles long and fifty broad, and, when full of water, might well have suggested great possibilities of internal navigation.

The area of these inland lakes presents roughly a division into a Western system, comprising Lake Gairdner and numerous adjacent smaller clay-pans; a Central system, of which Lake Eyre, Lake Eyre South, and Lake Torrens are the chief members; and an Eastern system, comprising, in their order from north to south, Lakes Gregory, Blanche, Callabonna and Frome. These three systems have no direct communication with one another; in fact, they are separated by more or less elevated ground.

From the fact of some of the early explorers, in proceeding northwards, having struck the apparently unending margins and impassable beds of the huge clay-pans, either of Lake Torrens, of Lake Eyre, or of those of the Eastern group, all of them were for some time supposed to be continuous and to form one great lacustrine surface. Indeed, for many years a familiar feature on the maps of Australia was an immense crescentic, or horse-shoe shaped, area with its two horns, formed by the present Lakes Torrens and Frome, directed southwards. Eventually the progress of discovery enabled this horse-shoe to be broken up into the constituents now called Lakes Torrens, Eyre, Gregory, Blanche and Frome, as they now appear. It is easy to see, on reference to the map, how great the chances were that explorers, having once passed into the then unknown region enclosed within the concavity of this great system of clay-pans, should have had their further progress checked at the shores of one or other of them.

The constituents of the Eastern system, with which we are more immediately concerned, form a chain of clay-pans connected by intervening channels, and together they present a curve with its concavity directed towards the west. The whole of the series is, according to the most recent maps, included between the meridians of longitude 138° 50′ and 140° 20′ East of Greenwich, and the parallels of south latitude 31° 12′ and 28° 50′.

On those rare occasions when the flood waters of the Barcoo come down in sufficient volume, from the immense area which it drains in Southern Queensland, they pass into the Strzelecki, a large effluent which leaves the main channel at Innamincka, a place of melancholy memory in the history of Australian discovery, as close by the present settlement lie the remains of the ill-fated Burke, who perished in 1861 after a successful transit of Australia. These floods may then fill Lakes Gregory and Blanche; the latter lake, indeed, was filled two years ago, when its waters remained fresh for six months. A channel from the Strzelecki leads into Lake Callabonna, and I am informed that this depression also was filled from the same source some years ago, a statement which is supported by the presence upon the sand-hills of numerous fragments of the eggs of fresh-water fowl and of bones of water-rats. On the older maps Lake Callabonna was depicted as a northerly extension of Lake Frome, and indeed these two are actually connected by a channel, but whether water has ever been known to flow from one into the other I have not been able to learn.

There is compensation for the unpromising physical features of Lake Callabonna, that will be afterwards described, in the fact that its bed has lately been shown to be a veritable necropolis of gigantic extinct Marsupials and Birds, which have apparently died where they lie, literally in hundreds. The facts that the bones of individuals are often unbroken, close together and frequently in their proper relative positions, the attitude of many of the bodies, and the character of the matrix in which they are embedded, negative any theory that they have been carried thither by floods. The probability is rather that they met their death by being entombed in the effort to reach food or water, just as even now happens in dry seasons to hundreds of cattle which, exhausted by want of food, are unable to extricate themselves from the boggy places that they have entered in pursuit either of water or of the little green herbage due to its presence. The accumulation of so many bodies in one locality points to the fact of their assemblage around one of the last remaining cases in the region of desiccation which succeeded an antecedent condition of plenteous rains and abundant waters. An identical explanation has been suggested by Mr. Daintree in his notes on the Geology of Queensland (*Journal Geol. Soc.* 1872, p. 275).

LAKE CALLABONNA.

Lake Callabonna, the description of which is, in its main features, applicable to its kindred clay-pans, has a length of over fifty miles. About ten miles wide at its northern extremity it narrows to four or five at the site of the recent excavations, which is some fifteen miles to the southward, and becomes still further constricted in the remainder. Its shores, especially on the eastern side, are as yet imperfectly surveyed, nor have, I believe, any levels been taken of its bed. Possibly, like Lake Eyre, it may actually be below the sea level, but in any case it is relatively low lying, for water-courses lead into it on three sides. The Mount Hopeless, Verila, Woratchie, Hamilton, Parabarana, and Pepegoona Creeks, all of which rise in the Flinders Range, enter it on the western side, and the Callabonna and Yandama Creeks, rising in the Grey Range, on the east. Though these only run after heavy rain, they may then bring down a considerable quantity of flood water. As I have already stated, water can flow into it at the northern end by the Moppa-Collina Channel which communicates with the Strzelecki. The occasional character of the surrounding country may be best appreciated by reference to some of the names given by the early explorers and settlers, such as Mount Hopeless, Dreary Point, Illusion Plains, Mount Deception, Mirage Creek, which tell their own story of drought, difficulties, and disappointments.

Speaking generally, the bed of the lake is a great flat clay-pan, depressed, but very little, below the surrounding country. In the neighbourhood of the fossiliferous area, however, this prevailing flatness is broken by the existence of an aggregation of dunes or hillocks of fine drift sand, not exceeding thirty feet in height, and with the ridges running more or less north and south at right angles to the direction of the prevalent westerly winds. These dunes are so far discontinuous that, did the lake contain a very few feet of water, they would be converted into a number of irregularly-shaped sand islets. From a foot to eighteen inches below their surface is a layer of loosely compacted sand rock in which were found the bivalve *Corbicula desolata*, Tate, now living in the Cooper River system, and the univalve *Blanfordia stirlingi*, Tate, not yet known to be living, though related to the common littoral species *B. striatula*.

The sand-dune area is about four miles long from north t south, and about three miles wide. The camp of the working party was at first pitched on the east side of the most southerly hillock, but the extreme exposure of the site to the prevalent winds and sand-storms soon compelled a change to the opposite side. Northward of the sand-hills, so far as the eye can reach, the whole lake bed is an unbroken flat expanse, covered with gypsum crystals of all sizes, from which the reflection of the bright sunlight causes a glare painful to the eyes. The greatest distance in this direction reached by members of the party was eight miles. Here there are a number of brackish springs in the bed of the lake, each surrounded by a fringe of "bull-rushes" (*Typha* sp.), and on the way thither a peculiar oval mound was passed, consisting of an interior mass of soft black mud covered by a greyish crust, the whole structure quaking on pressure like a jelly. The size was about twelve feet long by eight feet broad and four feet high.

South of the camp is another flat expanse on which water very readily collects even after a light fall of rain. When this is dry the surface is white from the presence of a saline efflorescence, probably sulphate of sodium. East and west the group of sand-hills are separated from the mainland by salt-encrusted flats of about half a mile in width, which in dry weather are passable for camels and even for light vehicles, but are extraordinarily boggy and sticky after rain.

There are a few shallow water-courses near the camp, the general direction of which is from north to south, and in some parts of these salt water stands permanently. The soft black mud which forms their bed contains in many places much decomposing vegetable matter, and often stinks horribly from the evolution from it of sulphuretted hydrogen gas. In one place there is, in the bed of the water course, a round black-looking hole standing full of water, which gave no bottom with soundings at twenty five feet.

After a continuance of dry weather, the flats around the camp become coated with a white amorphous saline crust with this peculiarity, that it does not form on surface tracks, and these thus appearing dark amid the surrounding white ground, the scene suggests with singular force the appearance of footprints on a snow field. On the other hand, whenever water collected in the tracks and other indentations has evaporated, which very soon takes place under the influence of the strong, dry winds of the locality, there are left behind large flat glistening prismatic crystals which, in excess of dryness, crumble into a fine white powder. Unfortunately, the nature of these crystals cannot now be precisely stated, as the samples collected have not reached Adelaide, but, from their shape and behaviour, there is little doubt but that they are composed of sodium sulphate.

Scarcely any vegetation relieves the prevailing desolation beyond stubbly "samphire plants" (*Salicornia*), which grow in patches upon the sand hills, and rarely exceed two feet in height. Judging by the unusual thickness of their stems, some of these bushes must be very old. A few scattered and still more stunted bushes of the same plant grow upon the intervening flats. To the north and south of the sand-hills not a bush relieves the unbroken monotony of the level, white crystalline surface.

On the western side, not far from the margin of the lake, are the Mulligan Springs, where a station hut was formerly in occupation, but this has been for some time abandoned. The [illegible] country is now under pastoral lease to the Beltana [illegible] Company, whose holding extends continuously to the westward for a distance of 150 miles. The eastern spurs of the [illegible] Range, the highest summits of which reach an elevation of [illegible] 3000 feet, approach to within about twenty miles of the lake, and at [illegible], on the eastern slope of the range, there are [illegible] springs. [illegible]onna Station, belonging to Messrs. [illegible] Brothers, borders the lake on the east, and consists [illegible] of [illegible] plains which stretch to, and beyond, the boundary of New South Wales. The station-house stands on [illegible] Creek, about four miles from the lake, and six from [illegible]. Farther south is the Mulloowurtina Station, belonging to Mr. D. McC[illegible]. The distance from Adelaide in a [illegible] line is about 400 miles, but to reach the lake by the [illegible] route necessitates a journey by rail of about that length and an additional 150 to 200 miles by road, according to the route selected. The whole journey thither occupies five to six days, or longer in bad seasons.

Such are the physical characters of this uninviting region; its geological features will be afterwards considered.

History of the Discovery.

During many years, and from many parts of South Australia, notably from the Lake Eyre district, the South Australian Museum has from time to time received teeth and fragments of *Diprotodon* bones, which were occasionally associated with fragmentary remains of Macropods, Crocodiles, Turtles, and large Birds.

Among such donations were some teeth and portions of the lower jaw, sent to us in 1885 by Mr. John Ragless, which were found by his son, Mr. F. B. Ragless, in a water-course at a depth of five feet, about two miles east of the margin of Lake Callabonna, and about twelve miles north-east of the place where the more recent discoveries have been made. It was not, however, until 1889 that the Museum obtained a very perfect skull, and several other bones in their entirety, from Baldina Creek, near Burra, a locality about a hundred miles due north of Adelaide. In the same year, from fragments found at Bundey, in the same district, we were able to restore incompletely another skull, which differs very considerably from the former. A little later a third, but more imperfect, skull was found at Gawler, twenty-five miles north of Adelaide.

Since the first discovery of *Diprotodon* remains in the Wellington Caves, by Sir Thomas Mitchell, in 1830, teeth and bones of this animal have been found over an extensive area which extends from the Gulf of Carpentaria to Victoria, and from the Darling Downs to the Lake Eyre Basin. They have also been found at Kimberley, in North-west Australia, and to the west of the head of the Great Bight; so that the *Diprotodon* appears to have had an immense range, and probably wandered over the whole continent of Australia.

The existence of bones in the actual bed of Lake Callabonna was made known to Mr. F. B. Ragless on January 10, 1892, by an intelligent aboriginal who described them as being very large and numerous, and two days afterwards Mr. Ragless himself visited the locality, which subsequently became the seat of operations. A few days later the place was visited by John Meldrum, who had been for some months in Mr. Ragless's employ, and by him some fragments were brought to Adelaide. These facts having come to the notice of the Museum authorities, Mr. H. Hurst, who had been previously engaged in geological and palæontological work in Queensland, was commissioned to inspect and report. The promising nature of the report of this gentleman ultimately led to the despatch to the lake of a party under his charge in January 1893.

The Work at Lake Callabonna.

Operations under Mr. Hurst's superintendence were continued for four months, during which time a considerable amount of material was obtained. Towards the end of June 1893, however, work, having been previously interrupted by rain, had to be finally discontinued in consequence of a heavy fall, and Mr. Hurst, with one of his party, returned to Adelaide, bringing with him as many bones as could be carried in a "buck-board" buggy.

At this stage it appeared desirable for various reasons that the work of excavation should be continued under the direction of a responsible Museum officer, and accordingly, at the desire of the Board of Management, I left for the field on August 11, 1893, in company with Mr. Zietz, the assistant director, and another member of the Museum staff. On our arrival at Lake Callabonna Mr. Hurst, who had by that time returned to the camp, resigned his appointment, with another member of his previous party.

As the result of Mr. Hurst's labours about a ton of bones were soon despatched to Adelaide. Shortly after our arrival a fall of rain, though not exceeding half an inch in amount, was sufficient to cause considerable sheets of water to collect on the low-lying flats, to fill up the holes which had been excavated, and to render the clay surface of the lake, at the best of times very soft and sticky, so boggy that further work on the field became for a time impossible. Further, it became a matter of great difficulty for the camels to pass over to the mainland for the requisite supplies, and it was occasionally necessary to remove their loads and dig them out of the glue-like mud in which they had sunk nearly to their bellies.

In consequence of the rain it was a fortnight before excavations could be properly resumed; meanwhile, being unfortunately obliged to return to Adelaide, I left the camp in charge of Mr. Zietz, the other members of the party being three assistants, a cook, and two Afghans in charge of five camels. The absence of all feed near the camp rendered it necessary that these latter should have their encampment on the eastern shore, at a distance of about two miles and a half.

The number of the party thenceforth remained unchanged.

Without the camels, which were lent to us by the liberality of the South Australian Government, it would have been quite impossible to carry on the work. By them meat, which sometimes went bad before the day was out, had to be brought a distance of six miles from Callabonna Station, as well as water from the same place, until, with the advance of summer, the station supply fell short, when it became necessary to send to a well at a still greater distance, and every stick of firewood had to be fetched several miles. From the ravages of rabbits, of which there will be more to say directly, it was difficult to keep the camels in sufficiently good condition for their work, and each journey for wood and water generally required two days.

were found lying close together. It may be mentioned that underground bones were usually discovered by probing with a wire rod, the sense of touch easily detecting the impact even with those that were soft.

CHARACTER OF LAKE BED.

The Lake bed in the fossiliferous area adjacent to the camp comprises what appears to be one of its most low-lying parts. Its superstratum is a layer of stiff yellowish clay of variable depth, but usually of not less than about a foot in thickness, not of uniform character, but marked by streaks or veins of a rusty colour, containing much fine, sharp sand, due apparently to surface cracks having been filled up with drift-sand. In some places this veining is so irregular and contorted as to give the clay a marbled appearance. On drying, the clay separates readily, along these streaks, into quadrangular or polygonal masses somewhat after the manner of coal.

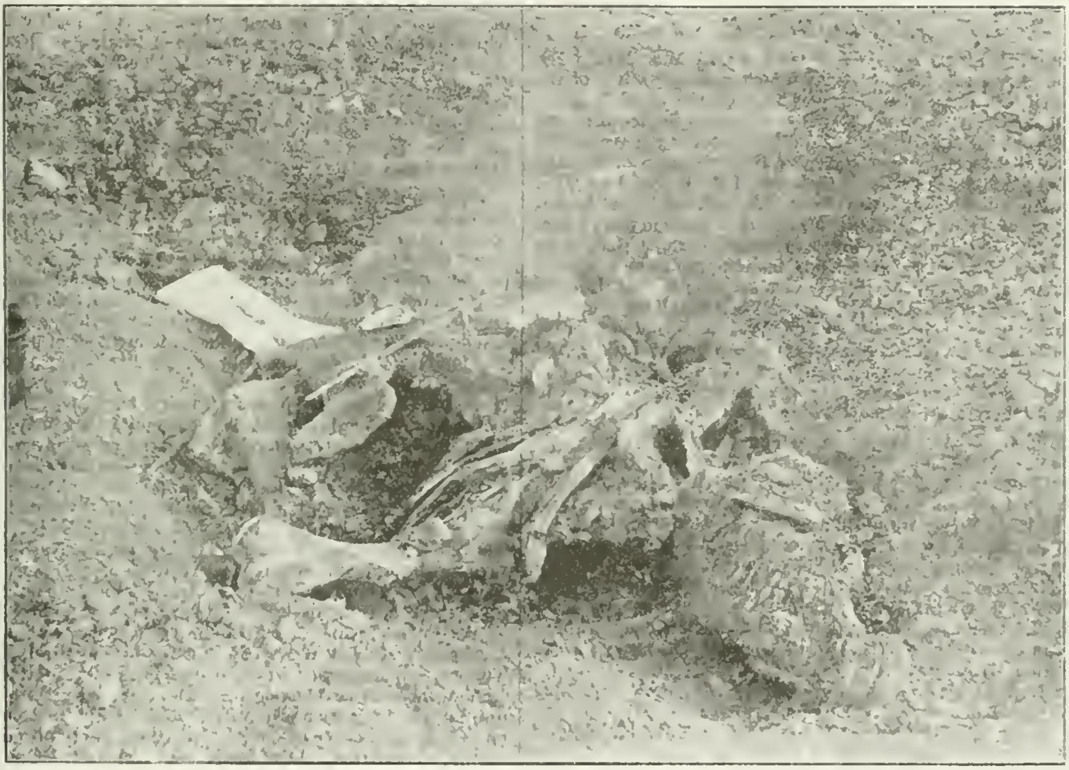

FIG. 1.—Diprotodon skeleton partially excavated.

When in the course of a fortnight after the rain, the ground had sufficiently dried to permit of the excavations being resumed, operations were commenced by Mr. Zietz at a place about a mile north-west of the camp from which his predecessor, Mr. Hurst, had obtained a number of bones. The subsequent yield, however, was inconsiderable in quantity, and such as were found were much broken and decomposed. They represented, however, a variety of species, odd bones of large and small Diprotodons, of the giant Wombat (*Phascolomys*), of Kangaroos, and of Birds being mixed together in great confusion; or it might be that the bones apparently of a single Diprotodon, even in previously unopened ground, were widely separated and broken, the fractures being sharp, and the missing pieces not discoverable.

This locality was consequently abandoned in favour of parts nearer the camp; from these good results were continuously obtained, and among them one apparently complete, and one nearly complete Diprotodon skeleton (Fig. 1), which were found in ground that had been tramped over hundreds of times in going to and fro between the camp and the more distant workings. Here also the remains of four birds

Beneath this superstratum is a layer of unctuous blue clay, of about two feet in thickness, resting upon a band of coarse sharp sand, beneath which no bones were ever found by Mr. Zietz. Below the sand the same blue clay occurs again for an undetermined depth, and shows in parts a laminated structure, with salt water lying in the interlaminar spaces. The greatest depth actually reached was between six and seven feet.

On physical analysis this clay yielded 15-20 per cent. of fine, sharp quartz-sand, while an approximate chemical analysis, kindly made for me by Mr. Turner, Demonstrator of Chemistry in the University, yielded the following results:—

Water	13 per cent.
Silica	40 ,,
Calcium carbonate	8·5 ,,
Alumina and iron	11·3 ,,
Magnesia	1·5 ,,
Alkaline chlorides and sulphates (mainly sodium sulphate)	25·7 ,,
Total	100·0 ,,

In the dry state numerous minute crystals of sulphate of calcium were visible in the clay.

In the least low-lying parts of the area salt water is reached at from two feet and a half to three feet; in the most depressed it remained permanently on the surface during the whole period of the excavations, which extended over the dry months of August, September, October, and November. In parts which are neither the highest nor the lowest the surface clay remains merely damp, and it was in ground of this character that the bones in best condition were found, provided that the underlying water did not approach the surface too nearly. In such cases, and in the very low places where the water remained permanently on the surface, it was impossible to excavate on account of the excessive inflow into the holes.

(*To be continued.*)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Sir Henry W. Acland, Bart., and Prof. J. S. Burdon Sanderson have been appointed representatives of the University at the eighth International Congress of Hygiene and Demography, to be held at Buda-Pesth in September.

The Sixth Annual Report of the Delegates of the University Museum has been published, and gives evidence of steadily increasing activity in the scientific work of the University. With increasing activity increased wants are felt, and the Regius Professor of Medicine, the Professor of Experimental Philosophy, and the Hope Professor of Zoology state that extra space is required for particular subjects required to be taught or exhibited in their departments. The reports of the Linacre Professor, and of the Curator of the Pitt Rivers Museum, contain long lists of specimens which have been added by gift, purchase, or exchange to the collections under their care, and one of the most satisfactory features of the report is the statement of the various researches which have been carried out in different laboratories during the past year.

CAMBRIDGE.—In addition to the honorary doctor's degrees to be conferred in connection with the visit of the Royal Agricultural Society to Cambridge, the honorary degree of M.A. will be conferred on June 27 on Mr. Ernest Clarke, secretary, and Dr. J. A. Voelcker, consulting chemist, to the Society.

Mr. A. E. Shipley, of Christ's College, has been appointed University Lecturer in the Advanced Morphology of the Invertebrata for five years from Michaelmas 1894, in the room of Prof. S. J. Hickson.

Mr. S. Ruhemann, of Gonville and Caius College, has been reappointed University Lecturer in Organic Chemistry for five years from Michaelmas 1894.

Mr. J. J. Lister, of St. John's College, has been appointed University Demonstrator of Comparative Anatomy.

At St. John's College the following awards in Natural Science were announced on June 18:—

Foundation Scholarships assigned or continued: W. L. Brown (Physiology); W. McDougall (Physiology and Anatomy); S. S. F. Blackman (Zoology); W. C. Brown, Butler, Orton, and R. J. Horton-Smith (subjects of Natural Sciences Tripos, Part I.); V. H. Blackman, Northcott, Tallent, West (second year subjects); Hemmy, Morgan (first year subjects). Hutchinson Studentship (for research in Pathology): F. Villy. Hughes Prize (third year): S. S. F. Blackman. Wright's Prizes: Tallent (second year), Hemmy (first year). Herschel Prize (for Astronomy), Fearnley.

SCIENTIFIC SERIALS.

The American Meteorological Journal for June contains a summary of an interesting article by Dr. F. Umlauft, on the names of the winds, originally published in the *Deutsche Rundschau für Geographie und Statistik* (vol. xvi. No. 3). The winds are mostly named according to the regions from which they come; thus winds blowing from land to sea are called land breezes, and *sea breezes*. The original names of the east and west points of the compass, and of the winds from those points, were derived from words connected with the appearance and disappearance of daylight; the names of north and south were principally associated with the kinds of weather that came from those points. Other names for the winds are associated with certain definite characteristics. In some places, on lakes, the winds are termed lower or upper winds, according to whether they originate at the lower or upper end of the lake; on the lake of Garda the upper wind is called *Sopero*, from the Italian *Sopra*, on the lake of Geneva; the wind coming down from the Vaud country is known as *Vaudaire*; and in the Rhine valley, the breeze blowing from the Wisp Valley is called *Wisperwind*. The Italians call their north-east wind *Greco*, and the Romans called the south-west wind *Africus*, while the Italians still call it *Affrico*. Homer names four winds only: Boreas, the north wind coming from Northern Greece; Zephyros, the west wind, from the word meaning darkness; Euros, indicating light, means a wind from the east; and Notos, from the word *Notios*, wet, a south wind in Greece. Winds are further named according to their influences and effects for good or evil; in Switzerland and the Tyrol the warm wind which melts the snow is known as *Aperwind*; while *Bise*, *Bis* or *Beiss* are the names given to the cold north wind; and *Maestro*, or master-wind, is the name given to the north west wind which prevails in summer over the Adriatic; in France the word becomes *Mistral*, and it is a destructive wind. The word *Samoom*, given to the destructive desert wind of Arabia, is derived from the Arabic word *Ssim*, poison. For further particulars we refer our readers to the original article, which has also been reprinted in the *Meteorologische Zeitschrift* for January last.

Wiedemann's Annalen der Physik und Chemie, No. 6.—On the radiation of gases, by F. Paschen. The long-wave spectrum of water vapour and the absorption spectrum of liquid water is here dealt with. Rubens's latest re-determinations of the dispersion curve of fluorspar show that all the author's wave-lengths above 2·6 μ, based upon Rubens' and Snow's previous results, are untrustworthy. The author deals fully with Pringsheim's criticism of his work.—On some methods of determining the pitches of high notes, by F. Melde (see p. 155).—On the relation between the lowering of the freezing-point of solutions and their osmotic pressures, by C. Dieterici. The author works out an equation by which the osmotic work may be calculated from the depression of the freezing point, even in cases where the latter amounts to 50° C.—On the absorption of hydrogen by water and aqueous solutions, by Paul Steiner. The coefficients of absorption may be roughly divided into two groups—those of solutions of monad salts, of K, Li, and Na, and those of dyad salts, such as K_2CO_3, $CaCl_2$, Na_2SO_4. The curves exhibiting the relation between absorption and concentration form two bunches for the two groups. The curve for sugar solution is approximately a straight line, intersecting the curves of the second group.—On the electric conductivity of some salts dissolved in ethyl and methyl alcohol, by B. Vollmer. The molecular conductivities of the electrolytes tested in the alcohol increase as the concentration decreases. With extreme dilution they approach a limiting value, except those of $CaCl_2$ and CaN_2O_6 in ethyl alcohol. The conductivity also decreases as the molecular weight of the solvent increases.—On the similarity of the light emitted by an after-glowing Geissler tube and the beginning of the glow of solid bodies, by Carl Kirn. The spectrum of the after glow contracted into a space between the wave-lengths of 555 and 495 $\mu\mu$, and appeared greyish-yellow. This is in accordance with Weber's observation, who noticed that a solid does not begin to glow red, but that the first colour to appear is a greenish-yellow band in the region of maximum luminosity of the solar spectrum.—On the electric and magnetic forces of the atoms, by F. Richarz.—On the forms of motion upon which electromagnetic phenomena may be based, by Hermann Ebert.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 24.—"On the Measurement of the Magnetic Properties of Iron." By Thomas Gray, Professor of Dynamic Engineering, The Rose Polytechnic Institute, Terre Haute, Indiana.

This paper gives the results of a continuation of the investigation which formed the subject of a paper communicated to the Royal Society in 1892, and published in the *Philosophical Transactions*, vol. clxxxiv. A. pp. 531–542. The results now given have been to a large extent obtained by the same method, namely, from the curves giving the relation of the current flowing in the circuit to the time measured from the application or the reversal of the impressed E.M.F. on the circuit. In this case, however, the personal element has been eliminated from the curves by the application of the autographic recorder referred to as under construction in the previous paper. This apparatus, which is a modification of the "Thomson siphon-recorder," has been found to work satisfactorily, and has considerably increased the ease and the accuracy with which the curves can be produced. A description of the apparatus and specimens of the curves drawn by it are included in the paper. There is also included in the paper a description of the apparatus and method of experiment in the application of a wattmeter to the determination of the energy dissipated by transformers under E.M.F.'s of different frequency of alternation. The accuracy of the measurements so made were checked by comparison with the results of measurements made by Joubert's instantaneous contact method. The apparatus and method of experiment adopted for the application of this method were to some extent different from those commonly employed, and they are therefore described.

The results of some further experiments on the large electromagnet used in the previous experiments, and described in the paper above referred to, are given, but a large part of the results quoted in this paper refer to closed circuit transformers of the types manufactured by the Westinghouse and the Genera Electric Companies. The experiments have been chiefly directed to the following points:—

(1) *A Comparison of the Total Energy required to produce Different Magnetic Inductions, and the Corresponding Dissipation of Energy.*—In connection with this, the effect of air gap in the magnetic circuit has been investigated somewhat more fully. It is shown that, by introducing a moderate air gap, the energy dissipated for a given induction through the coils may be reduced one-third.

(2) *The Law of Variation of Hysteresis with Variation of Induction.*—The experiments indicate that, although for any special case the energy dissipated can be approximately expressed by an equation of the form $E = AB^{\alpha}$, that both A and α are different for different kinds of iron. It seems probable, also, from the results obtained, that α is not absolutely constant for any one iron, but that it increases with increase of B.

(3) *The Effect of Increased Frequency of Cyclic Variation of Magnetism on the Dissipation of Energy.*—In this investigation a transformer, the iron case of which was made up of very thin sheets, was used. The thickness of the sheets was about 16-tooths of a millimetre, and the sheets were insulated from each other by means of thin paper. The full load capacity of the transformer was about 6000 watts. The range of frequency including the autographic recorder, the wattmeter and the Joubert's instantaneous contact method experiments) was about from 3 per minute to 8000 per minute. The results indicated that, throughout this range, there is no variation in the dissipation of energy per cycle when the inductions are equal.

Data deduced from these experiments as to the magnetic qualities of the iron used in the different transformers is given in the paper.

Zoological Society, June 5.—Sir W. H. Flower, K.C.B., F.R.S., President, in the chair.—The Secretary read a report on the additions that had been made to the society's menagerie during the month of May.—Mr. Sclater made some remarks on the chief animals that he had observed during a recent visit to the Zoological Gardens of Rotterdam, Amsterdam, Hanover, Berlin, and Hamburg.—A communication was read from Dr. E. A. Goeldi, containing critical remarks on the opossums of the Serra dos Orgãos, Rio de Janeiro, Brazil.—Mr. O. Thomas gave an account of the gazelles of Algeria, chiefly based on specimens brought home by Sir Edmund Loder, and distinguished three unquestionable species, *Gazella dorcas*, *G. cuvieri*, and *G. loderi*, the last being a new species of which examples had been obtained by Sir Edmund Loder in the sand-hills three days south of Biskra. A fourth gazelle, of which a skin and skull had been bought by Sir Edmund Loder in Algiers many years ago, was referred with some doubt to *Gazella corinna*, the Corinne of Buffon.—Sir Edmund Loder then gave an account of his expedition in search of the "Reem," as the *Gazella loderi* is called by the Arabs, and stated what he had learnt of its habits and distribution.—A second communication from Sir Edmund Loder contained remarks on the period of gestation of the Indian antelope, as observed in captivity.—A communication was read from Dr. W. B. Benham, containing notes on a particularly abnormal vertebral column of the bull-frog (*Rana mugiens*), and on certain other variations in the anurous column of this frog.—Mr. Lindsay Johnson read a communication on the pupils of the felidæ, and stated that, after an examination of the eyes of 180 domestic cats, as well as the eyes of all the felidæ in the society's gardens, he had come to the conclusion that the natural shape of the pupil in *Felis* is circular. Although under various degrees of light one might get every shape from the circle through all degrees of oval to a perfectly vertical line, yet instillations of atropine or cocaine solutions caused every pupil to become a true circle. The younger the cat the greater the tendency for the pupil to become pointed oval in ordinary light, and, conversely, the older the cat the more frequently did we find a circular pupil. Brilliant light always caused contraction to oval, and direct sunlight to a thin line in the smaller felidæ; in the larger felidæ Mr. Johnson had frequently found the pupils contract to a small circle. Suddenly alarming a cat had the effect of momentarily dilating the pupil; while in sleep the pupil was always contracted The communication was illustrated by models and diagrams.

Entomological Society, June 6.—Henry John Elwes, President, in the chair.—Mr. W. F. H. Blandford exhibited a series of eleven male specimens of *Rhina barbirostris* from British Honduras, of which the largest and smallest examples measure respectively 60 and 17 mm. The difference in bulk, supposing the proportions to be identical, is as 43 to 1. He remarked that this variation of the size is especially common in the *Brenthidæ*, *Cossonidæ*, and other wood-boring Coleoptera. The President, Dr. Sharp, F.R.S., the Rev. Canon Fowler, Mr. Jacoby, the Hon. Walter Rothschild, Mr. Merrifield, and Mr. Champion took part in the discussion which ensued.—Mr. A. J. Chitty exhibited specimens of *Cardiophorus equiseti* taken near Braunton, on the north coast of Devon, in May 1891. Mr. Champion and Mr. Blandford made some remarks on the species.—Mr. McLachlan, F.R.S., exhibited for Mr. J. W. Douglas male specimens of a Coccid (*Lecanium prunastri*), bred from scales attached to shoots of blackthorn (*Prunus spinosa*) received from Herr Karel Sulç, of Prague. Mr. Douglas communicated notes on the subject, in which he stated that the species was common on blackthorn in Germany, and should be found in Britain.—Lord Walsingham, F.R.S., exhibited a series of *Cacœcia podana*, Scop., reared from larvæ feeding on *Lapageria* and palms in Messrs. Veitch's conservatories in King's Road, Chelsea, including some very dark varieties. The Hon. Walter Rothschild stated that he had taken the species on lime. Mr. Hampson and Mr. Tutt also made some remarks on the habits of the species.—Mr. C. Fenn exhibited a long series of *Selenia lunaria*, bred from one batch of eggs, which included both the spring and summer forms; and also two unforced specimens, which emerged in November. He remarked that the variation between the two emergences, viz., spring and summer, is considerable, and also the range of variation *inter se*, especially in the spring form; but it is very remarkable that the summer form has one or two representatives among the specimens of the spring emergence. He said that the parent female was taken at Bexley in May 1893.—Mr. F. Lovell-Keays exhibited a variety of *L. alexis* (female), having the marginal ocelli on the hind wings entirely without the usual orange-coloured lunules. The specimen was captured at Caterham on May 22, 1894, and was the first example of the species observed by the captor this season. Mr. Barrett made some remarks on the specimen.—Mr. J. H. Durrant exhibited a series of *Steganoptycha pygmæana*, Hb., taken at Merton, Norfolk, between March 25 and the middle of April last. Lord Walsingham made some remarks on the species.—Mr. H. Goss read an extract from a report from Mr. J. R. Preece, her Majesty's consul at Ispahan, to the Foreign Office, on the subject of damage caused to the wheat crop in the district of Kafsinjan by an insect which was called "Sen" by the natives, and which he described as "like a flying bug, reddish-olive in colour, with heavy broad shoulders." Mr. Goss said he had been asked by Mr. W. H. Preece, F.R.S., to ascertain, if possible, the name of the species known to the natives as "Sen." Dr. Sharp said that in the absence of a specimen of the insect it was impossible to express an opinion as to the identity of the species.—The Rev. Canon Fowler exhibited for Miss Ormerod specimens of *D[illegible]*, Sturm, *[illegible]*, Brull., and *Megathopa violacea*, Blanch., which she had received from the La Plata district of the Argentine territories, where they were said to be damaging the grass crops. He also read notes from Miss Ormerod on the subject.—Mr. Hampson raised an important point as to what was the legal "date of publication" of part i. of the *Transactions* of the Society, 1894. He pointed out that the question of the priority of the names of certain new species described therein would depend upon the date of publication. A long discussion then ensued, in which Dr. Sharp, the Hon. W. Rothschild, Mr. Goss, Mr. McLachlan, Lord Walsingham, Prof. Poulton, F.R.S., and Mr. Verrall took part.—Prof. Franz Klapálek, of Prague, communicated a paper entitled "descriptions of a new species of *Raphidia*, L., and of three new species of Trichoptera from the Balkan Peninsula, with critical remarks on *P[illegible]*, McLach."—Lord Walsingham, ex-President and Vice-President, then took the chair, and a special general meeting convened under chap. xviii. of the bye-laws was held.

Geological Society, June 6.—Dr. Henry Woodward, F.R.S., President, in the chair.—On the banded structure of some tertiary gabbros in the Isle of Skye, by Sir Archibald Geikie, F.R.S., and J. J. H. Teall, F.R.S. After calling attention to the previous references to the pseudo-bedding and banding of the gabbro masses of the Inner Hebrides, the authors described the rocks which form the rugged ridge of Druim-an-Eidhne, near the head of Glen Sligachan. This ridge is made up of parallel beds, sheets, or sills disposed in a general N.N.W. direction with a prevalent easterly dip. Four distinct types of gabbro occur: (1) dark, fine-grained, granulitic gabbros; (2) well-banded gabbros; (3) coarse grained massive gabbros; and (4) pale veins of a highly felspathic gabbro. The relative ages of the banded and granulitic gabbros have not been definitely settled; but the coarse, massive gabbros are certainly intrusive in the banded series, and the pale veins cut all the other varieties. The authors dealt mainly with the banded gabbros. These occur in successive sheets or sills which vary from a few feet to many yards in thickness, and consist of parallel layers of lighter and darker material which correspond in direction with the trend of the sheets, and are usually inclined to the east or south-east at angles ranging from 20 to [illegible]. In some cases the bands can be seen to have been [illegible] folded. The minerals entering into the composition of the banded, as also of the other varieties, are labradorite, pyroxene, olivine, and titaniferous magnetite. The banding is due to a variation in the relative proportions of the different constituents, and especially in the amount of magnetite. Some narrow bands and lenticles are composed entirely of [illegible] and magnetite. The variations in chemical composition were illustrated by three analyses by Mr. Player. The [illegible] characters of the rocks were described, and it was [illegible] the minerals of the banded gabbros have not [illegible] broken since they were formed. The authors [illegible] the banding is the result of the intrusion of a [illegible] magma, and that similar banding in certain portions [illegible] gneiss may have been produced in the [illegible]. Dr. [illegible]-Lavis, Prof. Blake, Dr. Hicks, Mr. [illegible] Herbert Player spoke upon the subject of [illegible] Archibald Geikie briefly replied.—On the [illegible] of the Derbyshire carboniferous dolerites [illegible], by H. H. Arnold-Bemrose. This paper dealt with [illegible] the toadstones or igneous rocks of Derbyshire. [illegible] was made to the work of previous petro[illegible] the rocks, and the question as to the [illegible]. The [illegible] mapped by the geological survey, [illegible] have been examined, and the results [illegible] given in a [illegible] for the purpose of the paper and for future [illegible]. The [illegible] was divided into massive rocks or [illegible] tuffs. The former consist of [illegible], either granular or with ophitic augite, and [illegible] is often very fresh, but in some places [illegible]. The principal constituent minerals were [illegible], optically like biotite [illegible] differing from it chemically, [illegible]. A discussion followed, in which Sir Archibald [illegible], Dr. W. W. Watts, and Dr. Johnston Lavis took part. [illegible] of the Permian breccias of the Midlands, [illegible] of them with the upper carboniferous glacial deposits of India and Australia, by R. D. Oldham. The author first described the Permian breccias of the Midland counties of England, which he had the opportunity of examining at Eastertide of the present year. He described the characters of the breccias, and concluded that they were formed subaerially as gravel-fans by rivers charged with a maximum load of sediment, and therefore incapable of performing any appreciable amount of erosion. An examination of many of the fragments at Abberley and some at Church Hill revealed the presence of scratches, which occur in such a manner that the author believed they existed on the fragments before they were transported, and discussed the evidence for their production by ice or soil-cap movement, deciding in favour of the former. A short description of the upper carboniferous deposits of India followed, and it was pointed out that they differ markedly from the deposits of Britain. Amongst other things the separation of different pebbles by considerable interspace of matrix, and the bending of stratification-planes round a pebble as though the pebble had dropped from above, was noted, and it was maintained that floating ice alone will account for these pebbles being dropped into the Indian deposits. Finally, it was remarked that the so-called upper carboniferous deposits of India and the Permian deposits of the Midlands of Britain may be practically contemporaneous, as maintained by the late Mr. H. F. Blanford, indicating a possible simultaneous existence of glaciers in England, India, and Australia. Prof. Lapworth made some remarks upon the paper, and the author replied.

Linnean Society, June 7.—Mr. C. B. Clarke, F.R.S., President, in the chair.—The President nominated as Vice-Presidents for the year Messrs. J. G. Baker, W. Carruthers, F. Crisp and Prof. C. Stewart.—Dr. John Lowe communicated the results of observations made by him in Madeira and Teneriffe on the habit in certain insectivorous small birds belonging to the genera *Sylvia*, *Phylloscopus* and *Parus* (of which specimens were exhibited) of puncturing the calyces of flowers for the purpose of attracting insects on which they feed. An interesting discussion followed, in which the President, the Rev. G. Henslow, and others took part.—Mr. Carruthers exhibited a series of photographs of the celebrated Cowthorpe Oak in Yorkshire, taken at long intervals, commencing with a reproduction of Dr. Hunter's engraving of 1776, and made remarks upon the rate of growth and decay, and probable duration of life in this tree.—Mr. Raymund Dowling exhibited and made remarks upon a dwarf glaucous pine, and some curiously shaped *Trapa* fruits from Japan.—Mr. Thomas Christy exhibited specimens of two species of *Polygonum* (*P. sachalinense* and *P. cuspidatum*), of value for forage, and pointed out that the roots of the mature plants, when cut, are, in the former species, of a whitish colour, and in the latter of a bright yellow, enabling the two to be readily distinguished apart from the leaves.—A paper was then read by the Right Hon. Sir John Lubbock, Bart., M.P., F.R.S., on stipules and the protection of buds. A discussion followed, in which the Rev. G. Henslow, Mr. A. W. Bennett, Prof. Marshall Ward, and Mr. John Fraser took part.—Before the meeting adjourned, the President announced that a bust of Charles Waterton, the Yorkshire naturalist, and author of "Wanderings in South America," had been presented to the Society by the trustees of the late Mrs. Pitt Byrne *née* Busk. This bust was executed in 1865 (the year in which he died, at the age of eighty-three) by the late Mr. Waterhouse Hawkins; it is an excellent likeness, and the only bust of him in existence. The only accessible portrait of him is a small engraving by Adlard, which forms a frontispiece to the third volume of the "Essays on Natural History," from an original oil painting by Charles W. Peale, made in Philadelphia in 1824, when Waterton was in his forty-second year.

CAMBRIDGE.

Philosophical Society, May 28.—Prof. T. McKenny Hughes, President, in the chair.—The announcement was made that the adjudicators of the Hopkins prize for the period 1889–91 have awarded the prize to Prof. J. J. Thomson, F.R.S., for his researches on electrical oscillations and other important contributions to electrical theory.—Mr. Warburton exhibited specimens of the nest of *Trochosa picta*, a Lycosid spider found in abundance on the sand-hills of Southport. The nest is not so simple as was supposed, as it possesses a pouch or off shoot from the main burrow directed upwards and forwards. In this the spider takes refuge when disturbed.

There are two well-marked varieties of this species, the one being pale and light-coloured, and inhabiting the sandhills of Poole in Dorsetshire and Southport in Lancashire, while the dark variety occurs in various localities on dark peaty soil.—Mr. S. Skinner exhibited specimens of magnetic rock. The fragments of rock shown were from the Riffelhorn, near Zermatt, a mass of rock which appears to be permanently magnetised in a direction E.—W. with north polar magnetism towards the west. They are composed of serpentine with small veins of magnetic oxide of iron. The magnetic fields of these fragments have been mapped with a small compass needle and show both regular poles and consequent poles. It is suggested that the magnetism preserved in these fragments was due to magnetic forces acting at the time of the formation of the veins of magnetic ore. With certain assumptions, it follows that these forces acted almost at right angles to the present direction of the magnetic meridian, a conclusion possibly consistent with our present knowledge of the secular variation.—Mr. A. C. Dixon read a paper on a "Geometrical proof of a Theorem of Convergency."

Dublin.

Royal Dublin Society, April 18.—The Earl of Rosse in the chair.—Dr. G. Johnstone Stoney, F.R.S., communicated a paper on a mounting for the specula of reflecting telescopes, designed to remove the impediment to their being used for celestial photography. The author observed that reflecting telescopes are much cheaper than refractors; moreover, their uniting rays of all refrangibilities in one focus would give them an immense advantage over refractors for photographing the heavens and in celestial spectroscopy, were it not for the difficulty of keeping their line of collimation sufficiently fixed. This difficulty arises from the necessity of supporting the speculum by a very equable pressure applied over its whole back. The mechanical appliances for securing this must be so delicate that they yield a little when the telescope is moved from one altitude to another. The author of the present communication proposes to get rid of this imperfection by substituting compressed air for the "bed of levers" or layers of flannel which have hitherto been employed, and he describes a regulator through the intervention of which the pressure will vary automatically according to the requisite law when the telescope is moved from one altitude to another. With this contrivance the speculum is made the front of a closed chamber, and rigidly maintains its position with reference to it, and therefore with reference to the tube of the telescope, however the latter may be moved about. — Sir Howard Grubb, F.R.S., read (*a*) a note on the effect of tarnish on the transmission of light through telescopic objectives; (*b*) a note on the construction of an equatorial with complete circumpolar motion.—Prof. W. Noel Hartley, F.R.S., exhibited photographic enlargements of band spectra of metals, and Bessemer flame spectra, and gave a description of these phenomena.—At the meeting held May 16, Mr. Albert Taylor read a paper (communicated by Sir Howard Grubb, F.R.S.) on the photographing of the solar corona during total solar eclipses (with special reference to the author's experiences at the Brazilian station at Para Curu, during the total solar eclipse of April 1893), and on the selection of suitable instruments. The author commented upon the results obtained at the various stations at which the eclipse of 1893 was observed, and suggested that the organisation of expeditions to observe the next total solar eclipse (August 8, 1896) should at once be begun.—Mr. A. F. Dixon exhibited models constructed from microscopic sections by a method first used by Prof. His. The sections are drawn by means of a camera lucida, on glass plates covered with negative varnish, and the model is completed by simply placing the plates in order one over the other. This method is found especially useful in tracing the courses and connections of fine nerves in the embryo.

Paris.

Academy of Sciences, June 11.—M. Lœwy in the chair.—Note on the great coudé equatorial of the Paris observatory, by M. Lœwy.—The green substance of Phyllum Orthoptera of the family of the Phasmidæ, by MM. Henri Becquerel and Charles Brongniart. A spectroscopic examination has determined the identity of this substance with chlorophyll.—On the homologues of quinine; their physiological and therapeutic action, by MM. E. Grimaux, Laborde, and Bourru. The substances cupreine, methyl cupreine (quinine), ethyl cupreine, propyl cupreine, and amyl cupreine have been studied. As the molecular weight increases the toxic dose becomes rapidly smaller, and the therapeutic action becomes more vigorous. The ethyl derivative should be used as an antiperiodic when quinine has failed, and the propyl derivative might perhaps be employed as a powerful antithermic in cases of continued fevers.—Observations of the planets AY (Courty, February 11, 1894), AZ (Courty, March 5, 1894), and of Denning's comet (March 26, 1894), made at Bordeaux by MM. G. Rayet, L. Picart, and F. Courty: note by M. G. Rayet. Discovery of Champsosaurians in beds of phosphorite in the Algerian suessonian, by M. A. Pomel.—On the chromosphere of the sun. A reply to the last note of M. Hale, by M. H. Deslandres.—A new application for bichromated gelatine, by M. Izarn. The material is proposed to be used for the protection of silver surfaces on instruments, backs of mirrors, and so forth. It has given good results in trial cases.—On an application of continued fractions, by M. Stieltjes.—On the algebraical integrals of linear differential equations of the second order, by M. P. Vernier.—On equations of derived partials of the second order, by M. X. Stouff.—On magnetisation produced by Hertzian currents; a magnetic dielectric, by M. Birkeland.—On the nature of electric conductibility, by M. Vaschy.—Measurement and comparison of coefficients of self-induction by alternating currents of great frequency, by M. H. Abraham.—On the mean geometric distance of the elements of a group of surfaces and its application to the calculation of coefficients of induction, by M. Ch. Eug. Guye.—On the estimation of iodine, by MM. A. Villiers and M. Fayolle. The iodine is liberated by means of ferric chloride, taken up by carbon bisulphide, and titrated in the separated solution by standard sodium thiosulphate.—On the acid sulphates of aniline and ortho- and paratoluidine, by M. Edmond Hitzel.—The synthesis of hexamethylene derivatives; triethylphloroglucinol, by M. A. Combes.—A note on the qualitative composition of officinal creosotes from oak and beech woods, by MM. A. Béhal and E. Choay.—Action of primary aromatic bases on dissymmetrical ketonic compounds, by M. L. Simon. The work was undertaken with the object of discovering in aniline derivatives of the form $\begin{matrix} R.C.R' \\ N.C_6H_5 \end{matrix}$ indications of an isomerism analogous to that obtaining among oximes. The condensations quoted in the communication were effected in the cold and in the absence of every condensing reagent capable of producing migrations. Isomerism has not been observed in any case.—On the stability of aqueous solutions of mercury bichloride, by M. E. Burcker. The author concludes that (1) ordinary waters cause the immediate decomposition of mercury bichloride, and this action continues under the combined influence of air, light, and the substances contained in the water or brought by the air; (2) the decomposition becomes insignificant when the solution is removed from the influence of air and light; (3) solutions made with distilled water undergo very little change, even when exposed to air and light.—On the preparation of tetrachlorethylene and the action of ozonised oxygen on this body, by M. A. Besson.—On a ptomaine extracted from the urine of cancer patients, by M. A. B. Griffiths. This substance has the composition C[illegible]H[illegible]NO[illegible], and is termed *cancrine*. It is a very poisonous base, giving alkaloid reactions and crystallising in microscopic needles. It is alkaline and soluble in water.—Researches on the internal ear of the "Roussette de l'Inde" (*Pteropus medius*), by M. Beauregard.—On the characteristics and the evolution of Lomisinés, a new group of anomurous crustacea by M. E. L. Bouvier.—On the development and formation of excretory canals in *Cer[illegible] echinata*, by M. Joannes Chatin.—Diptera parasitic on Acridians: oviparous Muscidæ (*[illegible] ophage*). Burrowing Diptera. By M. J. Kunckel d'Herculais.—Intercellular communications in lichens, by M. Georges Poirault.—On the geological lines in the neighbourhood of the observatory of Abbadia (Basses-Pyrénées), by M. P. W. Stuart-Menteath.—Defence against Phylloxera, by M. Kaourdin.

Berlin.

Meteorological Society, May 1.—Prof. Hellmann, President, in the chair.—Dr. Süring gave an account of a winter sojourn, from December to March, on the Brocken. During the three months he experienced several anticyclones, two periods of storm, and several of complete envelopment in clouds, all of which he described in detail, and then dealt briefly with a whole series of isolated observations made at a height of 1140 m., that is, at the level of the lower clouds. The phenomena touched upon were the formation of rime, force of the wind, sequence of depressions, and maxima of pressure, &c. The outcome of his remarks showed the necessity for a properly equipped station on the Brocken, under expert management. One point of interest may be mentioned, namely that on the Brocken, during an anticyclone the lowest temperature was always observed at the beginning, followed by a rise of temperature in the second half of the period, whereas, as is well known, on the plains the temperature continues to fall right to the very end of the anticyclone.

Physical Society, May 4.—Prof. du Bois Reymond, President, in the chair.—Dr. Pringsheim alluded in appropriate terms to the death in Brooklyn of their foreign member Dr. F. Schulze-Berge.—Prof. König spoke on the number of distinct differences of colour and brightness which can be discriminated in the spectrum. He had made experiments in conjunction with Prof. Dieterici, subsequently verified by Prof. Uhthof, on the mean error existing when matching two tints, and from this he had been able to deduce the total number of differences in tint which a normal trichromatic eye can discriminate from the red to the blue end of the spectrum. Sensitiveness to difference of tint showed two maxima, one in the yellow and one in the greenish-blue, and the total number of distinct differences discriminated was 165. A dichromatic eye, on the other hand, can only discriminate 140 differences. Experiments of the speaker and of Dr. Brodhun formed the basis for determining the number of differences of brightness which can be discriminated, starting with liminal light and increasing it up to a blinding intensity. For both the tri- and di-chromatic eye the number was found to be 650. If it be desired to deduce from the above data the total number of possible visual differences which can be discriminated in a spectrum, it must be remembered that as the intensity of light diminishes, so also does the number of discriminated tints, so that the result is in round numbers $80 \times 700 = 56,000$. In connection with the above, Prof. von Bezold suggested that by using complementary colours it may be possible to discriminate a much larger number of tints, since, as is well known, two colours which are indistinguishable when compared directly often give quite different complementary colours, and can thus be distinguished.

Physiological Society, May 11.—Prof. du Bois Reymond, President, in the chair.—Dr. Max Verworn spoke on the polar excitation of cells by galvanic currents. Unicellular freshwater infusoria (Paramœcium) were experimented on, and showed always, on making a constant current, cathodic galvanotropism; by this is meant that all the infusoria in a drop of water placed themselves with their anterior end towards the cathode. They then moved towards and congregated at the cathode. When the direction of the current is reversed the infusoria turn round and move away towards the new cathode. When strong currents are employed it is found that the hinder end of the organism is contracted, and if the stimulation is prolonged the protoplasm is disintegrated. From this the speaker drew the conclusion that the infusoria are anodically excitable, and that the cathodic galvanotropism is due to anodic stimulation. The exact reverse holds good for Opalina, since they are cathodically excitable and anodically galvanotropic. A third group of infusoria (Spirostomum) is transversely galvanotropic.—Dr. Lilienfeld gave an account of his researches on the clotting of blood. He had succeeded in separating Al. Schmidt's fibrinogen into two substances, "thrombosin" and an albumose. The former unites with calcium and forms fibrin, while the albumose retards clotting. The separation of fibrinogen into these two constituents may be brought about by means of acetic acid, nuclein, nucleic acid, and other substances. Blood-clotting accordingly consists in a disintegration of leucocytes setting free nuclein; the latter then decomposes the fibrinogen, and enables the thrombosin to unite with the calcium salts of the blood. While the blood is circulating in the body it contains no free nuclein in solution, and hence clotting is impossible. The speaker further considered that peptones (albumose) and leech-extract prevent clotting by themselves uniting with the calcium of the blood, and thus preventing its union with thrombosin.

Note.—In the report of the meeting of the Meteorological Society for April 3 (NATURE, vol. l. p. 95), for Kassner read Kassner, and for Hasen read Hazen.

STUDIES IN FORESTRY.

Studies in Forestry. A Short Course of Lectures on Silviculture, delivered at the Botanic Garden, Oxford, 1893, by John Nisbet, D.Oec. (Oxford : Clarendon Press, 1894.)

DR. NISBET is an officer of the Indian forest department, specially trained in forestry in Germany, and after spending a number of years in the charge of extensive forests in Burma, he was, a year or two ago, permitted by the Secretary of State for India to make a further study of German forestry in Bavaria. Whilst in Bavaria he wrote six useful essays on forest subjects, which have been published by order of the Secretary of State for India, and they are now being circulated to subscribers to the *Indian Forester*, a monthly magazine published in Dehra Dun, where Dr. Nisbet is now serving as deputy director of the Indian Forest School.

The author states in his preface that he has, with the consent of the Secretary of State, embodied much of the matter in these essays in the "Studies in Forestry," and much of the remainder occurs in Dr. Nisbet's "British Woodlands," or in his translation of a German work on forest protection.

Much of the matter contained in the "Studies" will also be found in Dr. Schlich's "Manual of Forestry," vols. i. and ii., which works are largely founded on the same authorities as those used by Dr. Nisbet, whose work must have been greatly simplified by having ready to hand Dr. Schlich's well-chosen English equivalents of the various German technical forest terms.

As all the books just referred to have been already reviewed in NATURE, a detailed notice of the present work is hardly called for, though it will prove instructive to those who have not seen the former books, if they allow for the author's want of practical experience in the British Isles, where forestry is under different climatic conditions to those prevailing in Germany. The first chapter of the book, however, on "Forestry in Britain," is very forcibly and well written, and contains much suggestive matter to which the attention of everyone interested in forestry should be drawn.

Taking the area of British forests roundly at 3,000,000 acres, and allowing ninety years as their average rotation, their cost of production is estimated as equivalent to :—

(Annual rental of 3,000,000 acres + cost of forming, or regenerating them) × $1{\cdot}0r^{90}$;

where r is the rate of interest at which a forest owner is content to lock up his capital of soil and growing stock.

This rate he, perhaps erroneously, urges should be higher than that used in agriculture, on account of the greater risk incurred by forests from storms, insects, fire, &c. Scotch owners who have suffered from the hurricane last December, which blew down $1\frac{1}{2}$ million trees in Perthshire and Forfarshire, will be disposed to agree with the author here ; but the fact is that all these risks would be very greatly reduced if British forests were properly managed so as to withstand storms and the other dangers referred to. However, owing to the appreciation of *broad acres*, Dr. Nisbet puts the rate of interest at $2\frac{1}{2}$ per cent., that of funded property, which is probably the correct figure after all. Placing therefore the average rental of woodland at 5*s.* an acre, and the cost of formation at £2, that of planting Scotch pine in Perthshire ; he arrives at the following figures :— (3,000,000 × £2 – 5*s.*) $1{\cdot}025$ = £20,500,000 nearly, which is the cost of production of our woodlands, the prospective value of the mature crop being much greater. On comparison with results in Germany, and assuming that our forests are as well managed as German forests, which is at present far from being the case, they should yield an annual revenue of £2,000,000, or at 25 years' purchase be worth £50,000,000. Forty years' purchase and £80,000,000 would, however, be the correct figure at $2\frac{1}{2}$ per cent.

After this estimate comes a reference to the value of our timber imports from Northern Europe, which in 1892 was £9,207,905, and the fact, to which Dr. Schlich in 1890 first drew public attention, that all this material might be produced on waste land in the British Isles, and employment thus provided for several hundred thousand people.

The rapidly approaching exhaustion of the North American forests is also referred to ; and considering that the United States is now importing annually enormous quantities of timber from the Dominion of Canada, and that the Canadian forests are being worked in the same destructive manner as in the United States, it is surely time for Canadian legislators to attend to the formation of large State timber reserves, and provide for the education of a trained forest staff to look after them. *Quis custodiet ipsos custodes?* the negligence shown by the Canadian Executive in this respect looks as if the lumber trade was more attractive than attention to the future welfare of the country. A reference to the latest number of the *Garden and Forest* shows that the United States Government has done nothing yet to protect and manage the vast tracts of forest which there, at any rate, have been for the present saved from alienation as State property. One of the strongest reasons in favour of our establishing national instruction in forestry on a proper scale, and bringing our own Crown forests into a high state of production, is the example it would set to our colonists, and the chances that more of them might come here to study forestry, as they do at present to study engineering, law, and the arts.

Dr. Nisbet refers in hard but not undeserved terms to the results of the Parliamentary Committees on Forestry, remarking that the solemn farce of appointing a Committee, and then letting the question slide, has twice been played with regard to forestry in Britain. The only results from the Committee of 1887 have been that the Treasury pays £100 a year to a lecturer on forestry at Edinburgh University, and £250 (half the salary of the professor of agriculture and forestry) at Newcastle, also £150 each to the Royal Botanic Gardens, Edinburgh and the Glasgow Technical Institute for free classes to foresters and gardeners.

The second Committee of 1889, to inquire into the administration of the Crown forests, came to the conclusion that they were being carefully administered, which does not tally with the previous finding of the 1887 Committee. "*In respect of the Crown forests, the difference between skilful and unskilled management would itself more than repay the cost of a forest school.*"

Certainly it would be for the national benefit, if purely pleasure-grounds, such as Windsor Park, were excluded from the Crown forests, and handed over to the Board of Works, and that the 57,300 acres of the Crown forests actually under timber crops, and worth at least £1,500,000, should be brought up to the highest degree of productiveness, and serve as models of economic forestry to all the private forest-owners in Britain.

Dr. Nisbet states that the salaries and allowances of the officers in charge of the Crown forests average £900 a year, and urges that in all future appointments to these posts a high degree of qualification in forestry should be required, and also from one of the Commissioners of Woods and Forests.

A most amusing account, taken from the Report of the Forestry Committee of 1887, is given by Dr. Nisbet of the examination of a lecturer in forestry of the Cirencester Agricultural College, who stated that he taught forestry in six or seven lectures, but admitted that he had himself learned forestry there, though he did not consider the course sufficient *even for land-agents.* Other quotations from the evidence of Mr. Britton, a leading timber merchant of Wolverhampton, and the late Mr. MacGregor, then in charge of 20,000 acres of the Athole forests in Perthshire, testify to the utter ignorance of forestry possessed by land-agents and factors in both England and Scotland.

In the present state of agriculture, where economic forestry alone will pay on the poorer lands, it is essential that land-agents should possess a fair knowledge of forestry. Broillard, the French silviculturist, goes even further and advises land-owners to learn how to manage their forests for themselves.

Dr. Nisbet refers to the well-equipped forestry staff at Cooper's Hill College, where the three years' course costs £183 a year, including the cost of a fourteen days' tour in the Norman forests, and five months' practical forestry instruction in Germany. He states, however, that the Forestry Branch was added to Cooper's Hill, to prop up an Engineering College which had ceased to pay its expenses, and that there is nothing in the situation of the college to have induced the Government to have located the Forestry Branch there. As a matter of fact, Cooper's Hill is admirably situated from a forest point of view; the 9,000 acres of the Windsor Forest, exclusive of the park, and stocked with every species of tree which will grow in Central Europe, is close to the college, and in it the college has leased 800 acres, chiefly of Scotch pine forest, for practical work for the forest students. There are excellent forest nurseries, osier beds on the Thames, a good Crown coppice with standards of 800 acres at Esher, and large areas of beech selection forests on the Chiltern Hills, all of which are regularly visited by the students, whilst the magnificent oak and beech forests of Normandy are only a night's journey distant, and in them the students spend fourteen days every year. One reads nothing but praise of the old Indian College at Haileybury; and *esprit de corps* among the scientific branches of the Government of India is certainly fostered by training engineers, telegraphists, and foresters at the same college in the loveliest and most wooded part of England. There are more distractions at Oxford, and longer vacations; and after allowing for the cost of all the necessary excursions and practical work in continental forests, it is doubtful whether living at Oxford would be cheaper than at Cooper's Hill, if it had been selected instead of the latter place for the training of future Indian forest officers.

There can, however, be no question that independently of the training of Indian forest officers, in which already men from the colonies have joined, and there is plenty of room for more, there should be available at our principal universities regular instruction in forestry for the benefit of land-agents and land-owners. Dr. Nisbet suggests that two chairs of forestry, each at £700, should be established by the State at Oxford, Edinburgh, and Dublin, and four instructorships in forestry, at £150 each, at Dunkeld, Grantown, Coleford, and Lyndhurst. This would cost in round numbers £5000 a year, which is a slight insurance to pay for the better management of woodlands which have already cost £20,000,000, and will most likely be considerably added to in the immediate future, being less than ¾*d.* an acre on land actually under timber.

Forestry is, however, eminently a practical profession, and the best teaching will not suffice unless extensive well-managed tracts of our Crown forests are also made available for practical illustration of the matter taught by professors.

Sir J. Lubbock quite recently stated at a public meeting that good forestry could only be initiated by the State, and it must be satisfactory to all lovers of forestry that he is again disposed to take interest in the matter, although when member of the Committee on Forestry his attention was unfortunately distracted by other pressing business, and no satisfactory results followed.

W. R. Fisher.

THE COMPARATIVE PATHOLOGY OF INFLAMMATION.

Lectures on the Comparative Pathology of Inflammation, delivered at the Pasteur Institute in 1891 *by Elias Metchnikoff, Chef de Service à l'Institut Pasteur.* Translated from the French by F. A. Starling and E. H. Starling, M.D. With sixty-five figures in the text, and three coloured plates. (London: Kegan Paul, Trench, Trübner and Co., 1893.)

THE work before us is a translation of Prof. Metchnikoff's well-known book on the comparative pathology of inflammation. This work has been so well reviewed by Prof. Ray Lankester in Nature (vol. xlv. p. 505), that it is almost superfluous to give a fresh account of it.

Readers of Nature will remember that the book is really an attempt at establishing a biological theory of inflammation, which is summed up by the author as follows:—"Inflammation generally must be regarded as a phagocytic reaction on the part of the organism against irritants. This reaction is carried out by the mobile phagocytes, sometimes alone, sometimes with the aid of the vascular phagocytes or the nervous system." This definition of inflammation of course differs essentially from that adopted in pathological text-books, for Metchnikoff places the vascular phenomena in the second rank, and reduces to a minimum the part played by the nervous system. It must be acknowledged, however, that the author brings forward a formidable array of facts observed in the various branches of the animal kingdom in order to place his theory on a sure footing; and he clearly establishes one point, namely, that inflammation may take place without the blood-vessels or nervous system playing any part in it. On the other hand, a critic might object that, in the higher animals at least, there are many forms of inflammation in which the amœboid cells take little, if any, part at all. The proposition is, nevertheless, for the most part true, and it has undoubtedly given us a key to the understanding of many obscure points connected with the problem of immunity against microbes.

To a large extent the process of resistance of the animal body against the invasion of micro-parasites is due to the action of cells derived from the mesoblast. This, Metchnikoff has demonstrated by a number of extremely interesting experiments, and has shown that, in vertebrate and invertebrate alike, this function is at all times carried on. He and his pupils have proved that it is a normal physiological function taking place in certain parts of the body, such as the tonsils and the Peyer's patches of the intestine.

The theory of Prof. Metchnikoff has not been accepted by the majority of pathologists, and has been treated with scant respect by many bacteriologists, more especially in Germany. In this country it has, however, been received with greater favour, and it is well that such a book should have been translated by Dr. and Mrs. Starling. Indeed, for the translation we have nothing but praise; it is worded in excellent English, and, what is more, the meaning of the author is, with very few exceptions, exactly reproduced.

It is interesting, however, to see how much of the work is controversial in character, and one might almost wish that Prof. Metchnikoff had not wasted so much time in disputing the many rival theories which have since been shown to be erroneous, and are no longer held even by their promoters. The theory, for instance, that the defence of the organism was due to the so-called bactericidal power of the serum, a theory which was defended by so well known an observer as Dr. Klein, has now been almost universally given up. Metchnikoff and his pupils hit the right nail on the head when they proved that the bactericidal action of the serum in a test-tube was a very different thing from the action of the serum in the living body. Indeed, it is difficult to understand how such a notion should have received any favour, when not a single fact could be produced to show that this bactericidal action ever takes place in the human or animal body. The experiments of Sanarelli, which seemed at one time to support it, have now received another interpretation from their author. When, later on, it was shown that the bactericidal action of the serum in immune animals was very much more marked than in non-immune animals, it was thought that a strong point had been scored against the phagocytic theory; but the discoverers of this fact, Messrs. Behring and Nissen, had to confess that this stronger bactericidal action was not always present in immune animals, and that it occurred in some diseases only. Lastly, the theory was finally buried when Metchnikoff showed that this bactericidal action of the serum had no power to check the reproduction of micro-organisms, and that the immunity was produced by the action of the despised amœboid cells. Indeed, to thinking pathologists, it was apparent from the first that a theory based on the action of the serum was an impossible one, for all the facts relating to serous effusion in the human and animal body pointed to an opposite conclusion. In the majority of cases, serous effusion produces no immunity, and, in many cases, the fact that a large quantity of fluid is exuded from the vessels shows that the disease must end fatally.

Of the anti-toxic theory, which was promoted at one time by Behring and his school, Prof. Metchnikoff speaks with great respect; but in a series of interesting pages he shows how it does not apply to all cases, and that even when the blood contains a large amount of anti-toxine the patient nevertheless dies of the disease; and conversely, that an animal may be immune against a disease without its blood having any anti-toxic power whatever on the toxines secreted by the bacillus which is the cause of the disease.

Prof. Behring himself has now been obliged to give up this theory, and it has been lately shown by Buchner and others that, as a matter of fact, the serum of an immune animal has no anti-toxic power at all, and that in such cases the animal recovers owing to the rapidity with which the immunity is produced.

Of the other rival theories it is unnecessary to speak, as Prof. Metchnikoff has himself shown that a great many facts which have been brought forward to support them cannot be maintained. Of all the theories, therefore, which have been thought to explain the natural and acquired immunity of animals and man against infectious disease, the phagocytic theory is the only one which still holds the field, and, although it will not explain all the phenomena of immunity, it is the only one which is based on accurately observed facts, and which will explain how microbes are destroyed in the body. Moreover, those who will read the present book, will see that Metchnikoff himself has always allowed that probably there are other factors in the production of resistance against infectious disease, but that the chief factor was the part played by cells derived from the mesoderms, and especially by the wandering amœboid cells.

OUR BOOK SHELF.

The Camel, its Uses and Management. By Major A. G. Leonard. (London: Longmans, Green, and Co., 1894.)

THE author treats in this work of the management of the camel in connection with military operations, the result of his experience in India, Afghanistan, Egypt, and the Sudan. He does not claim to have produced a scientific essay on the animal, but rather to furnish officers and others in charge of camel transport with a practical description of the camel, his treatment and management, so as to enable them to avoid the causes to which the enormous mortality of baggage camels in recent expeditions has been mainly due. After describing the anatomy and temperament, the author considers it to be essentially a stupid animal, and incapable of looking after itself, though a model of patience under most trying conditions.

In mentioning the principal breeds of African camels, the Maazee tribe north of Kena is omitted, also the Howetat, who, though now poor and few in numbers near Cairo since the railway has robbed them of the carrying trade between Cairo and Suez, are still a large and important tribe in the Sinai peninsula. The Kabbabish tribe from the neighbourhood of Dongola, mentioned as a powerful and wealthy tribe, has, since the beginning of the Mahdist movement, been practically wiped out.

The author strongly advocates the establishment of stud farms to improve the breeds, as has been done by the French in Algeria, and then goes on to the important subject of watering, strongly combating the common belief that a camel does best on a small supply of water, and that before a desert march they should be watered at intervals, so as to train them, and to make them drink the more before starting. Doubtless many errors on this subject and that of feeding have sprung from information obtained from Arabs, who, though skilled in management, cannot always be depended on for their explanations, as in the case of a Sheikh whom we heard say that "a camel required less food on a hard desert march than when in camp, because the stomach shrunk when in work." Without doubt they should always start on such marches in the best possible condition, and not weakened by previous fasting, while, as the author points out, a main reason of the Arabs' success with their camels on long and arduous marches is that they do not hurry them, and afterwards graze them for days and even weeks to recruit, a thing impracticable on service, where work is at high pressure, and a large reserve of baggage camels is rarely available.

The importance of careful loading and suitable saddlery is strongly insisted on, and this latter point might with advantage have been gone into more fully with figures of the various riding and baggage saddles in use, since we have not yet got a satisfactory service pattern saddle. A diagram of the camel's skeleton might also have been added to the chapter on loading and marching. Chapter iii., setting forth the author's views on the instinct and intelligence of various animals, might have been omitted or greatly curtailed, seeing how little of it relates to the camel.

The subject is of great importance, and, as a practical work, the result of much experience, this book meets a want, though reference would have been greatly facilitated by an index.

Modern Plane Geometry. By G. Richardson, M.A., and A. S. Ramsey, M.A. (London: Macmillan and Co., 1894.)

A close examination of this small treatise shows at a glance that the usual method of treatment has undergone considerable alteration. The proofs contained therein are of those theorems in the syllabus of modern plane geometry which was issued by the Association for the Improvement of Geometrical Teaching. The range of the subject treated may be gathered to a certain extent from the statement that the work is intended to serve as a sequel to Euclid, or to the "Treatise on Elementary Plane Geometry" issued by the above-mentioned Association, and, as the authors state, as a systematic means of procedure from Euclidean geometry to the higher descriptive geometry of conics and of imaginary points. The chapters treat of the geometry of the triangle, quadrangle and circle, harmonic ratio, geometrical maxima and minima, that relating to the first being fully considered and containing an introduction to more recent work on special points connected with the triangle. Other chapters deal with cross ratios, involution and reciprocal polars, and projection. The authors inform us that there has been practically no departure from the syllabus referred to above, with the exception of a few additions and the interpolated examples and problems. The theorems are for the most part accompanied by clearly drawn figures which considerably facilitate the rendering of the text.

A little familiarity with this treatise will commend it to many of our readers, for the authors are clear and concise in their treatment of the theorems with which they have dealt.

Chemistry Demonstration Sheets. (London: Blackie and Son, 1894.)

In our opinion, the series of diagrammatic sketches of chemical apparatus just published by Messrs. Blackie may be put to extremely harmful use. "The sheets have been designed," say the publishers, "as a lecture-room aid in the teaching of chemistry. They present, drawn in bold outline, the apparatus used in the experiments of a first course, and underneath each diagram is set down the chemical formula of the experiment. The diagrams are drawn in elevation, and are just what a student requires to sketch in the examination room, while the formulæ, being constantly before the eye along with the diagrams, will become indelibly imprinted on the memory." If the sheets are merely used to describe the arrangement of apparatus for experiments actually performed, no one will, of course, object to them. But if (and this is more likely) the sheets are employed to impress upon the student's memory chemical reactions and apparatus never seen in reality, they could not be condemned too strongly. Teachers are often too glad to avoid experimentation and to refer their classes to text-books for descriptions of chemical changes brought about by various means. Messrs. Blackie's wall sheets will facilitate such a shirking of responsibility.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Panmixia and Natural Selection.

Mr. Weldon's letter on this subject, in Nature of May 3, calls, I think, for a few further observations. He first criticises the statement that "the survival-mean must, on cessation of selection, fall to the birth-mean," by showing that there are probably cases in nature in which the survival and birth-means may coincide, owing to the removal by selection of all individuals above and below the mean, they being approximately equal in number. This is, no doubt, the case with certain characters of a species, but probably never with all or even with most characters. Darwin states that in France and Germany white pigeons are killed off by kites, and that on the coast of Ireland black fowls are also killed off by sea-eagles. These and other analogous facts render it probable that in many species of animals colour is kept to the inconspicuous and protective mean tint by the elimination of all individuals which vary much on either side of it, and thus, as regards colour, the birth-mean and the survival-mean may be almost identical. But with many other characters this is not the case. In sheep, cattle, and horses it has been observed that when the larger lowland breeds are taken to bleak mountain regions they gradually dwindle in size, only the smaller and hardier of each generation surviving the severe winter and spring climate and the comparatively innutritious food. Here the elimination is clearly in one main direction; and the absence of this selection due to the transference of the whole body of such reduced individuals to a milder climate and better pastures, would no doubt lead to a slight increase of average size, indicating that the birth-mean had been above the survival-mean. So also in the case of the half-wild horses of Circassia, which are greatly exposed to attacks of wolves and to extreme vicissitudes of climate, swiftness, strength, wariness, and a hardy constitution must be kept at a high level of efficiency by the elimination of the less gifted in these qualities; so that here again the birth-mean must be below the survival-mean. In such cases as these there seems no difficulty in the fact that the mean characters do not change for many generations; for this is in accordance with Darwin's principle that natural selection "cannot produce absolute perfection, but only relative perfection." When the average characters of a species have reached a point such that it can permanently maintain itself in a given area, then no further change will occur; but, the less efficient being constantly weeded out, the survival-mean will be necessarily a little above the birth-mean. Both means will, however, be sensibly permanent as long as the environment remains unchanged.

Mr. Weldon says that it has not been shown that, in some given case, Panmixia does in fact occur; and further, that in the only case which has been experimentally investigated—that of the stature of civilised Englishmen—the consequences said to result from it do not, in fact, occur. To obtain absolute evidence of Panmixia, or of the action of Natural Selection, is extremely difficult, because we cannot first compare and measure minutely a large number of individuals in a state of nature, and then follow those same individuals throughout their lives and see how nature deals with them. We can, however, observe what happens in the case of semi-wild animals, and the examples already cited show that natural selection must, and actually does, act on the character of colour, weeding out those which diverge on both sides towards whiteness or blackness, and in the case of physical and mental activities destroying those which fall below the standard of excellence requisite for the preservation and continuance of life.

In our domesticated animals, on the other hand, we find what are probably examples of the effects of Panmixia. The wing-bones of our pigeons, fowls, and ducks, as compared with wild individuals, were found by Darwin to be decidedly reduced in size in proportion to the leg-bones; but a part of this may be due to disuse in the individual, and to determine the share of the two causes seems impossible. There are, however, a few characters in which we see Panmixia alone at work in our domesticated animals. Such are, for example, the constant appearance and increase among them of prominent *unsymmetrical* markings, as in dogs, cats, cattle, and horses. Such markings never occur in wild races, or if they occur in individual cases they never increase; and I have given reasons for thinking that symmetrical colour and marking is kept up in nature for facility of recognition, a factor essential to preservation, and to the formation of new species. In this case, there can be no question of disuse, while as we know that white and unsymmetrical individuals do occasionally occur in wild species, but never increase, the fact of their increase under domestication must be due to the absence of whatever form of natural selection eliminates them in nature; that is, to Panmixia. Another illustration may perhaps be found in the fact of curled tails appearing in domestic pigs and some races of dogs, while no wild animal is known which has a curled tail. We can hardly doubt that the special form of tail in each animal is of use to it, and that any abnormality, like a curled tail, would be eliminated under nature. Its appearance and perpetuation under domestication is therefore a fair example of Panmixia.

The slow increase of the stature of civilised Englishmen, which Mr. Galton is said to have proved, may, it seems to me, be partly a result of Panmixia, and partly due to more healthy conditions of life acting on the individual. It is, I presume, a fact, as generally stated, that old armour shows that the knights of the middle ages were rather short men. This may have been a result of natural selection, because, as a rule, the strongest and most active men are rather under than over middle height; while tall men would certainly be more exposed to danger, would have to carry a greater weight of armour, and by thus overloading their horses would be under a disadvantage in battle. Tall men would thus be killed off rather faster than short men; and the same might be the case even after the disuse of armour, so long as rapine and civil war prevailed over a large part of the country. But during the last two centuries of comparative peace tall men have been under no such disadvantage, and their survival may have aided in bringing about the slight increase of average stature which has been observed.

One other point in Mr. Weldon's communication requires notice. He considers that the frequent occurrence of abnormalities and the wide range of variation in many species, show that "natural selection is in most cases an imperfect agent in the adjustment of organisms." This conclusion does not appear to me to be a logical one, since it ignores the admitted fact of the exceedingly intermittent character of selection and its constantly varied *locus* of action. Each species of animal is subject to a number of quite distinct dangers—hunger, cold, wet, disease, and varied enemies—and all these are separately intermittent in their action. Some affect the species at one time of the year only, some at another; but most of them only reach their maximum of intensity at long intervals—once or twice, perhaps, in a century. Whether cold winters or hot summers, excessive drought or excessive wet, deep snow or phenomenal hail or wind-storms, all are intermittent and occur with extreme severity only at long intervals. These intermittent waves of meteorological phenomena have their corresponding "waves of life," as Mr. Hudson well terms them, such as phenomenal swarms of locusts or of wasps, of caterpillars, mice, or lemmings, and to a less conspicuous degree of almost every living thing. It follows, that during a succession of favourable seasons variation can go on almost unchecked, and even hurtful abnormalities and imperfections may survive for a few years, but soon there comes a check to the increase, and the most abnormal forms die out; while after a greater or less interval either adverse seasons or an increase of living enemies weed out all the extreme disadvantageous variations, leaving only the pick of the typical form to continue the race. This may occur again and again, each special period of stress affecting different organs or faculties—now abnormal colour, now deficient agility, now again incaution or a weak digestion—till in turn every departure from the best adapted mean form is eliminated, to again arise and again be extinguished as favourable or unfavourable conditions prevail. Thus, I am fully in agreement with Mr. Thiselton Dyer when he said: "I feel more and more that natural selection is a very hard taskmaster, and that it is down very sharply on structural details that cannot give an account of themselves." (NATURE, vol. xxxix. p. 9.) The appearance of imperfect adjustment is thus only a temporary phenomenon, while that there is an underlying permanent adjustment is indicated by the long-continued identity of specific characters to which Mr. Weldon refers.

As it is very important to obtain some direct evidence of the action of natural selection, I wish to suggest a mode of doing so which might probably be successful. There is much evidence to show that the migrating birds which visit us in early summer are very largely old birds which have lived through two or more migrations; and, consequently, that of the large number of young birds which migrate in autumn for the first time a very small proportion return to our shores. If this is so, then the extreme severity of the selection during migration would afford us the opportunity of determining some of the physical characters which influence it, combined no doubt with mental characteristics which we have no means of gauging. I would suggest, therefore, that two or three common species of migrants should be chosen, of which the young birds of the year can be distinguished with certainty. Of these birds a number of observers should collect specimens just before their autumnal migration, and should carefully record the characters fixed upon in the case of the young and old birds separately. Probably the weight, the total length, and the length of the wing, would be sufficient, since heavy birds with comparatively short wings would hardly be adapted for long-continued flight. By laying down the dimensions of some hundreds of specimens in curves of variation, whatever difference existed between the young and old birds would be easily detected; and this difference would presumably be the difference between the birth-mean and the survival-mean, so far as the selective influence of migration is concerned. In the following spring another set of specimens of the same species should be collected and measured; and we should then perhaps be able to determine the characters which had led to the selection of the young birds which had survived the double migration.

ALFRED R. WALLACE.

Discontinuous Colour-Variation.

I HAVE just received a copy of Mr. Bateson's most valuable work on the "Study of Variation"; and although it will take many weeks to read it as it deserves to be read, a few remarks are now ventured as the result of perusing pp. 42–48, which relate to the discontinuity of certain colour-variations.

Without attempting to discuss Mr. Bateson's general propositions, I desire to point out that the facts related in the portion of the work cited, and the "many similar cases" which might be added, do not altogether support the idea of *discontinuous progressive colour-variation*, as distinguished from *atavism*.

Various writers, including myself, have on sundry occasions endeavoured to demonstrate that both in plants and animals a definite succession of colours may be observed. In flowers, for instance, from pink to purple, and from yellow to red; in birds and insects, and many molluscs, the yellow to red succession is commonly observed. In such instances as these, it has been held that one colour represents a lower stage of evolution or a less degree of metabolism than the other; and it has been many times pointed out, that *discontinuous atavistic variation*, *e.g.* from red to yellow, is commonly to be seen.

Now I take it that Mr. Bateson considers the evidence which he adduces, to illustrate the frequency of *discontinuous progressive variation* in colour, not merely *reversion*. Let us examine this evidence a little more closely.

According to the views held by the writers above mentioned, red is "higher" than yellow, and red varying to yellow is reversion. Such reversion is well known to be often discontinuous, as in the yellow-fruited yew, the yellow tomato, the yellow-fruited raspberry, the yellow varieties of various red moths, and so forth.

But is the yellow to red variation, which is supposed to be the progressive one, discontinuous? Let Mr. Bateson himself tell us. On p. 45 he cites the variations of the yellow *Gonepteryx rhamni* towards orange. Are these discontinuous? Do we find among the yellow *rhamni* some that are entirely orange? Not so, "there are records of specimens . . . more or less flushed with orange."

Exactly: whereas among the red species of *Callimorpha*, *Arctia*, *Zygæna*, &c., we find varieties not flushed with yellow but entirely yellow in place of red (the dark markings being of course as usual), in the yellow *G. rhamni* we find continuous variation towards orange, none yet having attained actual red.

In birds red species may vary to yellow; green also to yellow, and such variation may be sudden. But yellow to green? or yellow to red? We have got our canary yellow easily enough, but all the art of the breeder cannot get him redder than orange, and the variations thereto are fairly continuous.

We cannot get a blue rose; but the blue *Delphinium*, the blue *Pentstemon*, these readily vary to pink. We may have a yellow rose, but it is pretty well agreed that if we ever do see a blue one, it will be by a process of continuous variation and selection. Will not Mr. Bateson admit that he would be immensely astonished to see a blue rose arise from seed of a red one, or a scarlet canary from eggs laid by a yellow one? Yet red from blue, or yellow from red, would seem scarcely worth comment in any group of animals or plants, so numerous are the recorded instances of this kind of variation.

On p. 44, Mr. Bateson cites instances of blue in place of red, which should be progressive variation. This occurs in *[illegible]*, for instance, but *very rarely*, and instances which seem rather intermediate are on record. Another sample cited is the blue-flowered *Anagallis arvensis*. Here the case is different, for the blue and red varieties are entirely distinct, and come true by seed. I have myself lived in districts where the blue and red varieties respectively abounded, and in neither locality did I ever see intermediates. They had all the appearance of true species, which they have often, I think with justice, been considered. The locality for the blue variety was Funchal, Madeira, and there the red pimpernel also occurs. But in England, where the red variety is so common, I never saw the blue one truly wild.

In *Primula* we have yellow species and red species, and, as everyone knows, our common primrose may vary to red. But also, as everyone knows, the variation is continuous. How well I remember as a child looking for those that were tinged with red, always hoping to get one redder than that last found!

The subject admits of much greater amplification than is now possible; and it is by no means denied that many instances may be selected, out of the thousands available which appear to indicate discontinuous progressive colour-variation. But nevertheless, taking the evidence as a whole, I will venture to urge the validity of the following statements:—

(1) Colour-variation occurs in a definite order, the colours forming one or more series.

(2) Variation from those lower to those higher in the scale of evolution, or from those representing less to those representing greater metabolism, is usually continuous.

(3) Reversion from a higher to a lower colour is usually discontinuous.

T. D. A. COCKERELL.

Las Cruces, New Mexico, U.S.A., June 1.

Niagara River since the Ice Age.

MUCH new light on the Quaternary history of the great lakes tributary to the St. Lawrence river has been contributed in three recent papers by Mr. F. B. Taylor, all published within the short time since Mr. G. K. Gilbert's writing on "The Niagara River as a Geologic Chronometer," which appeared in NATURE for May 17 (page 53). These papers are in the *Bulletin of the Geological Society of America* (vol. v. pp. 620–626, April 30, 1894), and in the *American Geologist* (vol. xiii. pp. 316–327 and 365–383, May and June, 1894). Supplementing the earlier observations and studies of Whittlesey, Newberry, Gilbert, Spencer, Lawson, Leverett, Wright, Baldwin, and the present writer, among others, these latest explorations and discussions by Mr. Taylor enable us to form a very definite and closely connected historical statement of the relationships of the ice-dammed lakes which preceded the present Laurentian lakes, and of their dependence on the gradual departure of the ice-sheet and on the accompanying northward uplift of that region.

The largest element of uncertainty in the estimate of 7000 years for the Post-glacial period, from the retreat of the ice-sheet to the present time, drawn from the rate of recession of the Falls of Niagara, consists, as Mr. Gilbert has shown, in the probability or possibility that for some considerable time, next following the melting away of the ice upon the area crossed by the Niagara river, the outlet of lakes Superior, Michigan, and Huron may have passed to the St. Lawrence by a more northern course, flowing across the present watershed east of lake Nipissing to the Mattawa and Ottawa rivers. Mr. Taylor's observations now indicate, however, if interpreted on the hypothesis of glacial lakes (which is believed by Mr. Gilbert and by the majority of other geologists of America to be the true view), that the glacial lake Warren, filling the basins of Superior, Michigan, Huron, and Erie, continued with its outlet flowing past Chicago to the Des Plaines, Illinois, and Mississippi rivers, while the country including lake Superior, the northern part of lake Huron, and lake Nipissing, that is, the whole northern side of lake Warren, was uplifted about 350 to 450 feet along its extent of 600 miles from east to west. The existence of lake Warren was terminated by the recession of the ice-sheet from the area between lakes Erie and Ontario, when the Niagara river began to flow and to channel the gorge six miles long below its receding falls, from which the computation for the time since the Ice Age is derived. The Niagara gorge measures the time after the outflow past Chicago ceased, lake Warren being then succeeded in the basins of the upper lakes, above Erie, by the glacial lake Algonquin, while in the Ontario basin the ice-bound lake Iroquois outflowed past Rome, N.Y., by way of the Mohawk and Hudson to the sea.

Seven-eighths of the differential uplifting which carried the watershed east of lake Nipissing above the level of lake Algonquin had taken place before the north-eastward retreat of the ice-sheet uncovered the Niagara area. For some later time the ice-barrier must have remained upon the Mattawa and Ottawa areas, forbidding any outflow there from lake Algonquin; and it seems very probable that within that time the continuation of the uplift had raised the watershed so high that no discharge from the upper lakes ever passed over it. During the ensuing existence of lake Iroquois the Ontario basin was undergoing a rapid northward uplift, which doubtless was shared by the Nipissing area, so that if any outflow occurred there it must have been very brief, being ended when the land east of lake Nipissing rose higher than the present course of outflow by the St. Clair and Detroit rivers to the Erie basin and Niagara river. The duration of the outlet to the Mattawa could probably have been only a few hundred years, at the longest, if it ever existed. With this possible exception, the present volume of the Niagara river has been maintained during all the time of its gorge erosion. Only an insignificant addition to the estimate of 7000 years can therefore be required by the diversion of the waters of the upper lakes.

The view held by Taylor, Spencer, and Lawson, that the high shore lines around the great Laurentian lakes are of marine formation, seems to be inconsistent with the total absence of marine fossiliferous beds overlying the glacial drift in all that region. So far as the sea did extend, after the further recession of the ice-sheet permitted it to come into the St. Lawrence and Ottawa valleys and into the basin of lake Champlain, marine fossils abound; but none are found above the Thousand Islands at the mouth of lake Ontario. We may therefore confidently accept the Niagara gorge as a measure of all the time since the departure of the ice-sheet from the northern United States.

In a recent paper in the *Journal of Geology* (vol. ii. p. 142, February–March, 1894) Mr. Andrew M. Hansen, of Norway, notes the approximate concurrence of about thirty independent measurements and estimates of the duration of the Post-glacial period, which have been made in North America and in Europe, all coming within the limits of 5000 and 12,000 years. He accordingly says: "With full regard to a legitimate calculation of probabilities, it may be predicated that the number of 7000 to 10,000 years is as nearly an exact estimate of the duration of Post-glacial time as can ever be expected."

Minneapolis, Minn., June 9. WARREN UPHAM.

The Teeth and Civilisation.

NONE of the writers of the interesting letters which have appeared upon this subject seem to have kept before them a distinction which is of the utmost importance in its investigation, and which I should like to state, in order that the attention of those who, like Mr. Wenyon, have opportunities of observation of any segregated community, may be drawn to it.

Dental caries is very prevalent, and its increase seems to be very rapid, so that the last few generations show a marked increase; at least so it is generally believed.

But its victims may be divided into two groups, namely, those whose teeth are apparently perfect in their construction, but nevertheless fall a prey to caries, and those whose teeth show, to the trained eye, clear evidence of structural weakness.

As the latter class present a problem in heredity, and for various reasons are likely to be more interesting to the readers of NATURE than the former, I will dismiss these with a very few words.

There is good reason for supposing that the proximate cause is to be found in vitiation of the oral secretions, as caries often occurs in an extreme degree after diseases of the digestive tract, and examples such as those quoted by Mr. Wenyon are probably to be explained as due to dyspepsia induced by the unhealthy way of feeding.

To the explanation that the enamel may be cracked by alternations of temperature which could be borne in the mouth, I am not inclined to attach importance. In the first place, as a matter of experiment, I have failed to crack enamel by plunging teeth alternately into boiling and ice-cold water, and, as a matter of clinical experience, teeth do not decay along the cracks which from some cause are common in the enamel, but in natural pits of larger size, or on surfaces of contact; the cause is to be sought either in decreased power of resistance, or in the intensification of deleterious influences.

Abnormal conditions of life are known to deleteriously affect the teeth of animals; for example, stall-fed beasts are more liable to diseased conditions in the mouth than those which are fed up in rich pastures; and it has been pointed out by Mr. Bland Sutton, that some animals in the Zoological Gardens suffer in this way, notably the Lemurs, whose teeth frequently loosen and fall out.

It is rare to meet with good teeth in children whose parents have had bad teeth, and peculiarities of form in the teeth and jaws are often inherited with curious exactitude. But it is quite common to meet with instances of healthy parents with good teeth bearing a family of children, also apparently healthy and well-grown, whose teeth, although to the casual observer normal in shape, size, and general aspect, are to the eye of the dentist doomed to early destruction, and speedily undergo it.

These teeth have an appearance somewhat difficult to describe; they have a glassy look, are more translucent than they should be, are softer, and are believed, though the proof is not complete, to be somewhat deficient in their proper proportion of lime salts. This kind of tooth is very apt to run through a whole family, and its causes must be sought either in some condition of inheritance, or if it be due to anything acting upon the individual, it must be something which commences to act immediately after birth. Comparative anatomy teaches us that the teeth are less variable than the jaws. In long-muzzled dogs the teeth are spaced; in short-muzzled dogs they are crowded, reduction in size having gone on faster in the bones than in the teeth; and the same thing is observed in the human subject.

Moreover in animals, whilst some variability is often observable in the teeth, that variability does not take the form of structural difference, but only of differences of size and shape.

Again, in rickets, where the bones are starved of lime salts, the teeth contrive to get more than their share; it is therefore not a little remarkable that we should find the teeth, and apparently the teeth alone, to have deteriorated in one generation.

On the other hand, it is equally difficult to find any cause which shall have operated alike upon all the children of a family if we reject inheritance as being at the bottom of it; it does not appear to be determined by the greater frequency of hand-feeding, as I know of instances in the same family where some children were nursed and others were not, and yet their teeth were alike of the poor structure to which I have alluded.

Upon the whole, I am rather inclined to attribute it to some causes operating shortly after birth, rather than before it, for the milk teeth, which are well started in utero, are far less liable to structural variation than are the permanent teeth, whose calcification is mainly effected after birth; but I need hardly say that the period of occurrence does not by any means exclude inheritance.

However the question, interesting and important as it is, is not so simple as some of your correspondents imagine, and there is a considerable amount of literature upon the subject which seems to have escaped them, some of it accurate and valuable, some of it quite the reverse.

CHARLES S. TOMES.

Electrical Theory of Vision.

IN my letter to Prof. Lodge, published in your last issue, I notice a printer's error, which I think should be corrected, as it gives an entirely wrong meaning to the sentence in which it occurs. As it stands it reads as follows: "The energy thus lost by the tissues was then *suppressed* from without by the vibrating fingers," whereas I said the energy was *supplied* from without by the fingers, the idea being that the shaking back of the eyes to their normal state of rest, evinced by the sensation of darkness, is perfectly analogous to the tapping back of Prof. Lodge's "Coherer" to its normal position, evinced by the return of the galvanometer needle to zero.

E. OBACH.

Old Charlton, Kent, June 23.

CLIMBING AND EXPLORATION IN THE KARAKORAM-HIMALAYAS.[1]

THE mountain district explored by Mr. Conway lies on the southern side of the watershed of the Karakoram chain, and is drained by tributaries of the Upper Indus. For most of the time he was in Baltistan, but ended his journey by a visit to Leh. Here, at about 11,500 feet above sea-level, is a small meteorological observatory, which enabled Mr. Conway to check his observations by a comparison of barometers. Besides himself, the party consisted of the Hon. C. G. Bruce, Mr. McCormick, the artist, Messrs. Eckenstein and Roudebush, Matthias Zurbriggen, the well-known guide from Macugna, four Gurkas, who took readily to ice work, and one or two two other native attendants, with, of course, a considerable but variable party of coolies.

As the author states, the party spent in all eighty-four days on snow or glacier. They were often encamped at

[1] "Climbing and Exploration in the Karakoram-Himalayas." By William Martin Conway, M.A., F.S.A., &c. With 300 Illustrations by A. P. McCormick, and a Map. (London: T. Fisher Unwin, 1894.)

elevations ranging from 12,000 to 15,000 feet above the sea, occasionally even up to 20,000 feet, and some of them accomplished the ascent of a peak approximately 23,000 feet—the highest summit which man has reached. But mountain climbing was far from the only purpose of the expedition. Mr. Conway surveyed the district, and has made many important additions to and corrections in the map which was constructed, about thirty years ago, by Colonel Godwin-Austen, after a journey—for that time—hardly less adventurous. He got together considerable collections, and noted, with the eye of an expert, the archæology and other peculiarities of this remote region. A supplementary volume, to be issued in the course of a few months, will contain reports on the zoology, botany, and geology, and on the other scientific results of the expedition. The separation of the two parts is to be regretted, but was probably almost inevitable.

FIG. 1.—The Ogre's Fingers, Biafo Glacier.

Incidentally, however, Mr. Conway tells us something of the natural history and geology of the mountain regions, and a note on the latter subject has been communicated recently to the Royal Society. This part of the Karakoram-Himalayas evidently consists of strips of sedimentary rocks infolded in crystalline masses, and often resembles the Alps of Europe not only in structure but also in mineral characters. Many of its glaciers are enormous; for instance, one proved to be forty miles in length; others are hardly less; their ice-falls sometimes are even more formidable than those in the Alps. This Mr. Conway attributes not so much to their greater steepness of slope as to the irregular form of their beds. They lie among peaks which often range from about 22,000 to 26,000 feet above sea-level, and in one case—the nameless K2—reach 28,278 feet. The snow-line, however, is much higher than in Central Europe. In the middle of April, at the beginning of his journey, Mr. Conway found the snow lying thickly below 13,000 feet, but later in the season an elevation of 15,500 feet in his district seems to correspond roughly with that of 8000 feet in the Alps. But in this respect, evidently, there is considerable variation; for the "col" between the vast Hispar and Biafo glaciers is only 17,600 feet above the sea, while further to the east, passes on the route from Yarkand to Leh rise to this height, or even more, and are almost free from permanent snow.

The first-named pass entailed the longest march over glacier and snow, for it occupied the explorers from July 11 to July 26; but the greatest height above sea-level was reached at the head of the Baltoro glacier. Here, on the flank of a huge mountain, called the Golden Throne, the party encamped for five nights at stations from 18,200 to 20,000 feet above sea-level, Mr. Conway sleeping two nights at the latter elevation, and he ascended, in company with Mr. Bruce, one of its peaks (Fig. 2). This, according to a barometric observation, is 22,600 feet in height, but by its level compared with K2 it should be not less than 23,000. On several occasions they reached elevations ranging from 17,000 to over 19,000 feet, and frequently camped out above the level of Mont Blanc. Thus they had exceptionally good opportunities of observing the effects of diminished atmospheric pressure. Their experience fully bears out that of Mr. Whymper in the Andes, though it affords some interesting differences in detail, while the effect produced, as usual, depended much upon the individual; it also seemed to vary with the environment. Occasionally the attendants suffered at from 13,000 to 14,000 ft., but, as a rule, the Europeans and stronger members of the party were not materially affected till about 15,000 feet, and then but slightly, unless they spent the night on the spot. This, it will be remembered, accords with Prof. Tyndall's experience on Mount Blanc.

FIG. 2.—Pioneer Peak (Golden Throne) from about 20,700 feet

The usual symptoms were felt: panting for breath, and quick, irregular action of the heart after the slightest exertion, with headache, more or less nausea, and a general sense of extreme lassitude and exhaustion. The travellers were most severely affected at the highest camp on Golden Throne, though even here, when completely at rest, the inconvenience was comparatively slight. The ascent from this camp—probably about 3000 feet, without any exceptional difficulties—took $8\frac{3}{4}$ hours. In such a district as the Pennine Alps this distance would probably have been accomplished in half the time. It is therefore obvious that the difficulties in reaching such a point as K2 will be extremely great, though possibly not insuperable. Among these the weather will be one of the most serious. This, in the Alps, is frequently not good; in Baltistan, unless Mr. Conway's experience was exceptional, it is habitually abominable.

Much interesting information in regard to physical geology can be gleaned from this volume. The beautiful illustrations enable us to form a good idea of the magnificent snow peaks; the lower mountains, as a rule, seem to be more precipitous and shattered, more weird and desolate than in the Alps (Fig. 1). The climatal conditions are probably favourable to rapid denudation; mud avalanches are frequent, sometimes on a gigantic scale; the fans of débris also are enormous. Mr. Conway's account of the alluvial deposits in the beds of the valleys, especially on the route to Leh, are most interesting (Fig. 3). These often make it difficult to discover the limits to what glaciers have extended. At the present day the larger ice-streams seem to end at 10,000 to 11,000 feet above sea-level, but here, as in other mountain regions, they were once much greater. Mr. Conway mentions the occurrence of old moraines at various elevations down to about 6000 feet, and we cannot be certain that this is the lowest limit.

Fig. 3.—Remains of Alluvium, Lama-yuru Valley

The volume contains, in addition to a map, three hundred illustrations, process-block reproductions of drawings by Mr. McCormick, some from photographs, and some from original sketches. They represent not only the scenery, but also incidents of travel, and greatly enhance the value of the book. It is worthy to take a place, for literary and artistic excellence, with Mr. Whymper's "Travels amongst the Great Andes of Ecuador," for it is a record of an adventurous journey, carefully planned and bravely effected, as well as a real contribution to knowledge. Clearly and pleasantly written, full of interesting information, not only on the geography, geology, and natural history, but also on the people, buildings, and customs of a rarely visited region, the book does honour to its genial and able author and to his companions in travel.

A NEW FORM OF OBJECT-GLASS MOUNTING.

AMONG the numerous details in telescopic construction that have become of greater importance in consequence of the increase in size of refractors, may be mentioned that relating to the form of mounting of the object-glass, which plays a leading *rôle* in the good working of a telescope.

The chief difficulty which has to be overcome is the great dearth of substances which have the same coefficient of expansion as glass. For small objectives brass fastenings are used, but for larger discs these have been replaced by the adoption of steel, the coefficient of expansion of which more nearly approaches that of glass. In the latter case allowances have to be made for the [d]ifference of expansions of the two substances (glass an[d] steel), and this is done by breaking the metallic band which encircles the objective, and connecting the two ends thus freed by means of one or more screws. In this way the pressure of the band on the circumference of the discs can be regulated by tightening or slackening the screws as the case may be, and the inequality of expansion or contraction can thus be counterbalanced.

If only one disc of glass were in question, the problem would be somewhat simple, but since an objective consists of two discs, and these of different kinds, each possessing its own special coefficient of expansion, the matter is distinctly complicated. With two discs it will be seen at once that the metallic ring may be made fast for one, while the other can be free to move, and therefore quite loose; this naturally raises numerous disturbances in the centering of the lenses.

The functions of a perfect cell are then, firstly, it must be capable of holding the lens firmly and without change of form; while, secondly, it must be so arranged as to allow for the different changes brought about by temperature without disturbing the centering of the lenses.

To produce such a cell as this has been the object of Dr. R. Steinheil's investigations [1] and the following summary contains his suggestions. The principle consists in leaving a space between the inside of the cell and the circumference of the two lenses, and placing rigidly between them blocks of particular substances and sizes, such that they compensate for the different expansions at work.

The amount a substance expands or contracts depends not only on its increase or decrease in temperature, but on its length; thus, for instance, a long rod when heated expands more than a short rod of the same substance. Making use of this fact, we may either assume the *length* of the blocks referred to above, and calculate of what substances it must be composed to give the exact coefficient of expansion required, or we may take any substance with a *known* coefficient of expansion, such as zinc, and determine the length it is required to be. The latter method, of course, by its simplicity commends itself, and if the length of the block be denoted by l we have the formula

$$l = \frac{\phi - \gamma}{\sigma - \phi},$$

[1] See "Ueber eine neue Art von Objektivfassungen" in *Zeitschr[ift für] Instrumentenkunde*, Heft 5, p. 170, 1894.

which gives l in terms of the coefficient of expansion of (ϕ) the cell material, (γ) the glass, and (σ) the material for the blocks. It will be seen from the formula that the shorter the blocks the more equal must be the coefficients of expansion of the glass and cell material, and also the greater the relative distance between the coefficients of expansion of the blocks and cell material.

Dr. Steinheil, as an example, determines the length of these blocks for an objective of 50 cm. aperture, the lenses being composed of common flint silicate marked O.544 in the Jena glass factory, and common crown silicate marked O.1022.

If the material for the blocks used be of zinc (coefficient of expansion $\sigma = 0{\cdot}00002918$), then their length, adopting for the flint glass (544) the value $\gamma = 0{\cdot}00000788$ and for the cell material the value $\phi = 0{\cdot}00001061$ for their coefficients of expansion, is given by the equation

$$l = \frac{1061 - 788}{2918 - 1061} = \frac{273}{1857} = 0{\cdot}147.$$

Similarly for the crown glass, the coefficient of which is 0·00000954, we obtain the length of its blocks

$$l = 0{\cdot}0576.$$

As the radii of the glass discs are the same and equal to 25 cm., the lengths of the blocks for each of the lenses must be $0{\cdot}147 \times 25$ cm. and $0{\cdot}0576 \times 25$ cm. or 3·675 cm. and 1·44 cm.

Dr. Steinheil proposes that for each lens three blocks should be used and placed at intervals of 120° round the circumference of the discs, the blocks fitting tightly between the discs and the sides of the cell. It might at first be thought that such tight-fitting as seems necessary could not be exactly enough done, but it is stated that accuracy in the length of the zinc block to 1 mm can be safely depended on, and the danger of strain by eliminating the disturbances of centering thereby reduced to a minimum.

That this new mounting for object-glasses has many points in its favour cannot be denied, but it is in such questions as these that we must look to the results after the method has been practically applied. Thus, practice would better settle the proper number of blocks for each lens; three seem at first sight somewhat too few, and might lead to local strains due to the weight of the lenses, whereas such strains must be avoided in any sort of cell.

W. J. S. LOCKYER.

NOTES.

WE are requested to state that a volume containing a memoir of the late Dr. Geo. J. Romanes, F.R.S., will be published. Those who possess letters of general interest written by him are requested to forward them to Mrs. Romanes, St. Aldate's, Oxford. The letters will be returned directly their contents have been noted and copies made.

A GRACE of the Senate of the University of Dublin has been passed, conferring the degree of Doctor of Science upon Mr. Daniel Morris, C.M.G., Assistant-Director of the Royal Gardens at Kew.

PROF. KARL GUSSENBAUER, of Prague University, has been appointed to the chair of Surgery at Vienna, in succession to the late Prof. Billroth.

A REUTER telegram states that at a meeting of leading citizens held at Toronto on June 23, it was unanimously decided to invite the British Association to hold the meeting there next year.

THE Council of University College, Liverpool, have appointed Dr. A. M. Paterson to the "Derby" Professorship of Anatomy, and Prof. R. W. Boyce to the chair of Pathology recently endowed by Mr. George Holt.

DR. AUGUSTUS SCHLOESSER, assistant to Prof. Henderson in the chemical department of the Glasgow and West of Scotland Technical College, has been appointed to the Principalship of the Storey Institute, Lancaster, rendered vacant by the resignation of Dr. G. S. Turpin.

A KINDLY and appreciative letter, by Prof. Poulton, F.R.S., on some incidents in the life of the late Prof. Romanes, appeared in the *Times* of June 19. The July number of *Science Gossip* contains an obituary notice of the lamented investigator, together with his portrait.

THE Cracow Academy of Sciences have awarded the Copernicus Prize of five hundred florins, founded by the town of Cracow, to Prof. Louis Birkenmajer, for his work "Sur la temperature des lacs des Tatres." A prize of one thousand francs (Priz Majer) is offered for the best work on "La Climatologie des pays Polonais"; papers to be sent in before December 31, 1896.

A SEVERE earthquake disturbance was experienced at Oran, Algeria, at about one o'clock on the morning of the 19th inst. The duration of the shock is said to have been four seconds.

A SPECIAL meeting of the Chemical Society will be held this evening, at nine o'clock, at the Royal Institution, when Prof. Dewar will lecture on "Phosphorescence at very low temperatures."

THE meeting of the Museums Association, now being held in Dublin, was opened on Tuesday with an address by the President, Dr. Valentine Ball, C.B., F.R.S., on "The Museums of Dublin."

IN the House of Commons on Tuesday, Colonel Howard Vincent asked the Home Secretary whether he had decided to adopt in the Metropolitan and City Police districts, and in the provinces, the recommendations of the committee appointed to inquire into the system of identifying criminals by measurement, invented by M. Bertillon, of Paris, and the finger-print test of Mr. Francis Galton; and, in such case, if, in order to facilitate research into the judicial antecedents of international criminals, the registers of measurements would be kept on the same plan as that adopted with such success in France, as also in other continental countries. In reply, Mr. Asquith said that the recommendations of the committee had been adopted, including the recommendations as to the mode of keeping the register.

IN connection with the Antwerp Exposition, a Congress has been arranged, under the auspices of the Société Royale de Geographie d'Anvers, having for its object the discussion of matters relating to the atmosphere. The Congress will be held on August 16, 17, and 18. The papers will be classified into two sections, one dealing with atmospheric movements, while the other is concerned with aerodynamics. The former section is divided into four parts as follows:—(1) General theory of atmospheric currents and the causes which affect them. (2) Methods of observation at different altitudes. (3) Instruments of observation and for automatic registration. (4) Maps of permanent and of variable atmospheric currents, and a comparison of them with ocean currents. In the aerodynamic section the subjects dealt with will be:—(1) The measurement of the velocity of wind. The action of wind on a plane normal surface and on an inclined surface will be considered, and the friction of air. Experimental apparatus is also included in this division, and the effects of wind on buildings, bridges, towers, &c. Aeroplanes, windmills, and turbines are classified under the motive power of wind, while transport by land, sea, and air are arranged in a sub-group of questions relating to the resisting power of air. The subjects of the second part of the second section are the special application to aerial navigation of data on the resistance of air, and the development of the motors required to render such means of transport an accomplished fact. From this summary it will be seen that the Congress has been organised not only with the idea of bringing together those who are working at the problem of aerial navigation, but also meteorologists, naval architects, and all whose experiences may help to elucidate the matter. The President of the Congress is Lieut.-General Wauwermans, and the General Secretary, Chevalier Le Clement de Saint Marcq, Rue du petit Chien, 16, Antwerp. M. Lancaster, of the Brussels Observatory, is the President of Section I., and Captain M. van den Borren, the President of Section II.

Everyone will agree that the Marine Biological Association of the United Kingdom has, since the opening of the Laboratory, six years ago, carried out the intentions of its original supporters, which were "to promote researches leading to the improvement of zoological and botanical science, and to an increase of our knowledge as regards the food, life, conditions, and habits of British food-fishes and molluscs." Scientific research, however, is not often generously endowed, hence the Association, like many similar institutions for investigation, has its activity greatly restricted by the need for further financial support. With the idea of showing the truly national importance of the work carried on in the Laboratory at Plymouth, the Association has issued a pamphlet, in which its aims are briefly stated, and a few of the many practical and purely scientific investigations carried out under its auspices are described. It is hoped that this statement will quicken interest in marine biology, and induce benefactors to science to give their support to its representative Association, not only because their assistance will help to extend scientific knowledge, but also because they will be assisting in the development of our sea-fisheries. The following extract from the pamphlet referred to shows how small are the funds of the Association in comparison with those of other establishments having similar objects:—"The income of the Association is derived partly from a grant by the Treasury, partly from the voluntary generosity of public companies and private individuals. The Fishmongers' Company contribute £400 a year to the Association, whilst Her Majesty's Government have given £500 a year in the years 1888-9, 1889-90, 1890-91, and £1000 a year in the years 1891-2, 1892-3, and 1893-4. The total income unfortunately falls considerably short of the amount necessary to place the Laboratory on a properly efficient footing. The purchase and maintenance of a sea-going steam-vessel, by means of which fishery investigations can be extended to other parts of the coast than the immediate neighbourhood of Plymouth, is a most pressing need. The admirable Marine Biological Laboratory at Naples, founded and directed by Dr. Dohrn, and devoted purely to zoology and botany, has cost about £20,000, including steam-launches, &c., whilst it has an annual budget of £7000. The United States Fish Commission receives from its Government more than £70,000 a year, and possesses a perfect fleet of vessels. Its work almost exclusively relates to fisheries. The Scottish Fishery Board is credited in the estimates for 1893-4 with £21,858, which (with the exception of £3000 for pier and harbour works) is granted for fresh and salt water fishery work. The Marine Biological Association, with the twofold aim of promoting pure zoology and scientific fishery investigation, received in 1892-3 only £2199 in all." We trust that the appeal of the Association will result in a large extension of the list of subscribers, so that biological science and the fishing industry may both be benefited.

A recent number of the *Comptes Rendus* contains a note, by M. Birkeland, on some recent work done in the late Prof. Hertz's laboratory. It is well known that Hertzian waves when they travel along an iron wire magnetise it transversely, although they only penetrate a very short distance below the surface of the wire. This being so, it was an interesting problem to investigate whether it would be possible to observe in such a wire nodes and loops in the magnetisation. Experimenting in this direction M. Birkeland was led to a negative result, which he attributed to the electrical conductivity of the wire, and hence he was led to experiment, not on cylinders of iron, but on mixtures of finely divided iron and paraffin. He uses a square resonator having each side 60 c.m. long, the opposite side to the spark micrometer being formed into a coil of twelve turns, well insulated from each other. If a cylinder of soft iron is introduced into this coil, the spark length is not changed; a fact which previous experimenters have shown to be due to the screening effect of the induced currents in the superficial layer of the mass of metal. When, however, a cylinder of the mixture of iron and paraffin is introduced into the coil, the spark length may be reduced from 9 m.m. to 0·05 m.m. or to 1/180th of its original value. The effects observed increase as the electrical conductivity of the cylinders diminish, so that the magnetic action of the iron becomes less masked by the conductivity effects. This is well shown by surrounding the cylinder with tin-foil, when the spark regains its original length. When a hollow cylinder of the mixture of iron and paraffin is introduced into the coil, the spark length is much shortened, but the effect is much enhanced when the hollow cylinder is filled by a solid rod. Thus the author finds that the magnetic action is felt through a thickness of 5 m.m. when the mixture contains 25 per cent. of iron, and through 7 m.m. when it contains 10 per cent of iron.

The Central Meteorological Office of France has just published its *Annales* for the year 1892, consisting of three large quarto volumes. Vol. i. contains a number of memoirs on special subjects, among which, as usual, there is one by M. Fron, on thunderstorms in France during the year. These summaries have been continued for thirty years, and furnish useful data for determining the laws which underlie the formation and propagation of those phenomena. M. Moureaux discusses the observations on terrestrial magnetism at the Parc Saint Maur, and gives curves from the self-recording instruments of the most remarkable disturbances, which were considerable during that year. He also contributes a paper on the magnetic conditions at 100 stations; there are altogether 428 such stations in France; those not yet dealt with will be discussed in subsequent years. The results of phenological observations and the migrations of birds during the years 1881-90 are discussed by M. Angot; this is one of the most comprehensive and complete papers of the kind hitherto published. He also contributes a valuable paper on the results of M. Vallot's first series of observations on the summit of Mont Blanc, made in 1887, and a comparison of the simultaneous observations made at the central office in Paris and on the Eiffel Tower, which confirm the principal results obtained in previous years. Finally, M. Durand-Gréville gives a detailed investigation of the connection between squalls and thunderstorms, and has determined some of the phenomena which regularly accompany the formation and propagation of the latter. Vols. ii. and iii. deal respectively with the ordinary observations and with rainfall values at a large number of stations. An important addition to this branch of the work has been made by the publication of the observations made in Senegal, among those referring to stations for various foreign places.

At the joint meeting of Cornish scientific societies, held at Penzance on June 15, Mr. Howard Fox, the president of the Royal Geological Society of Cornwall, read a paper on "Some Fossils from the Coast Sections in the Parishes of Padstow and St. Mervyn," in which he showed that a hitherto unexamined portion of the North Cornish Coast is Upper Devonian. Mr. G. L. Crick, of the British Museum, recognised amongst the fossils found, Orthoceras, Bactrites, and Goniatites, and determined two species, *Bactrites Budesheimensis* and *Goniatites Simplex*. Both these species occur in Germany in Lower Beds of the Upper Devonian, and both forms are likewise present at a corresponding horizon in the red shales of Saltern Cove, near Torquay. In the same horizon at Trevone several specimens were found of the small bivalve shell *Cardiola retrostriata (Cardium palmatum)*, also found at Saltern Cove and in the Upper Devonian beds of Budesheim. The occurrence of these characteristic fossils in the Trevone rocks leads to the conclusion that the beds are on the same geological horizon of the lower portion of the Upper Devonian as the Budesheim strata. A portion of a plate of a ganoid fish imbedded in the blue shale of Trevone was recognised by Mr. Smith Woodward as undoubtedly Devonian and belonging to a genus not yet described, distinct from the *Steganodictyum* of Ray Lankester. Remains of Trilobites, apparently species of Phacops, with several corals, viz. Favosites, Amplexus, and Pachypora, were found in the friable cliffs, which also yielded two bivalves not determinable, and a small brachipod, with a minute punctate structure, closely similar to that of the Devonian genera *Centronella* and *Cryptonella*. In the foreshores of the northern part of Constantine Bay a palmate form of coral was found, from which a section was made, and determined by Dr. Hinde to belong to the genus *Pachypora*, but the particular species could not be identified. The fossil which most distinctly characterises this foreshore is a species of Conularia. In surface markings this form, according to Dr. Hinde, differs from all other known species from the Devonian rocks of America and Germany, principally in the marked fineness of the transverse lines, and it probably belongs to a new species.

NEW bread and the hot morning roll, though difficult of digestion, may have some advantages. According to the *British Medical Journal*, Dr. Troitzki, writing in the Russian medical periodical *Vratch*, states that he has found that new and uncut bread contains no micro-organisms, as the heat necessary to bake the bread is sufficient to kill them all. As soon, however, as the bread is cut and is allowed to lie about uncovered, not only harmless but also pathogenic microbes find in it an excellent nutrient medium. White or wheatmeal bread is a better medium than black or rye bread, as the latter contains a greater percentage of acidity. Dr. Troitzki's experiments with pathogenic bacteria gave the following results:—*Streptococcus pyogenes aureus* retains its vitality on the crumb of wheatmeal bread for twenty-eight to thirty-one days, on the crust for twenty to twenty-three days; the bacillus of anthrax (without spores) remains alive on the crumb for thirty to thirty-seven days, and on the crust for thirty-one to thirty-three days; the typhoid bacillus remains active twenty-five to thirty days on the crumb, and twenty-six to twenty-eight on the crust; whilst the bacillus of cholera lives twenty-three to twenty-five or twenty-seven days on both.

A RECENT number of the *Arbeiten a.d. Kaiserlichen Gesundheitsamte* contains an interesting paper, by Dr. Dunbar, on the detection of cholera vibrios in river-water. As many as 1100 samples in all were examined, 855 being abstracted from the river Elbe alone, whilst samples from the Rhine, Weser, Oder, and other rivers were also submitted to the special tests necessary for the isolation of cholera vibrios. The investigations were begun at the beginning of last August, and were continued until the middle of December. Only those vibrios which gave the cholera red reaction were submitted to further cultivation and examination. Dr. Dunbar exercises great caution in the classification of the numerous vibrios he has isolated, and although in all important respects it was impossible to distinguish them from undoubted cholera vibrios, yet he prefers to describe those obtained from the river Elbe as Elbevibrios, those from the river Rhine as Rhinevibrios, those from the river Oder as Odervibrios and those from the river Amstel as Amstelvibrios. Some of these vibrios when cultivated in ordinary peptone broth in the presence of air and at a suitable temperature, gave rise to phosphorescence, a phenomenon which was never obtained with the cholera vibrio; but even this failed to serve as a mark of distinction, for out of 68 cultures in which this characteristic appearance was exhibited, 38 only gave it occasionally, losing this power in some instances and exhibiting it in others. Elbevibrios were detected in the vicinity of Hamburg from July 19 down to November 4; after that date, although samples were daily examined, none were found. But whereas these cholera-like vibrios were not found after November 4 in the running water, they were found more than a month later, on December 19, in the mud at the bottom of the river; the latter, remarks Dr. Dunbar, probably offering them an opportunity of remaining in a dormant condition for considerable periods of time until chance and suitable circumstance enable them to become again redistributed in the stream itself. These Elbevibrios were found on 21 occasions in the tap-water as delivered to the city, and once in this water after passing through a Berkefeld cylinder, which was investigated on 50 successive days.

WE have received part iii. of the *Proceedings* of the Academy of Natural Science of Philadelphia, extending from October to December 1893.

MESSRS. J. WHELDON AND CO., Great Queen Street, W.C., have issued a catalogue of books and papers on microscopic zoology and botany they offer for sale.

THE June number of the *Journal* of the Royal Microscopical Society, just issued, contains the sixth part of Mr. A. D. Michael's "Notes on the Uropodinæ," in addition to the useful summary of current researches relating to zoology, botany, microscopy, &c.

THE "Beginner's Guide to Photography" (Perken, Son and Rayment) is in its fortieth thousand. Evidently the purchasers (and their name is legion) of the cheap cameras with which the market is glutted, appreciate this guide to the methods of the "black art."

To the third edition of his "Epitome of the Synthetic Philosophy" (Williams and Norgate), Mr. F. Howard Collins has added an abridgement of the "Principles of Ethics." The volume thus presents, in a condensed form, the whole of Mr. Spencer's philosophical principles, so far as they have been published.

THE volume of *Proceedings* of the Liverpool Naturalists' Field Club for the year 1893 has been issued. It contains an interesting address by the President, Mr. G. H. Morton, on museums of the past, the present, and the future, accounts of the excursions and evening meetings of the Society, and summaries of the botanical and entomological work done. We regret to note that this Society, like many others in the provinces, is not flourishing, the number of members this year being forty less than last year.

THE Alembic Club Reprints, published by Mr. W. F. Clay, Edinburgh, are handy little volumes enabling a retrospective view to be obtained of scientific researches that have become classical. In No. 6, a copy of which is before us, we have the Bakerian Lecture delivered by Davy before the Royal Society in 1807, and a part of a paper communicated by him to the

Society in the following year. The papers, as is well known, deal with "The Decomposition of the Fixed Alkalies and Alkaline Earths." Priestley's experiments in 1775, which led to the discovery of oxygen, will be reprinted in No. 7, and Scheele's work of 1777 in the same direction will form the contents of No. 8. No. 9 will be made up of reprints of Davy's papers on the elementary nature of chlorine. These three volumes of the series are in the press.

THERE is a certain amount of satisfaction in identifying wild flowers gathered during country rambles. To assist amateur botanists in and near Edinburgh to carry out this kind of determination, Mr. C. O. Sonntag has prepared a little book of handy size, viz. "A Pocket Flora of Edinburgh and the Surrounding Country," and Messrs. Williams and Norgate have published it. Therein will be found, to quote the sub-title, "a collection and full description of all Phanerogamic and the principal Cryptogamic plants, classified after the natural system, with an artificial key and a glossary of botanical terms." It may be doubted whether a student derives any great advantage from the dictionary method of classifying specimens, nevertheless he may be led through such work to higher studies. Another local flora of which we have received a copy is a "Vade-mecum to the Alpine Flora," by L. Schröter and Prof. C. Schröter (London: David Nutt). This book is in its fourth edition. It contains one hundred and seventy coloured representations of Alpine flowers, so that every bit of bloom which beautifies the Swiss mountainside can be easily identified by tourists without any botanical knowledge whatever. No attempt is made to describe or classify the plants in a systematic manner. Unlike Mr. Sonntag's book, that by Prof. Schröter appeals to the curious tourist rather than the investigating student. The text is in English, French, and German.

THE first edition of Quain's renowned "Dictionary of Medicine" was published in 1882; the second edition was issued by Messrs. Longmans, Green, and Co. last week. For twelve years Sir Richard Quain's comprehensive work has been the standard dictionary of medical knowledge, and the practitioner, teacher, and student alike have put their trust in it. The fact that more than 33,000 copies of this work of reference have been issued in this country and America suffices to show the manner in which the labours of the editor and his eminent staff are appreciated. To bring the book up to the present state of knowledge was a laborious task, for, since the first edition was published, the science and practice of medicine have made enormous progress, and many new developments have occurred. The work had, in fact, to be completely revised, and a large number of new articles had to be prepared. The result of these expansions is that the Dictionary now consists of two volumes, entirely reprinted, while the number of pages have been increased from 1834 to 2518. The editor, and his assistants, Drs. F. T. Roberts and J. Mitchell Bruce, are to be congratulated upon the accomplishment of their task. With the co-operation of numerous members of the medical profession, they have launched their treatise for a second time. We do not doubt that its future career will be as successful as its past.

UNDER the title "Proof Spirit and Fiscal Hydrometry," Mr. John Heywood has published a small book by Dr. B. Derham. The author arraigns the legal definition of proof-spirit, because it depends upon the indications of a certain Sykes' hydrometer. This instrument, and the tables for use with it, are shown to be open to objection. According to Dr. Derham, the proper allowances for variations of the temperature of the hydrometer, and of the spirit stored in bonded warehouses, are not made. Accepting this, it is shown that the Revenue suffers a considerable loss of duty on proof-spirits. In fact, it is asserted that the Revenue estimate, for the year 1892-93, of the total quantity of proof-spirit, fell short of the true estimate by 186,542 proof-gallons; and that, consequently, the loss sustained was £93,271. And, it may be added, since the funds for technical education came from the wine and spirit duties, Dr. Derham's book would seem to show that the moneys available are less than they ought to be. Thus it appears that the progress of technical instruction is dependent upon the graduations of Sykes' hydrometer, a connection that reminds us of Darwin's story of the relation between cats and clover. Having pointed out the seeming defects in Sykes' system, Dr. Derham develops a new system of hydrometry, and describes a new form of hydrometer for carrying it into effect. His suggestions may be worth the consideration of those responsible for the proof standard.

THE hitherto unknown dimethyl arsine, $(CH_3)_2AsH$, has been isolated by Dr. Palmer in the laboratory of the University of Illinois, and is described by him in the current *Berichte*. It was obtained by the reduction of cacodyl chloride. The most advantageous mode of preparing it is as follows:—Granulated zinc is first slightly platinised, then covered with absolute alcohol, and sufficient hydrochloric acid added to produce a rapid current of hydrogen. A mixture of cacodyl chloride, hydrochloric acid, and alcohol is then allowed to fall into the flask from a dropping funnel; a reaction immediately commences, and copious vapours of the reduction product are carried away by the escaping excess of hydrogen. The vapours are conducted first through water contained in a couple of U-tubes, then dried by passage through a calcium chloride tube, and eventually led into a suitable receiver immersed in a freezing mixture of ice and salt. The dimethyl arsine rapidly condenses in the receiver to a colourless mobile liquid which boils at 36°. It is endowed with the characteristic cacodylic odour, and spontaneously inflames with some violence in contact with the air. When air is admitted to the mixture of its vapour with hydrogen a dense white cloud is produced, which rapidly settles upon the walls of the vessel in the form of a crystalline deposit, which is very soluble in water. Dimethyl arsine is completely absorbed by silver nitrate from the mixture of its vapour with hydrogen, with formation of a precipitate of metallic silver and an acid substance which appears to be cacodylic acid. The reaction which occurs in its preparation may be represented by the equation:

$$(CH_3)_2AsCl + H_2 = (CH_3)_2AsH + HCl.$$

If the cacodyl chloride is allowed to enter the reaction vessel too rapidly, or if there is an insufficient supply of acid present, the chief product of the reaction is cacodyl itself, $(CH_3)_4As_2$. Owing to the high boiling point of cacodyl, however, it is either retained entirely in the reaction vessel or in the washing tubes, so that the purity of the escaping dimethyl arsine is not appreciably affected, although its amount is considerably diminished. Dr. Palmer expects shortly to have a further communication to make concerning the remaining unknown organo-arsenic compound, monomethyl arsine, CH_3AsH_2, experiments being now in progress with a view to its isolation.

THE additions to the Zoological Society's Gardens during the past week include a Black-headed Lemur (*Lemur brunneus*, ♂) from Madagascar, presented by the Hon. Mrs. Fellowes; a Green Monkey (*Cercopithecus callitrichus*, ♀) from West Africa, presented by Mrs. Flowers; a Leonine Monkey (*Macacus leoninus*, ♂) from Burmah, presented by Mr. J. W. Hunter; a Brown Capuchin (*Cebus fatuellus*, ♀) from Guiana, presented by Mrs. J. L. Johnson; a —— Mangabey (*Cercocebus*, sp. inc. ♂) from Ujiji, Lake Tanganyika, a Yellow Baboon (*Cynocephalus babouin*, ♀), a Duyker-bok (*Cephalophus mergens*,

♀), an Æthiopian Wart Hog (*Phacochærus æthiopicus*, ♂), a Banded Ichneumon (*Herpestes fasciatus*), a Milky Eagle Owl (*Bubo lacteus*), a Black-crested Eagle (*Lophoaëtus occipitalis*), a Marabou Stork, (*Leptoptilus crumeniferus*), two Green-necked Touracous (*Corythaix chlorochlamys*), two White-crested Touracous (*Corythaix albo-cristatus*), a Bell's Cinixys (*Cinixys belliana*) from British Central Africa, presented by Mr. H. H. Johnston; a Black faced Kangaroo (*Macropus melanops*, ♂) from Australia, presented by Dr. G. Lindsay Johnson; a Black-headed Conure (*Conurus nanday*) from Paraguay, presented by Mr. A. Harrison; a Golden Eagle (*Aquila chrysaëtos*) from Scotland, presented by the Maclaine of Lochbine; a Stump-tailed Lizard (*Trachydosaurus rugosus*) from Australia, presented by Capt. Jamieson; a Maholi Galago (*Galago maholi*) from South Africa, an Arabian Gazelle (*Gazella arabica*, ♂) from Arabia, an Indian Gazelle (*Gazella bennetti*, ♀) from Persia, a Lioness (*Felis leo*) from East Africa, a Military Macaw (*Ara militaris*) from South America, deposited; a White-tailed Gnu (*Connochetes gnu*), three Ypecaha Rails (*Aramides ypecaha*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE NATIVE CALENDAR OF CENTRAL AMERICA AND MEXICO.—The native races of Mexico and Central America used a calendar differing completely from those employed by the ancient nations of the Old World to reckon time. Many explanations of the origin of the calendar have been suggested, some referring it to series of recurring events in nature, others to astronomical phenomena, while a third section of inquirers regard it as purely mythical and terrestrial. Dr. D. G. Brinton has lately studied the peculiar calendar from the point of view of linguistics and symbolism, and his results are given in the *Proceedings* of the American Philosophical Society, vol. xxxi. p. 258, 1893. As the calendar system investigated is not widely known on this side of the Atlantic, it may be well to give an outline of it. "The basis is a so called 'month' of twenty days. Each day is designated by a name of some object, animate or inanimate, and besides its name, each day is numbered, but not from one to twenty, but only from one to thirteen, when the numbering begins again at the unit. The result of this combination evidently is, that a day bearing both the same name and the same number will not recur until thirteen of the 'months' have elapsed. This gives a period or cycle of 260 days, and this anomalous period is at the foundation of the native calendar." Dr. Brinton's linguistic analysis of the names of the twenty days in the Maya, Tzental, and Quiche-Cakchiquel dialects, and in the Zapotec and Nahuatl languages, shows that they are all identical in signification, and therefore must have had one and the same origin. By arranging the symbols represented by the day-names in order from one to twenty, it is found that they exhibit a sequence covering the career of human life, from the time of birth until death at an old age. Thus, in all the five languages and dialects, the name of the first day signified birth or beginning, that of the tenth day, success (through hardship and suffering); of the eleventh, difficulties surmounted; of the thirteenth, advancing years; of the eighteenth, war and death; of the twentieth, the sun, or house of the soul. It appears, therefore, that the calendar conveyed a philosophical conception of life; which may or may not, however, have originated contemporaneously with it. The period of twenty days was doubtless derived from the vigesimal system of counting in use among the tribes employing the calendar. The number 20 is based on finger-and-toe counting, and Dr Brinton points out that in the languages investigated its name has the signification "completed" or "filled up." "In this way," he thinks, "the number came to represent symbolically the whole of man, his complete nature and destiny, and mystically to shadow forth and embody all the unseen potenesis which make or mar his fortunes and his life." Each of the twenty signs in the primitive calendar had 13 numbers, and also 13 names, or rather 13 varieties of the same name. Apparently the ancient seers of Mexico and Central America believed that by assigning thirteen modes of activity to each of the twenty headings under which the agencies that influence human life were arranged, they had taken into account the thirteen possible relations of each to both the material and immaterial worlds; and the fact that the result of 20 × 13 days is 260 days or approximately nine months, that is, the period from conception to birth, would, according to Dr. Brinton, have appeared to confirm the mystic potenesis of these cardinal numbers. But whatever theory is accepted to account for the adoption of the factor 13, there is little doubt that this period was posterior and secondary to the 20 day period.

THE APPEARANCE OF THE HELIUM LINE.—M. A. Bélopolsky contributes to the *Memorie delle Società degli Spettroscopisti Italiani* for May an account of some observations made by him on the apparent reversal of the Helium line, D_3. He noticed, while observing solar prominences, that this bright line frequently appeared double and contained a dark line, not running down its middle, but nearer to one edge than the other. A close investigation on several occasions showed that the one-sided appearance was not produced by instrumental defects. And since it was found that the line was sometimes visible, while at other times it could not be detected, M. Bélopolsky concluded that it was produced by absorption in the earth's atmosphere. The fact that the line did not split D_3 in halves, and that a second similar line could sometimes be seen, indicated that the appearance was not merely one of reversal. To locate the positions of these dark lines, the third order of a spectrum produced by a Rowland grating having 14,438 lines to the inch was employed. It was then found that the bright badge of Helium was almost exactly in the middle of two fine lines, of which the one near the redward side was double. Their telluric origin was evidenced by their absence on one occasion when the air was very dry and the temperature 4° C. At other times, when the atmosphere was full of moisture, and the temperature comparatively high, the lines were perfectly seen. With a spectroscope of small dispersive power, the double line on the red edge of D_3 appears as a single line stronger than the really single line on the violet side, which can only be seen under good observing conditions. M. Bélopolsky gives the following wave-lengths of the lines, on the Potsdam scale: 587·65 (double), 587·60 (D_3), 587·58.

EPHEMERIS FOR TEMPEL'S COMET.—In continuation of the ephemeris for Tempel's periodic comet, given in these columns on May 31, the following ephemeris for Paris Midnight (from *Astr. Nach.* 3229) shows the positions of the comet until the middle of August:—

1894.		R.A. h. m. s.		Decl. ° ′
July 1	..	2 16 48	..	3 15
5	...	2 26 5	...	3 34
9	...	2 35 2	...	3 50
13	...	2 43 39	...	4 3
17	...	2 51 55	...	4 14
29	...	3 14 34	...	4 30
Aug. 2	...	3 21 20	...	4 29
6	...	3 27 41	...	4 26
10	...	3 33 36	...	4 21
14	...	3 39 4	...	4 13

The comet is in Cetus, and is moving towards Taurus. It will pass about a degree to the north of α Ceti in the middle of July.

THE RECENT DISCOVERY OF FOSSIL REMAINS AT LAKE CALLABONNA, SOUTH AUSTRALIA.[1]

II.

GEOLOGY.

FOR what I have to say under this head I must express my obligations to my colleague, Prof. Tate, whose observations in Australia have now extended over many years. He has recently summarised the whole history of its geological progress in a very able presidential address to the Australasian Association for the Advancement of Science, and I have had no hesitation in quoting freely from this and from other writings of so competent an observer.

There appears to be no doubt, both from geological and

[1] By Dr. E. C. Stirling, F.R.S., C.M.G., Hon. Director, South Australian Museum. (Continued from page 1[illegible])

biological reasoning, that in the Lower Cretaceous period a great part of Central Australia was covered by a sea which extended from the Gulf of Carpentaria to the Great Bight, and so divided the continent into an eastern and western moiety. Following this, an upheaval of the sea-covered area took place, succeeded by a denudation of the cretaceous deposits. Unequal movements of depression then brought about lacustrine conditions on portions of the now uplifted bottom of the old sea strait and, in other portions, permitted of the admission of the waters of the ocean. Finally a general upheaval, followed by utter desiccation, placed the deposits of the period just concluded in nearly the condition as that in which we now find them.

The systems of existing lakes, which have been mentioned in an earlier part of this paper, are evidently the shrunken remnants of the much larger lacustrine area of Pliocene times —a condition which demanded for its existence a much greater rainfall than now exists, and was contemporaneous with that which gave rise to the glacial phenomena at places in more southern latitudes in Australia. The region of Lake Eyre was then, as now, the centre of the inland continental drainage. Towards this depression are directed many dry water-courses, of which those of the Macumba, Finke, Cooper, and Diamantina are the chief. For miles around extends an area of sand-hills, separated by loamy interspaces, which are littoral sand-banks marking the successive changes in the contraction of the waters. Within its basin the Pliocene sands and loams have yielded further proof of its lacustrine origin in the remains of Diprotodon, Turtle, Crocodile, and Ceratodus.

In Prof. Tate's opinion, Lake Torrens may have belonged to a lacustrine area distinct from that of Lake Eyre, as with the existing contour of the country a submergence of at least four hundred feet would be necessary before the two systems could be connected.

Such a submergence would also unite in a vast inland sea the whole of the lake region around Lake Eyre and to the westward of Lake Torrens. A very much less considerable submergence would connect Lake Eyre with Lake Frome and the lakes to the north of it. Much of the Murray Desert to the eastward of Overland Corner, and perhaps the whole Riverine region, was at this time a lacustrine area, though probably disconnected from those of Lakes Eyre and Torrens.

The following table, based on Mr. Hurst's report, and revised by Prof. Tate, represents approximately the classification of the formations of the district :—

Recent.—Loose sand generally forming low ridges, sand-hills, or dunes overlying in places the Pliocene beds.

Pliocene.—Lake Callabonna ; fossiliferous formation.

Bands of unctuous blue clay containing abundant quantities of saline minerals and concretions of carbonate of lime ; thin seams of sand ; inflorescent deposit of salts upon the surface. Fossils : Extinct Mammals, Birds, a fresh-water Mollusk (*Potamopyrgus*, sp.), Entomostracans, and a few plants of living species (*Charæ* and *Callitris robusta*).

Mesozoic.—(*A*) "Desert Sandstone" or Upper Cretaceous (hard quartzites or porcellanized sandstone, gritty sandstones, and conglomerates). Fossils : Dicotyledonous leaves. (*B*) "Rolling Downs" formation or Lower Cretaceous ; shales with fossiliferous limestone bands.

Azoic.—Metamorphic schists.

Clay slates, mica, talc, and hornblende slates, metamorphic and intrusive granite and greenstone.

The Pliocene formation in which the extinct Marsupials occur does not appear to be restricted to the present boundaries of the lake, since wells, sunk a considerable distance from the present shore, have yielded fragments of bone in exactly the same formation, thereby showing that the lacustrine area, in Pliocene times, occupied a larger area than at present.

The Mesozoic formation is limited upon the surface to a line of outcrops along the eastern slope of the Flinders Range. At Parabana, Pepegoona, Hamilton and Paralana Creeks, these beds occur as the edges of an immense mesozoic basin which underlies Lakes Frome and Callabonna. The detritus of this formation forms the stony table-lands and plains of the country, and the, so-called, stony deserts of the early explorers have their origin in the same formation.

The Azoic rocks are restricted to the Flinders Range, and are of doubtful age. These rocks were pierced by the Government boring party at Lake Frome several years ago, while boring through the Post-tertiary and Mesozoic formations in search of artesian water.

FOSSILIFEROUS AREA.

The area that has been more or less well explored, is not more than a mile long by about half to three-quarters of a mile wide, but this forms but a small portion of the fossiliferous ground. Bones were dug up at the springs lying in the lake bed eight miles to the north of the camp, and were observed on the surface in a very weathered condition all along the track thither. In fact Mr. Zietz informs me that traces of bones and teeth exist on the surface in almost every part of the lake he examined. Nor, as has been said, are they restricted to the present boundaries of the lake.

SURFACE SKELETONS.

One very remarkable feature is the existence of surface skeletons, indicated by the presence of concretionary limestone, or travertine, which has formed for the bones a sort of cast, elevated a few inches above the surrounding level. In some cases the relative position of the bones has been preserved to such an extent that the limestone mass presents a striking outline of the form of the skeleton. Usually in such cases the animal is lying on its side with the head and limbs plainly visible and more or less extended. The actual osseous substance has, in many of the bones of these surface skeletons, completely disappeared, but not however, in all cases, some of them, usually the limb-bones, are more or less imperfectly preserved and devoid of concretion. Several of these surface skeletons existed near the camp at the time of my visit, but Mr. Zietz informs me that after the drying up of the rain which then fell they were no longer visible, having been covered up by the general saline encrustation which has previously been spoken of.

CONDITION OF THE BONES.

The condition of the bones varied very much ; some were so friable that they crumbled into powder and could not be removed ; others, usually in moist places, were wet, soft, and of the consistency of putty. Curiously enough, for reasons which are not clear, some bones from wet places were firm and hard, while others from ground that was comparatively dry were soft. As a rule, those in best condition came from localities which, without being too wet, were moderately damp. The bones, thus varying in condition and consistency, required very different methods of treatment. The greatest difficulty was undoubtedly due to the circumstance that the bones were saturated with what was practically a concentrated saline solution. In fact, all their cavities were so filled with this fluid that it was necessary to allow a considerable time for it to drain away. In other cases the bones were encrusted and impregnated with gypsum crystals. From such causes the bones became in dry weather brittle and liable to break or crack, and in damp weather difficult to dry. Very careful and patient methods of treatment had consequently to be adopted, and will still be necessary until the salt is removed.

When dry, the fractured surfaces adhere strongly to the tongue, and an approximate chemical examination, by Mr. Turner, of a clean piece of Diprotodon bone gave the following composition :—

Substance dissolves almost entirely in dilute hydrochloric or nitric acids. Contains—

Moisture	3·76 per cent.
Organic matter	7·4 ,,
Inorganic matter, mainly phosphate of lime with some carbonate	88·84 ,,
Total	100

POSITION AND ATTITUDE OF SKELETONS.

The heads were pointed towards all directions, and the remains of different animals frequently much mixed. Where, however, the bones of an individual were lying in juxtaposition they preserved fairly constant relations to one another. The vertebræ, for instance, often formed a more or less continuous series or were broken up into segments, of which the constituents were in such close apposition that they could be removed entire. These bones and the head, which was often much flattened laterally, as if by pressure, were usually lying either in their proper position with the dorsal surfaces uppermost, or were turned over on their sides. The pelvis was usually horizontal ; of the ribs, some were *in situ*, others either widely separated from their fellows, or several firmly welded together. The limbs, almost invariably at a greater depth than the rest of the skeleton, had their various segments greatly flexed. The feet were deepest of all. This attitude, together with the frequent approximation of the bones of individual skeletons, is, as has been observed, strongly suggestive of death *in situ* after being bogged. A very similar attitude was assumed by the camels on the occasions when they got bogged in crossing from the sand islets to the main land.

The four Birds whose remains were found close to the camp had their heads all pointing to the south-west, that is towards the part of the lake-bed considered to be the deepest, but their bones, especially the ribs and short bones, were much broken and mixed together. The larger bones, however, were well preserved, and in one skeleton the cervical and dorsal vertebræ formed a continuous series. It was, unfortunately, only possible to secure two heads, and these, though apparently entire, were so soft and fragile that they had to be set immediately in a half-mould of plaster of Paris.

determined by Prof. Tate to be *C. robusta*, a species now living, were found embedded in the same blue clay, and some fructifications of *Charæ* were washed out of it.

Food Remains.

Associated with the skeletons of Diprotodon, in a relative position which corresponded with that of the abdominal cavity, were occasionally found loosely aggregated globular masses of what I judge to be the leaves, stalks, and smaller twigs of some herbaceous or arboreal plants. The fragments are very uniform in length, thickness and character, rarely exceeding an inch in length or a line in thickness. They are solid, often irregularly branched, frequently retaining portions of the bark, and have their ends often frayed or crushed as if by the action of teeth. Microscopic examination showed the structure of the sclerenchyma tissue to be well preserved, and gave clear indication of the existence of dotted ducts, but I could find no trace of leaves that might have indicated a diagnosis. Judging from this entire

Fig. 2.—Head of Diprotodon (Lying in clay matrix which has been partially removed.)

The position of the Bird-remains were here, as elsewhere, indicated by the presence of circular surface patches of "gizzard-stones," consisting of fine and coarse sand and small siliceous pebbles not exceeding three-quarters of an inch in diameter, the surfaces of which were smooth and worn as if by attrition.

The stones comprised in one entire patch weigh fourteen ounces, and include examples of siliceous sandstone, jasper, claystone, blackened on the outside, black quartz, clear quartz, chalcedony, together with a few fragments of blue brittle clay with worn edges. Such stones are not now found on the Flinders Range, but are characteristic of the great Central Australian plain formation, which extends from the Lake Eyre basin across the continent to the Gulf of Carpentaria.

Such pebbles occurred either scattered or in groups at various places in the lake, and were the only stones of any kind to be found anywhere on its surface. The only shell found in the clay matrix of the bones was a minute fresh-water Mollusk (*Planorbis* sp.). Three fruits, however, of a *Callitris*

absence of leaves and from the degree of maceration, or entire absence of the bark, these masses probably represent the contents of the intestines. No traces of coprolites were anywhere met with.

I have submitted a sample of these food remains to Baron von Mueller, who recommends that it should be sent to Prof. Radlkofer, of Munich, whose special investigations in xylography may enable a more accurate determination to be made.

Material obtained.

At the present time it is impossible to give more than a very bare outline of the extent of material obtained. In the first place, more than a third (and that the best) of it has not yet reached Adelaide, nor can do so for another month, and the unpacking of what has already arrived has only just been completed. On the field itself there was no time or means for careful examination and comparison, Mr. Zietz very rightly understanding his duty to be that of gathering in and of preserving as much material as possible while conditions, which might at any time alter, were favourable for work. In this and in the all-important work of careful labelling and packing, his time was fully occupied as long as daylight lasted, and as soon as the bones were sufficiently hardened they were packed up so as to be out of harm's way; consequently, the opportunity has never yet occurred of examining the collection in the aggregate.

Mr. Zietz is, however, confident that he has one fine skeleton of the large *Diprotodon australis* complete, and a second nearly so. The indications afforded by differences in the shape of the skull and other bones, together with the great variation in size, shape and section of the great upper incisors, render it probable that, even among the moiety of specimens already unpacked, there are at least three or four species of large Diprotodontoids represented.

We have nearly a dozen heads in good or fair condition, either intact or in pieces which can be put together; a very extensive series of limb bones, including some perfect feet removed entire with their envelope of clay, which, in some cases, will be found to show the impressions of the soles.

Of the feet, in which from our previous ignorance of their constitution much interest is centred, I prefer not saying much at present. Among the first consignment of bones brought down by Mr. Hurst, were the supposed bones of a fore and hind foot, but a careful examination of them satisfied me that they were not only incomplete, but that the assigned constituent bones did not all belong to the same individual, or possibly even to the same species. When at Lake Callabonna I made a further attempt to ascertain their structure from apparently untouched and entire specimens, but the wet weather had made the bones so exceedingly soft and fragile, that they collapsed under the gentlest handling, and I was consequently unwilling to risk further damage. Several of those we have were removed without disturbance of the enveloping clay, and are presumably complete, but the clay has now, with exposure, become so hard that they require for development more time than we have been able to devote to them under our present great pressure of work. Besides, there are many other bones the condition of which demands more immediate attention, so that I fear the feet must wait. There are hundreds of separate carpal, tarsal, metacarpal and phalangeal bones, many ribs, several more or less perfect pelves, and a very few marsupial bones. The vertebræ are the weakest point in the collection, as these are usually in bad condition or broken, and, in all cases, they were very difficult to remove and to prepare without further damage. Several small bones, which are almost certainly those of a very young Diprotodon, were found by Mr. George Hurst in such a position relative to the pelvis of an adult animal as to suggest that the parent had died with a young one in its pouch. Other such bones were found by one of Mr. Zietz's party. Of an apparently smaller species of Diprotodon, possibly *D. minor*, we have several heads and many other bones.

How many separate individuals of Diprotodon have been met with it is difficult to say with accuracy, on account of the way in which they were often scattered and mixed, and the fact that the work of Mr. Zietz overlapped that of his successor, but it would probably be safe to say that there was some indication or other of the existence of at least 100 distinct animals.

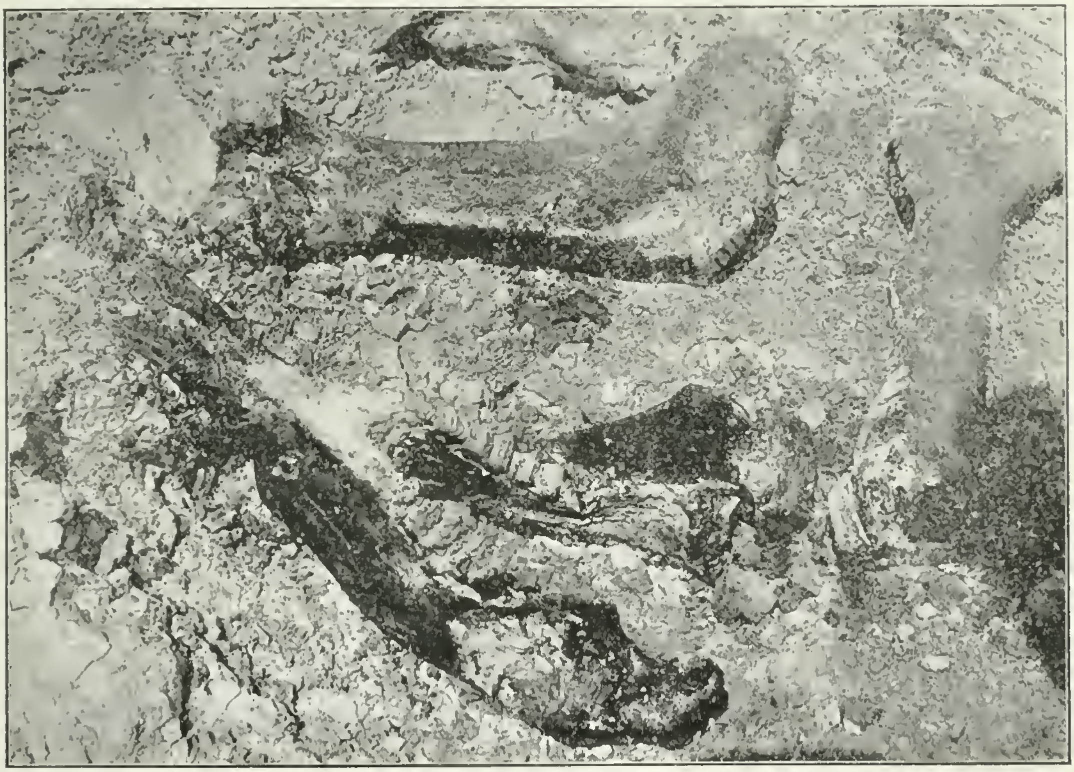

FIG. 3.—Diprotodon bones partially excavated.

Remains of a large Wombat, which appears without doubt to be *Phascolomys gigas*, were very scarce; most of the bones of the appendages, however, are represented more or less perfectly, as are also the marsupial bones. Unfortunately we have only fragments of two skulls, of which one can be made fairly complete when the pieces are put together. There appears no doubt but that the adze-like teeth, described by Sir R. Owen as those of *Sceparnodon*, belong really to this animal, as anticipated by Mr. Lydekker ("British Museum Catalogue of Fossil Mammalia," part v.). The name, however, is a misleading one, as the animal could not have exceeded three feet in height, though the bones are very massive.

Of fossil Kangaroos we have one small but very complete skeleton, and a large series of separate bones of several larger kinds, including a fairly complete skull, which has a length of 33·5 cm.

Of *Nototherium*, so far as we are aware, no remains have been met with, unless, perhaps, some teeth which differ from the ordinary type of those of Diprotodon may prove to be referable to this animal.

Besides the above, which constitute the bulk of the mammalian specimens, there are odd bones and fragments of bones belonging to some, as yet, undetermined small animals.

Of the great Birds which appear to be all of one species, and of nearly one size, we have, as stated, two skulls of extraordinary size, in passable condition; but as these have not yet been developed, it is not possible to give their characters or exact measurements. They, however, certainly exceed eleven inches, and possibly reach twelve inches, in length. There are besides three pelves, one sternum, a whole vertebral series, including the tail, several ribs, two partially complete sets of wing bones, and a dozen or more legs complete, so that the collection probably comprises nearly all the bones of the skeleton. The femur is of the same massive build as that of *Dromornis australis*, and even exceeds it in size. Moreover, so far as can be judged from description and plates, it differs from it in contour and section, which is greatly compressed antero-posteriorly, and in some other particulars. The differences between the two tibiæ are also considerable, especially in respect of the existence in the new fossil of a bony ridge across the precondylar groove. The proximal end of the femur differs also from the fragment assigned by Mr. De Vis to *Dinornis queenslandiæ*, but not accepted as such by Captain Hutton. Apart from the vast differences of proportion, the leg-bones of the new fossil have many points of resemblance to those of *Dromæus* in the disposition of salient anatomical features, a similarity which has been noted by Sir R. Owen in the case of *Dromornis*. The foot, relatively small, when compared to that of *Dinornis elephantopus*, is tridactyl, the outer toe appearing to possess only four phalangeal segments.

The following measurements present, roughly, a comparison between the dimensions (reduced to the metric system) of the femur of Owen's *Dromornis*, as stated by him (*Trans. Zool. Soc.* vol. viii. p. 381), and one of the largest of the femora of the Lake Callabonna fossil.

—	Extreme length.	Lat. diameter at middle-third.	Antero-posterior diameter.
	cm.	cm.	cm.
Dromornis australis	[illegible]2	6·4	4·0
Lake Callabonna bird	35·1	7·9	[illegible]

A further idea, also, of the comparative proportions of the various segments of the leg may be gained by reference to the subjoined table, in which the comparison is made between the leg of a *Dinornis elephantopus* in the South Australian Museum, the Lake Callabonna fossil, and a large Emeu (*Dromæus novæ-hollandiæ*):—

	Femur.		Tibio-Tarsus.		Tarso-Metatarsus.		Middle toe.
	Extreme Length.	Girth at middle.	Length.	Girth.	Length.	Girth.	Total length.
	[illegible]	[illegible]	[illegible]	cm.	cm.	cm.	cm.
Dinornis elephantopus	[illegible]	[illegible]	[illegible]2	14·[illegible]	22·2	14·[illegible]	1[illegible]
Lake Callabonna Fossil	[illegible]	[illegible]3	[illegible]	1[illegible]	7[illegible]	14·[illegible]	[illegible]3
Dromæus novæ-hollandiæ	21[illegible]	[illegible]	[illegible]6	[illegible]	[illegible]·4	7·[illegible]	14·[illegible]

The combined lengths of the three principal segments in the Callabonna fossil thus exceed those of the Emeu by more than a foot, and those of *D. elephantopus* by about the same amount.

Of the wing we fortunately possess two examples, one wanting only in the phalangeal portion, the other more imperfect. Comparing it with the appendage of the same Emeu, whose humeral and radio-ulnar segments are respectively 10 cm. and 7·5 cm. in length, I find that the corresponding segments of the fossil bird are 8·9 cm. and 10 cm. and considerably thicker.

The remaining bird-bones are in the collection which has yet to reach Adelaide, and I can therefore give no particulars of them from personal observation. There can, however, I think, be no doubt, even from the above limited observations, that these bird-remains indicate the former existence of a large extinct struthious bird distinct from either *Dromornis* or the *Dinornis queenslandiæ* of De Vis.

It is estimated that altogether about three to four tons net weight of bones have been, so far, obtained.

Although the most careful search was constantly made, no traces whatever of *Thylacoleo* were discovered, which, under the circumstances, is rather remarkable if the habits of this beast were as predatory as is believed by some. Its remains have, however, been found in other parts of South Australia, associated with those of Diprotodon. Nor were there any signs of the contemporaneous presence of man.

Meteorological.

Arriving at the camp on August 16, the party experienced fine weather, but very cold nights for about a week. Strong winds, mostly south-easterly but veering in all directions and increasing in strength for about twenty four hours and eventually subsiding, then became of frequent occurrence. Later on, towards the end of October, these gales, now usually from northerly quarters, increased in force and frequency, beginning at any time in the day and lasting twelve to eighteen hours, carried dense clouds of fine sand from the dunes, and pulverised saline matter from the lake, and were most irritating to the eyes.

In November these gales blew almost continuously and with still greater force, raising sand-storms so dense that it was impossible to see more than a few yards, and work was consequently impossible. Empty cases, and even the bones laid out to dry, were blown about the camp, sometimes to a distance of a hundred yards. The nights were intensely dark. Heavy clouds to the northwards seemed to threaten rain, but none came for some days. These clouds appeared to separate at the northern end of the lake, to travel southwards on each side of it, and then to unite again. Mr. Ragless, at Callabonna, was convinced that in some way or another the lake bed was an obstacle which the rain clouds from the west did not readily pass. During the day the heat was often intense, the thermometer in the tent rising frequently to 110° F. or not unfrequently even to 120°, but the nights were still comparatively cool. Innumerable flies were, in the day-time, a constant and maddening source of annoyance to man and beast, and so tortured the camels that the margin of their eyelids became quite raw. About the middle of November there was heavy rain for eighteen hours, and a week later a severe sand-storm from the west, bringing a sharp thunder-shower, in which an inch fell in a quarter of an hour, and its impact on the surface of the lake was so heavy that it could be heard at Callabonna Station six miles distant. A fortnight later a second severe sand-storm from the west was followed by another heavy shower. Just previous to the latter rain large flocks of the Australian Swift, *Cypselus australis*, locally called rain-birds, and considered to be a sure sign of heavy rain, passed over the lake. On one night only was there a fog, which was of such peculiar denseness that the candle in the tent threw hardly any light, and its flame appeared surrounded by a yellow halo.

Previous to heavy weather immense numbers of nocturnal insects came round the camp fire at night, and a large collection of them was made.

Rabbits.

During November the camp became almost unbearable from the stench produced by the dead carcases of rabbits which came to drink of the waters of a very brackish, in fact salt, spring at the base of the sand-hill, about a hundred yards from camp. Round this they died after drinking, or else perished after crawling for shelter into the tents and empty boxes. It became part of the routine of the camp to bury upwards of fifty bodies every night, but still the nuisance was hardly lessened. The rabbits also caused many bones to be broken by crawling under them in search of little pools of salt water which dripped from them as they were laid out to dry. In their frantic search for water they gnawed holes in the water-bags in camp, and on the mainland bit through the stems and roots of the "needle-bush," a species of *Hakea*. In one night at Callabonna Mr. Ragless killed 1400 with poisoned water, and what with drought and the ravages of these pests, which stripped the scanty bushes of every green leaf till they were nothing more than bundles of bare sticks, the surrounding country presented an appearance of desolation that defies description.

Under such circumstances of heat, sand and effluvia, it is not surprising that the health of the party suffered eventually from ophthalmia and gastro-intestinal complants, and, indeed, it was chiefly this which led to the breaking up of the camp at the end of November for the time being.

It would be an unworthy omission if I were not finally to acknowlege the cheerfulness and skill with which Mr. Zietz performed his duties under somewhat arduous and depressing circumstances; indeed, whatever satisfactory results may have been achieved by this expedition they are most chiefly due to his indefatigable zeal in the interests of palæontology and of his museum. To the Messrs. Ragless our best thanks are due for their kindness and hospitality to members of the party at various times, and for many necessary articles supplied, sometimes, I fear, at their own inconvenience. Our great obligation to the Government of South Australia for the loan of camels, granted through the mediation of Mr. Goyder, the Surveyor General, I have already acknowledged.

For the preceding notes I can only claim that they comprise but a rough and imperfect epitome of the physical features of the fossiliferous area, and of the conduct of the Museum party's operations up to the present time. As has been already stated, until the whole of the specimens have been unpacked, cleaned, mended, examined and compared, no accurate summary of the palæontological results can be given. It must further be remembered, that the South Australian Museum has recently shared in a general retrenchment imposed upon all Government institutions by the financial exigencies of the day, and that at this very time when the limited museum staff is called upon to deal with, for it, an unprecedented mass of material, it is also called upon to remove and re-arrange, with expedition, the whole of its collection in a new and more commodious building. I mention these facts as a plea for some indulgence for the delay that must inevitably take place, even with such collaboration as we may hope to secure, before the full scientific results can be made known.

Recognising the extreme promise of this discovery at Lake Callabonna, no hesitation was felt by the Museum Committee in subordinating all other work for a time to its vigorous prosecution. But for reasons, to which I have just alluded, excavations could only have been continued for a very limited time, had it not been for the very timely, generous, and unconditional assistance afforded by Sir Thomas Elder, G.C.M.G., a gentleman who stands conspicuous amongst Australian colonists for the liberal support he has so frequently and so munificently displayed in the interests of education and exploration in South Australia. This latest benefaction has enabled much to be done under undoubted difficulties, but much yet remains to be done, and it is hoped that, at a more favourable season, the work now for a time suspended may be resumed, to yield results still more favourable than those hitherto achieved. In the meantime the area comprising the lake has been reserved by the Government for the purposes of further exploration to be carried on under the authority and direction of the South Australian Museum.

KAFIRISTAN.

THE concluding meeting of the Royal Geographical Society for the present session was held on June 25, when a paper on Kafiristan was read by Surgeon-Major G. S. Robertson. Kafiristan is the least known part of Asia, and Dr. Robertson is the first European who has succeeded in penetrating its remote valleys, and making the acquaintance of the primitive tribes who dwell there.

Kafiristan is a geographical expression used to designate the country of those non-Mahomedan tribes who inhabit that space left blank in our maps, which is bounded on the east by Chitral and the Kunar valley, on the south-east by the Kunar valley, on the west by Afghanistan, and on the north by the Hindu Kush and by Badakhshan. Politically speaking, the whole region is bounded on the east by Chitral and the debatable land of the Kunar valley, and on all other sides by Afghan territory. All the rivers of Kafiristan drain into the Kabul river. The parts of this country explored during a year's stay included the Bashgul valley and many of its subsidiary valleys, from the head of which a passage was made to the Minjan valley of Badakhshan. The Kunar valley was also visited, and the valley known as Viron by the Mahomedans, and Presun by the Kafirs, was finally reached and found to be the most sacred part of this well-secluded country and the most interesting. Tribal jealousy made progress very difficult, but Dr. Robertson's journey and sojourn did not cost a single life, a very remarkable fact in a country where homicide is not regarded as criminal. All the passes leading into Kafiristan from Badakhshan are more than 15,000 feet in elevation, and internal communication between valley and valley is completely cut off in winter, when the various tribes live in absolute seclusion, each in its own district. The tracks which take the place of roads are narrow and difficult, running along the river valleys in many parts; they can only be traversed by experienced men; dogs cannot pass some of the difficult points without assistance.

The origin of the people is unknown. Classifying the tribes according to speech, there are, first, the Siah-Posh; secondly, the Wai, including probably the Ashkun; thirdly, the Presun. The Presun are certainly unlike all other Kafirs; they are possibly an aboriginal race. Dr. Robertson could never learn to repeat nor could remember one single word of their language; indeed, at their religious functions the sounds uttered by the officiating priests seemed more like a soft musical mewing than anything else.

Their customs are very peculiar and extremely primitive. One of the most curious is that a chief on his appointment, or anyone who excels in athletic exercise, does not receive tribute or reward, but is expected to feast all his neighbours as a thanksgiving for his exceptional distinction. The physique of the people was splendid, perfect muscular development being the rule, and fat men were quite unknown amongst them. They are great dancers, and have many ceremonial dances of much complexity. Funeral ceremonials are elaborate, and last a long time; but marriage is performed with the minimum of ceremony, the only essential being the payment of purchase-money to the bride's parents. The people were boastful, and at first it was impossible to get them to speak the truth on any subject: but they are brave to the last degree, and have maintained their independence for centuries against all comers.

A short paper was read at the same meeting by Mr. F. G. Jackson, describing the equipment of the Jackson-Harmsworth polar expedition and its proposed route.

SCIENTIFIC EDUCATION AND RESEARCH.[1]

ENGLISH boys and girls at the present day are the victims of excessive lesson learning, and are also falling a prey, in increasing numbers year by year, to the examination-demon, which threatens to become by far the most ruthless monster the world has ever known either in fact or in fable. Ask any teacher who has to do with students fresh from school his opinion of them: he will say that in the great majority of cases they have little if any power of helping themselves, little desire to learn about things, little if any observing power, little desire to reason on what they see or are called on to witness; that they are destitute of the sense of accuracy, and satisfied with any performance however slovenly; that, in short, they are neither inquisitive nor acquisitive, and as they too often are idle as well, the opportunities offered to them are blindly sacrificed. A considerable proportion undoubtedly are by nature mentally very feeble; but the larger number are by no means without ability, and are, in fact, victims of an acquired disease. We *must* find a remedy for this state of things, or perish in the face of the terrific competition now setting in. Boys and girls at school must be taught from the very earliest moment to *do* and to *appreciate*. It is of no use our teaching them merely *about* things, however interesting—no facts must be taught *without their use* being taught simultaneously; and, as far as possible, they must be led to discover the facts for themselves. Instead of our placing condensed summaries in their hands, we must lead them to use works of reference and acquire the habit of finding out; they must always be at work applying their knowledge and solving problems. It is a libel on the human race to say, as many do, that children cannot think and reason, and that they can only be taught facts; early childhood is the time at which these faculties are most apparent, and it is probably through failure to

[1] Extracted from the Presidential address delivered by Dr. H. E. Armstrong, F.R.S., at the Chemical Society, on March 22.

exercise them then that they suffer atrophy. The so-called science introduced into a few schools in answer to the persistent demands of its advocates has been in most cases a shallow fraud, of no value whatever educationally. Boys see oxygen made and things burnt in it, which gives them much pleasure; but, after all, this is but the old lesson learning in an interesting shape, and has no superior *educational* effect. I would here repeat what I have recently urged elsewhere, that in the future *all subjects* must be taught *scientifically* at school, in order to inculcate those habits of mind which are termed scientific habits; the teaching of *scientific method*—not the mere shibboleths of some branch of natural science—must be insisted on. No doubt some branch of chemistry, with a due modicum of physics, &c., is the subject by means of which we may best instil the scientific habits associated with experimental studies, but it must be the true chemistry of the discoverer, not the cookery-book receipt pseudo-form which has so long usurped its place. Whatever be taught, let me repeat that mere repetition work and lesson learning *must* give place to a system of allowing children to *do* things themselves. Should we succeed in infusing the research spirit into our teaching generally, then there will be hope that, in the course of a generation or so, we shall cease to be the Philistines we are at the present time; the education given in our schools will be worthy of being named a "*liberal education*," which it never will be so long as we worship the old world classical fetish, and allow our schools to be controlled by those who reverence this alone, having never been instructed in a wider faith.

As regards our college courses, I see no reason to modify the views expressed in my address to the chemical section of the British Association at Aberdeen in 1885; on the contrary, the experience I have since gained as a teacher and examiner has served only to strengthen them and to convince me of the paramount necessity of a very radical change in our system of instruction, and I rejoice at the increasing evidence of a state of unrest both at home and abroad. The "thorough" course of qualitative analysis which it has long been customary to impose at a very early period of the student's career must, I venture to think, be relegated to near its close; this course certainly has not the effect of producing competent analysts, and but too often reduces those who toil through it to the dead level of machines; in hundreds of cases I have seen students, as it were, hang up their intelligence on the clothes-peg outside and enter the examination room masked with a set of analytical tables, through which alone they allow themselves to be actuated, and to which they render the blindest obedience. Qualitative analysis actually requires the fullest exercise of the mental faculties as well as considerable manipulative skill. By introducing this branch of study at too early a period we force our students to act as machines, inasmuch as they do not, and cannot, know enough to work intelligently; we are but trying to make them run before they have learnt to walk. Even when the interactions on which qualitative analysis is based are fully studied, and the equations relating thereto are conscientiously written out, the result is not much better, owing to the slight importance of so many of the interactions apart from their technical application in analysis, and especially on account of our ignorance of the precise nature of many of the interchanges of which we avail ourselves: the persistent misrepresentation of facts which such a course encourages is, in my opinion, one of its worst features.

I believe that in the near future our students will first be set to solve problems, each in its way a little research, and involving much simple quantitative work; they will thus be taught chemical method, or, in other words, *the art of discovery*. They will then be taken through a course of quantitative exercises with the object of making them acquainted, by direct contact with the facts, with the fundamental principles of our science, which are but too rarely appreciated at the present day. After this, they will seek to acquire proficiency in quantitative analysis and in the art of making preparations; and subsequently they will give sufficient attention to the study of physical properties to enable them to appreciate the physico-chemical methods of inquiry which are now of such importance. The study of qualitative analysis in detail will be left to the last, as being an eminently technical subject. Meanwhile, by attendance at lectures, by reading carefully chosen works of a kind altogether different from the soul-destroying text-books we now possess, and especially by the study of classical models in chemical literature, they will have acquired what is commonly spoken of as theoretical knowledge, but too often regarded by us as of secondary importance, and which it is so difficult to make Englishmen realise means a proper understanding of the subject. Students so trained—imbued from the outset, even from early school days, with the research spirit—will at all times be observant and critical, nay, even logical; dogmatic teaching will cease to have any charm for them: they will actually take deep interest in their studies—a result devoutedly to be hoped for, as nothing is more galling to the teacher at the present day than the crass indifference of the average student and his refusal to give attention to anything unless it will pay in an examination. At the close of such a course, the student will be thoroughly prepared to undertake original investigation, distinctly with the object of exhibiting his individuality and originality, and not, as at present, with the object of acquiring for the first time an insight into the methods of the investigator; he will thus be spared the unpleasant discovery which the advanced student now too often makes that his early training has unfitted him, rather than prepared him, for the task of original inquiry.

But to attain to this happy state it will be necessary that school education be "rationalised" and improved, as I have already indicated; that the material placed at our disposal be of far higher average quality than heretofore; and that the period of study be lengthened.

As it offers but few prizes and unfortunately has no sinecures—which, however objectionable from an abstract point of view, are actually of the greatest service to many causes—chemistry has hitherto failed to attract much ability. Very many commence its study because they have an idea that chemists are always making interesting experiments of the firework order such as the conventional lecturer shows to a popular audience, and when the drudgery of actual practice is discovered by the young worker to be something very different from the rosy picture which such displays had excited in his mind, it often turns out that a mistake has been made in the choice of a career; such mistakes will occur less frequently when our schools are so conducted that we shall be able to find out what our boys and girls are fit for. Too often those who take up the study of chemistry are destitute of the mental ability required to comprehend so difficult and wide a subject, even if possessed of considerable manipulative skill; very many of these never can rise to the dignity of chemists, and it is clear that in the future some distinction must be made between cultured chemists and those who are but mere skilled workmen in some special branch of the subject; even "analyst" is too broad a term, in many cases; "tester" might, perhaps, be coined for the purpose. When we teachers are in a position to advise a parent that his son has not the making of a chemist in him, but that he would do well as a food tester, manure tester, or iron tester, for example—and the advice is understood and appreciated—we shall be relieved of much anxiety. We have to bear in mind Huxley's remark—that the future of the country depends, in industries as in everything else, on getting our capacities to the top and, if possible, sending our incapacities to the bottom. Infinite mischief has been done in this country by the intrusion into our industries of large numbers of men dubbed chemists, who have no right whatever to the name—from no fault of their own, but owing to their imperfect training, and more especially the ignorance of employers. Experience has shown only too fully that no one has derived any real advantage from this state of affairs. We may hope for better things in the future, especially if our colleges generally are led to impose an entrance examination. I am satisfied, from the experience that we have had at the City and Guilds of London Central Technical College, that it is of utmost importance that those who are to study chemistry should at least have acquired a sound elementary knowledge of mathematics; that those who prove to be satisfactory students of chemistry are almost invariably those who are fairly proficient in mathematics, and *vice versa*. "It is almost impossible to become a chemist in less than three or four years of constant application." (Author's preface to Lavoisier's "Elements of Chemistry," English translation by Kerr, 5th ed. 1802.) Such being the opinion nigh on a century ago, what must our view now be? And yet there is a strange illusion abroad that a *three years' course* suffices to make a lad who has had no previous training whatever in scientific method a "full blown" chemist, worthy of considerable hire! It is often heart-rending to the teacher to see lads of great promise forced out into the world, largely by this prejudice, just at the most critical period of their career, when they are on the very verge of acquiring real understanding of their subject, and of developing originality, as well as the power of working independently: abandoning their studies in this way, they too often degenerate into mere machines, capable of doing what they are told, but rarely more. And the manufacturer, who is too short-sighted to discriminate, then complains that he gets very little help from his "chemist," and seeks for a superior article abroad.

If we consider what a chemist, to be worthy of the name, must know in these days, it is clear that public opinion as to the duration and nature of his studies needs much emendation. He must be both artificer and artist. By constant practice and persevering application, he must acquire the manual dexterity, manipulative skill and neatness required of the analyst, while, at the same time, he must gradually become imbued with that high sense of accuracy, without which his labours will ever be untrustworthy; he must also acquire manipulative skill of an entirely different order by preparing a variety of typical substances, so that he may understand how to set to work when he subsequently engages in original labours involving the preparation both of materials already known and of new ones; and he must be practised in the more important methods of determining physical constants. While thus engaged in the laboratory, he must also be studying hard, constantly reading and *occasionally* attending lectures. To be a chemist it is necessary, moreover, to know much besides the practice and theory of chemistry proper: no slight amount of mathematical knowledge is also requisite for the proper understanding of the fundamental problems of our science, and no mere acquaintance with the first principles of physics, especially electricity, suffices; some acquaintance with biological science is indispensable, if we are to understand the manifold applications of our science in agriculture and in medicine, or are to assist in unfolding the nature of physiological processes generally; without some knowledge of mechanical drawing it is impossible to deal with machinery or to understand the language in which machinery is described; and it is necessary to read French and German fluently, the latter especially, in order merely to follow with intelligence what is being done by chemists. All this cannot be compressed into three years, and be it remembered I have said no word as to the necessity of every student who aspires to rank as a chemist undertaking some research work in order that he may acquire independence and the ability to solve problems and to progress.

So long as it is commonly supposed that it is but necessary to learn how to "analyse" in order to become a chemist, there will be but little progress; but when it is realised that chemistry is an exceedingly difficult subject to master, requiring a high order of intellect and breadth of mind, combined with extreme patience and perseverance and much mechanical dexterity, other views will prevail, and we may hope that we shall then count as of us very many who will rank high as artists and designers, and statesmen even—instead of being for the most part mere bricklayers, carpenters and joiners, capable only of working to order.

I have great hope that in the near future there will be many inducements held out to capable students to prolong their period of study to a satisfactory extent. At present, scholarships are mostly given to lads on their leaving school and commencing their technical training; the method by which such lads are selected is, in too many cases, an unsatisfactory one, the award being made on the result of an examination for which the candidates have been carefully prepared and crammed beforehand: the result too often affords but a proof of the power of lesson learning, and but little evidence of real ability. Serious injury is done at the Universities, owing to the stilted and artificial character of many of the college examinations, mere lads being required to answer questions of a highly technical character, far beyond the standard of school knowledge of the subject; those who are successful are more often than not overtrained—purely artificial products, whose mental digestion has been impaired, if not altogether ruined, by skilful tutors up to the tricks of the examiners. Such a system is partly responsible, also, for the growing practice of keeping lads at school—and even establishing "technical" sides for their special benefit—far beyond the age at which school should be quitted; such lads usually acquire bad habits during the last year or two of their school career, growing lazy; they are more often than not very poor material when they come to college; and in cases in which they are successfully pushed through public examinations, such as those of the London University, not having enjoyed the advantages of college life and instruction, they are too frequently but provided with a varnish of knowledge. However, it will probably be thought necessary to offer such entrance scholarships in order to attract ability, and they will be regarded with favour by schools as they obviously afford a means of advertising—in fact, they are used as such; it is, therefore, all the more important that the conditions under which they are awarded should be such as to favour rational methods of teaching and which as nearly as may be correspond with the natural conditions of school life; especially should we guard against encouraging the tendency which undoubtedly exists in schools to lavish attention on those of great promise at the expense of those of average ability. Genius will ever take advantage of opportunities, while necessarily it will benefit from careful training; but it may be overtrained and dulled, or made priggish by undue specialisation at too early an age. Yet to make changes is difficult, as there are so many rivals interested; and although the evils of our system are recognised, no one is willing to take the first step, fearing that this may entail individual sacrifice.

It has long been my opinion that scholarships would be of most use if given to those who have gone through a systematic course of training—lasting say about three years—and who are on the verge of learning to become capable independent workers; an additional two years spent in acquiring the power of undertaking investigations will render such students highly competent. But most parents can ill afford the necessary outlay, and it is astonishing how little at this stage lads themselves realise how extraordinarily important it is for them to continue their studies; that, in fact, they are worth very little to anybody. A limited number of such scholarships are available in some of our provincial colleges, and those given by the 1851 Exhibition Commissioners are also of this kind. In London, however, there has long been a strange deficiency in this respect, but I rejoice to say that this is on the eve of being remedied by the enlightened action of the Salters Company, by whom not only has a scholarship of £150 per annum been offered to my Institute for the encouragement of higher research in chemistry, but also one of £100 tenable in the research laboratory of the Pharmaceutical Society, as well as one of like amount to aid in the investigation of the more medical aspects of pharmacology, tenable in the school attached to St. Thomas's Hospital. The influence of the example thus set will, I trust, be widely felt—may our sore needs be met ere it is too late!

In my address at Aberdeen I dwelt much on the necessity of creating *an atmosphere of research in our colleges*, and to-day I am but repeating much that I said then; I regret to say that meanwhile no great progress has been made, although indications are not wanting that the foundation is being laid on which, if conditions become more favourable, we shall be able to build extensively. I venture to think that the time is come when we must appeal to our senior students to help us: hitherto the majority of these have gone to Germany to complete their education, Liebig's magnetic influence being in no wise exhausted—for it was he who gave direction to the stream which ever since has steadily flowed in one direction, and deep beyond description is the debt we owe to his memory in consequence. Time was when it was necessary to take passage on this stream, but this is no longer the case, or need not be if advanced students will but collect around us in sufficient numbers to enable us likewise to form schools of original workers—for we, like the ancient Egyptians, cannot make bricks without straw, and to be condemned always to teach the rudiments, more often than not to unwilling ears, takes the very life and soul out of those among us who by nature have any higher aspirations. There are undoubtedly advantages to be gained from a residence abroad—no one can recognise this more fully than I do; but I believe the case to be one of such gravity that some sacrifice must be made, and that if national interests are not to be put aside as of altogether secondary importance, individual preferences must, for a time at least, be subordinated to higher considerations. It is not accounted necessary in Germany to study abroad, and severance from apron strings is effected when desirable by visiting a university away from home. Why should not English students in like manner pass from college to college in this country, and thus help us to help them?

But we want help also from another quarter—or rather, let me say, that there is another section, and that a very large one, of the community *must help us* far more than they have hitherto done *to help them*; I mean *our manufacturers* generally. Let me remind you that the Chemical Society *was established for the general advancement of chemical science as intimately connected with the prosperity of the manufactures of the United Kingdom*: these very words form part of our charter. Yet to how small an extent is it recognised that chemistry is of service—that many of our manufactures, in the words of our charter, mainly depend upon the application of chemical principles and discoveries for their beneficial development? It is of no use to manufacture goods if you cannot sell them, and that is too often our position. Every teacher of any standing in Germany can count on placing his students so soon as he is in a position to state that they are fully capable and worth a trial; but here there is no such relationship established between the schools and the works; no proper opportunity is given to young men to prove their fitness for an industrial career. It is not even recognised that the discipline afforded by the study of our subject is an admirable preparation for an industrial career. Take the brewing industry, which in this country has availed itself far more than any other of our services—the brewer is called on to conduct operations involving chemical changes of a most complex and delicate character, subject to variation if the slightest departure be made from a very limited range of conditions, and this too with a material subject to constant fluctuation in composition and character, requiring the most vigilant and appreciative watching. Every brewer ought consequently to have received a chemical training: yet those who enter this industry are, with very rare exceptions, pitchforked into it as raw lads from school, without any preliminary training whatsoever, having received their position through the influence of a friend and from no merit of their own. The same might be said of the dyeing industry, of that of gas manufacture, and of many others. Some of you may have seen the list of subscriptions to the proposed Schorlemmer laboratory at the Owens College, Manchester, and may have marked with sorrow, as I have done, how few and small are the contributions from those connected with the local industries, and how large and numerous relatively are those from friends and admirers of the deceased chemist and from members of the college staff. Contrast with this the great number of subscriptions towards the erection of the Hofmann-Haus in Berlin. Although the comparison is not quite a fair one, perhaps, yet it illustrates my meaning, the reception accorded to the Manchester scheme being sufficiently indicative of the absence of appreciation of the real value of chemical science to industry in one of our chief industrial strongholds. . . .

The proposed Teaching University in London and the Commission on Secondary Education may help in an extraordinary degree to improve our position. But it is to be feared that our subject will not attain to its proper condition unless some action be taken which will consolidate the teaching—which will lead to the centralisation of students of chemistry proper, so they may enjoy the inestimable advantage of intercourse, and have at their disposal a complete staff of competent teachers, each one of whom thoroughly represents some special branch of the subject; so long as students are distributed about the town in half-dozens and each chief teacher is called on to cut himself up into any number of small pieces, so as to deal with the subject of chemistry as a whole, true higher teaching is impossible.

Much to be feared, also, is the tendency to over-estimate the value of examinations, and the great work of the future will be so to improve these that they shall have no prejudicial influence on the student's work and in no way check the development of original methods of teaching; we must fix our attention mainly on the influences to which the student is to be subjected during his career; the competent teacher will ever study his students while they are at work, and do the best for them, provided he be not rendered powerless by the trammels of an examination system which heeds "results" only and not individuals.

Finally, let me say that, while sympathising most fully with those who advocate a complete course of study, I feel that it is very easy to demand too much—very easy to make it impossible for students to do justice to their work by imposing too many subjects. Our chief desire must always be that students shall acquire a knowledge of scientific method and the power of working independently. Certain subjects must be insisted on—for example, mathematics and drawing: if a knowledge of these be not acquired early it will never be acquired; but apart from these and a competent knowledge of the main subject, we probably may, as a rule, be satisfied with comparatively little. Those who have once learnt to work and acquired a knowledge of scientific method will of their own accord, in proportion to their intelligence, apply themselves also to the study of other subjects—as many among us have done; those who are not sufficiently intelligent to do this are not, as a rule, improved by being forced to pay attention to unpalatable studies; on the contrary, they are, more often than not, thereby hindered from acquiring a competent knowledge of some one subject which does appeal to them, and are spoilt for life in consequence.

SCIENTIFIC SERIALS.

Bulletin de l'Académie Royale de Belgique, No. 4.—On the hydrates of the alkyl-amines, by Louis Henry. It has been known for some time that ammoniacal bases form compounds with water, a typical example being $2CH_2 . 2NH_2 . H_2O$, ethylenic diamine. Their properties have not yet been fully investigated. The author distinguishes between hydrates whose bases are soluble, and such whose bases are insoluble in water. He deals with methyl, ethyl, propyl, butyl, and amyl compounds, with the aromatic series, and with nitrites and amides. Their density increases with the percentage of water contained in them, even if the molecular weight diminishes. Their power of combining with water increases with their solubility and their richness in hydrogen, whether this be contained in the nitrogen radicle or the hydrocarbon.—On the creation of an International Bureau of Bibliography, by M. Mourlon. M. F. Vander Haeghen had proposed to the literature class of the Academy to initiate a movement for the compilation of a universal catalogue of public libraries. This proposal coincides with that for the establishment of a comprehensive and international catalogue of scientific papers, brought forward by the Royal Society. M. Mourlon proposed the deputation of three delegates to confer with the other two classes of the Academy with a view towards co-operation with the Royal Society.—On the aurora borealis observed at Louvain on March 30, 1894, by F. Terby. The author points out the recurrence of the monthly period previously observed in the appearances of February 28 and March 30.—Vascular hyphæ of the mycelium of the Autobasidiomycetes, by Ch. van Bambeke. The mycelium in question always contains vascular hyphæ, varying in number, distribution, dimensions, and form according to the species of mycelium. They are larger than ordinary hyphæ, and are usually cylindrical, with occasional fusiform or claviform extensions. They consist of a thin, extensible, and elastic envelope containing a substance which is usually homogeneous and highly refracting, but sometimes granular. They may be considered as a conducting apparatus playing an important part in the distribution of nutritive materials

Symons's Monthly Meteorological Magazine, June.—The May frost of 1894. M. Symons publishes minimum temperatures in the shade, obtained from forty-six counties in England and Wales, in which the thermometer fell below the freezing point between the 20th and 22nd May. In six counties minima of 25° or lower were recorded, while on the grass, readings of 18° in Nottingham, and 19 in Stafford were registered. The readings were not excessively low for May, which has always a cold period about the middle or latter part, for during a frost in May 1891 these low temperatures were exceeded by about 1°. Letters from correspondents show that the wide-spread disaster to vegetation was caused not so much by the lowness of the air temperature, as by the radiation, which was facilitated by the clearness of the sky, while owing to the mildness and dampness of the weather previously the vegetation was more forward and fuller of sap than usual, which froze and burst the cells by expansion. The frost was, as usual, most severe in the lowlands, near streams, and except in the north-east, where the temperature just touched 32°, none was recorded on the English sea-coast.

SOCIETIES AND ACADEMIES.

London.

Royal Society, May 31.—"Propagation of Magnetisation of Iron as affected by the Electric Currents in the Iron." By J. Hopkinson and E. Wilson.

Consider a solid, cylindrical electromagnet, it is well known that, in reversing the magnetising current, the induction does not instantly reverse, but a certain time elapses before it again attains its full value, that it reverses at a later time at the centre of the core than near its surface, and that the delay in reversal near the centre is due to the electric currents induced in the iron. The object of the present paper is to investigate these effects.

The magnet experimented upon had a diameter of 4 inches, and formed a closed magnetic circuit. Through a part of its length the cylinder of 4 inches diameter was formed of an iron core surrounded by two concentric, closely fitting tubes. Exploring coils of fine copper wire were bedded in the iron between the surfaces of the tubes. The currents induced in these exploring coils were observed when the current in the main coil of the magnet was reversed. These currents in some cases last for over half a minute.

Inferences can be drawn from these results as to the behaviour of other diameters than 4 inches. Comparing two cylinders of different diameters, similar events occur, but at times proportional to the squares of the diameters of the cylinders. From this consideration and the experiments, a judgment is formed as to the effects of local currents in the cores of transformers and of the armatures of dynamo machines.

June 14.—"The Effect of Mechanical Stress and of Magnetisation on the Physical Properties of Alloys of Iron and Nickel and of Manganese Steel." By Herbert Tomlinson, F.R.S.

Royal Meteorological Society, June 20.—Mr. R. Inwards, President, in the chair.—Mr. R. H. Scott, F.R.S., read a paper on fogs reported with strong winds during the fifteen years 1876–90 in the British isles. Out of a total of 135 fogs, 108 were associated with cyclonic, and twenty-seven with anticyclonic conditions. The majority of the fogs occurred with south-westerly winds and with temperatures very close to the maximum for the day.—Mr. R. H. Curtis read a paper on some characteristic features of gales and strong winds. After calling attention to the unsatisfactory state of anemometry, and after describing the "bridled" anemometer at Holyhead, Mr. Curtis stated that the greatest force of an individual gust which he had met with was registered in December 1891, and amounted to a rate of 111 miles per hour, which with the old factor would be equivalent to a rate of about 160 miles per hour. Gusts at a rate from 90 to 100 miles per hour have many times been recorded, but the usual limit for gusts may be taken to equal about 80 miles per hour, which on the old scale would be equivalent to about 120 miles per hour. Gales and strong winds differ in character very much; and as the result of a prolonged study of their general features, as recorded by the bridled anemometer, the author has been able to group them into three general classes. He then described those gales which are essentially squally in character, in which the gusts constitute the main feature of the gale. In an average gale the ordinary gusts follow each other at intervals of about ten to twenty seconds, while the extreme gusts occur at the rate of about one per minute. Another class of gales are those in which the velocity of the wind is tolerably steady. In the third class are gales which appear to be made up of two series of rapidly succeeding squalls: the one series at a comparatively low rate of velocity, the other at a much higher one, the wind-force shifting rapidly, and very frequently from one series to the other. Mr. Curtis also stated that, on looking carefully over the anemometer records, he had not unfrequently found very distinctly marked a prolonged pulsation in the wind-force, which recurs again and again with more or less regularity, of perhaps twenty minutes or half an hour in some cases, and in others at longer intervals of about an hour, more or less.

Physical Society, June 8.—Prof. A. W. Rücker, F.R.S., President, in the chair. Prof. Ramsay, in opening the discussion on experiments on the relations of pressure, volume, and temperature of rarefied gases, by Mr. E. C. C. Baly and himself, recapitulated the chief points in the paper. Siljeström, in 1873, and Mendeléef, in 1875, he said, had both found that gases become less compressible than Boyle's law would give, as rarefaction proceeds. Amagat, in 1883, examined the subject, and concluded it was impossible to make measurements sufficiently accurate to decide the question one way or the other. In 1886 Bohr investigated the compressibility of oxygen, and found its behaviour abnormal about 0·7 m.m. pressure. Van der Wen's experiments (1889) led him to conclusions opposite to those of Siljeström and Mendeléef, and those of Melander (1892) gave support to Van der Wen's results. To decide the question at issue the authors took up the subject, and their results confirm the conclusions of Siljeström and Mendeléef. They also prove that oxygen behaves abnormally about 0·75 m.m., as found by Bohr. Prof. Perry said some of the terms used in the paper required alteration. The word "elasticity" was employed in several senses; sometimes being used to denote "pv," the product of pressure and volume, whilst at others its ordinary meaning was intended. He did not quite understand the connection between pv and the thermal expansion, to which the authors refer at the end of their paper. Taking Ostwald's equation for gases $(p + a)v = Rt$, he proceeded to show that the coefficient of expansion would be constant whether pv was constant or not. Dr. Burton said he had been accustomed to think as pressure was reduced gases approached the simple or "perfect" state. It was very desirable that similar experiments be made on other gases, to ascertain if any had constant coefficients of expansion. He failed to see why the internal energy should increase as the pressure decreases, unless, under these conditions, energy travels more by radiation than by conduction or convection. The President, speaking of the adhesion of gases to the surface of glass, suggested experiments on the effects produced by varying the ratio of the surface to the volume of the gas. On the subject of distribution of energy he was inclined to agree with Dr. Burton's view, rather than with the author's suggestion. One would not be led by *à priori* reasoning to expect that the internal energy would increase with decrease of pressure. Prof. Ramsay, in reply, said that in the experiments on oxygen at about 0·75 m.m. pressure, the greater part of the gas was sometimes found in one McLeod gauge and sometimes in the other. Only after standing seventy-eight hours did the quantities trapped in the two gauges become equal. The only explanation they could think of was that the temperatures of the gauges might not have been absolutely the same. Speaking of the suggested increase of internal energy with decrease of pressure, he said Prof. Dewar's experiments tend to show that there was little conduction through vacuous spaces. The President thought Dr. Bottomley's researches had shown that radiation also falls off rapidly as the pressures become very small.—Owing to the absence of Captain Abney, the exhibition of photographs of flames, which had been announced, was postponed. A paper on the isothermals of ether was read by Mr. Rose Innes. Taking the important linear law $p = bT - a$ connecting the pressure and temperature of substances (liquid and gaseous) at constant volume, given by Ramsay and Young (*Phil. Mag.* vol. xxiii. p. 436), and subsequently confirmed by Amagat and Tait, the author has endeavoured to express the constants b and a in terms of the volume v. Using the results of Ramsay and Young's experiments on ether, because they extended over a large range of volume (1·9 to 300), the following formulæ were found to give the best approximation, viz.

$$b = \frac{751 \cdot 9}{v - 0 \cdot 9173\, v^{\frac{2}{3}}} \quad \text{and} \quad a = \frac{23{,}300{,}000}{v^2 + 11 \cdot 05\, v^{\frac{5}{3}}}$$

Tables and curves accompany the paper showing that for volumes between 6 and 300 the agreement of calculated and observed values of p do not differ more than can be accounted for by errors of experiment. For volumes less than 5 the formula for p gives numbers quite wrong. In searching for a physical basis for the expressions for b and a the author puts l^3 for v in the above formula, l being the side of a cube whose volume is v. The expression for p then becomes

$$p = \frac{RT}{l^3 - cl^2} - \frac{A}{l^6 + kl^5} \quad \dots \quad (3)$$

Writing the coefficient of T in the form $\frac{R}{l^3} \cdot \frac{l}{l - c}$, the author goes on to show that this form might be expected if the molecules had finite dimensions, for the number of impacts on the faces of a cube would be increased in the ratio $\frac{l}{l - c}$, where c is a quantity depending on the size of the molecules. Ingenious arguments suggested by Van der Waal's remark that his formula must not be pushed beyond the point where the actual volume is less than eight times the volume of the molecules, lead the author to infer that for ether this limiting volume is somewhat above 6. Hence he would not expect his (Mr. Rose Innes) formula to hold below this volume. The formula for a, the "internal pressure," is explained on the supposition that a "skin" effect exists between the matter in the vessel and the boundary layers. By clearing expression (3) of fractions the author shows that the shape of the isothermals are represented by an equation of the seventh degree in l, which cannot have more than three positive roots, and thence infers that isothermals are not necessarily represented by cubic equations, as is sometimes assumed. Prof. Ramsay said Mr. Rose Innes' formula was much more satisfactory than that of Van der Waal's, which was at best only a rough approximation. The President objected to the use made of the word "discontinuity" in the paper, as being quite different to its precise mathematical meaning. He also pointed out that the author's arguments respecting the effect of finite molecular dimensions was much less general than that of Van der Waal's. Although the new formula agreed with experiment over a longer range of volume than that of Van der Waal's, it would not be safe to argue beyond the range of the experiments it represented.

Paris.

Academy of Sciences, June 18.—M. Lœwy in the chair.—On the satellite of Neptune, by M. F. Tisserand.—The principle of maximum work and entropy, by M. Berthelot. A general discussion of the theory of maximum work, treated under the heads—(1) Chemical action and the disengagement of heat; (2) the principle of maximum work; (3) entropy; (4) a comparison of the consequences of the principle of maximum work and those of entropy.—Note on *Phyllium pulchrifolium*, by M. Sappey. The author shows that *Phyllium pulchrifolium* exhibits only a superficial resemblance to leaves, and is a true insect in all essential particulars.—On the *Dyrosaurus thevestensi*, by M. A. Pomel. This fossil reptile is the same as that described by M. Phil. Thomas as *Crocodilus phosphaticus*. It is not a crocodile, and should perhaps be termed *Dyrosaurus phosphaticus*.—On the astronomical observations made at Abastouman by M. de Glasenapp, director of the St. Petersburg Imperial Observatory, by M. Lœwy.—A memoir was presented on a theoretical study of the elasticity of metals, by M. Felix Lucas.—Solar observations made during the first quarter of the year 1894, by M. P. Tacchini. A progressive diminution in spots and faculæ has been recorded.—Researches on continued fractions, by M. Stieltjes.—On four connected solutions of the problem of transformation relative to the elliptic function of the third order, by M. F. de Salvert.—The expression of the number of classes deduced from the transformation of elliptic functions, by P. de Seguier.—On the surfaces capable of forming, by a helicoidal displacement, a *famille de Lamé*, by M. Albert Petot.—On a system of chromato-diatonic gamuts, by M. Edmond de Polignac.—The detection of traces of chlorine, by MM. A. Villiers and M. Fayolle. The chlorine is liberated by permanganate in presence of sulphuric acid, and shows, even in small traces, a blue colouration becoming red violet when treated with the following reagent in excess: saturated aqueous solution of colourless aniline 100 cc., saturated aqueous solution of orthotoluidine 20 cc., and glacial acetic acid 30 cc.—On the emetics, by M. E. Maumené.—Preliminary notice on a meteorite of a type distinct from the ordinary stony meteorites, by M. G. Hinrichs.—On the influence of fluorine compounds on beer ferments, by M. J. Effront. It is shown that ferments which have gradually become inured to the action of fluorine compounds give more alcohol and less glycerine and succinic acid than ordinary yeast from a given quantity of glucose.—Anatomy of the digestive tube of Hymenoptera, by M. Bordas.—On the presence of a thread cell in the spores of Microsporidiæ, by M. P. Thélohan. The author concludes that the Microsporidiæ should belong to the group of the Myxosporidiæ, as their spores present the same characteristics.—On the structure of the plants of Spitzbergen and of the island of Jan Maven, by M. Gaston Bonnier. The following conclusions have been formulated:—(1) Arctic plants as compared with Alpine plants of the same species are thicker and present a differentiated structure, and contain more numerous lacunæ; (2) the greater humidity of the air and the different character of the light play the principal part in this adaptation of Arctic plants.—The *gommose bacillaire* of vines, by MM. Prillieux and Delacroix. On the presence of remains of Foraminifera in pre-Cambrian rocks of Brittany, by M. L. Cayeux.—Impermeability of healthy epithelium to drugs and poisons, by MM. Boyer and L. Guinard.—Regulation of thermogenesis by the cutaneous action of certain alkaloids, by MM. L. Guinard and Geley.

THURSDAY, JULY 5, 1894.

A LABORATORY FOR PHYSICAL AND CHEMICAL RESEARCH.

IT is now about twenty years since the Duke of Devonshire's Commission pointed out that the needs of chemical and physical investigators, upon whose work our national industries so largely depend, were entirely neglected by the Government. Money has been freely lavished that artists may have all they require; biology and archæology have been well equipped, and students of literature have been provided with the finest library in the world; but such is the chaos and disorganisation of our scientific system that many industries are languishing, and some have already left the country because those who are able to foster them by making new discoveries find absolutely no help, and have neither places to work in nor instruments to use, although the sum which the Government has not hesitated to give for one picture would have been more than is needed to correct a condition which is really disastrous from the national point of view.

We rejoice to learn that this state of things, so little to the credit of successive ministries, is now to be partially corrected by the munificence of an individual, Dr. Ludwig Mond, one who, though not an Englishman by birth, has already aided English science by large endowments in other directions.

We learn from a communication which we have received from the Royal Institution, that Mr. Mond last year bought the large freehold house, No. 20 Albemarle Street, contiguous to the Royal Institution, and formerly the residence of the Earl of Albemarle, and has resolved to convey it in fee simple to the Royal Institution. He further proposes to defray the whole expense of converting it from its present uses into a laboratory of chemical and physical research, to be called the Davy-Faraday Research Laboratory, and of equipping it with everything needful for the conducting of scientific research upon a large scale. In addition to this, he proposes to endow the new laboratory first with an income sufficient to defray all local expenses; and, secondly, with a further and of course much larger income, sufficient to pay the salaries and incidental expenses of a trained scientific staff.

Mr. Mond thus realises an idea which engaged the attention of Faraday and Brande and the managers of the Royal Institution half a century ago. In the year 1843 a proposal was made to establish at the Royal Institution a school of practical chemistry, which was not only to give practical and systematic instruction to students, *but was also to provide a place where original researches could be conducted by individuals skilled in manipulation, and where the professors could work out their problems by the aid of many qualified hands.*

In a letter addressed to the managers of the Royal Institution, Mr. Mond writes:—

"I have felt that the need for such a laboratory has become greater and greater since the work of the scientific investigator has become more and more subtle and exact, and, in consequence, requires instruments of precision and a variety of facilities which a private laboratory can only very rarely command; and surely this need exists nowhere to a greater extent than in England, and nowhere can such a laboratory be expected to bear more abundant fruit than in this country, which possesses such an unrivalled record of great scientific researches, which have emanated from private laboratories not connected with teaching institutions, and amongst which the laboratory of the Royal Institution stands foremost, and has kept up its reputation for nearly a hundred years.

"It has been my desire for many years to found a public laboratory which is to give to the devotees of pure science, anxious and willing to follow in the footsteps of the illustrious men who have built up the proud edifice of modern science, the facilities necessary for research in chemistry, and more particularly in that branch of the science called physical chemistry.

"I have come to the same conclusion as the promoters of the scheme of 1843, viz. that such laboratory would still have the greatest prospect of success under the ægis of the Royal Institution, that in fact it would be the consummation of the work which this great Institution has been fostering in its own laboratory, with such remarkable results, by the aid of the eminent men whose services it has always been fortunate enough to procure.

"As only want of space prevented the Royal Institution undertaking this task fifty years ago, I took the opportunity which offered itself last year of acquiring the premises, No. 20 Albemarle Street, adjoining the Institution. This property I found very suitable for the purposes of such a laboratory, and large enough to afford, besides, facilities to the Royal Institution for a much needed enlargement of its present laboratory and its libraries and reception rooms, which I should with great pleasure put at the disposal of the Institution.

"Being convinced that the managers of the Royal Institution will give all the encouragement and aid in their power in the foundation and working of such a research laboratory, I hereby offer to convey to the Royal Institution the freehold of No. 20 Albemarle Street, and also the lease I hold from the Institution of premises contiguous thereto, to be held by them for the purpose of a laboratory, to be named 'The Davy-Faraday Research Laboratory of the Royal Institution,' and also for the purpose of providing increased accommodation for the general purposes of the Royal Institution, as far as the available space will allow, after providing for the requirements of the research laboratory.

"I also offer to make, at my own expense, all structural alterations necessary to fit the premises for these purposes, and to equip the Davy-Faraday Research Laboratory with the necessary apparatus, appliances, &c., and to make such further adequate provision as will hold the Royal Institution free from all expense in connection with the premises and the working of the said laboratory. . . . .

"I am aware that my offer will not provide for the third object of the scheme of 1843, viz. to enable the professors to work out their problems by the aid of many qualified hands; but I trust that if the laboratory which I offer to found proves successful, others will come forward who will supply the means for attaining this end, by the foundation of scholarships and bursaries to qualified persons willing to devote themselves to scientific work and not in a position to do so without assistance."

It is almost impossible to overrate the importance of the results which may be expected to naturally follow this noble endowment. The new Institute will not fill the gap to which we have previously referred, but it will emphasize its existence. It will not fill it because we suppose that when it is in full work it will not hold as many workers as are to be found in some of the research laboratories which form an integral part of many industrial establishments on the continent.

Further, here at last we have from one who is both a practical man of affairs and a successful student of science, a distinct endowment of research such as was advocated now many years ago to deaf ears.

We believe that Dr. Mond's noble endowment, for which all true lovers of science must thank him, will have far-reaching effects.

THE HISTOLOGICAL INVESTIGATION OF DISEASE.

Methods of Pathological Histology. By C. von Kahlden. Translated and edited by H. Morley Fletcher, M.D. With an introduction by G. Sims Woodhead, M.D. (London: Macmillan, 1894.)
