SHRUBBERIES AND THEIR MANAGEMENT.

NEXT to the contour of the ground it is the trees and shrubs of a garden and their arrangement that give to it its broad effects. If the trees and shrubs are not themselves the chief objects of interest there, they must, in all but the smallest areas, form at least the setting of whatever else the garden may contain. Whatever the picture may be, it is the arboreal vegetation that makes the framing. Therefore it is strange that in so many gardens one should see such striking evidence of the absence of any special thought or care for the trees and shrubs they contain.

How seldom one sees that there has been any endeavour to obtain the most suitable species for the place or the most beautiful and interesting subjects; in other words, any attempt to draw upon that wealth of material which modern travel, enterprise, and skill have brought to us. Who does not know that depressing thing—the ordinary "mixed shrubbery"—a crowded mass of shrubs, with here and there perhaps a tree, where all the weaker species have disappeared, and in which the stronger are left to fight each other for light and space? The result is that what remains is a survival perhaps of the strongest, but certainly not the most beautiful. If it were not that we see them any day of one's life in the making in the gardens and public parks of this country, we might hope that this type of shrubbery was a relic of less enlightened days.

It is easy to trace its origin and development. A student of human nature would probably say the "mixed shrubbery" we rail against is only one more evidence of the evils of procrastination. At the time of planting the material is naturally small, and in the hope of producing an immediate effect the plants are put in rather closely together. This, of course, is perfectly right, but too often the work stops there. Plants do not cry aloud, and they grow while we are sleeping. When the time comes that they are closing up and ought to be given more space, the work is passed by in favour of something seemingly more needful, but probably really less important. For when once the proper season has passed by it becomes increasingly difficult to treat the shrubbery satisfactorily. The plants become drawn and their sides thin, and any interference with them means, at the least, a temporary unsightliness. The remedy for all this is to be found in the adoption of a definite plan at the commencement and its rigorous carrying out afterwards. And here a few words may be devoted to the

ARRANGEMENT AND PLANTING

of trees and shrubs. When either a tree or a shrub is to be grown as an isolated specimen with plenty of space for its development, as on lawns or in parks, it has simply to be considered in its present and ultimate relationship to the general features of the landscape. Its natural increase in size and height does not involve transplanting and re-arrangement. It is, however, quite otherwise with the cultivated shrubbery, which, either large or small, forms so important a part of every garden. Such shrubberies are used to mask the boundaries of gardens and to make secondary boundaries within the garden itself; they are useful in forming dividing lines between plots where special cultures are carried on; as backgrounds to borders of herbaceous plants, as shelterbelts, and so on. The point is that wherever it is, or whatever its special object may be, it should not be merely a block of monotonous greenery serving no other purpose than to shut out a view. It should be, in itself, as much an object of beauty and interest as any other part of the garden.

The initial mistake that is so often made in the planting of shrubberies is the indiscriminate mixing up of the material employed. The value of what we know as grouping—that is the bringing together of several individuals of one kind, or even of two or more kinds that enhance each other's attractions—is not generally appreciated.

Without attempting a psychological explanation of the fact, it seems that the eye derives the greatest pleasure when a tree or shrub (but more especially a shrub) is seen either perfectly isolated or when it helps to compose a group made up, chiefly or wholly, of several specimens of the same species. This is even more the case with beds cut out on lawns than it is of continuous shrubberies. Here the indiscriminate mixture looks its worst, and here more than anywhere else should an arrangement of shrubs, be it of one or more species, strike a clear note. For large gardens and spacious areas I prefer, myself, the grouping together of individuals of the same kind; in smaller areas a combination of two or more may be desirable or necessary. But, to borrow a musical illustration, one should never strike all the notes of the octave at once—it should be either a single note or a chord. Take, as an example, what is one of the noblest pieces of shrub-grouping in any public garden in the British Isles—the Rhododendron Dell at Kew. No doubt this owes much of its beauty to the contour of the ground, but one cannot conceive any mixed arrangement of shrubs, however beautiful they might individually be, so impressive and effective as this massing of Rhododendrons, only relieved here and there by the introduction of a few dissimilar things.

In the case of shrubs of medium and small size and, indeed, of almost all the smaller species we cultivate, it is essential, if their beauty and individuality are to be revealed to the full, that this system of grouping should be adopted. The size of such groups must be regulated in consideration of several circumstances. The chief of these is the dimensions attained by the plant itself. The smaller it is, the smaller, of course, should be the group. Then one has to consider the extent of the shrubbery or garden of which it forms a part, and the other things with which it is in immediate association. In large gardens and in large shrubberies broad, massive effects can be obtained that would be out of place where the general scheme is on smaller lines. In grouping it is necessary to observe the strictest sense of proportion.

The massing of shrubs has one advantage that should be adverted to. It simplifies the management and reduces the labour of keeping the shrubbery in order. Presuming that the plants were first set closely enough together to pretty nearly cover the ground and produce an immediate effect, when the time comes—as it soon will—that more space is necessary for each specimen, it can easily be afforded by a judicious thinning out. The trouble and expense of an entire replanting are avoided. If, however, either through neglect or deliberate choice the shrubs are allowed to remain as originally planted the crowding does little harm. Each group becomes, as it were, one plant, and the general effect is not spoilt as so often it is where the shrubbery degenerates into a featureless jumble.

A FEW EXAMPLES

may be given of effective combinations of shrubs. Where a group consists of but one species no problems of course arise, but where two or more are used some thought must be given as to colour, diversity of habit, rates of growth, and time of flowering.

The double-flowered Gorse planted in a mass, with a few Tamarix tetrandra sprinkled among them, makes a pleasing group. The plants flower at the same time, and the graceful feathery branches of the Tamarisk laden with lilac-coloured flowers rising out of the solid mass of yellow Gorse form an effective contrast.

For yellow-flowered shrubs the common Mahonia (Berberis aquifolium) is a very useful associate. Forsythia suspensa, for instance, which is charming anywhere, has its attractiveness enhanced if it rises out of a mass of this dark purplish-leaved shrub. The same may be said of the early-flowering species of Hamamelis. Naked of foliage themselves, at the flowering time they need either a background or an undergrowth such as is afforded by a dark evergreen. Jasminum nudiflorum as-

sociated with the Mahonia will often make a very pretty winter picture. Indeed, a thin arrangement of deciduous flowering shrubs rising out of a dwarf evergreen mass is always pleasing.

A very striking feature in a garden may be made by associating together in a broad mass a collection of shrubs having variegated and coloured leaves. Here variety is desirable. A mass of Pissard's Plum alone, with its dark purple foliage, is heavy and unattractive, but associated with white variegated shrubs like Cornus mas variegata and Acer Negundo variegatum, or with yellow leaved ones like Cornus Späthii and Acer Negundo odessanum, and the beauty of all is brought out and enhanced.

The True Mixed Shrubbery.

There is, of course, another type of shrubbery which also has its own distinct attractions. This is where each individual plant has to stand on its own merits and where no attempt is made to produce broad or imposing effects by associating together a number of similar plants. This plan has, perforce, to be adopted where the space available is restricted and where the taste of the planter leads him to prefer variety rather than beauty merely. Such an arrangement appeals with special force to the *connoisseur*, and is the one which makes the small private garden most interesting. But it is unquestionable that such a shrubbery is not so easily managed as the one where the grouping system is adopted. It gets out of hand quicker and demands more persistent attention. Each plant, in order that it may show its true character and beauty, must attain to a certain minimum size and needs a certain space for its development to that size. But both the plant and its neighbours keep on growing, and it consequently becomes necessary to keep them within certain limits by pruning, or else to provide room for their enlargement by an occasional thinning and re-arrangement. Such a shrubbery ought never to be allowed to get crowded, otherwise the individuality of each plant is lost. A "loose" arrangement should be maintained. It is because shrubberies made on this plan are so often neglected, and the coarse growing plants so often allowed to crush out the weaker species, that I advocate the grouping system wherever possible. For public parks it is decidedly the best, as it is also for large private gardens or, indeed, wherever sufficient space is available for planting on broad lines.

It would be absurd to suggest that any one with a small garden should make what little shrubbery they may have consist of masses of a few things merely. But I am inclined to think that even in a small garden, if the planter is using for his shrubbery ten or a dozen of (say) Berberis stenophylla, or Forsythia, or Mezereon, or whatever it may be, he will do better to make a group of each sort than to sprinkle them over the whole length of his border. It is, indeed, for new shrubberies that the grouping system is so desirable. In old, well-managed ones, planted in the mixed style, each plant is attaining, or has attained, its full size, and produces somewhat the same effect as a group of younger ones. Here, at any rate, dignity is not lacking. But nothing can look more feeble than the common "mixed" shrubbery in the early years of its being. *W. J. Bean.*

TREATMENT OF CANKER IN APPLE TREES.

Where the trees are growing in a heavy, clayey sub-soil, canker is most destructive, but during the past few years we have been trying to keep it under, and have to some degree succeeded. When planting an orchard here, some few years ago, it was found necessary to dig the holes out 3 feet deep and 8 feet wide, and place a 2½ inch drain pipe to run into the main drain in the middle of the rows that were to be planted, afterwards filling to within 12 inches deep of rubble, clinkers, &c., before using turf. The surface soil was kept 12 inches above the level, and this allowed a few inches for settling. Afterwards, when having to lift the trees, I found this mound of earth a great advantage, as the roots were better to lift and prune, but the proceeding was a very expensive one. Unfortunately several of the varieties proved even then to be useless on this soil. For exposed positions trees with 3 feet stems are amply tall enough. When planting in such soils a free use of lime should be made, and those varieties planted that will to some extent resist the canker. Among the few that will do this are Cox's Orange Pippin, American Mother, Lemon Pippin, Irish Peach, Beauty of Bath, Lady Sudeley, Worcester Pearmain, and Rosemary Russet. The first to be attacked among these is Cox's Orange Pippin. Among culinary varieties Lord Grosvenor, Lord Derby, and The Queen are good ones. The Queen never fails to crop, the trees are clean, they grow into a good shape, and yield good fruits. Bismarck, Bramley's Seedling, Warner's King, The Sandringham, Kentish Fillbasket, and Newton Wonder succeed well on the espalier, as also does Bramley's Seedling.

Peasgood's Nonsuch, Stirling Castle, Baumann's Red Reinette, and Yorkshire Beauty have all succeeded here. Yorkshire Beauty as a standard never fails to crop well, and the fruits will keep in good condition for a long period. Any trees that are infected with canker should, after replanting, be kept quite 6 or 8 inches above the level of the ground. If the stem of a standard tree is diseased burn it, as it would never be of further use. When replanting, work in plenty of wood ashes, road scrapings, lime rubble, and a little slacked lime amongst the roots, as these materials will keep the roots warm during the winter. Before the leaves fall in the autumn syringe them with Bentley's Alkali, and again in the spring before the buds expand. When using this preparation before the leaves fall it should be applied at half-strength only. A free use of fresh lime is one of the best preventives, and if applied as a top-dressing in autumn and spring, the rains will wash it in. I have also used for dressing the ground the following mixture: 35 lbs. super-phosphate of lime, 21 lbs. nitrate-potash, 28 lbs. nitrate-soda, and 28 lbs. sulphate-lime. These were all mixed together and applied at the rate of a quarter of a pound to the square yard, but a little more may be given if desired. The trees are now gradually growing out of the canker, but it cannot be too often repeated that for heavy soils it is necessary to make an extremely careful selection of varieties, and, if possible, they should be obtained from a stock that has been growing on similar soil. Pruning should be done in the summer, for winter pruning aggravates the disease, and, if possible, let the trees have a clear run of growth. Any branches that may be overcrowding the centre of the tree may be removed in October before the leaves fall, and the wounds afterwards dressed with whale oil or Stockholm tar. *A. B. Wadds, Paddockhurst, North Sussex.*

NEW AND NOTEWORTHY PLANTS.

TRITONIA BRACTEATA (SP. NOV.)

The "hatchet-bearing" section of this genus includes four species (securigera, Nelsoni, flava, and bracteata), and forms an interesting group, structurally distinct from the rest of the Tritonias. This structural difference consists in three horny and probably gland-bearing processes, shaped like the head of a hatchet, which issue from the three lower segments of the corolla at the orifice of the tubular portion of the flower. No one has given any conclusive explanation of the functions subserved by these processes. Some have suggested that the narrowing of the "throat" of the flower would insure insect fertilisation; others that the processes were three effete stamens and that the ancestral forms had been true hexandrian plants. At any rate the structure of the flower in this section is sufficiently distinct to support the contention of a new genus.

T. bracteata was sent to me two years ago by Mr. Layton, from the mountains above Greytown, S. Africa, and flowered for the first time in my bulb-flue this September. It is an inconspicuous little plant, with spathes almost as large as its leaves. It is near T. securigera (Redouté, 53, *Bot. Mag.* 383) in the colour of the flowers, but differs therefrom in the flowers being only half the size, whereas the leaves are twice as large. The spathe-valves are also longer and acuminate, the scape is more flexuose, branching and floriferous, and the horny processes more developed. The hooded upper segment connects with T. Nelsoni; which latter sp. has narrow, linear leaves.

Description.

Scape, a foot high, flexuose, very hard, much branched, bearing thirty to forty scentless flowers, of a tawny-red colour, opening, singly or in pairs, and fading before others expand. Bracts very large and foliose, the lower ones 4 inches long. Flowers irregular, 1 inch span, the three inner segments narrower (over ⅛ inch wide) and recurved, the three outer wider (¼ inch) and not recurved. The upper segment is slightly wider still, and is incurved to form a hood protecting the stigma and anthers. The three lower segments marked with a yellow basal mark.

Filaments, all erect and contiguous. Style shorter than stamens. The inflorescence is irregular (all the flowers facing in the one direction) and appears in autumn on the new autumnal growth (in England, but probably spring-flowering in South Africa); this leaf-growth consists, at first, of three leaves of irregular shape each under 1 foot in length, by ½ inch in maximum width. The narrower leaf-growths, appearing with the flowering stem, are mostly, if not entirely, bracts.

Several of the Maricas are noticeable for similar foliose bracts. *A. Worsley, Isleworth*, 1905.

ORCHID NOTES AND GLEANINGS.

SCUTICARIA STEELII.

A photograph of a very fine specimen of this beautiful and rare South American Orchid is sent by Mr. J. Simon, gr. to W. W. Mann, Esq., Ravenswood, Bexley, Kent. The plant is growing on a raft, its slender, whip-like, terete leaves, 3 feet in length, falling perpendicularly. Clustered at the base of the leaves are 18 flowers, each about 4 inches across. All the segments are broad; the sepals and petals of a yellow colour, handsomely marked with chocolate purple; the lip is cream-white marked with purple. It is a very effective species and is not difficult to grow if placed on a block or raft and suspended in an orchid house having an atmosphere of an intermediate temperature.

SERAPHYTA MULTIFLORA.

A striking instance of the beauty to which a "botanical" orchid, which is an insignificant subject as a small or ill cultivated specimen, may attain when mature and well-grown is afforded in a fine inflorescence of Seraphyta multiflora sent by Mr. H. Haddon, gr. to J. Neale, Esq., Lynwood, Penarth. The inflorescence has seven branches, reaching about 18 inches from the extreme points, the branches being again divided, and the whole bearing about 200 flowers. The individual flowers are only about half an inch across, and of a pale greenish colour, but borne in such numbers at the tops of the reed-like growths that they make a very pretty display. The plant carries several spikes. Flowers of Liparis longipes and Camaridium ochroleucum were also received from Mr. H. Haddon.

CYPRIPEDIUM × SIDNEYANUM.

A new and pretty hybrid, said to have been raised between C. insigne, Harefield Hall variety,

and C. × Leeanum Massereelsianum was recently in flower in the Orchid Nurseries of Mr. H. A. TRACY at Army and Park Road, Twickenham. The large, flat dorsal sepal is pure white with a small apple-green base. The lower half is finely spotted with purple, the spotting changing to dark rose colour towards the upper half. The petals are honey-yellow veined with purple, and bearing some blackish spots on the under side. The labellum is tinged with purplish red. It approaches the favourite C. × Leeanum but is a pleasing break from it, and also very different from other hybrids obtained from forms of C. insigne and C. Leeanum. *J. O'Brien.*

CROSS FERTILISATION OF APPLES.

THE cross fertilisation of Apples forms an interesting study. In the ordinary course of events, it is a number of years before the seedling bears fruit, but a quicker way of attaining this object is by grafting a scion, taken from the seedling when strong enough—which it should be in about two years from the date of sowing the seed—then, under favourable conditions, the graft should bear fruit in about three years, or five years from the time the seed was sown. An interesting hybrid is Allington Pippin, the result of King of the Pippins × Cox's Orange Pippin (the latter being the seed parent).

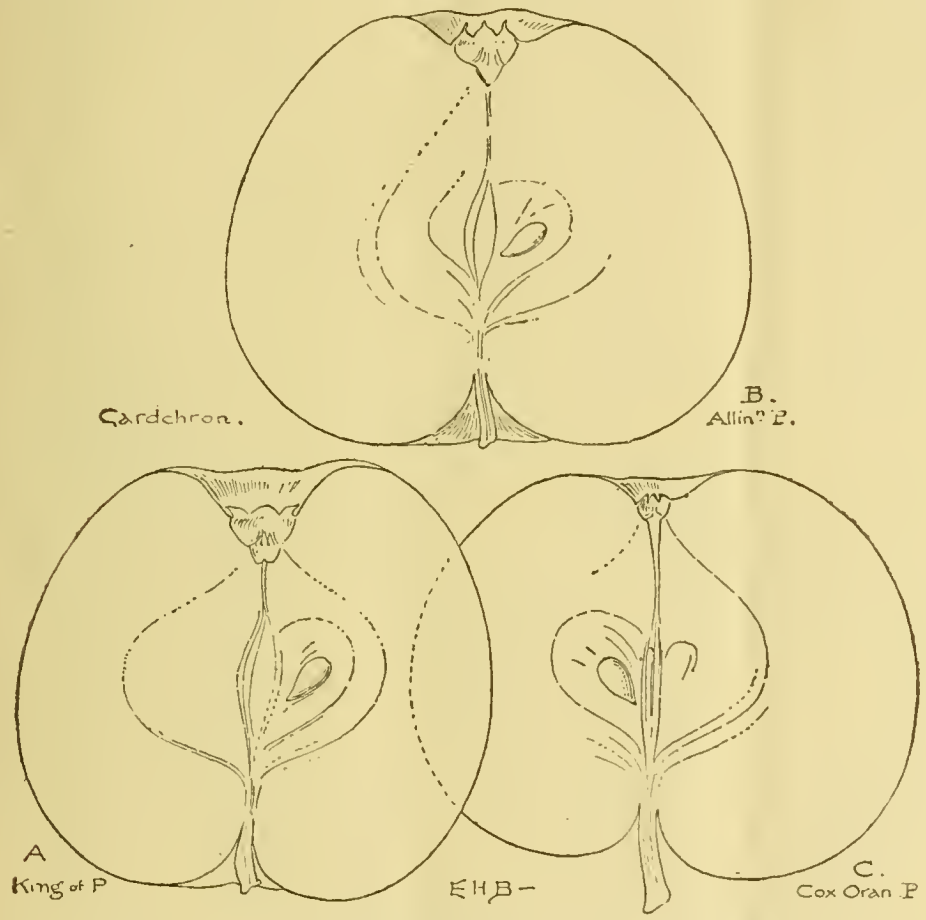

FIG. 1.—SECTIONS OF APPLE ALLINGTON PIPPIN AND ITS PARENTS.
(See text.)

The seedling approaches Cox's Orange Pippin in flavour, and in shape it is midway between the two parents, being more conical than Cox's Orange Pippin and not so "oblong" or "square-shouldered" as King of the Pippins. A curious point is that it succeeds in districts where neither of its parents will flourish. It will be seen on reference to the diagram (Fig. 1) (which was drawn from ripened fruits) that the calyx tube of King of the Pippins is broad and conical, while in Cox's Orange Pippin it is small and funnel-shaped, and in Allington Pippin it partakes of the form of both in being V-shaped, and is larger than that of Cox's Orange Pippin. Again, the sepals of King of the Pippins are reflexed, forming a broad, open eye, while those of Cox's Orange Pippin are inflexed, pointing towards the centre and closing up the eye, but in Allington Pippin they point upwards, forming a partly open eye. *E. H. Bowers, Glasnevin.*

NOTICES OF BOOKS.

THE FORESTER: A Practical Treatise on British Forestry and Arboriculture for Land-owners, Land-agents and Foresters. By John Nisbet, D.Œc.

FIFTY-EIGHT years ago the first edition of *The Forester* appeared. It was a small (crown octavo) volume of 215 pages, and from this small beginning has been evolved the largest and most complete text-book on British forestry which has yet appeared. *The Forester* passed through six editions, and in the last of these, published in 1892, in two volumes, an endeavour was made by the Editor to "engraft the modern Continental science of Sylviculture upon the old British stock of Arboriculture." In this, however, Dr. Nisbet was not very successful, and now Dr. Brown's work has given place to another which, though based on the sixth edition of *The Forester*, is, to all intents and purposes, a new work, and one which, in the words of its author, is "intended to serve as a text-book dealing chiefly with British Forestry and Arboriculture (two really separate branches of Rural Economy, which have usually been treated as synonymous in Britain), and with the reasonable possibilities there are of improving the existing condition of our woodlands, and of planting waste land for the growth of timber on business principles, with a fair prospect of success." The work consists of six parts, dealing respectively with introductory matters, the British silva, sylviculture, the protection of woodlands, the management and valuation of woodlands, and the utilisation of woodland produce. The book is well illustrated and provided with an ample index.

As to the subject-matter of the book, it must be said that, as regards certain of its aspects, Dr. Nisbet has not approached the question with which he has so ably dealt in a very optimistic spirit. He is well aware of the difficulties with which economic forestry is beset, and he is thoroughly alive to the drawbacks to it which have to be overcome in this country as compared with what obtains in some Continental countries to which we have been rightly asked to turn our attention for guidance in economic sylviculture. On the question of afforestation of waste lands in Britain, for example, Dr. Nisbet does not hold out such tempting inducements as have been put forward (sometimes with rather more zeal than discretion, perhaps) by some writers on forestry. For example, in reference to the extent to which waste lands in Britain may be planted, Dr. Nisbet says (Vol. I., p. 94):—"Our waste lands undoubtedly offer a wide field for planting; but it is impossible to say in any general way (as has been stated) that 'land yielding a smaller net rental than 8s. an acre' for agriculture or pasture will now pay better under timber. The reason why any such statement must be misleading is that favourable local opportunity for disposing of wood at a profit is a main factor entirely overlooked, or, at any rate, presumed, in the actuarial calculations—and, unfortunately the favourable local market is often wanting"; and in estimating the proportion of the 16,710,788 acres classed as waste land in Britain which may be planted "with a reasonable chance of direct monetary profit," Dr. Nisbet gives it as his opinion that at present this is limited to about 3,340,000 acres, about one-fifth of the whole, and "about one and one-tenth times the existing area now classed as 'woods and plantations.'" This may seem a pessimistic view to take of the afforestation of our waste lands, as compared with the very fine prospects which have been held out in this direction by others; but when it is taken into account that, as Dr. Nisbet puts it, "if a great national scheme of planting were to be adopted with a view to supply part of our future requirements in timber, the cost of planting these 3,342,000 acres of waste land would probably . . . mean a total actual outlay of about £20,000,000 (disregarding compound interest)" the magnitude of the undertaking assumes more gigantic proportions than appear on the first blush; and over and above this there is the further drawback that, as Dr. Nisbet points out (p. 95), "a large proportion of the waste lands are above the 1,000 feet contour line, and in the open, wind-swept, unsheltered condition of the country very little of this higher land can possibly be planted at present with any fair chance of profit; while there is also a large percentage of peat-bogs where no timber crops will thrive until the bog is cut away so far as to allow the young trees to get their roots down into the mineral soil."

In the introductory part, which contains an extremely interesting historical sketch of forestry and arboriculture in Britain, there is much matter which will amply repay careful perusal; but it is in the third part, which treats of sylviculture, that the practical forester will probably find most food for reflection, and

* Wm. Blackwood & Sons, Edinburgh, 1905. Two vols. Price 42s. net.

perhaps the most interesting chapters to him will be those dealing with the planting and tending of woodlands. In respect to "the best distance for planting," Dr. Nisbet has much to say, and we may here give a brief quotation or two to show to what conclusions he has been led regarding this important matter. "The probable profit," he says (Vol. I., p. 407), "of any plantation depends mainly on the local market for thinnings and for mature timber. One cannot plant simply the number of trees that will form the mature crop. Of the far larger number originally planted, only a small proportion of the fittest survive to the end, and the others have to be thinned out from time to time. If, therefore, the soil and situation do not of themselves necessitate close planting (as, say, at 3½ or 3¾ feet apart in squares or triangles on poor, exposed land), the market for thinnings may well be considered before one decides on planting at 4 by 4 feet, or at 4¼, 4½, 4¾, or even 5 feet apart. If there is a good local market for thinnings, close planting will be profitable; if not, then in place of being profitable it must cause a double loss, because while costing more, it will lead to the landowner being forced, sooner than otherwise necessary, to incur expense in thinning the young plantations without being able to dispose of the small poles with advantage"; and, again, he says (p. 408):—"Taking the three main factors of cost, probable profit, and soil productivity into consideration, it will be found that for ordinary planting with transplants from 1 to 3 feet high, 4 by 4 feet in squares (2,722 plants per acre), is, on the average, usually about the best distance for planting in Britain on medium classes of land for the given kind of tree." And in arriving at these conclusions, Dr. Nisbet is backed by Continental opinion, for it seems that "investigations at the Saxon Forest School (Tharandt) have shown that, on the whole, planting at 4⅓ by 4⅓ feet apart is the most profitable distance—and this even in a country where early thinnings are always saleable"; while Lovey (Germany) gives 4 by 4 feet as what may be called the "mean average," and Boppe and Tolyet (France) recommend "for all kinds of trees a distance of 5 feet between plants, in lines 6½ feet apart—or at least 5 feet in squares." It will thus be seen that the planting distances given by Brown were not so far amiss according to this, the latest, view; but where Brown did err, and err most egregiously, was in the after-treatment which he prescribed for the crops.

The volumes are dedicated to the Royal Scottish Arboricultural Society "in commemoration of the fiftieth anniversary of its foundation," and the work will, no doubt, form a most reliable and up-to-date source of information on all that pertains to correct sylviculture. Principles must be linked to a practice adapted to the climatic and economic conditions of this country, and these are in many respects distinct from those of Continental countries from which in recent years we have learned much, but which it is possible to imitate too closely. *R.*

NOVELTIES OF 1905.

ORCHIDS.—As usual, in recent years, the productions of the hybridist are strongly in evidence. In Odontoglossums some specially noteworthy novelties have been brought forward, such as the handsome O. × Smitbii, of Messrs. CHARLESWORTH & Co.; O. × Vuylstekeæ, of M. CHAS. VUYLSTEKE; O. × Thompsonianum, of W. THOMPSON, Esq.; and the generic hybrid Odontonia × Lairesseæ, of M. LAIRESSE. Others standing well above the general run of novelties are the superb Cypripedium × Thalia Mrs. Francis Wellesley, from FRANCIS WELLESLEY, Esq.; C. × Leeanum, J. GURNEY FOWLER; C. × The Baron, and Cattleya Schröderæ The Baron, of Messrs. SANDER & SONS.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), the owner of the oldest and most varied collection, has the longest list of plants honoured at the Royal Horticultural Society, many of them "botanical" Orchids known to science but rare in gardens. The florally beautiful include the pretty white Schomburgkia chionodora, and its purple variety Kimballiana, Odontoglossum ramosissimum Burford variety, Cœlogyne Lawrenceana, Brasso-Cattleya × nivalis, and B.-C. Mrs. J. Leemann; Epi-Lælia × Sylvia, E.-L. × vitelbrosa, and Epidendrum × radico-vitellinum; and the botanically interesting, but still pretty, Bulbophyllum Reinwardtii, B. radiatum, Vanda Watsoni, Stanhopea connata, Cycnoches peruvianum, Grobya galeata, Dendrobium æmulum, D. ciliatum annamense, D. striatum, D. crumenatum, Epidendrum tricolor, E. pterocarpum, Seraphyta multiflora, and others.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. Ballantine), from his grand collection, has exhibited several fine groups of rare Orchids during the year. Among the exhibits selected for awards were Miltonia vexillaria The Dell variety, the largest known Miltonia; Odontoglossum liliflorum, a unique specimen; O. × Lucasianum Heatonense, the handsome O. × Wilckeanum Schröderianum, and O. × Adrianæ aureum.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), is well in the front rank of modern Orchidists. At the first show of the year he secured awards for the two fine Cypripediums, viz., C. × Memoria Jerninghamiæ, and C. × Westfieldiense; and at the last for that perfection of C. Fairrieanum crosses C. × Thalia Mrs. Francis Wellesley; the interval bringing to his credit among others, Cypripedium × Godefroyæ leucochilum citrinum, C. × Germain Opoix, C. × Thalia giganteum, Cattleya × Peetersii Mrs. Francis Wellesley, C. Schilleriana Westfield variety, C. × Maroni Westfield variety, Lælia × Iona nigrescens, and Lælio-Cattleya × Charlesworthii magnifica.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), great in Odontoglossums and Cypripediums, gained honours with the beautiful Odontoglossum × ardentissimum Doris, O. × a. Sibyl, O. crispum Smeeanum, O. c. Prince Leopold, O. × mirificum, Calanthe × Chapmani, Cypripedium × San-actæus, C. × San-acderæ, C. × Dom Carlos superbum, C. × villoso-Rothschildianum, Cattleya × Kienastiana, Oakwood variety Dendrobium × Venus, Cookson's variety; and Polystachya Haroldiana, a pretty white species sent by Mr. Harold Cookson from Lake Tanganylika.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. Alexander), scores with a very varied and beautiful series, many of them raised at Westonbirt, and all finely grown. They include Lælio-Cattleya × Berthe Fournier, Westonbirt variety; L.-C. × Clive, Westonbirt variety; L.-C. × crispo-Hardyana, Cattleya × Iris magnifica, C. × Mrs. Pitt magnifica, Sophro-Lælia × læta Orpetiana, Lycaste Skinneri atro-sanguinea, Dendrobium fimbriatum, Westonbirt variety; Cypripedium × Chas. Rickman magnificum, and C. × Alcibiades, the last-named being shown in Major Holford's gold medal group on January 3, 1905, in which were many fine specimens which secured the Lindley medal for the grower.

JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. W. P. Bound), who has one of the very best-grown collections, showed well during the year, his best being the charming Lælio-Cattleya × Epicasta, Gatton Park variety; and Miltonia Regnelli, Gatton Park variety; while among hybrids raised at Gatton the pretty orange-scarlet Epidendrum × Boundii is an almost perpetual flowering and useful plant.

G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page), has secured awards for Cypripedium × G. F. Moore, C. × Actæus Chardwarense, C. × Actæus F. H. Cann, Dendrobium Phalænopsis, Chardwar variety, of a bright magenta-rose colour; D. p. Miss Louisa Deane, a pretty light variety; and the delicately tinted Lælio-Cattleya × Chardwarensis.

J. BRADSHAW, Esq., Southgate (gr. Mr. G. G. Whitelegge), has for his best of the year the very remarkable Cymbidium rhodocheilum, for which he secured a first-class certificate on May 10; Cattleya Schröderæ Robin, and the giant Cattleya labiata Hercules.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), who secured the gold medal for a magnificent group at the last show of the year, secured awards for fine varieties of Cypripedium × aureum, C. × Lawrebel, and Oncidium crispum, all distinguished as The Shrubbery varieties, and very handsome and distinct.

Two superb novelties came from the rare collection of Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), viz., the fine Odontoglossum × Wiganianum (Wilckeanum × Rolfeæ), and the large and perfectly-shaped pure white Lycaste Skinneri alba magnifica.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed the beautiful Odontoglossum × Hallio-crispum Theodora, the clear yellow O. Lindleyanum aureum, and Zygopetalum × Crawshayanum.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. Davis), exhibited the large and finely coloured Cypripedium × Daisy Barclay, and the elegant Cymbidium × Maggie Fowler.

ELIJAH ASHWORTH, Esq., Harefield Hall, Wilmslow (gr. Mr. Holbrook), presented the rose-purple and white Zygopetalum × Ballii, and the rare Oncidium corynephorum.

Mrs. HAYWOOD, Woodhatch, Reigate (gr. Mr. C. J. Salter), supplied Cypripedium × Haywoodianum, Dendrobium × Haywoodiæ, and Miltonia vexillaria radiata magnifica.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), sent Odontoglossum crispum Britain's Queen, and Cattleya × Pittiæ.

J. LEEMAN, Esq., Heaton, Mersey, furnished Odontoglossum crispum Louis L. Sander, one of the handsomest blotched forms; O. c. aureum, and O. c. Titus.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), showed Lælio-Cattleya × Harry Goodson, and Cypripedium Godefroyæ, Goodson's variety.

R. G. Thwaites, Esq., W. M. Appleton, Esq., Drewett O. Drewett, Esq., R. Briggs Bury, Esq., and others have contributed good things, the pretty Disa pulchra and its finer Tring Park variety, and Mormodes badium, being sent by the Right Honble. LORD ROTHSCHILD (gr. Mr. A. Dye); some curious and pretty botanical species by the Honble. WALTER ROTHSCHILD, M.P.; and the white Brasso-Cattleya × Digby-ano-Schröderæ var. Tankervilliæ, the pretty Cypripedium × Lord Ossulston, and the fine Vanda Sanderiana, Chillingham variety, from the Right Honble. the Earl of TANKERVILLE (gr. Mr. Hunter).

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, has kept the botanical interest in Orchids frequently supplied from the rich store in the Dublin Gardens, in which he takes such pride. Dendrobium triflorum, and D. cymbidioides, sent by him, served to settle the confusion between the names of those species; and Aerides Ortgiesianum was an interesting plant.

(To be continued.)

CYPRIPEDIUM × THALIA, "MRS. FRANCIS WELLESLEY."

This grand hybrid, the result of a cross made between C. insigne and C. Baron Schröder, was exhibited by Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins), at the meeting of the Royal Horticultural Society, held on December 19, when the Orchid Committee recommended it the award of a First-class Certificate. It is a flower of the highest perfection, being well balanced, of perfect shape, beautiful in outline, and pleasing in colour. The large posterior sepal is almost circular in shape, and quite flat, the colour being white, with a small shining green base, and rich and relatively evenly disposed purple markings that extend almost to the margin. The petals are honey-yellow in colour, but tinged and veined with purple brown, and with a few darker markings on the lower half nearer the centre of the flower. The tip is tinged with red-brown, and the staminode is yellow.

Fig. 2.—CYPRIPEDIUM MRS. FRANCIS WELLESLEY.
(See text.)

CULTURAL MEMORANDA.

SALVIA SPLENDENS IN SMALL POTS.

It may not be generally known how useful plants of the above-named Salvia are at this time of the year for brightening the conservatory. The main batch of these plants, grown in large pots, will have now flowered, and these may, with advantage, be supplemented by growing a batch of summer-struck cuttings and flowering them in 6-inch pots.

Cuttings may be taken in July or early in August from plants that were rooted in the preceding spring. The cuttings should be inserted either singly in "thumbs" or around the edge of a larger pot, shifting them subsequently into 5-inch and finally into 6-inch pots. It is important that the plants be allowed the maximum amount of light, an ideal spot on which to place them being a shelf in a moderately warm, airy house. Allow the plants ordinary treatment in the matters of soil, feeding, etc., and take care to keep them free from red-spider. They will begin to produce flowers at the end of November, and will look bright considerably past Christmas. The variety grandiflora, bearing large, strong, flowering spikes, is suitable for this method of growing *F. T. S.*

PLANT NOTES.

THE STREPTOCARPUS.

The Streptocarpns is a useful greenhouse plant, and is also very effective when used for the decoration of the dinner table, especially in conjunction with Dendrobium Phalænopsis.

The introduction of Streptocarpus Dunnii from the Transvaal to Kew in 1886 led to various crosses, which have been followed by most valuable results. S. Dunnii develops but one leaf, which is very large, being sometimes as much as 3 feet in length. The flowers are produced on crowded, erect panicles, which are developed from the base of the leaf. This species was crossed with S. Rexii, the latter having numerous small leaves, the result being the hybrid named S. Kewensis. It has also been crossed with S. parviflorus, a white-flowered species of similar habit to S. Rexii, and from this cross was produced S. Watsoni. These various hybrids were again intercrossed with each other and with various other species, the ultimate result being the production of a race showing distinct "breaks" and improvements.

The cultivation of Streptocarpi presents no difficulties, and once they become established they grow with great freedom. Although perennials, the best results are obtained when they are treated as annuals or as bi-ennials, for which purpose a fresh stock should be raised annually from seeds sown during February.

Good plants will, by this means, be obtained by the following August, and these will flower continuously through the autumn and winter.

These plants succeed admirably when planted in beds or on rockeries under glass, and thrive in shaded positions where many plants would fail for want of light. Streptocarpi prefer a compost which consists of equal parts of loam and leaf soil, together with one-eighth part of sand. When the plants are a year old they should be allowed 5-inch pots, and these will be found quite large enough for their further requirements. They will commence to flower about the beginning of May, and will furnish a succession of bloom until late in the autumn. During the summer months, when the plants are in flower, soot-water may be given them with advantage. The plants should be partially dried off and allowed a rest of several weeks' duration during the winter.

Streptocarpi are liable to the attack of mealy-bug, which usually appears on the under side of the leaves. The usual methods for eradicating this pest should be employed. *J. Gardner, Aldenham House Gardens, Elstree.*

VEGETABLES.

NEW VARIETIES OF POTATOS.

There must exist among cultivators of Potatos many who are at a great loss in selecting from the novelties enumerated in lists, and shown at exhibitions, those that shall be grown in a particular garden. Varieties differ so much in appearance, flavour and texture, that nothing short of an authoritative list dealing with the behaviour of varieties in different soils and localities, and more especially their ability to resist disease, their form, texture, cropping and cooking capabilities, would be sufficient. I read recently in a trade list a number of testimonials supplied by market-growers, gardeners, nurserymen and others concerning the merits of a certain new variety whose name it is not necessary for me to give. The writers made mention of all its good points as to cropping, power of resisting disease, shape, weight of crop &c., but one only had a word to say about its cooking quality. Potatos being primarily grown for human consumption, of what significance are its various good points if the quality of a tuber when cooked be not good? This and its flavour should be the supreme tests. In this instance the writer describes it as being "good."

Varieties vary greatly according to soil, climate, and the sort of cultivation pursued, and there are so many of them found in trade-lists nowadays as to make an authoritative list a prime necessity. Until such a help to purchasers is forthcoming, buyers should make small tests in their own gardens and fields, and thus ascertain if the varieties selected come up to their expectations in the more essential points. We are much indebted to the raisers of new varieties, but we need to have the results of their labours summarised, and inferior varieties consigned to a "black list." *F. M.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Cypripediums which flower in winter.—Up to within the last few years, mid-winter has always been considered a dull season for the production of Orchid flowers, but, thanks to the skill and perseverance of many enthusiastic hybridists, we are now, at this particular season, able to enjoy an abundance of flowers suitable for almost any decorative requirements. These remarks are applicable chiefly to the cooler or intermediate growing Cypripediums such as were to be seen at the last show of the Royal Horticultural Society. It is impossible to enumerate all the species, or the multitude of hybrids, but among them the following stand out conspicuously:—C. insigne and its varieties Sanderæ, Harefield Hall and Aberdeen, C. Leeanum giganteum and C. L. Clinkaberryanum, C. Euryades, C. Beekmanni, C. Actæus Langleyense, C. Thalia, C. Alcibiades, C. aureum, C. Sallieri Hyeanum, &c. Considering how easy it is to cultivate this section of Cypripediums, and how invaluable the flowers are at the present time, lasting as they do in good condition for weeks together, even when separated from the plants, they should be grown in quantity, and by everyone who is an admirer of beautiful flowers. As regards the lasting qualities of C. insigne, a correspondent in the *Gardeners' Chronicle* in 1842, p. 253, stated:—"On the first of December I placed eight plants in the drawing-room; there they revelled in the greatest luxuriance for three successive months, and, when taken out in March, were as fresh and vigorous as the day they were put in." The best time for repotting, or dividing up large specimens to increase the stock of any particular variety, is at the end of the season of flowering, but unless the compost has become sour or decayed, or a larger pot is needed, annual repotting is not necessary. Strong healthy plants that have become pot-bound may be placed into pots two inches more in diameter than those they are growing in. The pots used should be thoroughly cleansed and well drained, and be secured by a layer of rough sphagnum-moss. A compost consisting of lumps of peat, good fibrous loam, and chopped sphagnum-moss in equal parts, mixed with moderate quantities of broken crocks and coarse silver sand, will grow to perfection any of the above varieties, and others of the same category. In repotting the plants, do not raise them above the rim of the pot, but keep the compost just below it, so as to make the process of watering more easy. Stand the plants in a moist, shady part of the intermediate house, and keep them moderately moist until each plant has become well rooted into the new soil, after which time water must be freely afforded them. It sometimes happens that for want of water, fresh compost or more root room many Cypripediums are seen in poor condition. C. Spicerianum, C. Charlesworthii, C. Arthurianum, and C. Fairrieanum may also be repotted now; the first-named species grows better when raised a little above the rim of the pot, and should be afforded more drainage material and less compost than is advisable for the others.

Temperatures.—The atmospheric temperatures of the various divisions at night during this month should be regulated as follow:—East India house 60° to 65°, Cattleya or intermediate house 55° to 60°, Mexican about 55°, and the cool or Odontoglossum house 45° to 50°. A few degrees lower during exceptionally cold nights is beneficial when the atmosphere is somewhat drier than usual, owing to the unusual amount of fire-heat that is necessary. In the daytime the higher numbers should be maintained by fire-heat, but it matters little how much the atmospheric temperature may rise by reason of sunshine, provided there is sufficient air and moisture to balance the extra heat. Almost all tropical Orchids can be grown more or less well in the various divisions mentioned, but where a large number of some particular class has to be grown it is wise to give them a structure to themselves. Thus in some gardens there will be found, besides those mentioned, separate houses for Phalænopsis, Dendrobiums, Cypripediums, Masdevallias, &c.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

In writing this Calendar for 1906, I intend not merely to indicate the weekly routine work necessary in the Flower Garden, but as far as possible to introduce notes on some of the most interesting and useful plants and shrubs suitable for Flower Garden decoration. At the same time I will offer suggestions in colour combinations and other simple arrangements in beds and flower borders whenever the occasion offers itself. Seasonable advice shall be given from time to time on the many different phases of flower gardening, whether it be the wild garden, the rock garden, the water, or wall garden—mentioning appropriate subjects for each without exactly confining myself to describing definite work relative to these for each week. Being employed in an establishment situated under favourable climatic conditions, I may at times be induced to descant on flowering shrubs and tender climbers that may not everywhere be suitable to outside culture. If so, I shall qualify such remarks, that no one may be led into error and meet with disappointment.

The Formal Garden.—Although at the present moment there is not much actual work in maintenance other than keeping them clean and tidy, the arrangements of the flower beds of the formal garden for next summer's display must necessarily be exercising the minds of every thoughtful gardener. In some instances the beds are now filled with bulbs and other spring flowering plants, so that nothing at present, if desired, could be done in the way of intended alterations; but where there is no spring gardening practised, the beds, if not already prepared for the summer bedding, could with advantage be dug and altered at the present time. For the successful management of the formal garden it is most essential that a record of each year's bedding arrangements be carefully kept to avoid making repetitions, except at long intervals—unless especially desired by those most interested in the garden. It is quite an easy matter, if forethought and consideration are exercised, to alter annually the arrangement of the plants, and sometimes even to alter the disposition and shape of the beds, where the designs are not those of old-established French or Dutch gardens. By this means novelty and freshness are imparted to each year's display, and monotony, which detracts so much from the bedding system, is avoided. If plans for the summer bedding have not yet been determined upon, no time should be lost before this is done, as stocks of Pelargoniums and other plants will soon have to be potted up, and before commencing this work it is convenient to know the exact numbers of the different varieties required for the several purposes, otherwise much labour will be wasted, and confusion the consequent result. Insufficient stock of any variety must be noted, and steps taken at once to remedy the deficiency by propagation. In propagating and preparing plants for bedding, always allow a margin of 10 per cent. for mishaps. In places where, owing to the caprice of the proprietor or other circumstances, the parterre is changed two or three times during a season, enormous surplus quantities of everything must be provided.

Shapes of Beds.—In making new beds and designs, or in altering the shape of old ones, it is advisable to make them as simple as possible. Intricate designs, be they dove-tailed, chain, ribbon, or star-like in formation, may look pretty enough on paper, but when "laid out" always appeal to one as being decidedly "gingerbread" in their conception. They entail more labour in their formation and maintenance than plain rectangular, oval, or oblong beds. Besides these considerations, simple designs lend themselves more easily to tasteful arrangement in planting, which, after all, is the chief consideration. No matter how pretty the actual shape of the design, it is a failure if its construction tends to interfere with effective planting. In planning the different arrangements for the summer bedding, much will depend upon the taste and ingenuity of the gardener, but simplicity of arrangement and the artistic harmonising of colours should certainly be important features. Next week I will cite a few examples which occur to me of some good simple summer bedding arrangements.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

General Arrangements.—With the advent of the New Year a general scheme of arrangements should be drawn up, embodying the work in the kitchen garden for the whole season, and including any alterations likely to be made during that time. A complete plan should also be made so that the work of arranging the various crops may be facilitated and that it will not be necessary at the last moment to plant the crops in a haphazard way.

Seed ordering—This is a matter of considerable difficulty to a beginner, or to a man having charge of a garden for the first time, until he exactly knows the requirements of the place. In ordering seeds beware of glowing advertisements of new varieties, but select those that are well known for their cropping qualities and good flavour, and of these there are plenty to choose from. The novelties of first-class firms are for the most part reliable, and no harm may be done in trying a few of them. A mistake often made is in ordering a small quantity of many varieties in a general way, when a greater quantity of fewer and more reliable sorts sown in succession would give greater satisfaction.

Preparing the ground.—The present winter so far has been very suitable for getting on with the work of digging and trenching, there having been an absence of severe frost. Advantage of this condition should be made full use of as long as it lasts, and the greater surface area that is thus exposed to the influence of the weather the better it will be for the crops.

Cabbages.—This crop promises well, having grown uninterruptedly. Care must now be given to protect the stems from frost by drawing the soil around them, first of all deeply hoeing between the lines to loosen the soil. In the advent of severe frosts a few Spruce boughs put in here and there will give much shelter in exposed gardens.

Broccoli.—As fast as the heads become fit for

use lift the plants and place them in a cold frame where they can be easily protected. A strict watch must be made daily for these heads turning in, for if they are exposed afterwards they may be soon ruined by rain, or by morning frosts.

Brussels Sprouts.—All decaying leaves should be cleared away from the stems, as these would affect the sprouts, and particularly the flavour of them when cooked. Avoid cutting the tops of the plants until all the Sprouts have been gathered.

Onions.—Where Onions of extra large size are required the present is the best time for sowing the seeds. They should be sown in boxes in a fairly rich soil which has been passed through a ½-inch sieve. Place the boxes in an atmospheric temperature of 55°, and if the seeds are in a fresh condition they will germinate in about 10 days. The best variety is Ailsa Craig, which, for practical purposes, is synonymous with Cranston's Excelsior, there being but little difference between them. Neither of the types is fixed, although some advance has been made in that direction.

Leeks.—These may be sown in the manner recommended for Onions, for Leeks require a long season of growth before giving the best results. The remarks as to Onions and Leeks, however, apply only if specimens are required for exhibition or other special purpose. The general crops need not be sown for two or three months yet.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

The Planting of Fruit Trees.—If this work has not been completed and the weather is wet, any trees that are on hand should be heeled in to await suitable weather for planting. But if some dry, friable soil can be mixed with the staple, planting may be proceeded with if desired, though at a disadvantage. When planting any kind of stone fruit, some lime rubble or mortar plaster should be mixed freely with the soil, or, failing this, some fresh lime may be used to advantage. More especially should this be done when only a little lime is already present in the soil. Young trees that are planted merely as supernumaries may have a slate or two put under them, so that the roots will be prevented from striking downwards; they will then suffer the less from check when they have to be moved to other positions. In preparing the ground for Peach and Nectarine trees it is sometimes necessary to drain the soil by artificial means, especially if the subsoil is of an unsuitable nature for promoting drainage. When such is the case, the soil under the positions where the trees are to be planted should be thrown out to a depth of 3 feet 6 inches, afterwards laying bricks in the bottom, placing them on edge. Another 4 or 5 inches deep of smaller drainage material, such as broken bricks, etc., should be placed over the bricks and be covered with some freshly cut turves, putting them grass-side downwards, which will keep the fine soil from getting down into the drainage. Over the turves may be placed the compost in which the trees are to be planted, which should consist mainly of some good fibrous loam that has been stacked for a considerable time. This should be well chopped to pieces and mixed with lime rubble and crushed bones or bone meal, at the rate of 50lb. to six barrowfuls of soil. If sufficient loam cannot be obtained, use one half of loam and the other half soil, in order that the trees may make as good a start as possible. In planting, cut off with a sharp knife all mutilated roots, and any extra thick roots may also be cut away, bearing in mind that it is the fibrous roots which are most valuable.

Orchard Trees.—In many orchards there is overcrowding of the trees, coupled with deficient drainage. Many old orchards could be improved at this season by thinning the trees and draining the soil. A commencement in thinning should be made by cutting away all the wood in a particular tree that is not exposed to the sunshine; next, by cutting away all dead branches; and finally by thinning out the head of the tree. When draining the land, plant young trees in every instance where there is an old, unproductive specimen. Select only good and reliable varieties for this purpose, and plant each variety in a colony together, so that when gathering the fruit, the work may be done quickly. A rough plan should be made giving the positions of each variety.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to F. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

The Cleansing of Plant Houses.—With the advent of the New Year, we as gardeners are reminded that the time has arrived when attention should be given to putting our plant-houses in order, and no time should be lost in doing this. The woodwork of the interior should be well washed with soft soap and hot water, and the glass will need washing inside and outside that it may be made capable of admitting all the light possible to the plants. Remove and wash the sparor gravel from the stages, as it will often be found that worms are secluded therein, and these would establish themselves in the newly potted plants. Every effort should be made that in these and other particulars the plant-houses are thoroughly cleansed before the work of potting the plants is commenced.

The Potting Shed.—Much may be done in getting materials in order to facilitate the work when the time arrives for potting. The sizing of crocks and charcoal, the chopping up of peat, and the drying of cow manure may be done at the present time, and the pot rack should be given attention, and be well stored with clean pots in their various sizes.

Insect Pests.—The present time affords an opportunity to thoroughly clean such plants as Ixias, Codiæums (Crotons), Gardenias, and other hard wooded stove or greenhouse plants which have not been syringed during the winter months. Red spider, thrips, or mealy bug, etc., may thus have established themselves. A very simple, safe and efficacious wash, and one which is constantly used here is prepared as follows:—One wineglass of paraffin and three ounces of soft soap to three gallons of soft water. The soap and paraffin should be blended together to the consistency of cream before applying the warm water. The liquid is applied through a coarse spray syringe. No time should be lost in attending to this matter, as insects increase to an alarming extent when the temperatures rise.

Gloxinias.—A batch of the most mature bulbs should be selected and placed in a moist atmosphere of the temperature of 65° to 70°. When they have started into growth shake them out of the old soil and re-pot them in a mixture of good fibrous loam—peat and leaf mould in equal parts—adding a little dried cow manure and sand. Place the plants well up to the light.

Plants for Early Forcing.—Azaleas, of the mollis section, Spiræas, Deutzias, Lilac, Rhododendron Mdme. Wagner, early Tulips, Narcissus, Freesias, Lily of Valley, etc., will now readily respond to forcing if a temperature of 60° to 65° be employed. The Rhododendron mentioned is an excellent variety for gentle forcing, and the flowers are of a lovely pink colour.

Ventilation.—Careful attention to the ventilation of all plant houses is very necessary, taking every opportunity to change the air in the houses when the condition of the external atmosphere will justify the use of the wall ventilators, at the same time admitting a little at the roof. By this method the air is moved through the whole part of the house. Maintain the atmospheric temperature of the stove at 65° to 70°; intermediate house, 60° to 65°; conservatory, 55° to 60°. These temperatures will not unduly excite the plants at the present time.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

The Renovation of Vine Borders.—It is a very common occurrence to see Vines in an unsatisfactory condition; they bear very little fruit, or what there is is of inferior quality through shanking or some other cause. Such a condition is in most cases due to deficient root-action. The roots have penetrated too far down in the border, and if this important matter has not already been given attention, no further delay should be permitted. If the conditions were allowed to continue season after season, the results would be increasingly unsatisfactory. Autumn is the best season for carrying out this work, while the foliage is still hanging on the Vines, especially if the Vines to be treated are such as fruit early. If the borders are inside and outside, the inside borders may be done at the present time, and those outside next season. Commence by getting all the best roots up near to the surface and relay them in the following compost, which should have been got ready beforehand:—Good fibrous loam, taken from an old pasture if possible, cut in turves 4 inches thick, adding charcoal, ½-inch bones, lime rubble, and some half decayed oak leaves, with about one pound of some approved Vine manure, and the same quantity of basic slag to each barrow load of soil. Work in the prepared compost well among the roots, and beat it down firmly as the work proceeds; the roots should be covered with 6 or 8 inches of soil when the work is completed. Apply a good mulch of strawy horse manure, and an application of tepid water to thoroughly moisten the border. Crop the Vines lightly for a season or two until better results are obtained, and do not subject them to hard forcing. If the borders have been properly made, and there is good drainage, the roots will soon begin to multiply in the new compost. Give daily attention to such matters as the ventilation and heating of the houses, and afford water to the roots as often as is necessary. The only soil obtainable here is of a strong, greasy loam, but it seems to suit Muscat of Alexandria Vines very well.

Cucumbers.—A few seeds should be sown singly in 3-inch pots for the raising of plants to succeed those now affording fruits. Sow the seeds in a compost of loam, leaf soil, and a little wood ashes, which should be warmed to the temperature of the atmosphere in the house. Place the seeds on their edges so as to keep them from rotting, and stand the pots in a bottom heat of 75°, but do not apply water until the seeds have germinated. Lockie's Perfection and the old Rollison's Telegraph are both reliable varieties.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* EDITOR, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Jan. 6	Annual Dinner, Société Française d'Horticulture de Londres, at Café Royal, Regent Street, London. 6.30 p.m. German Gardeners' Society meet.
TUESDAY,	Jan. 9	Royal Horticultural Society's Committees meet.
THURSDAY,	Jan. 11	Royal Horticultural Society's Examination of Public Park Gardeners.
SATURDAY,	Jan. 13	Dutch Gardeners' Society meets at Richmond.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—36·3°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Jan.* 3 (6 P.M.): Max. 51°; Min. 39°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 4 (10 A.M.): Bar., 29·7; Temp., 50°; *Weather*—Slight rain.

PROVINCES.—*Wednesday, Jan.* 3 (6 P.M.): Max. 51° S.E. of England; Min. 41° E. Coast of Scotland.

SALES.

MONDAY AND FRIDAY NEXT—
Herbaceous and Border Plants, 1,500 Roses, Hardy Plants and Bulbs, Azaleas, Fruit Trees, Dutch Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Hardy Border Plants and Bulbs, Liliums of sorts, Herbaceous Plants, Dutch Bulbs, &c., at 12. 3,000 Roses at 3 and 5. Palms and Plants, Azaleas, Rhododendrons, &c., at 5. By Protheroe & Morris, at 67 and 68, Cheapside, E.C.

WEDNESDAY NEXT—
At Stevens' Rooms, King Street, Covent Garden.—Roses, Lilies, Plants, &c.

1906.

In our last issue we passed briefly in review the salient events of the past year. We are absolved from the necessity of posing as prophets for the year now beginning by the publication of the almanac presented to our subscribers with the present number. In it the reader will find announcements of as many of the appointments for the year as we have been able to obtain. We have taken pains to render the list as accurate as possible, but some of the dates are liable to alteration, and other appointments have as yet not been decided on. Omissions and rectifications of this kind will be supplied each month as may be required. So far the year does not promise to be quite so eventful as the last, but appearances are deceitful, and the coming season may after all prove as crowded as the past. As novel features we may mention the proposed conversazione of the Royal Horticultural Society on July 30 and the Plant-Breeding Conference on the following three days. Adverting, for a moment, to matters in which we have special personal concern, we have to tender our most cordial thanks to our contributors and to our readers, and especially are our thanks due to the writers of our weekly Calendar. Our object is to secure that the directions for practical cultivation shall be given by actual practitioners of the highest repute. Last week we gave a series of portraits of those who had so kindly assisted us during the past year. It is from no sense of the inefficiency of our Calendar-writers—quite the contrary—that we make yearly changes, but simply that we may get fresh ideas from different parts of the country and afford others a chance of narrating their experiences. We introduce a new band of Calendar-writers this week in the confidence that they will do the fullest possible justice to their subject, and rival, if they cannot excel, their predecessors.

The mention of the alterations in our own department reminds us of the change at Kew, to which we had occasion to allude in a recent issue. We are enabled this week to present our readers with an illustration (see page 9) showing the staff of the Royal Botanic Garden, Kew, to one and all of whom we and our readers have been, from time to time, so greatly indebted. The photograph (by Mr. Stuart, of Richmond), which we are privileged to be able to reproduce, contains the portraits of Lt.-Col. D. Prain, the present Director, lately head of the Botanical Survey of India, and Superintendent of the Royal Botanic Gardens, Calcutta. Of his qualifications and the well-grounded hopes they engender, we have already spoken. In a similar way we have alluded to the most valuable services rendered to the establishment by Sir William Thiselton-Dyer, who though no longer director, remains for a short period as advisory officer. Mr. W. Botting Hemsley, the keeper of the Herbarium or Library, is one of our oldest and most valued contributors, and a botanist of world-wide reputation. Among his staff are Dr. Otto Stapf, to whom we were indebted for a valuable article on the Pampas Grasses and other plants; Mr. George Massee, the leading vegetable pathologist of the country, to whom our readers have been under constant obligations; Mr. N. E. Brown, whose precision and accuracy of detail are admired by all botanists; Mr. R. A. Rolfe, who has filled the place among Orchidists that Reichenbach once occupied; Mr. Duthie, formerly of Saharunpore, a frequent contributor; besides Mr. C. H. Wright, Mr. S. A. Skan, Mr. T. A. Sprague, and Mr. A. D. Cotton. To one and all of these, as we have said, the readers of this journal are under great obligations, and to them we are personally grateful for long continued courtesy and assistance. The physiological laboratory is under the superintendence of Dr. Dukinfield Scott, the value of whose researches is only equalled by his genial courtesy. Mr. Leonard Boodle acts as his assistant, and is well known in the botanical world. The museums, so long under the management of Mr. J. R. Jackson, are now confided to the care of Mr. J. M. Hillier and his assistant, Mr. Holland.

We come now to the garden staff proper, to whom our obligations are no whit less. Mr. W. Watson is universally known as the successor to Mr. Nicholson, and the assistant curator, Mr. W. J. Bean, has won the suffrages of the gardening community. Mr. Irving, the foreman of the herbaceous department, is highly esteemed by the large and always increasing number of lovers of hardy plants. Mr. Arthur Osborn has charge of the ever attractive "No. 4," and of the flower garden. Mr. Dallimore reigns in the arboretum; Mr. Hackett sees that things are as they should be in the stove-houses, including the Palm stove; Mr. Raffill has charge of the great Temperate house. In addition to these good men and true are others less well known perhaps to the outside public, but equally deserving of our consideration in their several departments. Among these are Messrs. Stocks and Aikman, W. N. Winn, Arthur Garnett, George Dear, and the Sergeant-Constable, Charles G. Norris. All these are depicted in our illustration, and have, in their several ways, amply won the confidence and esteem and the gratitude of the gardening community.

Our older readers will remember that the connection between the staff of the Royal Gardens and this journal, though entirely unofficial, has always been intimate, and the re-organisation of the garden in 1841 (the year in which the *Chronicle* was established), and the appointment as director of Sir William, then Dr., Hooker, were very largely due to the direct influence of the first editor of the *Chronicle*—the ever memorable Dr. Lindley.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Royal Horticultural Society in 1906 will be held on Tuesday, January 9, in the Society's Hall, Vincent Square, Westminster. To prevent misunderstanding it may be mentioned that the committees of 1905 do not vacate office until the date of the annual meeting 1906, and in like manner all Fellows Tickets of 1905 are available until February 13, 1906.

REHMANNIA ANGULATA.—One of Mr. WILSON'S introductions from China to the nurseries of Messrs. JAMES VEITCH & SONS is the subject of a coloured illustration in the number of the *Revue Horticole* for December 16, M. GRIGNAN recommends the plant as furnishing "cut-flowers" for decorative purposes. The plants require to be raised under glass and planted out at the end of May. It will be prudent to give it the shelter of a cot and frame in winter. The plant was figured in a supplement to our issue for May 9, 1903.

FLOWERS IN SEASON.—What between the gardener and the hybridiser we have got to the point when we can include Rhododendrons among flowers at any season. Together with some good trusses of Rhododendron × Nobleanum came, just after Christmas, the following letter from Mr. R. BROOMAN WHITE, of Arddarroch (S.W. Scotland):—"I have a tree here about 4 feet in diameter and about 5 feet 6 inches high. It is one mass of bloom, and was open on Christmas Day, making a beautiful sight for this time of the year. There are four Rhododendrons in bloom just now, but none so full of open bloom as the one from which these trusses are cut. Should the weather continue mild they will in another fortnight be also one mass of bloom—very acceptable at this season of the year."

—Mr. T. SMITH, Daisy Hill Nursery, Newry, sends us flowering sprays of two interesting species of Rhododendron, R. dahuricum and R. parvifolium. Both are perfectly hardy, and they possess small rose-coloured flowers, those of the latter species being somewhat brighter than those of the former. R. dahuricum is a deciduous

(*Photograph by W. S. Stuart, Richmond.*

THE PERMANENT STAFF, ROYAL GARDENS, KEW

Front Row (reading from left to right). George Dear, S. A. Skan, George Massee, Dr. D. H. Scott, W. Botting Hemsley, Lt.-Col. D. Prain (Director), Sir W. T. Thiselton-Dyer, Dr. Otto Stapf, J. F. Duthie, L. C. Burrell, M.D., N. E. Brown.

Centre Row. W. N. Winn, W. J. Bean, R. A. Rolfe, C. H. Wright, J. M. Hillier, J. Allen, W. Watson (Curator), T. A. Sprague, W. Dallimore, W. Irving.

Back Row. J. H. Holland, A. Osborn, John Aikman, L. Boodle, A. Garnett, J. Stocks, A. D. Cotton, C. P. Raffill, W. Hackett, Sergeant-Constable Norris.

species, while R. parvifolium is evergreen, the small leathery, oblong leaves being responsible for the specific name. Although the period of flowering in both cases is very early springtime, it has been somewhat advanced in the case of Mr. SMITH's plants, who describes them in his communication as winter-flowering species.

HORTICULTURAL CLUB.—After the next House dinner of the Club on January 9, Mr C. JORDAN, Superintendent of Hyde Park, will speak about "British and Foreign Parks—a Comparison."

THE LATE MR. BURBIDGE.—It was our sad duty last week to announce the death of Mr. F. W. BURBIDGE, and to offer a portrait of the deceased gentleman, but circumstances then prevented us from referring in detail to the excellent work he has done for horticulture. Mr. BURBIDGE commenced his horticultural career as a student in the Royal Horticultural Society's gardens at Chiswick, which he entered in 1868. On leaving Chiswick, Mr. BURBIDGE removed to the Royal Gardens, Kew. From 1873 to 1877 he was one of the most active of the staff of *The Garden* newspaper, started by Mr. W. ROBINSON. During this period, he wrote several works on gardening subjects, including "Cool Orchids" (1875), "Domestic Floriculture," one of the best of its kind in the English language; "A Monograph of the Genus Narcissus," and "Cultivated Plants" (1877), an excellent text-book for young gardeners. In 1877-1878 he went on an exploring mission to North Borneo on behalf of Messrs. JAS. VEITCH, and during the trip he visited the little-known Sulu Archipelago. This mission resulted in the introduction of several plants new to British gardens, including Cypripedium Lawrenceanum, one of the finest of the genus. Mention may also be made of Burbidgea nitida, a Scitamineous plant previously unknown to science, and upon which Sir J. D. HOOKER founded the genus "in recognition of his eminent services to horticulture" (*Botanical Magazine*, t. 6,403). After his return, Mr. BURBIDGE published a narrative of his mission, entitled "Gardens of the Sun," a work of considerable literary merit, and which doubtless did much to secure for him the honorary degree of M.A., conferred on him by the Dublin University in 1888. In 1879 he was appointed Curator of the Botanical Garden at Trinity College, Dublin, to which was added the Keepership of the College Park in 1894. Mr. BURBIDGE was a Fellow of the Linnean Society, a member of the Royal Irish Academy, a member of the Scientific Committee of the Royal Horticultural Society, a Victorian Medallist of the latter society, a Veitch Memorial Medallist, and an honorary life member of the Scottish Horticultural and Botanical Society.

BRUSSELS BOTANIC GARDEN.—The exchange list of seeds, etc., just issued differs remarkably from most lists of the kind that we receive. In addition to the general catalogue, it contains an enumeration of the plants to be had from each of the botanical stations in Belgium, thus representing the floras of the salt marshes, the sand-hills, the polders, the heaths and bogs, the Beech woods, the limestone rocks of the Ardennes, and so forth. In the same way plants of "ethological" interest are offered. These plants are selected to show the influence of external conditions on structure and the means which plants possess of adapting themselves to various circumstances; thus examples are selected to show their adaptation to mechanical forces, resulting in differences of "habit," erect, prostrate, etc., or in differences of substance, turgidity, deposits of woody matter, folding or rolling of leaves, etc. Other plants are grouped according to the diversities in the processes of nutrition, to the organisation requisite for defence in the struggle for existence; variations in the methods of propagation and of sexual reproduction are also illustrated. In fact, so far as circumstances will allow, the whole life history and manners and customs of plants are illustrated, and seeds or plants useful as affording examples of these phenomena are offered for exchange. The perusal of the catalogue in itself is an intellectual exercise and should open the eyes of young and old gardeners to the significance and purport of the forms and variations they see around them in their everyday work. It is one thing to read of these matters in a text-book or to hear of them in a "popular" lecture; it is quite another thing to see the things themselves collected together so that "he who runs may read."

ECKFORD MEMORIAL CUP.—We are informed by Mr. HORACE J. WRIGHT that the firm of HENRY ECKFORD has placed at the disposal of the National Sweet Pea Society a silver cup, value 50 guineas, in memory of the founder of the firm. It will be offered for 12 bunches of Sweet Peas, distinct, to amateurs (members of the trade excluded), at the Show to be held on July 5th next, and the Society also will give a gold medal to the winner. The trophy must be won three times in succession before becoming the property of any exhibitor.

FIG. 10.—THE "ECKFORD" CHALLENGE CUP.
(See text.)

UNUSUAL COLORATION IN A NARCISSUS.—The small yellow form of Narcissus Tazetta, lately appearing in the street vendors' baskets, shows rather curious variations in the colour of the cup. When fully opened the flowers are ordinarily yellow, with an orange cup, but in some specimens there occur on the same truss with these normal flowers others of which the cups are pale green when first open, and that never exceed pale yellow in tone. It is difficult to account for a variation under circumstances apparently identical.

BRACTS OF THE LIME.—A pretty and curious effect was produced this autumn on some Lime-trees, the leaves of which had fallen while the reddish bracts still remained in their places. An un-botanical lover of nature looking up, and seeing the trees decked with objects that are not leaves, nor flowers, nor galls, may well feel puzzled. Even now the bracts remain attached to the trees, although diminished in number and rendered dull in colour.

ASPARAGUS SPRENGERI. — Mr. STEPHEN CASTLE has sent us specimens of a variety of this Asparagus, which has very narrow, silver-coloured margins to the narrow leaves, and in consequence is unusually attractive.

COLOUR-SENSE IN BEES. — M. GASTON BONNIER, in a paper read before the Paris Academy of Sciences, treated of the habits of bees in connection with the colours of flowers. According to the author, says *Nature*, the contradictory experiments of various observers on the relations between bees and colour are due to a lack of knowledge of the habits of bees There is a division of labour among the honey-fetching bees, the duty of those first issuing from the hive being to seek out honey and not to fetch it. After a certain hour all the bees are engaged in fetching and carrying, and none in hunting for fresh sources of honey, and hence, in selective experiments of this sort, quite different results may be obtained according to the hour of the day fixed for the experiment. The author's own experiments lead to the conclusion that the bees are not influenced by colour in their search for honey.

FORESTRY IN BELGIUM.—A recent number of *Nature* contains an account of the visit paid last August to the Belgian forests by the Royal English Arboricultural Society already alluded to in these columns. One of the most interesting excursions was that made to the geographical arboretum at Tervueren. "Here," says Mr. FISHER, "75 acres of good undulating loamy land, with a crop of small oak and other saplings, which serve as a shelter-wood, are being planted with exotic trees. The whole area is sub-divided into the Old and New Worlds, and each of these smaller sections, representing countries running from north to south. Thus the 'New World, is first sub-divided into the Pacific and Atlantic regions, and the former into Alaska, Rocky Mountains, Pacific Coast region, and Chile. The Atlantic region into Canada and the Alleghany Mountains. The Old World comprises Northern, Central, and Eastern Europe, Siberia, Caucasus, the Himalayas, Japan, and N. China. In each of these regions the characteristic trees, broad-leaved and Conifers, are planted in their natural mixture. It is also intended to plant among them the shrubs and herbaceous plants that naturally grow with the trees, and this has already been done in the case of Japanese species. Mr. BOMMER, the curator of the Botanical Museum at Brussels, is in charge of this arboretum. He has an extensive forest nursery, where he rears the necessary plants. This bold and scientific design is due to the initiative of the King of the Belgians, who has presented the State with the splendid domain of Tervueren, the management of which he still controls."

ARMSTRONG COLLEGE, NEWCASTLE-UPON-TYNE.—The work done in the four Northern Counties in connection with the Forestry branch of Armstrong College consisted of:—(*a*) Lecturing in the college, (*b*) lecturing at outside centres, (*c*) advising and reporting on the management of estate woods, (*d*) measuring and investigating sample plots of woodland Investigation of Woodlands.—The work consisted in selecting ideal samples of ordinary woodlands, measuring the timber upon them, and noting all particulars of soil, elevation, etc., as

set out in a circular issued by the college. Mr. FORBES, the lecturer on Forestry, will, at the request of landowners or their agents within the above counties, visit existing woods or lands which it is proposed to plant, and advise generally on the subject, including suitability of soil, site, selection of trees, treatment of woods, sale of timber, nurseries, fencing, roads, etc., etc., on payment to the college of a fee at the rate of one guinea per day. Lectures to working foresters are arranged to be delivered at selected centres in the four Northern Counties, further particulars of which may be obtained at the college.

THE HONEST PACKAGE.—Under this title the *Fruit, Flower, and Vegetables Trades' Journal* figures a basket intended to supersede the ordinary "Southampton gallon." The proposed basket has a handle across the top, a metal label that cannot be easily detached, and is guaranteed to contain an average weight of 5lb. of strawberries. It is entitled, as we have said, the Honest Package, and it is "made in Belgium!"

OBSERVATION AND MEMORY.—In the American journal *Horticulture* for December 9, 1905, is an illustration showing portraits of the heads of the firm and of several of the staff of Messrs. F. SANDER & SONS. Some of them are well known to us and held in high esteem, but we confess to a feeling of envy at the qualifications of MICHAEL SOMERS, the Azalea boy, who is said to "know 100 varieties by looking at the leaf only." Even a Thrips could not be more observant.

HORTICULTURAL DIRECTORY, 1906.—We have received from the office of the *Journal of Horticulture*, Mitre Court Chambers, Fleet Street, a copy of the *Horticultural Directory and Year Book* for the present year. No words of ours are needed to commend to the notice of our readers a publication which is in its forty-seventh year. It is in constant use in the Editor's work room. More we need not say.

BUD ROT IN COCOA-NUT PALMS.—A mysterious disease is reported to occur in various tropical countries. The interior of the bud rots and is reduced to an offensive mass. As the consequences are very serious, investigations have been made, which tend to show that the mischief is due to the agency of bacteria. The *Agricultural News* (Barbados) recommends drastic measures and the destruction by fire of all affected trees.

SUGAR-CANE EXPERIMENTS.—Sir DANIEL MORRIS reports that in Barbados advance is being steadily made in raising and growing new varieties of canes richer in sugar and more capable of resisting disease. A form known as B 208 is largely cultivated, not only in the West Indies, but in Natal and Queensland, where it is regarded as one of the richest canes under cultivation.

THE PROTECTION OF WOOD AGAINST WHITE ANTS.—All timbers, in tropical districts, with the exception of a few of the more expensive kinds, are subject to the depredations of white ants, whilst so far no treatment for the protection of wood against these pests has been commercially successful. Creosote and other mineral oils have been tried, but they are not lasting, only partially impregnate the wood, and cannot be used for indoor work. Various chemicals have also been employed, but in general these are inefficient or too costly. The method introduced, however, by the Powell Wood Process Syndicate, to which we alluded some time since, appears to overcome these objections. This process consists in first boiling the wood in a saccharine solution, which expels the air. In the subsequent cooling the solution is absorbed by the tissues, with the result that the wood is strengthened and improved in quality. It is afterwards artificially dried, and the ordinary process is then complete, the wood being thoroughly seasoned. In order to render wood proof against the attacks of white ants, it is only necessary to combine with the saccharine solution certain substances obnoxious to these insects, which substances are absorbed by the wood along with the saccharine solution. The extra expense is thus confined to the bare cost of the materials added, which is very small. Samples treated in this manner were sent out to India by the above Syndicate, whose offices are in Temple Bar House, E.C., and satisfactory reports regarding the same have recently been received. The application of this treatment will now permit of the more extended use of wood in tropical countries for all purposes, and may lead in many cases to the substitution of ordinary timber for more expensive hardwoods.

RADIUM.—Dr. GAGER, as quoted in the *Garten Flora*, writes concerning the action of radium upon plants that the effect of the rays is to promote their growth in proportion to the intensity and strength of the radium. The degree of the influence depends upon the thickness of the coats of the seeds, on the distance of the radiating body, and upon the keeping of the seed covered with damp earth. The favourable influences have well-defined limits. Excessive irritation may be occasioned by the rays, and germination may be retarded or entirely prevented. The changes that take place in the cellular tissue are the same as are noticed under any other conditions where there is excess of illumination. Experiments with the material known as the "Radiotellur" afforded similar results, but the contrary occurred with the use of the light-producing element "polonium," which has no recognisable influence. If the air is filled with the "emanation" of radium the growth is retarded or comes entirely to a standstill.

PUBLICATIONS RECEIVED.—*Agricultural Bulletin of the Straits and Federated Malay States.* Edited by H. N. Ridley, September. Contents: Agricultural Exhibition in Penang; Water and its relations to Plant life, by Stanley Arden; Rubber in Sarawak; &c.—*The Agricultural Gazette of New South Wales*, November. Contents: Seeds and Seed-testing, C. F. Musson; Notes on Green Manures, F. B. Guthrie; Fumigation with hydrocyanic gas for ladybird larvæ and other parasites; the Wheat harvest; Forestry Notes for New South Wales, J. H. Maiden; &c.—*Official Catalogue of the Exposition d'Agriculture Coloniale au Jardin Colonial, Nogent-sur-Marne*, made interesting by the introduction of various illustrations.—*Bullettino della Societa Botanica Italiana*, October-November.—*Nuovo Giornale Botanico Italiano*, October.—This issue is dedicated to the memory of the late President of the Societa Botanico Italiano, Federico Delpino, and contains a portrait of him and an appreciative memoir.—*The Animal World*, January, 1906 (New Series).—Imperial Department of Agriculture for the West Indies: Pamphlet 38.—*Cultivation and Curing of Tobacco*; deals with one of the most promising of the Jamaica new industries, for which an important future is predicted.—*Annual Report, Botanical Department, Trinidad.* To March 31, 1905. By J. H. Hart, Superintendent. According to the report of Sir Daniel Morris, the Garden is in a satisfactory condition, and efficient work is being carried on there in assisting the development of the island. The Garden is, throughout, in a high state of cultivation.—*Report on Botanic Station, Grenada*, 1904-1905. The general condition of the Station is satisfactory. In future the Botanic Station will be carried on mainly on agricultural lines, and ornamental plants will not receive as much attention as formerly.—*Nova Scotia: Provincial Government Crop Report*, November, 1905. Returns from every part of the Province indicate a better season for the growth of crops than for several years, but not for Apples. It is noticeable that the returns are largest in all parts where the most modern methods of farming are carried on.—*The Botanical Magazine*, Tokyo, October 20, 1905. Contents: "Are the centrosomes in the antheridial Cells of Marchantia polymorpha imaginary?" and various articles in Japanese.

SEED LISTS RECEIVED.—*List of Seeds collected during the year 1905 in the Garden at La Mortola, Ventimiglia, Italy.* All seeds are offered in exchange: no seeds are for sale. *Liste des Plantes Vivantes offertes en echange* par le Service des Terres froides et du plein air, Année 1905. Applications should be addressed to the Curator, Jardin Botanique de L'Etat, Bruxelles.

KEW NOTES.

CLERODENDRON CAPITATUM, SCHUMACHER.—This handsome species has been flowering in the Palm-house during the past three weeks, and has still a good show of bloom. It is a species that has not been in cultivation at Kew for many years, and possibly not elsewhere in this country, notwithstanding the fact that it was originally introduced in 1846 by Messrs. Lucombe, Pince & Co., of Exeter, from Sierra Leone. The Kew plant was obtained from seeds forwarded to the Royal Gardens by Mr. J. Mahon from British Central Africa in 1901, thus showing that the species is widely distributed. It has very stout, woody, vine-like stems, with numerous short lateral branches, on which the dense capitate inflorescences are borne. The leaves are obovate-oblong, acute at the apex, 6 to 8 inches long, 3 to 4 inches broad. They are somewhat membranous in texture, with soft hairs scattered over the upper surface. The inflorescence is composed of about 30 large flowers; they are white in colour, with a slender, hairy corolla-tube about 3½ inches in length. The stamens are very much exserted, giving the inflorescence a light, graceful appearance.

An excellent figure of C. capitatum is given in the *Botanical Magazine*, tab. 4355. It is closely allied to C. cephalanthum, *Botanical Magazine*, tab. 7823, which was introduced from Zanzibar by Sir J. Kirk in 1886, and is also growing in the palm-house. C. capitatum has the same remarkable character in the persistent petioles, which form a woody, recurved spine, as in the former species. C. cephalanthum has small leaves which are quite glabrous, and coriaceous in texture. The calyx is also light red in colour (green in C. capitatum); the corolla-tube is also quite glabrous, and the filaments of the stamens are of bright pink colour, which characters make the species perfectly distinct. *W. H.*

FORESTRY.

BRITISH AND BELGIAN FORESTRY.

IF Mr. Forbes had felt able to credit me with ordinary intelligence and candour, he would not have suspected me of supporting my argument in favour of the British climate by citing exceptional instances of tree growth. Only one of the examples I gave can be reckoned exceptional, namely, the Pinus insignis [= radiata], which has attained a height of 61 feet in 21 years. I mentioned that tree because it happened to be before my eyes as I wrote. Even that tree is exceptional only because it has outstripped the Corsicans among which it is growing by 20 feet. It is growing in ordinary hazel-loam, about 12 or 14 inches deep, overlying an impenetrable bed of boulder clay, upon a slope facing the western sea, which is only three-quarters of a mile distant, so that its exposed top is open to every gale that sweeps across the Irish Channel. The other examples I cited—Oak, Ash, Larch, etc.—are all on the same exposed seaboard, the only exceptional circumstance in their favour being that I have abandoned the old fashion of planting in strips and clumps, and endeavour to secure the forest soil, indispensable to proper tree growth, by forming continuous masses. We shall do no good in forestry till we have done croaking about the British climate, in the possession of which most Continental foresters envy us. *Herbert Maxwell, Monreith, December 23.*

THE FALL OF ELM BRANCHES.

IN the *Gardeners' Chronicle*, October 30, 1905, "R.I.L." seems to be in doubt as to the cause of the falling of Elm branches. During the 18 years that I lived in Dyrham Park I had abundant proof of the cause. I daresay "R.I.L." does not recollect the branches falling in the winter time, except in violent storms of wind. In Dyr-

ham Great Park, as well as in the "Little Park," there was a great number of large Elm trees, and as these had had plenty of room in their younger days their lower horizontal branches extended a long way from the boles. It was no unusual occurrence for the heavy branches to snap off close to the bole, but this never happened in the winter time, nor in rough, wet weather, but only in dead calm, foggy weather, when the air seemed laden with moisture. In these circumstances the moisture seemed to condense and remain on the leaves until the branch could no longer bear the weight. I never could see any decay or flaw in the timber. All know that violent storms of wind will break off branches and uproot trees, but that is quite a different matter, and I think "R.I.L." will find that it was under the calm, moist conditions of the atmosphere that the damage was done. *D. Buchanan, Mackay, Queensland.*

LEGISLATION, AND THE SPREAD OF PLANT DISEASES CAUSED BY FUNGI.

(Concluded from Vol. xxxvi., page 458.)

Imported Fruit.

The importation of ripe fruit into a country is undeniably a source of danger. Many kinds of foreign fruit examined at Kew have furnished fungus spores which have germinated readily, and which, if they had found their way to the proper host-plant, would undoubtedly have established a disease. One redeeming feature in this case lies in the fact that the bulk of imported fruit is consumed in towns, consequently the spores are not so likely to reach those places where infection would result.

Two of the most injurious and most widely distributed diseases on ripe apples are "Brown rot" (*Monilia fructigena*), and "Apple scab" (*Fusicladium dendriticum*). It is very important to remember, however, that the spores from the ripe fruit are not the sole means of propagating these diseases. Although fruit growers only recognise these as fruit-diseases, as a matter of fact in both instances the disease first attacks the leaves, where its presence can only be detected by an expert. The spores formed on the leaves are washed by rain on to the young fruit, and in course of time the disease shows itself under the form of scab or brown rot.

It is obvious that in these instances scab and brown rot could be conveyed from one country to another quite as readily on living trees as on ripe fruit. Furthermore, trees conveying the disease need not necessarily bear leaves. If a tree has suffered from disease, spores of the fungus are washed by rain down the stem and branches, and remain in cracks in the bark until the following spring, when they germinate and, in many instances, gain access to the leaves, and infection results.

Is Legislation Desirable?

It is mostly in connection with the importation of living plants and fruit that legislation has been called in as a safeguard, but, as will be seen from the above account, as at present carried out, that is, examination at the port of entry, it merely touches the fringe of the subject, and in the proper sense is but a very poor makeshift for securing immunity against the entrance of fungus diseases into a country.

To render legislation more effectual in the case of imported living plants, all such should, immediately on arrival, be submerged for five minutes in a tank containing a fungicide, the nature of which would depend on whether the trees were in a resting condition, or bearing foliage. After this preliminary precaution the plants should be placed in quarantine for at least a year. That is, they should be planted in a certain place under the control of a specialist, whose duty would be to spray the plants *all over*, from time to time, more especially when in a resting condition, as at this period far more drastic measures can be applied with safety. By such means all superficial spores would be killed. On the other hand, if an active disease showed itself the plant should be promptly destroyed. It seems absolutely necessary that all these precautions should be taken before living plants imported into a country should be allowed to be sold and scattered broadcast through the country. If once distributed, the purchaser may not recognise a disease, or, if he does, would not in all probability promptly destroy the tree, but hope for the best, until the disease becomes established and beyond control.

As to whether such methods will be followed, remains to be seen. So far as the importation of ripe fruit, more especially Apples and Pears, into this country is concerned, there is nothing to fear; we are already well provided with all known diseases.

Finally, it is more than doubtful whether diseases are mainly introduced into a new country through the ordinary channels of trade. It is directly opposed to common experience, also to careful investigation, to conclude that diseased plants are sent out by nurserymen.

In these days of rapid transit numerous packages containing seeds which may have fungus spores adhering, or a few Potatos which may possibly contain mycelium of the fungus causing Potato blight, or leaf-curl in their substance, are being constantly sent to friends residing abroad, and by such means diseases are disseminated in a way well outside practical legislation.

In discussing the spread of disease from an infected area to another adjoining area, or, in other words, from one part of a country to another, the subject has to be viewed from a different standpoint to that followed up to the present. New factors of importance have to be considered, as the dispersion of spores by wind, animals, insects, and perhaps most of all through human agency. The constant interchange of seed grown in different districts, etc., favours the dispersion of disease. These all lie outside the sphere of legislation, and, unfortunately, it must be admitted, also often outside the sphere of preventive measures that can be applied by the practical man. It is in this connection that spraying is of real service in checking the spread of a disease, and if used as a preventive rather than as a cure, beneficial results will follow.

Negligent Cultivation.

The only remaining point requiring notice, perhaps the most fruitful of all in disseminating diseases to surrounding areas, is the occurrence of neglected gardens and orchards which in this country are far too abundant. Such places become in time centres of disease from which material for infection spreads in every direction. To suppress this possibility, the outcome of sheer neglect or thoughtlessness, drastic legislative measures are in force in some countries.

The above statements must not be interpreted as a tirade against legislation, but simply to indicate some of its weak points, as the law is at present administered, and at the same time to prevent disappointment on the part of those who are inclined to expect through legislation, however strictly enforced, any marked decrease in the number or intensity of plant-diseases caused by fungi.

Several definitely proved examples of modes of disseminating disease have been indicated which are obviously outside any possible legislative code that could be formulated. These, however, by no means exhaust the list of cases. The transportation of straw and forage is a wholesale means of diffusing diseases of cereals and grasses, as the spores of many of these fungi suffer no injury even in passing through the alimentary tract of an animal. Again, no law would insist on a man collecting and burning all diseased Potatos or Turnips met with in a field, even if in a condition to be collected. *George Massee.*

LEAVES FROM MY CHINESE NOTE-BOOK.

WA-SHAN TO FULIN.

(Continued from Vol. xxxvi., page 459.)

July 6th.—I left Yin-Kou at 5.45 a.m., having enjoyed a good night's sleep in spite of my filthy surroundings. We crossed a cultivated flat and passed the village of Yin-Shui-Ping. This hamlet bore strong evidence of a recent large fire. Carpenters were busy, and one new house, nearly completed, looked as if it would afford good accommodation later on. Soon after passing the above village we descended by a good road to a broad torrent. Following this road for a mile or so we eventually crossed the torrent by a rotten wooden bridge at an altitude of 6,100 feet. The cliffs of this torrent are of limestone and often a thousand feet sheer. In places they were clothed with vegetation; a species of Corylopsis being a common shrub here, and our old friend Rodgersia was still abundant.

Near the bridge was a house, and behind this house some trees of Sambucus racemosa nearly 30 feet high, and covered with panicles of red fruits. Leaving this bridge, we followed a path, on the right bank of the torrent, for a couple of miles, ascending and descending in a most exasperating manner. Eventually we left the torrent, skirted the mountain side and crossed over at 6,300 feet. Between the bridge and the pass Lilium concolor was not uncommon. I also collected a curious Primrose having a very tiny flower peeping out from an enormous calyx (P. pycnoloba). Crossing an undulating plateau we reached the village of Huang-mao-ch'ang, altitude 6,300 feet, at 10 a.m. and lunched there. It was at this village that Baber was regaled with a kind of tea having the natural flavour of milk, or, perhaps, more exactly that of butter. I did not have the same good fortune, and, therefore, can throw no light on the source of this curious tea.

The village of Huang-mao-ch'ang is a filthy place; its only street an open sewer. Its inhabitants are in harmony with the place. They crowded around me as I lunched, and their stench was almost too much for endurance, hungry though I was.

The road afterwards was fairly flat, though we had to make many sharp ascents and descents to cross the beds of torrents, most of them dry. This plateau, or series of plateaux, is highly cultivated: Wheat, Barley, Maize, Irish Potatos, Peas, Glycine hispida, Nicotiana rustica, Cannabis sativa, and two kinds of Buckwheat are the chief crops. One kind of Buckwheat grows 2½ feet high, and has greenish inconspicuous flowers. The other kind has bright pink flowers, and grows only a foot or a foot and a half in height; next to a field of Opium, I know

no prettier sight than a field of this pink Buckwheat. Walnut trees are very abundant, all cultivated. The houses are nearly all surrounded by stone walls, on the top of which Rosa moschata makes an impenetrable hedge. It was then in full flower, and its myriad blossoms scented the air. Our coolies bought excellent peaches here at the rate of 500 a shilling! The cuckoo was singing gaily, and altogether the tramp across this "flat" was very pleasant.

After a time our road led under the lee of some high cliffs, and in the far distance on our left some very high mountains were prominent. So cold was the wind that I thought it must be blowing across some snow-clad peaks, but the people say it is not so.

Leaving the plateau, we ascended by a good road and crossed over at 7,200 feet. Descending rapidly by a steep path, we crossed a stream, and another steep ascent brought us to Tsai-erh-di, our resting place for the night. In the descent I noted several small bushes of the Davidia. All the trees have been felled, and the hill-sides are covered with a dense scrub. This wanton destruction of the forests is much to be deplored, and makes a botanist feel aggrieved.

Tsai-erh-di is a tiny hamlet of half-a-dozen huts, altitude 7,100 feet.

This day's journey was tame after the one previous; nevertheless, I gathered several fresh plants; the most remarkable being a new species of Buddleia (B. nivea) with stems and foliage covered with a dense white tomentum. The people en route, though filthily dirty, looked both healthy and happy: this applies particularly to the women and children. The comparative absence of goitre is very surprising; ophthalmia is, however, terribly prevalent. The day was fine, with much mist. It was very cold hereabouts, and the people were all clad in their padded clothing.

The following were the noteworthy plants met with en route to-day:—Tetrastigma sinensis, Boenninghausenia albiflora, Lysimachia clethroides, Epimedium sagittatum, Lindera glauca, Populus lasiocarpa, Epilobium augustifolium, Rosa sericea, Olea fragrans var., Jasminum sp., Picea sp., and Actinidia sp. I also gathered seven fresh ferns. Astilbe Davidii and Ilex Pernyi were not uncommon in places. *E. H. Wilson.*

(To be continued.)

TREES AND SHRUBS.

IDESIA POLYCARPA.

This interesting tree is this year bearing a more plentiful crop of fruit than I have seen before at Kew, and as the species is now spreading in cultivation, an illustration of a fruiting branch (see Fig. 11) may be of interest. It is not generally known, I believe, that the species is dioecious—that is, its male and female flowers are borne on separate trees. Representatives of both sexes must, therefore, be planted before fruit can be obtained.

It is a Japanese tree, said to grow 40 to 50 feet high, and was first brought into notice by Richard Oldham, the Kew collector, who gathered specimens of it in Japan in 1862-3. Maximowicz found the species again in 1866 and gave it the name it now bears. The tree must have been introduced to Europe then or soon after, for it was growing in the collection of the late M. Lavallée at Segrez in 1869. In general appearance the tree is like a Catalpa, but the leaves, whilst not so large, are thicker and firmer in their texture. It may rank as one of our fine-foliaged, hardy trees, for I have this year measured leaves 10 inches long and 7½ inches broad. The outline is heart-shaped, with an oblique base, and the margin is coarsely serrate. Both surfaces are quite glabrous. The branches grow out mainly in a horizontal direction from the trunk.

The species is figured in the *Botanical Magazine* (t. 6794), but although male and female flowers are differentiated, it is not stated that they are borne on different trees. This is the case, however, at Kew; of the two trees grown in the collection one only ever bears berries, and only pollen-bearing flowers appear on the other. It is not as a flowering tree, however, that the species has any merit, for the flowers, which have no corolla, are small and of dull yellow colour. The fruits, however, are rather ornamental, being of brownish red colour and hanging in abundant grape-like clusters. Each berry is only about the size of a large Pea.

The genus Idesia is at present monotypic, but Mr. E. H. Wilson has recently introduced for Messrs. Veitch from China a nearly allied and somewhat similar tree. This is the Poliothyrsis sinensis of Oliver. It differs from Idesia in having capsular instead of baccate fruit. Both belong to the natural order Bixaceæ. *W. J. Bean, Kew.*

Fig. 11.—Fruiting spray of Idesia polycarpa from Royal Gardens, Kew.

HARDY FLOWERS.

FREE FLOWERING OF IRIS STYLOSA.

Iris unguicularis, more generally known as I. stylosa, is apparently, according to the notes of various correspondents, unsatisfactory in the colder portions of the kingdom, where it is said to require a position at the base of a warm wall. In the south-west, however, it flowers profusely through the entire winter and in the open as freely as with wall protection. Two plants that have been under my notice for the past few years have done remarkably well. They are growing in pockets on each side and at the top of a flight of steps. The size of the pockets is 24 inches by 17 inches, and these are now completely filled. Last season they produced 631 blooms—viz., 47 in November, 222 in December, 206 in January, 135 in February, 18 in March, and three in April. The largest daily gathering was on December 31, when 54 blossoms were cut. This Iris increases with remarkable rapidity. About ten years ago I gave six small roots to a nursery firm, and the produce of these has completely filled a steeply sloping bed about 15 yards long and three yards across. Some hundred or so plants have been sold, and this year it has been found necessary to lift and replant in more spacious quarters. Curiously enough, after such a hot summer and dry autumn the plants are, this year, a full month late in blooming. They often commence to flower in the last week of October, and almost invariably early in November, but this season hardly any of the plants known to me bloomed before December. When growing, they cannot be said to be highly decorative, as the long, arching leaves somewhat hide the flowers, but for indoor decoration, the flowers when picked in the bud state, are unrivalled. There are many named varieties, of which one of the best is speciosa, with purple flowers. Others are the white (of which there are two forms) atroviolacea, pavonia, superba, purpurea, magnifica, marginata, lilacina, and Kaiserin Elizabeth. In a large collection many shades are to be seen in the flowers, but it is doubtful if any exceed the beauty of the lavender type. All varieties are deliciously fragrant, a fact which adds greatly to their value. *S. W. Fitzherbert, S. Devon.*

FRUIT REGISTER.

PEAR TRIOMPHE DE TOURNAI.

A pear ripening in January. The fruit is of moderate size, oblique, unsymmetrical, about 4 inches long by 3 inches in width, with a short stalk, skin yellow, flesh juicy sugary, "good or very good." A coloured figure is given in the *Revue Horticole* for November 1.

PEAR COMTE LELIEUR.

A variety raised by M. Ernest Baltet, of Troyes. The tree is pyramidal, very hardy and prolific; the flowers are double, so that when in blossom the tree is very ornamental. The fruit is of medium size, regularly pyriform with a moderately long stalk. The skin is olive-yellow, speckled with small brownish spots, and sometimes flushed with crimson on the side exposed to the sun. Flesh melting, delicate, juicy, and of first-rate quality. Season, from the middle of September to the end of October, or even November. This Pear is described and figured in the November number of the *Bulletins d'Arboriculture*, etc., where it is highly spoken of both by M. Burvenich and M. Charles Baltet.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

"CARNATION."—In tracing the name "Carnation," as applied to the flower, Mr. Henslow has overlooked an earlier instance than those given by him, though it is quoted in the new English Dictionary. Turner, in 1548, says, "Vernacula lingua vocamus a Gelofer aut a Clowgelofer aut an Incarnacyon." *H. E., Bitton.*

THE NATIONAL POTATO SOCIETY'S EXHIBITION.—Having received a somewhat strong protest from a Potato exhibitor with regard to the announcement recently made that the Society's exhibition of 1906 will be held on December 13 next, certainly a very late date, and presumably following the Smithfield Cattle Show, I wish it to be known that I have been compelled to resign, from lack of time and ability to attend meetings of the Society, and preferring to give place to some one younger, and having more leisure. The mention of that fact will, I trust, prevent other protests being made to me. They should go to the secretary. In the interests of the Potato, I feel the deferring of the show to so late a date as the middle of December is injurious. The shows of the old International Committee were always held at the end of September, or early in October, but the committee controlling those shows gave first place invariably to the amateur or gardener competitor, and those who remember those exhibitions remember also that quite an army of such competitors had grown up under the auspices of the Society. I could wish that the National Potato Society would arrange for an early autumn show in the south, and a later one for the trade, and northern growers, in the Midlands or Edinburgh, in November or thereabouts. The Potato trade, in order to recoup itself for costly exhibitions, had to depend on the business done at shows, and to secure such business the best possible course is to encourage the creation of myriads of private Potato growers and competitors, as these become ultimately the backbone of business. As the decision to hold the next exhibition was presumably made at the annual meeting held in December at the Agricultural Hall, no doubt the members present thought the late date best. I hope I offend no one in differing from them for the reasons stated. *A. Dean.*

ROYAL BOTANIC GARDENS.—At the Royal Botanic Gardens, Regent's Park, there is a house containing an interesting collection of economic and medicinal plants. Of late years a great improvement has been effected in the arrangement and upkeep of the plants, and the result has been to make this range of houses more valuable to botanical students. It is a three-quarter span house and has a south aspect, and of the three divisions which it comprises the central is heated to suit plants from a tropical climate, the two outside ones having the more moderate temperature of our English climate. A system of labelling has recently been introduced by which the genus, the species, the home, the common name, the Natural Order of each plant may be rendered familiar to the visitor. The plants themselves offer various attractions, some have a Biblical, some a commercial, some a medicinal interest. Among the "Biblical" specimens we may mention here are St. John's bread (Ceratonia siliqua). St. John's bread, or, to give it its other name, the Locust bean. This is supposed to have sustained St. John the Baptist's bodily needs in his desert career, and it has the additional interest, apart from its Scriptural one, that the single seed in the pod represented (so we may believe) a weight in use by jewellers. The Sacred Fig tree (Ficus religiosa) is more interesting in the acuminate shape and the leathery texture of its leaves (unique features to be noticed) than from any Scriptural association. The commercial plants are more numerous; those to be noticed especially are:—Monstera deliciosa, Logwood (Hæmatoxylon campechianum), Loquat (Eriobotrya japonica), Mango (Mangifera indica), Mangosteen (Garcinia mangostana), New Zealand Flax (Phormium tenax), Sugar cane (Saccharum officinarum), Japanese pepper (Piper futokadsura), Nopal (Opuntia cochinellifera), Sarsaparilla (Smilax Sarsaparilla), Sandbox-tree (Hura crepitans), Sweet orange (Citrus aurantium), Ginger (Zingiber officinale), Chian turpentine (Pistacia terebinthus), and Olive tree (Olea europæa). The Monstera is an epiphytal climber, a gigantic Aroid, the leaves are cordate and perforated with large holes; the aerial stems develop long, somewhat woody roots which branch considerably on reaching moisture. The fruit when ripe is not unlike the Pineapple in taste. A fine healthy specimen is now in fruit. The Logwood is a native of parts of Central Africa and America. The wood yields a blood-coloured stain used extensively for dyeing and for staining microscopic sections. The Loquat is cultivated in Japan and China for its fruit; this has the flavour of an apple. The many specimens here fruit nearly every year. The leaves of Phormium tenax possess extremely tough fibres, which are most valuable in the manufacture of ropes and mats. The fibres are extensively used by the natives of New Zealand. The Nopal plant is interesting in that it forms the home of the cochineal insect. The commercial cochineal is the dried female. The Ginger of commerce is the fleshy rhizome of Zingiber officinale. The best kinds are imported into this country from Jamaica. Pistacia terebinthus yields a well-known gum resin, it is a native of North Africa. Lastly we come to the plants from which are derived some of our most valuable medicines. Under this category come the Blue gum (Eucalyptus Globulus), Quinine plant (Cinchona officinalis), Castor oil (Ricinus communis), Papaw tree (Carica papaya), Barbadoes aloes (Aloe vulgaris), Gamboge (Garcinia pictorum), Cassia bark (Cinnamomum cassia). Quinine is obtained from the bark of Cinchona officinalis. Castor oil is expressed from the seeds of Ricinus communis. Our supply is derived principally from India. The fruits of this plant, which can now be seen, are not unlike those of Datura in appearance, being covered with little spines. The purgative drug known as bitter aloes is squeezed from the thick leaves of Aloe vulgaris. An oil known as Gamboge butter is obtained from the fruit of Garcinia pictorum. *G. W. D.*

CALANTHE VEITCHII SPORT.—At a recent meeting of the members of the Egham and District Gardeners' Mutual Improvement Association, a plant of C. Veitchii was exhibited that in a very important particular had diverged from the normal habit of this plant. The specimen grew from just one pseudo bulb, that had, early in spring, been put into a 5-inch pot. This had made two growths, which had developed into pseudo bulbs of large size, each one carrying a flower spike of about 3 feet in length. The peculiarity of this, however, was that while one spike bore flowers of the usual rosy-pink colour, the other spike had flowers of a very pale-flesh colour. The contrast between the two spikes was great, and the novelty was much admired by the large company present. I can only imagine the pale form to be a sport from the normal type, not at all, I suppose, an unlikely matter, yet I confess that after considerable experience of this class of plants, I cannot call to mind any occasion when such a marked departure from the original was observable. Doubtless C. vestita rosea and C. limatodes have been fertilised in many establishments, and the result has been that considerable variation has resulted in depth of colour in the flowers of the seedlings raised. It may be that the nature of the parent has occasionally asserted itself more strongly at one time than another. The plant in question was exhibited by Mr. W. Wilkins, Park House Gardens, Englefield Green, who kindly placed the flowers at my disposal, which I am now forwarding you. *W. Swan, Thorncote Gardens, Staines.*

[The failure of the flowers on one spike to develop the richer colouring possessed by those on the other spike may be due to one of many possible causes. In order to determine if it is a sport, let the pseudo bulb be marked, and cultivated another season.—ED.]

MASDEVALLIAS AT WOODHATCH LODGE.—On December 21, upon entering one of the Orchid houses at Woodhatch, Reigate, the residence of Mrs. Haywood, I was astonished and delighted to see a number of well-grown and splendidly-flowered plants of the well-known Masdevallia tovarensis. Altogether there were 19 plants arranged in one row through the entire length of the house, which is about 25 feet long. Each plant was a picture in itself, being literally covered with flowers; one specimen produced as many as 90 spikes, and each spike was carrying two or three white spicy-scented flowers, the aggregate number of spikes being 1,700, carrying in all over 4,000 flowers. Being a compact growing subject, throwing its flowers well above the dark-green foliage, M. tovarensis is indeed an extremely charming Orchid, and a valuable plant for decorative purposes, especially when seen in such luxuriant health as are these plants under Mr. Salter's skilful management. The plants are grown in moderately shallow pans, about 8 or 9 inches in diameter. Good drainage being essential, the pans are about half filled with broken potsherds; over these a layer of moss is placed, and in potting the plants are placed so that the surface of the compost is about level with the rim of the pan. The rooting medium is compost of fibrous peat and live sphagnum-moss in equal parts, and a very small quantity of leaf soil mixed with it. Plenty of living heads of sphagnum-moss are put on the surface, and by the time the plants are in full growth, the whole of the compost is covered with living moss. After the disturbance caused by re-potting, the plants are very carefully watered, but when they commence to make roots and new leaves, water is again supplied liberally and continued through the growing season. This Masdevallia should be grown in the cool house from April until October, and requires an abundance of air and shade. From October till April the plants thrive best in an intermediate temperature. On the day of my visit to Woodhatch, the temperature of the house was 57 degrees at 4 p.m. *W. H. W.*

HARDY PLANTS IN FLOWER IN NORTH WALES.—As proof of the mildness of the season I was able to note on Christmas Day in blossom out-of-doors in the garden here the following 40 plants:—Christmas Rose, Hardy Chrysanthemum, Carnation, Double and common Daisy, Wallflower, Polyanthus, Primrose (red, yellow and blue), Candytuft, Arabis, Snapdragon, Hepatica, Winter Aconite, Colchicum, Violets, Pansy, Lophospermum, Stocks, Aubrietia, Forget-me-not, Periwinkle, Erica carnea, E. Allporti, E. vagans, Menziesia polifolia, Jasminum nudiflorum, Teucrium fruticans, Hamamelis japonica, Laurustinus, Berberis Mahonia, Garrya, Gorse, Andromeda floribunda, Rose, Hazel, Polygala buxifolia, Escallonia Philippiana, Pernettya, Arbutus Unedo and A. Andrachne. Wild Campion and a wild flower, which, I think, is a wild Geranium. In some cases, of course, there was only one isolated flower, but some of the varieties made quite a show of bloom. Clematis Mrs. Hope has a faded flower which was in bloom a week ago. Magnolia grandiflora has a dozen big white buds, two with the outer petals unfolding, Daphne Mezereum, red and white, is out at the date of writing. No doubt others could add to this list Snowdrop, Cyclamen Coum, Iris stylosa, and Cratægus præcox. *H. D. McLaren, Bodnant Hall, Tal-y-Cafn R.S.O., North Wales.*

PROTECTING FIG TREES.—*Ficus Carica* has attempted to analyse my statements in such a manner as to uphold and substantiate his contention that the old method of thatching or protecting Fig trees is now no longer necessary. The severe winters experienced many years ago were, it is true, even more disastrous to the Fig than in recent times when the seasons have been less extreme. *Ficus Carica's* experience 700 miles north of London takes him to a district where I believe the air and climate, although severe, is light and dry, consequently the Fig is better able to stand unprotected than it is in some of the cold and wet counties of England. My practice is no rule of thumb, I have tried non-protection, and witnessed disastrous results in this vicinity. The trees here are still growing in cold, retentive soil, and although excavations be made, drainage, and a calcareous compost provided, it will not prevent the naturally moisture-laden soil from percolating into the prepared compost, rendering it cold and unsuitable. *Ficus Carica* now says (p. 457) with reference to my remark that in "some severe winters the points of unripened shoots were killed down a few inches," "I should have said when severe winters followed wet autumns." If he follows his own advice (p. 457) and has excavated holes, provided good drainage, and formed a suitable compost, he cannot now say the tips of the shoots were killed from the effects of a wet autumn; if so, of what benefit is his artificial drainage

provided to carry off the superfluous water? Should he join the ranks of the protectionists again he will lose no shoots, but with good culture and properly ripened shoots he may obtain some of the finest fruits possible. *W. H. Clarke, Aston Rowant, Oxon.*

[Sufficient has now been said on this subject. A gardener may easily prove which advice is the best to be followed in his particular district by adopting the method recommended in the Calender by Mr. Clarke, but leaving one tree unprotected. The value or otherwise, however, of protection can only be determined in a severe winter.—ED.]

IRIS CRETENSIS.—This little Iris is seldom met with in cultivation, and I have never as yet come across its name in any nurseryman's catalogue. It is a pretty flower, somewhat after the style of I. unguicularis or stylosa, to which species it is said to be allied. In comparing the flowers of the two, those of I. unguicularis are found to be considerably larger and handsomer. In I. unguicularis the falls are 3½ inches in length and 1½ inches in breadth, while the standards are 1½ inches in breadth. In I. cretensis the falls are 2½ inches in length and three-quarters of an inch in breadth, while the standards are only half-an-inch in breadth. In I. unguicularis the yellow band, which is margined with purple veining on a white ground, reaches half-way down the fall, the lower half being self-coloured lavender or purple, according to the variety, while in I. cretensis the band and veining occupies the whole of the fall except the lower half-inch, which is self-coloured. With this exception, the colouring is the same in the two species, but with the larger amount of lavender or purple in the fall the blossoms of I. unguicularis are more striking. Still, one would not care to be without I. cretensis at this season of the year. The leaves of I. cretensis are about 20 inches in length and only a sixth of an inch in breadth. It is a native of Crete, Greece, and Asia Minor, whereas the home of I. unguicularis is on the North African shores. Both require similar treatment, doing best in a light soil in a sunny position, and both flower profusely in the south-west. *S. W. Fitzherbert.*

BOYCOTTING JUDGES.—With regard to the remarks of *A Judge*, p. 444, most of us are aware of the difficulty judges encounter in endeavouring to please everyone, but surely qualified men who execute their duties in a conscientious and straight-forward manner should have little fear of open criticism from exhibitors. I think Horticultural Judges are very indiscreet persons and much to blame for the position in which they often find themselves when they engage so freely in public discussion with unsuccessful exhibitors. This can only create annoyance to those interested, and a very bad impression upon those that are not. Should a question arise and an exhibitor feels that he would like the personal opinion of the judges for his future guidance, let it be obtained in privacy; then those concerned will get the knowledge they require to the satisfaction of themselves and their adjudicators. *H. Harris, Wenvoe.*

FROST-RESISTANT APPLE BLOSSOM.—Mr. W. H. Divers' note upon the hardiness of Lord Suffield Apple flowers (p. 457, *Gardeners' Chronicle*, December 30th, 1905), introduces a subject of much interest and importance. I have had the opportunity of studying the behaviour of about 200 varieties of Apples in the respect named, and several of these stand out prominently for their powers of resisting frost when in flower. For some time I was very doubtful on the matter, but repeated observations have proved that the structural or constitutional differences are very marked. Stirling Castle and Lord Grosvenor have, with me, been most conspicuous for resisting sharp frosts, for the fully expanded flowers have been frozen so that all the parts could be broken short like thin ice, and yet a crop of fruit has followed. Other varieties under the same conditions have lost the whole of their blossoms. Lord Suffield I have not observed to endure frost like the two varieties named; in fact large plantations of healthy trees of that variety have been cut back and grafted with other Apples because the flowers so frequently failed from frost and other causes. Plenty of evidence is available, however, to show that Lord Suffield and a few other Apples are very quickly affected by deficient soil fertility, and some of the failures recorded are certainly due to that cause. *R. L. Castle.*

THE LONDON MARKETS AND THEIR SUPPLIES.

(Continued from Vol. xxxvi., page 451.)

In 1887 a Royal Commission on Market Rights and Tolls was appointed, the special objects of which were to enquire as to the extent to which market rights are in the hands of (1) local authorities; (2) trading companies; and (3) private persons, or bodies of persons. But the enquiry was also to include an examination of the revenues, distinguishing the tolls, rents, stallages, the accommodation given, and the ratio of market tolls and dues to the value of the commodities. Several interesting and important reports have been issued, but as regards questions of value and quantities much of the earlier information given is now out of date. An annual Market Report dealing with the relative quantities and proportions of home-grown and imported garden produce would be of much value, even if it was confined to a selection of the principal markets, just as are the weekly reports of prices. In all markets some form of record must be kept, but in most cases this does not distinguish the class or kind of produce, nor is the source of supply indicated. In some cases where a toll is charged at a fixed rate per basket or bag, even the total weight cannot be obtained. The essential details would not be very numerous, the work entailed in setting them out would be comparatively slight, and in a matter which affects the public interest, there ought to be little difficulty in securing the information desired.

When we turn to home-grown crops, with which the market gardener and fruit-grower are concerned, similar obstacles are encountered. For the purpose of the Agricultural Returns I am officially informed that no separate record is made of the acreage under market-gardens, and to my knowledge considerable areas are returned as farm land which are employed mainly or exclusively for vegetables and fruits grown entirely for market. Some attempt is, however, made in the Income Tax returns to distinguish such land, though not with much success, judging by the evidence of Mr. Bell, one of the superintending Inspectors at Somerset House. Under Schedule B there is a special rule for the assessment of market gardens and nurseries by which the tenant pays on the estimated profits instead of on one-third the annual value. It is stated that no certain definition exists to clearly distinguish "a market garden" or "nursery," and the rule is said to only apply to "4,749 acres of fruit-land, pure and simple, in England and Wales, and to 27,413 acres of market gardens in which vegetables, flowers, &c., as well as fruit, are grown for sale." It is obvious that the latter acreage can in no sense represent the area of the land under market garden crops in this country, especially as regards vegetables and flowers. Taking the metropolitan counties of Essex, Kent, Middlesex and Surrey alone, the area returned as under small fruit, i.e., 30,000 acres, is largely market-garden land as well. Adding the land under vegetables and flowers to the fruit lands the total cannot be much less than 100,000 acres, and it may be more, for that represents a small proportion of the area (under crops and grass) in the four counties named, viz. 1,900,000 acres.

The estimates of produce in British official records are confined to the farm crops, Wheat, Barley, Oats, Beans, Peas, Potatos, Turnips, Swedes, Mangolds, Hay, and Hops, but a portion of the acreage returned under Peas, Potatos, and Cabbages is unquestionably used for market garden purposes. In some of the foreign and colonial Agricultural Returns attempts are made not only to separate market garden and fruit or other special crops, but also to give estimates of the amount produced or their value. Thus in Bulgaria the area under Plum trees is given as 8,472 acres with an estimated produce (1898-9) of 280,984 cwts. Other fruit trees are returned as occupying 2,845 acres, and the produce is 76,675 cwts., while Rose gardens are stated to occupy 12,582 acres, yielding 133,311 cwts. of flowers. In Roumania Plums are said to have 174,619 acres, producing (1904) 5,611,742 cwts.; Onions on 10,416 acres, yielding 21,492 tons, Servia has 250,806 acres of Plums, the estimated produce (1900) being 7,268,352 cwts. Amongst the Colonies, New South Wales returns for 1903-4 the area of fruit and orchards as 27,576 acres, the estimated value of the produce being £211,318; while market and kitchen gardens are given as occupying 8,756 acres, with a produce value of £213,412. Again in Tasmania the Apple orchards are said to cover 9,819 acres, with a total produce of 977,362 bushels; and in Natal the orchards are given as 3,458 acres, the produce being valued at £53,120.

There are difficulties in the way of carrying out such a system in any country, and these would be especially marked in the United Kingdom, where the methods and results are so diversified. But even approximate estimates would be useful, and these might be obtained in many cases with little more difficulty than applies to the ordinary farm crops.

Where special districts are devoted to certain crops the railway companies would be able to furnish statistics regarding the quantities forwarded in particular directions. But the officials in the majority of cases decline to furnish any details that would be of service in forming a reliable judgment in the matter. We must therefore see what can be learned in the markets themselves. *R. Lewis Castle.*

(To be continued.)

Obituary.

JOHN DILLWYN SIMS.—We regret to record the death of Mr. John Dillwyn Sims, of the firm of Messrs. Ransomes, Sims and Jefferies, Ltd., Orwell Works, Ipswich, who died at his residence, on December 30, and was interred at the Ipswich Cemetery on January 2.

TRADE NOTICES.

The British West Indian Fruit Co., Ltd., have acquired the fruit-importing business of Messrs. W. Pink & Sons, and will conduct their affairs on the same lines as heretofore.

R. PAGE & CO.

The partnership hitherto existing between R. Page and J. J. Allen, Tangley Park Nursery, Hampton, Middlesex, has been dissolved, and the business will in future be carried on by J. J. Allen, at the same address as above in his own name.

ST. ALBANS XL-ALL SEED COMPANY, LIMITED.

This company has been registered with a capital of £2,000 in £1 shares. Object, to carry on the business of nurserymen, seed growers and merchants, &c. No initial public issue. Registered without articles of association. The first directors are W. J Hart, Jeannie S. Anderson, Mrs. J. Anderson, Margaret G. Anderson, J. Wright, T. F. Hale and T. Hale. Registered Office—591, High Road, Leytonstone.

THOMSON AND COMPANY, LIMITED.

This company has been registered with a capital of £3,000 in £1 shares. Object, to acquire as from June 30, 1905, and carry on the business of seedsmen, nurserymen, florists, landscape gardeners, corn merchants, horticultural implement and sundries dealers, &c., carried on by R. Thomson & S. S. Thomson, at 20, High Street, and Central Avenue, Market Hall, Birmingham, and at the nurseries, Sparkhill and Shirley, as Thomson & Co., to adopt an agreement with R. Thomson & S. S. Thomson. No initial public issue. The first directors (to number not fewer than two nor more than five) are R. Thomson and S. S. Thomson. Qualification, £500. Registered Office—20, High Street Birmingham.

GARDENERS' DEBATING SOCIETIES.

CHESTER PAXTON.—The annual general meeting of this Society was held in the Grosvenor Museum, Mr. N. F. Barnes, Eaton Gardens, presiding. The annual report of the Hon. Secretary, Mr. G. P. Miln, revealed the fact that the list of members and subscribers had increased during the year from 530 to 560. The finances of the Society showed a credit balance at the bank of nearly £80. On account of the President, Major MacGillycuddy, leaving Chester, Mr. T. Gibbons Frost was elected President for the ensuing year, Mr. N. F. Barnes being re-elected Chairman of Committee, with Mr. G. P. Miln as Hon. Secretary, and Mr. Robt. Newstead, A.L.S., as Consulting Naturalist.

EGHAM AND DISTRICT GARDENERS'.—At the last fortnightly meeting of this society, Mr. W. Swan in the chair, Mr. G. Baskett, of Woodlea, Virginia Water, read a paper on "Orchard House Fruits." The essayist mentioned two suitable types of orchard houses, the one a span-roofed house running from north to south and the other a three-quarter span running east to west. Both should be provided with means for providing plenty of ventilation. Mr. Baskett also gave cultural details and a list of varieties of fruits suitable for the purpose. A discussion followed. *T. J. W.*

SHIRLEY, MILLBROOK, AND FREEMANTLE HORTICULTURAL.—The annual meeting of this society was held at the Shirley Hotel on Friday, December 22. The fortieth annual report showed that notwithstanding having to start the year with a deficit balance of £2 14s. 2d., the committee were able to put before its supporters a very satisfactory condition of affairs. The balance sheet showed a total receipt of £107 15s. 0d., of which £36 13s. 0d. represented subscriptions and £38 7s. 3d. money taken at the gate. There was a balance in the bank of £12 16s., and in the treasurer's hands of £6 11s. 5d. The officers of the society were all re-elected and Messrs. Fry and Sheppard included in the committee.

PLYMOUTH AND DISTRICT BRITISH GARDENERS' ASSOCIATION.—A well-attended meeting of the above Association was held in the schoolroom, Ivybridge, on December 20, John Bayly, Esq., in the chair. A paper was read by Mr. W. Selley, of Delamore, Cornwood, on "Fruit Culture." The essayist dealt with the Vine, Peach, Nectarine and Apple, giving the leading varieties of these fruits and the proper methods of their culture under glass, including propagation, pruning, planting, etc. A discussion followed, and a number of questions put to Mr. Selley were ably answered. Collections of Apples were displayed by Mr. F. Seward, gr. to the Earl of Morley, Saltram, and by Major Parker, of Delamore, Cornwood. The latter also exhibited plants including Begonias, Cyclamen, &c.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending December 30, 1905:—

1905. December 24 to December 30.	Temperature of the Air. At 9 A.M. Dry Bulb.	Wet Bulb.	Day. Highest.	Night. Lowest.	Lowest Temperature on Grass.	Temperature of the Soil at 9 A.M. At 1-foot deep.	At 2-foot deep.	At 4-foot deep.	Rainfall.	Sunshine.	
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr.	min.
Means	39	38	44	35	33	41	43	45	Tot 0·19	—	36

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending December 30, is furnished from the Meteorological Office:—

The *weather* was generally mild and rather dull over the Kingdom as a whole, but rain was neither heavy nor frequent over England. In the Channel Islands and Scotland E. small amounts fell on four days, and in Ireland somewhat larger quantities on four or five days.

The *temperature* was above the mean in most districts, equal to it in Scotland N., England N.W., and the Midland Counties, and slightly below it in Scotland E. In Ireland S. the excess was as much as 4°. The highest of the maxima were registered early in the week, and were 50° or above in every district except England E. In Ireland S. the thermometer rose to 56°. During the early part of the week the minima were very high for the time of year, but they became much lower some days later, and towards the close of the period they ranged from 20° in Scotland N. and E. and 22° in England S.W. to 31° in Ireland S. and to 37° in the Channel Islands.

The *rainfall* was considerably in defect over Great Britain, but equalled the mean in Ireland S. and exceeded it in Ireland N.

The *bright sunshine* exceeded the normal in the Channel Islands, Scotland N., and England N.W., but in all other districts there was a deficiency. The percentage of the possible duration ranged from 25, 22 and 21 respectively in the three districts just named to 10 in Ireland S. and to 4 in Scotland E.

THE WEATHER IN WEST HERTS.

Sudden changes in temperature.—On the first day of the week the temperature in the thermometer screen rose to 45 degrees, but a few days later only to 34 degrees, since which it has risen to 47 degrees. Then on one night the exposed thermometer fell only to 35 degrees, whereas on the coldest night the same thermometer registered 10 degrees of frost. The ground temperatures have fallen, and are now about seasonable, both at one and two feet deep. Nearly three-quarters of an inch of rain fell during the week. On the 2nd inst. the fall, although little more than a quarter of an inch, was the heaviest for any one day for five weeks—showing how very dry for the time of year the weather has recently been. Two gallons of rainwater came through each of the percolation gauges. The sun shone on an average for about three-quarters of an hour a day, which is about half an hour a day short of the usual duration at this season. Calms and light airs again prevailed. For the first time for four weeks the direction of the wind was some point between North and East. There was again about a seasonable amount of moisture in the air at three o'clock in the afternoon.

DECEMBER.

Exceptionally dry and calm.—This was a warm December, with no cold period worth mentioning. On the warmest day the temperature in the thermometer screen rose to 54 degrees, and on the coldest night the exposed thermometer showed only 13 degrees of frost—the latter a remarkably high minimum reading for the month. Rain fell on but thirteen days, and to the aggregate depth of little more than an inch, which is less than half the December average. It is now fifteen years since the last month of the year has been as dry. The total fall for nineteen consecutive days amounted to only about a tenth of an inch. The sun shone on an average for little more than an hour a day—which is ten minutes a day short of a seasonable duration. Only twice before in the last twenty years has the atmosphere in December been as generally calm. At no time did the velocity of the wind in any hour exceed thirteen miles. The direction of the wind was for only thirty-six hours altogether from any point between north and east. The atmosphere was not only calm, but humid, the mean amount of moisture in the air at 3 p.m. exceeding the average by 2 per cent.

THE YEAR.

Taking the past year as a whole, the temperature has been about average. The only cold months were August, September, October, and November. The most unseasonably cold ones were October and November, and the most unseasonably warm ones February, March, and July. The total rainfall fell short of the average by 4¼ inches. There were no very wet months. The sun shone on an average for four hours a day, or for about five minutes a day longer than usual. The sunniest months were May and July.

Our Underground Water Supply.—The rainfall for the last three months has fallen short of the average for the same period in the last 50 years by 2¾ inches, which is equivalent to a loss of rain on each acre in this district of 50,450 gallons. *E.M., Berkhamsted, Jan. 3, 1906.*

HARRISON WEIR.—The *Central News* announces (Thursday afternoon) the death of this distinguished artist at 10 p.m. on the 3rd inst. In our next number we shall make allusion to the work of our old friend and contributor.

ENQUIRY.

VINES, WHITE NICE AND BLACK DAMASCUS.—Can any reader tell us where either of these varieties are now growing? They appear to have passed quite out of cultivation. *K. W. and Co.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ADDRESS: *T. R. P.* J. Forbes, Nurseryman, Hawick, Scotland.

CORRECTION, see p. 447, col. 1, For Cypripeduim, read Cymbidium Maggie Fowler.

DAISIES IN LAWN: *J. F.* If the lawn is in such a bad state as you have described, it will be best to eradicate the daisies by spudding them out by the roots. Afterwards apply a little rich top dressing over the entire lawn and sow fresh grass seeds in March in places where they appear to be required.

ECZEMA; *A.E.B. & R.P.* It is a well-known fact that some persons are subject to severe skin irritation from handling bulbs and Daffodil blooms, probably due to the minute needle-like crystals which abound in the plants. The fact that Primula obconica also causes severe skin irritation is well known. In both cases the affection is local only, so that it is only necessary to avoid handling the plants to get rid of the irritation. True eczema, due to constitutional causes, is a different matter altogether, and for its treatment you should apply to a medical practitioner.

NAMES OF FLOWERS: *W.C.* We cannot undertake to name varieties of Chrysanthemums. Send them to a nurseryman who can probably match your flowers in his collection.

NAMES OF FRUITS: *A. Chapman.* Passe Colmar. *Gardener, Norfolk.* 1, Uvedale's St. Germains. Usually a good grower and heavy cropper. One of the best varieties for stewing; 2, Easter Beurré a variety that succeeds well against a wall, but requires a good deal of thinning and watering during the growing season to produce fruits of the finest quality; 3, Sam Young; 4, Rymer; 5, Brabant Bellefleur.—*J. E. S.* Green Tiffing.

NAMES OF PLANTS: *W. & E.* 1, Monstera deliciosa; 2, Cestrum fasciculare; 3, Trachelospermum jasminoides; 4, Juniperus chinensis; 5, Taxus baccata aureo-variegata; 6, Eriobotrya japonica.—*J. O. C.* Kindly send further specimens of the Codiæums you require to be named.—*A. Y. L.* 1, Epidendrum floribundum; 2, Liparis longipes.—*B. M.* 1, Oncidium stramineum; 2, Stelis micrantha; 3, Polystachya Oltoniana; 4, Angræcum arcuatum.—*F. W. C.* The essential part of the inflorescence of the grass is wanting Send perfect specimen.

POINSETTIA: *R.E.F.* The structure is essentially the same as in the common Spurges (Euphorbia). The "inflorescence" may be said to begin with the first coloured bract. Within these red-floral leaves or bracts is a dense mass of small flowers with glands. There are no true sepals or petals, and the male and the female flowers are separate, though approximate. The "glands" secrete honey, the coloured bracts show where the nectar is to be found. The plant is a native of Mexico, but we are unable to inform you what insects visit the flower. In this country probably flies would find the honey to their taste if it be not imbued with the poisonous quality one would expect to find more or less developed in the plant. Now-a-days botanists are agreed that the plant is a true Euphorbia, and speak of it as E. pulcherrima. The name Poinsettia, no doubt, will still continue to be used in gardens.

SITUATION IN THE UNITED STATES: *E. J. H.* That there are good openings in the United States for well-trained English gardeners is proved by the success already obtained by many who have gone there previously. Your best plan will be to advertise in the American horticultural papers, or write to several of the best known nurserymen in New York and Boston.

VINERY: *C. J. S.* No absolute rule can be laid down in regard to the number of times a vinery should be afforded water during the summer season. Much will depend upon the position of the border, the character of the soil, the efficiency of the drainage, the degree of sunshine, and the number of roots there are in the border. If you have had practical experience in the cultivation of plants, you will be able to determine when the soil is becoming too dry for the roots to obtain full benefit from the food it contains, but if you have not had such experience we are afraid we cannot enable you to act exactly as those who have. The border should not be allowed to get very dry even in the winter season, although much less water is required at that period than others.

THE TRUE PROVINCE OF NATURAL SELECTION.

IN a previous article on "The True Darwinism" (see Vol. xxxviii., p. 401), I pointed out that "ecologists" are rapidly replacing the conception that specific characters arise by means of natural selection, by the view that there is an immediate and responsive adaptation to changed conditions of life; and, in conclusion, I observed that the assertion that "No one had ever seen Natural Selection in action," might be replaced by the statement that "Everyone may see natural selection everywhere in action," whenever two or more plants are contesting for the same area, or any plant alone with an inhospitable physical environment. But the issue of the struggle determines the *Distribution* of species and not their *Origin*. I purpose now illustrating this fact:—

First, however, it is necessary to observe that Darwin says that the struggle for existence and the survival of the fittest is "the Doctrine of Malthus applied with manifold force to the whole animal and vegetable kingdoms"*; and he devotes the third chapter to explaining how "the geometrical ratio of increase" only leaves an average amount of beings to survive.

All this is true enough, and runs parallel with Malthus' statements; but in applying that writer's theory to *The Origin of Species*, Darwin was obliged to introduce the factor of *Morphological Structures*; because it is on *these alone* that systematists found their specific characters. However impoverished a being may be which succumbs in the struggle for existence, such a condition has nothing to do with the origin of species, which is based on structure alone.

This is obviously not only a weak point in Darwin's theory, but, as I maintain, an uncalled-for addition to Malthus' argument. That variations of structure among seedlings have been a source of injury, detriment and destruction to them, has never been exemplified. In a mass of seedlings of any kind, some start in the race better equipped than others, by having been better nourished in the ovary, and by starting into growth earlier. The result is that many succumb because they do not get enough light, air, water or food. But specific characters are not, as a rule, developed in the extremely young state when thousands of them perish.

Malthus says that the ultimate check to population is want of food. The immediate checks are diseases, customs, as well as "all those causes . . . whether of a moral or physical nature, which tend prematurely to weaken and destroy the human frame."†

To add, therefore, structure, on the one hand, as a possible cause of elimination, as being "injurious"; or, on the other hand, as "favourable" or even neutral, in enabling the seedling to survive, had no place in Malthus' *Essay*; and—unless practical experience could show there might be some grounds for it—such should not have been inserted; consequently "The Origin of Species by means of Natural Selection" has no basis in fact.

In order to illustrate true natural selection, it will be as well to choose simple and easily-seen instances; for, as soon as an observer has had his attention called to it, just as occurred to Darwin in the matter of Adaptation in 1876, "proofs will be plentiful."

Let us take a derelict meadow, still retaining the ridges and furrows which it had when it was formerly arable land. Such may be seen by hundreds in the Midlands. In early summer the bulbous Buttercup (Ranunculus bulbosus), naturally a xerophyte, but adaptable to moisture, as in a uniformly wet meadow, may be observed covering the ridges, sometimes 20 feet across, but they stop short about one foot from the bottom of the furrow, on each side of it. In the furrows there is not one plant. If the achenes or fruit could spread over 20 feet, there could be nothing to hinder them from filling the furrows. They perish, presumably, from excessive moisture.

On the contrary, R. acris, the field Buttercup, affects the furrows rather than the ridges. Adaptation and natural selection thus effect the distribution of these two species. As another instance of seeds failing to germinate, apparently because they cannot stand a struggle among grass, is the Wild Chamomile (Matricaria Chamomilla). This is a common weed on arable land, at the corners and edges of the fields where it has some freedom; but, by whatever means the achenes unprovided with pappus manage to reach the grass outside the field and between the hedge and the road, it will be found to occur plentifully on any bare place, as where a heap of stones had been deposited, or where turf had been cut, etc., in each case being sharply bounded by the grass surrounding it, in which not a single plant occurs.

As another instance, a Quickset hedge is fringed at its base with a long line of Hordeum murinum. This runs along the edge of an asphalt footpath. On the other side of this is a strip of grass, one foot wide, entirely composed of Rye-grass (Lolium perenne). In the depression beyond, where the road begins, there are Plantains. These three different species have thus been located by natural selection and adaptation.

Turning to cases of intense struggle between totally different species, on the broad pieces of grass on either side of a road—a common feature in Warwickshire—numerous interlopers may be seen, elbowing their way and ousting the grass. The following are examples:—Dutch Clover, creeping Buttercup, Coltsfoot, stinging Nettle, dead Nettle, Bracken; and, in damp shady places, ground Ivy, etc. Now, there are two features which apply to all of them—viz., a broader foliage and creeping stems. The latter rooting at the surface absorb the superficial moisture, the result being that the grass is starved. Mr. T. Kirk attributes to the same causes the case of the Dutch Clover bringing about the destruction of the New Zealand Flax (Phormium tenax).

A point to note here is one which concerns plant-surveying, for in many "formations" or "Plant-Associations" it must be borne in mind that the collection of species may be different to a greater or less degree, say, in five years' time. Thus there are two meadows in the experimental grounds at Rothamsted which have not been touched for twenty years. A census of the number of species in each was taken in 1862, again in 1867, and also in 1872. In one the number had varied from 44 to 50, and the other from 50 to 43 and 49, respectively, while the grasses, leguminous plants, and "mixed herbage" had also varied between the periods when each census was taken.

As another illustration the following is one of changes in a copse. In woods the struggle for existence is often intense. In a certain small wood in Warwickshire a quantity of Campanula latifolia was abundant some five years ago, forming a perfect "sheet of blue." At the present time not a plant is to be seen. Mercury and nettles have invaded the place by means of their creeping stems and driven the Campanulas away.

On the other hand in another open wood Foxgloves have driven out pretty well everything else, and now form an immense mass of purple. It was long ago observed that if Oaks and Beeches be planted together, after some years nothing but Beeches will be left.*

Now let us consider the case of a hedge.

* Origin of Species, &c., 6th ed., p. 50.
† Essay on Population, 7th ed., p. 7.

* The Forest Trees of Britain, by Rev. C. A. Johns, p. 152.

It is made of Quickset (cratægus); but birds (presumably) have dropped berries or seeds of Elder, Privet, Holly, Mountain Ash, &c. The seeds have germinated, grown into goodly-sized bushes and trees, and completely destroyed the hedge wherever they occur.

Another common occurrence is for the roots of an Elm tree to run along the bank under the hedge and send up innumerable suckers, until the Quickset has been completely converted into an Elm hedge for several yards on both sides of the tree.

As an example of an annual expelling perennials, I made a lawn with turf cut from a hay-field; but there was a good deal of Poa annua, as a weed, in the garden. It invaded the lawn, and as the lawn was regularly mown, it seeded profusely, gradually superseding the perennial grasses, becoming itself a perennial till the whole lawn was made up of it.

This shows how plants which oust others under one condition will be themselves destroyed under a different state of things; for while Poa annua, Daisies, and Plantains have all their own way in a mown lawn, let the latter return to a hay-field and the usual perennial grasses will soon assert their superiority and prove themselves to be the better adapted to survive under the circumstances.

Natural selection is thus and in many other ways seen to be dominant everywhere. It accounts for the presence and *distribution* of species in any plant-association; but it has nothing whatever to do with their *origin*. *George Henslow.*

NEW AND NOTEWORTHY PLANTS.

THE GENUS CORYLOPSIS,

WITH A DESCRIPTION OF A NEW SPECIES.*

THE genus Corylopsis was founded by Siebold and Zuccarini (*Flora Japonica*, Vol. I. (1835), p. 45, tt. 19 and 20), who described and figured the now well-known C. spicata (*Gardeners' Chronicle*, 1865, p. 172) and C. pauciflora (*Gardeners' Chronicle*, 1899, Vol. XXV., p. 211, f. 80) from specimens cultivated in Japan, both of which have since been found growing wild in that country. They also mention (p. 49) a wild species, to which they gave the name of Kesakii, stating that it differs essentially from the other two in foliage and in fruit, but without giving the points of difference. Miquel (*Ann. Mus. Bot. Lugd.-Bat.*, Vol. III., p. 207) describes the leaves; but both flowers and fruits were unknown to him. The most obvious difference is the smaller number—five or six on each side of the midrib—of primary lateral veins. There is one small, barren branch in the Kew Herbarium which I take to be this species, and, if I am right, it is a slenderer plant than C. pauciflora.

Franchet and Savatier describe (*Enum Pl. Jap.*, Vol. II., p. 367) a fourth Japanese species—C. glabrescens—which "differs from C. spicata in the primary veins of the leaves being more numerous and closer together, and in the axis of the inflorescence and the calyx being quite glabrous." I have seen no specimen that I could refer to this species.

In 1837-8 William Griffith collected specimens of Corylopsis, both in Bhotan and Khasia, and they were subsequently described (*Journ. As. Soc. Bengal*, Vol. XXIII. (1854), p. 641, with a figure) as C. himalayana. In 1884 a cultivated Corylopsis was figured in the *Botanical Magazine*, t. 6,779, under the name of C. himalayana.

A Chinese species—C. multiflora—had, in the meantime, been described (*Ann. Sc. Nat.*, 4 me. série, Vol. XV., p. 224) by Hance.

FIG. 12.—CORYLOPSIS SINENSIS (HEMSLEY).

Fig. 1, flowering branch of Corylopsis sinensis, Hemsley, bearing near the base two undeveloped leaves, which are almost concealed by the stipules. Fig. 2, a flower, subtended by a bract and two bracteoles. Fig. 3, a flower from which the calyx-lobes and petals have been removed. Fig. 4, a nectary or staminode. Fig. 5, fruiting-branch bearing two fully-developed leaves. Fig. 6, a seed. Figs. 1 and 5 natural size; the rest enlarged.

Both Dr. A. Henry and Mr. E. H. Wilson collected specimens of Corylopsis in various localities in China, and two species at least have been raised by Messrs. James Veitch and Sons from seeds sent home by the latter.

One of these flowered last spring, and, on comparing it with the dried specimens, I discovered that Kew possessed two or three, or perhaps even more, undescribed Chinese species. This led to an examination and comparison of the specimens from the mountains of North India, and the discrimination of three species instead of one. The main botanical results of these investigations will appear in the forthcoming part of Hooker's *Icones Plantarum*; but I will here give a few notes on the genus Corylopsis as a whole, and a description of the species flowered by Messrs. Veitch.

Among deciduous shrubs or small trees, flowering in winter or early spring, the species of Corylopsis constitute a very distinct and elegant type; and of those in cultivation C. spicata is perhaps the most ornamental. The foliage, which is very much alike in all the species, bears a general resemblance to that of the Lime and Hazel (Corylus), hence the generic name; but it exhibits quite peculiar and distinctive characters. As in many other plants, the leaves of the flowerless shoots are larger and somewhat different in shape from those of the flowering shoots. Otherwise they are alike, and their prominent characteristic is afforded by the straight, parallel, primary veins, which run out from the midrib at an acute angle, and terminate beyond the margin in small, thickened teeth. A few secondary and tertiary veins run out in the same way below the middle of the leaf. In the bud the leaves are beautifully folded, the pleats corresponding to the primary veins. The young parts are mostly clothed with long, silky hairs, simple and stellate intermixed. The flowering and fruiting branches present very great differences, and I will try to describe the nature of the evolution. A young flowering branch is not unlike that of the female Hop; but its composition is quite different. At first it is horizontal, or nearly erect, but as it lengthens it droops, and it hangs almost straight down in the flowering stage. It then consists of an axis bearing a few brown, empty scales at the base, followed by one, two, or three pairs of opposite organs, bract-like in texture and colour, but which are really stipules, as is attested by the presence of as many young leaves. Then come the sessile flowers, each one subtended by a bract and two lateral bracteoles. After flowering, the axis still further elongates, and straightens and stiffens; the stipules fall away, the leaves develope, and the Hop-like body becomes an ascending or erect branch, bearing one, two, or three leaves, and terminating in a rigid spike of seed vessels. The stipules of the barren branches are smaller and different in shape and even more caducous. The nature and composition of the flowering shoots of many Willows is almost exactly the same as in Corylopsis, except that the stipules

* *Corylopsis sinensis*, *Hemsley*: species nova ex affinitate C. spicatæ et C. Griffithii; ab illis foliis supra medium latioribus, ramulorum floriferorum stipulis latioribus quam longis, petalis fere orbicularibus abrupte unguiculatis et seminibus albis recedit; a C. Griffithii etiam staminibus petala fere æquantibus et nectariis vel staminodiis 5 planis bifidis differt. Frutex vel arbor 10—15 pedalis, ramulis annotinis glabratis, hornotinis pubescentibus. Folia breviter petiolata, demum subcoriacea, obovato-oblonga, rarius fere ovalia vel orbicularia, sæpius 2—3 poll longa, apice abrupte breviterque acuminata, acuta vel obtusa, basi cordata, lobis brevibus, interdum leviter obliqua, calloso-denticulata, dentibus venas excurrentes terminantibus, primum utrinque, præcipue subtus, pilis longis setaceis stellatis vestita, supra demum glabrescentia; venæ primariæ laterales utrinque circiter 8, Stipulæ ramulorum floriferorum fere orbiculares, coloratæ; ramulorum sterilium lanceolatæ, acuminatæ. Calycis lobi ovales, glabrescentes, Petala lutea, fere orbicularia, unguiculata. Stamina petala fere æquantia, antheris luteis. Staminodia calycis lobos excedentia. Styli basi pubescentes, Semina alba.—*C. spicata*, Hemsley in *Journ. Linn. Soc.*, vol. xxiii., p. 290, non Siebold et Zuccarini.

are smaller on the flowering than on the barren shoots.

The structure of the flowers of Corylopsis is very simple, consisting of a calyx tube, more or less adherent to the ovary, with or without five free lobes or teeth; five petals; five stamens; five or ten bodies, variously described as scales of the disk, glands of the nectary and staminodes; a two-celled ovary, one pendulous ovule in each cell, and two long, slender styles. The fruit is a woody capsule, splitting open to allow the seeds to escape the bifid valves tipped by the hardened bases of the split styles.

Corylopsis sinensis differs from C. spicata, to which it is most closely allied, in the stipules of the flowering branches being broader than long; in the leaves being broadest above the middle; in the orbicular petals being suddenly narrowed into a distinct claw; in the yellow anthers and white seeds.

The Bhotan and Khasyan specimens, doubtingly referred as varieties by Griffith to the C. himalayana, I consider as representing two distinct species, and to the former belongs the name himalayana, of which G. grata is a synonym, used by Griffith in the publication cited above in his description of the plate, and on the plate. This species has not been collected since Griffith's time.

For the plant cultivated as C. himalayana I propose the name Griffithii, and I shall discuss the differential characters of these two species in another place. C. sinensis inhabits the provinces of Kiangsi, Hupeh and Szechuen, and flowers freely while still quite young and small. *W. Botting Hemsley.*

CHRYSANTHEMUMS.

AN AUDIT OF JAPANESE VARIETIES.

I HAVE made a careful audit of the varieties contained in the winning prize stands of 36 Japanese and 24 incurved Chrysanthemums throughout the country and the following shows the number of times that individual varieties have been exhibited. Altogether some 130 varieties have been shown in the prize stands. It will be noticed that last year's novelties have not been shown very extensively, the two most prominent in this respect being Mrs. W. Knox and Mrs. T. Dalton.

CYPRIPEDIUM TESSELLATUM RUBENS.

THE attractive and distinct flower shown in fig. 13 was exhibited by Messrs. Sander & Sons, St. Albans, at the meeting of the Royal Horticultural Society on 19th ult., when the Orchid Committee granted it an Award of Merit. The colour of the flower is almost unique, being of a dark shade of red, with an infusion of yellow, and including some purple spotting. It is the result of a cross between C. concolor and C. barbatum grandiflorum. Not the least beautiful portion of the plant is the foliage, the markings on which present a pleasing tessellated appearance.

VEGETABLES.

EARLY POTATOS.

How is it that amidst the wealth of new varieties the old Ashleaf Kidney seems almost lost, whilst the perhaps older Walnutleaf Kidney, once resuscitated as Mona's Pride, seems to have entirely disappeared. Good as the Ashleaf and Walnutleaf Kidneys were they had their faults, and sometimes failed to give a satisfactory crop. Although classed as first earlies, they were not so early as the newer varieties. There was, however, a characteristic flavour in the cooked tubers that is not always apparent in other varieties. It would be specially interesting could we have a real trial of early Potatos at Wisley this year. It has been shown during the past year that Potatos succeed well on the Wisley soil, and that those grown there develop excellent quality. Potato trials there, as formerly at Chiswick, usually suffer from the neglect of those who send tubers for trial to specify the ripening season of the varieties, whether early, mid-season, or late; also the average height of plant-growth. All such information should be rigidly insisted upon on pain of neglect to test any variety received. If this information were afforded it would then be easy to plant each section separately, and thus ensure a very satisfactory trial. Still farther, every set of tubers should be sent in not later than the middle of March so as to give time for the tubers to be set up in boxes to sprout ready for planting. By this sprouting alone much would be done to enable identity or distinctness to be recognised, as the elucidation of synonyms should be an important feature in any trial. To avoid the harm so frequently done to Potato tops in the spring, planting should be deferred until the last week in April. Many a first-rate variety, in trials of this description, has suffered in reputation so far as cropping was concerned, because of the injury from frost inflicted in the spring.

Besides such a trial (and here I would add that the place of growth of the tubers of each variety should also be stated) there should be not later than the end of July or early in August an exhibition in London of early varieties. It is not needful to have many classes. A few would suffice so as to bring samples of lesser known varieties more fully before the public. Good samples from the Wisley collection should also be staged, and doubtless members the trade would readily send collections, not necessarily large ones, but such as would enable the public to note good varieties, with which, so far, they may not be generally familiar. Such an exhibition would in no case introduce the huge ungainly tuber so often seen at late exhibitions. It would also emphasise the importance of first early Potatos to the consumer, an importance that is just now somewhat overlooked when late varieties only are exhibited. We are getting very fine additions to our first early varieties every year. This season Messrs. Sutton & Sons are offering for the first time a semi-kidney in Gladiator, one of great excellence; and from Scotland both Messrs. Dobbie & Co. and Mr. T. A. Scarlett are offer-

FIG. 13.—CYPRIPEDIUM TESSELLATUM RUBENS.

ing their Midlothian Early. From the same sources comes the earliest of the Rosebery strain in Dalmeny Early. No doubt there are others offered as well and not yet widely known, but if some half-dozen only of quite new early varieties come out each year, then the numbers of the section must grow rapidly. Of older varieties there are Harbinger, May Queen, Ringleader, Sharpe's Victor, Duke of York, Early Puritan, Beauty of Hebron, Sharpe's Express, Pride of Tonbridge, Sir J. Llewellyn, Snowdrop, Recorder, Epicure, Ninetyfold, and many others, all more or less favourites with various growers. A cooking test for first earlies would also be most interesting, especially were the old Ashleaf Kidney, always so much liked for its yellowish flesh and pleasant, nutty flavour, included as a test variety. There is to be a special competition for early Potatos at Marks Tey, Essex, on August 1, when no doubt many excellent varieties, new and old, will be seen. But what is needed is a tuber competition and growing trial, such as the Royal Horticultural Society could conduct at Vincent Square and at Wisley. In the past the Society's trials have been confined too much to the testing of varieties. We need wider experiments now, and early Potatos present most excellent material to start with. *A. D.*

OUT-DOOR GRAPES AT DROITWICH.

At fig. 14 is reproduced a photograph of the out-door vines in the Worcestershire experimental garden at Droitwich, which was obtained at the time the fruit was being gathered last autumn for the purpose of making into wine. Mr. J. Udale, who is the chief horticultural instructor for the county, cultivates in the manner shown in the illustration about 40 vines of the variety Gammy Noir. This is the same variety as is grown in the Marquis of Bute's vineyards near Cardiff, which were planted by the late Mr. Pettigrew in 1886, and subsequently, and of which a descriptive account was published in these pages on September 9, 1893. Those at Droitwich are cultivated on the same system as is practised at Cardiff, and before establishing the latter vineyards the late Mr. Pettigrew studied personally the conditions of the vineyards in France, and the practices adopted there. The vines are cut down to within two feet of the ground each year, and below this point are pruned to long spurs. A stout stake is fixed near each vine, and the young growth tied thereto and allowed to extend to the top of the stake, where it is stopped. The reason for cutting the vines near down to the ground as Mr. Udale explains in his recently-published work, *The Handy Book on Pruning*, is to secure to the Grapes the latent warmth of the soil, which materially aids their ripening.

The figure abundantly shows that good crops are obtained at Droitwich, and we have reason to know that the Grapes last season, some of which were exhibited at the Birmingham Chrysanthemum Show, were ripened sufficiently for use in making wine.

SEED PACKING.

In the *Gardeners' Chronicle* for February 11, 1905, p. 90, there is a note of mine on seed packing, in which I stated that "For seeds generally I know of nothing better than paper packets and calico bags, and the more moisture there is in the seeds themselves when thus packed the better. Hermetically-sealed tins or bottles should never be used." In subsequent issues of the *Gardeners' Chronicle* this recommendation was adversely commented upon; Messrs. J. CARTER & Co. wrote (p. 124):—"It has been over and over again proved that the ordinary vegetable and flower seeds will rarely retain their vitality if sent away from here without some special treatment which eliminates a large percentage of the moisture contained in them, when harvested naturally in our temperate climate. To overcome this difficulty, we have for many years not only subjected this class of seeds to a special drying process, but enclosed each packet in tinfoil, and this again is placed in a hermetically-sealed covering, from which the air is exhausted." Mr. J. W. T. DUVEL, of Washington, U.S.A., wrote (p. 163):—"Carefully conducted experiments have given results which are diametrically opposed to those set forth by Mr. WATSON." Mr. H. R. WHITELAW (p. 171) attributed the failure of a collection of seeds sent from England to the Transvaal to their having been packed "as if they were only to go a few miles."

FIG. 14.—THE OUT-DOOR VINES IN THE COUNTY EXPERIMENTAL GARDEN, AT DROITWICH, WORCESTERSHIRE.

I have also received protests from others, including seed dealers, who accused me of a desire to injure the seed trade between this country and the tropics! My feeling in the matter has always been that if this special treatment and expensive packing were necessary in the case of seeds supplied by dealers, then the thousands of packets of seeds of all kinds sent from Kew should have failed to grow in consequence of our packing them in the manner recommended above. But reports were always to the contrary effect. For years we have made a practice of sending to some tropical garden all the flower seeds left from our annual sowing, the bulk of them having been obtained from British and Continental dealers, and they have invariably given satisfaction to their recipients. There can be no question of the success of the seeds received at Kew from all parts of the world when they are packed in a common sense way; failure is generally in those cases where sealed tins or bottles have been used.

Mr. WILSON, Messrs. J. VEITCH & SONS' collector in China, had really wonderful success with the seeds he brought and sent home, they numbered some thousands of packets; and he informs me that he employed the Kew methods, with which he was quite familiar, having had charge of our tropical seed department for about a year.

As I was unable to speak from actual experience as to the requirements of vegetable seeds sent from this country to the tropics, I decided to test some, and, therefore, with the permission of the director, I obtained from Messrs. SUTTON & SONS a collection of vegetable seeds as supplied for sowing in this country, divided each packet into three lots, placed each lot in an ordinary paper packet, and packed each set of 43 packets in a thin wooden box. Each set contained seeds of Bean, Beetroot, Broccoli, Brussels Sprouts, Cabbage, Carrot, Cauliflower, Celery, Cress, Cucumber, Endive, Kale, Leek, Lettuce, Marjoram, Mustard, Parsnip, Parsley, Pea, Onion, Radish, Spinach, Tomato, Turnip, and Vegetable Marrow. The three sets were then forwarded by parcel post on April 11, 1905, to the following:—

Mr. W. N. SANDS, Curator, Botanic Garden,

St. Vincent, West Indies; Mr. F. S. SILLITOE, Superintendent, Palace Gardens, Khartoum, Soudan; Mr. J. W. CAMPBELL, Superintendent, Government Gardens, Taiping, Perak, Federated Malay States.

To each of these I sent a copy of the following note:—

"Dear Sir,—You may have seen in the *Gardeners' Chronicle* recently some notes by me and others on the best methods of preparing and packing seeds for transport to tropical countries. Some authorities consider it necessary to prepare the seeds by a special drying process, wrap them in tinfoil, and pack them in hermetically-sealed tins, from which the air is exhausted, to preserve them from the effects of heat and moisture during the journey. As you are aware, we do not treat seeds distributed from Kew in this way, and I believe our seeds travel well. But it has been stated that seeds of English garden vegetables would not survive our treatment. To test this I am sending you a collection of 43 packets of seeds purchased for the purpose, and I shall be greatly obliged if you will carefully note the behaviour of each kind after sowing, and report the results to me. —Yours, etc., W. WATSON."

In selecting these three stations, the aim was to get as diverse conditions as possible. Perak is in the Malay Peninsula, and is distant nearly a month's journey through the tropics, including the passage through the Red Sea, whilst the conditions of the Government garden at Taiping are extremely moist, and, therefore, trying for seeds of temperate plants. Khartoum, on the other hand, is extremely hot and dry, and gardening is, according to Mr. SILLITOE, very difficult. The West Indian test would apply to most countries in the Western Hemisphere.

No report has yet been received from Mr. SANDS, of St. Vincent, but he wrote on May 5:—"The box containing 43 packets of vegetable seeds arrived safely on April 25, and I shall have much pleasure in carrying out your wishes. I intend dividing each packet into several lots and testing the germinating power at intervals. I obtain the greater part of the seeds required for the department here from the United States, so that I have no previous notes to give you, but will supply full details of the behaviour of this lot later on."

Mr. SILLITOE wrote from Khartoum on November 25 as follows:—"The box of vegetable seeds arrived here in May, after I had left for England. It, therefore, had to await my return in August, but that being one of our hottest months nothing was sown till September, and the majority not till October. The last sown were the Peas on November 17. They are now looking very promising. Peas, as a rule, are not a success here; they make plenty of growth but little flower. I suppose the seeds sent to me have experienced the hottest time of any that have been sent from England. With the exception of three or four small storms, we have had no rain for five months, and a daily average maximum shade temperature of nearly 100° F., the highest maximum being 112° F. At the time of writing, 4 p.m., it is 95° in my verandah. The maximum daily shade temperature in September was 100°-105° F. and the minimum 80°-85° F. at night. The seeds sown then were Lettuce, Endive, Cabbage, Cauliflower, Tomato, and Onion. They all germinated well in two or three days. Those sown later were Beans, Carrot, Cucumber, Radish, Turnip, Marrow, and Spinach. These also germinated well in a few days. The only failure in the whole collection was Celery, which often fails here; in fact, the only Celery seed that has grown is some I obtained from Cairo. This season I have had seeds from most of the leading English dealers, packed either in hermetically-sealed tin boxes or wrapped in tinfoil, but in my opinion all this extra care is unnecessary for seeds coming to a dry climate like this, although it may be advisable for a wet one. If large seeds, as Peas and Beans, are not absolutely dry when packed in air tight tins, the moisture from them causes all the smaller seeds in the tin with them to mould. This has occurred with several collections that I have received, but it would not happen if a plain wooden box were used."

Mr. CAMPBELL wrote from Taiping, Perak, on July 14:—"The seeds were received in good condition on May 12, and were sown the following day. With the exception of Parsnips, everything germinated splendidly. Peas were all up in seven days, and American Wonder Pea was ready for table in six weeks. Broad Beans, Carrots, and Turnips were up in eight days; Radish, Cabbage, Spinach, Lettuce, and Endive in six days; Mustard and Cress in two days. All the crops promise well, except Spinach; this germinated well but grew badly, owing to the heavy rain we had at that time. Parsnips always germinate badly here. I have twice before sown Parsnip seeds that have been specially dried, but they failed to germinate. This garden is at an elevation of 3,400 feet; the average night temperature is 63°, day temperature in shade 78°; average rainfall about 185 inches per annum. The actual rainfall for May, the month the seeds were sown, was 21.83 inches, there being only nine dry days in the month. The question of seed packing is important. If you can succeed in proving that seeds can be sent safely from England to the tropics without special drying, airtight cases, etc., it will make a considerable difference in their cost." *W. Watson, Kew.*

MANURES FOR APPLES.

WE extract the following particulars relating to the use of artificial manures from a letter contributed to the *Daily Graphic* by a correspondent. They may be compared with interest with the results obtained at Woburn, where the results from the use of artificial manures were found much less favourable.

The experiments were carried out in Germany with a large orchard of King of the Pippins Apple, five long rows of which received different manurial treatment. One row was left untreated, while the four others had different manurial combinations. The row left unmanured yielded 104 lbs. of Apples per tree during the five years reported on by Dr. Wagner, and in the fifth year (1904), which was the year of maximum yield for the entire orchard, the weight of the Apples per tree was 55 lbs., and the number 294.

The best results from manuring were obtained by the use of a complete mixture consisting of 1½ lbs. of sulphate of ammonia, 1½ lbs. of muriate of potash, and 3½ lbs. of basic slag, applied to the roots during the winter. During the five years the yield per tree from this dressing was 163 lbs. of Apples, while by the fifth year the crop had increased to 401 Apples, weighing 105 lbs. per tree. That is, the weight of Apples per tree was increased by this plan of manuring from 56 lbs. per tree on the unmanured trees to 105 lbs. per tree on the manured trees, or 90.9 per cent., while the number of Apples per tree was increased from 294 to 401, or 36 per cent. The increase in the average size of the Apples is, perhaps, as remarkable as any feature in these experiments. Those from the unmanured trees averaged 2.98 ounces each, and those from the manured trees 4.19 ounces each—an increase in the average size of the Apples of over 40 per cent.

The trees were planted in 1891, eight yards apart in every direction. Up to 1896, the soil under and between the trees was used for Raspberries, Gooseberries, and Currants; in 1897 the land was fallowed; in 1898 and 1899 Early Potatos were grown; in 1900 a mixture of Peas, Beans, Vetches and Oats were grown and cut green; in 1901 Early Potatos were again grown; while in the autumn of that year the orchard was sown to grass, in which it has remained ever since. The lessons of the manurial experiments are that Apple and Pear trees require as plant-food the same fertilising ingredients, whatever the variety. They need nitrogen, phosphoric acid, and potash, and the quantities to be applied depend less on the variety than upon the nature of the soil and the age of the trees.

If the orchard is a large one, and closely planted, the most convenient method of manuring the fruit-trees is to apply the quantity of manure per acre. For fruit-trees on a medium soil in fair condition, about 3 cwt. of nitrate of soda (or 2½ cwt. of sulphate of ammonia), 3 cwt. of muriate of potash, and 7 cwt. to 10 cwt. of basic slag per acre per annum give the best results. For smaller orchards or gardens the quantities used per square yard per annum would be 1 ounce of nitrate of soda (or 1 ounce of sulphate of ammonia), 1 ounce of muriate of potash, and 2½ ounces of basic slag. If the soil is a heavy clay, the quantity of basic slag may be increased to 3 ounces per square yard, and the quantity of muriate of potash reduced to three-quarters of an ounce. On lighter soils, the muriate of potash might be increased to, say, 1¼ ounces. As to the application of the manures, the muriate of potash and basic slag are mixed together, but only just before using, and broadcasted in the autumn or early winter.

If the orchard is under grass the muriate of potash and basic slag are best applied in November or early December, and, if possible, harrowed in. If, however, the soil under the trees is grown with other crops which require a tillage of the soil, then the application of these two manures may be made up to the end of January. As soon as the sap begins to rise in the fruit-trees (in February or early March) the nitrate of soda (or sulphate of ammonia) should be given as a top dressing. If it is intended to manure the trees singly it must not be forgotten that the root system extends over a larger area than that covered by the overhead branches. The area dressed should be not only that covered by the branches of the tree, but also two yards in addition all round. Although it is often recommended to dig a pit or hole round the tree, and to put the manure into this, so as to get it into immediate contact with the roots, a good many recent investigations show that it is not necessary. Some American experiments even show that it is injurious. All that is necessary is to broadcast the manure over the surface, and then either harrow it in or stir the soil lightly with a rake or spade.

It is worth noting that a report has come to hand from the United States Department of Agriculture on small fruit and orchard cultivation in that country, and in this is a strong recommendation to use artificial manures, and not farmyard or stable dung, for such orchards or fruit plantations. The reason given is that dung has been found to be a frequent carrier of noxious weed seeds, and that orchards and small fruit plantations are kept more free of these and cost less for cleaning cultivations when artificials are employed. The dressings recommended, and based on an enormous number of American experiments, are almost identical with those which Dr. Wagner has found so successful in Germany.

NURSERY NOTES.

MR. P. LADDS, SWANLEY.

THIS well-known market-nursery contains upwards of 100 glasshouses, almost all of which have a length of 200 feet. The object of my visit was to view the Chrysanthemums, and to observe the treatment they receive, enabling Mr. Ladds to produce such beautiful blooms as he has exhibited in such good style on several recent occasions. Although the major portion of these flowers were over, sufficient remained for my purpose. I found some are grown in outside beds, and later in the season replanted in the large Vineries. Others are grown entirely in pots and finally flowered in 24's (8 inch). No exceptional treatment is accorded to the plants, but they are never allowed to suffer from want of attention. A number of shoots are grown on each plant, but one flower only is allowed to develop on each break. On some plants I counted from 8 to 10 blooms. Some of the more noticeable varieties included Nagoya (a large batch of this variety made a brilliant show), Winter Koenigin, an incurved Japanese

flower of a pretty shade of blush-pink; Mdme. Paolo Radaelli, Mdme. P. Rivoire (white), Lady Roberts (the flowers of this variety were almost over, but it is worthy of note), White Major Bonnaffon, a very late white variety, in condition in January; W. H. Lincoln, Lord Hopetoun, and Princess Victoria. It may be of interest to note that the first flowers for market were cut on July 18th, and that a regular supply has been consigned to Covent Garden each day the flower market has been open, and this will continue until well into the present month, making a continuous supply for a period of almost six months of the year. The first blooms sold readily at 3s. per dozen, and growers such as Mr. Ladds, who start early and maintain a regular supply, are enabled to rely upon constant customers and to make profitable prices.

Among subjects of interest other than Chrysanthemums were several houses filled with large bushy plants of Genistas. Some of the plants were already starting into growth, and looked promising for a profusion of bloom. Callas are also extensively grown, as is also Asparagus medioloides, the long trails of the latter being trained on thin string. The "Smilax" is grown in rows in boxes with just sufficient room between to permit of their being cut. Asparagus plumosus nanus filled several houses. This is grown in pots, and thread is used for training the growths. Asparagus Sprengeri is also extensively grown in pots. The pots are suspended from the roofs of the plant houses. Zonal Pelargoniums receive special attention, being grown for the spring-trade. Thousands were already in 48 size pots. About 50 sorts are grown, but the bulk consists of a limited number of these. Snowdrop is the favourite white variety grown. Paul Crampell (deep scarlet), Hall Caine (light red), and Henry Jacoby is always in demand. King of Denmark still takes the lead as a salmon-coloured variety; but Mrs. Lawrence is also becoming a favourite with buyers. Raspail is not yet surpassed for quality. Ville de Poitiers (light scarlet), Constance (an old pink variety still grown extensively), Mrs. R. Cannell (single salmon), are other notable varieties. The Zonal Pelargoniums are marketed in well-flowered plants suitable for furnishing window boxes and for decoration. Ivy-leaved Pelargoniums are also extensively grown, and while a few new sorts are tried the stock consists mainly of Chas. Turner, Galilee, and Madame Crousse. Large batches of Marguerites were seen in various stages of growth. Verbena Miss Willmott receives attention. Mr. Ladds was the first grower in the market with this flower last spring, and the first plants for next spring are already in pots, while in the propagating house large batches of cuttings of this variety were seen. Here, too, I noticed a large batch of Roses, chiefly of the newer sorts, including Lady Gay, and Richmond, a new variety of the Liberty type. Genista cuttings are here treated differently to those I have grown or seen elsewhere. They are rooted in pots suspended from the roof. The pots are filled to within an inch or so of their tops, and the cuttings being almost below the rims do not dry from the heat below.

In the Chrysanthemum department I found propagating well advanced for next year's supply. The culture of Ferns forms an important feature, and it was interesting to note from the sown spores upwards through the various stages of growth they were all in good order, and promised well for a regular succession. The more useful market sorts only are grown, but these are well grown, and nothing in the way of starved or stunted stock was seen.

I may conclude by adding that during the last few years the nursery has been under the control of Mr. F. W. Ladds (the youngest son of the late P. Ladds), who manages it for his mother, and much credit is due to him for the great improvement that has been made during his stewardship. *A. Hemsley, December.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Calanthes.—Many of the deciduous Calanthes of the C. vestita section which commenced to bloom in November have now passed out of flower, and it will be necessary that the pseudo-bulbs should have a short season of rest, during which water must be withheld from them. The plants should be placed on a shelf in a position that is free from drip or damp, and close up to the roof glass, where the full sunlight will reach them and cause them to become thoroughly matured and hardened. Keep the plants in an atmospheric temperature of about 60°, and do not permit white or brown scale insects to infest the pseudo-bulbs, or they will injure the dormant "breaks." Another good plan is to turn the plants out of their pots, shake away the soil, etc., and lay the pseudo-bulbs in a slanting position in open shallow boxes, keeping the face or front of each pseudo-bulb towards the light. By this method they require very little room, and can be easily examined and cleansed of insect pests. Calanthes of the C. Regnierii section which flower in the spring have their flower spikes well advanced at the present time, and only a moderate amount of water is needed at the root till the flowers have expanded, when water should be gradually withheld. When the first flowers open the plants may be removed from the East Indian house to the Cattleya house, and if the atmosphere be kept moderately dry the flowers will fade less quickly after being cut than they would if left in the warmer temperature.

Catasetums, Cycnoches, and Mormodes.—Amongst other Orchids that require a decided rest are the Catasetums, Cycnoches, and Mormodes. The majority of these plants are now fast losing their leaves, and as they turn yellow and fall off the plants should be kept quite dry at the roots. Badly ripened growths will probably require water occasionally in order to preserve them in a plump condition, but pseudo-bulbs that have been properly matured will keep fresh-looking and plump all through the resting period without needing any water. Suspend the plants close up to the roof in the East Indian house in full light. If these Catasetums and Cycnoches are rested in this house they retain their roots much longer than if placed in a cooler temperature, consequently the pseudo-bulbs remain plump for a greater length of time than those whose roots die prematurely. The Mormodes prefer a light position in the Cattleya house while at rest. Where a collection of these curious and interesting plants is grown some of the specimens will have been in flower for several months past. Even at the present time the following varieties are in bloom at Burford:—Catasetum splendens aureum, C. s. punctatissimum, C. fimbriatum, C. galeritum pachyglossum, C. Bungerothii, C. albo-roseum, C. discolor, C. labiatum, C. macrocarpum, C. intergerrimum, C. bidentatum, and C. ferox; also Mormodes buccinator Rolfei, and M. Warscewiczii.

Odontoglossums such as O. læve, O. Reichenheimii, and O. citrosmum have completed their growth. The two first named species should be afforded a sufficient quantity of water only to keep the roots alive and the pseudo-bulbs plump, but O. citrosmum requires a long dry rest; owing to the absence of moisture the pseudo-bulbs will shrivel considerably, but this will not affect the health of the plants, as they will readily plump again to their normal condition when the flowering season arrives. The best position for these Mexican Odontoglossums while at rest is one near to the roof glass of the Mexican house.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to F. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Stove and Greenhouse Climbers in Borders.—If these have not been already pruned or thinned out, all weak and worthless shoots should now be removed, retaining only those which are most vigorous and thoroughly ripened; few rather than many will afford best results. Afterwards see that the shoots to be retained are thoroughly cleansed from insects by sponging or washing before replacing them in their respective positions. Examine the roots and remove any spent soil, afterwards top dressing with a compost suitable for the particular species of plant.

Lilium longiflorum.—Plants which were potted in autumn should now have an abundance of roots, and therefore with safety could be placed in an atmospheric temperature of 55° to 60°. It is a mistake to over-force these plants in their early stages of growth. Spray the plants lightly overhead, and be watchful for green-fly, which, if permitted, would establish itself very early in the young growths. Spray once a week with a weak solution of soft soap, adding about a teaspoonful of the XL-All Insecticide. This is an excellent remedy, but fumigation with XL-All I have found to be dangerous while the plants are so young, though it can be applied with good effect when they are approaching to the flowering stage.

Begonia Gloire de Lorraine.—Plants which have been flowering for some time in an intermediate house should now have their old flowering growths shortened to half their length, and be removed to an atmospheric temperature of 55°, keeping the roots rather sparingly supplied with water until young suckers are seen coming from the base, when the remaining portion of the old flowering stems may be further shortened. Before cutting away the old stems, some of the best leaves can be taken for the purpose of propagation, if desirable, and inserted in pans or boxes in soil of a light, sandy nature. Afford them a temperature of 65° to 70°, and do not keep the atmosphere very close; otherwise damping will take place. About two inches of stem should be taken with each leaf, and these when well rooted will produce very strong plants. I prefer plants which have been raised from leaves, inasmuch as they are not so persistent in flowering in the growing season, and they have a more robust habit. It is most important to get a good batch of plants early in the season.

Caladiums.—A batch of these should now be started. The varieties of C. minus erubescens and C. argyrites are most useful in furnishing the front of stages, and if hardened a little are found useful in many forms of decoration. If placed in a moist atmosphere at a temperature of 70°, the young growths will soon appear, when the plants may be shaken out of the old soil and re-potted, first warming the new soil, which should consist of good loam, peat, and leaf mould in equal parts, with some sand and finely broken crocks to keep the compost open. Afford plenty of water to the roots as growth increases.

Sowing Seeds.—Flower seeds should be ordered at once, so as to have them for sowing immediately. Gloxineas, Begonias, and Streptocarpus, raised from early sowings, are always found useful in the autumn.

Salvias.—Those plants which are indispensable, and which have finished flowering, should now be pruned back and induced to break into growth again for the purpose of providing sufficient clean cuttings.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Early Vines in Pots.—In most large establishments grapes are required as early in the season as possible, and for this reason pot vines have to be cultivated. Those which were started in November will be in various stages of growth at the present time. Continue to syringe them when the weather is favourable until their growths are about two inches in length, each morning and again early in the afternoon so that they may become dry again before night. The atmospheric temperature of the house should be increased by about 5° at night, and 10° by day, admitting just a little air for an hour or two in the day when the weather is mild. This will strengthen the shoots very much, but it is necessary to prevent cold draughts at all times. The rooting medium should be examined carefully twice each day and water afforded as soon as it is necessary, for if the roots become too dry they will certainly suffer a check. Afford soft water which has been warmed to the same temperature as that of the atmosphere in the house, and use similar water also for syringing purposes.

At the flowering period the atmosphere of the houses should be kept a little drier, and the temperature at night be maintained as near as possible at 65°. That good old grape Black Hambro is the gardener's favourite for forcing purposes, and it is generally a free setter; at the same time, it is wise to give the rods a tap each day when the flowers are open to aid in distributing the pollen. When the roots are seen growing near to the top of the pots apply a moderate top-dressing with good turfy loam, a little guano and finely broken oyster shells. The rods should be trained at about 18 inches from the roof glass, and the laterals be tied down gradually when they have made considerable growth, for if brought down too soon they are apt to snap off at the base. The laterals will require to be stopped at the first and second joint beyond the bunch of fruit, and the sub-laterals will need almost daily attention. When the conditions of the weather are unfavourable to syringing let the paths and stages be damped down instead.

Early Permanent Vinery.—This house should be started, commencing with a temperature at night of 48° to 50°, and 53° to 55° on dull sunless days. Syringe the rods twice each day on favourable occasions. Examine the border, and if the soil appears to be at all dry, afford a copious application of tepid water to thoroughly moisten the border through its entire depth.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Pruning.—Continue the work of pruning as fast as possible in good weather. All Plum trees will be the better for being pruned at once. Trees growing against sheltered walls may be done in rough weather, and those in the open during the warmest part of the day. By a little skilful management in this way much of the work of pruning can be done quite comfortably, and if it is carried out in this manner it will be done more efficiently. When pruning Plum trees, do not hesitate to thin out the spurs, as overcrowding is one of the worst evils in fruit culture; but if the trees were carefully pruned and regulated during summer, they will not require much pruning at the present time. Keep the spurs cut well back, and if these have already become too long, let every alternate one be pruned severely, when, if the trees are healthy, they will afterwards break into growth in due course.

Tieing or Nailing.—Train the long shoots straight from the base to the apex, and when tieing or nailing be careful to leave sufficient room for the expansion of the shoots. The main branches should be tied with soft-tarred string, and the more slender branches with good matting, or be nailed with small narrow shreds as the case may be. Regulate the main branches, so that they will be an equal distance apart all over the tree. Fan training is perhaps the best system to adopt for this fruit tree.

Training Pear Trees.—Pear trees are grown in various forms, including cordons, and fan-shaped and horizontal trained specimens. Cordons can be employed where quick fruiting trees are required, and if good strong trees are planted, some returns should be obtained in the second season. If a wall or fence be less than 9 feet in height, train the cordon obliquely, as by so doing a greater length of rod will be secured. For fences of greater height, cordons may be trained in a vertical position. In tieing or nailing these, use the same methods as advised for Plum trees.

Fan-shaped Trees.—One of the advantages of fan training is that by this system the upper portion of the wall is more quickly covered. This method is also suitable for the covering of gable ends of buildings. The branches should not be placed closer together than 9 to 12 inches, and the middle or centre shoot should be vertical, while those at the base should be nearly horizontal.

The Horizontal System.—The branches of the tree to be trained in this style should be not less than three courses of bricks apart—better, rather, if four be allowed, and the first branches should be 15 inches from the ground level. Great care is necessary in pruning for the first two or three years, especially when pinching the shoots in the early summer.

Fruit Room.—Keep this structure well ventilated and clean, and the atmosphere as dry as possible. Examine the fruit carefully very frequently, as at this season many varieties are at the point of decay. All damaged and decaying specimens should be promptly removed.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Peas.—While it is too early to recommend sowing this crop outside, the present is a good time to make a large sowing indoors. Four-inch pots are the most useful for the purpose, using soil that has been stored for some time, or a very suitable compost would be that obtained from shaking out old Chrysanthemum "stools." Dibble 6 or 8 seeds deeply in each pot, and if the soil is in a moist condition at the time of sowing, no water should be afforded until germination has taken place. A cold frame will suit well if the plants are intended for planting outside, but a slightly warmer atmosphere should be afforded if they are intended to perfect a crop indoors. Dwarf growing varieties are the most suitable for this purpose, Chelsea Gem and Sutton's Green Gem being two of the best. As a successional batch use Early Giant, which is a large podded marrowfat Pea of medium height.

Cauliflowers.—Young seedling plants of these will soon grow apace, but it is an easy matter to ruin them by "coddling." Admit plenty of air to the frame when the weather is suitable. Sow a small quantity of seeds once a fortnight, and this will ensure a continuous supply. Select the small varieties, of which Magnum Bonum is a splendid type. Plants raised in the autumn, and stored in frames, will require care. Avoid keeping them in a close atmosphere, as mildew would then soon make its appearance and destroy the plants. Be careful also lest the plants should become dry at the root, and premature flowering ensue.

Potatos.—The forcing of this crop must now be taken in hand, if it is not in hand already. Good crops can be had from pot culture where frame room is scarce, but frame culture occasions the least trouble, and affords the greatest return if the room can be spared. The key-note to success is the use of well-sprouted tubers that have been carefully prepared for the purpose. Well-rotted leaf mould placed on a hot-bed to the depth of 12 inches, together with some light soil sifted from the refuse of the potting bench, are all that is necessary for the tubers. Plant them in the ordinary way, but afford them plenty of room, as more often than not the growth becomes drawn through overcrowding, and a poor crop is the result. Sharpe's Victor and Ringleader are two of the best varieties for cultivation, either in frames or pots. Give attention to the tubers intended for the main crop by exposing them to the light to enable their sprouts to become consolidated gradually. Keep these as cool as possible, without permitting frost to reach them.

Broad Beans.—Make a sowing of these on an early border out of doors, but the main sowing should be made next month. Rich soil, which has been deeply worked, is best for Beans. The Longpod varieties mature as early as broad Windsors, but the latter afford the greatest return as an early crop. A great advance has lately been made in fixing a green-seeded type. To secure an early crop of this vegetable, seeds should now be sown in a few boxes, with a view to transplanting the seedlings into frames. The Beans may be expected to be in a condition for consumption towards the end of the month of May.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

The Formal Garden.—As mentioned last week, the present is the proper time (in view of preparing the stock of the different plants required) to decide upon the summer arrangements of the beds in the flower garden. The following are a few simple arrangements which occur to me, and which could be easily adapted to suit many styles of bedding. Blue Agapanthus and Salvia patens, mixed with a groundwork of Sutton's compact azure Lobelia, is very suitable for a narrow border. A striking picture could be made in a design by planting representative beds of Mrs. Pollock or Mrs. Cox, or Flower of Spring Pelargonium, Coleus verschaffeltii, and Iresine Lindeni. A design composed of a circular bed in centre, with eight plainly shaped beds—four small beds and four larger ones—surrounding it, could be prettily bedded for autumn effect by arranging it thus:—In the centre bed Nicotiana sylvestris (white); in the two small beds on opposite sides of the design, that very early-flowering dwarf Dahlia named Sunset (red); in the other two small beds, Calceolaria amplexicaulis (yellow). Two of the larger beds could be planted with Aster Amellus (mauve), and the remaining two with the Chinese Aster, Callistephus hortensis (mauve). Very effective and pleasing combinations in colour can be had by planting beds with the following in mixture. Flower of Spring Pelargonium and Perilla nankinensis; Henry Jacoby Pelargonium and Calceolaria amplexicaulis; Lady Plymouth Pelargonium and any free flowering, blue variety of Viola; Perilla nankinensis and a dwarf flowering variety of Canna; Heliotrope and a pink flowered Pelargonium or a pink flowered Petunia, similar to the variety Lord Courtenay; Blue Lobelia, and the ordinary red Virginian Stock—the latter to be sown after the Lobelia is planted.

Carpet Bedding.—The principal thing to avoid is the perpetuation of duplicated designs. If it is desirable in certain positions to have beds in juxta-position to balance and harmonise, it can be done by a judicious employment of colours, without the need of repeating the same arrangement again and again. A free use should be made of the softer coloured plants at one's disposal, in order that the stronger colours shall not predominate. As "carpet bedding" is too complicated to attempt to describe without the help of a plan, it may suffice to enumerate some of the best plants in their colours suitable to this system of bedding. *Blue.*—Compact growing Lobelia of the pumila section, and Kleinia repens. *Yellow.*—Pyrethrum aureum, Alternanthera paronychioides aurea, Lysimachia nummularia aurea, Mesembryanthemum cordifolium variegatum, and Sedum Lydium. *Glaucous.*—Cotyledon secunda glauca, Sedum glaucum, Sempervum calcareum. *Crimson.*—Coleus Verschaffeltii, Amaranthus ruber, Iresine Lindenii, and I. Herbestii. *Orange red.*—Alternanthera paronychioids, A. p. major and A. amabilis. *White.*—Antennaria tomentosa, Santolina inana, Cineraria maritima, C. compacta, and Stachys lanata. *Carmine.*—Alternanthera amœna and A. magnifica. *Green.*—Mentha pulegium, Herniaria glabra, Tagetes signata, Sedum acre, and Sempervivum montanum.

Propagation.—Now is a good time to prepare for propagation by cuttings and seed sowing. A large quantity of light soil, with plenty of leaf mould might be sifted and placed under cover to keep it dry, and ready for use. The soil—especially the leaf mould—usually contains so much undesirable living matter, that a capital plan is to heat it, previous to storing, so as to destroy insect life and seeds. With a sheet of iron, a grating, and a few bricks, a suitable heating arrangement can easily be improvised for this purpose in any open position. Boxes, pans, and pots should be prepared and methodically arranged ready to hand. If hot beds are to be used, and are not already made, a quantity of fermenting material such as leaves, and long stable litter must be collected, and well mixed together prior to the erection of a frame. Where there is a well-heated pit or a propagating house, this is not necessary. Cuttings of such plants as Alternanthera, Iresine, named varieties of Lobelia, Tropæolum, Heliotrope, Calceolaria, Ageratum, and Pelargonium can now be made. With the exception of the Pelargonium, the best method is to insert a number of cuttings of the above-named plants, plunging them in a frame in the propagating house in a bottom heat of 75°. After affording water, let the frame be shaded during sunshine, keeping the structure closed for about a week. If Alternanthera, Iresine, and Lobelia are required in large quantities it is preferable to make a bed of soil three or four inches in depth on the hot-bed, in which to insert the cuttings. Pelargonium cuttings succeed better if inserted singly in small pots, because when subsequently shifted into pots of a larger size they suffer no check, and when required for planting out are consequently almost equal to plants that were propagated in the previous autumn.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Jan. 13	Dutch Gardeners' Society meet at Richmond, Surrey.
MONDAY	Jan. 15	Lecture at Surveyors' Institute.
WEDNESDAY,	Jan. 17	Annual Meeting Brixton, Streatham and Clapham Horticultural Society.
THURSDAY,	Jan. 18	Annual Meeting and Election of Pensioners of the Gardeners' Royal Benevolent Institution at Simpson's Restaurant, 101, Strand, London, W.C. 2.45 p.m. Linnean Society meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—36·7°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Jan.* 10 (6 P.M.): Max. 46°; Min. 39°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 11 (10 A.M.): Bar., 30·3; Temp., 39°; *Weather*—Fair and bright.

PROVINCES.—*Wednesday, Jan.* 10 (5 P.M.): Max. 45° Isle of Wight; Min. 39° E. Coast of Scotland.

SALES.

MONDAY NEXT—
1,500 Roses, Herbaceous and Hardy Plants, Liliums, Gladiolus, Azaleas and Rhododendrons, Border Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Sale of Roses, Shrubs, Lilies, &c., at Stevens' Rooms, King Street, Covent Garden.

WEDNESDAY NEXT—
Hardy Border Plants and Bulbs, Herbaceous Plants, Lilies, Begonias, Gladiolus, Carnations, &c., at 12. 3,000 Standard and ½ Standard, Dwarf and other Roses at 1 and 3. Palms and Plants, Azaleas, Rhododendrons, Aspidistras, &c., at 5. By Protheroe & Morris, at 67 and 68, Cheapside, E.C.

WEDNESDAY NEXT—
Cases Japanese Liliums, &c., also Lily-of-the-Valley, Spiræas, Gladiolus, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 3.

FRIDAY NEXT—
Imported and Established Orchids, variety, also choice Hybrids, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

The Chinese Flora.

The last part of the "Enumeration of all the plants known from China proper" and neighbouring countries has been issued lately by the Linnean Society, together with a "List of the genera and species discovered in China since the publication of the various parts of the Enumeration," from 1886 to March, 1904.

This undertaking has been on hand for nearly twenty years, the first part having been issued on May 20, 1886. The Enumeration occupies the whole of Vol. 23 of the Journal of the Linnean Society (Botany), 1886-1888. Vol. 26, published at intervals between April 30, 1889, and October 21, 1902, was likewise devoted to it, and now the 36th volume, completing the undertaking, which has been in progress since 1903, is brought to an end The list of the names of additional genera and species, not included in the main body of the work, but published elsewhere, occupies no fewer than 79 pages. These additions are incorporated in the very complete index supplied to the present volume, so that botanists have now at their disposal a complete list of the Chinese Flora, so far as known up to March, 1904, together with detailed descriptions of the previously undescribed species. Mr. Wilson's later introductions collected for Messrs. James Veitch and Sons, are thus not included; indeed, many of them are not yet determined. If botanists have had to wait, they have got something which will go far towards compensating them for the delay they have been exposed to. In the "historical" note Sir W. T. Thiselton-Dyer gives, by way of preface, a brief note of the inception and progress of the work. Mr. F. Blackwell Forbes began the list and allowed the use of his collections and notes, but circumstances soon prevented him from co-operating in the preparation of the catalogue, which was continued by Mr. Hemsley, with the assistance of various members of the staff of the Kew herbarium and others. The index alone will be of extraordinary value. It contains some 17,000 entries, and is due to the indefatigable industry of Mr. Daydon Jackson, the general secretary of the Linnean Society. The wonderful richness of Dr. Henry's collections in Western and Central China induced Messrs. Veitch, of Chelsea, to despatch Mr. E. H. Wilson to make further botanical explorations, with a view of collecting and introducing some of the many valuable and beautiful plants not previously known in our gardens. Wilson made two journeys, one in 1899 and the second in 1903. The record of his journeyings is in course of publication in these columns, and has, as we learn from our correspondents, excited much attention even in far-off Queensland. Horticulturists have also profited largely by the numerous introductions made by him to the Veitchian nurseries, many of which have been shown at meetings of the Royal Horticultural Society, including the lovely Meconopsis, a whole series of Primulas, numerous ornamental trees, etc. Several have been described and figured in our columns, as will be seen from the record of novelties of the past year now in course of publication. There are, as we know, many more to come which will excite the interest of plant-lovers and refute the impression that the supply of "new plants" is practically exhausted, and that all that systematic botanists will have to do in the future will be to revise and co-ordinate the labours of the past. In particular, we may mention that many of the recent introductions, whether of herbaceous plants, of shrubs, or of trees, will be of great value to lovers of hardy plants and trees.

The present Enumeration contains, we are told, the names of some 8,271 species, of which 4,230 are endemic, or not known to occur outside the Chinese Empire. The most moderate estimates, therefore, show that the Chinese Flora consists of not fewer than 12,000 species. The nature of the flora of Japan and the Eastern Himalaya, Assam, Burma, and Siberia will thus eventually be made clearer. Much of the surface of the country has been denuded of its forests, but here and there, especially in the extreme east, Wilson encountered tracts of virgin forest teeming with new and interesting Conifers and other subjects. Some of these may even serve to connect the remains of the still existing flora with that revealed to us by the geologist and the student of fossil plants. The gardener and the lover of hardy plants will also, as we have said, profit largely by the discoveries and introductions of Henry and of Wilson, and will have cause to appreciate the intrepidity and diligence of the collectors, and the enterprise of Messrs. Veitch.

OUR SUPPLEMENTARY ILLUSTRATION.—PETREA VOLUBILIS is a very old inhabitant of our stoves, though rarely seen outside botanic establishments, in spite of the great beauty of its flowers. It is a twining shrub with opposite, leathery leaves and conspicuous violet or purple flowers arranged in rather dense pendulous racemes. The flowers are remarkable for their tubular calyx, the five lobes of which ultimately become greatly enlarged as growth goes on and assume a violet colour. The corolla is of a deeper purple, and looks like a violet surrounded by the paler sepals. The enlarged sepals are sometimes spoken of as an epicalyx, but that is due to a misapprehension. Our illustration was taken by Mr. WORTHINGTON SMITH from an unusually fine specimen grown in the garden of Sir TREVOR LAWRENCE, Bart., the President of the Royal Horticultural Society. Mr. SMITH also represents the unusually large pollen-grains or microspores. About the same time that this specimen was received we were favoured by Sir DANIEL MORRIS with two photographs of a white variety grown in the Newcastle Plantation, Barbados, under the name of the "White Wreath," where it forms a most attractive and beautiful object. One of these photographs is reproduced in fig. 15. The Palm-leaves are those of Sabal Palmetto. The fern is Nephrodium exaltatum. The plant requires the usual treatment bestowed on stove climbers, but a watch should be kept for mealy-bug.

MR. WILLIAM MARSHALL.—Mr. W. MARSHALL will shortly enter upon his twenty-first year as chairman of the Floral Committee of the Royal Horticultural Society. In order to celebrate this event, to show their esteem for Mr. MARSHALL, and their high appreciation of the honorary services he has rendered to horticulture, the members of the Floral Committee decided on Tuesday last to entertain him at dinner on a date which has yet to be fixed. A sub-committee was appointed, consisting of Messrs. H. B. MAY, GEORGE PAUL, J. F. MCLEOD, J. HUDSON, and GEORGE GORDON (secretary) to arrange details. It has been decided that the dinner shall take place at the Hotel Windsor, and that the price of tickets shall be six shillings each. Anyone wishing to be present at this interesting function may apply for particulars to the gentlemen named above. This compliment to Mr. MARSHALL has been thoroughly well deserved.

M. MASSART.—We learn from Brussels that M. J. MASSART has been appointed director of the Institute of Botany at Brussels founded by the late Prof. ERRERA, and that he has also succeeded him as Professor of Botany in the University. The "Ethological" collections in the Botanic Gardens, to which we have from time to time alluded, were under his charge, as also was the extremely novel and interesting botanic station in the sand hills at Coxyd in Flanders, to which we devoted an article in our volume for 1904, November 19, p. 345.

PÆONIA DELAVAYI LUTEA.—The *Revue Horticole* for January 1 consecrates a coloured plate and a description of the yellow-flowered Pæony, known in our gardens as P. lutea. According to the article in question we are, in future, to speak of it as a variety of P. Delavayi. This species was first found on [near] the glacier of Li Kiang, in Yunnan, at an altitude of 3,500 metres, by the Abbé DELAVAY. It now appears that the plant is very variable in the colour of the foliage and of the petals. Some of the variations are, in the article alluded to, described by M. M. LEMOINE, who further say that it blooms in the early part

of June, thus succeeding the varieties of the Moutan Pæony, but flowering before the ordinary herbaceous Pæonies. Layering or grafting are recommended as the most successful means of propagation. Grafting is carried out in August under a bell glass.

BOTANICAL MAGAZINE.—The January number contains coloured illustrations and descriptions of the following plants:—

ASPARAGUS SPRENGERI, *Regel*, tab. 8,052.—A well-known species, which has also been called A. ternifolius. The berries are here figured. They are produced very freely, and are globular, of the size of a small pea, and of a rich crimson colour.

CYNORCHIS COMPACTA, *Reichenbach*, tab. 8,053.—A terrestrial Orchid from Natal, with solitary ovate leaves and erect spikes of whitish flowers, the three-lobed lip being slightly purple-spotted, and with a short spur. Kew.

OXALIS ADENOPHYLLA, *Gillies*, tab. 8,054.—A charming little species, with tuberous roots, tufted habit, palmately divided leaves, and rose-pink flowers. It is closely allied to O. enneaphylla. The plant was collected in Chile by Mr. ELWES, and by him presented to the Royal Gardens, Kew, where, for the present, it is grown in a cold frame, though doubtless it will prove as hardy as O. enneaphylla.

COLCHICUM CROCIFLORUM, *Regel*, tab. 8,055.—A very pretty but a very deceitful little plant, for in flower it has all the appearance of a Crocus, with pale perianth-segments, having a central purple stripe. The six stamens, however, suffice to reveal its lineage. It is a native of Turkestan, and flowered in the Alpine House at Kew. It was introduced from Kokan by Mr. C. G. VAN TUBERGEN, of Haarlem.

WITTMACKIA LINGULATA, *Mez*, tab. 8,056.—A West Indian Bromeliad, with broad, oblong, abruptly acute, finely and remotely serrulate leaves, and a loose, much-branched, many-flowered inflorescence, the individual flowers being whitish and relatively inconspicuous. The plant figured was grown in the Royal Botanic Gardens, Glasnevin.

A NEW YEAR NUMBER.—We congratulate the *Gardeners' Magazine* on the bright and attractive New Year number which it offers to its readers. In addition to appropriate letterpress there is an abundance of pictures and a calendar inserted in a pretty coloured plate of Rambling Roses.

FIG. 15.—PETREA VOLUBILIS, WHITE VARIETY, FLOWERING IN BARBADOS.
(See also Supplementary Illustration and p. 24.

THE GHENT QUINQUENNIAL.—A provisional programme for the Ghent Quinquennial to be held in 1908 has already been published. This exhibition is the sixty-ninth organised by the *Société Royale d'Agriculture et de Botanique de Gand*, and will be contemporary with the centenary of the foundation of the Society. The date proposed is from April 26th to May 3rd, 1908, and all exhibitors wishing to secure space for products which cannot be included under the sections as now arranged should make special application before June, 1906. The programme contains a preface by the president, the Comte de Kerchove de Denterghem, intimating that at the forthcoming exhibition an increased importance will be devoted to the higher branches of horticulture; to biology and other scientific aspects of the subject.

H. G. MOON.—The sixty-eighth volume of the *Garden* is dedicated to the memory of the late HENRY GEORGE MOON, of whom a good portrait is given.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Sixty-seventh Annual General Meeting of the members and subscribers of this institution will be held at "Simpson's," 101, Strand, London, on Thursday, January 18, 1906, at 2.45 p.m., for the purpose of receiving the Report of the Committee and the Accounts of the Institution (as audited) for the year 1905; electing Officers for the year 1906; and for the election of 18 pensioners on the funds. The chair will be taken by HARRY J. VEITCH, Esq., F.L.S., Treasurer and Chairman of Committee, at 2.45 o'clock. The poll will open at 3 o'clock, and close at 4 o'clock precisely, after which hour no voting papers can be received. The voting papers have been issued. Any subscriber not having received a copy should communicate with the Secretary, GEORGE J. INGRAM, 175, Victoria Street, Westminster.

JUBILEE OF A NURSERY EMPLOYEE.—The completion by Mr. L. E. THOMAS of 50 years' connection with Messrs. LANE & SONS, Berkhamsted Nurseries, was celebrated on Friday, January 5, by a dinner given by the firm at the King's Arms, Berkhamsted. A company of between 80 and 90 employees and a number of personal friends was present to testify to the general good feeling towards the guest of the evening.

LINNEAN SOCIETY.—A meeting will be held on Thursday, January 18, at 8 p.m., when the following papers will be read:—1. Mr. A. W. ALLEN, The Life-history of Margaritifera Panasesæ; 2. Mr. A. D. COTTON, F.L.S., On some Endophytic Algæ; 3. Dr. R. BROOM, Jacobson's Organ of Sphenodon.

TOO LATE FOR OUR ALMANAC.—The Harrow Horticultural Society will hold its annual exhibition on Tuesday, July 3, and the Barnsley Chrysanthemum Show is provisionally fixed for November 15 and 16.

HANDKERCHIEFS FOR THE PRINCE AND PRINCESS OF WALES.—The British Cotton-growing Association, through their President (Sir Alfred Jones), forwarded to Marlborough House recently two boxes of handkerchiefs made from West Indian cotton for their Royal Highnesses the Prince and Princess of Wales. The handkerchiefs were made from cotton grown in Barbados and St. Vincent from American Sea Island seed, which, when manufactured, has a natural gloss, and is said to be very much superior to similar cotton grown in the United States. Sir Alfred Jones has received the following acknowledgment:—

Dear Sir,—I have received to-day the two boxes containing handkerchiefs made from West Indian cotton, which the British Cotton-growing Association have been kind enough to offer for the acceptance of the Prince and Princess of Wales.

I am directed to convey to you and the members of the Association the best thanks of their Royal Highnesses for these specimens of manufactured West Indian cotton.

Their Royal Highnesses are interested to know that the cotton grown from Sea Island seed is of such superior quality, and they trust that the efforts of the Association in other parts of His Majesty's dominions may be as successful as they have been in the West India Islands.

(Sgd.) ARTHUR BIGGE.

PUBLICATIONS RECEIVED.—From the Board of Agriculture: Leaflets No. 155: *Larch Canker.*—(Dasyscypha calycina); No. 156: *Hedgerow Timber.*—*Farm and Home Year Book* for 1906. Containing articles on live stock of the farm, useful tables, lists of societies, &c.—*Report of the Botanical and Agricultural Department, Gold Coast*, for 1904. By W. H. Johnson. Two new ex-

perimental cotton farms were started, and the interest taken in Cotton, Rubber, and other crops is increasing, thus bringing more work upon the staff.—*The Animals' Friend*, January.—*Annual Report of the New Zealand Department of Agriculture*, 1905. The returns from the main products—wool, meat, butter, cheese, and Phormium fibre have been especially good. Grain-growing, however, is decreasing as it proves less remunerative than the other industries. Root crops are increasing. Good work was done at the experimental stations and the biological and horticultural department was kept busy.

SEED LIST RECEIVED.—We have received a list of fruits and seeds offered for exchange by the Botanic Garden of the University of Zurich. Applications for exchanges should be made before the middle of February to Dr. Hans Schinz, Direktor des botanischen Gartens u. Museums der Universität, Zürich, Switzerland.

THE FERNERY.

A NEW FORM OF REPRODUCTION IN FERNS.

As an entirely new form of Fern reproduction may interest many readers of the *Gardeners' Chronicle*, I append the details of my recent exhibit at the Linnean Society of a plant of Cystopteris montana which presented such a phenomenon.

In 1904 a friend sent me a normal plant of C. montana, and as it was small and the season advanced, it appeared to perish, but in the subsequent spring on turning out the pot I found a spark of life remaining, replanted it, and in time the plant established itself so far as to send up two normal fronds some 4 inches high. In July on examining it I perceived a clump of very small, almost sessile, pinnatifid fronds had formed on the caudex at the base of one of the normals, and as these were peculiarly thin and translucent it struck me that they were aposporous growths, i.e., fronds modified into a prothalloid form. With this idea I detached one and layered it. This and the undetached ones have retained their green and living character through the winter, i.e., up to the present, although the normal fronds followed the habit of the species by dying down at the end of August or beginning of September. In October, examining the culture under a lens, I detected two apogamic bulbils, each situated in the sinus or indentation which characterised the tips of the pinnatifid subdivisions, and at the time of my exhibit both these were clearly buds showing the incipient circination of rising fronds, and evidently capable of establishing themselves. We have here, consequently, not merely one, but several, unrecorded features, viz.:—

1.—A normal plant yielding aposporous prothalli; all examples so far have been varietal forms.
2.—A new species displaying this character.
3.—A normally deciduous fern producing evergreen fronds.
4.—Entire fronds of a prothalloid texture, while so far all examples of apospory have been either extensions of terminal points on large fronds or modifications of the soral growths on such.

I may add that the prothalloid fronds numbered half-a-dozen and were only about ½ inch long, with a very short stalk and three or four pinnatifid pinnæ each ending in a blunt indented tip resembling an incipient prothallus. Several others have partly risen, and the clump is firmly attached to the creeping rhizome characteristic of this Cystopteris. Furthermore, despite the number of those which have finished growth, they are all of the same size, displaying no tendency to successional enlargement as do young independent ferns. Subsequently I severed and layered two more in November, and these are perfectly healthy, and I have little doubt will follow the same course as the first, when the growing season arrives. The culture has been under quite cold conditions but under glass slips. *Chas. T. Druery, V.M.H., F.L.S.*

HORTICULTURE IN THE PUNJAB.

A common remark addressed to residents in India is, "What lovely flowers you must have in your garden out there!" and, so far as shrubs and trees suited to the climate go to make a pleasaunce, there are gardens in Calcutta and Bombay that will compare with anything of the kind in corresponding latitudes. In many places, more especially where European planters or others are settled—in the Himalayan or Suralit valleys, for example—in the Nilgiris, or in Behar, such home favourites as Roses, Heliotrope, and, where the seasons permit, Mignonette and other annuals are grown successfully; but in North-Western India, for the most part, the only gardens, as we understand the word in England, that attain more than a hand-to-mouth existence are those kept up with aid from the public funds by organised subscription.

This is due in great part to the fact that the wealthiest natives of the Punjab, for example, are only beginning to take a slight interest in scientific horticulture; while the Europeans there are necessarily, in most cases, only birds of passage. At the same time, the remarkable extremes of temperature which prevail from East Persia almost to the borders of Bengal have to be reckoned with, and are mainly answerable for the rather meagre limits of indigenous gardening and fruit-growing. The hot winds that sweep the Central Punjab from the end of April till well on in June wither all but the toughest forms of subtropical vegetation, unless water is constantly supplied; but water can be got solely from wells that are liable to fail, or from canals, which, however splendidly organised, can only give a share to every thirsty claimant in his turn. Then the rainy season may occasion floods, or it may fail altogether; and the winter, while it brings relief to such representatives of temperate floras as have struggled through the vicissitudes of the hot weather, may usher in a sweeping frost to annul the toil and care of years in the small hours of a single morning.

In such a climate, or, to speak more correctly, such a series of climates, horticulture must be often costly, commonly precarious, and, for those practically engaged in it, continually arduous.

In reviewing the operations of the Lahore Agri-Horticultural Gardens for the last year, the "Civil and Military Gazette" observes:—

"An unfavourable season greatly interfered with successful work last year; the damage done by the failure of the monsoon and the shortage of irrigation water in the summer, and by the unprecedented severity of the weather in January and February last being most serious. Nevertheless, the President of the Gardens Committee and the Punjab Government alike congratulate the superintendent, Mr. Hemsley, on the progress he has effected under adverse circumstances, and those who remember the unfavourable conditions and the state of the gardens during the year will cordially re-echo the praise given."

"The frost last winter caused severe damage to over three thousand fruit-trees, of which nearly two thousand were Mangoes. But the drought and shortage of water were responsible for much more serious loss, estimated at over 50,000 trees, cuttings, and seedlings, valued at nearly Rs.18,000."

The loss entailed on the management by drought alone, therefore, exceeded the whole annual grant which the garden receives direct from the Exchequer, as stated in the same article; but the difficulty and discouragement involved cannot be so readily expressed or estimated.

We must hope that for gardening, as for all other branches of enterprise in the "Land of the Five Rivers," a brighter cycle will follow the period of stress and calamity through which it has been passing. It is stated that the committee, acting, doubtless, largely on the skilled advice of the superintendent, have resolved on certain changes of a practical kind in the conduct of their operations. Mangoes will be reared, as hitherto, for grafts; but "no further attempts will be made to grow them for the market on a large scale."

Grapes, to which the local climate is unsuitable, will not be tried further and experiments with the Arabian Date have also been discontinued.

As what may be termed the spontaneous distribution of the Arabian Date palm shows that its cultivation cannot be carried on profitably in India proper except in the extreme south-west corner of the Punjab and in Sindh, we must attribute previous efforts to acclimatise it elsewhere to a laudable reluctance on the part of our countrymen to acknowledge themselves beaten. Of the Mango, "after its kind," there is plenty grown where it will pay, in private or in village orchards already, and those who require superior varieties find it easy nowadays to import them from Bombay, for example; but a stock of cuttings for the supply of local gardens, public and private, cannot be dispensed with; for it must be remembered that there are no independent nurseries nearer than Calcutta from which growers can obtain improved varieties. Throughout the Punjab there are practically neither nurserymen nor seedsmen, in spite of the enormous agricultural interests involved; such seedsman's business as there is being in the hands of petty market gardeners, who supply small quantities of vegetable seeds at intervals, chiefly to the members of their own community. As a means for disseminating grafted and improved varieties of shade and fruit trees, the Lahore garden has an important function to discharge, and in a country of largely commercial estates and peasant holdings it is closely associated with the Agricultural Department. At the same time, it is pleasant to note that other aims and uses of a leading public garden have received due recognition; and that the recent administration of the garden has elicited popular as well as official approbation. "Much attention," it is noted, "has been paid to the improvement of the lawns and grass borders," and the next step is to screen the "mounds" with shrubs and plants. Anyone who may have been fated to acquire a direct acquaintance with the "mounds" referred to must agree in the congratulations tendered to the committee and to the superintendent on their scheme of improvement and the advances actually made towards its accomplishment. The Lahore *Jardin des Plantes* follows a distinguished precedent in embracing a zoological department, and Mr. Hemsley's Kew experiences have been amplified with the aim of securing an effective and humane accommodation for a considerable Fauna also. *J. R. W.*

[Since the receipt of this communication the sad intelligence of the death of Mr. Oliver Hemsley has reached us. See p. 32.—ED.]

NOTICES OF BOOKS.

* THE HANDY BOOK ON PRUNING. By James Udale.

ALTHOUGH the author of this little work has nothing new to teach, the chapters dealing with the various up-to-date methods now generally employed are written in a pratical, lucid, and concise manner. To the amateur and inexperienced it will prove useful and instructive. If the illustrations had explained by means of diagrams where to pinch the shoots in summer and where to prune them in winter, it would have conveyed to the reader more than is possible by pages of text.

When dealing with Roses the author refers to individual varieties, and many mistakes may be avoided in this manner if reference be made to these chapters. The book includes instructive advice upon the pruning of flowering trees and shrubs, as it gives a tabulated number of kinds requiring such treatment at different seasons.

* Published by W. & H. Smith, Ltd., Evesham. Price 1s.

NOVELTIES OF 1905.

(Continued from page 4.)

NURSERYMEN.

Messrs. SANDER & SONS, St. Albans and Bruges, notwithstanding the vast extent of their undertaking and the varied character of their productions, still manifest their enterprise in importing good and new Orchids even now that the hybridist has introduced a competition bearing hard on the expensively-acquired imports. If we look back on the number of fine species which would have been lacking in gardens had it not been for the enterprise of Messrs. Sander, it is a source of gratification that their efforts in that direction have not ceased. Following the fine Cymbidium Parishii-Sanderæ and other first-class plants of the year before, their 1905 record includes the beautiful Cymbidium Sanderi, the new and pretty C. erythrostylum, which recently flowered at Glasnevin; Vanda Watsoni, Cœlogyne Lawrenceana, C. speciosa alba, and some other pretty species and varieties. Their efforts in raising new hybrids were rewarded with Cypripedium × Leeanum "J. Gurney Fowler," and C. × "The Baron"—two marvellous Cypripediums, of which they may well be proud; C. × G. G. Whitelegge, C. × tessellatum rubens, and a number of other Cypripediums, Cattleya Schröderæ "The Baron," C. × Iris inversa, C. Mossiæ "White Lady," C. M. Reineckiana excelsa, C. Warscewiczii "Our Queen," Odontoglossum × crispo-Harryanum "King Edward," O. × amœnum, Sander's variety; Warczewiczella discolor atrocœrulea, and others. Messrs. Sander & Sons were also "first in the field" with Cypripedium Fairrieanum.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, continue to develop grand novelties out of their well-known hybrid Cattleyas, Lælio-Cattleyas, and Brasso-Cattleyas, and their work in Odontoglossums of the last few years begins to be productive. Out of their hybrid Odontoglossums, home-raised O. × excellens and others have flowered, the two best being the beautiful O. × Smithii (Rossii rubescens × Harryano-crispum), and the elegant O. cirrosum cross named O. × Phœbe. Others which secured awards were Cattleya × Octave Doin, C. × Lord Rothschild Fairy Queen, a pretty white-petalled form of a showy and fragrant hybrid; C. × Iris His Majesty, perhaps the richest in colour in its class; C. × Germania magnifica, Brasso-Cattleya × Digbyano-Trianæi, Heaton variety; Lælio-Cattleya × luminosa Rosita, L.-C. × Issy cuprea, and many others. Messrs. Charlesworth during 1905 received a first-class certificate for the rare Cymbidium Huttoni, and rendered a service to gardeners by importing a great quantity of the fine Phalænopsis Rimestadiana, and other showy species and varieties.

Mr. H. A. TRACY, of Twickenham, secured awards for the showy Odontoglossum × loochristyense, Tracy's variety, and Cypripedium purpuratum, Tracy's variety. Messrs. HUGH LOW & Co., Enfield, for the beautiful white Lycaste Skinneri alba magnifica, the handsome Cattleya Mendeli "Cicero," and the fine rose-purple Dendrobium Phalænopsis Thundersleyense. Messrs. JAMES VEITCH & SONS showed the massive and richly-coloured Cattleya × "King of Spain," fine forms of Odontoglossum × ardentissimum, and other hybrids; and other contributions came from various raisers.

CONTINENTAL NOVELTIES.

M. CHAS. VUYLSTEKE, of Loochristy, Ghent, was well first with his grand hybrid Odontoglossums, his O. × Vuylstekeæ being a marvellous production, and his O. × amabile and variety Ixion, and the handsome O. × Lawrenceanum, worthy novelties.

M. PEETERS, of Brussels, has his hybrid Odontoglossums perfecting, and O. × Lambeauianum, and its variety exquisitum, of his production, have both been illustrated in the *Gardeners' Chronicle* in 1905. Odontonia × Lairesseæ, of M. Lairesse, is a remarkable novelty; and the Marquis de Wavrin (gr. Mr. de Geest), who has been a frequent exhibitor in England, has secured awards for several good things.

The following Novelties and rare Orchids were illustrated in *The Gardeners' Chronicle* in 1905:—

Bulbophyllum Lobbii colosseum, Supp. Sep. 2.
Cattleya Mossiæ, White Lady, July 1, p. 7.
Cattleya Schröderæ, The Baron, p. 1, Supp., June 3.
Cymbidium Huttoni, July 22, p. 63.
Cymbidium Gammieanum, Dec. 16, p. 427.
Cymbidium rhodocheilum, Supp., June 17.
Cymbidium Sanderi, Feb. 25, p. 115.
Cypripedium debile, Dec. 23, p. 442.
Cypripedium Fairrieanum, Aug. 26, p. 168.
Cypripedium Gratrixianum, Feb. 4, p. 77.
Cypripedium × Haywoodianum, Apr. 1, p. 195.
Cypripedium × Leeanum J. Gurney Fowler, Supp. Feb. 11.
Cypripedium × The Baron, Dec. 9, p. 405.
Dendrobium parcum, May 20, p. 314.
Dendrobium triflorum, Jan. 7, p. 15.
Lissochilus purpuratus, May 13, p. 290.
Odontoglossum × amabile, "Ixion," Supp., p. 2, June 3.
Odontoglossum × crispo-Harryanum, "King Edward," May 6, p. 276.
Odontoglossum crispum, Raymond Crawshay, June 17, p. 375.
Odontoglossum crispum "Solum," May 27, p. 322.
Odontoglossum × Lambeauianum, Nov. 4, p. 324.
Odontoglossum × Lambeauianum exquisitum, Dec. 23, p. 434.
Odontoglossum × Lawrenceanum, Apr. 1, p. 197.
Odontoglossum × Smithii, Dec. 16, p. 427.
Odontoglossum × Thompsonianum, May 6, p. 285.
Odontoglossum × venustulum, July 1, p. 2.
Odontoglossum × Vuylstekeæ, Nov. 25, p. 379.
Odontoglossom × Wigganianum, May 6, p. 274.
Odontonia × Lairesseæ, July 1, p. 2.
Oncidium corynephorum, Nov. 1, p. 340.
Oncidium robustissinum, July 15, p. 45.
Phalænopsis (Charlesworth's), May 4, p. 131.
Phalænopsis Schilleriana, Supp., March 11.
Sophro-Cattleya × Doris, Dec. 9, p. 412.
Stanhopea Wolteriana, Aug. 5, p. 102.
Vanda Sanderiana, Chillingham variety, Dec. 23, p. 438.
Vanda Watsoni, Feb. 25, p. 123.

(To be continued.)

LEAVES FROM MY CHINESE NOTE-BOOK.

WA-SHAN TO FULIN.

(Concluded from page 13.)

JULY 7TH.—We left our inn at 5.45 a.m.; mists were falling and the outlook was very dreary. We followed an up-and-down path, which skirts, ribbon-like, the side of the mountain and reached Malie-Hsao, altitude 7,700 feet. We continued to ascend and descend, and eventually made a precipitous descent to a torrent, and rested at a house at an altitude of 5,800 feet. Before we began the descent small bushes of the Davidia were common. This tree doubtless at one time formed a fair percentage of the forest flora. The descent was through dense scrub and coarse herbs. Amongst the latter Astilbe grandis was abundant. Hydrangea Davidii was also common. Leaving our resting place we continued to descend, and eventually we crossed a broad torrent and ascended a few hundred feet to the village of Malie at an altitude of 5,200 feet; ten miles from Tsai-erh-di. Just before crossing the torrent I discovered a Pine new to me (P. yunnanensis)—see p. 227, Sept. 23, 1905. In the bed of the stream Watercress was very abundant. On the stone walls here I collected a new Davallia, and near the bed of the stream Leycesteria formosa for the first time since leaving Yunnan.

This valley enjoys a warmer temperature than its altitude should warrant. This is evidenced by the flora. Trachycarpus excelsa, Phyllostachys mitis, Cratægus pyracantha, Alnus nepalensis, and the Loquat were quite common. Near the village we passed a grove composed entirely of Rhus semialata and R. hypoleuca, with an occasional bush of Clerodendron trichotomum; Panax ricinifolium also occurs here. Malie is quite a large village, and the people were, as usual, very filthy and inconveniently curious.

We left here at 11 a.m., glad to escape into the open country again. Rice is cultivated just outside the village. Ascending a hundred feet or so we reached the top of a ridge and got a magnificent view of the valley around Fulin, with the Tung river and two large tributary streams. The scene is one of those unexpected ones that constantly surprise the traveller in China. The mountain-slope was a mass of green of Rice and Maize, with thousands of small trees of Ligustrum lucidum around the fields, all in full flower. This mountain side is well irrigated by means of a conduit, which conducts the water from a torrent. This water turns numerous horizontal water-mills in its course, and afterwards branches off in many channels, irrigating the rice fields. After being shut up amongst rugged mountains for several days we were able to appreciate a valley scene once more. From this ridge the town of Fulin looked scarcely twelve miles away, but it proved a long twelve ere we arrived there.

The descent, at first steep, became more gradual till we approached the first large tributary stream, where it was very precipitous. In the descent we met many coolies carrying opium from the Chien-chang Valley to Omi Hsien. With them were several dealers all armed with old tower muskets, pistols, swords, and knives of various designs. They looked more like brigands than peaceful traders.

On the Ligustrum tree was plenty of white wax, looking just as good as that on the Fraxinus around Mount Omi. Indeed, this mountain side reminded one of that fertile region, and compares favourably with it. In the descent I gathered Lilum Bakerianum, but it was not common.

Crossing the broad stony stream by means of several plank bridges, we rested at a small village, altitude 2,800 feet. Indigo (Strobilanthes flaccidifolius) is sparingly cultivated here. After a steep ascent from this village, we crossed the ridge (altitude 3,500 feet), which separated us from the valley of Fulin. In this ascent, to my great delight, I gathered Scolopendrium Delavayi for the first time since leaving Yunnan in 1899.

Descending from this ridge by a precipitous path we reached the stony bed of a broad and nearly dry torrent, and in a little time arrived at the town of Fulin, altitude 2,150 feet, a large and populous place noted for its fine wheaten flour. Dogs here were more numerous and ferocious than anywhere I have been. My coolies, armed with sticks, with difficulty kept them from tearing my poor dog to pieces. My dog excited even more curiosity than I did; together we appeared to amuse and astonish the natives.

We found lodgings in a large and comfortable inn, quite away from the gaping crowd. Soon after our arrival two men came and called, bringing cards. On enquiring their pleasure, I found they were beggars, and wanted me to assist them with money. On refusing they became insolent and demanded it in the name of the Custom. I sent my card to the military official complaining. He came round immediately, bringing with him a dozen soldiers. He was in a fright, and after apologising and explaining at great length, offered to arrest and punish them if I so willed. I told him I did not wish the men to be punished, provided they did not

pester me any more. After much talk, the affair was settled amicably, and the official, his men, and the crowd went away and all was quiet once more. I think the explanation of this unusual affair is that these two men were "undesirables" stranded here, and the inhabitants were anxious to get rid of them.

My collections grew apace, and it took all hands three hours changing papers. Travelling 20 miles a day as we had been doing, and collecting every day, though very interesting, is exceptionally hard work. This day was very interesting. It is not every day we find a new Pinus. In addition to those already mentioned, the following were the most interesting plants noted to-day:—Berberis acuminata, Taxus baccata, Fraxinus platypoda, Halesia hispida Chelidonium Franchetianum, Sapindus Mukorossi, Pieris sp., Acer sp., Hydrangea pubescens, Astilbe chinensis, and Cedrela sinensis. *E. H. Wilson.*

(To be continued.)

COLONIAL NOTE.

GRENADA.

MR. W. E. BROADWAY, the late Curator of the Botanic Station, has started a large nursery of economic and ornamental plants, and is prepared to accept orders for strong, healthy plants to be delivered early in 1906, Among his list of economic plants we note the grafted Ceylon Mango, which is generally recognised as the best of the imported mangoes. We hope Mr. Broadway will be successful in his venture.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CROSS-FERTILISATION OF APPLES.—I have read with interest Mr. E. H. Bowers' notes on this subject in your last issue, and certainly the diagrams given would go far to prove the parentage of "Allington Pippin," though I fear there are no facts to substantiate the theory. Mr. Bowers gives the parentage, and even the seed parent, but I am at a loss to know from whence he obtained the information. In 1894 I paid a visit to Messrs. W. & J. Brown's nursery at Stamford, and there found this Apple growing and fruiting well. The foreman asked my advice as to the desirability of sending fruit up to the Royal Horticultural Society for certificate, and I strongly advised him to do so, the result being that it obtained a first class certificate under the name of "South Lincoln Beauty." I asked the foreman its history, which was as follows. The late Mr. Thomas Laxton raised a large number of seedling Apples, and after his death a number of these were sold by auction; some varieties of which there were a stock were sold in their entirety, and others were put in bundles and sold without any names or anything to identify them. A gentleman residing in Stamford bought one of these bundles and planted the trees in his garden. Messrs. Brown's foreman subsequently pruned this gentleman's trees for him, and being taken with the appearance of this particular Apple, and having seen the fruit, begged the prunings and worked them in Messrs. Brown's nursery, his employers knowing nothing of this until the tree fruited, when he showed them to Mr. W. Brown. I think I can trust my memory upon these points, as I am pretty keen upon these matters, and I fully intended to purchase the stock, but as we were just then removing our nurseries we had not much opportunity of taking up a new variety, and Mr. Bunyard made a better offer for it, which was accepted, and the name was subsequently changed to "Allington Pippin." The Apple will be no better or worse whatever its parentage, but those who look at these matters from a scientific point of view will like to make sure of their facts before they build upon them. I may say that I am often dubious upon the question of parentage, because I have investigated cases where the parentage given has been pure guess-work. Take for instance "Newton Wonder," which has scores of times been said to be a cross between Dumelow's Seedling and Blenheim Pippin. The man I bought it from told me he found it growing in the garden of the house when he went to live there, and that it was a chance seedling; subsequently a parentage was invented for it. The fact is that in the years gone by there were very few people who knew how to cross an Apple, and still fewer who kept any record of their crossing. Mr. Laxton most undoubtedly did both, but from what I have stated I don't think that any record kept would apply to Allington Pippin. *A. H. Pearson, Lowdham.*

THE HARDINESS OF LORD SUFFIELD APPLE (see December 30, 1905, p. 457; January 6, p. 15).—All Apples of the Codlin group, to which the variety Lord Suffield belongs, expand their leaf-buds and develop their leaves at the time of flowering, and, as generally there are only two or three blossoms to be found upon each cluster, they are sheltered by the foliage, and thus protected against frost. As regards the other varieties enumerated, a good deal of the crop is often lost as a result of the pruning. I have never seen the trees at Belvoir Castle Gardens, Grantham, but I have been into a large number of Kitchen and Fruit gardens, and, speaking generally, have invariably found the pyramid and bush trees of all varieties pruned in the same fashion and form, regardless of their habit, constitution, or fruiting qualities. I am afraid a good deal of the pruning is done by copy from Mr. So-and-So's garden more than from practical experience. Many trees I have seen appear as "pollard" trees. I have seen unpruned bush trees last year (1905) in this locality of Lane's Prince Albert, Worcester Pearmain, Cox's Orange Pippin, and others, bearing good crops. I would recommend Mr. Divers, if he has not already pruned his pyramids, and he possesses two or more trees of a variety, to leave one unpruned this year; simply cut away unsightly portions, or a branch which comes in the way of another crop or the garden path, and watch the result. To cut away all the terminal branches or growth made in one season is wrong. Nature provides that the Apple tree should make these terminal growths, which burst into leaf about the time of flowering, and these twigs of greenery make, so to speak, "break-frosts" against the trusses of bloom, and thus save the crop from destruction. When all the wood is cut away, and the branch is become a regular pollard, exposing the flowers to all dangers from frost or rains, it is little wonder the crop is lost. Of course where an abundance of young wood has been made, I would recommend shortening back, but not close down to near the base of the growth. Dealing with the varieties named, a knowledge of the character of the particular Apple is necessary to ensure success. Red Bietigheimer, for example (and I could name many others), if a crop is to be looked for, and the trees are worked on the paradise stock, should be lifted and replanted every two years. If this were done many varieties would produce more fruit than they do under present conditions. Mr. Divers has stated that his trees of Bess Pool have cropped well. I know of other late flowering varieties, including Court pendu plat, King of Tompkins' County, that yielded good crops in 1905. From appearances the earth has shifted on its axis, and thrown our seasons as they were by report 50 years ago, two months behind. We get December weather in February, frosts in May and June as in 1905. If our seasons are thus to become later year by year, in a few years what is to become of the fruit-growing industry in this country? I believe that a stock which will come into leaf later in spring than the Paradise or the Crab is required in order to retard the flowering season of the Apple. I have looked for such stock for years past in beds of seedlings, and have found a few, but the process is slow and no useful results have been obtained. I would, therefore, use the late flowering varieties, Bess Pool, Court pendu plat, for budding on the Paradise or Crab stocks, and afterwards graft the desired variety, say Cox's Orange Pippin upon Court pendu plat. For a culinary Apple I would choose a cooking Apple as the intermediary agent, and dessert kinds in the same way. I believe the late varieties would then retard the earlier flowering varieties. To obtain standards I would bud my selections on to the agent in order to run up clean straight stems, for grafting, I find, throws the subject more quickly into fruit. For espaliers, cordons, and pyramids, grafting on to the agent saves time in reaping a crop. *John Smith, care of Messrs. Keynes, Williams & Co., The Nurseries, Salisbury.*

—I have found that Lord Suffield Apple is a tender variety and requires a fertile soil and sheltered situation. Lord Grosvenor is recommended in place of it for that reason. Apple blossoms escape frost in May when protected by the foliage. This is especially the case where, as with my trees, hard pruning is avoided. Nearly all my Lord Suffield and many other varieties of Apple last year were borne on the extremities of shoots that naturally drooped and sheltered the blossoms with tufts of leaves. In many instances the Apples were in clusters of three fruits and had to be supported. That neglected Apple "Smart's Prince Arthur" was quite ornamental with its pendent shoots laden with ruddy fruits. I found the same thing occurred with "Pitmaston Duchess" Pear, of which I had several trees laden with fine fruits equal to any that I saw exhibited. These also had to be supported and in some cases thinned. My advice is to cut back some shoots for furnishing wood and leaves only and to leave others unpruned for bearing fruit. *W. Roupell, Harvey Lodge. Roupell Park, S.W.*

SOWING SEEDS OF PENTSTEMON.—When for particular purposes decided colours are required of this profuse blooming and invaluable plant, it is essential that cuttings should be taken of the desired varieties in the autumn. Where, however, they are only wanted in mixed masses in borders with other flowers or in beds by themselves much may be said for propagation by seeds There are such excellent strains, that a fine display of blooms can be depended upon. The strain of selected "pink shades" offered by one or two firms is particularly good, as in it the less pleasing purple colour is nearly if not entirely eliminated. To obtain plants for flowering at the end of June and beginning of July and continue blooming until October, seed must be sown in heat at once. In a few weeks' time the seedlings will be fit to be pricked out into boxes, in which, after they have made sturdy growth they can be placed in a cold frame to harden off, and by April they will be ready for planting out. *Hugh A. Pettigrew.*

WEATHER IN NORTH CORNWALL.—While London commenced the New Year with hard frost we in North Cornwall suffered from a deluge of rain. On Monday ·83 inch fell, and on Tuesday over 1¾ inches (1·79) fell. This is the heaviest 24 hours' rainfall of which I have any record. The previous record rainfall was 1·73 inches on November 28, 1902. During the first six days of this year our rainfall amounted to 4·35 inches. This will go far towards making up the deficit of 9 inches on last year's rainfall. *A. C. Bartlett, Pencarrow Gardens, Cornwall.*

PRUNING.—The pruning of Pear trees, etc., may be proceeded with in suitable weather. The fruit buds can be very easily distinguished, and may be thinned out if too numerous. Some varieties have the peculiarity of fruiting on the extreme end of the shoot, and in this case the operator should prune accordingly. Comte de Lamy (one of the best Pears) is one of these. The wood buds or spurs should be cut back to two eyes, as too many shoots on a tree in a limited space is a disadvantage. Long, ugly spurs may be cut right back, half of them one season, and the remaining half the next. *W. A. Cook.*

EAST LOTHIAN STOCK.—No plan for a flower garden would be complete without a place being assigned to this lovely strain of intermediate stock. It is so ornamental during the summer and autumn months, and can be used either in the formal design or in the herbaceous borders, where its colours can be easily arranged. Last year I had a formal garden entirely filled with this delightful plant, and the effect elicited admiration from all who saw it. For preference, the rose and the crimson coloured are best for massing, as they are more profuse and showy in their flowering. The purple one is inclined to be shy in blooming. Seeds should be sown now so as to raise early plants and obtain a lengthened flowering period. Sow the seeds thinly in boxes and place them in a moderate degree of heat, and when the young

plants are large enough prick them out into fresh boxes, filled with a light and rich compost. When they again become crowded, pot them up into large four-inch pots, in which as soon as they become established they can be placed in shallow cold frames. By April they will have become strong, sturdy, well-rooted plants, fit for planting out in the open ground without fear of suffering check. Treated thus, these stocks will give a display of flower from June until September. *Hugh A. Pettigrew.*

HANGING BASKETS.—Where there has been a demand for material for table decorations, tracery, etc., baskets containing Asparagus Sprengerii, A. deflexus, and other varieties will have been very much reduced by cutting. The present is a suitable time to re-basket any that need it, and if there is a necessity to increase the stock, this can now be done by division. If this is done now, the baskets will become well furnished with young growing shoots early in the season. Owing to the large demand for cut growths of A. Sprengeri, it is advisable to sow a few ripe seeds each year. Plants that were raised from seeds sown last year, if placed in baskets, will provide very useful sprays for cutting next autumn and winter. The baskets should be provided with a lining of moss. The rooting medium should be of turfy loam, leaf mould, and peat in equal portions, with a liberal addition of coarse sand. Afford manure water or other stimulants liberally, when the plants are growing freely. An atmospheric temperature of 65° will cause the plants to grow freely, but when growth is finished much less heat will suffice. *B. Cromwell.*

THE LATE HARRISON WEIR.—The death of Mr. Harrison Weir at the ripe age of 82 years is a loss to those of us who have known him well for a quarter of a century and upwards. Our friend was an enthusiastic amateur gardener and a lover of what are termed "florists' flowers," such as the Auricula, Carnation, etc., and he was frequently to be met with at the fortnightly meetings of the Royal Horticultural Society until quite recent years. At his profession as an artist he obtained world-wide fame for his inimitable drawings of natural history, birds, and poultry. As early as 1843 he exhibited an oil painting of a wild duck, and subsequently he exhibited at the Royal Academy and the Society of British Artists. He must have made thousands of drawings in black and white and many in colours, for publication in books. He was a member of the staff of the *Illustrated London News* from its inception, and was the only survivor of the original artists. His last, and certainly his greatest, work was "Our Poultry and all about them." This monumental work occupied him for the best part of twenty years. The letterpress, comprising 600,000 words, was written by him; he made nearly all the 350 black and white drawings and the 37 coloured plates. He was the originator of the first cat show, and a good judge of poultry and pigeons. He was a strenuous worker, and his relaxation was gardening. Mr. Weir was at one time a member of the Fruit Committee of R.H. Society, and had a good knowledge of all hardy fruits. His birthday was May 2, 1824, but I sometimes sent him a few Auricula plants in April as a reminder of his birthday. These were great favourites, and he especially admired the "Fancy" varieties; they appealed most strongly to his artistic eye. The Alpine varieties he planted in his garden. I have one of his letters before me which is dated May, 1903, thanking me for a few plants. He wrote:—"You have added much joy to the remnant of my life. How beautiful they are—sweet, pleasurable, and delightful. . . They are a new joy to the garden. . . My garden is coming on bravely, and my heart swells with a joy the world knows not of." His last letter to me was in October, 1904. I will make one short extract. "It is not the first time by many that you have gladdened my heart by the gift of beauty made by nature with your skill and help. I think we all might do a little more than we do to pleasure each other." I possess several of his beautiful drawings; kind gifts to me, which I greatly value. My friend was a true lover of the garden and of everything beautiful in nature. He has finished his life's work. His work was that of an earnest and true man, and we can truly say of him: "Well done, good and faithful servant." *J. Douglas*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 9.—The first meeting of the Committees in 1906 was held on Tuesday last in the Royal Horticultural Hall, Westminster. Some of the Committees were unusually well attended. The display of exhibits was satisfactory for a mid-winter exhibition, and Orchids thus early in the year claimed a large share of the space on the tables and of the interest of visitors.

The FLORAL COMMITTEE awarded medals to excellent groups of Cyclamens in pots, also of forced plants of Rhododendron molle, Hippeastrums, cut flowers of Carnations, and many other species of flowering plants, and others, but no award was recommended to any novelty shown.

The FRUIT AND VEGETABLE COMMITTEE recommended a First Class Certificate to the variety of Orange which the Floral Committee honoured at the previous meeting, and also awarded several medals to collections of fruit. A vote of condolence was sent by this Committee to the widow of the late Harrison Weir, Mr. Weir having been at one time a member.

The ORCHID COMMITTEE recommended one First Class Certificate, one Botanical Certificate, and five Awards of Merit to novelties, and on this occasion the new scheme under which Diplomas will be awarded for particular plants came into operation, the plants for the day being Lælia anceps and Calanthes.

There was no lecture delivered at this meeting.

Floral Committee.

Present: W. Marshall, Esq., chairman, and Messrs. C. T. Druery, H. B. May, W. Cuthbertson, Geo. Nicholson, Jas. Walker, G. Reuthe, C. J. Salter, W. J. James, E. Molyneux, J. F. McLeod, W. Howe, R. W. Wallace, J. Jennings, C. Blick, H. J. Cutbush, Geo. Gordon, Chas. Dixon, C. E. Pearson, C. E. Shea, E. H. Jenkins, W. J. James, R. Hooper Pearson, Geo. Paul, J. Green, E. Mawley, Jas. Hudson, J. W. Barr, and E. T. Cook.

The Rev. H. BUCKSTON, Sutton Hall, Etwall, Derby (gr. Mr. A. Shambrook) exhibited a large array of Cyclamen plants of exceptional merit. Among the extensive collection white-flowering varieties predominated, but flowers of red, salmon, pink, and other shades were included, and all alike were sturdy in growth, clean in appearance, and of floriferous habit. (Silver Gilt Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, staged a group of Cyclamen of the variety "Low's Salmon," a strain of very pleasing shade of colour and of neat, compact habit; also a number of Cyclamen flowers in vases, including examples with fimbriated and others with papillose petals. In addition to the Cyclamen, Messrs. Low contributed some excellent vases of Carnations. (Bronze Flora Medal.)

Mr. K. DROST, Kew Nurseries, Richmond, Surrey, put up a showy group of forced flowering plants. The display was arranged in a semi-circular manner, the centre being occupied by a grand batch of Hippeastrums (Amaryllis), which, although flowering so early in the season, were shown remarkably well, some of the inflorescences carrying as many as four, five, and even six flowers. Azalea mollis found a place in the foreground, which was completed by a band of Tulips. On either flank were banks of Lilac, flowering profusely, and rosettes of Tulips, the whole being intermixed with suitable foliage plants, and having as a background tall specimen Palms. (Silver Gilt Banksian Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, displayed a batch of rare and interesting Ferns, all of which were well grown and staged with good taste. We noticed Asplenium scandens, A. elegantulum, Doryopteris nobilis, Drynaria quercifolia, Polypodium irioides ramo-cristata, etc. (Silver Flora Medal.)

Messrs. W. PAUL & SON, Waltham Cross, Herts, showed nice specimen plants of Camellias, and a few baskets of cut flowers of the same. A feature was a number of well-trained examples of the old alba plena, still one of the best of the double white flowering type. Single varieties were also prominent, and among these Vesta (red), Minerva (salmon pink), Jupiter (a large flower, with a prominent ring of stamens, set off to advantage against the large red petals) were noticed. Other good things were Lady Hume's Blush and Reine des Fleurs, the latter almost unsurpassable for freedom of growth and flowering. (Silver Flora Medal.)

Lord ALDENHAM, Aldenham House, Elstree (gr. Mr. E. Beckett), staged a miscellaneous collection of flowering plants, including Begonias, Mignonette, Cyclamen, Carnations, Cypripediums, Euphorbia Jacquiniæflora, and a batch of seedling Streptocarpi, the progeny of the variety Royal Blue. The seedling Streptocarpi included many promising plants; some had flowers of the darkest shade of blue, and others were of a lighter colour, while the range of form and size was almost as wide as that of the shade of colouring. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a number of sturdily-grown plants of Primulas. The colour and size of the "pips" indicated the excellence of the strain.

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, put up a large batch of Coleus thrysoideus, whose tall, pyramidal spikes of blue flowers were very noticeable. Intermingled in the group were plants of Jacobinia coccinea, and at either end were specimens of the Witch-hazel—Hamamelis arborea. Messrs. VEITCH also showed a Begonia, named Copper King, the bronzy-coloured flowers being responsible for the name, and plants of the Japanese long-fruited Orange. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, showed berried and ornamental foliage plants, Erica codonodes, Daphne indica rubra, Garrya elliptica, Nerium splendens variegatum, &c.

Messrs. JOHN WATERER & SONS, Bagshot, Surrey, staged a number of ornamental Conifers, such as Cedrus atlantica glauca, Juniperus japonica aurea, Cupressus Lawsoniana erecta viridis, Irish Yews (Taxus baccata hibernica), gold and silver forms of Juniperus Sabina, &c.

Messrs. JOHN PEED & SONS, West Norwood, London, S.E., showed an extensive collection of Alpine and rock garden plants. We noticed Primula denticulata, Lachenalia pendula, and coloured Primroses in flower. (Bronze Banksian Medal.)

The Misses HOPKINS, Mere, Knutsford, Cheshire, displayed a small collection of Alpine plants—coloured Primroses, Christmas Roses, Hepaticas, Gentiana acaulis, &c.

Messrs. BARR & SONS, King Street, Covent Garden, W.C., had bowls containing Hellebores and vases of Iris unguicularis.

Messrs. THOS. S. WARE, Ltd., Feltham, Middlesex, showed several species of bulbous Irises, I. histrioides, I. alata, &c., a batch of Primula obconica, plants of Cheiranthus kewensis, pans of Alpine plants, and winter-flowering Carnations. (Bronze Banksian Medal.)

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, displayed a charming group of cut flowers of Carnations of popular and choice varieties. A few pot plants were included in the display. (Silver Flora Medal.)

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury Park, Acton (gr. Mr. George Reynolds), exhibited three bush-trained plants of Jasminum primulinum that were perfect pictures of beauty, the long, graceful, arching shoots being crowded with their beautiful Primrose-like flowers. (Silver Flora Medal.)

H. J. ELWES, Esq., Colesbourne, Cheltenham, presented two interesting plants—Veltheimia glauca, with Lachenalia-like inflorescences, and the curious Massonia pustulata, a Liliaceous plant, with broad, pustulate adpressed leaves, and a rosette of flowers arising from the plant's centre. (See *Bot. Mag.*, t. 642.)

Sir. ED. LODER, Bart., Leonardslee, Horsham (gr. Mr. W. A. Cook), showed a remarkable plant of Sarracenia purpurea, just as lifted from the open ground, and being about 2 feet across. It is rarely such a specimen as Sir EDWARD LODER'S plant can be seen in the open air, and it was awarded a Silver Banksian Medal, with a Cultural Commendation to the cultivator.

Mr. JAMES O'BRIEN, Marian, Harrow-on-the-Hill, showed a dozen inflorescences from a plant of Cyrtanthus lutescens, the plant having been continuously in flower for a period of six weeks.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (Hon. Sec.), Dr. Hans Goldschmidt (invited), De B. Crawshay, N. C. Cookson, J. Douglas, F. Wellesley, W. Cobb, R. G. Thwaites, W. H. White, F. W. Ashton, G. F. Moore, H. Ballantine, A. A. McBean, H. G. Morris, H. A. Tracy, H. J. Chapman, J. W. Odell, J. Wilson Potter, W. H. Young, W. Boxall, H. Little, W. A. Bilney, and Harry J. Veitch.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), was awarded a Silver Flora Medal for an excellent group, in which good Cypripedium × Maudiæ, varieties of C. insigne, two batches of the orange-coloured Lælio-Cattleya × Charlesworthii, scarlet Sophronitis, varieties of Lælia anceps, and a grand specimen of Lycaste × Balliæ, for which a Cultural Commendation was given, were noted.

Messrs. SANDER & SONS, St. Albans, secured a Silver Flora Medal for a good group rich in Cypripediums. C. × The Marchioness (Almos × Leeanum), C. × The Duchess (insigne Bohnhoffianum × aureum), and the fine C. × Earl of Tankerville being novelties. Also included were 20 varieties of Cypripedium insigne, Lælia × Finckeniana alba, Maxillaria elegantula, hybrid Epipendrums, &c.

Messrs. JAS. CYPHER & SONS, Cheltenham, were awarded a Silver Flora Medal for a very fine and well-staged group made up of the best forms of Lælia anceps, Cypripedium × Leeanum giganteum, with sixteen blooms; the distinct C. × Leeanum, Cypher's variety; the large C. × Charlesianum, Cypher's variety; C. × Arthurianum, with 25 flowers, and other good Cypripediums; Odontoglossums crispum, Hallii, and Adrianæ; Masdevallia Schroderiana, M. Heathii, &c.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), showed an effective group, in the centre of which was a large pan of the pretty yellow Oncidium cheirophorum. With it were good Calanthes, Odontoglossums, Cypripedium × Chameleon with large flowers having striped yellow and brown petals, and other Cypripediums. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, staged a group in which were Vanda Amesiana, Bulbophyllum Dearei, a fine Dendrobium heterocarpum, Cypripedium villosum auriferum, and other Cypripediums; Lælia albida, Masdevallias, &c. (Silver Banksian Medal.)

Messrs. STANLEY & Co., Southgate, arranged a group of Cattleyas, Odontoglossums, &c., in which were noted Cattleya Trianæi alba and a good-coloured form of the species with purple feather on the petals; Odontoglossum × Loochristiense, O. crispum, various Masdevallias, Lælia anceps Amesiana; Cypripediums, &c. (Silver Banksian Medal.)

M. CHAS. VUYLSTEKE, Loochristi, Ghent, showed a small group of excellent hybrid Odontoglossums, including two O. × ardentissimum, three O. × Loochristiense, O. × amabile, O. × Vuylstekei, and others. (Silver Banksian Medal.)

Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. H. White), showed a fine yellow Mormodes, and a singular Orchid resembling Schlimia.

FRANCIS WELLESLEY, Esq., Westfield (gr. Mr. Hopkins), showed the large Cypripedium × Ville de Paris with four flowers, the neat white Cattleya Trianæi Wellesleyæ with six blooms, the elegant Cypripedium × Bella, Westfield variety, C. × Memoria Jerninghamiæ, C. × Tracyanum, and others.

A. L. WIGAN, Esq., Forest Park, Windsor, showed Cypripedium × Joyce.

J. GURNEY FOWLER, Esq., South Woodford (gr. Mr. Davis), showed four varieties of Cypripedium × aureum; C. × Mrs. Wm. Mostyn, Chadwar variety, C. × Milo, Cobb's variety, and C. × Actæus Langleyense.

NORMAN C. COOKSON, Esq. (gr. Mr. H. J. Chapman), showed Cattleya × Chapmani (Hardyana, Oakwood variety, × Trianæi).

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. Day), showed Cypripedium × Niobe superbum, C. × Nellie Goodson, and Lælio-Cattleya × Mrs. Ernest Bourdas, a bright, rosy-purple flower.

Messrs. WILLIAM BULL & SONS, Chelsea, showed Sophro-Cattleya × Doris, recently illustrated in *The Gardeners' Chronicle*, with a pretty, reddish-yellow coloured flower, and two other hybrids.

HARRY D. HEADLAND, Esq., Balham, sent Cypripedium × Headlandianum (Lathamianum × Memoria Moensii).

H. J. ELWES, Esq., Colesborne Park, showed a fine plant of Pleione humilis and Habenaria Bonatea.

AWARDS.

FIRST CLASS CERTIFICATE.

Cypripedium × *Alcibiades magnificum* (Leeanum giganteum × Mons. de Curte), from Major G. L. HOLFORD, Westonbirt (gr. Mr. Alexander). A truly magnificent specimen; flowers very large, and of fine substance. The large dorsal sepal is white, with an emerald green base, and dotted lines of purple; petals and lip yellow, tinged and marked with purple-brown.

AWARDS OF MERIT.

Catasetum splendens punctatissimum, from Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. H. White). A fine and distinct form of the natural hybrids of C. macrocarpum × C. pileatum. Lip fleshy, bright yellow. Sepals and petals whitish, densely spotted with purple.

Cypripedium × *Bella*, Westfield variety (vexillarium × philippinense), from FRANCIS WELLESLEY, Esq. (gr. Mr. Hopkins). A graceful and floriferous hybrid, with numerous flowers, arranged like those of C. philippinense, but of the rose tints of C. vexillarium. Cut spikes of the lighter typical form were also shown.

Lælio-Cattleya × *Helena*, Westfield variety (L. cinnabarina × C. Schilleriana), from FRANCIS WELLESLEY, Esq. A tall-growing hybrid, with distinct orange-coloured flowers having a purple-veined labellum.

Brasso-Cattleya × *Pyrrha* (B. glauca × C. labiata), from Messrs. JAS. VEITCH & SONS, Chelsea. Flower large, fragrant, and firm in substance, bright rose colour; plant dwarf.

Cypripedium × *Earl of Tankerville* (exul × nitens, Sanders' variety), from Messrs. SANDER & SONS. A charming and distinct hybrid, with well-formed flower of very thick substance. Dorsal sepal white with a small emerald-green base, the lower part bearing heavy chocolate-purple blotches, and the middle area large rose-purple spots; the broad petals and lip honey-yellow, marked with light reddish-purple and brown.

BOTANICAL CERTIFICATE.

Brassavola glauca, from H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. Day). This is a well-known, white-flowered, fragrant species.

DIPLOMA COMPETITION.

This was the first event of the year under the new rules designed to bring out the best of new or already shown hybrids and species. Coloured varieties of Lælia anceps, and species and hybrids of Calanthe were set down for the day. With these plants were arranged all the Society's paintings bearing on the subjects, and thus an instructive opportunity for comparison was given.

Major G. L. HOLFORD, DE B. CRAWSHAY, Esq., FRANCIS WELLESLEY, Esq., Messrs. MCBEAN and others showed good forms of Lælia anceps, the L. a Schroderæ, and especially the fine varieties of it named Raymond Crawshay, Lionel Crawshay, and Theodora, which were far the best.

In Calanthes NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), staged a very fine group of the beautiful hybrids, principally raised at Oakwood, and ranging in colour from white to bright blood-red, that tint being reached in C. × Chapmani, the richest in colour and brightest in tint of any known Calanthe. Other good specimens were C. × atrorubens, C. × Sedeni lactea, C. × Phoebe, C. × Sibyl, C. × Victoria, C. × Bryan, C. × Wm. Murray, &c. JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. W. P. Bound), also staged a fine and varied group of C. vestita varieties, C. × Sandhurstiana, C. × Veitchii varieties, C. × Alpha, &c.

AWARDS.

Hybrids.—Calanthe × *Harrisii* (First Diploma), from NORMAN C. COOKSON, Esq.; the best white. First shown by Messrs. Jas. Veitch and Sons, 1895.

Calanthe × *Veitchii* (Second Diploma), finely shown by JEREMIAH COLMAN, Esq., and still the best for general cultivation in its section on account of its strong constitution and bright rose-pink flowers.

Species.—Calanthe vestita nigro-oculata gigantea (First Diploma), from NORMAN C. COOKSON, Esq. A very strong grower, with large white flowers with reddish crimson eye.

Fruit and Vegetable Committee.

Present: Jas. Cheal, Esq., in the chair, and Messrs. W. Bates, S. Mortimer, Alex. Dean, J. McIndoe, Geo. Kelf, H. Markham, Ed. Beckett, Jno. Lyne, F. Q. Lane, J. Willard, H. Parr, Chas. Foster, Owen Thomas, and W. Poupart.

The principal exhibit brought before the Fruit and Vegetable Committee was a magnificent collection, embracing over 100 varieties of Apples and Pears, shown by Messrs. GEORGE BUNYARD & Co., Maidstone, Kent. All the specimens were in fine condition, being large, plump, and highly coloured. As a selection of the more prominent varieties shown we may mention Bismarck, Belle du Bois (very large handsome fruits), Barnack Beauty, Cox's Orange Pippin, Wealthy, Pomme de Neige (small, handsome, highly-coloured fruits), Twenty Ounce, King of Tompkin's County, Newton Wonder (fruits coloured to a high degree), Striped Beefing, Blenheim Pippin, Belle de Boskoop (rough, russety fruits, with good dessert appearance), Christmas Pearmain, Cornish Gilliflower, and Brabant Bellefleur. Among Pears were good fruits of Ramillies, Verulam, and Uvedale St Germain, one fruit of the latter variety weighing 2¾lb. (Hogg Memorial Medal.)

Sir E. G. LODER, Bart., Leonardslee, Horsham (gr. Mr. W. A. Cook), displayed a collection of Apples and Pears, many from standard trained trees. We noticed good dishes of Duchesse de Nemours, Beurré de Nemours, and Olivier de Serres Pears. (Silver Banksian Medal.)

W. SHUTER, Esq., 22, Belsize Grove, Hampstead, N.W. (gr. Mr. J. Armstrong), displayed five stands of Black Alicante Grapes. The bunches, although small, had been well kept, the bloom especially being well preserved. (Silver Banksian Medal.)

Messrs. GEO. MASSEY & SONS, Spalding, Lincolnshire, staged a good collection of Potato tubers in 33 varieties.

Two dishes of Mushrooms shown by Lord ALDENHAM, Aldenham House, Elstree (gr. Mr. E. Beckett), being of nice appearance, were awarded a Cultured Commendation.

Varieties of Apples were shown by Messrs. CROSS & SON, Wisbech, and other exhibitors.

FIRST CLASS CERTIFICATE.

Citrus japonica fructu elliptico. This is the decorative Orange which received an Award of Merit from the Floral Committee at the previous meeting (See our issue for Dec. 23rd, p. 446.)

THE HORTICULTURAL CLUB.

JANUARY 9.—The last meeting of the members of this club before the annual dinner, which will take place on February 14 next, was held on the above date in the club room at the Hotel Windsor, Westminster. The subject for discussion was "British and Foreign Parks—A Comparison," and Mr. Jordan, Superintendent of the Royal Parks in London, read an exceedingly interesting paper. Mr. Jordan gave some details of the principal parks and gardens in Paris, including the famous garden at Versailles, which belong to the State; also the Bois de Boulogne, Champs Elysées, and other open spaces which are managed by the City of Paris Parks Department. The management of these latter parks was described as first-rate, and the glasshouses for purposes of propagation and for the protection of tender plants all that could be desired. These and other necessaries were provided for the department at a cost of £100,000. Turning to Brussels, Mr. Jordan said that the parks there were scarcely so interesting, and remarked of the Botanic Gardens that they were patronised by the near residents as a pleasure ground pure and simple, but the Garden contains some very valuable and rare plants. Laeken was referred to in greater detail, and a tribute was paid to the enthusiasm King Leopold has always shown for gardening. Mr. Jordan admired the methods of planting the grounds, for good breadths of different species were planted in groups, and such shrubs as Magnolias and others are thus exceedingly effective. In Vienna the parks are well kept, but all of them are not free from a rather low form of entertainment. The boulevards are very fine, and Roses succeed particularly well in the gardens. After a few remarks about Buda-Pesth, Mr. Jordan described Berlin as the cleanest and best city he had visited. There was neither abuse nor destruction of public property there, and, as a park superintendent, the lecturer feelingly attributed this excellent state of things to the Berlin populace having been taught unusually good discipline when they were children. There were no notice boards and no boundaries needed! Further remarks were made upon Potsdam, the Palm Garden at Frankfort-on-the-Main and the wonderful carpet bedding there; also on the gardens at Cologne, &c. Mr. Jordan having visited all the places mentioned, was able to offer some criticism on the various foreign parks from the point of view of a specialist who has had wide experience.

The second part of the paper dealt with the parks in this country. It was pointed out that in London the Royal Parks, under the management of the Commissioners of H.M. Works, numbered 21, and comprised nearly 6,000 acres. Those under the City Corporation, including Epping Forest, amounted to over 6,000 acres; the London County Council had 95 parks, which, together, comprise about 4,000 acres. Including these and a few belonging to other authorities, there are in London 224 parks, which include 17,956 acres. Interesting particulars were related of Greenwich, Hyde, and the Green Parks, and of the alterations that have lately been made in the Green Park; also of tree life in the parks, showing that the Elm is longer lived in London than is the Oak. The magnificent parks and gardens in Edinburgh were referred to, and then Mr. Jordan proceeded to point out some of the contrasts between English parks and those to be seen abroad, in the course of which he lamented the fact that Roses will not succeed well in London, and also that fogs were destructive of some of the best work that is done in the parks; but, on the contrary, the grass in the London parks is always green, and of very much better colour, and it wears better than any lawn grass that is cultivated abroad. A note was sounded as to the danger, as well as the benefit, that may possibly arise from following a good lead, and we gathered that Mr. Jordan very properly considers that it would be a pity if efforts were made to make the Vienna or any foreign and London parks after the same pattern. We need variety even in our parks at home, and, as Mr. Jordan pointed out, an authority when it obtains possession of a piece of land should not endeavour to follow some model, but rather to make the best of the natural features of the site, and thus impart to the place an effect that will be different from other places of a similar character. Credit was given to the L.C.C. for having done this in some of the London parks. In the subsequent discussion, remarks were made by Messrs Assbee, C. T. Druery, Geo. Monro, W. Marshall, White, Simpson, and H. J. Veitch (chairman), &c. Mr. Veitch said Vienna was much the finest city he has seen, and described the shores of the Bosphorus, near Constantinople, in the highest terms of appreciation. The effect to be seen there when the Judas trees (Cercis siliquastrum) are in flower is indescribably good.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 21, 1905.—There was a moderate display of plants at the meeting on the above date.

G. W. LAW-SCHOFIELD, Esq. (gr. Mr. Shill) staged a group of Cypripediums, for which a silver medal was awarded. Cypripedium × Thompsoni was shown in very good form. Awards of merit were granted for Cypripedium × Thalia, Schofield's variety, C. × Stottianum, a hybrid between C. × Lathamianum × C. insigne var. Sanderæ, and C. aureum var. Cyrus superbum.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Cypher) exhibited a splendid Cypripedium × Leeanum var. Gratrixæ. (First class certificate.)

R. ASHWORTH, Esq., Newchurch (gr. Mr. Pidsley) obtained a first class certificate for Cypripedium × bingleyense var. "Œneas."

Mr. A. J. KEELING, Bradford, obtained an award of merit for Cypripedium insigne var. confusa, and a bronze medal was awarded for his group.

O. O. WRIGLEY, Esq., Bury (gr. Mr. Rogers) exhibited a distinct form of C. insigne named Clinkaberryanum. (Award of merit.)

Messrs. CHARLESWORTH and Co., Bradford, staged a bright group of hybrids. (Silver medal.)

Votes of thanks were passed to Messrs. Sander & Sons, Mr. J. Robson, Mr. D. McLeod, and Mr. H. H. Clegg for exhibits. *P. W.*

SOCIETE FRANCAISE D'HORTICULTURE DE LONDRES.

JANUARY 6.—At the Café Royal, Regent Street, the members and friends of the above society celebrated its seventeenth anniversary. Mr. John Harrison, of Leicester, occupied the chair, and the company was almost as numerous as last year, and comprised Messrs. Thomas Bevan, A. Taylor, Harman Payne, representing the N.C.S., Geo. Coleman, Foster, J. Collingridge, D. Ingamells, of Covent Garden, Otto Hiehle, Brian Wynne, Tucker, Cochrane (of Hurst and Sons), Gaskill (of Cooper, Taber, and Co.), Munson and Cornant (of Carter and Co.), Torkildsen, Cuthush, Duckham, of New York, and many other well-known representatives of the horticultural trade in its various branches.

The Chairman proposed the health of the President of the French Republic, which was followed by the singing of the "Marseillaise." Next came that of "The King," and afterwards a verse of "God Save the King" was sung.

The toast of the evening was that of "La Société Française d'Horticulture de Londres." In proposing this, the Chairman dwelt upon the fact that the society had now existed for 17 years and was really a practical form of the entente cordiale long before the good understanding generally known by that name existed. It was interesting to see such a society make such progress as it had done, for, beginning with only 12 members, it now numbered no fewer than 600. He hoped it would continue to flourish and continue to receive the support of the leading horticulturists in all countries. He welcomed there to-night one from Tokio. He was pleased to see so many young Frenchmen present and also some young Englishmen who had lived in France. He himself had occasion to visit that country at times, and was always received in a kindly way. If there was anything he felt jealous of it was the French climate. Seeing so many young men present, he would offer a little advice, and it would be for them all, whether English or French, to lead steady, honourable lives, to be honest in all their dealings, and to see to it that their word could always be relied on. In ordinary business matters there was no need to give themselves away, but they should be truthful and honourable. The toast was then proposed amid much enthusiasm, coupled with the name of Mr. George Schneider.

Mr. GEORGE SCHNEIDER, in reply, said their chairman was a man well known and greatly esteemed. He was the head of a large firm in Leicester, and was eminently qualified for the position he occupied that evening. They were all grateful to him for the good advice he had given and for coming among them to preside over the meeting. So far as the society was concerned, it had not been quite so successful last year as it had been in former years, conditions of trade being somewhat less favourable. He then gave various statistics concerning the society, its members, literary and financial condition, and explained that they were in a large degree indebted to many of their English friends. He would ask them to drink to the prosperity of English horticulture and to their English friends and supporters.

Mr. HARMAN PAYNE replied, saying that if they had so many friends it was because the society, by its enlightened policy, had deserved it. There had long existed a bond of sympathy between them and the society he represented. The National Chrysanthemum Society and these two societies had laid the foundation-stone of the entente cordiale horticole as it existed to-day. Their prosperity was due in a large measure to their president, who, with the members of the bureau, had made the society what it was. He asked them to raise their glasses and drink to the Bureau of the Society.

M. VERBOONEN proposed the English Horticultural Press, to which Mr. B. Wynne replied. Mr. T. Bevan proposed a vote of thanks to the chairman. During the evening it was announced that several new honorary members had added their names to the list—viz., Messrs. Witty, Johnstone, Hill, Hooper, J. Collingridge, J. Foster, etc., and that donations of a guinea each had been forwarded by Messrs. Ouvrard, Cutbush, and Messrs. Howcroft and Watkins.

Music and recitations enlivened the proceedings, Messrs. Schneider, Tucker, Gaskill, Taylor, and Verboonen being among the principal performers. A presentation consisting of cutlery in a case was made to Mr. Schneider by the young members of the society for his interest in their welfare.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JANUARY 8.—The usual monthly committee meeting was held at the Royal Horticultural Hall, Vincent Square, Westminster, S.W., on the above date, Mr. T. Winter in the chair. Fourteen new members were elected, and one nominated. Six members were reported on the sick fund. The amount paid out for sickness since the last meeting was £22 19s. Messrs. W. Gunner and T. H. Puzey were elected to audit the society's accounts for the past year.

Obituary.

HARRISON WEIR.—Not unexpected, but none the less to be lamented, was the death, as briefly announced in our last issue, of this well-known artist on the 3rd inst. To many of our readers he was personally known, to a vastly greater number his name was familiar as the illustrator and author of countless books and papers on natural history subjects, particularly birds. His sympathies were broad. He was genial to all, and to his associates "a fellow of infinite jest, of most excellent fancy." To those who knew him intimately his loss will, therefore, be a severe one. He was born at Lewes in 1824. Like many another boy he was a naturalist in his early youth—self taught and untrained. The preface to a delightful little book of his, entitled "Every day in the Country," contains an illustration showing Harrison with his brother Jenner, as little lads, roaming hand-in-hand together through the woods and admiring the gambols of a squirrel on a branch overhead. Jenner Weir, we may add, who died some few years since, became a well-known entomologist, and was a member of the Scientific Committee of the Royal Horticultural Society. Harrison was apprenticed to Baxter, one of the originators of colour-printing, but soon betook himself to painting, and attracted public attention by his careful and, so to speak, sympathetic representations of birds and animals. He became an exhibitor at the Royal Academy and other kindred societies, but it was as an illustrator of books, newspapers and other periodicals that he attained the widest celebrity. He was one of the first to join the artistic staff of the *Illustrated London News*. This was, of course, before the days of the camera and of "half-tone" blocks. It is beyond the power of computation to estimate the many thousands of persons to whom he afforded delight and instruction in this way. He was a most industrious and prolific artist. But art did not exhaust his sympathies; he was an authority on Pigeons and on Poultry—his latest book entitled "Our Poultry," a work of life-long research and observation, will be the standard text-book for many a year to come. His services as a judge were constantly in request, and he did his best to counteract the inanities of the exhibition-table and to substitute a more reasonable and useful standard of merit. He was the founder of the Cat Show and laid down the rules for judging the domestic pet. His little book on the Cat is remembered for its delightful representations of the several breeds of this animal, and the likenesses they suggested to some of his friends.

THE LATE HARRISON WEIR.

To us he was best known as an enthusiastic gardener and lover of florists' flowers. He practised "wild gardening" before the name was invented. He found beauty in the meanest weed. Did such a plant appear in his borders, he did not uproot it, but let it display its foliage and its flowers in such a way that the visitor was often surprised at the elegance of form in what before he had considered as an unsightly intruder. But Harrison Weir's tastes were more catholic, and in his garden at Brenchley, at Sevenoaks, and, lately, at Appledore, he showed his artistic instinct in the selection and arrangement of his plants, and in his appreciation of

subtle harmonies of colour in his flowers. He studied, too, the utilitarian side of things. Like his friend R. D. Blackmore, he was an ardent pomologist, as well as a connoisseur in Potatos. In these matters the extent of his knowledge was sometimes only imperfectly appreciated by his fellows, simply because he looked at things from a different point of view from that adopted by the specialist and the professional cultivator.

In addition to all these occupations he found time for journalism. He was a frequent writer in the *Field*, and at one time edited a provincial weekly journal with much ability. To our own columns he was an occasional contributor, and drawings from his pencil have from time to time found a place in our pages. The portrait we are enabled to give shows that if he was a keen critic when occasion demanded it, his judgment was always tempered with such kindliness and good nature that, while we know he made many friends, it is difficult to conceive that he could have had any enemies.

OLIVER TIETJENS HEMSLEY.—We regret to record the death of this promising young Kewite, which took place at Lahore on January 6 last. The deceased was the only son of Mr. W. Botting Hemsley, F.R.S., the Keeper of the Herbarium, Royal Botanic Gardens, Kew. He was born in February, 1876, was educated at Dr. White's School, at Turnham Green, and at King's College School, London. When he was 17 years of age, in 1893, he entered the service of the Royal Gardens, Kew, and worked in several departments. As a young gardener he earned the goodwill and respect

THE LATE OLIVER TIETJENS HEMSLEY.

of all his chiefs, and the results of his application to study was apparent when he gained the highest number of marks in several of the courses of lectures, Chemistry, Physics, Economic Botany, &c. He left Kew in 1898 to work at the Government Cinchona Factory at Mungpoo in September, 1898. In 1902 he was at Delhi where he had much work in preparing for the Durbar. An attack of fever caused him to be invalided for some months, but in October of the same year he was put in charge of the Government Gardens and Zoological Gardens at Lahore. The official reports prove him to have been an energetic and successful superintendent, the new works and improvements undertaken by him being spoken of most highly. A couple of hours after the receipt, by his parents, of the cable-message announcing the death of their son the Indian mail was delivered and a characteristic letter from him was received in which he cheerily wrote about his work and intentions in spite of the fever from which he was then suffering. Mr. O. T. Hemsley leaves a widow and one daughter only seven months old.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending January 6, 1906: –

1906. December 31 to January 6.	Temperature of the Air. At 9 A.M. Dry Bulb.	Wet Bulb.	Day. Highest.	Night. Lowest.	Lowest Temperature on Grass.	Temperature of the Soil at 9 A.M. At 1-foot deep.	At 2-foot deep.	At 4-foot deep.	Rainfall.	Sunshine. hr.	min.
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.		
Means	41	40	47	38	35	41	42	44	Tot 1·14	—	26

THE WEATHER IN WEST HERTS.

A very warm, wet and windy week.—On each day the weather continued warm for the time of year, both during the daytime and at night. On the warmest day the temperature in the thermometer screen rose to 53 degrees, and on two nights the exposed thermometer did not fall lower than 40 degrees—the former being 12 degrees, and the latter 13 degrees, higher than their respective averages for January. The ground temperatures have consequently risen, and are now about 3 degrees higher than is seasonable, both at one and two feet deep. Rain has fallen on all but one day since the year began, and to the total depth of two inches, which is only half an inch short of the average quantity for the whole month. During the same nine days nine gallons of rainwater have come through each of the percolation gauges, which are a yard square. The sun shone on an average for 1¾ hours a day, or for about a quarter of an hour a day longer than is usual at this season. On each of the last six days the maximum velocity of the wind has been in excess of the average. The windiest day was the 6th, when for the twelve hours ending 9 p.m. the mean velocity amounted to 21 miles an hour. In the windiest hour 26 miles was recorded—direction W.S.-W. It is now over twelve months since the wind has been in any hour as high as this. The mean amount of moisture in the air at 3 p.m. was 3 per cent. less than is seasonable for that hour. The Winter Aconite first showed an open flower in my garden on the 7th, which is twelve days earlier than its average date in the same spot for the previous 17 years, and, with two exceptions, earlier than in any of those years. *E. M., Berkhamsted, January* 10, 1906.

OUR ALMANAC NUMBER.—Such was the demand for our last issue, that although a larger number than usual was printed, our publisher soon found himself unable to comply with the demand. Means are being taken, as far as possible, to supply the deficiency.

ANSWERS TO CORRESPONDENTS.

AMERICAN AND COLONIAL GARDENING PAPERS: *A. C. Cornhill.* America: *The Florists' Exchange*, 2-8, Duane Street, New York; *The Weekly Florists' Review*, 520, Caxton Buildings, 334, Dearborn Street, Chicago; *Horticulture*, 11, Hamilton Place, Boston, Mass. Australia: *The Sydney Mail*, Pitt and Hunter Streets, Sydney; *Garden and Field*, Adelaide, South Australia.

BOOKS: *M. & S.* There is no book that fulfils your requirements. You must consult separate works for the information on the propagation of fruit trees, hardy flowering plants, trees and shrubs, &c., &c.

CARNATION LEAVES SPOTTED: *E. M.* The spotting is the result of the fungus Helminthosporium. Burn the diseased leaves and afterwards spray the plants occasionally with a weak solution of permanganate of potash.

CARNATIONS: *D. & Co.* The plants are attacked by the Carnation maggot—Hylemia nigrescens—a small, yellowish-white grub that is hatched from an egg laid on or in the leaf. The maggot works its way down under the outer skin of the leaf until it finds its way into the shoot, where, eating out the very centre of the stem, it eventually kills it. No dressings or solutions are efficacious in dealing with the pest, and it must be destroyed by piercing the body with a sharp, narrow-pointed knife, or with a stout pin. The work of the pest is mainly observable in young plants such as layers and seedlings, and after the plant has attained a moderate age it appears to enjoy a comparative immunity from attack.

CINERARIAS: *Puzzled.* We are unable to give an opinion as to the cause of the failure, not having seen the plants. The degree of atmospheric heat mentioned (50°) is quite sufficient. Have you applied water in excess to the roots of the plants? Examine the leaves for insect pests.

COLEUS THYRSOIDEUS: *G. W.* The injury to the leaves is probably the result of a check sustained by the plant. This may have been caused either by a low temperature, excessive moisture, cold draughts, or from fumigating too strongly. We have also seen these plants suffer badly from the effects of fog.

CUCUMBER: *F. K.* The Cucumber, like the Melon, is a fruit. It is not used for dessert purposes, but that has nothing to do with the question. Rhubarb though used as a fruit is not a fruit, but the petiole (leaf stalk) of an herbaceous flowering perennial plant.—*A Constant Reader.* Instead of fresh lime it would be better to get some old mortar rubble, or, failing this, slaked lime.

CURRANT SHOOTS: *W. R.* The shoots are infested with the Currant-bud mite. The best practice will be to take away and burn the bushes which are most affected. Cut the infested shoots from the remaining bushes, and rake away the surface soil from under the bushes, so far as this can be done without damaging the roots. Afterwards top dress the roots with fresh soil. A correspondent recommended on page 330, May 21, 1905, an application of quassia and soft soap as a remedy, applied at intervals during June and July.

MARKET GARDENERS' SOCIETY: *Protection.* Apply to the Nursery and Seed Trades' Association, Ltd. Address the Secretary, Mr. W. J. Worrell, 30, Wood Street, Cheapside, London.

MESEMBRYANTHEMUMS: *R.M.C.L., Nice,* Old mortar rubble is a very valuable material for these plants when cultivated in pots. In mixing a compost you might have one-third of this material.

NAMES OF PLANTS: *A. W.S., Basingstoke.* The Editor cannot undertake to name Carnations nor, any florists' flowers. These should be sent to a nurseryman who makes a speciality of the particular flower you wish to have named.—*R. H.* Calanthe vestita luteo-oculata.—*G. F. T.* Cypripedium × Dauthieri viride. It is a variable form often giving purple-tinted flowers together with those like yours.—*W. S.* 1, Lastrea aristata variegata; 2, Aspidium trifoliatum; 3, Asplenium alatum; 4, Cyrtomium Fortunei; 5, Blechnum occidentale; 6, Polypodium Phyllitidis.—*W. T.* Probably Jacaranda mimosifolia.

NOTICE TO LEAVE: *Weekly Reader.* You have not given sufficient particulars, but assuming that you fill the situation of under garden, we think that in the circumstances a fortnight's notice either way should suffice.

PEAR: *Sir J. T. R.* Leon Leclerc de Laval.—*J. B., Bucks.* 1, Wilson's Prolific; 2, Adam's Pearmain; 3, not recognised, send earlier next season; 4 and 5, Cox's Orange Pippin.

TWIN VIOLETS: *T. H.* The abnormal condition has been caused by the fusion of the two flower stalks, a not uncommon occurrence in flowers, though we do not remember having seen it before in the case of Violets.

VINES FAILING: *H. W.* We suspect the trouble arises from the unsuitable condition of the borders, and the Vines themselves appear to be of considerable age. Fungus is present on the roots, but this probably appeared after the roots had perished. The better plan will be to renew the borders and plant afresh. You can remodel a portion of the border this season, and complete the operation next or even the following year, and thus ensure a portion of your crop. Meantime you could furnish the vacant space with pot-vines, which produce good results if given suitable treatment.

DALKEITH.

(See figs. 18 & 19; also Supplementary Illustration.)

THE present gardens attached to Dalkeith Palace, near Edinburgh, were made during the years intervening between 1840 and 1845 by Charles McIntosh, who was commissioned to do this work by the fifth Duke of Buccleuch, father of the present Duke. The gardens soon became famous, partly because they were then amongst the largest and most up-to-date in the kingdom, but chiefly owing to McIntosh having written one of the largest and most expensive books on gardening in the English language; a book which contained many illustrations, obtained from the new gardens, and much matter connected with them. Gardening, however, at that period of the nineteenth century was being practised at many private residences over the country by young men of superior intellect, and when the end of the decade 1850 to 1860 was reached, the standard of gardening that was common from 1840 to 1850 had been excelled in every direction,

At about 1850 William Thomson was brought from Wrotham Park, Hertfordshire, to succeed McIntosh as head-gardener at Dalkeith, where he remained until 1870. Thomson had shown considerable ability at Wrotham Park, particularly in the culture of Vines, and he soon won for the Dalkeith gardens not merely national, but European repute. This was accomplished by a complete revolution in practice, particularly in vine culture, for Thomson's treatment of vines and his subsequent book embodying the details of that treatment became the standard on which the vastly increased number of cultivators have since based their practice.

The requirements of such an establishment as that of the Duke of Buccleuch are unusually extensive, and the gardens at Dalkeith are therefore of large size, although of less extent than those attached to the Duke's residence at Drumlanrig. The kitchen garden, devoted to the growth of fruit and vegetables, is an area of 12 acres, and the ground occupied by the greenhouses four acres. There are also contained inside the garden walls several acres of flower borders, and a large collection of exotic trees and shrubs. During the period from 1860 to 1870, the gardens were in a better state of cultivation, and were maintained more perfectly, than had ever been the case previously. Dalkeith was then particularly celebrated for its extensive and effectively arranged flower borders, an unusually good collection of Heaths, a large collection of Orchids, a fine collection of specimen stove and greenhouse plants, and its extensive fruit houses, containing large quantities of Pineapples, Grapes, Peaches, &c.

In the decade between 1870 and 1880, agricultural depression set in, and landowners having suffered considerably from depreciation in rents reduced the labour bill in their gardens to one-fourth of the former expenditure in some cases and one-half in others. Since the year 1880 only two-thirds of the number of men have been employed in Dalkeith gardens that were engaged formerly.

Malcolm Dunn succeeded William Thomson as gardener in 1871. Dunn was an enthusiast in the cultivation of hardy fruits, and he formed, at Dalkeith, one of the best collections of all out-door fruits in this country. He was equally enthusiastic in Arboriculture, and planted a large number of exotic trees and shrubs. He completed, only a few days before his death, a most efficient system of heating all the glasshouses in the gardens from one centre. The system resulted in a saving of one-half of the fuel that was used formerly, and it has been copied on a large scale in the King's gardens and in other important establishments. Dunn died in 1899, and was succeeded by Mr. James Whytock, who had been gardener to Earl Fitzwilliam for 21 years at Coollattin in Ireland. Mr. Whytock is keeping up the reputation of this fine place and is generally respected by his brother gardeners.

The illustrations in the present issue have been reproduced from photographs taken in September last. At that period of the year the flower borders at Dalkeith are a feature that excites the admiration of all visitors to the gardens. In the first place, they are abundant, and the long stretches of colour produce an effect which is more imposing than can be obtained from less extensive planting. But in addition to the borders being numerous and of unusual size, they are planted in the best manner and with the most suitable plants for producing the effect which is sought, and the plants grow so vigorously and flower so profusely that the visitor is soon impressed with the skilful management to which they are subjected. Begonias are employed unsparingly; there are many thousands of the tuberous-rooted and fibrous-rooted sections raised annually. They enter into almost all of the floral arrangements and they are equally effective everywhere. In the Supplementary Illustration is shown a view of a formal flower-garden 400 feet in length, which of its kind is one of the most effec-

FIG. 18.—VIEW IN DALKEITH PALACE GARDENS, SHOWING GARDENER'S HOUSE IN THE DISTANCE.

tive possible. The small circular beds in the centre of the design were last season planted with a pink-flowered zonal Pelargonium, and the scroll that surrounds each bed contained blue Lobelias. The scalloped margin was planted with tuberous-rooted Begonias and had an edging of fibrous-rooted varieties just inside the box edging. All the intervening space between the beds is kept quite white with a covering of shell. If the visitor were to stand at the end of this flower border shown in the illustration he would see some fine specimens of conifers and other trees on the near lawn, and beyond them on his left a boundary wall which divides this part of the pleasure ground from the park further east. Against this wall, and in the border at its foot on the west side, is a very choice and interesting collection of flowering and other species of shrubs, many of which we were on a former occasion surprised to find succeeding so well

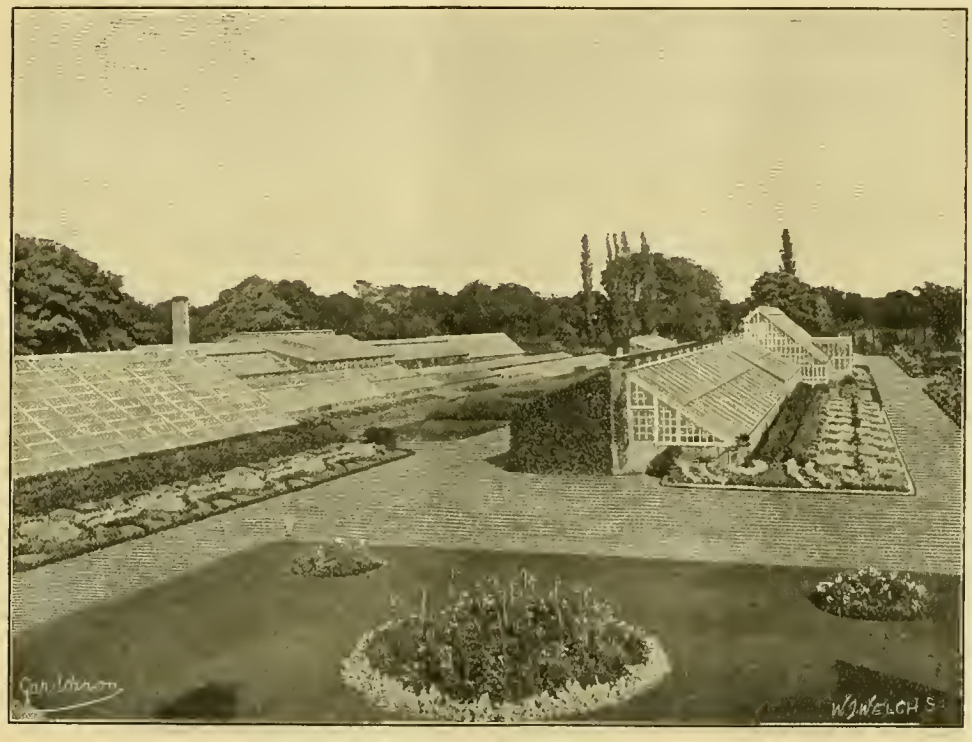

FIG. 19.—VIEW IN THE GARDENS AT DALKEITH PALACE, SHOWING HOW THE GLASS HOUSES ARE SURROUNDED WITH FLOWER BORDERS.

in this locality, even though afforded such shelter. The wall shown to the west of the flower garden is utilised for the cultivation of fruit trees. The illustration at fig. 18 shows a broad gravelled path, terminated by Mr. Whytock's residence, which is seen in the distance. On the right hand side is one of the ranges of glass houses, and the border in front of those houses and that on the other side of the path were a perfect blaze of floral colour. The wide border on the left hand side of the picture is 400 feet long, and affords sufficient space for the planting of Dahlias and other large growing plants, in the scheme of mixed bedding. Last season the bold patches of rich blue colour afforded by the very old garden plant Salvia patens were much admired, and the species appeared to us to be growing with greater vigour than is usually the case. In the opposite border—also 400 feet long—there was also a considerable variety of plants, and included were numberless Violas, which flower so much more freely and longer than they are capable of doing in southern gardens, unless extraordinary treatment is given them. A favourite Viola at Dalkeith is one named "Bluebell," having blue flowers and a habit of blooming over a very long period. A view of some of the other houses, which it will be seen are of various forms and sizes, is afforded in fig. 19, and again the striking feature of Dalkeith, namely, its flower borders, is brought into prominence. Almost every glass house is partly surrounded by them, and they are also a conspicuous adornment of the kitchen garden. Those shown in the illustration under notice, being of less width than some of the others, are planted with dwarfer growing plants, which in some instances assume the appearance of true, carpet-bedding.

Mr. Pettigrew in the last issue (see p. 28), wrote on the merits of the East Lothian Stock and we can fully agree with his appreciation of the plant, having seen the display of its varieties in the Dalkeith gardens. Last season one of the broad paths which cross the kitchen garden had a line of this stock on either side, and we have rarely seen plants growing and flowering so freely and well. A length equal to 1,200 feet of kitchen garden border was decorated with these Stocks. A similar path which crosses this one at the centre was flanked with lines of Chinese Asters.

THE GLASS HOUSES.

It was generally conceded by the visitors to these gardens last autumn that the vines were looking better than for many years past, and there were excellent crops of ripe Grapes, including the varieties Muscat of Alexandria, Sprotboro' Muscat, Trebbiano, Appley Towers, White Tokay, Lady Hutt, Golden Queen, Gros Colmar, Mrs. Pince, Black Alicante, and others. Those of Mrs. Pince and Muscat of Alexandria were perhaps the most remarkable for their unusual weight and good colour. The Sprotboro' Muscat, though regarded by some gardeners as the same as Muscat of Alexandria, is found at Dalkeith to "set" its flowers well in an atmosphere of a lower temperature than is necessary for the better-known variety. In an article by the present writer in these pages on February 1, 1902, p. 82, were given the dimensions of the New Vinery built in 1901 by McKenzie & Moncur, and other particulars relating to the system of glazing by which the panes overlap each other a little at the ends, so that there is ⅛ inch of space between them, the lower one passing under the higher one. There is therefore no "drip" and the air admitted from the top of the house in small quantities is beneficial to the vines. The Grapes, as we saw them in September last, afforded quite sufficient evidence of the good effect of the system. We may add that this Vinery of Teak wood is 75 feet in length, 20 feet in width, and 20 feet in height.

The numerous Peach houses, Plum houses, Fig houses, also those containing Tomatos, Cucumbers, and other crops, of which mention may be made of the excellent collection of fruiting Pines, all bore the appearance of good management, the trees and plants being in a vigorous growing condition and bearing good crops, in the instances where the fruit still remained to be gathered. Such a collection of Pines as is cultivated at Dalkeith can only be seen in very few gardens at the present day, but in connection therewith it should be remembered that in few districts can coal—that expensive requisite—be purchased so cheaply as in that neighbourhood. Strawberry plants are forced in large numbers, and of the varieties that known as Scarlet Queen is the favourite.

In the plant houses we had occasion to admire the well-grown Codiæums (Crotons) and other fine foliage plants, Pelargoniums, Calanthes (very large pseudo-bulbs that ere this have doubtless produced a fine display of flowers), Dendrobiums (which are given moderately cool treatment at Dalkeith), Chrysanthemums, Carnations, tree, border and Souvenir de la Malmaison types; Oncidium varicosum, of which a large number of plants were flowering unusually well, and other species which we must forbear to enumerate.

We might have referred more fully to the well-managed kitchen garden, to the extraordinary collection of fruit trees, the rose-covered trellised walk, the trellis being probably a century and a half old, the magnificent hedge of Scots Roses 100 yards in length, supposed to have been planted by MacIntosh, conspicuous specimens of trees and shrubs in the pleasure grounds, and to the aged oaks in the part of the old Caledonian forest which is included in the pleasure grounds. But our note is already long, and some of these omitted details were published in the article already referred to, whilst a description of the varieties of Scots Roses in the hedge was printed in the *Gardeners' Chronicle*, July 16, 1898, p. 41.

VEGETABLES.

VENETIAN CHICORY.

THE *Revue Horticole* recently published a coloured figure of the leaves of this variety of broad-leaved Endive, which is remarkable for its diversity of colours, ranging from yellow to red, in dots, stripes, blotches, or in self-colours. In winter all the leaves become of a reddish-purple hue. It appears that the variety is largely used in Italy, and demands no special care.

PRODIGIOUS "CUTTINGS" OF ELM.

Three years ago, when making some alteration in the garden here I had occasion to remove a large Elm tree, and selected some of its timber for use in making arches for supporting roses. In the following spring five of the posts or uprights started into growth. Little attention, however, was paid to that circumstance, as I had previously seen green stakes when inserted into the ground directly after being cut, show signs of life and then die away; but, to my surprise, in the following spring three of the posts again commenced to grow, and I then came to the conclusion they had made roots. The matter was brought to the notice of my employer, Mr. N. F. Stapylton, and he suggested that it might be considered sufficiently interesting for recording in the *Chronicle*. Not feeling quite sure, however, that they had rooted I waited for a further length of time to see what would be the result. During 1905 the post in the photograph [see fig. 20] with the figure of myself standing near to it, has made growths of three feet in length. The other two have not made so much headway, but are decidedly flourishing. I think, therefore, there can be no doubt but that the posts

Fig. 20.—Elm branches which have rooted

have made roots. The trunks measure respectively, at two feet from the ground, 15, 22 and 23 inches in circumference. The cause of their growing may be the mild, damp atmosphere of Devonshire and the drizzling, wet summers of 1903 and 1904. *W. Foote, The Gardens, Redworth, Totnes.*

KEW NOTES.

Jasminum Maingayi, Clarke.

A tropical species that was discovered by Dr. A. C. Maingay in Penang many years ago, but which has not yet found its way into general cultivation. The plant now in flower was obtained from Messrs. F. Sander & Co., of St. Albans, in 1900, and flowered in the Water-Lily house at Kew in the following year, being then figured in the *Botanical Magazine* (*tab.* 7,823), since which time many plants have been distributed from Kew, especially to foreign botanical gardens.

The plant in the Lily-house is a large one, carrying a profusion of flower-heads; it is planted out in a border, and this appears to be the ideal treatment for producing a mass of growth and flowers

J. Maingayi belongs to the simple-leaved section of the genus; its habit of growth is that of a slender scandent shrub, the branches are short and wiry, nearly all being terminated by a many-flowered head of white flowers, measuring about 3 inches in diameter. The leaves are of very deep green colour, of a hard, horny texture, ovate-acuminate, and entire on the margins. The corolla tube is 1 inch in length, and the limb rather more than an inch in diameter; the number of segments varies from 7 to 10, though usually there are 8.

This is a useful species as a pillar-plant for an intermediate-house, or stove, the flowering period being so prolonged; the new plant has been growing and flowering since July last. *W. H.*

Solanum giganteum.

The genus Solanum is a very large and varied one, some 750 to 1,000 species having been described. Introduced as long ago as 1792 from India, the plant under notice is a very bold and handsome plant for the adornment of large greenhouses and conservatories, also for use in sub-tropical gardening. Several plants 4 feet to 5 feet in height are flowering in No. 4 greenhouse in 8-inch pots. The flowers are of pale blue colour, small, terminal in a compound cyme, branches developing later immediately below the cyme. It is said to grow to a height of from 16 feet to 20 feet in its native country, with a stem as thick as a man's arm. It can be propagated by seeds or cuttings. For sub-tropical bedding sow the seeds in autumn or early in January, growing the plants on in an intermediate house. It is figured in the *Botanical Magazine*, tab. 1,921, where its native country is stated to be the Cape of Good Hope, but this is evidently an error. The *Index Kewensis* gives it as India.

Hippeastrums (Amaryllis).

One of, if not the brightest patch in No. 4 on the last Sunday in the old year was a small group of five Hippeastrums, carrying in all about 20 fully expanded flowers. The bulbs were started into growth in the second week in November. Four of the five plants had light-coloured flowers, two of them seedlings flowering for the first time. The Kew strain of Hippeastrums have previously been conspicuous for the fine rich red hybrids of the "Sir William" type. More recently attention has been paid to the lighter forms, as well as the still further development of the shades of red.

Rhododendron præcox.

This hybrid Rhododendron, the result of a cross made by Mr. Isaac Davies, of Ormskirk, in 1860, from a cross between R. ciliatum and R. dauricum, is a gem for flowering early under glass. With only a little forcing it can be brought into flower by Christmas. A number of large plants in pots are covered with rosy-purple flowers in No. 4 greenhouse. Grown in these pots for three years, they are placed in a warm greenhouse after flowering to make their growth. During this period applications of manure water, especially cow-manure, are beneficial. In June they are placed in the open air. Planted out in the beds or borders, a good show of flower can be obtained for a year or two in large houses, but unless the position is especially favourable they do not continue to flower so freely year after year as those in pots. Plenty of sun and air are necessary for the ripening of the growths, and for developing the flower-buds for the following year. It flowers so early when planted outside that unless the plants are in a very sheltered position, they are injured by spring frosts in the London districts and farther north. *A. O.*

FORESTRY.

CLIMATE AND FORESTRY.

The comparative merits of the climates of the British Isles and of the Continent (Belgium, France and Germany) constitute a complicated question, which could only be solved by a long series of observations made under similar conditions as to soil. For trees growing in forest masses no reliable data are forthcoming. We have, however, many measurements of isolated trees which afford a fair criterion. Tree growth depends, for a given species, on soil and climate; and of climate the most important features are a heavy rainfall and the absence of cold drying winds in winter. *A priori* in most parts of the British Isles there exists a climate eminently favourable to tree growth. The influence of rainfall on height-growth is well seen in the natural forests of Douglas, this species attaining a great height in the moist maritime region of Oregon, Washington and British Columbia, and gradually becoming smaller in size as its distribution is traced inland. Abies concolor attain 250 feet in height on the Californian Sierras, whereas in the dry interior of the continent it only reaches 125 feet.

Certain species, of course, will not grow well, or even fail to grow at all, in England, either because they do not receive enough heat in autumn to ripen their wood, or else they put forth their shoots too soon in spring, and in both cases are retarded by frosts. Such species are, however, of no importance as forest trees.

Mr. Elwes and myself have collected during the past two or three years an array of facts relating to tree growth, and I am justified in asserting that the growth of many species here equals, or excels, that on the Continent. The following trees, for example, to give a short list, succeed in our climate, make rapid growth, and attain a great height. Amongst Conifers, Scots Pine, Larch, Douglas Fir, Menzies Spruce, Common Silver Fir, Austrian and Corsican Pines; amongst hardwoods, Oak, Beech, Ash, Sycamore, Alder, Black Italian (?) Poplar. These are all useful trees.

With regard to plantations I may adduce an interesting comparison. In Argyllshire, on poor soil, rocky and originally covered with heather, Douglas Fir has made in 23 years, over a considerable area, an average height of 58 feet. This is precisely its record in Germany, according to Schwellech, on an experimental plot where the soil was certainly superior in quality to that of the Argyllshire plantation. We have many similar

instances of magnificent growth in plantations of other species.

People may raise objections to afforestation on the economic side; but so far as climate is concerned, I am convinced that it is certainly in our favour. This is the opinion of all the Continental foresters with whom I have talked on the subject. *Augustine Henry.*

THE MAKING OF ORCHARDS.—I.

ANOTHER planting season is with us, and there are no doubt many who at the present time are contemplating the formation of an orchard, either for the purpose of supplying private needs or with a view to obtaining profit. Fruit-growing is undoubtedly a pleasant occupation for those who can afford to sink the necessary capital and take some risks as to the results, but it may be anything but the easy means of obtaining a living that many have suggested it to be. About such an occupation, which depends so largely upon circumstances of climate, soil, situation, and last, but not least, personal ability to undertake a business of the kind, there is always a very large element of speculation, and he who embarks upon it with an idea that it is a simple calling, not requiring a considerable amount of knowledge, is doomed to disappointment and pecuniary loss. Even those possessed of a certain amount of common sense and learning in this particular branch of horticulture have time and again failed to make it pay for various reasons, sometimes through faults of their own, but only too frequently owing to causes over which they had no control. For all that there is not the slightest doubt that many of these causes of failure are attributable to lack of foresight in the first place, chiefly as regards the situation selected for the orchard. It is not good enough in these days, when everything must be of the best if it is to hold its own, to allow anything to be left to chance, and the man who contemplates growing fruit for profit must choose the most suitable situation he can find for his venture. But besides this he must, having decided on his spot, take careful consideration of the kind of trees best suited to his soil and his purpose, for to grow the best crop of Apples, Plums or Pears, of a kind which the market does not want, is just so much time and money wasted. On the other hand, it is useless to attempt to grow popular market varieties on a soil that will not grow them to perfection, for one's trees must bear passably well and be capable of producing quality as well as quantity, if good prices are to be realised. The would-be fruit grower must therefore bear these essential points in mind when selecting his trees and be guided by the opinions of those who have had experience in these matters. A thoroughly reliable nurseryman can generally give the desired information as to which kinds of fruit trees will do well on a particular soil, but one must be careful to go to one who has some reputation as a learned man in these matters, and not to him who will palm off on the unsuspecting purchaser those varieties of which he—the seller—has most in his nursery, and of which he is naturally most anxious to dispose. A better plan, though it is not always feasible, is to enquire in the neighbourhood of one's prospective orchard which varieties of trees thrive best in the locality, and form one's own opinion on the matter. It is not always possible to obtain the names of these local trees, whose labels have probably been lost long ago, but if samples of the fruit and the leaves of the trees can be obtained, any good nurseryman can tell the names of the variety.

The ground and the trees selected (it depends, of course, upon the length of the purchaser's purse as to what age the latter are when he buys them), the next step is the planting. This operation is as important as the selection of soil and varieties, yet it is perhaps the most carelessly carried out of any of the early steps of orchard making. The old plan, which one regrets to see is still observed by the ignorant in all parts of the country, consisted simply of digging a hole and dumping the unfortunate tree therein. It did not matter in the least whether the soil was deep or shallow, wet or dry, clean or full of weeds; nor was any variation made in the size of the holes according to the space required by the roots of the tree. These were twisted round and jammed in in any fashion, the sour soil was thrown in upon them just as it was, and the whole well stamped in with the heavy foot of the planter. And subsequently the owner, waiting in fond expectation for a crop that never came, wondered why his trees did not thrive, and why so many of them, after a year or two's struggle with a cruel fate, gave it up and died Nowadays, fortunately, we know rather better than that—at least, there are some who do—although the "tree-dumper" is by no means extinct nor likely to be for a long time to come.

The orchard planter is generally in too great a hurry to get his trees into the soil, with the result that the proper preparation of the ground is not attended to as it should be. This cleaning and breaking up of the soil ready for the trees is one of the most important steps towards the ultimate success of one's labours, for if the ground is not thoroughly clean to begin with it is almost impossible to get it into proper order afterwards. Added to this, work of this nature amongst a lot of trees is always more difficult and more expensive than it would have been before they were planted. To get the ground properly cultivated, horse tackle will be necessary, and a horse or two with harrow or hoe attached cannot be said to be conducive to the welfare of the trees. The horse, indeed, is best kept out of the orchard after the trees are once planted, for never mind how careful the man or men in charge of him may be, it will be almost impossible to prevent some injury to bark and branches. It will be far better to postpone one's planting till the following season if need be than to put the trees into a piece of land only partially ready for their reception. The summer is usually the best time to clean the ground, as it then is a comparatively easy matter to get rid of weeds, but it is of course possible to clean the land at other seasons of the year

FIG. 21.—A LIVING "POST" AT TOTNES, DEVON.
(For text see p. 35.)

in the absence of excessive rain or hard frost. The ground that is to be planted will in any case be all the better if it can be left fallow in a rough state for a season before it is wanted, but it is not actually essential that this mode of procedure should be adopted except in cases where the land is very foul. A field that has been regularly cropped with corn or roots is practically ready for planting so soon as it has had the plough over it twice, followed by the harrow, but it is more often than not that the field selected for the orchard is laid down to grass. Such a crop is about the worst possible to go before fruit trees, though no doubt it will surprise many to be told so. There is an idea deeply ingrained in the mind of nearly every Englishman that an orchard should consist of trees planted in grass, but never was there a greater mistake committed. Not only is grass the worst possible crop to associate with young fruit trees when planted, but it is also one of the worst possible crops, even when entirely broken up, to precede fruit trees. Pasture land is full of all sorts of injurious insects, which have for years bred and multiplied without disturbance, and unless the grass crop can be thoroughly and entirely broken up and the land repeatedly cultivated for at least two seasons before the trees are planted, an orchard should never be contemplated in such a situation. Meadow land is all very well under trees when they have attained a vigorous growth of 10 or 15 years, during which time the grass must be kept a long way back from the roots of the trees, but under such circumstances a meadow is not particularly useful and the cost of keeping the grass from encroaching on the cleared spaces around the trees is so great as to be well nigh impracticable. It is really much better not to plant in meadow land at all, but, if it must be done, then there must be a clearing round each tree from the very beginning and the clear space must be enlarged every year as the roots of the trees spread outwards. The admission of sheep or cattle to eat down the grass between the trees is impossible unless one goes to the great expense of wiring in each stem in the case of high standards or of the whole tree in the case of pyramids or bush fruit. Such expense as that cannot be contemplated, and the only possible use of the grass will be as hay. Here we are faced with another difficulty, for to mow and cart the hay, horse-tackle will probably be necessary, and damage will be done to the trees unless they are planted at ridiculously wide intervals. It will, therefore, be seen that the association of fruit trees with meadow land is a mistake from every point of view, unless indeed the idea of the planter is picturesqueness rather than a crop of fruit. Even this effect will not be obtained unless the grass is kept well away from the trees for the first few years of their growth, for, failing that, the trees will never grow out at all, and many of them, probably the majority, will die. Scores of such instances are to be seen in all parts of the country, and the writer has in his mind's eye at the moment a couple of orchards in Sussex, planted respectively 12 and 15 years ago, both of which are practical illustrations of the folly of planting fruit trees in meadow land. In both instances about 30 per cent. of the trees died within the first five years after planting, and none of them in all these years has made more than three feet of growth in any direction. Half of them are cankered and diseased, and the few bushels of fruit that they have produced could never command a sale. They have been a dead failure all round, and after involving their owners in a loss of several hundred pounds, they are not worth cutting down for firewood. *East Sussex.*

(To be continued.)

NOTICES OF BOOKS.

NEW CREATIONS IN PLANT LIFE. An Authoritative Account of the Life and Work of Luther Burbank. By W. S. Harwood. (Macmillan & Co.)

THIS book, written by one who appreciates most highly both Mr. Burbank himself and his work, contains a general account of his methods and results, with descriptions of several of his most remarkable "creations." The first chapter is devoted to "The Man," giving a brief account of his early life and struggles, but ever showing a determination to follow and succeed in carrying out the inherent bent of his mind. His aim was (1) the improvement of old varieties; (2) the union of wild with cultivated types; (3) the creation of new forms. Breeding and selection were the two main processes, trial and quantity being practically unlimited. Thousands upon thousands were bred of one kind or another to select from, but of which one or two only might satisfy him; then all the rest were burnt to make way for fresh thousands for trial.

With regard to native grasses, the author says: "Mr. Burbank has been studying for a long time the question of providing a rich, nutritious grass for barren regions." This suggests questions not answered in the book, viz., what ingredients does he put into the soil, and what is the geological nature of the sub-soil? How is it possible to raise a "nutriticus grass," capable of continuing such, in a barren region? For the nitrogen required is not supplied by the air, though the author seems to think a tree "has the capacity to take so much nourishment from the air."

With regard to his crosses, some are peculiar. Thus, (a × b) × (c × d) is stated to have given certain forms required. A Poppy's pistil may be quartered, and each quarter separately pollinated, giving rise to an annual, a perennial, a crimson, and a white progeny. This is analogous to other cases, where white eliminated either the red or yellow of an orange-coloured flower, as of Abutilon and Rhododendron javanicum.

Remarkable crosses are reported to have been made among the Rosaceæ, not only between members of the same tribe, as between Blackcurrant and Raspberry, the Plum and the Apricot, or "Plumcot," said to be a delicious product, and the "Primus" berry, between the Californian Dewberry and the Siberian Raspberry; but he is stated to have succeeded in crossing members of the Rubeæ and Pomeæ, viz., the Raspberry and Apple, of which "the Blackberry seeds of the cross produced the Apple-tree growth!" But of four to five thousand trees all but two were barren. A Raspberry and Strawberry cross (i.e., of the tribes Rubeæ and Potentilleæ) resulted in plants bearing tall stems (3 to 5 feet), but with Strawberry characters. It also was barren.

Mr. Burbank shows that there is a close parallel between the effects of grafting and those of crossing. Speaking of new "species," used in a general sense, Mr. Burbank says: "Crossing makes perturbations or variations and new combinations of these forces, as well as a radically changed environment; both of which produce somewhat similar results."

Two chapters deal with "How may I do it, too?" One is on "Breeding," the other on "Grafting." In the latter are some interesting observations on the effects of the scion on the stock, as in strengthening the roots, etc. As an example, Mr. Burbank grafted a Japanese Pear upon a Bartlett Pear. The cross between them took on a greatly increased vigour.

A Plum from France was grafted on a Kelsey Plum, but the graft itself, though growing well, bore no fruit. The stock, however, bore French Plums instead, so that "the life of one entered into and transformed the life of the other."

In making selections Mr. Harwood tells us that Mr. Burbank "will choose the very best from 100,000 seedlings with unerring eye in a single day's time." But as his day's work, we are told, is one of 10 or 11 hours—if we say 12—that would be 8,333 per hour, or 140 per minute, or two per second, without stopping for one second during the 12 hours!

An important question for scientists is whether Mr. Burbank can support the Mendelian law. The author says that he "has disposed of it"; but he seems to be confounding true hybrids between well-pronounced species used by Mr. Burbank, and crosses between "varieties" of one and the same species. He refers, for example, to Walnuts, the offspring of two distinct species (English and Californian).

We are not aware that Mendel's law has ever been tested between species, the rule of which is that well-defined hybrids, sooner or later, break up into a heterogeneous mass of differences, which, as the author remarks, "show no regard for law and order." If Mr. Burbank proves anything it is that Mendel's law will not apply to hybrids; just as Galton's will not apply to them.

Mr. Burbank has also refuted Weismann's statement that characters accquired by the "soma," i.e., the vegetative system in plants, are never transmitted, because, he maintained, that any external influence could not reach the germ-and-sperm cells.

Mr. Burbank's experience being mainly with crossings, his hybrids would rather go to support Weismann's contention that the external influence must be impressed on the so-called "germ-plasm."

Better illustrations might be taken from biennial crops (as of roots) and foliage (as of parsley), for numerous forms of these now come true by seed, though they were all primarily acquired by the soma, long before they could flower in the second year, being biennials.

Again, Mr. Burbank is said to have apparently upset De Vries' idea of Mutation; but while the former is dealing with hybrids, the latter is concerned with sports of the "elementary species" arising without any crossing at all.

He touches upon the subject of mimicry among plants, but not with that idea, for he observes, "A study of plants or animals belonging to widely different species and even genera (e.g., Cactaceæ in Mexico, Euphorbia and Stapelia in East Africa), which have been under a similar environment for a long time, will always show a similarity in many respects. . . . . Similar environments produce similar results on the life-forces, even with the most distantly related plants or animals. This fact alone should be proof enough, if proof were still needed, that acquired characters are transmitted." Evolution cannot be explained if it were not so.

It may be added that such is the conclusion the "ecologists" of to-day have arrived at. Prof. Warming thus speaks of Cactaceæ, etc.: "I answer briefly to the question, viz., whether these adaptations to the medium, against loss by transpiration, are to be regarded as a result of natural selection, or whether they owe their origin to the modifying action exercised directly upon the forms by the conditions of the medium. *I adopt this latter manner of right.*"

In conclusion, it may be added that, besides many writers who are most appreciative of Mr. Burbank's remarkable personality and his work, many others are not so affected with "Burbankitis," as they call it, and find fault with certain writers for their effusiveness, partly from their over-zealousness to enhance Mr. Burbank's reputation and partly from want of

knowledge. Thus it is said that the spineless Opuntia, which Mr. Harwood attributes to Mr. Burbank's skill, was a variety known before, and was actually given to Mr. Burbank by the Department of Agriculture.

However, as to Mr. Harwood's book, it is very readable, but obviously written with a strong personal feeling of admiration for the Californian experimenter and a complete disregard of what has been done by Knight, Herbert, Rivers, Laxton, Naudin, Dominy, Seden, Laing, and very many others whose results are as remarkable as any mentioned in this book. Astounding statements are made, but little or no corroborative evidence is offered. They may be true, we do not say they are not, but assertion is not evidence. Indeed, if ever a man had occasion to be saved from his too zealous friends it is Mr. Burbank. If we may judge from the examples that have been exhibited here, Mr. Burbank's success in developing new varieties is not more than that attained by other experimenters.

TREES AND SHRUBS.

DECIDUOUS SHRUBS FOR FOREGROUNDS AND SHRUBBERIES.

For this purpose may be recommended :—Andromeda arborea, A. speciosa, A. calyculata, Berberis Thunbergi, Caryopteris Mastacanthus, Clethra alnifolia, Comptonia asplenifolia, Daphne Mezereum, Hypericum, Kerria japonica var., Ononis fruticosa, Potentilla fruticosa, Philadelphus coronarius aureus, Spiræa Anthony Waterer, S. bullata, Tamarix, Vaccinium corymbosum, and Weigela "Eva Rathke."

TREES AND SHRUBS WITH ORNAMENTAL BARK.

The following plants are all of much value:—Acer striatum, Betula alba and its varieties, B. papyracea, Cornus sanguinea, Neillia opulifolia, Rosa sericea, R. rubrifolia, Rubus biflorus, R. leucodermis, R. phænicolasius, R. "Schaffers Colossal," and Salix alba britzensis. *W.A.M.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Vanda cærulea and V. Watsoni.—V. cærulea should be now in the Cattleya house, and in a position where there is free circulation of air. Fresh air at all times is undoubtedly one of the principal requirements of this beautiful species. The new white V. Watsoni is in flower; it appears to thrive well at the cool end of the Cattleya house; the plants are well rooted in small pots, and are kept moderately moist at all times.

Brazilian Miltonias.—Among these there are many beautiful varieties that are well worth more extended cultivation than they now receive. Such are M. Moreliana atro-rubens, M. spectabilis, M. Lubbersiana, M. Peetersiana, M. candida grandiflora, M. Russelliana, M. Clowesii, M. Regnellii, M. bicolor, M. Veitchiana, M. Lamarckiana, M. Binotii, the new Gatton Park variety of M. Regnellii, &c. Their flowering season is during the autumn months, and the majority of the plants, especially those with creeping rhizomes, have comparatively little rest, for within a few weeks after the flowers have been cut the slow development of their new growth commences. The plants should now be examined to see if any of them need more root-room, as the present time is the proper season for repotting. All of the strong growing varieties may be grown in pots, but shallow pans are preferable for the dwarfer kinds. The receptacles should be made at least two-thirds full with drainage material, consisting of a few large pieces of crock placed over the bottom of the pot, and afterwards well dried fern rhizome. As regards compost, I have tried many sorts, and for several years past the plants have succeeded very well in what is known as American fern (Osmunda regalis) root fibre. This is pulled apart into lumps, and placed firmly among the roots, filling up to within ½ inch of the rhizome of the plant; the space thus left should be filled close up to the base of the plant with living sphagnum-moss made moderately fine by cutting up. Keep the plants elevated a trifle above the rim of the pots, with the base of the bulbs just touching the moss on the surface, so that the young "breaks" that are now commencing to grow will be free from anything that is likely to cause them to rot. Some of the dwarfer kinds, as M. spectabilis, should be allowed considerable rooting space, as the growths rapidly extend themselves in every direction, and any plants that have over-grown their pans or have become bare in the centre may be divided. All useless bulbs and dead roots should be cut away, and the growing pieces made up into neat compact specimens. It is not necessary to retain all the old bulbs, two or three behind each young growth are quite sufficient. In remaking up the specimens, some pieces will be found with but few roots, and these must be pegged down to the compost, as they never succeed unless fixed in a manner that will prevent them from shaking. Wooden pegs made from old bass brooms I have found the best means for securing them till the roots have penetrated into the new material. If it is found desirable to increase the stock of any particular variety, the severed pieces, if healthy, may be placed in shallow pans filled with sphagnum-moss and a little sand, and when growth has commenced pot them up as advised for the others. M. cuneata should not be disturbed now, as the spikes are in course of development. This section of Miltonia will grow thoroughly well in a cool and shady part of the intermediate house, for if placed in a strong light the foliage becomes more yellow than is desirable. For a considerable time after the disturbance caused by repotting, the plants need but little water. If the sphagnum-moss on the surface be damped two or three times each week it will be sufficient, and for this purpose the fine sprayer now generally in use is the most suitable apparatus. A very important item towards success in growing these Miltonias is to see that the numerous small roots now pushing forth are in no way injured or eaten by woodlice or other insects.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to F. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Adiantum Ferns.—Any plants that have been used for house decoration or around groups of Chrysanthemums in the cool conservatory should be allowed to become a little dry at the roots, after which the fronds may be cut off the plants. Examine the drainage, and if it is in a good condition return the plants to a warm house, where they will soon make new growth and be found most useful in forming a groundwork for setting up the early batch of Gloxinias when these come into flower.

Poinsettias.—Let those plants which may have been cut over for Christmas decorations be placed together in a warm, dry position to thoroughly mature and ripen their stems, as they will eventually be used for supplying cuttings. Afford the plants just sufficient water to keep them from shrivelling without starting them into growth.

Pot Roses.—If these have been well cared for, and prepared for forcing, a batch may now be placed in heat, and if given a start in a mild hot bed made of clean leaves and short stable litter the roots will soon become active. The moisture arising from the bed of leaves also will be very beneficial to the young growths, which will under these conditions break much stronger. The atmosphere of the house should not be warmer than 30° at this stage. Air should be admitted to the structure very carefully, seeing that fluctuations in temperature are as a rule productive of mildew, that great enemy to the Rose.

Camellias are found most serviceable at the present season, when flowers for cutting are at their lowest ebb. Chrysanthemums are past, and only the early forced bulbs, &c., are supplying our needs. As soon as the Camellias have flowered, they should be placed in a position in a moderately warm structure to make their growth. They will then flower under natural conditions in the winter season. This is important, for the plants will not stand much forcing at this period of the year without suffering disastrous results.

Chrysanthemums.—The earliest cuttings have made roots, and should be given a position near to the glass, where they may receive all the light possible. Proceed with the potting of those which made roots first; and if any have been rooted in boxes, care should be taken not to cramp the roots by putting them into pots which are of too small a size; failure in the young plants to start away into free growth is often the result of carelessness at the first potting.

General reminders.—Continue to stake up Freesias. The prunings of Privet, if stripped of their leaves and dried, provide excellent material for this purpose. The watering of Primulas, Cinerarias, and Calceolarias should be done carefully. Avoid pouring the water into the centre of the plants. Weak liquid manure, if applied twice each week, will stimulate the plants into healthy growth and induce them to flower freely.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Peaches and Nectarines.—If fruits are required to ripen in May, and the trees in the early houses have not yet been started, this should be done at once, commencing at first with a temperature at night of from 40° to 45°, and permitting a rise of 10° during the day. If the borders appear to be at all dry, a thorough soaking should be given them with tepid water. Syringe the trees twice daily unless the weather is dull or wet, when once will be sufficient. If such varieties as Early Alexandra Peach, Advance, Cardinal, and Early Rivers Nectarines are planted permanently in the early houses they will ripen in the order named, provided the new shoots have matured well, which is doubtless the case if, having been kept free from overcrowding, they have been exposed to the influence of the sun, light, and air during the past summer and autumn months. When I came to these gardens it was found necessary to take down a long range of fruit houses, which contained some large Peach and Nectarine trees, each of which covered a space of about 9 yards wide by 7 yards in length. These trees were very carefully removed to a new range of fruit houses in the month of January. It was rather late in the season to remove such large specimens, but careful attention was given to watering and syringing them afterwards, and they carried good crops of fruit the same year, and in each year which has followed. This experience shows how late Peach trees may be removed successfully if the work is done with care.

Second Peach House.—Let this be got into readiness. Cleanse all the wood and trellis work and paint the trees with a mixture of Sulphur, Gishurst compound, Soft soap (thoroughly dissolved), clay and a little soot, all of which should be mixed together to the consistency of paint. Brush the mixture well into the crevices of the old wood. Top-dress the border with loam and lime, adding short cow manure to finish off with. There is nothing gained by allowing the fruit bearing shoots to be trained too closely together; a distance of 5 or 6 inches apart is best.

Pine Stove.—This structure will now demand attention, as early fruits are always appreciated. Cleanse the house thoroughly and make up the bed with fresh tan or good Oak leaves, making them firm by treading, and when the bottom heat has fallen to 90°, the pots can then be plunged into the bed. Always select for the earliest batch those plants having the stoutest stems. Before water is applied to the roots let it be warmed to a temperature of 85°. The atmospheric temperature at night should be 65°, and a rise of 15° may be allowed during the day. Damp the walls and paths occasionally on fine days, and admit a little air to the structure when the weather is favourable.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Currants and Gooseberries.—Keep a sharp look-out for the birds, or at this season they will destroy many buds. Where birds are troublesome, lose no time before trapping them, or as a preventive cover the bushes with fine mesh netting, or dust them with lime in the morning when the branches are damp. If netting is put over them, let it be raised sufficiently high that other operations may be carried on conveniently, such as pruning and mulching. If some long poles be put into the ground, leaving a length of about 6 feet above, and on the top

of these some pieces of deal be nailed cross-ways, strong twine can be strained for the netting to rest on. Peg the sides down to the ground, so that the birds cannot get under the netting. This may then be left in position until the fruit is gathered, and it will by that time have served a double purpose.

The Pruning of Bush Fruits should be pushed forward during suitable weather. Gooseberries against walls are generally grown on the gridiron style, that is, partly horizontal and partly perpendicular. Good crops are obtained by this method, and the fruit is more easily protected than when the plants are grown as bushes. Nail in all the terminal leads, which should be at 7 inches apart, and prune the spurs back to about three or four eyes.

Standard Gooseberry Trees should be secured to a strong stake in order to keep them upright, and afford protection against wind. Thin out the growths only, and do not shorten them. This method not only looks well, but produces fruit of the best quality.

Gooseberry Bushes should be merely thinned out, leaving the remaining branches intact, and cutting back those not required to one eye; this will produce a strong shoot for the succeeding year. Bushes pruned in this manner bear well, and the fruit is easy to gather. So long as strong, healthy shoots can be obtained good fruit will result. If the bushes are getting beyond bounds shorten the branches in order to keep the bush of a good shape.

Raspberries.—It is not too late to plant Raspberry stools, but if this is done the plants should not be allowed to fruit in the present year. The ground should have been well trenched and plenty of good decayed manure mixed with the soil. If the canes are to be tied to wires plant in clumps of five or six crowns together at 2 feet apart; the wires need not be put up this season. If the growths are to be secured to stout stakes, plant three to five, crowns together, at 5 feet apart, and allow 6 feet between the rows. Prune the plants hard back, or even to the ground-line in order to encourage strong vigorous shoots.

Medlars may still be planted. A site in a portion of land where sewage is present suits this tree perfectly. The "Dutch" and "Nottingham" are good varieties.

Fruit-room.—Keep a keen eye on the fruit stores, and collect all decaying fruits. Admit air daily, and keep the atmosphere cool and dry.

Stocks.—When seeds are sown for producing stocks for budding or grafting, always select those that grow most strong and healthy.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

The Forcing Ground.—Such vegetables as Rhubarb and Seakale are in constant demand, and in large establishments there is usually plenty of provision for meeting the supply, but in small gardens it is not so often the case. A simple method of keeping up a supply is by throwing out a trench about 6 feet wide and about 8 feet deep in the frame ground, and filling this with hot dung, planting over this in the usual way and covering with boards, afterwards putting more dung on the top. Splendid produce can be had by these simple means. Cover up Rhubarb crowns in the open with long litter, which will hasten the growth by a fortnight (see also p. 46).

French Beans.—The forcing of these will now be an easier matter than it was earlier in the winter. I prefer to use flat pans instead of deep pots at this season, as Beans sown in January do not require very much soil owing to the comparative small amount of roots they make. The water drains away more rapidly and the plants are therefore not so liable to "damp" when placed in a close and warm atmosphere. About eight seeds are sufficient to sow in a 10-inch pan, and there is no need to make allowance for top dressing in filling the pans, as the stems will not throw roots with sufficient freedom to make it worth doing. The pans, therefore, are best filled up to within an inch of the rims. When making sowings later in the season the deeper the pots used the better it will be, for there will then be no fear of failure from the causes already mentioned. Of varieties I like Osborne's Forcing, to be followed by Ne Plus Ultra and Canadian Wonder. The dwarf Sugar Bean may be quite easily forced in the same manner, and it makes an excellent "dish."

Seakale.—The mushroom house offers most suitable conditions for blanching Seakale, but if a little bottom heat can be given the Seakale will need less time to become fit for consumption. Excellent produce can be grown in deep frames with a hot bed underneath, keeping the light excluded by a covering of heavy mats or a good thickness of straw. In any case the plants need much atmospheric moisture, this having the effect of increasing their tenderness. Rich soil is another point that must be insisted upon.

Chicory.—Treat this in the same way as Seakale, and to maintain a supply introduce fresh roots as necessity requires. If they are grown in frames, place 6 or 7 inches of light soil over the crowns, to induce solidity of growth. The main crop of Seakale and Chicory may be lifted, if this has not yet been done, that the roots may be trimmed and stored ready for forcing. A few of the best crowns should be selected and planted closely behind a north wall and blanched with leaf mould so as to prolong the season as far as possible. Cuttings of Seakale should be prepared at the time of lifting in readiness for planting later on, laying them in bundles in any spare corner free from frost.

Endive.—Continue to lift Endive from the open garden, and place the plants in frames. Blanching can easily be done, either by covering with freshly gathered leaves or tying the outer leaves over the inner ones, keeping the frame dark. The plants may also be easily blanched in any dark shed, mushroom house, or outbuilding, but the atmosphere must not be heated or the plants will damp off.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

The "Annual" Flower Garden.—Having endeavoured to suggest a few seasonable preparations for the summer bedding, I will now draw attention to "annuals." The garden, if it is devoted mainly, but not exclusively, to hardy and half-hardy annuals, should by this time be completed, so that the soil will become mellow and settled by the planting and sowing season. If there is any re-modelling or there are any alterations of beds and borders yet to be done, let the work be pushed forward without delay. Remember that small beds measuring three or four feet wide are best for the dwarfer annuals, especially when each bed is devoted entirely to one kind. Larger annuals may have larger beds, so that they will not be cramped or have their individual beauty impaired. It is essential also, in order to make the most of the "Annual" Flower Garden, that a few borders should possess sufficient width and breadth to afford scope for the exercise of good taste in bringing together annuals of different colours, shades of colour, and habit of growth. As for the parterre bedding system, it is equally necessary for the Annual Flower Garden that plans should be made of the contemplated displays and effects for the coming season, so that the half-hardy flowers to be used in its decoration should be propagated at the proper time, exactly in the quantities required for planting out. If this is not done, there will either be an insufficient supply of certain plants or, almost as bad, much precious time will be wasted in pricking out or potting off a quantity of plants the ultimate consignment of which will be to the rubbish heap. In preparing one's plans inspect the collection of seeds saved last autumn and note the requirements, so that if necessary seeds, especially those of half-hardy annuals, may be ordered without further delay. No collection of half-hardy annuals should be without the following plants:—Asters in sorts, Abronia umbellata, Alonsoa Warscewiczii compacta, Anagallis grandiflora Phillipsii, Arctotis grandis, Antirrhinum—particularly self-coloured pink and red varieties—Browallia, Catananche cœrulea, Marguerite Carnations, Commelina cœlestis, Cosmea, Pentstemon (pink shades), Diascia Barberæ, Delphinium, Queen of the Blues, Dianthus Heddewigii, Gaura Lindheimeri, Petunia, Hollyhock, Lantana hybrida, Lobelia, Marigold (African and French), Marvel of Peru, Mesembryanthemum tricolor, Mina lobata, Nemesia strumosa (in distinct colours), Nicotiana—particularly N. Sanderæ—Phlox Drummondi (in distinct colours), Rhodanthe, Salvia farinacea, and S. Horminum, Salpiglossis, Scabious, Schizanthus, the different kinds of Stocks, Tagetes, Verbena, and Zinnia. It will be noticed that some of the above-named plants are perennials, but they are each capable of being treated as half-hardy annuals.

THE APIARY.

By CHLORIS.

A Review of the Past Year's Honey.—The past season produced varying results. Those who live in places where the soil is gravelly or sandy felt the drought severely, while others who were living on rich loamy soils had some excellent results. Let us hope all have sold their honey profitably. Personally, I am about £8 to the good, and find that during the last six years I have disposed of a little more than half-a-ton of honey and am in pocket £50.

Painting the Hives.—Nothing will bring on disease sooner than dampness, which is the forerunner of dysentery. Before painting, rub the hives well with rough sandpaper, and scrape off any loose paint. Make the first coat thinly, mixing equal quantities of linseed oil and turpentine, and, as the weather is bad at this time of the year, add about an eggcupful of gold size to make it set quickly; about 1 lb. of white lead will be needed for any ordinary hive. Let the colour be thoroughly mixed and strain well before using. If it be necessary to have it coloured, use a little lamp-black to produce a slate colour, or sienna to bring about a good stone tint. It is generally best not to use boiled oil as it is liable to blister in the sun. After the first coat put putty in the cracks and lay a strip of old calico, wetted with paint, over the joints, and the hives will be watertight.

Entrances.—Keep these free of dead bees, but disturb the inmates as little as possible.

Feeding.—Those who did their work well before the autumn had become cold will have no fear of starving bees. Others should only slip under the quilts a cake of candy or better still a piece of comb containing honey, and this only in good weather.

Preparing Frames.—In connection with all bee operations it is well to be prepared for the honey season, and I know of nothing which is more carelessly done, when done in a hurry, than fitting up frames with foundation. To produce straight combs should be our object, and to do this it is a very good plan to wire the foundation in. Needless to say the most economical way of fitting up is to use full sheets of foundation for two reasons, one is because, in the long run, it is by far the cheapest; and, in the second, it will secure a greater proportion of cells for worker bees. Cut out a **V**-shaped piece on the top of the foundation in the centre and a piece off the corners [see fig. 22 (1)]. Open the split top of the frame with a wide nail and slip the foundation well through, leaving a piece about ¼ of an inch above the frame [see fig. 22 (2)].

To make the foundation secure in the top bar run a hot poker slowly along the split to melt the

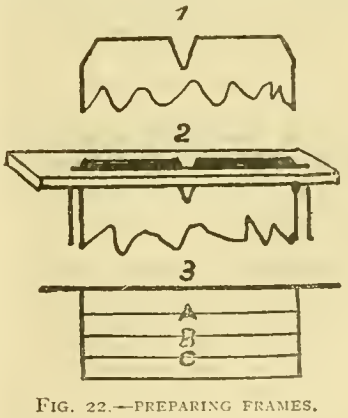

FIG. 22.—PREPARING FRAMES.
(See text.)

protruding piece of comb. This done, bore three holes in each side about 2 inches apart. Use No. 30 tinned wire, and after the wire has been drawn moderately tight use an embedder which has been heated in a candle flame, and pass along the wire to make it embed itself in the foundation. About 8 ounces of this wire will be sufficient for 100 frames. In fig. 22 the letters A, B, C represent the strands of wire. When the foundation is wired-in, thinner sheets may be used, otherwise it is not safe to use thinner than that which is eight sheets to the pound.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	Jan. 23	Royal Horticultural Society's Committees meet.
WEDNESDAY,	Jan. 24	Annual Dinner Croydon Horticultural Society.
FRIDAY,	Jan. 26	Royal Botanic Society meet.
SATURDAY,	Jan. 27	Annual Meeting National Auricula Society (Northern Section), at Manchester. Dutch Gardeners' Society meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—37·9°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Jan.* 17 (6 P.M.): Max. 47°; Min. 39°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 18 (10 A.M.): Bar., 29·6; Temp., 49°; *Weather*—Much rain, with high winds.

PROVINCES.—*Wednesday, Jan.* 17 (6 P.M.): Max. 46° Isle of Wight; Min. 39° N. Coast of Scotland.

SALES.

MONDAY NEXT—
Hardy Border and Herbaceous Plants, Lilies, Roses, Azaleas, Fruit Trees, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Sale of Roses, Lilies, Shrubs, &c., at Steven's Rooms, King Street, Covent Garden.

WEDNESDAY NEXT—
Carnations, Pinks, Hardy Border and Herbaceous Plants, Liliums, Begonias, Gloxinias, &c., at 12. 3,000 Roses and Fruit Trees, at 1 and 3, also Azaleas, Rhododendrons, Palms and Plants, by Protheroe & Morris, at 67 and 68, Cheapside, E.C.

FRIDAY NEXT—
Roses, Azaleas, Herbaceous and other Plants, Perennials, &c., by Protheroe & Morris, at 67 and 68, Cheapside, at 12.

Apple Orchards. THE management of Apple orchards is carried on in the United States not only on a larger scale than in this country but also more systematically. This is well illustrated by a "Bulletin" issued by the Agricultural Experiment Station of the College of Agriculture connected with Cornell University.

The document in question has been prepared by Mr. G. F. Warren and Mr. W. E. McCourt, the last-named gentleman dealing especially with the geology of Wayne County, wherein are situate the orchards principally studied.

The demand for fresh fruit in the States has more than kept pace with the increase of population, so that, in the census year 1900, whilst the population was, roughly speaking, more than seventy-five and a half millions (a gain of 52 per cent. in ten years), the value of orchard products was nearly eighty-four million of dollars (a gain for the same period of over 64 per cent). The growth and development of Apple culture are fully dealt with in a separate chapter, which shows not only how rapid has been the progress but also how comparatively recent was its origin. Tillage, manuring, pruning, spraying, planting, and cultural operations, leasing and renting, all receive attention, as well as information relating to the soils and aspects, the varieties grown, the fungus and insect pests, the markets, and the prices obtained. In order to give a better notion of the contents of this "Bulletin," we may here extract the "condensed conclusion" arrived at by the reporter:—

"Tillage, fertilization, pruning and spraying are the chief factors that enter into good care of an orchard. One or more of these may sometimes be omitted or poorly done without any serious results. To some extent tillage may replace fertilizers, or vice versâ. A thrifty orchard may resist the attacks of disease. In some years there are few insects or fungi, so that spraying is not so much needed. A farmer frequently gets good results from some one of these factors, and becomes so impressed with its importance that he makes a hobby of it, to the exclusion of all the others. But the most successful Apple-grower is the man who keeps a proper balance between all four agencies, and does not expect good care in one respect to make up for neglect in other ways.

"But these factors are not all. The successful man must study; he must learn something of the life-processes of the Apple-tree; he must know the most serious insect and fungous diseases, and why certain treatment is effective in combating them; he must know something of the drainage, humus, and other soil-problems. No set rules can cover all these points. The Apple-grower must go into the orchard and get acquainted with his trees. As one farmer expressed it, he must go into the orchard occasionally, and say to his trees, 'Good morning! Is there anything that you would like to-day?' There are many more or less successful farmers who never really see the Apple-tree—they look only to the crop. Any treatment that will temporarily increase the crop seems to them to be good; but this very treatment may be destroying the prospects for future crops. Nor is success in orcharding wholly dependent on a large crop. There is a business side to the question. Does it pay to grow cheap Apples to be evaporated or to be sold at the lowest market price, or would it pay better to grow a first-class article that costs more but then commands the highest price? A few men in each county are known as growers of good Apples. Some other men grow just as good Apples and yet have no reputation. Sometimes it is because their 'firsts' and 'seconds' all get into one barrel; sometimes it is because the growers are not known. The grower of good Apples should establish a business reputation that will bring buyers to him, and make a competition for his product.

"Last of all, let me urge the advisability of keeping an account with the orchard, and with the other important crops. See which crops really pay. If the Apple orchard proves to be the most profitable crop, then give it first attention.

"The most progressive fruit-grower studies his business, not only in his own orchard, but in every way possible. To keep abreast of the progress made in orchard management, he must know what other orchardists are doing, and must be familiar with the results of experiment station work."

ROYAL BOTANIC SOCIETY.—Dr. FANCOURT BARNES has presented this Society with a cheque for £1,000 from his father, Dr. ROBERT BARNES, in memory of Mr. PHILIP BARNES, one of the original founders of the Royal Botanic Society, and also as evidence of the continuing interest of the family in the society and their confidence in its council.

THE SWEET PEA ANNUAL.—This is the official organ of the National Sweet Pea Society and is in its second edition. It affords evidence of the still growing popularity of the Sweet Pea and contains much cultural information. We note articles on Cross-fertilization and Sweet Peas in Canada, by LESTER L. M. MORSE. Mr. MASSEE contributes a paper on the fungoid diseases of the Sweet Pea. There are many illustrations, and a portrait of Mr. ALFRED WATKINS, president of the society, is given as a frontispiece. Other portraits of well-known growers are also to be found in these pages which are lightened by various poetic effusions. Amid so much that is useful or interesting it is difficult to make a selection, but we shall at any rate be doing a service by repeating Mr. G. STANTON'S 12 words: trench deeply, manure liberally, plant thinly, stake quickly, water freely, dispod promptly.

WILLING'S PRESS GUIDE.—This most useful work will be found acceptable to all connected with magazines and newspapers. It supplies a concise and comprehensive index to the Press of the United Kingdom, and it even includes a list of Colonial and Foreign journals. The thirty-third annual edition seems in no way behind its predecessors in clearness and comprehensiveness. It is published at 125, Strand, London.

BRITISH WEATHER CHART.—Mr. JENKINS has again published his Weather Chart for the coming season, and a card calendar showing the days of the week of every day of the month for 25 years. We have no doubt that these will prove useful for reference in many offices and other business places.

WEBSTER'S FORESTER'S POCKET DIARY.—This is a very compact and useful publication, containing many details of importance to all concerned in forestry, as well as a diary and the usual items of information that are sought in a calendar. Here and there some misprints have escaped the proof-reader, particularly on page 21, where several of the names of Fungi are mis-spelt, and it is an oversight to speak of the "berries" of the Laburnum as poisonous. Writing on the question of afforesting waste land the author suggests that the State should acquire and plant suitable waste lands at the rate of 40,000 acres annually for a period of 25 years. The purchase of such land would entail a cost, on the average, of forty shillings an acre. Mr. WEBSTER estimates that for the first 20 years no return will be derived from hillside plantings. From 25 to 40 years an annual return of fully 12 shillings an acre has been forthcoming, whilst the value of the standing crop was found to be about £60 per acre. We commend Mr. WEBSTER'S notes on afforesting, and the returns to be expected from it, to the notice of all concerned, and especially to those desirous of finding profitable work for the unemployed, and of turning to ultimate use land that is now practically useless. The book is published by Messrs. RIDER & SON, 164, Aldersgate Street.

THE RAINFALL IN 1905.—That so many gardeners now record and tabulate the climatic conditions prevalent in their gardens, is a sign of the interest and value attached by an ever-increasing number to the proper study and observation of meteorological conditions. Although these conditions vary from a multitude of causes, they form a valuable guide, nevertheless, especially when conducted over a number of years, such as, for instance, those recorded in the old Chiswick Gardens of the Royal Horticultural Society. It is curious and instructive to notice with what great regularity the "means" of a period of over 40 years taken in these gardens ascend and descend in the recorded scale according to the

season of the year. Many of our readers have kindly forwarded to us the record of the rainfall in their immediate neighbourhood for the past year, and though our limited space will not allow of these being given in detail, we have pleasure in appending the totals. Mr. H. HARRIS, The Gardens, Denne Park, Horsham, Sussex, records 27·66 inches, with the remark that 2·84 inches fell on the first seven days of the new year; Mr. C. A. BAYFORD, Shugborough Gardens, Stafford, registered 23·78 inches; Mr. J. B. LOWE, D'Abernon Chase Gardens, Leatherhead, registered 23·46 inches, as against 24·68 inches in 1904; Mr. A. B. WADDS, The Gardens, Paddockhurst, Sussex, 27·51 inches. Paddockhurst enjoyed 1,469 hours of bright sunshine, recorded on 236 days. The wettest day in these gardens was June 6, when there were 1·22 inches of rain. Mr. W. J. SHORT, Freeland Lodge Gardens, Woodstock, sends 23·98 inches as his recorded total, against 26·37 inches in 1904. Warwickshire was apparently drier than most counties, for only 21·63 inches fell in Hampton Manor Gardens, Hampton-in-Arden. Mr. NEIL SINCLAIR in his note says: "The greatest fall during 24 hours was on July 1, when 0·94 inches fell." The highest amount of sun-heat was on July 11 and 25 when the thermometer stood at 130°. The highest shade temperature was 80° registered on June 22, the lowest 14° on January 20. Mr. W. A. COOK, Leonardslee Gardens, Sussex, records 147 wet days, during which period 24·74 inches of rain fell, almost identical with 1904, when 24·80 inches were registered. The average rainfall in these gardens for the past 12 years is 28·30 inches. The maximum temperature was 139° on July 27. The highest night temperature was 64° on July 2. The highest temperature of the soil was 65° on July 15, which high temperature continued until August 4. Mr. H. WILSON, Cole Orton Hall Gardens, Ashby-de-la-Zouch, recorded 22·27 inches, the wettest month being August when there were 3·30 inches of rain. The number of wet days in these gardens totalled 179. Mr. JOHN JEFFERY, Idlerocks Gardens, North Staffordshire, registered 134 wet days, during which period 26·65 inches of rain fell. August was also the wettest month in these gardens, the fall during that month amounting to 5·06 inches. It is interesting to note that the amount registered during 1904, viz., 26·16 inches, approximated to that recorded during 1905, but the number of wet days in these gardens last year was 134 compared with only 107 in 1904. Mr. H. PARR sends the record of rain falling in Trent Park Gardens, New Barnet, Herts., as 26·5 inches. Mr. JAMES SMITH, F. R. Met.Soc., Crathes, Aberdeenshire, has compiled some interesting meteorological notes. Had it not been that November was an abnormally wet month, with a rainfall of 9·41 inches, instead of an average of 3·34 inches, the past year would have been the driest recorded at Crathes since observations were commenced in 1900. At certain periods of the year water was exceedingly scarce, old springs dried up, and gravitation supplies failed. Many persons had to cart water from a considerable distance, not only for live stock but for personal use. The rainfall for the district was 28·6 inches, the number of rainy days being 218.

BULLETINS D'ARBORICULTURE, ETC.—We notice with much regret an announcement that the December number of this useful periodical is to be the last. It was founded in 1864 by four of the professors of the Ghent School of Horticulture—four men of great enthusiasm, activity, and intelligence. They constituted what was familiarly known as the four-leaved Shamrock. One after the other VAN HULLE, PYNAERT, RODIGAS have been called away, till M. BURVENICH, the eminent pomologist, alone remains. For some time he continued to edit the publication. At length the death of his son JULES BURVENICH, the Curator of the Botanic Garden, to whom the father looked for assistance, has induced M. BURVENICH to retire from his post. The note in which he announces his intention is touching, and conveys a feeling of sadness to those among us who had the privilege of the friendship of each of the four professors. M. BURVENICH may, at least, look back with satisfaction on his 40 years of labour. Much was attempted and much was done—and well done. It is to us a matter for as much surprise as regret that the Committee of the "Cercle" have decided to discontinue the publication. The last words of the address are "Place aux jeunes," but we do not hear that the young are coming forward to supply the place of their predecessors. Surely there is no lack of enthusiasm and capability in the younger race of Belgians.

THE ATTRACTIONS OF JAMAICA.—*Jamaica in* 1905, is the title of a "Handbook of Information for intending Settlers and Visitors," written by Mr. FRANK CUNDALL, and obtainable from H. SOTHERAN & Co., 140, Strand, W.C. The pamphlet gives a favourable account of the climate of the island, and has special reference to the possibilities offered by agriculture and planting in general. An account of the history and geography is included, as well as a large scale map of Jamaica. The Royal Mail Steam Packet Company, 18, Moorgate Street, E.C., forward an attractive time table and description of tours in the West Indies. The beauties of climate and scenery and the pleasures of life in general are recommended both to tourists and settlers in the islands. The same company also publish a handy little pamphlet on West Indian Fruit and Produce that contains some useful recipes.

MY GARDEN DIARY FOR 1906.—Messrs. SUTTON & SONS, Reading, again offer their friends a diary full of useful gardening hints for every month, in a very pretty cover, and with a pleasing frontispiece. Implicit confidence may be placed on the cultural notes, and the diary and calendar accompanying them will also be found acceptable to amateurs.

PICTORIAL PRACTICAL FLOWER GARDENING.—This book is one of a series of "Pictorial Practical" handbooks, and should prove as popular and useful as the earlier volumes. The authors, Messrs. W. P. WRIGHT and EDWARD J. CASTLE, claim that their work shows concise arrangement and abundant practical illustration, and they demonstrate how even the smallest of flower-gardens may be made beautiful. Certainly the subject is inexhaustible, so that these experienced writers, aided by their many illustrations, are sure of an appreciative public. The publishers are CASSELL & Co., Ltd.

PROPOSED AGRICULTURAL SETTLEMENT.—Miss EDITH BRADLEY, whose interest in field and garden work for women is well known, is sending out a pamphlet relating to a Scheme for an Agricultural Settlement. This, described in brief, is an estate wherein shall be congregated men and women fully trained in agriculture, horticulture, dairying, poultry and bee-keeping, fruit culture and preserving; who shall rent plots of ground, with or without dwellings thereon, and shall make a living out of the land under the most favourable circumstances of modern up-to-date methods. Capital, labour, and ability are to combine to render such a plan possible. It is proposed that the settlement shall be in the Midlands, in one of the districts or counties that were included in the great Saxon kingdom of Mercia, and the name suggested for it is the Mercia Agricultural Settlement. Co-operation is a great feature of the plan, both as regards the various pursuits undertaken and the domestic economy of the settlement. A bank, sick fund, old age and pension fund are details of Miss BRADLEY's plans; her idea of expenses being to start with from £10,000 to £20,000 for essentials, and to increase this amount and the general scope of the undertaking as success becomes more assured. Those of our readers who desire to know more of "The Mercians," should write for particulars to Miss BRADLEY, care of The Studley Castle Agricultural Association. We suppose this address to be sufficient, as none more definite is mentioned in the circular before us.

CHECKING WIREWORMS BY MEANS OF FERTILIZERS.—The last issue of the *Woman's Agricultural Times* gives the abstract of a lecture, given under the auspices of the Essex County Council, by Mr. W. J. Moss, on the prevention of injury by wireworm. The speaker discovered that after the use of an American fertilizer-drill of a pattern which sows the artificial manure down the conveyor tube with the corn to the coulters, the resulting crop was notably free from attacks of wireworm. The pest had been checked in a curious manner. The field, when treated, was badly overgrown with weeds; the Barley (which, as it happened, was the crop sown) proved uninviting to the wireworm, owing to the acid in the manure with which it was treated; the pest, being there and hungry, had to feed upon what they could get, and ended by clearing off nearly the whole of the weeds. "Since that time," says Mr. Moss, "I have had no fear of wireworm in a Corn crop. I have simply used a fertilizer-drill and deposited the artificial manure down the coulters with the Corn, and the wireworms have helped to clear the field of weeds. I have not proved that artificial manure is inimical to the wireworm, but this is not important if the presence of the creature can be made to assist in the economy of the farm and the pest be converted into a friend. I believe superphosphate is sufficient for the purpose; but I have found a 'complete' manure the best to adopt and the most economical, as the increased yield obtained invariably more than compensates for the increased outlay."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be on January 23. Mr. MARTIN H. SUTTON will lecture at 3 p.m. on "The Formation and Care of Lawns and Golf Greens."

THE FRUIT INDUSTRY.—We have received the following letter from the Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W.: "I am directed by the Board of Agriculture and Fisheries to acquaint you that they have been in communication with the Postmaster-General with reference to the recommendation made by the recent Departmental Committee on the Fruit Industry as to the desirability of the further extension of the telephone system in country districts, and that the Board are informed that for some years past the Post Office has been steadily extending the trunk wire system to small provincial towns, and building up local Exchange systems in rural districts which had previously been left untouched. There has been increased activity in this branch of Post Office expansion since, in March, 1904, Parliament granted additional funds for the development of the telephone system, and it is now in operation in a considerable number of towns. Among other extensions benefiting fruit growers an Exchange system has been established in the district of Swanley, Farningham, Hextable and Crockenhill, also at Westerham, Kent and Winchcombe in Gloucestershire. In some cases the distance of towns or villages from any existing trunk wire centre renders the cost of extensions prohibitive, but as the system of main wires extends, these difficulties will diminish. The Postmaster General informs the Board that he will be glad to receive any specific suggestions as to further improvement which may be submitted on behalf of fruit growers, and also as to the localities

where the need of the telephone for the purposes of this industry are most pressing. The Board would be glad if they might be favoured with any information which your readers may be in a position to supply as to particular places where the introduction of a telephonic service would be attended with special advantage to fruit growers, and also to receive any suggestions generally on the subject. I may add that the Board are addressing a similar communication to the principal fruit and horticultural associations and societies.—I am, sir, your obedient servant, (signed), T. H. ELLIOTT, secretary."

TOWN AND COUNTRY LIFE.—The disadvantages of overcrowding cities and depopulating country villages are a constant theme of discussion and constitute a serious problem. The "Garden City" is an attempt to solve the difficulty by ensuring that new towns shall be accompanied by sufficient open spaces to ensure healthful and sightly surroundings. It is not so much room that is lacking, but a redistribution of the town and country areas. "We talk about the stately homes of England," says Mr. RIDER HAGGARD in the "Garden City," "but what I should like to see greatly multiplied are the humble homes of England. It is our duty to multiply those humble homes, and to make sure that the land is devoted to the original purpose for which Providence gave it, for the production of men, women, and children. There is plenty of room for pheasants, but there is also plenty of empty room that can be occupied by men and women." The buildings necessary to accommodate the people should be considered not merely from the standpoint of the individual but from that of the whole population. Instead of the inconveniences inevitable from the gradual growth of old towns, new settlements should start with every possible advantage. On another page of the publication quoted above we read that—"Local conditions—inherited street plan, topography, the location of railroad stations, and many other factors—determine which plan is best for any particular city, but quick transportation demands the development of civic centres with a system of avenues radiating from the business and other important local centres, and towards this end European cities are working. It is also advisable that boulevards should be so planned as to connect the parks of a city." That it is possible, by gradually improving old-established neighbourhoods and by laying out new ones with due prevision, to combine convenience and effectiveness is, it is said, demonstrated at Letchworth. In the Garden City Estate Professor PATRICK GEDDES considers that: "The union of the claims of the past and present is being happily managed in a way which shows how needless and how wasteful are the proceedings of the ordinary suburban builder, whose supposed sacrifice of beauty to utility and gain is often but the most wastefully extravagant sacrifice by brutish worshippers to a dim ideal, that of mechanical æstheticism, of dreary regularity. Here old trees are preserved, picturesque hedgerows stand undemolished, the common remains with its shady lanes and labyrinths and open glades; its wealth of wild flowers are left to be a joy to the lover of nature, and all this with an economy to the company where your speculative builder usually spends money freely to destroy."

ANNALS OF THE ROYAL BOTANIC GARDEN, CALCUTTA.—A new instalment of this valuable publication has lately been issued. The volume, of which this is the second part, is dedicated to SIR GEORGE KING, who for twenty-seven years had charge of the garden. The part before us is devoted to a monographic enumeration of the Aconites of India by Dr. STAPF. The importance of being able to discriminate the species is shown by the fact that whilst some species are extremely poisonous others are relatively, at least, innocuous. From this point of view the microscopic anatomy of the tubers is of material value, so that in addition to the external characters of the several species Dr. STAPF has also given details of their anatomical structure so far as is necessary for the purposes of discrimination. According to the differences in the root characters the Aconites are divided into three sections—(1) Lycoctonum, with perennial roots; (2) Napellus, with biennial tuberous roots in pairs—each tuber producing normally one simple or rarely branched stem; (3) Gymnaconitum, with annual fusiform roots. The descriptions are very elaborate, and a great deal of information is given as to the geographical distribution of the species, the vernacular names and the properties of the several species. A very copious bibliography, a list of the vernacular names, and an index complete a monograph which is further illustrated by 24 quarto lithographic illustrations drawn by Miss SM.TH. Lt.-Col. PRAIN (the new director of Kew) supplies an account of the life of Dr. BUCHANAN HAMILTON, who succeeded ROXBURGH as superintendent, and was himself followed shortly after by WALLICH (1816). The letters here printed are of great botanical interest. During his residence in Nepal he collected largely, and his specimens formed the basis of DON's Prodromus Floræ Nepalensis.

REFRIGERATING APPARATUS.—The students of the West of Scotland College of Pharmacy, says the *Journal of the Pharmaceutical Society*, paid a visit to the "Telemon" in the Queen's Dock for a lesson in practical physics, viz., the refrigerating apparatus on a fruit-carrying ship. In theory, the process was seen to be very simple. Liquid carbon dioxide is allowed to evaporate from its original container into the "condenser," where under a pressure of 75 atmospheres, it is condensed to a liquid, the process being assisted by the cooling action of sea-water. The liquid is now allowed to escape through pipes laid in large tanks of brine, which is thereby cooled to a very low temperature, the now gaseous dioxide returning to the condenser to be liquefied once more. The cooled brine is in turn led through a series of tubes, and between these the air in the hold of the ship is forced by fans, and is thereby kept at a temperature of between 40° and 43° F. At this temperature the fruit can be brought with perfect safety from Australia or other distant port of shipment. In order to avoid absorption of heat from the engine room, etc., the whole apparatus is enclosed in boxes with double walls, between which there is a 9-inch layer of fine charcoal, the walls of the hold itself being protected in the same way.

MONOGRAPH ON TOBACCO. — Dr. Prof. O. COMES has published a handsome monograph on the species of Tobacco (Delle Razze dei Tabacchi, filogenesi, qualita ed uso), describing the various species and varieties in cultivation, and tracing them to their indigenous and original forms. The work is abundantly illustrated and should prove of great value to all concerned in this important industry. Professor COMES' monograph is addressed primarily to botanists and should prove a standard reference book for them, and, incidentally, for cultivators also. It is published by the Societa Co-operativa Tipografica, Naples.

A GOOD RESPONSE FOR GARDENING CHARITIES.—The members of the Altrincham and Bowdon Gardeners' Improvement Society have raised, by means of dramatic performances, held on December 5 and 6, 1905, a sum of £60 in aid of the gardening charities. Of this sum the Gardeners' Royal Benevolent Institution benefits to the extent of £31 10s., while the handsome amount of £15 is given to the Royal Gardeners' Orphan Fund. The surplus of £15 5s. is applied to the local Orphan and Emergency Fund. Altrincham has always done well in these matters, but the amount available for distribution this year shows an increase of £12. It would be a great help to these deserving institutions if other gardening societies would follow the example of Altrincham. At the annual meeting of the Gardeners' Royal Benevolent Institution, which is being held as these pages are printed, there are 44 candidates seeking relief, but of this number it appears that help can only be extended to 18.

BOTRYTIS CINEREA.—The December number of the *Œnophile* contains an article by Dr. GY DE ISTVANFFI upon the treatment necessary to be adopted in the case of vines affected with grey-rot. In summer the fungus lives on decaying foliage and on weeds—so that it is recommended that these should be at once destroyed. In wet weather the fungus attacks the living leaves and in autumn the berries. Moreover, in autumn it forms small hard nodules called "sclerotes," which persist during the winter in the shoots that are left and form new spawn (mycelium) and conidia (bud-spores) in the following spring. The vines should be washed over with a 5 per cent. solution of bisulphite of lime. Bordeaux mixture may be employed as a spray on the berries, or bisulphite of soda may be applied in the form of powder. But preventive measures and the destruction by fire of all affected leaves, shoots, &c., are the most effective measures to be adopted.

PUBLICATIONS RECEIVED. — A useful Blotter, Almanac, &c., from W. Wood & Son, Ltd., Horticultural Sundriesmen, Wood Green, London.—*The Book of Cut Flowers*, by R. P. Brotherston: published by T. N. Foulis, Edinburgh and London.—*The Garden Album and Review*. A monthly periodical, with coloured plates. Price 7d. nett.

NOVELTIES OF 1905.

(Concluded from page 27.)

HARDY PLANTS.

THE most remarkable horticultural event of recent years, so far as new plants are concerned, has been the introduction of so many new and pretty hardy plants from China by Messrs. JAS. VEITCH & SONS, of Chelsea, through their collector, Mr. E. H. WILSON, whose account of his travels now being given in the *Gardeners' Chronicle* gives pleasure to a large number of garden-lovers. The genus Primula has been greatly added to by P. pulverulenta, P. Cockburniana, P. Veitchii, P. vittata, P. deflexa, and P. tangutica, which Messrs. VEITCH are now distributing, along with the pretty rose-purple coloured Geranium platyanthum, Artemisia lactiflora, Rodgersia æsculifolia, and R. pinnata alba. Other fine novelties brought into notice during 1905 by Messrs, VEITCH (though some were figured in these pages in 1904) are the handsome Meconopsis punicea, M. integrifolia, and Buddleia variabilis magnifica, all of which secured First Class Certificates; Senecio (Ligularia) speciosa, Lilium leucanthum, L. sutchuenense, Lobelia tenuior rosea, Astilbe grandis, and others, most of which have been described in the *Gardeners' Chronicle*, and references will be found in the appended list of illustrations. Messrs. VEITCH are also distributing the handsome Deutzia discolor major, Vitis Henryana, V. flexuosa Wilsoni, Lonicera tragophylla, Rubus lasiostylus, and other fine hardy plants.

Messrs. CUTBUSH & SONS, of Highgate, had awards for Adonis amurensis, Pulmonaria arvensis alba, and some other hardy plants, including the fine Carnations General Kuroki and Lord Charles Beresford, both good for outdoor and greenhouse culture.

Mr. AMOS PERRY, Winchmore Hill, has developed new tints in Autumn Asters, and obtained Awards of Merit for Aster sub-cœruleus and Betonica spicata robusta.

Messrs. Kelway & Son, Langport; Ware, Feltham; R. Wallace & Co., Colchester, and others have contributed much to the improvement of garden-flowers.

Florists' Flowers.

Chrysanthemums, Dahlias, Roses, Carnations, Begonias and other of the large classes have been satisfactorily increased by cultivators of the different classes of plants, and most of these have been reported at various times in the *Gardeners' Chronicle*, many of the best being now enumerated in the list of good subjects illustrated in 1905. Of those which have received Awards it is at present impossible to say how many will become standard varieties for general cultivation, though all showed distinctive merits as novelties. Mr. Jas. Douglas, of Edenside, Great Bookham, took the lead with Auriculas and Carnations and secured many Awards. In Carnations he has arrived at the point formerly considered to be impossible, viz., a specially-saved strain of seeds warranted to give a large proportion of double flowers of good quality. Mr. Martin R. Smith, Mr. S. Mortimer, and Messrs. Bell & Sheldon also received Awards for Carnations.

Messrs. Dobbie & Co. extended their fame for bedding Violas by getting Awards of Merit for Violas, Councillor Watters, Doctor McFarlane, Isolde, and Royal Sovereign.

Narcissus.—These charming flowers increase in favour, though the good work already done in producing fine florists' varieties renders it difficult to secure Awards for recent novelties of superior merit. The best of the year which secured Awards were Narcissus Countess of Radnor, a white Ajax shown by Miss Willmott, V.M.H., who also secured an Award for Tulipa Fosteriana; Narcissus King's Norton, a Giant Yellow Ajax from Messrs. Pope and Sons, King's Norton; N. Lord Kitchener, a pale bicolor, sent by Mrs. Backhouse, Sutton Court, Hereford; N. Alice Knight, a pretty white Ajax with yellow centre from Messrs. Barr and Sons, Covent Garden; N. Cornelia and N. Masie Hall from R. H. Bath and Co., Wisbech; N. Banzai from Messrs. de Graaff, Leiden; and N. Countess of Stamford from Mr. E. M. Crossfield, Wrexham.

Stove and Greenhouse Plants.

These have been recruited chiefly by home-raised varieties, and by a few newly-imported species.

Fine novelties of the year were Crinum Rattrayi, the perfection of the C. giganteum class for which Sir Trevor Lawrence received a First Class Certificate, the same exhibitor securing an Award for Anthurium Scherzerianum burfordense, with showy spathes nearly six inches in length.

From the Right Hon. Lord Rothschild's garden came the handsome Nymphæa zanzibarensis rosea and the fine Gloriosa Rothschildiana citrina; from Leopold de Rothschild, Esq., the compact bright red Ixora "Mars"; and some other novelties were noted from other gardens.

Messrs. Sander & Sons, St. Albans, have attained great perfection in their beautiful strain of foliage Begonias and in the now popular Nicotiana Sanderæ, which is being still worked for novelties. Of their imported species Cycas Micholitzii is the most remarkable introduction.

Cyrtanthus angustifolius grandiflorus shown by Miss Willmott, V.M.H., and C. sanguineus glaucophyllus secured Awards of Merit, and the new C. inæqualis flowered from bulbs imported by Messrs. W. Cutbush & Sons, Highgate.

The following Novelties and interesting plants and fruits have been illustrated in the *Gardeners' Chronicle* during 1905:—

Abelia uniflora, May 27, p. 323
Adonis amurensis, Mar. 25, p. 188
Agapanthus umbellatus globosus, Sep. 23, p. 237
Aloe Chabaudii, Aug. 5, p. 102
Aloe decora, Dec. 2, p. 386
Aloe Orpenæ, Dec. 2, p. 386
Anemone nemorosa double, May 20, p. 307
Angiopteris evecta Teysmanniana, Supp. May 27
Apple, "Coronation," Oct. 14, p. 281
Apple, Fenn's Wonder, Jan. 14, p. 20
Apple, King's Acre Bountiful, Nov. 11, p. 341
Asparagus Sprengeri in flower, Jan. 7, p. 10
Aster sub-cœruleus, July 8, p. 23
Astilbe grandis, Supp., Dec. 16
Begonia, Duchess of Cornwall, p. iv. Supp., June 3
Begonia, Ne Plus Ultra, p. iii. Supp., June 3.
Bougainvillea spectabilis in California, Supp., Mar. 18
Brunsvigia gigantea, Supp., Mar. 25
Brunsvigia Josephinæ, Mar. 25, p. 186
Buddleia nivea, Oct. 14, p. 275
Calodendron capense, Supp., May 13
Campanula carpatica, "White Star," Aug. 19, p. 145
Campanula michauxioides, Supp., Aug. 12
Campanula Zoysii, Sep. 23, p. 288
Campanula punctata, Supp., Aug. 26
Canna Papa Crozy, June 10, p. 356
Cantua buxifolia, Mar. 18, p. 173
Carnation Bob Acres, July 22, p. 65
Carnation Elizabeth, May 6, p. 285
Carnation Countess of Radnor, Aug. 5, p. 113
Carnation Miss Willmott, July 22, p. 73
Carnation Pride of Westbury, July 29, p. 88
Castanospermum australe, Sep. 30, p. 245
Ceanothus thyrsiflorus, Mar. 25, p. 179
Ceropegia Woodii seed-pod, April 22, p. 244
Chrysanthemum Miss Irene Cragg, Nov. 18, p. 363
Chrysanthemum Mrs. R. Hooper Pearson, Supp., Dec. 2
Chrysanthemum Souvenir de Petite Amie, Dec. 16, p. 419
Citrus japonica, Dec. 23, p. 445
Clusia grandiflora, Dec. 2, p. 389
Cordyline indivisa, Feb. 4, p. 66
Crassula columnaris, Aug. 26, p. 162
Crinum Rattrayi, Supp., July 1
Crocus Malyi, Mar. 18, p. 163
Crowea angustifolia, Apr. 22, p. 242
Cycas Micholitzii, Aug. 19, pp. 142-3
Cyrtanthus angustifolius grandiflorus, Apr. 29, p. 261
Cyrtanthus inæqualis, Aug. 29, p. 261
Diervilla rivularis, Nov. 11, p. 339
Dimorphotheca aurantiaca, Aug. 12, p. 127
Echium Wildpreti, July 1, p. 5
Eleutherococcus Henryi, Dec. 9, p. 403
Eleutherococcus leucorhizus, Dec. 9, p. 404.
Eupatorium micranthum, Sep. 23, p. 229
Ericas Veitchii, arborea and lusitanica, Apr. 15, p. 228
Fig Bourjassotte grise, Oct. 7, p. 258
Gentiana Lawrencei, Oct. 28, p. 307
Gladiolus tristis concolor, Sep. 2, p. 187
Gloxinia Kaiser Wilhelm, June 10, p. 356
Gloriosa Rothschildiana citrina, Sep. 16, p. 211
Grape Prince of Wales, Oct. 14, p. 277
Heliamphora nutans, Apr. 1, p. 194
Heliopsis breviscapa, Mar. 25, p. 178
Inula Royleana, Supp., Oct. 7
Impatiens Holstii, July 1, p. 14
Iris tingitana, June 3, p. 339
Lachenalias, aurea, Brilliant, Jean Rogers, and pendula aureliana, pp. 210, 211
Lachenalia liliflora, Oct. 7, p. 259
Lilium Bakerianum, July 22, p. 75
Lilium Glehni, Jan. 7, p. 3
Lilium myriophyllum, Supp., Nov. 4
Lilium sutchuenense, Supp., July 29
Magnolia Kobus, Supp. Ap. 29
Meconopsis grandis, June 17, p. 369
Meconopsis integrifolia, May 13, p. 291
Narcissus (monophylla × Tazetta), Feb. 11, p. 82
Narcissus Nectarine and Pelops, May 20, p. 309
Nerines (Blenheim Palace), Nov. 18, p. 357
Nymphæa zanzibarensis rosea, Supp. Nov. 25
Orange, Japanese, Dec. 23, p. 445
Pear Louise Bonne of Jersey, Oct. 14, p. 283
Pear Madame Treyve, Supp. p. ii., Oct. 14
Pear Passe, Crassane, Jan. 7, p. 11
Pear Marie Louise, Oct. 14, p. 285
Pear Marie Louise d'Uccle, p. iii. Supp., Oct. 14
Pear Santa Claus, Jan. 14, p. 21,
Pear Roosevelt, Sep. 30, p. 243
Pelargonium Madame Crousse, Feb. 25, p. 116
Pelargonium "Clorinda," Supp., Ap. 15
Physalis (hybrid), Oct. 28, p. 315
Pinus Nelsoni, May 20, p. 306
Pinus Pinceana, Aug. 12, p. 122
Pinus radiata, Dec. 23, p. 435
Pinus yunnanensis, Sep. 23, p. 227
Primula Cockburniana, May 27, p. 331
Primula deorum, Feb. 18, p. 98
Primula ovalifolia, Supp., July 22
Primula tangutica, July 15, p. 42
Primula sinensis (stellata), Supp., Feb. 25
Primula Veitchii, Supp., June 3
Primula vittata, June 24, p. 390
Pteris aquilina, crested, Sep. 2, p. 189
Rhabdothamnus Solandri, Mar. 11, p. 146
Rhododendron Lady Godiva, June 17, p. 371
Rhododendron Pink Pearl, June 10, p. 354
Rhododendron Sappho, June 17, p. 370
Rhododendrons (Waterer's), June 10, p. 355.
Rosa gigantea, Supp., Mar. 4
Rosa sericea pteracantha, Oct. 7, pp. 260-1
Rose Lady Gay, June 3, p. 349
Roses Waltham Bride and Debutante, June 3, p. 347
Rubus innominatus, Oct. 21, p. 291
Sarracenias, Temple Show, June 17, p. 373
Senecio auriculatissimus, Apr. 8, p. 213
Senecio Veitchianus, Supp., Dec. 30
Schizandra Henryi, Aug. 26, p. 162
Schizanthus (Endcliffe), Aug. 19, p. 155
Spiræa Aitchisonii, Aug. 5, p. 114
Spiræa bracteata, March 11, p. 149
Spiræa pachystachys, Nov. 4, p. 322
Strawberry Bedford Champion, July 15, p. 43
Sweet Pea Helen Lewis, July 8, p. 35
Sweet Pea Henry Eckford, July 15, p. 47
Syringa villosa pubescens, Aug. 12, p. 123
Thalictrum Delavayi, Dec. 30, p. 450
Thunbergia natalensis, Mar. 18, p. 162
Veronica Hulkeana, Sep. 30, p. 242
Vitis Henryana, Oct. 28, p. 309
Widdringtonia Whytei, Jan. 14, pp. 18, 19.

PEARS AT HARTHAM PARK.

A visit paid in autumn to Hartham Park, Corsham, the residence of Sir John Dickson-Poynder, afforded an exceptional instance of successful Pear culture, conducted by Mr. W. J. Welch, the gardener in charge. Pears were unsatisfactory prior to Mr. Welch's time, and a remedy was sought by him in cordon-trained trees, planted in a well-prepared border consisting largely of maiden loam incorporated with some of the original garden soil, to which were added some bone meal and wood ashes. A wall having a southern aspect was cleared of derelict trees, the adjacent border excavated to the extent of a yard in width and depth, and drainage provided prior to this space being filled up with a prepared mixture of soil. Trees were purchased from a good source, in some cases six of one kind, the after-growth of which gave ample return for the labour involved. Fruits of good appearance, high quality, and large size were soon forthcoming, and they increased in quantity as years passed. Failure due to spring frosts is unknown here, and is largely due to the protection afforded the flowers; double or treble thicknesses of fish-nets are suspended and kept rigid by means of fir-poles placed in position in good time. The same provision has to be made in autumn to protect the fruit against the attack of birds, some of which show so marked a partiality for Pears. To give a greater length of main rod, the trees are trained obliquely. Beurré d'Amanlis following so closely on Williams' Bon Chretien, perhaps affords a solitary instance of complaint as to high merit, and this, I think, is readily admitted, and often experienced by others, for it is difficult to "take on" another Pear once the Bon Chretiens are over. Louise Bonne of Jersey, Souvenir du Congres, Comte de Lamy, Beurré Superfin, and Beurré Hardy afford a succession of high-class, clear-skinned fruits. Of Doyenné du Comice, several trees have been planted, and their yield is always satisfactory, for the clearness of the skin and large size of individual fruits gives this, the best of all Pears, its true value and position. Pitmaston Duchess necessarily grows to a large size, as do Beurré Alexander, Lucas, Princess, Durondeau, Beurré Diel, and Beurré Bachelier. This last-named Pear is grown more as an accommodation than for quality, keeping up, as it does, a succession, when other and better ones have been used. Emile d'Heyst and Marie Louise both do well, and give of their best, being always reliable in crop and flavour. Of smaller kinds, Winter Nelis is always good, so, too, is Josephine de Malines, Easter Beurré and Bergamotte d'Espéren. One of the finest specimens I have ever seen of this variety grew at Hartham; the fruit, typical in shape, was distinctly out of proportion to the familiar size. Both Marie Benoist and Nouvelle Fulvie succeed well. These are varieties that are not universal successes, but the same may be said of many other varieties, soil playing so large a part in the successful culture of any particular kind. Beurré Rance, if it does not always ripen sufficiently for the dessert table, can be turned to useful account by the chef. Mr. Welch makes an effort to induce surface root action by mulching and feeding. The border is so

fully occupied with roots that no part of it could be disturbed without injury to the fibres. To this fact, no doubt, is due much of the success of the system of culture adopted. There is no gainsaying the fact that cordon training here gives much better results than could possibly be got from any other form of tree, because the space at disposal on the walls is not of great extent. *W. Strugnell.*

MASSONIA PUSTULATA.

THIS very curious and interesting plant was exhibited by Mr. Elwes at the last meeting of the Royal Horticultural Society, when it received a Botanical Certificate from the Scientific Committee. The plant is by no means new in gardens, as it was introduced by Masson, and was figured in the *Botanical Magazine* more than a century ago (tab. 642, April 1, 1803), but it does not seem to have been found wild since Masson's time. Mr. Elwes' plant differs from the one originally figured in having three leaves in place of two—otherwise it agrees exactly. Mr. Worthington Smith's drawing shows the pustulate leaves, "like shagreen," as stated in the *Botanical Magazine*. He also supplies details of the flower which will be very useful. From them it is evident that the plant is Liliaceous with a head of green flowers, each of which has a cylindrical perianth tube, from the edge of which proceed the six narrow spreading segments and as many stamens. The tube of the flower is filled with nectar, formed as it would seem from the blackish tissue at the base of the stamens. This is well described in the *Botanical Magazine* as "a clear nectareous liquid which, rising above the brim, adds to to the singular appearance of the plant." The pollen grains, as observed by Mr. Smith, are relatively large and ellipsoid. The genus Massonia, according to Mr. Baker's monograph of the Liliaceæ contains 23 species, all natives of the Cape of Good Hope. The exact habitat of the present species is unknown. See Baker in Flora Capensis, vi. (1897), p. 410. A warm greenhouse temperature with plenty of water in the growing season and little or none during the resting stage seem to be indicated.

LAW NOTE.

POISONOUS WEED KILLER.

At the Chertsey County Court, on January 11, before his Honour the Hon. A. Russell, the Pharmaceutical Society of Great Britain sued Messrs. Jarvis & Mackie, seedsmen, &c., of Weybridge, for a penalty of £5, under section 15 of the Pharmacy Act, 1868, for selling arsenic contained in and forming part of the ingredients of a compound known as Bentley's Weed Killer. A witness named Waldock said he called at the defendant's premises, and asked for some Aqua weed killer, but the assistant said they only kept Bentley's. The witness then purchased a tin (produced), which had nothing on it to show at which shop it was purchased. Mr. Moon, Secretary of the Pharmaceutical Society, said the compound sold as Bentley's Weed Killer was a most deadly poison, and should only be sold by a chemist after enquiring the name and address of the purchaser. Mr. P. C. Burley, of Petersfield, who appeared for the Society, said the object of the prosecution was to protect the public against the sale of this deadly poison except by qualified persons under special restrictions. His Honour gave judgment for the Society, awarding the penalty asked for, and costs.

NURSERY NOTES.

AMERICAN CARNATIONS AT MESSRS. WALSHAW & SON'S, SCARBOROUGH.

A VISIT to these nurseries during the winter months will amply repay all who are interested in the American Carnation and its culture, for here these lovely flowers are grown to perfection. The American Carnation is an improved type of the old tree or perpetual flowering varieties, being of larger size and possessing longer stems than the older race, thus rendering them more suitable for use as cut flowers, or as decorative plants. The plants should be rooted early in the year, potted in the spring into 5-inch and 6-inch pots, placed outside until the end of August, when they should be removed to their winter quarters. A span-roof house, provided with abundant means for ventilation, forms a suitable structure for their accommodation. They can be had in flower all through the winter months without the aid of much fire heat. It is necessary to fumigate the plants once a month or thereabouts, in order to keep down green-fly. Some growers succeed with them when they are planted out into prepared beds of good soil under glass during the winter months. The dreaded rust, I am told, may be ignored in these American introductions, for they grow out of it, and are none the worse for its attack.

At the time of my visit (November 28), several houses contained these plants in their various stages of growth, from the cuttings, which are struck singly in small pots in a little bottom heat during the winter months, to well-flowered

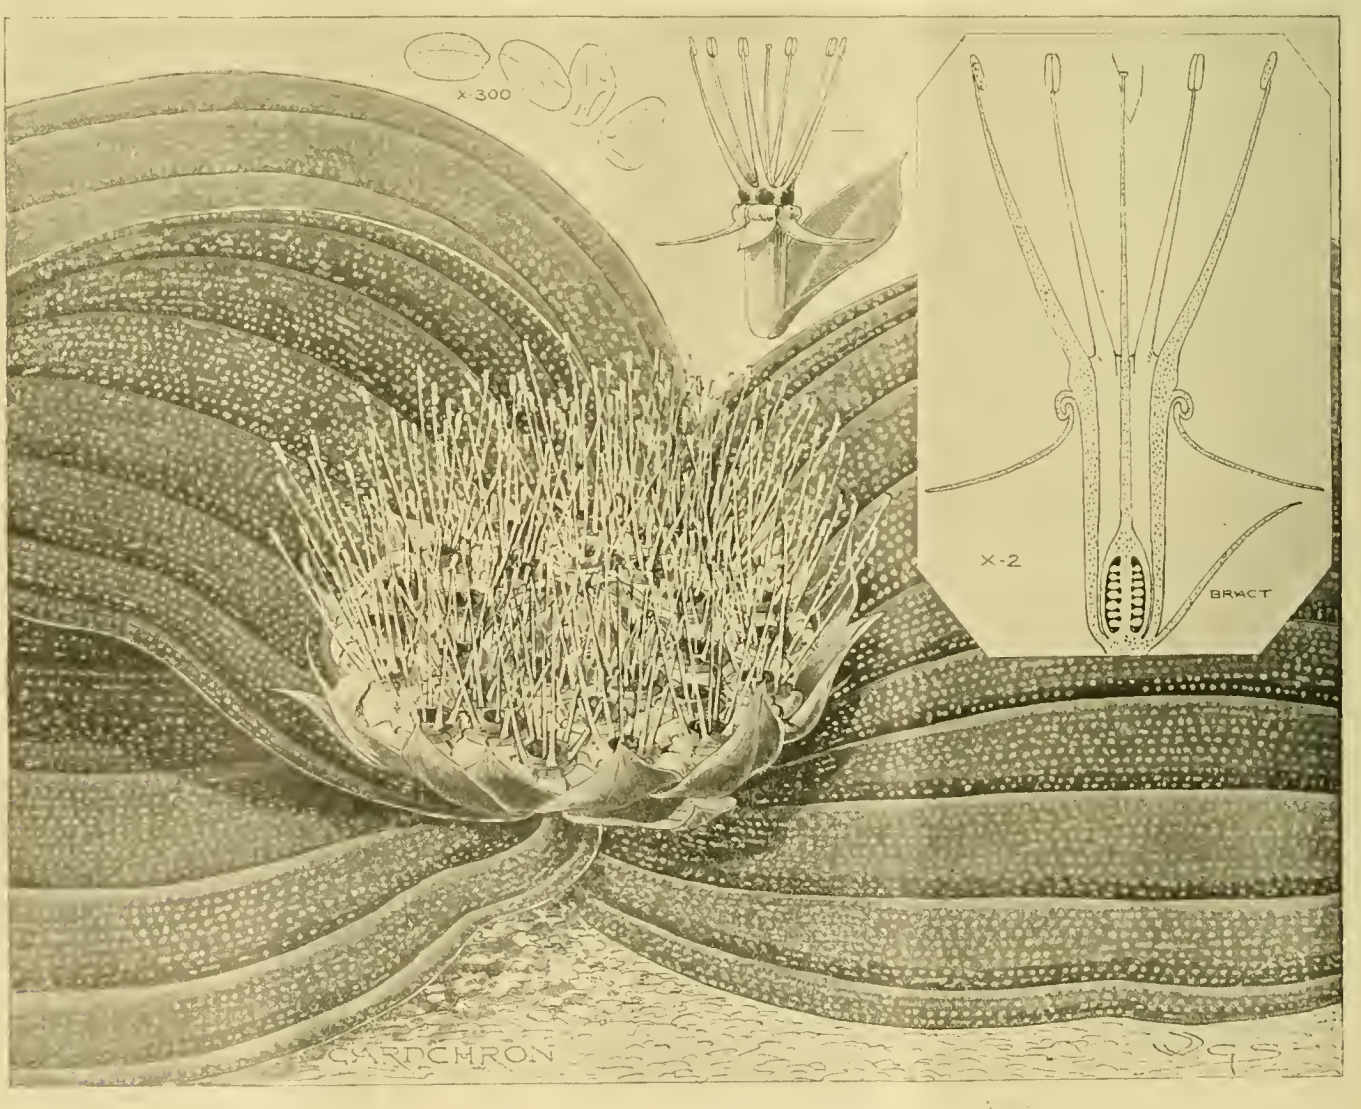

FIG. 23.—MASSONIA PUSTULATA. REAL SIZE; FLOWERS GREEN, WITH A BLACK CENTRE.

plants in 5-inch and 6-inch pots. Older and standard varieties include Mrs. T. W. Lawson, a well-known variety, having large, deep-pink coloured flowers; Harry Fenn, a large crimson flower, with a long, stiff stem; Floriana of coral-pink colour, and possessing a very sweet perfume; Prosperity, a large fringed flower, colour, a whitish-pink; and Governor Wolcott, a large pure white variety.

Varieties of 1904.—Judge Hinsdale, Mrs. M. A. Patten, MacRinde, The Belle, Lady Bountiful, the three last named being white varieties; Enchantress, a very large flower of flesh-pink colour; Ethel Ward (rose-pink), Flamingo (brilliant scarlet); Christmas Eve, a variety flowering late in the season; The President (bright crimson), and Octoroon (the petals of this variety are fringed).

Among the new varieties of 1905 are Lieut. Peary (snow-white), Fiancée (pink), Cardinal (brilliant scarlet). Most of the above-named varieties are deliciously scented, and seem destined to become popular favourites. They are more easy of culture, and better to manage in every way than Souvenir de la Malmaison Carnations, and afford a supply of flowers during the winter months without entailing great expense.

Other interesting things noticed at the time of my visit were a large House of Begonia Gloire de Lorraine, the plants, in 4 and 5-inch pots, all showing excellent health and good development of colour; a splendid lot of Poinsettia pulcherrima, in 5 and 6-inch pots; quantities of Lilium lancifolium, etc., in various stages of development; thousands of plants of Lily of the Valley, Chrysanthemums in great variety, Callas, Kentias, and other Palms. *Bailey Wadds, Birdsall Gardens, York.*

THE HARDY FLOWER BORDER.

KNIPHOFIA CAULESCENS.

THIS is one of the strongest growing species, and, if planted in a slightly sheltered position, soon grows into a mass. A fine clump in the Cambridge Botanic Gardens is growing near to the south side of a greenhouse. The clump occupies a space about 10 feet by 4 feet, and flowers very freely during July and August. The red and yellow flower heads are produced on strong scapes about 4 feet in height, and they give a bold display of colour even when viewed from a distance.

In the colder parts of the country some protection from severe frost is necessary, and may be provided by placing a good coating of leaves or any rough litter about the bases of the plants on the approach of rough weather. *E. J. Allard.* [This species was figured in a supplement to the *Gardeners' Chronicle*, November 16, 1889.—ED.]

GYPSOPHILA ROKEJEKI.

G. ELEGANS, G. paniculata, and the earlier blooming G. Stevensi are the best known species of Gypsophila. But this one with the outlandish name is well worth introducing to their circle. In our cool climate it reaches a height of 6 feet, and increases in comeliness—it cannot be called beautiful—as the days shorten. The plant looks its best when isolated in a group of low-growing plants. It is then handsome, but in a mixed company of tall plants it is passed unnoticed. Like other Gypsophilas, it grows and produces its flowers without causing any trouble, and also like them, it is of much use as a cut flower.

ACONITUM AUTUMNALE ALBUM.

NOT many white varieties of blue flowers are better than the type, and when the species is in every respect possessed of so much beauty, alike of foliage, habit, and colour as this, one hails a good white variety with the greater pleasure. The plant has yet to make its way, but it is in every respect so fine that is is only a question of time to find it occupying a prominent place among the best herbaceous plants. The flowers are really not white, but a sheeny, silky approach to it, and one of its greatest charms. The Autumnal Aconite is usually grown as large single plants, but to secure its fullest beauty strong single crowns should be selected and planted at a foot apart. The white variety blends admirably with the blue, but is also invaluable if grouped separately.

CELSIA CRETICA.

FEW plants attract more attention than Celsia cretica when grown, as it ought to be in large groups, yet, judging from the enquiries made as to its identity, the plant is but little known. I treat it and other Celsias as half-hardy annuals. From seeds sown in February the plants begin to flower in July, and continue till the end of the season. The effectiveness of large groups is increased when plants here and there are topped early in the season, which induces a more dwarf and bushy growth. Here the spikes attain to a height of 4 to 5 feet. Also handsome and much taller is C. coromandelina, another yellow-flowered species, which is useful to mix with low-growing herbaceous plants. C. pontica has white flowers, with free branching spikes rising to a height of eight feet. It is one of the best autumnal hardy flowers we have, and well worth extended cultivation. Those who have seen it only as a half-starved and old specimen in the herbaceous border can form no idea of how handsome and effective a subject it is when grown as an annual. I have no doubt that in the southern counties seeds sown in the open in March will yield good autumn flowering plants. In the north they are too late, though this year I have the pretty C. Arcturus flowering from open-air seedlings. The above-named are the best of the Celsias I have tried, and they are all so good that they can be safely recommended for general cultivation, only it is essential to grow several together, and not one here and there singly. *R. P. B.*

FRUIT REGISTER.

BALGOWAN NECTARINE.

I HAVE found this old, but seldom seen, Nectarine, an excellent variety, both under glass and outside. On our stiff limestone soil, we cannot get either of those two fine varieties, Early Rivers and Lord Napier, to succeed. The trees of these two varieties produce abundant crops, and the fruits attain a fine size, but they always shrivel at their crowns just before ripening, although we have tried shading them heavily after the commencement of their second swelling. We have lifted the roots in winter, but all to no purpose. As will be known to experienced fruit growers, some varieties of fruits, and these often good kinds, fail to finish well in particular localities. In our case no Nectarine that has any of the Old White Nectarine parentage does well. I think both the varieties named are of that lineage. There was a fine tree of Old White in one of the Peach-houses when I came here in 1872, but its fruits never finished satisfactorily. I well remember my predecessor, Mr. W. Denning, telling me it had not done well under his care. The varieties, Violette Hative and Elruge, generally succeed well with us. Balgowan is of the same type, but its fruits are larger, and are equally as good in colour, texture of flesh, and flavour. As its name implies, it is of Scottish origin. *H. J. C., Grimston.*

THE VILMORIN MEMORIAL.

BY the courtesy of the director of the *Revue Horticole* we are now enabled to lay before our readers an illustration of the model of the proposed Vilmorin monument. On the death of the late Henry de Vilmorin it was suggested that a memorial should be erected which should perpetuate his memory and serve to recall the great services to horticulture and agriculture rendered by the Vilmorin family. It has been said that but for them there would have been less wheat in our fields, less sugar in our Beet-roots, and fewer flowers in our gardens. Although the saying applies especially to France it is by no means inapplicable here and in America. No foreigner, we venture to say, was more beloved in this country by those who knew him than Henry de Vilmorin

FIG. 24.—THE VILMORIN MEMORIAL.

Our fathers said the same thing of his predecessors, and the present representatives nobly uphold the traditions of the family. The group modelled by M. Carlier is suggestive of Agriculture and Horticulture and of the work done by the Vilmorins in these departments. On the pedestal are placed four medallions representing four generations of the Vilmorin family. The total number of subscribers up to the present time is 3,822, and the amount received is 37,151 francs (about £1,486). As showing how wide was the respect felt for Henry de Vilmorin it may be noted that a large number of the subscriptions are for small amounts of one franc and upwards. In order to complete the monument as designed further subscriptions are requested. We shall be pleased to remit to M. Bourguignon, the Treasurer, any sums that may be entrusted to us for the purpose.

PLANT NOTES.

MOMORDICA ELATERIUM.

THIS plant is said (*Bot. Mag.*, tab. 1914) to survive only two or three years in the open. I have a specimen in my garden which has now survived 12 years, and possesses a very large rootstock. Many other specimens have established themselves at a short distance from the old plant, sprung up, of course, from the scattered seeds. Some of them have already survived six years.

MIMOSA DENHARDTI.

CAN anyone let me know something about this plant, of which I have four fine specimens, with leaves almost as sensitive as those of Mimosa pudica? It is a greenhouse plant. I cannot find any reference to it in the *Index Kewensis* or its supplements. *M. Buysman, Middelburg, Holland.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

HELLEBORUS NIGER.—Mr. C. Ruse, in writing of the different varieties of Christmas Rose, p. 444, vol. 38, states that St. Brigid's Christmas Rose is synonymous with Helleborus angustifolius. This is certainly not the generally accepted opinion, for amongst those who have made a study of the Hellebores, the correct name for St. Brigid's Christmas Rose is recognised as H. juvernis. This is quite a distinct plant from H. angustifolius, and is one of the most beautiful forms of H. niger. It bears pure white flowers, which are cup shaped, upon apple-green foot-stalks, the foliage being little serrated and of lightish green colour. Of H. n. angustifolius there are two forms, the Scotch and the Manchester varieties, the former being sometimes known as H. n. scoticus. In the variety scoticus the blossoms are often suffused with rose at the back of the petals, but in the Manchester variety the flowers are pure white. In both forms the blooms are somewhat starry in shape and quite lack the cupped appearance of H. n. juvernis. Some nurserymen also err in cataloguing H. n. angustifolius and H. n. juvernis as identical. *S. W. Fitzherbert.*

RHUBARB.—Where fresh plantations are required (and it is best to make a new one each year) the present is a good time to do so. Rhubarb being a gross feeder, rich, well-trenched ground is essential to quick growth. Divide up as many crowns of a good variety as necessary, choosing a variety that will force easily, and plant them in rows 3 feet apart, allowing the same between the plants. A good, strong knife is the best instrument to use in dividing the old plants, as there is less likelihood of causing injury than when the spade is used. Dig up and thoroughly expose to the weather all plants intended for forcing, as growth will then be much quicker after they are subjected to the influence of heat. *James Gibson, Welbeck Gardens, Worksop.*

ROOTS IN STORE.—Examine all roots in store, and it is worth while even to re-store the whole at this season. There is then less likelihood of decayed parts passing unnoticed. No attempt should be made to keep the soil around them excessively dry, or such roots as Beet and Turnips will lose some of their juice and other qualities. *James Gibson, Welbeck Gardens, Worksop.*

SEED PACKING.—Early in the year 1890 my brother, Harold E. Bartlett, who was then 200 miles up the Niger in the service of the Royal Niger Company, wrote home asking me to send him a few seeds of common annuals and perennials, such as, Mignonette, Stocks, Asters, Sweetwilliams, Foxgloves, etc., and two or three Grape stones, as, although surrounded by noble Palms and many gorgeous flowers of the tropics, he, like many of our countrymen similarly situated, longed for the sight and smell of the common flowers of our English cottage gardens. "I want to make, as far as I can, a little English flower-garden in front of my bungalow," he wrote; "so just send me the merest pinch of each kind in your next letter. I don't much care even if they are mixed up, I can sort them as they grow. Don't take any trouble with packing as postage is very dear (6d. per ½-ounce), and all these patent paraphernalias are quite unnecessary. When I came out I brought some seeds from Kew in ordinary paper packets, and to my great surprise nearly every-kind germinated very quickly and freely. I expected a large proportion of failures." I do not know what these seeds were, but as the journey to the Niger at that time included a fortnight in a coasting steamer along the Gold Coast, one of the notoriously hot and dry regions of the world, this was a good test of the vitality of seeds under the impossible conditions of Mr. Watson's critics. The few mixed seeds which I sent were duly received, but I fear were never sown, for my poor brother, after struggling manfully against nine months of intermittent fever, succumbed to an unusually severe attack which brought to an untimely end a very promising career. *A. C. Bartlett.*

ANTHRACITE COAL AT A BARGAIN!—Can any reader throw some light upon the reason why trucks loaded with anthracite coal are so constantly breaking down? About once a month I receive a letter from sellers of such coal telling me that they unfortunately have some trucks of anthracite coal broken down near my station, and asking if I would care to avail myself of the opportunity of buying this coal at such and such a price. The last firm I heard from made me an offer of coal of this kind at about the ordinary market price at the time. My curiosity was aroused, so I wrote to the vendors asking where the broken down trucks were. I was told "they were at a certain station"; but the stationmaster there informs me he can find no trace or record of any broken down trucks, or, indeed, of any trucks of anthracite coal awaiting order. I write this wondering if other readers of the *Gardeners' Chronicle* are pestered by similar attempts to induce them to buy anthracite coal at market price under pretence that they are being offered a bargain because of a misfortune which has fallen on the coal-seller. *A. Holland Hibbert.*

THE UNEMPLOYED.—Instead of sending money to the Queen's Enemployed Fund, Sir Charles Hamilton, Bart., Hatley Park, has given work to a dozen men with large families to support living in the neighbouring parish. As there are in most gardens at this time of the year additions and alterations to be made in the pleasure grounds, &c., these men are proving very useful to the gardener. It is a good idea, and should be followed by other generous employers. *B.*

WHITE NICE GRAPE (see p. 16).—This grape used to be, and may be still, grown at Arkleton, Langholm, Dumfriesshire. *H. W. W.*

THE WILLOW FOR CRICKET BATS.—What is the botanical name of the particular Willow of which the best cricket bats are made? The question is not so easily answered as might be supposed. I have consulted the authorities at Kew, but they could only refer me to their issue of the *Kew Bulletin* of September, 1905, p. 239, where there is a paragraph relating to "Salix alba"—the Huntingdon or White Willow used for making cricket bats. From this it appears that the supply is falling off and the demand increasing, as much as 5s. per cubic feet having been offered for "the right stuff." All the authorities that I have consulted, such as Loudon, Forbes, and the greatest authority on Willows of all, Borrer, make no mention of this particular use to which the wood of "Salix alba" is put, probably because the modern bat was unknown in their time. As my own botanical friends could not help me, the next step was to consult the bat-makers; and what did I find? That they also were quite ignorant of the correct name, but knew the tree when they saw it, and I gathered in the course of my enquiries that so keen where they to secure the "right stuff" that they were constantly sending men to scour the country for it. I ascertained that the trade name for it is the "Close barked White Willow" as opposed to the open barked sort, and that the best comes from Essex. The qualities required by the makers are lightness and straightness of grain, and the ordinary White Willow as found in the Midlands and the North is deficient in these qualities, being, in fact, much too heavy and solid. Now, all botanists are aware that the Willows constitute one of the most involved genera of plants to study, and no two authorities agree as to what are species and what are varieties. There are so many hybrids and they differ much according to the sex of the tree, soil, and climate. Thus Alpine willows 6 inches high, with narrow leaves, when planted in an English garden, develop into bushes and change their character completely. Whether the climate and soil of Essex have anything to do in this case with the quality of the wood, or if it is the particular variety that grows there, I am unable at present to prove. I have secured some cuttings that are supposed to be of the variety required, but the species cannot be proved until they have grown large enough to produce flowers. My own theory is that the "close barked White Willow" will be found to be Salix alba var. cœrulea, and possibly the female, which is the more vigorous. It is the quickest grower of all the tree Willows in a moist soil, reaching 18 inches in diameter in as many years, when it is ready to cut down. The quicker the growth the lighter the timber and the better the price, and the profit from the planting of this ought to compare very favourably with any other timber with which I am acquainted. *L. Fosbrooke, Ravenstone Hall, Leicestershire.*

TO BRIGHTEN BEDS OF AZALEA, RHODODENDRON, ERICA, SKIMMIA, ETC.—That the beds and borders consisting of these plants want some other species to give colour to them should they form prominent objects in or about a flower garden, is a thought that would occur to most persons, and these same individuals would most probably choose some members of the genus Lilium to fulfil this purpose. In many cases this would result from conscious or unconscious copying, a thing we all do too commonly. There are many other species of plants which would do equally well. Even Lilies do not flower all the summer and autumn seasons, unless you make use of the bulbs in pots, and possess cold storage, so as to have them in bloom in nearly every month when blossoms are to be found in the open. And few of us can do that. The main consideration is the time of year in which the beds of shrubs are to be brightened. Is it before the blooms of the chief permanent occupants of the beds appear, or after the flowering is over? There are Roses of various classes which would be very suitable as affording flower colour in quantity; for example, the various Ramblers, Fellenberg Noisette, Scots Roses, the common China or monthly Roses, as Cramoisie Supérieure and Hermosa, very regular and constant bloomers; the so-called Bedders, viz., Fisher Holmen, Duke of Wellington, Captain Christy, General Jacqueminot, Grace Darling, Gruss as Teplitz, Mad. Victor Verdier, Magna Charta, etc.; and the Rosa polyantha varieties. Roses, like all other plants that do not succeed in peat, must be planted in properly prepared suitable composts, in stations excavated between the bushes; not a difficult matter if the latter are not standing too closely together. The chimney Campanula (C. pyramidalis) would show up with fine effect where the bushes are not taller than four feet, and C. carpatica might be employed near the margins of the beds. Ajuga reptans, Plumbago Larpentae, the bright, free flowering varieties of Pyrethrum roseum, Gaillardias, and Aubrietias, make showy permanent borders to beds of Azaleas, Rhododendrons, etc., as do the various species of hardy Ericas. For interspersing between the permanent shrubs, Hyacinthus candicans, Hemerocallis flava, aurantiaca and fulva are showy and of moderate growth, also Lythrum virgatum, Pentstemons, Golden Rod, Phlox decussata, and the bulbous and other Irises offer good material of a showy character. Dahlias of the Pompon and dwarfer single-flowered forms would not be out of place in such beds, and such Spiræas as Bumalda, the taller varieties of Callosa; Antony Waterer, S. Thunbergi, S. Sorbifolia, and S. Douglasii, would afford desirable colours and pretty flowers. Where the beds of shrubs are of large size, it would not be inadmissible to plant a few standard Crabs, such as the Siberian, coronaria, florepleno, floribunda, Orientalis, Dartmouth, etc., such objects assisting in the breaking up of the contour of flat-headed colonies of evergreens. But the employment of such objects demands careful consideration, otherwise incongruous combinations will result. The mixing of but few species of plants in beds adjacent to each other would be preferable to too large an assortment, that would only be productive of a bizarre effect. In most cases one bed one species of plant should be the rule with regard to those employed for brightening, excepting if the bed or border is of great extent, when more latitude may be indulged. *F. M.*

CITRUS JAPONICA FRUCTO ELLIPTICO.—The First Class Certificate granted to this most unhappily named little orange by the Fruit Committee, on the 9th inst., had nothing whatever to do with the decorative appearance of the plants shown by Messrs. Veitch & Sons, but solely with the fruit as produced and tasted. Those who may not have seen plants in fruit, and know Golden Nugget Tomato, can understand that each plant, though but 18 to 20 inches in height, bushy and well-foliaged, carried scores of golden-coloured fruit, just about the size of those of Golden Nugget, but a little more cylindrical. Most certainly this remarkable prolificacy helped to the award, but more still did the tasting of the ripest fruits, and the riper the sweeter, for they were, though of brisk taste, yet the sweeter the more eaten, and the committee regarded them as presenting a most interesting and useful addition to our too limited list of house-grown dessert fruits. *F.R.H.S.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 9TH.—*Present:* Dr. M. T. Masters, F.R.S., in the chair, and Messrs. Massee, Saunders, Odell, Elwes, F.R.S., Michael, Douglas, Bowles, Pickering, F.R.S.; Dr. A. B. Rendle; F. J. Chittenden, hon. sec.

Botanical Certificate.—Mr. H. J. ELWES, F.R.S., V.M.H., showed Massonia pustulata [see Fig. 23 on page 44], a curious Liliaceous plant from S. Africa, having a very short stem bearing three large dark green pustulate leaves and a flattened circular inflorescence. It was figured in the Bot. Mag., No. 642. Mr. ELWES remarked that it was of exceedingly slow growth. On the motion of Mr. DOUGLAS, seconded by Mr. BOWLES, a Botanical Certificate was unanimously awarded.

Apple diseased.—Mr. SPENCER PICKERING, F.R.S., showed fruits from a tree grown in Bedfordshire, and known locally as the "Ring Pippin." Two trees of the variety were growing in an old orchard, and every fruit every year was grooved transversely, so that a deep ring was made in the flesh. No fruits on the trees of other varieties in the orchard were similarly affected. Other members of the committee remarked that similarly cracked fruits were not uncommon, but that they had not seen so extensive an occurrence of the trouble. Mr. DOUGLAS thought that cold winds in the spring were a possible cause. Mr. MASSEE took the fruits for further examination.

Silver-leaf in Apple.—Mr. PICKERING also reported that upon the trunk of the Apple tree in Devonshire, which he had previously mentioned as being affected with silver-leaf, the fungus Stereum purpureum, which is so often, if not invariably, associated with the disease, had made its appearance.

Clematis stem cracked.—Mr. SAUNDERS showed a piece of the stem of Clematis Jackmanni which had split open for a distance of 2ft., starting about 3in. above the surface of the ground. In the interior of the stem a callus-like growth had developed. The stems were referred to Mr. MASSEE.

Fruits, &c., from New South Wales.—Dr. MASTERS showed the following on behalf of Mr. BLAND, of Soham, Cambridge:—

Macadamia ternifolia ("Queensland Nut").—The tree, which belongs to the Proteaceæ, grows wild in the large scrub in the colony. The nuts are very nutritious and of very fine flavour, but are encased in an exceedingly hard shell, which can only be broken by the aid of a hammer. [See *Gardeners' Chronicle*, 1870, p. 1181.]

Castanospermum australe.—The large pod of this, the "Australian Chestnut," with ripe seeds, was also shown. [See *Gardeners' Chronicle*, Sept. 30, 1905, Fig. 93.]

Gleditschia triacanthos.—Legumes of this plant, which occasionally fruits in this country.

Aleurites moluccana.—The Candle Nut tree produces edible nuts, which contain a considerable quantity of oil. From the roots the Sandwich Islanders extract a brown dye.

Coffea arabica var. angustifolia. Grown in New South Wales.

Dodonæa triquetra.—Fruits of this Sapindaceous plant with winged carpels giving a superficial resemblance to hops.

Panicum maximum.—A specimum of this grass, which produces three crops per annum. Stock are very fond of it. An analysis of the grass gives—Moisture, 18.9; albuminous compounds, 7.8; carbonaceous matter and woody fibre, 58.32; mineral ash, 14.97.

Mr. BLAND also sent a silken case into which pieces of twig had been interwoven, and in which a caterpillar lives. The larva suspends the case from branches, fences, etc., and protrudes its head from the opening. At the slightest noise or touch it withdraws its head instantly.

Excrescences on Logan berry.—Mr. J. S. TURNER sent specimens of large, almost spherical, growths of about 3in. in diameter on roots and stems of the Loganberry, very similar to those frequently seen on the roots of Maréchal Niel Roses, formed just below the surface of the soil. The formation of these swellings has been attributed to frost or in other cases to irritation set up by a mite, a species of Rhizoglyphus.

Excrescences on Roots of Birch.—Mr. NOTCUTT, of Woodbridge, Suffolk, sent an example of a similar but much larger growth on the root of Silver Birch. The formation of this gall-like growth on the Birch roots has been attributed to the presence of Schinzia betuli.

Water for Spraying, &c.—Lady St. OSWALD sent the following communication concerning the rainwater supply for garden purposes:—"We are situated in the midst of collieries, brick, coke, and other works, and we think our water supply, which is collected into cement tanks in the usual way, contains an injurious amount of sulphuric acid, &c. Our reasons for thinking the water is harmful are that when used for syringing plants and fruit trees the points of the leaves where the water has been hanging gradually die away until nearly the whole of the leaf is gone. This has been a regular occurrence here, particularly with Peach leaves. Sphagnum-moss on orchid pots and pans does not thrive, and goes brown and dies, but if the syringing is discontinued the young leaves grow healthily. Even roots of some things unaccountably die away." It was recommended that lime should be added to the water except that which was to be used for spraying; to this common ammonia may be added.

GLASGOW SEED AND NURSERY TRADE ASSISTANTS' ASSOCIATION.

JANUARY 13TH.—The members of this Society held their annual dinner on the above date, Mr. A. N. Hunter occupying the chair. In all sixty-three members and friends, representing most of the seed and nursery firms of the city, sat down to dinner.

The principal toast, "Seed and Nursery Trade Assistants," was given by Mr. WILLIAM LEIGHTON, who recalled the days of his apprenticeship, when the regular closing hour in the trade was eight o'clock, Saturday included. In those days there were not so many opportunities for improvement as now, and he thought that the Association was a step in the right direction.

Other toasts followed, and the local Secretary for The Royal Gardeners' Orphan Fund (Mr. JAS. H. PARKER), was afforded an opportunity of speaking on behalf of this laudable Society, with the result that a collection of three guineas was taken in aid of this charity.

NATIONAL CHRYSANTHEMUM.

At a meeting of the Executive Committee on Monday evening last, Mr. Thomas Bevan presided.

Mr. HARMAN PAYNE announced that, in accordance with the resolution of the Committee, a copy of the "repertoire des couleurs" had now been purchased for the use of the Floral Committee, and the same was handed over to the Chairman.

Mr. DEAN, the Secretary pro. tem., then laid before the Committee the balance-sheet for the past year and rough draft of the annual report to be submitted to the annual general meeting of the Society in February next. Mr. C. H. CURTIS submitted a report of the "Early Flowering" Conference, and it was resolved that the papers read and the discussion which ensued should be printed and issued as a separate publication of the Society. A vote of thanks, accompanied by a silver medal, was accorded to Mr. Curtis for his services in connection with that gathering. Some discussion then ensued upon the advisability of the Society publishing a year-book or journal, and this matter was referred to a sub-committee consisting of Messrs. Crane, Curtis, Hawes, Harrison, Jones, and Foster.

Mr. HARMAN PAYNE gave a report of the steps taken by the sub-committee in whose hands the consideration of applications for the post of general secretary to the Society had been entrusted, and it was resolved to adjourn the meeting for another week. It was resolved that in future the awards to be made to miscellaneous exhibits at the Society's shows shall be entrusted to the Floral Committee.

Obituary.

G. W. MAIR.—We regret to announce the death of Mr. G. W. Mair, Superintendent of Victoria Park, Handsworth, near Birmingham, on the 3rd inst. Mr. Mair was born in the county of Fife, Scotland, and received his early training in gardening in the Royal Botanical Gardens, Edinburgh. He was afterwards employed in the nurseries of Messrs. Thomson, at Clovenfords, and when the managership of the Aston Lower Grounds became vacant he was elected to that office. About 15 years ago the Handsworth District Council opened the Victoria Park to the public, and a year or so later Mr. Mair was appointed Superintendent, a position he occupied until his death. Many improvements have been effected in the park during that time, notably the extension of the area, the addition of a large sheet of water, &c. Mr. Mair who was connected with the management of the Handsworth Floral Fete was in his fifty-sixth year, and is survived by a widow and one daughter.

NATURAL HISTORY MUSEUM APPOINTMENT.—It is stated that Dr. A. Barton Rendle has been appointed to be keeper of the Herbarium in the British Museum, in succession to Mr. George Murray, who recently retired from the post on account of ill-health. Dr. Rendle has served as an assistant in the botanical department of the Museum for a period of 16 years.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending January 13, 1906:—

1906. JANUARY 7 TO JANUARY 13.	TEMPERATURE OF THE AIR. At 9 A.M. Dry Bulb.	Wet Bulb.	Highest.	Lowest.	LOWEST TEMPERATURE ON GRASS.	TEMPERATURE OF THE SOIL at 9 A.M. At 1-foot deep.	At 2-foot deep.	At 4-foot deep.	RAINFALL.	SUNSHINE.	
	deg.	deg.	deg.	deg.	deg.	deg.	deg.	deg.	ins.	hr.	min.
MEANS	42	40	49	37	33	41	43	44	Tot. 1·10	3	28

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 13, is furnished from the Meteorological Office:—

The *weather* was extremely unsettled in all parts of the Kingdom. Rain was general, and at times heavy, but there were several fair intervals, especially over England and Ireland. Thunderstorms, with hail, were experienced very generally in the south-west of Ireland and the southern counties of England on Tuesday, at Portland Bill on Wednesday, at Glencarron and Laudale on Friday, and at Blackpool and Aberystwyth on Saturday.

The *rainfall* exceeded the average in all districts both in frequency and amount. Except in the east of Scotland and north-east of England the excess was large.

The *temperature* was a degree below the average in Scotland N., but in all other parts of the Kingdom it was again above the normal, the excess in England S. amounting to as much as 4·6°. The highest of the maxima, which were recorded on rather irregular dates, ranged from 54° in England E. and 53° in several other districts to 45° in Scotland N. The lowest of the minima occurred on the 7th in Scotland, but much later in the week over the Kingdom generally; they were as low as 23° and 24° respectively in Scotland N. and E., and elsewhere ranged from 27° in England S.W. to to 33° in England N.W. and to 36° in the Channel Islands.

The *bright sunshine* exceeded the average duration over Ireland and in most parts of England, and equalled it in Scotland and in England N.E. and N.W. The percentage of the possible duration varied from 12 in Scotland N. and 14 in Scotland W. to 35 in England E. and to 37 in England S.

THE WEATHER IN WEST HERTS.

Warm and showery weather.—The first day of the year was cold, but since then there has not been a single unseasonably cold day or night. For the last eight days the highest day temperatures have been remarkably uniform, varying only from 46 to 48 degrees, or from 5 to 7 degrees warmer than is usual at this, the coldest period of the whole year. The ground temperatures are now unusually high for the time of year, being 3 degrees higher at 2 feet deep, and 4 degrees higher at 1 foot deep, than is seasonable. As far as the present month has yet gone, there have been only three days without rain—the aggregate fall for the 16 days being 3 inches, or half an inch in excess of the average fall for the whole month. During the same period 14 gallons, or nearly the whole of the rainfall, has come through each of the percolation gauges. The past week was a very bright one for January—the dullest month but one of the year. The sun shone on an average for over 3½ hours a day, or for more than two hours a day longer than is usual. The wind continued moderately high throughout the week, the direction being almost exclusively some point between south and west. The mean amount of moisture in the air at 3 o'clock in the afternoon was as much as 10 per cent. less than is seasonable for that hour. Saxifraga apiculata was first in flower in my garden on the 15th inst., which is a remarkably early date, and several weeks earlier than in either of the two previous years. *E. M., Berkhamsted, January 17, 1906.*

TRADE NOTICES.

MR. EDWARD SLATER, late gardener for 10 years to Sir R. M. BROOKE, Bt., Norton Priory, Runcorn, has purchased the Padgate Nurseries, Warrington, Lancashire, and will enter into occupation on February 1.

Mr. A. DIMMOCK, who has represented the firm of Messrs. F. SANDER & SONS, St. Albans, for 25 years, and has spent a large portion of that time in the United States of America, has been appointed European Agent for the YOKOHAMA NURSERY CO. OF JAPAN and for Messrs. SUZUKI & IIDA, of 31, Barclay Street, N.Y., U.S.A., wholesale importers and exporters of bulbs, seeds and nursery stock.

ENQUIRY.

MENTO [?] BOILERS.—Can any gardener who has been using one of these boilers give me his opinion of them, with respect to heating power and length of time the fire will last after each "stoking up"? Also what sort of fuel will last longest—best anthracite coal or coke?—*J. C.*

ANSWERS TO CORRESPONDENTS.

BEECH COCCUS: *T. H. W.* Thoroughly scrub the infested bark with petroleum emulsion, or with a mixture of soft soap and caustic soda. Work the insecticide well into the crevices of the bark, and any other parts where the insect may be in hiding. You can perform the work at the present time. Use the caustic soda with care, and remember that gloves should be used when spraying with this strong alkali.

BEES AND CUCUMBERS: *G. H. S.* All the harm the Bees are likely to do to the Cucumbers is that by their agency the flowers may become properly fertilised and produce a quantity of seeds. As cucumber "fruits" will often swell perfectly without fertilisation of the ovules or young seed having taken place; it may possibly be considered a disadvantage if they are made to produce numerous seeds. In no other way can we explain your neighbour's somewhat unreasonable grumble.

BOOKS: *Constant Reader.* The book you mention has just been published. Apply to our publishing department.—*A. C. A Synopsis of the British Mosses*, by Chas. P. Hobkirk, F.L.S. Apply to our publishing department.—*F. E. F.* In *Johnson's Gardener's Dictionary* the names of the plants are accented, with a view to showing how each should be pronounced, and this may be sufficient for your purpose. In the Appendix to Nicholson's *Dictionary of Gardening* there is a very useful chapter on this subject.

CAMELLIA BUDS FAILING: *F. S.* Without knowing all the circumstances of the case we can only suggest that your flower buds failing is due to the roots having suffered a check. Although you are satisfied that the plants have not been allowed to become dry, you may possibly have kept them too wet for a time, and a check from this cause would be quite as disastrous as one from drought. When Camellias are full of strong growths, unless the supply of water is restricted at the time when the flower buds should set, they are apt to push all their energies into growth, and the flower buds suffer in consequence. The quantity of water which these plants require, especially in the growing season, makes it necessary that the soil in which they are grown should be of such a character that it will not become too close and compact. When you top-dressed the plants last spring, did you interfere with the roots? Camellias are somewhat impatient of disturbance at their roots.

CHIRONIA IXIFERA: *Jeannot.* Increased attention has certainly been given to this pretty plant during the last few years. Chironia ixifera can be had in bloom at any time during the summer and autumn months, but is not suitable for flowering in winter. If young growing shoots are inserted in an ordinary propagating frame, in well-drained pots or pans, containing either sand exclusively, or fine peat and sand mixed together, they will soon make roots. As soon as these cuttings have made roots pot them into small thumb pots and use a compost of good fibrous loam and peat in equal parts adding a liberal quantity of silver sand; cultivate the plants in an atmospheric temperature of 60° at night, and shade them from bright sunshine. Spray them occasionally and let the atmosphere of the house be maintained in a moderately moist condition. Repot the plants, as soon as they are ready, into 54 or 48-sized pots. The latter are large enough for the plants when in flower, unless specimens are required for exhibition. The same kind of compost as already mentioned may be used at the final potting. A temperature of 55° at night will be high enough after the plants have made this progress, but it may be allowed to increase during the day. A higher temperature would tend to induce too much growth. At the same time if the plants are required to flower at any special time they may be afforded rather more heat after the buds have formed. Do not allow them to suffer at any time from want of sufficient water, but provide them with shade from bright sunshine during the middle of the day, or the thrips will soon become troublesome and cause the narrow leaves to curl, which would give to the plants an unattractive appearance. When the pots have become filled with roots, a little Clay's Fertiliser or weak liquid manure or even clean soot water may be applied. The stimulant will impart a dark green tint to the foliage and a deeper colour to the flowers. If plants are grown in 60-sized pots they will make bushy little specimens and flower freely. Such plants can subsequently be cut down, kept moderately dry through the winter months and be repotted early in spring; they will then come into full flower in May. Pinch out the points of the shoots as often as required to produce bushy shaped plants, and after placing a neat stake in the centre of each plant sling the side shoots to this by means of fine shreds of raffia which have been stained a green colour.

EUCHARIS MITE: *A. A. Mc.K.*—In our experience the bulb mite has only attacked Eucharis bulbs when owing to some cause the bulbs have become weak and the outer scales partially decayed. This particular pest may be found in almost any kind of bulbs if serious decay is present, and it undoubtedly hastens the destruction of the bulbs. The best preventive, therefore, is to treat the plants as naturally as is possible in our glass-houses, and so maintain them in a vigorous condition. If decay has already set in and mites are numerous, do not waste time in trying to kill these latter, but rather burn the stock, disinfect the house, obtain fresh bulbs, and endeavour to keep them in a healthy condition.

GYPSUM: *A. G. P.* This substance is sulphate of lime containing water in combination. Pure gypsum contains 32·5 per cent. of lime, 46·5 per cent. of sulphuric acid, and 21 per cent. of water. Plaster of Paris is prepared from gypsum by burning, which drives off the water it contains. But for agricultural purposes gypsum is used in its natural condition. This material, like other forms of lime, furnishes directly the element calcium and exerts a favourable solvent effect upon the soil. It was formerly used in large quantities, particularly for crops of Mustard, Turnips, Grasslands, Potatos and Clover, at the rate of about 1,000 lb. per acre, sown during the winter or early spring. It is believed that its favourable effect is due not so much to the direct addition of lime, as to its action upon insoluble potash compounds in the soil in setting free potash. Thus the application of gypsum causes an increase of crop, because of the potash made available. Should the soil be light and sandy, and thus contain but little natural potash applications of 4 cwts. kainit or 1½ cwt. muriate of potash per acre must be given with the gypsum, otherwise but little beneficial effect will be produced. Gypsum is also useful to spread over floors of poultry-houses, stables or heaps of farmyard manure to absorb the ammonia gas given off in the decomposition of the animal excrements, to be afterwards spread and ploughed into the soil.

MEALY BUG ON VINES: *Gardener.* The following treatment is recommended by Mr. H. W. Ward, author of *The Book of the Grape.* Smear the Vines with a mixture of coal tar and clay, using one part of the former to nine parts of the latter. The clay should be dried and powdered, so that it may be passed through a quarter-inch sieve. Then mix the tar and clay together in the proportions named above, afterwards adding sufficient boiling water to give it the consistency of ordinary paint. Apply the mixture by means of a stiff paint brush to every crevice in the bark of the Vines, including that on the spurs. This is a very old and effective method of destroying bug.

MUSHROOMS: *M. Liddiard* and *H. G. M.* The disease is not due to the spawn, but is caused by a fungus called *Hypomyces perniciosus*, which was probably introduced with the soil or manure. If the disease has spread much, the only means of preventing its continuance and attacking other beds is to remove all the soil and manure, and thoroughly disinfect the house by spraying every part with a solution of sulphate of copper—one pound of sulphate to 15 gallons of water.

NAMES OF FRUITS: *J. C. T.* Bramley's Seedling.—*Saltmarsh.* We cannot recognise your Apples. Certainly they are not the varieties you mention. Our opinion is that they are local sorts.

NAMES OF PLANTS: *C. K. E.* 1, Pinus excelsa; 2, Probably the Deodar cedar, but we cannot tell without seeing the tree.—*W. S.* 1, Adiantum cuneatum grandiceps; 2, Adiantum macrophyllum; 3, Selaginella Mertensii; 4, Lygodium scandens; 5, Pteris longifolia; 6, Adiantum tenerum.—*C. W.* 1, Begonia manicata; 2, Begonia nitida; 3, Begonia Weltoniensis; 4, Begonia prestoniensis: 5, Begonia fuchsioides; 6, Codiæum (Croton) aureo-maculatum; 7, Codiæum angustifolium.—*F. W. C.* Aira caespitosa, Windlestraws or Snizzle-grass.—*F. E. F.* Send better specimen.

NOTICE TO LEAVE: *Perplexed.* We believe that the notice may be tendered on any day of the week, and after 12 o'clock mid-day. In the case of a second gardener who is paid weekly, a week's notice should be deemed sufficient, always, of course if no agreement has been made to the contrary.

ONCIDIUM SERRATUM WITH INFLORESCENCE 21 FEET IN LENGTH: *E. D.* It is not uncommon for Oncidium serratum and some other Oncidiums to produce the long trailing flower-spikes you mention. They continue the growth of the inflorescence throughout the dull weather which is not favourable to the production of flowers and afterwards bloom in summer and autumn.

PINE SHOOTS DISEASED: *G. E.* Although we have not been able to discover the actual insect there is little doubt but that the injury to your trees is the work of the Pine Beetle, Hylurgus piniperda. The following remarks are condensed from Miss Ormerod's book. The female appears in April or May, and begins her operations by boring a hole through the bank, beneath which she forms a tunnel along which she lays her eggs. The maggots soon hatch and eat their way forward beneath the bark. They are about a quarter of an inch long, and white, except their extremities, which are ochreous in tint. The maggots turn to pupæ at the ends of their tunnels, from which the beetles are developed in July and August. These come out and fly to neighbouring trees, where they may be found in September in great numbers, boring into the young shoots and causing great injury. Clearing the infested shoots from the trees in summer or from beneath them in winter is one means of preventing recurrence of attack. The removal of thinnings, pieces of felled Pine or other Pine

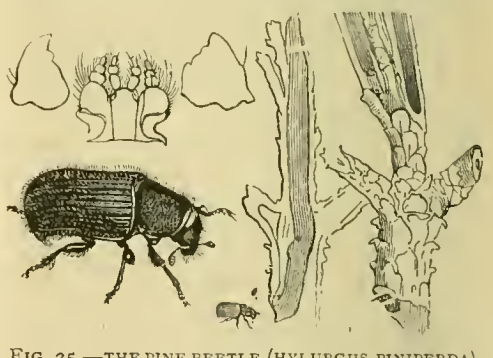

FIG. 25.—THE PINE BEETLE (HYLURGUS PINIPERDA).

rubbish beneath the bark of which the beetles will tunnel and form their maggot nurseries is also necessary. The removal of the bark should not be permitted within the plantation. The beetles lay their eggs on trees which have only lately been felled, or on decaying standing trees, and these should therefore be removed. Beetle-traps can be laid in the plantation and are thus arranged: cut in the autumn a quantity of young Scots Pine tops and thin off all the branches. Lay these props about the young plantations, or up against the lower part of the standing trees, so that the under side will rest on the ground, because the beetles will not lay their eggs on damp, wet wood. Collect these props in the month of June or sometimes earlier and you will find present under the bark a great number of the beetles.

TOMATOS: *F. E. F.* Shake the plants a little during the warmest part of the day to disperse the pollen, or touch each flower with a rabbit's tail bearing pollen attached to a small stake. Tomato flowers usually set easily enough later in the season, when there is more sunshine, and the houses are given freer ventilation. We cannot name the plant unless you send a better specimen.

ODONTOGLOSSUMS: PAST, PRESENT, FUTURE.

THE last four years have been so remarkable for the introduction of fine forms of both species and hybrids that it makes one think somewhat wonderingly of what my third sectional heading may have in store for us. Careful observers time after time have said, "We have reached the top, there *must* be a fall in price." This meant more a waning of the taste for them than the financial depreciation the words conveyed, but neither the one nor the other have come to pass in a general sense. Here and there, from special causes, temporary retrograde movements take place, but what is the consequence? The succeeding wave overflows the former one, and another wave effaces the temporary trough.

The taste in Odontoglossums has changed of late years as compared to what it was in the days of 25 or 30 years ago, for now the heavily blotched forms are the most-sought-after, whereas then, the fine unspotted forms were considered the more beautiful. There may have been very good reasons for this want of taste for the spotted forms, for as there were but very few of them (and these were not all of good shape) it did not fall to the lot of all to see them; but slowly, though surely, the spotted forms came to the front, first in the hybrids Andersonianum and Rückerianum, and then a little later in the spotted and blotched crispums.

From 1880 to 1885 the natural hybrids were much in vogue, the rosy and coloured forms being highly valued. Then in 1886 began the great wonders of high-priced Odontoglossums, and the Orchid world was wondering what would come of it.

We all have to thank Baron Schröder for "leading off" in that year by the purchase of O. excellens Knox's var. at Stevens' Rooms on April 14, 1886, for 165 gs. This was then called a "yellow Pescatorei," and constituted the first well-known hybrid at a "high price." The Baron followed it up by buying Odontoglossum crispum apiatum at Protheroe's Rooms for 160 gs. upon April 19, 1886. Shortly afterwards Sir Trevor Lawrence purchased a plant at Protheroe's Rooms on June 4, 1886, for 150 gs., which became O. crispum burfordense.

Then things were pondered over, and nothing similar occurred for a long time; but the ball had been started rolling with a will, and it has never since stopped, and shows no indication of stopping—indeed, it is gathering force annually, and if one "pusher" drops out, there are always a ready two to take his place (and his plants also).

The demand for "spotted crispums" began growing, the supply came also, and to-day it is going on merrily; the appreciation of the hybrids became less owing to their narrower segments, and to-day, in comparison to a fine crispum, unspotted or spotted, they are nowhere, and deservedly so, as form is the paramount factor in all flowers. There is another good reason why the natural hybrids could not in many instances possess good form: it is very improbable that an insect should take the pollen of O. gloriosum to the flower of a good variety of O. crispum, as it only seeks honey and not the making of hybrids. We do the reverse; we seek hybrids not honey (we can get that after from the conversion of the good hybrids into cash); hence our garden hybrids will be always finer in the aggregate than the natural ones.

To do ample justice to the Odontoglossums of the present day would need a very long article, but in a review necessarily short as this must be, it is only necessary to name a few of the actual leaders of the genus. It is an invidious task to compare the great gems, therefore I place them alphabetically: apiatum, Baroness Schröeder, Cooksonæ, F. K. Sander, Franz Masereel, Luciani, Pittianum, Roger Sander. Though these eight contain some that might be considered of the past section, they hold their own easily among the fine ones of to-day, and, to quote the prices these seven have realised gives us a range of from £108 in apiatum to £1,500, the price commonly spoken of and said to have been paid for F. K. Sander.

It may be fairly said that the plants of to-day are pre-eminently the blotched crispums; but they must possess extremely fine form and fine markings to be able to command these high values.

Whilst considering the present, the garden hybrids come to the front, in such a manner that anyone who observes carefully the signs of the times can see that they will form the great future of the genus. In Cattleyas and Cypripediums, it has been, so Odontoglossums will follow, and the hybrids in a great measure will displace the species, always excepting the fine varieties (of the species) which will be more and more needed to create new hybrids and infuse new blood, as in the case of all other breeding of either animal or plant life.

The first hybrid of great note, of course, is O. ardentissimum, which we all know approaches in its best form very nearly to a finely blotched crispum. O. Vuylstekei, O. Vuylstekeæ, O. Rolfeæ, and O. Smithii take front rank at present. The range of value here is upwards of £425, but the most remarkable have not changed hands.

We all know that in Orchid-raising there is no finality for the hybridist, his cry being always "Better things are coming," and up to the present he has not been far wrong, though, of course, the art is only yet in its very infancy; but if it goes on for, say, 20 years, with the relative improving ratio of the last 10, well, what will there be then for the hybridist of that day to cry? I hope I may be there to hear him and help him, as now, cry out, "Better things will come." That the future has some marvellously fine things in store goes without saying. The crosses made and young plants resulting contain a wonderful harvest of fine things for us all, and as each year goes by more care is taken to cross only what will give a good result, profiting by the experience of past failures, of which I am sorry to say some raisers do not speak; if they did so, it would be to the general benefit of all others.

Some may say that I could have condensed this article by simply stating that I considered the future of Odontoglossums lies in the hands of the hybridist. I do not hesitate to say "You are quite right, I do," for certainly it does, he will always need the fine imported forms, but after a time the worse natural forms will be less and less required, except occasionally by those who prefer to have a good variety, and by beginners, and the cut-flower or market traders; for who will take the trouble to grow and bloom thousands to get 10 or 20 worth having when he can raise them and have certainties from every pod he sows; but here again no one need think each one in a pod is going to be a fine variety. There will always be reversion, but there *must* be some good ones; whereas in imported plants there *may* be a fine variety, but there *must* be hundreds quite worthless either for commercial or amateur tastes, and in these days it is difficult to say which is the more fastidious.

In considering the future, we conjecture the possibilities of even finer things than we are now used to, but we have, even at present, a very large mass of information which, if carefully examined, will give a good idea of what we may expect. The self-colours, if brilliant, seem to appeal to the majority of colourists, although we admire leopard-like arrangements in Odontoglossums, and no one will dispute the fact that we should all go more or less mad if we obtained either a scarlet or a blue crispum—of course, I mean a blue crispum of fine form. The one colour is undoubtedly possible, though it may not be for all of us who are now working to see it. The accession of red in Odontioda Vuylstekeæ furnishes a parallel case, and as soon as some one gets a good pod upon crispum crossed by Cochlioda Noezliana, the first step will have been gained and the rest will only be a process of time.

The probabilities of obtaining a blue crispum are much further away; but many years ago the introducers of the blue Primrose might have been considered bereft of their senses had they prophesied they would be able to produce one. In Odontoglossum Smithii we have a deep violet ground colour, the result of the rose in O. Rossii being acted upon by the cyaneous-brown of O. Harryanum, even though it had passed through the white of O. crispum.

If the violet of O. Smithii could be acted upon by the red of C. Noezliana, we ought (theoretically) to obtain a bluish or cyaneous shade. If, perchance, one of these seedlings were to be crossed by a very lilac-suffused

ardentissimum, there is no telling what might be the result, and, perhaps, by the time this seedling is ready to cross there may be other useful things ready for the hybridist of that day. Violet has been produced, blue may follow.

An article on the future without any reference to the garden-raised blotched crispum would be incomplete and wanting in an essential point, for all of us are doing our best to raise this much-sought-for plant in quantity. I say in quantity advisedly, for it has been done, but if only one now and then appears we shall still be where we are at present. It is amusing to see those who hold quantities of very valuable plants attempting to destroy their value by producing them artificially. The reason is, I think, that none of us believe we shall succeed so as to damage the value of our present blotched crispums.

Hybrids between fine forms of blotched O. crispum and O. ardentissimum will not yield a pure blotched crispum, though they will doubtless be near to it. Sentiment will keep up the value of a natural crispum in a measure, and the difficulty of producing a garden-raised one will also help, as though a hybrid (of possibly very complex parentage) in my opinion, it is in quite a different category to a direct hybrid like Wilckeanum, which anyone who likes can create.

The last two years have seen the linking up of the chain by the production of a hybrid between a Colombian Odontoglossum and a Brazilian Cochlioda, as well as a Mexican Odontoglossum and a garden-hybrid (the produce of two Colombian species). These two great "breaks away" are a grand pair of "first footsteps" of horticultural interest, for though it is not the first time that Mexican and Colombian species have been united (it having been effected in 1902 in the hybrid Pescatoreo-cordatum which I have seen and consider as only of botanic interest), O. Smithii is the first true international Odontoglossum of any note.

Contemplating the work done already and considering the many intelligent workers there are both here and upon the Continent, who will say that "the future" does not contain a vision of hybrids that will possibly, may probably, make some of our present-day wonders look quite ordinary things? I have no doubt we are upon the threshold of a great advance in Odontoglossum raising, and I wish all possible success to all who are diligently working with the same object in view as I am—improvement in this all-absorbing study and pursuit. *de B. Crawshay.*

WAINSFORD, LYMINGTON.

THE view represented in our illustration at fig. 26 was taken from the gardens at Wainsford, Lymington, the residence of Mrs. E. Powell King. These gardens have been greatly improved and enlarged during recent years by their late owner, E. Powell King, Esq., a devoted garden-lover, who spared neither labour nor expense in his endeavours to make his garden beautiful, but he unfortunately died at a comparatively early age. A part of the gardens was, five years ago, merely a piece of rough field. A fountain now stands in the centre of this portion of the grounds, and is surrounded by flower beds, borders, and pergolas, the whole forming a charming retreat. The basin of the fountain is composed of an old granite cider press, which was brought over from Guernsey for its present purpose, for which it is well adapted. A pathway composed of large stones leads to a rose garden, the paths through which are also made of old paving stones with box edgings.

Fig. 26 shows a portion of the original garden, which was re-arranged during last winter, when the wall with the archway in it was built. This wall is faced with stone on either side, the interior being filled with soil, to allow of plants ramifying in the sides and also at the top. In the foreground of the picture is part of a lily pond. There is an open well at the junction of the paths shown, but this was hidden by a bed of Heliotrope seen near the figure, at the time the photograph was taken. The greater part of the residence also was hidden by trees from this point of view, the one in front being a fine specimen of the Evergreen Oak. *R. W. D., Wainsford.*

FLORISTS' FLOWERS.

EXHIBITING CHRYSANTHEMUMS.

I QUITE agree with the remarks on p. 332, Vol. XXXVIII., that boards for exhibiting cut blooms should be dispensed with, but it will take time to eliminate them, as old customs die hard An exhibitor having a "shady" bloom in his exhibit has not much chance of escaping detection when the flowers are displayed in vases or as small groups of cut blooms with foliage and plants, for then every bloom is thoroughly exposed to view, while this cannot be said of flowers shown on boards.

One often sees at Chrysanthemum shows eight or ten stands of 24 Japanese blooms, all presenting a great sameness. How much nicer these would look were they displayed on longer stems with plants and foliage intermixed, each exhibitor having a space of, say, 8 feet by 4.

FIG. 26.—VIEW IN THE GARDENS AT LYMINGTON, HANTS, SHOWING A NEWLY-CONSTRUCTED WALL-GARDEN IN THE BACKGROUND.

Now is the time for Chrysanthemum societies to take these matters in hand, for there is scope and need for originality. *A Grower.*

CHRYSANTHEMUM, BARON DE VINOLS.

THIS variety is one of the prettiest and most effective for decorative purposes or for groups, but as yet it does not seem to have found its way into English collections. I have several times admired it abroad, where it is largely used as a front row plant in collections in pots. Of medium size, it is a stiff petalled Japanese of deep rosy amaranth colour, with pure white points. It has sported several times, Mme. George Barré, rosy bronze, and Dr. George Barré, of deep rich purple amaranth colour, being the two best of its offspring. *C. H. P.*

THE ROSARY.

ROSE CULTURE UNDER GLASS.

EXPERIENCE, they say, has to be bought, and generally at a dear figure. It is good, no doubt, to gain experience at one's own cost, for, in such cases, the first expense is probably the last, but it is far better, if one can so arrange it, to purchase one's knowledge at the expense of somebody else. Some years ago, at considerable cost to my own pocket, I bought and essayed to grow a number of Maréchal Niel Roses, and subsequently discovered that my property consisted rather of dearly-bought experience than of Roses. Of the former I had a good stock, of the latter very few. But I believe that my money was well spent, for, if I paid for my lack of knowledge and foresight in the first instance, I had a good stock of wisdom for later efforts in the same direction, and ultimately my attempts were crowned with very respectable success. In the hope therefore that what I have learned may be of interest to others, and save them to some extent from falling into the errors which I committed, I should like to tell, as briefly as I can, the story of my experiences as a grower of Tea-roses under glass.

I will not pretend that any one can nowadays make any considerable profit in the matter of Rose-growing, although I believe that there are worse things done in these degenerate days than Rose-growing. The foreigner, who has the climate that we in England cannot command, is of a necessity a severe competitor, more so to-day than he was some ten or twelve years ago, when I made my first attempt at growing flowers for market. Roses, by which I mean really good Roses, not the poor little shrivelled-up things that are not worth the picking, are still marketable, but if they are to sell at remunerative prices they must be of the very finest quality, in order to compete with those which the foreigner sends over here in hundreds of dozens at a time. It really costs no more, in the long run, to produce a good article than a bad one, because whereas the best article will obtain the best price of the moment, the slightly inferior product will fetch practically nothing in comparison. Of this latter class the market always has plenty, and the cost of producing them is almost as much as in the case of that of the finest. Indeed, there are instances in which the inferior product may have cost the grower quite as much in hard cash, because in his eagerness he is often induced to employ certain expensive means, which, being overdone, do more harm than good to his crop. The general principles of successful Rose-growing under glass are in the main similar in all cases, but it is the attention to small details, and an ever-watchful supervision that lead one on the road to success.

The very first mistake which I made was to buy my Roses—Maréchal Niels—at a sale. They cost about one and sixpence each, but several of them were not worth the value of the pots they grew in. For the first winter I kept them in pots, which, as I learnt later, were much too small, and the plants made practically no growth during the first year. The following autumn I planted out the survivors at intervals of a few feet in two glass houses—100 feet by 14 feet each, and about 10 feet from ground to ridge of roof in the centre of the middle pathway. These houses, which were really too high for their width, were used for Tomato-growing in the summer, and for Arums and Chrysanthemums in the winter. It is perfectly possible to grow these crops with Roses if they are properly arranged, the only drawback being that the Roses do not get a rest at any time of the year, when the house is constantly heated during the colder months. They will, however, do fairly well for a few years, even without this annual rest, but their life is, I believe, shortened thereby. Only three out of several dozen of my Roses did any good at all after being planted out in borders. The soil consisted of a good fibrous loam, and was about a foot in depth, made up on a hard subsoil, partly clay and partly sandstone. The rest of the trees either stood still or died, and had to be replaced. Those which grew, however, did well, and made a great deal of young growth, which, as the veriest beginner knows, is essential to a good crop of blooms of nice size and quality. One of these trees in particular thrived amazingly. In a single season it sent out little branches of forty feet in length in one direction, and, in the other, two of about twenty feet. Its stem increased in the meanwhile from about the thickness of one's little finger to a circumference of eight inches. But it soon reached the subsoil of sour material, became cankered, and died, as did the other two. For two or three reasons, however, these three trees produced a profusion of bloom, and the largest of the trio yielded an average of over a thousand marketable buds for two seasons of its existence. The trees were liberally fed as soon as they began, in February, to make new growth, with top-dressings of old stable manure and occasional applications of artificial fertiliser. The result of my first experiment, which was of course by no means a success as a whole, showed me what could be done by better attention to certain points in the future, and, as a result, my subsequent efforts have been distinctly more encouraging.

My advice, therefore, to anyone who wishes to grow Tea-roses under glass, either for profit or pleasure, is summed up in the following directions: Content yourself with one or two varieties at first, say, Maréchal Niel and Niphetos—two of the best to grow, from every point of view. Prepare within your house, the dimensions of which do not particularly matter, so long as it is of fair size, a good deep border of any loam of good quality, with plenty of fibre in it, and some sound red clay mixed therewith if you can get it; if not, the loam alone will do. Previous to making up your bed, which should be not less than eighteen inches in depth, you must break up the subsoil roughly to the depth of a foot, and if there is no natural drainage, this must be supplied by laying down a quantity of old brickbats, large stones, or clinkers from the furnace. Mix some old rotten manure with the soil—one part of the former to five of the latter, and plant your trees firmly therein at their original depth. In the case of a lean-to house, the Roses will do better if planted on the lower side, and trained up over the roof towards the wall, but in a span-roof house you will train them towards the middle from either side. The young shoots as they appear should be trained along the wires running from end to end of the house, at a distance of some eight inches from the glass. The trees are best purchased from a respectable nurseryman, and should be selected by someone who knows what he is buying. Choose those which show signs of active growth, and be sure that you get the ones which you have selected. You should avoid any plants which have been in pots too long which show signs of stunted growth. Once planted, attention to temperature, ventilation, watering, and pruning cover the chief points of cultivation. Planted in the autumn, your trees should never be allowed to put out growth of any consequence till the following January at the earliest, and if all heat can be dispensed with till then, so much the better. The thermometer, with fire heat only, should never rise above 60 degrees Fahr. at first, nor over 70 degrees later on. As soon as the young dark-coloured growth begins, and the spring sunshine raises the temperature of your house, the fire must be damped down during the middle hours of the day, and a light shading of limewash or tiffany will be necessary. Of air your Roses must have plenty whenever the outside temperature is not too low or damp, but direct draughts will do irretrievable damage in the way of mildew, which is always difficult to check once it has started. Watering must be done, whenever needed, with tepid water, and the roots of the plants must never be allowed to suffer for want of moisture. You must remember also that they spread a long way from the stem of the tree. Your trees will require no pruning beyond cutting back the blooming stems after flowering to within a couple of eyes of the main branch, and thinning out old wood wherever you can. Canker, that bugbear of the Rose-grower, will overtake your trees sooner or later, but if you have a good reserve of young trees coming on in large pots, you can replace any tree directly it shows a falling off in health. And, finally, if you follow as nearly as you can the foregoing directions, always at the same time remembering that the greatest of all blessings to the gardener as to others is common sense, your crop of Roses every spring from the latter end of February to the end of April should be the admiration of all beholders, whether you try to turn an honest penny by them or distribute them among your friends. *East Sussex.*

TWO HYBRID ROSES.

Coloured figures of two hybrid Teas are given in the December number of the *Rosen-Zeitung*. Hermann Raue is a pale yellow Rose flushed with pink. It was sent out by P. Lambert in 1904, and is the offspring of a cross between "Grand Duchess Victoria Melita" and "La France of 1889." Contessa Lurani is also a hybrid Tea of deep rosy pink colour.

FRUIT REGISTER.

GOLDONI NECTARINE.

THE craze for large fruits is possibly the cause of this variety being not more often seen. Having grown it amongst a collection of 20 varieties, and having given it a fair trial in different aspects, I have nothing but praise for it. The tree is a good grower, has a robust constitution, and bears freely, the fruits being of medium size and of a bright orange-yellow colour, streaked with crimson. The flesh is very rich and juicy. Goldoni was introduced by Messrs. Rivers, and is certainly one of the most valuable of the many varieties of Nectarines raised by this firm. *W. H. Clarke, Aston Rowant, Oxon.*

APPLE MANX CODLIN.

I HAVE endeavoured to propagate many varieties of Apples from cuttings, but have succeeded only with the above-named variety. Last year

I had a full crop on two bushy dwarf trees that I raised from cuttings a few years ago. These trees are particularly healthy, and the really handsome, clean fruit ripened in September to a lovely yellow colour under a red exterior on the sunny side. With liberal manurial aid, these trees promise all that could be wished, and I see no reason why any number of trees should not be raised in the same manner. Manx Codlin, as an early culinary Apple, certainly merits the attention of growers.

APPLE COCKPIT.

IN the garden at Stillington Hall, ten miles from York, where I served my apprenticeship, several standard trees of this Apple were planted forty-five years ago in a grass orchard, and the trees invariably bore heavy crops of fruit. Visiting this garden in September last, after an absence of thirty-six years, I found the same Cockpit Apple trees in a still flourishing condition, the long semi-drooping branches being plentifully covered with fruit. The value of an Apple like Cockpit, during a season such as the past, when the Apple crop was almost nil in parts, is extremely great, and the variety is worthy of consideration when planting. As the fruit ripens the colour changes to yellow. It is a good kitchen variety in use during November and December. *E. M.*

NEW AND NOTEWORTHY PLANTS.

GERANIUM PLATYANTHUM, DUTHIE N. SP.*

A VERY handsome Chinese species allied to *G. eriostemon*, Fischer. The erect stems, which sometimes grow to a height of 3 feet, are densely clothed with white spreading hairs and with many gland-tipped hairs on the inflorescence and its branches. The lower leaves have very long petioles and are usually five-lobed, whilst the uppermost are almost sessile and often only three-lobed; the lobes are broad and coarsely toothed, and the under surface of the leaves is densely clothed with grey appressed shining hairs. The corolla is 16 lin. in diameter, and of a beautiful rose-purple colour. The horizontal spread of the petals gives the flower a strikingly flat appearance. Plants were raised last summer by Messrs. J. Veitch and Sons from seed collected by Mr. Wilson in W. Hupeh (No. 1948), and near Ta chien lu in W. China (No. 3298). It is a taller and more hairy plant than *G. eriostemon*, the leaves are not so deeply cut and the lobes are broader; the peduncles are shorter and stouter; the flowers are larger, the corolla much exceeding the calyx, and the petals are broader and flatter; it may also be distinguished by the hairs on the ovary and lower portion of the valves being tipped with bright red glands. *G. platypetalum*, Franchet in Plantæ Delavayana (1889), p. 777, may, from the description, be distinguished from *G. platyanthum* by the retrorsely appressed hairs on the stem, the reflexed pedicels (after flowering) and by the much smaller flowers.

* GERANIUM PLATYANTHUM, n. sp. Caudex adscendens, sublignosus. Caulis 2-3 ped., erectus, siccitate sulcatus et subangulatus, patule pilosus, superne glandulosus. Folia ambitu late reniformia, 5-7 poll. lata, e basi ad apicem 2-4 poll., supra adpresse pubescentia, subtus dense canescenti-villosa, ad medium 3-5-lobata, sinubus acutis; lobi ovato-oblongi, interdum obscure 3-lobulati, grosse inciso-dentati, dentibus cuspidatis; petioli inferiores ad 1 ped. longi, dense pilosi; stipulæ binæ, 9 lin. longæ, ad basim 5 lin. latæ, caudato-acuminatæ, marginibus ciliatis. Pedunculi duo vel plures, axillares; folia floralia bina, superioria sæpe valde diminuta et sessilia; pedicelli dense glanduloso-pilosi, in fructu erecti; bracteæ binæ stipulis similes sed multo minores. Alabastra ovato-elliptica, nutantia. Sepala 7 lin. longa, 3 lin. lata, elliptico-oblonga, cuspidata, 3-5-nervosa, externe pilis glandulosis canescentia. Corolla 16 lin. diametro; petalis omnino patentibus, roseo-purpureis, basi rotundato-quadratis, ad apicem integris aut interdum sub emarginatis; unguiculâ minimâ, imâ barbatâ. Filamenta gradatim deorsum dilatata, dorso, versus basim, pilis longis candidis munito. Ovarium pilis nitidis rubro-capitatis densis obsitum. Carpella (cum rostro) 1·5 poll. longa, valvulis patentim glanduloso-birsutis, rostro 10 lin. longo, pilis brevioribus sursum directis. Semina non visa. *J. F. Duthie, Kew.*

CYPRIPEDIUM ALCIBIADES MAGNIFICUM.

THE most remarkable feature of this truly handsome flower (fig. 27) is the great width of all its parts. As will be seen on reference to the figure the dorsal sepal is broadened to such a degree as to become almost rounded in shape, while the squat, broadened lip is in keeping with the anterior sepal. It is the result of a cross between C. Leeanum giganteum and C. Mons de Burt, and was shown by Major Holford at the meeting of the Royal Horticultural Society, on the 9th inst., when it received a First Class Certificate.

The large dorsal sepal is white, with an emerald green base, and dotted lines of purple. The petals and lip are yellow, tinged and marked with purple brown colour.

FIG. 27.—CYPRIPEDIUM × ALCIBIADES MAGNIFICUM, AS EXHIBITED BY MAJOR HOLFORD AT THE ROYAL HORTICULTURAL SOCIETY'S MEETING ON JANUARY 9.

LEGISLATION WITH RESPECT TO PLANT DISEASES CAUSED BY FUNGI.

In some recent numbers of this journal, an article appeared entitled, "Legislation and the Spread of Plant Diseases caused by Fungi." In this article, professing to deal with the general question of the possibility of employing legislative means against fungus diseases of cultivated plants, Mr. Massee cites a number of specific diseases, and claims that in many of these preventive legislation would be impracticable.

The object of the present paper is to consider some of these cases; to show that certain of the assumptions made are unsupported; to correct a serious misstatement made in connection with a recently-introduced Gooseberry disease; and, finally, to refer to some of the legislative steps taken by several Governments acting on the advice of plant pathologists of high scientific authority.

I will consider now the cases quoted first by Mr. Massee, viz., the following six diseases: (1) The wheat-rust; (2) the maize-smut; (3) the hollyhock-rust; (4) the bean-rust; (5) a fungus attacking lucerne; (6) a fungus attacking Verbena. These cases are given as instances of "diseases that appear when the host-plant is introduced to distant localities, even to a new continent, where the fungus was not known to exist previous to the introduction of its host-plant." Mr. Massee states further: "A point of importance in connection with the above examples is the fact that in every instance the introduction to a new country must necessarily have been by means of seed," and tells us we may accept "without doubt as the true solution" the supposition that the spores of the fungus causing the disease "were imported along with the seed, adhering to its surface."

We may first ask whether the cases chosen may be regarded as representative of fungus diseases against which plant pathologists have recommended legislation; and, secondly, whether there is really scientific proof of this introduction into foreign lands of new diseases by means of seed. It will be worth while to examine the cases separately.

(1) The wheat-rust fungus is often found in a vegetative state within the coats of the wheat grain.

(2) The maize-smut is one of the Ustilagineæ, a group of fungi peculiar in producing its spores in the ovary of the diseased plant; when ripe the spores disperse, and adhere to neighbouring seeds.

Cases (1) and (2), then, may be regarded as quite exceptional, since the fungus chosen is one specialised as a seed-inhabiting fungus.

(3) The hollyhock-rust. Prof. H. Klebahn—an authority on the *Uredineæ*—to whom I applied for information—states that the exact manner of the first introduction of this disease into Europe is still an unsolved problem.

(4) The bean-rust. Mr. Massee states that he found this species on French beans grown at the Botanic Station, British East Africa, and assumes that rust-spores must have been sent out with the bean seed to Africa. No proof, however, that this really occurred is given; and it may be pointed out that it is quite as likely that the fungus in this case is indigenous to Africa, and that it has spread to the cultivated beans from some allied indigenous wild plant—just as "it is almost certain that the coffee-leaf disease passed on to cultivated coffee from a native wild plant." (See Massee, "Text-book of Plant Diseases," p. 28.)

(5) The lucerne fungus referred to is, I presume, Uromyces striatus. I can find no evidence given anywhere that it has been introduced to foreign lands in the manner assumed.

(6) The Verbena fungus referred to is (as I happen to know from material received at the same time), the conidial (Oidium) stage of one of the Erysiphaceæ, probably Erysiphe Cichoracearum DC. In this case it is certain that Mr. Massee's assumption that introduction into Australia took place by means of spores adhering to seeds is incorrect, since it has been proved that the summer spores lose their power of germination in a few days. Moreover, as E. Cichoracearum is a cosmopolitan species, it is only reasonable to suppose that in this case nothing more has happened than that the fungus has spread from some native host-plant to the cultivated plants of Verbena.

Three of the last four cases belong to the rusts; the fourth must certainly be excluded from the category in which it is placed. Now, the view that rusts, on account of their wide distribution, are among the fungus diseases which cannot be reached by legislation was very clearly put forward in 1897 by Prof. B. T. Galloway (Chief of the Division of Vegetable Pathology, U.S. Department of Agriculture), in some remarks to which I shall refer again later.

We shall obtain no clear view as to what could be effected by legislation, if we confuse together, as Mr. Massee has done, diseases which are practically cosmopolitan, with those which appear first as epidemic diseases confined to definite areas. It is the stamping out of the diseases of the latter class, and the prevention of their introduction or re-introduction, which lie within the province of legislation.

Mr. Massee writes: "Packets of a dozen kinds of seeds purchased at random were carefully examined, and in four instances spores of the fungus well known as causing a disease on the plant in question were obtained from the seeds." To what fungi did the spores belong? Were they spores of fungi causing local epidemic diseases, such as those against which legislative means have been employed, or have been recommended? Without the names of the fungi being given, the statement can carry little or no scientific value.

The further statement that "apple-tree mildew" cannot be detected when the apple foliage is not present, "as the mycelium of this fungus hybernates in the branches," is not supported by the observations I have made on this disease. There are always present in winter some external signs of the disease, if not in the presence of black fruit-bodies, then in the form of more or less conspicuous hybernating superficial patches of mycelium. No scientific proof has yet been given that the mycelium enters the tissues of the branches.

I must now refer to the statements made in connection with a dangerous disease recently introduced into Ireland. Writing on this disease, Mr. Massee remarks: "The point is, was it (1) introduced on living plants in its fully-developed conspicuous condition, in which case it could not have escaped the eye of an official on the look out for diseases? Or (2) did it come under the form of spores adhering to the plant, which in due season produced the disease? In the latter case no official, however observant, could have detected its presence. To state that if legislation on the point had been in force the disease would not have entered Ireland is only the expression of an enthusiast, and will not bear criticism."

I have carefully studied this disease, and followed the course of the outbreak in Ireland since it occurred in 1900: and I have, in an article just preceding Mr. Massee's in this journal, as well as on several occasions in the Journal of the Royal Horticultural Society, advocated prompt action by the Authorities, and the employment of legislative measures to stamp out the disease.

I state here again emphatically that if legislation, such as that employed against this disease by other countries at the present time, had been in force, the disease would almost certainly have been prevented from entering Ireland. That stage of the fungus, viz., the stage in which the fungus is carried about by naked spores adhering to the plant, assumed above (2) by Mr. Massee, does not, as a matter of fact, occur in the life-history of the fungus. In the whole group of these mildews, the resting spores are enclosed in conspicuous fruit-bodies throughout the winter, and are not to be found as isolated spores adhering to plants; only in the spring at the moment of infection are the resting spores of the fungus liberated.

Further, in the case of the present disease, the fungus is distinguished by possessing persistent superficial brown mycelial patches, in which the fruit-bodies enclosing the winter spores are embedded. These brown patches of mycelium are superficial on the young wood, and being conspicuous the disease can easily be detected.

Hence Mr. Massee's assumption that no official could detect the disease on imported stock is quite unfounded; his failure to ascertain the life-history of the fungus seems to show that his article was written from a preconceived opinion that legislation in this case, as in other cases quoted by him, is impracticable.

And here, in a few words, I should like to recall the main facts concerning the outbreak of this new disease threatening Gooseberry growers in Europe. The disease was first observed in 1900, in a garden in Ireland; by 1904 it was established in nine localities in six counties. In spite of repeated warnings, which I gave in several papers, published in 1900-1905, dealing with this dangerous disease, no systematic attempt has yet been made by the Authorities to stamp out the disease in Ireland, or to prevent further importation of diseased Gooseberry bushes.

At the present time the disease still flourishes in the very same garden in which it was observed in 1900.

Let us remember that the danger in connection with this disease, which now confronts Gooseberry growers, is no problematical one. The disease has proved year after year in the United States, and in Europe every year since its introduction, to be a most devastating one. In my previous articles the extracts I have given from a number of Bulletins of various American agricultural experiment stations, also from the report of the Commissioners of Agriculture, show that the mildew is the one great enemy of the Gooseberry in the United States. In Bulletin No. 39 of the Idaho Agricultural Experiment Station, just received, Prof. L. F. Henderson writes of the mildew as "one of the three most serious diseases of fruits" in that State; and makes the following observation: "Eight or ten rows of Gooseberries were planted on our station ground several years ago, and I am perfectly safe in saying that from that time till 1903 not a single crop of fruit was gathered, owing to the presence of the mildew." In the Year-book of the Department of Agriculture (United States) for 1899, in an article on "Progress of Plant-breeding," an account is given of how the American Gooseberry growers were forced to give up the cultivation of the European Gooseberry on account of its susceptibility to mildew, and have had to depend upon raising improved strains of native American species, which are much less susceptible to the disease.

This Gooseberry disease is now reported in Europe from Ireland, Russia, Denmark, and Germany. During last June it was discovered in Sweden; the Government of that country decreed immediately a temporary prohibition against the importation of foreign Gooseberry plants and Gooseberries. I have received within the past few days a communication that the disease has now appeared in Finland, and that legislation on the same lines is to be at once employed.

In the case of the coffee-leaf disease, caused by the fungus Hemileia vastatrix, strenuous measures were taken by the Government to control the disease and prevent its introduction into the West Indies and into Africa. Will nothing be done to stamp out the Gooseberry disease in Ireland—where it constitutes a standing menace to the English grower—and prevent any further importation of diseased Gooseberries? *Ernest S. Salmon, South-Eastern Agricultural College, Wye, Kent.*

(To be continued.)

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Cattleya Trianæ.—The many beautiful forms of this species now coming into bloom will require to be kept moist at the root until the flowers are fully developed. C. Schroderæ is just beginning to show its flower buds at the base of the sheath, and will also require more water at the root. When the flowers have been cut of the following hybrids now in bloom: C. Octave Doin, Lælio-Cattleya Charlesworthii, L.-C. Illustræ, L.-C. Myra, L. Haroldiana, Brasso-Cattleya Queen Alexandra, B.-C. Orpheus and Brasso-Lælia Mrs. M. Gratin, let the plants be kept rather on the dry side until growth recommences. Congeneric species and hybrids that are making new growth should be afforded sufficient warmth, light and moisture to enable them to complete strong flowering pseudo-bulbs that will flower well. C. gigas, C. Dowiana and its variety aurea appear to require exceptional treatment. Immediately these plants start into growth they should be elevated so that their foliage almost touches the roof glass of the house, for the more light they can get without strong direct sunshine, the more likely are they to produce flowering growths. Water must only be afforded in small quantities until the new growths have attained a considerable length, and the flower sheaths are perceptible, when the amount should be increased, and each plant be given a good watering when the soil has become sufficiently dry. Do not keep the compost in a saturated condition, or the old roots may decay.

Cœlogynes.—Plants of the useful species C. cristata, also its varieties Lemoniana and holoeuca, will now be coming into bloom. Before the flowers are open a thorough watering of weak liquid cow-manure will greatly assist the plants during their flowering period. When the flowers have commenced to open very little water is then needed, for if kept too moist at the roots the flowers are apt to damp off. C. pandurata is just commencing to grow, and may be repotted if necessary. It is a strong growing species and requires considerable space to root in and abundance of water until growth is completed. When repotting the plants cut away all useless back pseudo-bulbs, two being quite sufficient to support each leading growth. Afford plenty of drainage material and the plant will succeed very well if potted in the usual mixture of peat and sphagnum-moss. As regards temperature, a moist warm corner of the East Indian house is the most suitable for

this species. The hard, shining leaves are often attacked by red spider, and they should be sponged often and periodically. The same atmospheric temperature will also suit C. Meyeriana, but this species succeeds best when planted in a shallow basket, and owing to its scandent habit, it is necessary to train and peg down each rambling rhizome on to the surface of the compost. Both species require to be shaded from the sun.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to F. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Azaleas.—Examine the stock of these, and remove any sour soil or moss there may be on the surface over the roots of any plant; afterwards apply a top-dressing of a compost consisting of peat, sand, charcoal-dust, and finely broken crocks, mixed well together. Much benefit will be derived from this top-dressing, for the roots will be more active at the time when the plants need additional support as they are developing their flowers; the flowers will be found to have much more substance and colour than those on plants which are not so treated. Any plants that may have got into a starved, stunted condition through inattention to potting or from overflowering (a frequent cause of impoverishment in Azaleas), should be denuded of their flower buds for a season. Afterwards place the plants in an atmospheric temperature of 70°, and so soon as growth has commenced repot the plants, and return them to the same warm atmosphere, where they should be syringed freely. By this treatment the plants may be thoroughly renovated by the flowering season.

Lapagerias.—The roots of Lapagerias are now becoming active, and any plants requiring potting or replanting should be given early attention, for if left until spring there will be risk of damaging the young shoots and roots. The securing of drainage is most important, for the plants require copious supplies of water during the summer months. Insufficiency of the water supply to the roots is the cause of many failing to grow and flower this plant successfully. Frequent applications of liquid manure and soot water—the latter especially—are very beneficial, and the soot water is distasteful to slugs, which are so fond of the young shoots.

Achimenes.—These plants are too often cast aside by plant growers. The first batch of tubers should now be started, and if successional lots are introduced until the end of the month of May, they will ensure a continuance of bloom. When the tubers have made shoots an inch or two in length, transplant them into the pots, pans, or baskets in which they are intended to flower. Basket culture is the best for producing effect, and if the different colours are mixed, the result is all the more striking. The plants delight in much heat, moisture, and partial shade from sunshine when making their growth, but when in bloom they may with safety and good effect be removed to the greenhouse or conservatory. A compost of peat and leaf-mould in equal parts, with well decomposed sheep manure added, also some sand, will be found to suit them best.

General Remarks.—Another batch of Hippeastrums (Amaryllis) should be started in an intermediate temperature. It is not necessary to plunge the pots in bottom heat at this time, as they will readily respond to the extra heat afforded. Continue to bring forward into gentle heat bulbs of various kinds, also plants of Lilac, Spiræas, Deutzias, Azalea mollis, Clematis, and Rhododendrons, all of which will be required to keep the conservatory gay from now onwards. Plants growing in rockeries or underneath the fronts of stages should be thoroughly cleansed during next month, at the same time adding a little fresh material to the roots. Take advantage of an evening when the weather is calm to fumigate all plant-houses, thus preventing insects from establishing themselves early in the season.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Pines.—Successional plants should not be allowed to become very dry at their roots, therefore those that are plunged near to the hot-water pipes will require daily attention in this matter. Maintain a steady bottom heat of 75°, and an atmospheric temperature at night of 60°.

Early Fig Trees in Pots.—Those that were removed to the forcing house at the beginning of December will soon be unfolding their tender leaves, and will require plenty of water both at their roots and in the atmosphere; otherwise red spider will be almost sure to attack them. If it is convenient to plunge the pots in a bed composed of leaves, which would give a temperature of 75° to 80°, this will encourage quicker root action, and the fruits will swell more rapidly. The atmosphere of the house should be kept at a temperature of 68° by day and 60° at night, admitting a little air whenever the weather is favourable, but closing the house early in the afternoons and syringing the trees immediately afterwards.

Permanent Trees.—It sometimes happens that a house cannot be set apart exclusively for the culture of Fig trees, and in such cases one has to use the back walls of Vineries and Peach houses for the purpose. The trees will succeed very well on the back walls of Vineries, providing their roots are kept within bounds, and this can in most cases be accomplished by building a brick wall, or by using thick slate slabs to confine the border. Narrow and shallow borders are far preferable to large ones, which tend to promote thick, sappy, and unfruitful growths. It must be remembered that when Fig trees are planted in Vineries and Peach houses they will have to be subjected to the same temperatures as the Vines and Peach trees; therefore plant them in houses where the conditions are likely to be most suitable. Later trees should now be thinned out a little, leaving the fruit-bearing shoots 8 or 9 inches apart, for their large leaves when fully developed require a great amount of space. Afford the roots a topdressing consisting of loam and old mortar rubble, with about 3 inches of cow manure to finish off with.

Strawberries in Pots.—The first batch of these that were started in December in a temperature of 45° at night should now be placed on a shelf well up to the glass, and be allowed 10° more warmth at night, and 15° by day, giving them twice a week a little weak manure water, which will greatly assist the flower scapes to get well above the foliage. Syringe the plants on all favourable occasions until they get well into bloom, when the foliage and flowers should be kept in a drier condition, and at the same time a little more air may be admitted to the structure. Pollenise each individual flower with a camel's hair brush every day at noon until 5 or 6 fruits are set on each plant, after which the other flowers should be cut off without delay, in order to induce the remaining fruits to swell more rapidly. Strawberry plants give a much better yield if some manure from an old Mushroom bed be run through a riddle (½ inch mesh) and be placed on the shelf for them to stand on. Roots then emerge from the bottom of the pot into and feed in this soil, which also acts as a store for moisture, and thus secures a double benefit.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Mint and Tarragon should be lifted and boxed up in readiness for placing in an atmospheric temperature of 55°. The heat may be lessened after a start has been made, in order that the produce may become strongly flavoured. The best way of meeting the demand for these herbs is to propagate cuttings in frames in August (if a clean, healthy stock can be got) and to grow these young plants in 6 in. pots. It is surprising the amount of growth they will produce throughout the winter when grown in an atmosphere of intermediate temperature. The difficulty in August is to get cuttings of mint that are clear of rust, the presence of which would be fatal to this method of procedure.

Horse Radish.—A fresh plantation should be made yearly of horse radish. Lift the old plantation and select long straight pieces of roots. Make holes with a bar on well-trenched ground and place one piece in each. The lines should be made at 2 feet apart and the cuttings inserted at 9 inches distance from each other. The strong crowns can be stored away behind a wall or in any cool place for use when required. There is no comparison between well-grown roots that are straight and fleshy and the old stunted pieces that result from growing the plants too long without replanting.

Mushrooms.—Continue to collect daily from the stables all the horse-droppings and place them over the floor in a dry shed. When sufficient have been collected to form a bed, put the whole together in a conical heap to ferment, and at the same time cover them over an inch or so deep with loamy soil to help absorb the ammonia that would otherwise escape into the atmosphere. A few half-decayed leaves are an excellent addition when droppings are scarce, and especially helpful are these leaves to the spawn when running through the bed. I have often noticed the spawn clinging to these. Turn the heap over several times before it gets too hot, otherwise many of the good properties will be lost. In forming the bed be careful to spread the manure thinly and equally all over in order that the heat may rise regularly. Make the materials as firm as possible by trampling or by other means when it is not convenient to tread them. When the heat of the bed has risen to its highest degree and has fallen again to 85 degrees, insert the pieces of spawn at 9 inches apart and immediately cover with good soil. We use roughly-chopped-up turf with good results, but it is well beaten down. An atmospheric temperature of 55 to 58 degrees is a very suitable one, but more heat than this shortens the duration of the crop. An excellent substitute for heating by hot-water pipes may be provided by a succession of hot beds, which give off just the kind of heat best suited to mushrooms.

Lettuces.—Successional sowings must be made regularly. Sow the seeds in boxes at present, as the plants can then be easily shifted about. Any seedlings requiring to be pricked off should be given attention without delay; prick them into rich soil in boxes. Select such varieties as Commodore Nutt and any of the small-hearting Cabbage varieties which begin to "head-in" early and are much appreciated in early spring. Sowings of Cos varieties may be made now with every prospect of success. Plants from these sowings will be in fine condition to plant on to hot-beds during February.

Radishes.—Sowings of these may be made regularly on hot-beds; also on ground where Potatos have been planted. The Radishes may be sown broadcast, for good roots may be had in this way without interfering with the Potato crop.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Bedding Begonias.—The great improvement which has taken place in the varieties during the last few years, together with the recognition of their complete hardiness for growth outside during summer, has caused the tuberous-rooted Begonia to become a feature in every garden where summer bedding is practised. The rich colours of the flower, the profuse blooming of the plant during the months of June, July, August, and September, the ease with which plants can be raised from seed, and the convenient way in which the tubers can be stored during winter, all contribute to the popularity of Begonias as bedding plants. Easy of culture, Begonias possess another advantage over many other plants in their adaptability to a wet summer, for although the plants enjoy bright sunshine, yet they give unstintingly of their wealth of flowers even in a dull, moist season, when the majority of flowering bedding plants are unattractive. When allocating the position of the Begonia beds in the flower garden scheme it is advisable to choose one which has full exposure to the sun, but at the same time endeavour to secure one in which the plants will be protected from the prevailing winds. The growths being soft and brittle are apt to be broken if wind-swept, and the drying effects of such winds are inimical to the best culture of the plant; therefore, precautions should be taken to guard against them. The preparation of the beds, if not filled with spring-flowering plants, might very appropriately be done at the present time. The special requirement to attain the best results in Begonia culture is plenty of good, well-matured farmyard manure. It is most important that in preparing the beds the first consideration shall be given to providing this in quantity. Leaf-mould and sand should be

added if the soil in the beds is in any degree inclined to be heavy. Tubers that have been stored away during the winter should, at the present time, be carefully examined and cleaned. Two or three weeks hence will be time enough to place them in shallow boxes filled with leaf-mould, leaving the crowns exposed and placing the boxes in gentle heat to start the tubers into growth. When the shoots have grown an inch or so in length, the tubers must be taken out of the leaf-mould and potted up singly, in a compost of loam and leaf-mould in equal portions, with sufficient sand to keep it open. The size of the pots must depend upon the size of the tubers. For some time after potting, let the plants be grown in an atmosphere of intermediate temperature, and as near to the glass as possible to prevent them being drawn. As soon as numerous roots have been formed, supply the plants with abundance of water, but be careful to ascertain that each pot is well drained. By the month of May they will be growing strongly and freely, and should be removed to cool frames, where though avoiding cold draughts, plenty of air must be afforded them, and at the same time care should be taken that they never suffer through becoming dry at the roots. Treated thus, by June they will have formed sturdy, robust flowering plants fit for planting out in the beds prepared for them.

Raising Seedlings.—From the present time until the end of February seeds may be sown for increasing one's stock of Begonia. Good unnamed varieties raised from a reliable strain of seeds are every bit as valuable for bedding out as the best named sorts. Sown in colours, and in quantity, the seedlings can be reassorted correctly into distinct colours, when they show flower in the first year, and then grouped suitably for any colour arrangement for the summer bedding in following years. Sow the seed in well-drained pans of finely-sifted loam and leaf-mould in equal proportions, adding some coarse sand and making the surface even and flat before sowing. The soil should be watered previous to the sowing, and afterwards, when necessary to apply water, it should be done by dipping ping the pans into a tank, allowing the moisture to reach the surface of the soil by capillary attraction. This is preferable to running the risks accruing by direct applications of water from a pot, no matter how fine the rose that is used may be. As the seeds are extremely small, great care must be exercised to distribute them thinly and evenly on the surface. To achieve this, a good plan is to mix them with some fine silver sand. After sowing, cover the pans with glass, shade them with paper, and plunge them in a slight bottom heat in an atmospheric temperature of about 70°. When the seedlings appear, expose them gradually to light and air to prevent their becoming drawn, and when large enough to be handled, prick them out into fresh pans. Continue to grow them on in moderate heat and near to the glass, but take care to protect them constantly from bright sunshine. About April they will require transplanting into single pots. In July and August many will show flowers, and the plants can be sorted into colours as above suggested.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Red Currants.—Young plants having a stem of 7 inches and consisting of three or four shoots should be cut back to three or four eyes on each shoot from which two shoots should be encouraged to grow. If the plants are standards, prune the shoots back to three eyes and keep the main stem steady and straight by affixing a stout stake. Those planted against walls should be pruned back to three or four buds and the terminal growths nailed up straight. Young trees may be pruned back to three eyes and the centre shoot fixed perpendicularly to the wall, the shortened shoots on either side being trained in a horizontal position.

Black Currant Bushes.—These should now be taken in hand, and if any mite (Phytoptus ribis) is present, pick off all buds that have swelled above the normal size and burn them. If the bushes are very badly affected it will be better to root them up and burn them. Very little pruning is necessary, but the bushes should be kept in good shape by systematically removing some of the oldest wood, which requires to be replaced with new growths. When the work has been done rake up and burn all the rubbish, and afterwards apply a good dressing of lime over the ground, dusting the trees with lime at the same time. Black Naples, and Carter's Prolific are good varieties. In making a new plantation, it would be prudent to trench another plot of ground in a different part of the garden.

Pear Enemies.—If the trees were attacked last season by the Pear midge (Diplosis pyrivora) or the ermine moth, steps should be taken to cleanse them in the following manner. Obtain a good insecticide—XL-all is very good for the purpose—and syringe every portion of the tree with insecticide. A home-made remedy may be made up as follows: Dissolve about 7 or 8 lbs. of soft soap in 7 gallons of boiling water; to this add ½ gallon of petroleum and stir them well together, making it up to 27 gallons by adding rain or other soft water. This should be mixed together thoroughly, and be afterwards applied vigorously all over the tree by means of a syringe, wetting every portion. If the trees are growing against walls, get a scrubbing brush and scrub behind the main trunk of the trees. If this solution be well worked into all holes and crevices, the caterpillars and chrysalids will be destroyed. Should any of the trees have suffered from red spider add 1 lb. of sulphur to the above mixture. Another application may be given the trees in April just before the flowers commence to open.

Fungus Disease on Apple Trees (see fig. 28).—A disease has in recent years attacked the main stems of young Apple trees, especially those growing on a stiff or clay soil. The first symptoms of the disease is the premature decaying and falling of the leaves, followed by a drying up and shrivelling of the bark on the stem during the spring following, and minute cracks appear in the bark. The spores of the fungus are mature during late spring, and it is at this season that infection takes place. In order to prevent spores germinating on the surface or stem, paint the entire surface with the following solution: Take 4 lbs. of soft soap, 1 lb. of caustic soda, and 1 lb. of lime. Mix these thoroughly together in 5 gallons of soft water, and apply with a stiff brush.

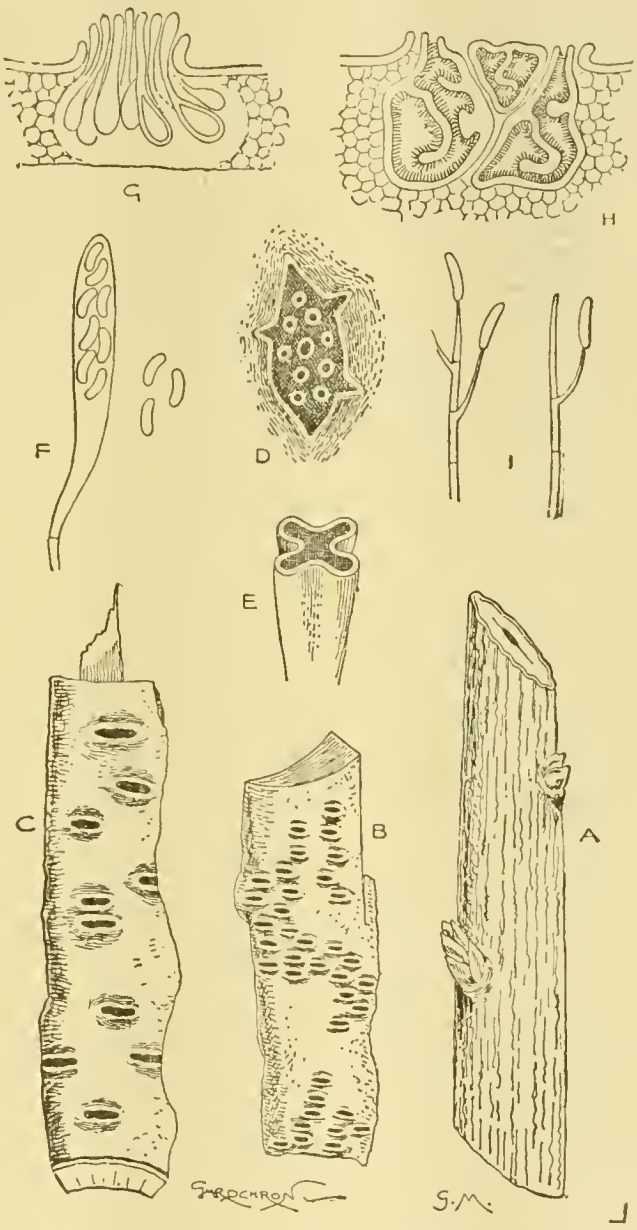

FIG. 28.—EUTYPELLA PRUNASTRI.

(See paragraph in "Hardy Fruit Garden" Calendar.)

A A young Peach branch becoming shrivelled, indicating that the stock is dying. (Natural size).
B The conidial stage of fruit bursting through the bark. (Natural size).
C The second or ascigerous condition of fruit showing at the surface through transverse cracks in the bark. Natural size).
D Surface of view of the second form of fruit, surrounded by the ruptured bark (× 40).
E Cruciate mouth of a perithecium. (× 400).
F Ascus and spores. (× 400).
G Section through ascigerous form of fruit. (× 80).
H Section through conidial form of fruit. (× 50). Conidia (× 1,000).

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS.

SATURDAY,	Jan. 27	Nat. Auricula Soc. (Northern Section) Ann. Meet. at Manchester. Dutch Gardeners' Soc. meet at Richmond.
THURSDAY,	Feb. 1	Linnean Soc. meet.
FRIDAY,	Feb. 2	Ann. Meet. Roy. Scottish Arboricultural Soc.
SATURDAY,	Feb. 3	Société Française d'Hort. de Londres meet. German Gardeners' Soc. meet.
THURSDAY,	Feb. 6	Nat. Amateur Gardeners' Assoc. meet.
FRIDAY,	Feb. 9	Ann. Meet. and Election of Candidates of the Royal Gardeners' Orphan Fund at Simpson's Restaurant, 101, Strand, London, at 3 p.m.
SATURDAY,	Feb. 10	Dutch Gardeners' Soc. meet.
MONDAY,	Feb. 12	U. Hort. Ben. and Prov. Soc. Com. meets.
TUESDAY,	Feb. 13	Ann. Meet. of the Roy. Hort. Soc. at 3 p.m. Committees meet at 12 noon.
THURSDAY,	Feb. 15	Linnean Soc. meet.
FRIDAY,	Feb. 23	Roy. Botanic Soc. meet.
SATURDAY,	Feb. 24	Dutch Gardeners' Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—38·9°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Jan.* 24 (6 P.M.): Max. 40°; Min. 29°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Jan.* 25 (10 A.M.): Bar., 29·8; Temp., 49°; *Weather*—Much rain.

PROVINCES.—*Wednesday, Jan.* 24 (6 P.M.): Max. 51° N.W. Ireland; Min. 37° Bury St. Edmunds.

SALES.

MONDAY, TUESDAY, AND WEDNESDAY NEXT—
Important Sale of Nursery Stock at the Nurseries, South Woodford, by order of Mr. J. Fraser, by Protheroe & Morris, at 11.

MONDAY NEXT—
Roses, Herbaceous and Border Plants, Lilies, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Sale of Roses, Lilies, Shrubs, &c., at Stevens' Rooms, King Street, Covent Garden.

WEDNESDAY NEXT—
Herbaceous and other plants, Gladiolus, Lilies, Begonias, Spiræas, &c., at 12; Roses, Fruit Trees, Palms, Azaleas, &c., at 1 and 3, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY NEXT—
1665 c/s Japanese Liliums, Tuberoses, Lily-of-the-Valley, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 3.

FRIDAY NEXT—
Imported and Established Orchids in variety, also choice Hybrid Cattleyas, Lælias and Lælio-Cattleyas, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

FRIDAY NEXT—
Hardy border plants and bulbs, Roses, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

The Gardeners' Benevolent.

WHILST in many places on on the 18th inst. elections were taking place with the usual accompaniment of noise, reckless statements, counter assertions, and partisan prejudices, there was one election which was carried out with decorum and, we venture to say, absolute unanimity. Some were no doubt anxious for the success of one candidate, whilst others cast their votes in favour of another. But everyone admitted that all the candidates were worthy and duly qualified, and the only regret felt was that they could not all be elected. The election we refer to was that of the Gardeners' Royal Benevolent Institution. The annual meeting of the society was held after we had gone to press, so that we were not able to announce the results of the voting in our last issue. The chair was occupied by Mr. HARRY VEITCH, the treasurer. The attendance was not large, but the business was carried out with the usual mechanical precision. Resolutions were proposed, seconded, and carried *nem. con.* with little or no discussion. All felt that the society is doing excellent work and that the management could not be in better hands. Indeed, the officers and committee have earned the gratitude of the gardening community for their devotion to the interests of the society and the excellent way in which they carry out its management. The objections that we used occasionally to hear have been met by judicious alterations in the regulations, and no one can justly complain that any one class of candidate is favoured at the expense of another. No one can say that the Metropolis and its neighbourhood have a monopoly, for the candidates hail from all parts of the country. Moreover, the establishment of those two most excellent adjuncts—the Victorian Era Fund and the Samaritan Fund—afford an indication of the desire of the committee to meet, so far as possible, the needs and the emergencies of all classes. We should greatly like to see those special funds largely augmented, and we should be delighted to see the gardeners rallying round the society and co-operating to aid their less fortunate fellows to a much larger extent than they do at present. As things are, the society has still to rely on the antiquated methods of begging, at, and in connection with, a public dinner, and on, we can but consider, an objectionable system of voting. This system, which is prevalent in most similar societies, entails an unnecessary amount of trouble and expense on the candidates and their friends, and is a source of annoyance to the subscribers for weeks or even months before each election. A better plan, we venture to think, would be to abolish all personal canvassing and to allow the committee to select a certain number from the list of duly approved candidates, submit that list to the members of the society at the annual meeting for modification, rejection, or confirmation as the case may be. Differences of opinion in particular cases might, as now, be solved by the arbitrament of the ballot-box, if such a procedure were found necessary.

But, after all, these are matters of detail on which the subscribers are likely to hold different opinions; the general principles, on the contrary, are so unquestioned and so unquestionable that we most earnestly plead for increased assistance on the part of the gardening community.

A report of the proceedings will be found on another page.

OUR SUPPLEMENTARY ILLUSTRATION.—On September 9 last we published several photographic views obtained in the Royal Botanic Gardens, Edinburgh, together with a descriptive article by Mr. R. L. HARROW, curator, in which he referred to some of the more interesting features in that well-known botanical establishment. Our Supplementary Illustration to the present issue comprises two further views, and of these the lower one is specially noteworthy, as it shows a system in use at Edinburgh for bringing the atmosphere about the alpine plants on the Rockery into a more suitable condition for producing growth than would otherwise be the case during dry weather in summer. This is done by means of the jets of water shown in the picture, which are thrown so high into the air that the spray in descending is scarcely discernible, but which has the effect of keeping the atmosphere in a humid condition and of depositing moisture on the plants. The Rock Garden at Edinburgh is a famous one, and it is remarkable for some of the best specimens extant of certain species of plants; but during the past few years a needed improvement has been brought about by partially reconstructing the rockwork, and by the placing of larger and more irregular stones, at the same time taking away the small pockets so long in use. The view at the top of the page shows some of the shrubberies, faced with a border of herbaceous flowering plants. Trees, including certain Conifers, succeed well at Edinburgh up to a certain age, but afterwards nothing will keep them in good condition. Especially is this true of coniferous and other evergreen species. For the photographs we acknowledge our indebtedness to the courtesy of Professor BAYLEY BALFOUR, director of these gardens.

THE ROYAL GARDENERS' ORPHAN FUND.—We may remind the supporters and friends of this excellent charity that the annual meeting and the election of pensioners will take place at Simpson's, Strand, W.C., on Friday, February 9, at 3 p.m. The annual festival dinner has been fixed for Thursday, May 10 next, and will be held at the Hotel Cecil, Strand, W.C., under the presidency of J. GURNEY FOWLER, Esq., Treasurer of the Royal Horticultural Society. We hope that Mr. FOWLER will be well supported on that occasion, and that the event will be attended with success, as the holding of this dinner is one of the primary sources of revenue to a fund that exists for the relief of necessitous orphans whose fathers belonged to our own profession.

THE JOURNAL OF THE KEW GUILD.—The Kew Guild is a private society having no official connection with the garden. Its aim is to bind together in social co-operation those who have in former years been associated in the Royal gardens, and those who are still employed within its boundaries. Old "Kewites" are dispersed throughout the world, and but for the institution of the Guild they would have few or no means of intercommunication. As in former years one of the most interesting features of the present publication consists of extracts from the letters from the officials connected with various Colonial and other gardens. In a letter from Rhodesia complaint is made of tourist visitors to the Victoria Falls who are already busy in uprooting ferns and other plants. The writer says he is very rude to them when they are caught in the act, but we fear that hardened sinners of this description need some stronger measures to secure their conversion. Mr. T. W. BROWN tells us of Mr. RUNBERG'S Rose and Carnation houses near Chicago, where over 1,000,000 feet of space is devoted to the growth of the plants just named, and this is only one among "thousands." To get some idea of the magnitude of the cut flower trade one has only to walk through the stores of the wholesale florists at Chicago whence immense quantities of flowers are daily despatched to all parts of the States. To enable the Committee to supply the Journal to friends and others interested in its contents a few extra copies have been printed. These will be supplied at 1s. per copy, postage 2d. extra, on application to Mr. W. N. WINN, Secretary, Royal Gardens, Kew.

ROYAL BOTANIC SOCIETY.—The recent gift of £1,000 from a Fellow of the Society, in aid of its funds, has been followed by donations of two £100 debentures from Lord LISTER, one of £100 from Mrs. ALFRED SCORER, and £200 from Mr. C. BRINSLEY MARLAY.

HONOUR FOR A GARDENER.—We have learnt with pleasure, says *Indian Planting and Gardening*, "that, on the occasion of the royal visit to Agra, H.R.H. the PRINCE OF WALES presented Mr. A. E. P. GRIESSEN, Superintendent of the Taj and other Government Gardens, with a Victoria Medal of Honour. We congratulate Mr. GRIESSEN on the honour conferred upon him. It is a fitting recognition of the excellent work he has done at Agra, but especially during the visit of the royal party to the famous Taj." What this medal may be we can only conjecture. It can hardly be the V.M.H.

THE GARDEN ALBUM AND REVIEW.—Once more we have to greet a newcomer in the ranks of garden-literature. The new publication is edited by Mr. JOHN WEATHERS, and is to be published monthly at 7d. Nothing in this country has been issued like this journal since the cessation of *The Florist and Pomologist*. Four coloured plates are to be given in each number, and the text is intended to deal with gardening in all its branches. The first plate is devoted to the illustration of some hybrid Irises raised between species of the Oncocyclus and of the Regelia types. The hybrids, unlike the members of the Oncocyclus section, prove easy to cultivate and flower readily. The second plate shows Impatiens Oliveri alluded to in our columns September 5, 1903, p. 178. Rose Frau Karl Druschki finds a place as the best double white H.P. in cultivation. Diervilla (or Weigela) Eva Rathke also figured is one of the darkest coloured forms of D. florida. In addition to notices on newly introduced plants, the "Album" contains many useful cultural suggestions. We wish our new contemporary a successful career.

A GARDENER'S TWO SONS ELECTED TO PARLIAMENT IN ONE WEEK.—It may be of interest to our readers to know that Alderman J. H. BETHELL, J.P., land agent and auctioneer, who has been returned to Parliament with such a large majority of votes in the Romford division of Essex, and Mr. T. R. BETHELL, barrister, the newly-elected member for the Maldon division of the same county, are sons of Mr. G. BETHELL, of South Woodford, who was some years ago gardener to Sir GREVILLE SMYTHE, Bart., Ashton Court, near Bristol. Another son is Mr. GEO. H. BETHELL, proprietor of the Hayes Nurseries, Hayes, Middlesex, who formerly was manager of Mr. GEORGE WHITELEY'S Nurseries, Hillingdon, near Uxbridge. This is probably the first occasion on which a gardener's two sons have been returned to Parliament in so short a time, or even at all.

NOS ARBRES.—Under this title M. CORREVON proposes to publish a book on trees, intended to interest the general reader and cause him to love trees and their associations. Intending subscribers should communicate with M. CORREVON, Chêne-Bourg, Geneva.

CINCHONA BARKS.—Mr. DAVID HOWARD, in a paper read before the Pharmaceutical Society recently, described the efforts made to obtain plants and seeds of the valuable Cinchonas by the Indian and Dutch Governments, referring to the admirable work of Sir CLEMENTS MARKHAM. Mr. HOWARD described the cultivation in India and Java, and specially pointed out the extraordinary effect of the careful selection of plants for propagation, which had raised the quinine contained in the best Ledgeriana bark to 10 per cent. from an average from good wild bark of 3 to 4 per cent. In collecting the bark the old practice was to cut down the trees, but nowadays strips of bark are cut off, and in due season the bark is renewed. The author described the process of renewing which is largely adopted in British India and Ceylon, and pointed out the very curious alteration, not only in the amount of alkaloid, but in the proportion of quinine to the other alkaloids in this renewed bark, and contrasted that with the accumulation of alkaloids in the root bark, especially of unhealthy trees.

ONE & ALL GARDENING.—Mr. EDWARD GREENING again sends forth his little book on One & All Gardening in connection with the Agricultural and Horticultural Association, Long Acre. The editor and his staff endeavour to make it useful as well as interesting, and have succeeded in putting together a good collection of practical articles by trustworthy authorities. There are plenty of illustrations, ornamental and instructive, and the "Novel Facts about Fertilizers" is likely to prove especially attractive, as Mr. JAMES SCOTT points a useful moral with some striking pictures. 'The Garden of Honour," by the Editor, treats of town gardening and its possibilities.

THE CANADIAN HORTICULTURIST.—This useful publication commences its twenty-ninth volume this year under the editorship of Mr. H. B. COWAN. The chief articles in the January issue deal with Co-operation by Fruit-growers, by PROF. REYNOLDS; Winter Work for the Amateur Florist, Summer-bedding, and Vegetables. The whole is nicely printed and got up, and brightened by numerous illustrations, so as to form a great improvement on its predecessors.

A NEW MARKET FOR CIDER. According to the *Journal of the Board of Agriculture* there is a continually increasing demand for English cider. Australia, South America and South Africa are already good customers, and recently a ready market has been found for cider in Holland. Dutch Apples have not been found suitable for cider-making, and the Dutch Department of Agriculture were last year instrumental in arranging an exhibition of English cider, to be held in Amsterdam. Cider is considered by the Dutch as a wine, and they would pay a remunerative price for the best qualities; those retaining the aroma and flavour of the fruit with some degree of sweetness being preferred to less pure and to acid or bitter varieties of the beverage. Perry was equally appreciated, and English growers and manufacturers of this and of cider are recommended to develop the trade with Holland as soon as possible before Dutch orchards and factories are capable of competing with them.

NEW INSECT PEST OF THE DOUGLAS FIR.—Dr. STEWART MACDOUGALL contributes to the *Journal of the Board of Agriculture* an account of a new insect pest of Pseudotsuga Douglasi. Mr. JOHN CROZIER, of Aberdeen, had sent some affected seeds and insects for examination, stating that the pest was at first of but trifling importance, but soon increased to a serious extent. The insect proved to be Megastigmus spermotrophus, and was hitherto not represented in the Natural History Museum. The eggs are laid in the young cones of the Douglas Fir, which showed no external mark of the presence of the larva. Each seed contains one larva, nourished on the reserves therein stored up. It is supposed that the species was introduced to Britain in seed from the native home of the tree in Western North America. The insects are so small and the cones often so numerous that sweeping and beating the trees is suggested as one means of reducing the numbers of adult Megastigmus. Dr. MACDOUGALL further recommends that the cones should be gathered when ripe, in late October, and the seed extracted and fumigated, thus:—"Place the material to be treated in an air-tight receptacle. Pour bisulphide of carbon in a shallow dish and lay this on the top of the material. Close the receptacle. The bisulphide of carbon vaporises, and as its fumes are heavier than the air they sink down through the material. The receptacle should be kept closed for 48 hours. One ounce of bisulphide of carbon will do for 100 lbs. of seed, or 1 ounce for every 50 cubic feet of air space. The treatment should be administered in not too cold a temperature. Bisulphide of carbon fumes being poisonous should not be inhaled by the operator, nor should a light of any kind be brought near." The operation does not hinder the germinative properties of uninfested seed and is fatal to the larva.

DO PLANTS THINK?—This is the question raised by Mr. ARGYLL SAXBY in a pamphlet concerning the neurology and psychology of plants. Its solution depends, of course, upon the meaning attached to the words "think" and "thought"; whether they may be applied to evidences of nervous sensitiveness or to powers of reasoning unaffected by the environment of the moment. Mr. SAXBY apparently attributes both sense and sensibility to plants, as he concludes that "all protoplasmic nature has the possibilities of sensibility and reason, whilst in some of these which we call the lower forms of life these qualities are abundantly evident. Robbed of the soul all sensibility is reduced to chemical reactions, and since both animal and vegetable forms are subject to similar reactions, the denial of sensibility as being possible in either case is manifestly absurd. It is merely a matter of development to make the lower equal to the highest." The author puts forward other theories and as he expects ridicule to attend his idea of spiritual thought permeating and controlling all nature, and therefore shared by all atoms of that nature, we will not further enlarge upon it here. We have still to meet the difficulty of how to recognise the boundaries that divide elaborate reasoning and the highest human faculties from the "chemical reactions" causing such phenomena as (say) heliotropism, or the movements of Mimosa or Drosera leaves. Mr. SAXBY'S little pamphlet can be procured from the "Guardian" Office, Pool Street, Bodmin.

DOCTOR UDO DAMMER, Curator of the Botanical Museum in Berlin, has been appointed a professor. Dr. DAMMER studied practical gardening at Potsdam, and was afterwards employed in the Botanic Garden in St. Petersburg. He has worked in the Botanical Museum of Berlin since the year 1889. Dr. DAMMER is well known as the author of various books, notably *Palmenzucht und Palmenpflege* (the Culture and Care of Palms). He was the translator of Dr. MASTERS' Vegetable Teratology into German, and is an occasional contributor to these columns.

ILLUSTRATIONS OF CHOICE VEGETABLES.—Mr. ERNEST BENARY, Seedsman, Erfurt, has issued Part II. of *Vegetables Photographed from Nature*, concerning the first part of which a note was published in our issue for March 18, 1905. The second part contains eight loose plates upon thick art paper, each measuring 20 by 18 inches, and representing selected varieties of the following vegetables:—Carrots (two plates), Summer Radishes, Cabbage Lettuces, Cabbages, Lettuces for forcing, Radishes, Kohl Rabi, and Corn Salads. The 16 varieties of Carrots represent all types from the short, thick rooted to that in which the roots are very much longer and of tapering shape throughout. One of the short-rooted varieties named Paris Market appears almost similar to a Turnip, so short is the swollen root. The varieties of Radish recommended for forcing, which are given a plate to themselves, appear excellent for the purpose, and the illustrations are capital. We do not think the Summer Radishes are represented in such good condition. They are described as of natural size, but the roots are shown to be so large that nine out of ten persons would fail to identify them as Radishes at all. In any case, no cultivator would allow them to grow to such a size if they

were intended for consumption. The Lettuces and Kohl Rabi make three very good plates, and on the remaining plate attention is drawn to seven varieties of Corn Salad (Valeriana), an excellent salad that is used freely on the Continent, but very little in this country. We may add that this is an English edition of the work, and copies may be had for six shillings each. One part is to be issued every year.

THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.—The December part is so voluminous that it will be impracticable to review its contents in any reasonable time. We must confine ourselves to saying that it is as usual a most valuable publication, from which we may, in future, make extracts. At present it is barely possible even to enumerate its contents, so numerous and substantial are they. The Secretary, in laying down his editorial functions, points out that on his accession to office in 1888 there were only 773 subscribing Fellows, of whom 221 immediately resigned, so that he was confronted with a debt of £1,152; an annual expenditure of £3,500, a subscription income little, if at all, more than £1,500 a year, and the publication of the Society's journal was suspended. The debt was paid off in 1888 and 1889, and there has since been an annual average increase in the Society's income of £753. In 1888 the Society was homeless and houseless. It now has a magnificient hall of its own, thanks to Baron SCHRÖDER and others, with convenient and suitable offices. The number of Fellows is now nearly 10,000. The gardens no longer consist of about 13 acres in the smoke-begrimed district of Chiswick, but exceed, thanks to Sir THOMAS HANBURY, 60 acres in the beautiful open country and clear air and sky of Wisley, near Weybridge. In 1889 the *Journal* was recommenced and numbered 404 pages. It has now more than 1,200 pages, with 234 illustrations and six coloured plates. In 1888 there was a debt of £1,152; there is now a reserve fund of £16,536. Mr. WILKS may well cry, *Nunc dimittis*. There may have been delay, but there has been no "break down" in the publication of the *Journal*. The only serious complaint we have heard concerning it is that it is too good, or at least too voluminous. The new editor, Mr. G. S. SAUNDERS, will, no doubt, use his pruning knife, and eliminate matters which are not strictly horticultural. The contents of the present part comprise the papers read before the Society, and even those which have formed the subjects of discussion at the Horticultural Club and the Chelmsford Gardeners' Association. The notes and abstracts constitute a valuable feature, occupying some 200 pages. A little more eclecticism in this department would be advantageous. Two indexes complete what is truly a *magnum opus*.

M. ERNEST FIERENS.—We regret to hear of the death, from pneumonia, of M. ERNEST FIERENS, of Ghent. M. FIERENS was well known as a Chrysanthemum grower, and also for his services in connection with the Société Royale d'Agriculture et de Botanique, of which he was the courteous and most efficient Secretary. By those who are in the habit of visiting the Ghent Quinquennial Exhibitions he will be greatly missed. It is but a short time since we had to record the death of M. DE MEULENARE, and now the Society is again plunged in sorrow. In communicating the intelligence our correspondent appropriately made the quotation, "Uno avulso, non deficit alter." Such is the vitality of the old Society and its managers that we doubt not this optimism will be justified.

ETHER-FORCED RHUBARB—Mr. W. STUART, of the Vermont Experiment Station, has communicated to the Department of Agriculture (U.S.A.) the results of his experiments in forcing Rhubarb by the aid of ether fumes. In his trials the roots to be treated were dug in autumn and allowed to freeze. In December they were gradually thawed in a cool cellar, and then part of the roots were subjected to ether fumes and part left untreated for comparison. The roots were etherised for 48 hours in an air-tight box, using 10 cubic centimetres of ether per cubic foot of space. Three other sets of roots were etherised at later dates and with varying proportions of ether. The earliest of the treatments proved the most successful as regards the total yield. The plants etherised were of earlier and more vigorous growth, and yielded increased weight of product when compared with the specimens left untreated.

AN ASSOCIATION OF HORTICULTURAL INSTRUCTORS.—A movement initiated by Mr. A. E. BROOKE-HUNT, Inspector under the Board of Agriculture and Fisheries, has resulted in the various lecturers on Horticulture in the United Kingdom forming themselves into an association. The members propose to have periodical meetings, when papers will be read and discussions conducted on the different phases of educational work in gardening. Mr. A. E. BROOKE-HUNT was elected chairman at a recent meeting, and Mr. WALTER P. WRIGHT, of Postling, Hythe, Kent, Hon. Secretary and Treasurer.

LINNEAN SOCIETY.—General meeting, January 18, 1906, Prof. W. A. HERDMAN, F.R.S., President, in the chair. Mr. WILLIAM CARRUTHERS, F.R.S., a past-President of the Society, on the part of the subscribers, presented a portrait of Prof. S. H. VINES, D.Sc., F.R.S., President from 1900 to 1904, painted by the HON. JOHN COLLIER, and the President in the chair accepted the gift on behalf of the Society. Mr. T. ERNEST WALTHAM exhibited a series of coloured transparencies from flowers in natural colours, partly by the three-colour process, partly by hand. They were shown on frames specially devised, the light being reflected from beneath, and a frame with stereoscope slid along above the series. One admirable lantern-slide was displayed upon the screen, to show the success of the process. Mr. A. O. WALKER and Dr. A. B. RENDLE contributed some remarks. The first paper was by Mr. A. W. ALLEN, on "The Life-history of Margaritifera Panasesæ," which was communicated and read by the Rev. T. R. R. STEBBING, Sec L.S. Mr. A. D. COTTON, F.L.S., then gave the main features of his paper "On some Endophytic Algæ," illustrating his exposition by drawings on the blackboard. A paper by Dr. A. BROOM, communicated by Prof. A. DENDY, F.L.S., was read in title, "On the Organ of Jacobson in Sphenodon," and was illustrated by coloured drawings. A meeting will be held on Thursday, February 1, at 8 p.m. when Mr. J. STANLEY GARDINER, M.A., Fellow and Tutor of Gonville and Caius College, Cambridge, will give an account of the Percy Sladen Trust Expedition to the Indian Ocean, of which he was leader, in H.M.S. "Sealark."

BRITISH BOTANISTS IN PRETORIA. — The October issue of the *Transvaal Agricultural Journal* contains a description of the visit paid by some of the botanists attached to the British Association to the "Wonderboom," *Ficus* sp. This is a wonderful tree, hemispherical and covered with evergreen leaves and small figs. Its diameter is 162½ feet and its height about 67 feet. "Some of the branches from the centre spread out laterally in a radial direction and gradually droop towards the ground. At a distance of about 30 feet they come in contact with it and send out roots from which new groups of stems arise. From these other branches may be given off, still in the same radial direction, and these, coming in contact with the ground, may become rooted in their turn and send up a third group of stems. . . . The district round the Wonderboom was especially interesting to the botanists present as being the old hunting ground of CHARLES ZEYHER, who obtained many of his type specimens here about 1842."

FORESTRY IN NEW SOUTH WALES.—In a lecture on Forestry given last autumn by Mr. J. H. MAIDEN, Director of the Sydney Botanic Gardens, we find many valuable hints concerning Forestry and timber. Mr. MAIDEN lays special stress on the necessity for the forester being also a good botanist and having a knowledge of the life-history of his trees; their habits, bark, timber, leaves, flowers, and fruits. The Australian student has not the book-lore of centuries to aid him, but has principally to deal with trees of the difficult and still partly unknown genus Eucalyptus, of which new species are yearly discovered. Only by careful and systematic examination of the trees and of the timber imported can the forester attain to a knowledge of the special properties and possibilities of the several species, and learn to recognise them apart.

SOUTH EASTERN AGRICULTURAL COLLEGE, WYE.—We are informed that a meeting of the Govenors of this College was held at the Westminster Palace Hotel, on January 22, Lord ASHDOWN, chairman, presiding. The Principal, Mr. M. J. R. DUNSTAN, reported 97 students to be in residence for the Spring Term; the appointment of Mr. PLYMEN, the soil analyst, to the Professorship of Agricultural Chemistry at Nagpor; and details connected with the new buildings, the electric light installation, and water supply. Mr. E. SALMON has been appointed Mycologist, and Mr. A. AMOS Assistant Chemist. The establishment of a Horticultural side to the College is under consideration.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, January 29, 1906, at 8 p.m., when a paper by Mr. F. MARSHALL, K. C. (Associate), entitled "The Valuation of Machinery for the Purposes of Rating," will be read. The annual dinner of the Institution will be held at the Whitehall Rooms, Hotel Metropole, on Wednesday, February 21, 1906, at seven o'clock precisely.

THE DINNER TO MR. W. MARSHALL.—It has been decided that the dinner already mentioned shall take place on March 6, at 6 p.m., at the Hotel Windsor, Westminster. Tickets for the dinner will be 6s. (exclusive of wine). Although the dinner is promoted by the Floral Committee, past and present members of all the Royal Horticultural Society Committees and other horticultural friends of Mr. MARSHALL are cordially invited. Application may be made to Mr. GEORGE GORDON, Endsleigh, Priory Park, Kew, or to members of the sub-committee mentioned in our previous note.

RAINFALL IN 1905.—Our correspondent, Mr. ERNEST WILLOUGHBY, sends us the following remarkable details of the rainfall at Glencarron, Ross-shire. Glencarron is situated inland with high hills surrounding it. The total number of inches recorded was 95·13, the wettest month being January with 13 39 inches. Rain fell on 280 days, October only escaping with one dry day. Mr. W. H. JENKINS, Wythenshawe Gardens, Northenden, Cheshire, sends the record of the past year's rainfall in those gardens as 27·61 inches, which is 2 inches below the average. No measurable rain was registered for a period of 14 days during May, thus causing a drought in the locality. The highest shade temperature was 89° on July 8, the lowest mean temperature 12° on November 19.

PUBLICATIONS RECEIVED.—*The Collector's Magazine*, January 13.—*Proceedings of the Agri-Horticultural Society of Madras*; July to December 1905.—*Bulletin of the Department of Agriculture, Jamaica*: December, 1905. Edited by William Fawcett, Director of Public Gardens and Plantations. The contents relate chiefly to Rubber and Cocoa.—*The Queensland Agricultural Journal*, December, 1905. This contains the usual notes on agricultural and horticultural subjects, and is edited by Mr. A. J. Boyd.—New York Agricultural Experiment Station: Bulletin No. 269.—*Winter Injury to Fruit Trees*. By H. J. Eustace.

A NEW VARIETY OF ORANGE.

The illustration at fig. 29 shows the pretty little variety of Citrus japonica, shown recently by Messrs. Veitch and Sons, of Chelsea. It is evidently a close ally of the Kum Quat, a variety much esteemed for decorative purposes as also for its candied fruits. For greenhouse decoration these plants are very desirable, as they flower and fruit while still in small-size pots, whilst, as we have said, they are valuable for other purposes. The present variety is remarkable both for its narrow foliage and its elliptical fruits. It will be remembered that a note was printed on p. 46 of the last issue relating that the Fruit Committee of the Royal Horticultural Society had awarded a First Class Certificate to this variety on the ground that the fruits are of excellent quality for dessert. It will be seen, therefore, that this orange is a useful acquisition.

Fig. 29.—Citrus japonica with elliptic fruit.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

Annual Meeting.

January 18.—The sixty-seventh annual general meeting of the members and subscribers of this institution was held on the foregoing date at Simpson's Restaurant, 101, Strand, London. The chair was occupied by Mr. Harry J. Veitch (treasurer). The secretary read the report and balance sheet for the past year, from which we give the following extracts:—

"At the beginning of the year there were on the funds 214 persons—127 men and 87 widows—receiving £20 and £16 per annum respectively for life, at an annual cost of £3,792, being an increase of seven persons as compared with the previous year. During 1905 eighteen pensioners died, four leaving widows, who, their cases being found eligible and deserving, were placed on the funds for the widow's pension without election, in accordance with Rule III., 13.

"Thus at the close of the year there were 200 persons receiving annuities for life, and, feeling assured of continued and, as they hope, increased support, the committee recommend the election this day of eighteen persons from the approved list of forty-four candidates. This will make a total of 218 annuitants on the funds—the largest number at any time in the history of the charity.

"Notwithstanding this, unfortunately there will be twenty-six unsuccessful applicants, who must anxiously await a further election a year hence before receiving the permanent aid they so much need. The committee wish the annual income enabled them to assist a larger number, but in adding four additional beneficiaries they feel they have done all that the state of the funds warranted. The special funds at the disposal of the committee are of the greatest benefit. The income from the 'Victorian Era Fund' has been applied in affording assistance to the unsuccessful candidates at the last election, who were formerly subscribers, £157 having been distributed among them during the year; while the income from the 'Good Samaritan Fund' has enabled the committee to make grants of nearly £100, as temporary help in cases of most urgent distress and need."

The balance sheet showed a total income of £9,263 18s. 4d., which includes a balance from last year of £1,048 10s. 4d. The annual subscriptions amounted to £1,638 17s., while the donations at and in consequence of the festival dinner, including sums raised by means of the collection cards, totalled £2,225 9s. The magnificent sum of £4,849 18s. was derived from the interest on the invested funds, truly a magnificent backbone to the institution. The expenditure on pensions and gratuities was £3,741 12s. 6d., and the committee has been enabled to place on deposit £3,665 10s.

The Victorian Era Fund had an income from all sources of £345 1s., out of which amount £157 has been expended in the form of gratuities.

The receipts to the Good Samaritan Fund totalled £302 3s., and from this amount necessitous cases had been relieved to the extent of £85, leaving a balance of £217 3s.

The Victorian Era and Good Samaritan Funds were both doing excellent work, and as an example of the usefulness of the latter fund, the relief of the daughter of a prominent gardener, a man who, before his decease, was widely known and respected by many present in the room, was cited.

The chairman referred to the management of the Society, and congratulated the subscribers upon the economical manner in which the funds of the institution, with a yearly turnover of nearly £10,000, were managed.

The adoption of the report was carried unanimously.

The officers of the institution were all re-elected, as were also the retiring members of the committee, with the exception of Mr. M. Gleeson, who desired to resign. The vacant place was filled by Mr. Ed. White.

The Successful Candidates.

The scrutineers having handed in their compilations of the votes recorded, the result was announced as follows:—1, Juliet Fitt, 3,307 votes; 2, Elizabeth Williams, 3,244; 3, Charles Rutson, 2,891; 4, Stephen Goddard, 2,734; 5, Isabella M. Clarke, 2,730; 6, Mary Ricks, 2,655; 7, George B. Scott, 2,655; 8, William Egglestone, 2,621; 9, Elizabeth Stubbs, 2,612; 10, William Wickens, 2,599; 11, Bethiah Ward, 2,543; 12, William Moore, 2,507; 13, James Stone, 2,444; 14, Mary Down, 2,363; 15, Richard Salway, 2,334; 16, Isaac Clement, 2,243; 17, Sarah A. Fenn, 2,236; 18, William Smith, 2,226; 19, Joseph Woods; 20, Thomas Smith. The two candidates last named were added subsequent to the original election.

The committee recommended Mr. Joseph Woods, a candidate who has for the past six years been endeavouring to obtain relief, as an additional beneficiary. This was carried unanimously, and it was further agreed by the subscribers present to add a 20th name to the list. The fortunate candidate was Mr. Thomas Smith, who had the next highest number of votes on the polling sheet. It was announced that no fewer than 52 voting papers had been rendered void by the omission of the subscriber's signature on the voting paper.

The Annual Friendly Supper

took place at 6 p.m., also at "Simpson's," and was attended by members of the Committee and their friends. Mr. Geo. Monro, V.M.H., presided. In the course of a speech delivered when proposing the toast of the evening, the Chairman said they were very pleased to be back again at "Simpson's." He related a number of interesting facts connected with the Institution and the disbursement of its funds, some of which were referred to at the afternoon meeting. But, in addition, Mr. Monro had a pleasing piece of news to announce, which came quite as a surprise. This was a message from Mr. N. N. Sherwood, who had asked his son, Mr. Edward Sherwood, to announce to those present at the dinner that he would be pleased to give a sum of £50 for division amongst the candidates who had been unsuccessful at the election. This intimation was received with much gratification, and a message of thanks was sent to Mr. Sherwood. In connection with the election that day, Mr. Monro drew attention to the circumstance that there were 52 unsigned voting papers received, which, therefore, could not be used. Some voting papers were also received after the declaration of the poll, and the Committee being anxious that all subscribers to the Institution should have a voice in the election of candidates, could not but regret that more care is not exercised in respect to this matter.

Mr. Harry J. Veitch, in responding, mentioned the fact that he had been treasurer for about 20 years, and though he would take no credit to himself for the amount of good work that had been accomplished in that period, he could not but rejoice that, whereas then there was £21,000 invested, there is now £42,000. Instead of there being 118 pensioners on the funds, there are now 220 pensioners. In addition, both those excellent funds, the Victorian Era Fund and the Samaritan Fund, had been established. Mr. Veitch coupled with this

response the toast of the country members and auxiliaries, to which Mr. H. G. Cox, Hon. Secretary of the Reading Branch, responded. Alderman Piper proposed the toast of "The Chairman," and Mr. Morgan Veitch that of "The Honorary Officers, etc.," the latter toast being responded to by Mr. Owen Thomas.

Mr. George J. Ingram, in replying to the toast of "The Secretary," moved by the Chairman, and referring to the institution of the Victorian Era and Samaritan Funds during the 15 years he has been in office, said that when sending the disagreeable intelligence to such candidates who had been unsuccessful at the poll, he had now the satisfaction of being able to tell them that their cases would be considered by the Committee, and if the circumstances warranted the Committee in making a special grant, they would do so. Before there were such funds, said Mr. Ingram, the communication of this news was a specially disagreeable duty.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from page 28.)

A STRETCH OF THE TUNG VALLEY.

Szechuan the name given to the largest, most western, and probably richest province of China, simply means "Four streams." The name is derived from the four large rivers, Kialing, T'o, Min, and Yalung, which flow through the province from north to south to join the mighty Yangtsze. These rivers take their rise in wild, sparsely-inhabited country, and for some hundreds of miles follow parallel courses separated by high mountain ridges. Their valleys are very narrow, very much shut in, enjoy a peculiar climate, and support a very curious and interesting flora. The object of this note is to illustrate, by reference to one river valley, the peculiar and altogether anomalous state of things which obtains in these river valleys of Western China.

The river Tung is, rightly speaking, the main branch of the Min river; it unites with the branch which rises north of Sungpan, at Kiating Fu. The stretch with which this note deals is some distance removed from the point of union of the two streams. It lies, roughly, in long. 102°, 32'E, between lat. 29°, 47', and lat. 30° 6'N. The stretch is quite a short one, following the windings of the river for not more than 35 English miles. The village of Lêng-che (alt. 4,300 feet) marks the southern point, and the hamlet of Wa-su-kou (4,600 feet), the northern point of the stretch.

The river between these points flows along the line where limestone gives way to granite, and is shut in by steep mountains on either side. Those on the right bank tower fully 10,000 feet, being spurs of the mighty snow-clad peaks of the Chino-Tibetan frontier. Shrubs and remnants of Conifer forests clothe the upper part of these mountains. The mountains on the left bank are not so high, and are clad with long grass, a few herbs, and stunted bushes. Numerous streams join the river from the right bank, but scarcely one from the mountains of the left bank. From Lêng-che to Luting-chiao (10 miles) the road skirts the left bank of the river, crossing to the right bank at the latter village by means of a fine iron suspension bridge, 107 yards long. From this bridge to Wa-su-kou, the road is for the most part hewn out of solid rock, and is one succession of steep ascents and descents. In many places it projects over the river, being supported on poles driven horizontally into holes blasted in the rocks. This road is seldom more than 4 feet wide, and is not only difficult, but highly dangerous to travel over.

This river-valley between the points mentioned above enjoys a much warmer climate than one would expect from its altitude, and in this is only a type of most of the river-valleys in these regions. Captain Gill ("River of Golden Sand," Vol. ii., p. 135), notes the presence of green parrots in the valleys of the Yalung and Kinsha rivers, in much the same latitude but farther west, and between 7,500 and 9,000 feet altitude. In a footnote on the same page we read: "Lieut. Garnier notices the warm temperature in the valley of the Kinsha at its confluence with the Yalung. The characteristic plants of Kiang-Hung on the Mekong, 4° south, were found there."

When passing through this portion of the Tung valley, I was struck with the peculiarity of its flora, but subsequently I found this peculiarity general to the river valleys of the west. The majority of the characteristic plants were the same as those of parts of Yunnan, 7° south. The flora is excessively poor, essentially xerophytic, and warm-temperate or sub-tropical in character. The herbs have fleshy leaves, bulbous, rhizomatous, or variously thickened rootstocks; the shrubs are dwarf, spinescent, with small leaves, or with leaves and stems covered with woolly hairs. The trees are such as are found to succeed best in dry regions.

By far the most striking and, possibly, commonest, plant is Opuntia Dillenii. This colonist is as much at home here as it is in parts of Texas and Arizona. Miles and miles of the river banks are covered with this plant, which forms large bushes 8 to 10 feet high, often one mass of pale-orange flowers. So much does the presence of this plant alter the appearance of the country that one could easily imagine it to form part of one of the arid states of Southern U.S.A. And as if to make the delusion complete, a Mimosa-like Leguminous plant is associated with the Opuntia exactly as one finds it in the above States! In parts of Yunnan, and more especially the low mountains around Lake Shi-ping, large areas are covered with this self-same Opuntia to the exclusion of nearly everything else. The fruits are eaten by the peasants, who thus help to propagate the plant. The extract from the stems on boiling them is considered a cure for hæmorrhoids.

The characteristic shrubs and sub-shrubs of this dry region are: Buddleia paniculata, Vitex Negundo, V. incisa, Sophora viciifolia (a very spiny form), Caryopteris Mastacanthus, Caryopteris sp., Ceratostigma minus, Bauhinia sp., Albizzia Julibrissin, Acalypha sp., Incarvillea variabilis var. latifolia, Amphicome Emodi, Indigofera decora, and Buddleia variabilis. Others much less common are Myrsine africana, Rosa Webbiana, Ligustrum Prattii, Jasminum floridum, Cotoneaster pannosa, C. Franchetii, Leycesteria formosa, Kölreuteria bipinnata (shrubby form), Xanthoxylum Bungei (cult.), Xanthoxylum sp., Sophora sp., Indigofera spp., and various sub-shrubby Labiates and Composites. Clematis Gouriana, two species of Ceropegia, two species of Ipomæa, and several species of Cynanchum are the common climbers.

In point of numbers Lilium leucanthum is the commonest herb. In the niches of the rocks and amongst scrub and long grass, it occurs in hundreds of thousands. In July and early August, when this Lily is in flower, the hillsides are dotted all over with its large, white, funnel-shaped flowers, and their fragrance fills the air. These Lily-flowers are eaten by the peasants, the perianth being broken up into its six segments, and the style, ovary, and anthers are discarded. The segments and stamen-filaments are then boiled, strained, and then dried in the sun, and preserved. They are eaten fried with salt and oil. The bulbs of this species are not eaten, but those of L. tigrinum and L. sutchuenense are consumed in various parts of China.

Datura Stramonium and Verbascum Thapsus are two common roadside weeds. The Chinese are well aware of the poisonous nature of the Datura, and the Verbascum is undoubtedly spontaneous. Another characteristic herb is Chelidonium Franchetianum. This is really a very pretty plant, with marbled leaves, and clear yellow, but very fugacious flowers.

Other common herbs hereabouts are, Barleria cristata, Platycodon grandiflorum, Oxalis corniculata, Taraxacum officinale, Ophiopogon spicatus, Thalictrum dipterocarpum, Hemerocallis fulva, Lythrum Salicaria, Polygonum spp., Pteris sp., Statice Bretschneideri, Sedum spp., Lepidium ruderale, Cheilanthes sp., Malva sp., Artemisia spp., Roscoea sp. (flowers pale yellow), Asphodelus sp., Zygophyllum sp., Selaginella spp., Boea sp., and various Compositiæ, Labiateæ, and grasses. The bare rocks fully exposed to the sun are frequently carpeted with Boea hygrometrica and Selaginella involvens. Amongst the grass, Lilium Bakerianum and L. sutchuenense occur sparingly. On bare cliffs Codonopsis convolvulacea, with its lovely blue flowers, and, on shady banks, Scolopendrium Delavayi are occasionally met with.

When in flower the herbs and shrubs of this dry region make a fine display by reason of their intense colours. Purple, blue, and red are the predominating hues, yellow and white being much less in evidence.

Trees are very scarce, being chiefly found around habitations, but although the number of individual trees is not great, the variety is considerable. The following are the chief: Erythrina indica, Thuya (Biota) orientalis, Trachycarpus excelsa, Salix babylonica, Populus euphratica, Alnus nepalensis, Sapindus Mukorossi, Gleditschia sinensis, Sterculia platanifolia, Pistacia Weinmanniifolia, P. chinensis, Cupressus funebris, Aleurites cordata, Pterocarya stenoptera, Diospyros Lotus, D. Kaki, Juglans regia, and Ailantus glandulosa. This latter tree is always spinescent in the dry valleys of the west. (This is probably the same as A. Vilmoriniana, see *Gardeners' Chronicle*, Vol. xxxviii. (1905), p. 276.)

Phyllostachys mitis is the common Bamboo around dwellings. The Walnut is the commonest fruit-tree, though Pears, Apples, Peaches, and Apricots are commonly grown. Rice is the common crop in the bottom-lands; Maize on the mountain sides up to 7,500 feet; Millet and Sorghum are the other cereals. The nature of the country does not lend itself to agriculture, and the population is very sparse. *E. H. Wilson.*

(To be continued.)

NOTICES OF BOOKS.

THE HORTICULTURAL NOTE BOOK. By J. C. Newsham, etc. (Crosby, Lockwood and Son.)

The sub-title of this book well indicates the nature of its contents as "a manual of practical rules, data, and tables for the use of Students, Gardeners, Nurserymen, and others interested in Flower, Fruit, and Vegetable Culture, or in the laying out and management of gardens." So far as we remember, we have had nothing so complete of its kind as this little manual. It reminds us of Professor Bailey's *Horticulturists' Rule Book*, and in so saying we are paying a compliment to the author of the present compilation. The chapters on weights and measures are, of course, indispensable, although they bring prominently into notice the utterly unsystematic and confusing nature of our present practice. Fortunately, the compiler has added the necessary information relating to the metric system, and the next generation will probably wonder how their fathers could have tolerated for so long such a medley of inconsequent details as now encumber our table-books. Garden-formation, horticultural structures,

hedges, fences, gates, soils, manures, the propagation of plants, hints on the culture of flowers, fruits, trees, shrubs, and vegetables all find a place in this little book, together with notes on insecticides and fungicides, and the weather as it affects gardeners. In this latter connection we may say that we find no mention of the newly-introduced "Pagoscope," which we have found useful. It is impossible to deal critically with such a mass of facts as are here got together; but we may record our impression that the note-book will be found most useful for consultation, and that gardeners will be amply repaid for the outlay they may incur in purchasing it. The price may seem at first sight high (7s. 6d.), but its possession will obviate the necessity for purchasing many books. In the geometrical definitions we are told "that an obtuse angle is greater than a right angle," which makes us think that the definition of a right angle should first have been given. As it is, we find no definition of a right angle at all! The results of the voting on Potatos and Apples throughout every county in the British Islands given in our columns might well have been inserted, but where so much is given it is ungracious to ask for more. We may add that, so far as we have seen, the proofs have been carefully read, and misprints are surprisingly few. The names of plants on p. 299 constitute a rare exception. There are numerous illustrations and a good index.

NICOTIANA SANDERÆ AT KEW.

Among the best flowering plants in the open garden at Kew last season were Messrs. Sander & Sons' hybrid Nicotianas. The plants were raised from seeds sown in cool frames, and afterwards cultivated in pots, from which they were transplanted to the beds at the end of May. The Curator, Mr. W. Watson, who is one of the keenest of plantsmen, informs us that they grew well, branched very freely, and flowered profusely until autumn. So much has been written in these columns as to the merits of Nicotiana Sanderæ, and its varied colours and suitability for bedding, that we need say but little at this time. Our readers, however, will agree that the illustration at Fig. 30, which has been prepared from a photograph taken by Mr. Wallis, shows unmistakably that the effect of such a bed as that portrayed must be brilliant and graceful. One of the most gorgeous sights we remember to have seen was a collection of these Nicotianas in the nurseries of Messrs. Sander & Sons, at Bruges, a year or two ago, where they filled house after house with sheets of rich colours.

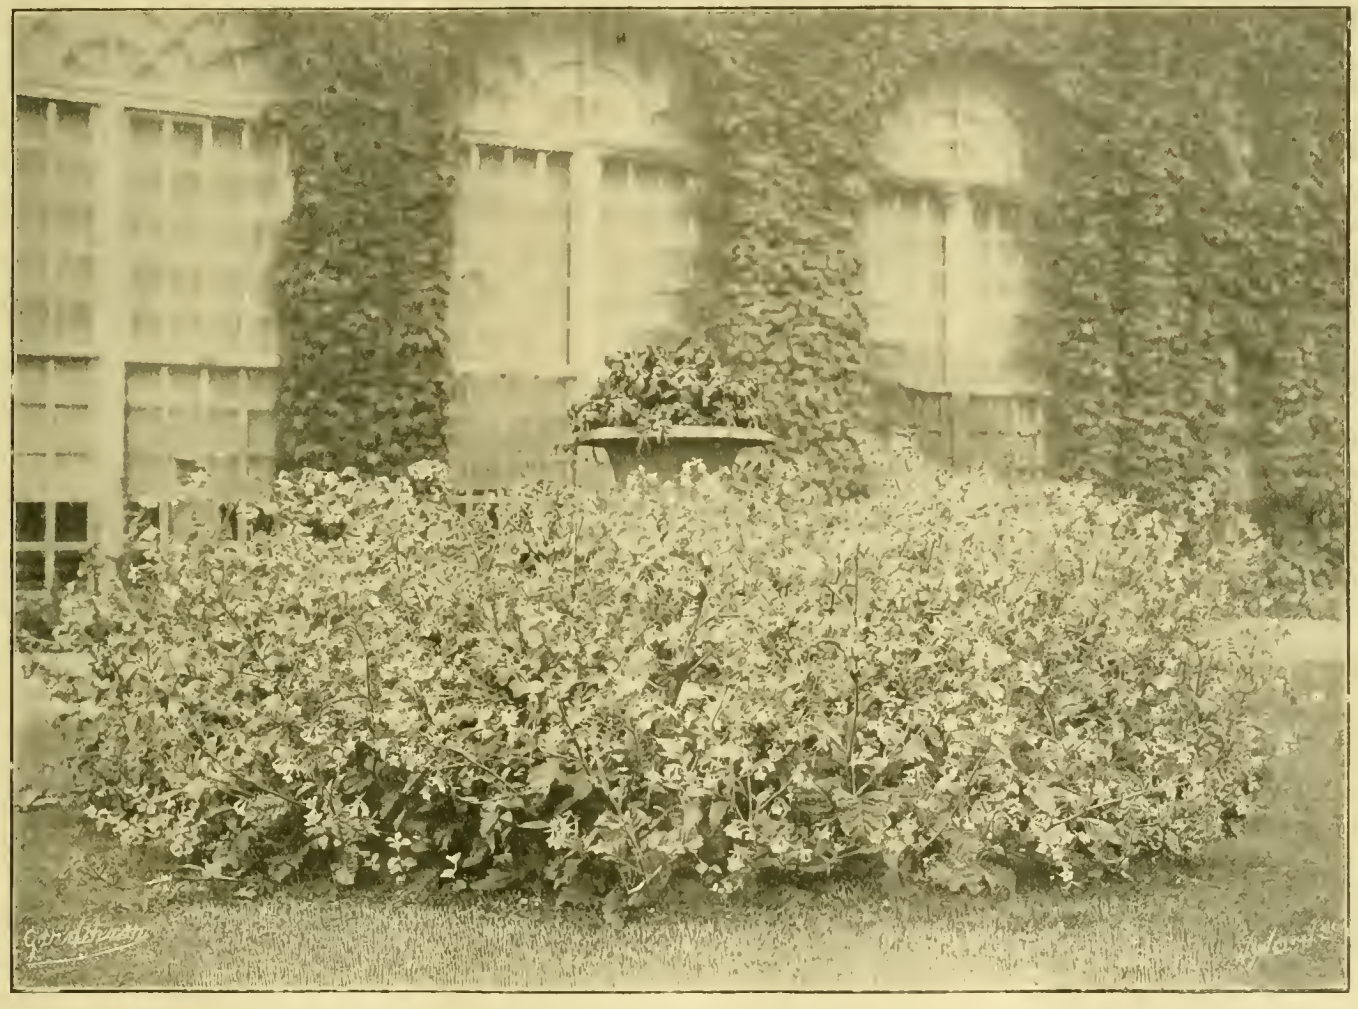

Fig. 30.—Bed of Nicotiana Sanderæ, as it flowered last season in the Royal Gardens, Kew. (From a photograph by Mr. Wallis.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Anthracite Coal.—Mr. A. Holland Hibbert, p. 46, enquires whether other readers of the *Gardeners' Chronicle* have been asked to buy trucks of anthracite which had "broken down a few miles from their station." I have been asked to do so many times during the past two years, and I have long been expecting some one to call the attention of your readers to the phenomenal bad luck which appears to attend the efforts of certain vendors of anthracite coal. At first I was offered coal which had "arrived too late for the vendor's customers," and after this had gone on for some time, trucks began to break down a few miles away from our station with great regularity. I fear I shall never have the courage to give an order to such an unfortunate firm, as, should the truck by a great stroke of fortune avoid a breakdown at that fatal spot, "a few miles away," it would probably, in accordance with precedent, arrive too late. I have not asked the price of any of this stranded coal, but I am not at all surprised to learn that the full market value is demanded. *C. R. Fielder.* [We have received several other letters to the same effect, and one of the original letters from a Colliery Company.—Ed.]

Apple French Crab.—I am sending you some Apples of the variety French Crab, which are still attached to the wood. The branch has been cut from the tree to-day, and there are many such branches. They have been subjected to from 10° to 18° of frost many times over, and this morning there was 12° of frost. Wind seems to have no effect on these fruits, as there have been many heavy gales since September last. Most of the fruits are quite sound, while some show frostbites. The crop of 1904 was not gathered until December, and the fruits were used in June, 1905, when they were still fresh and good. *Fredk. Bedford, Straffan House Gardens, Co. Kildare. Jan.* 22. [The fruits are exactly as described by our correspondent. Those which are perfectly sound, however, have commenced to become a little "mealy," or dry. —Ed.]

Canker and Frost-Resisting Apples.—Two questions of great importance to fruit growers were raised in the *Gardeners' Chronicle* of January 6. One is the canker-resisting constitution of certain varieties of Apples, alluded to by Mr. A. B. Wadds; and the other the frost-resisting capabilities of some kinds of the same fruit, mentioned by Mr. R. L. Castle. If readers would compare notes in your columns as to the varieties of the Apple most and least liable to canker and to damage by frost respectively, much valuable information might be obtained. In my own experience I have found King of the Pippins, Ribston Pippin, and Cellini Pippin more liable to canker than any other of over 30 varieties that I grow in my plantations and private orchard. Potts's Seedling also has been attacked somewhat

badly, though not as extensively as the varieties named above. My experience with certain of the varieties named by Mr. Wadds as comparatively free from canker coincides with his, while others in his list I do not grow. Irish Peach, Beauty of Bath, Lady Sudeley, Worcester Pearmain, and Lord Grosvenor have suffered but little from canker, and Cox's Orange Pippin less than many varieties. I have only a few trees of The Queen; but they are fairly healthy. Bismarck does not thrive on my light land; but I have not noticed much canker in the trees. My trees were planted six years ago, and they had not suffered much from canker until after the wet season of 1903. The soil in my oldest plantation is of a lightish loam over the Tunbridge Wells sand, which dries very quickly after rain. I thought when I planted the trees that canker would not be troublesome on such land; but the texture of the soil is extremely fine, and it holds water like a sponge while the weather remains rainy. In relation to the frost-resisting question, I have not made any observations. *An East Sussex Grower.*

THE WILLOW FOR CRICKET BATS.—The best Willow for the purpose is Salix Russelliana, and it also commands the best price, from 5s. to 12s. 6d. per cubic foot. I saw a lot sold last season at 10s. 6d. per cubic foot. A good set costs from 1s. to 1s. 6d., and, if planted in suitable position and does well, is worth from £5 to £8 in 15 years. I planted 500 sets here last season that were cut from the tops of some trees; the owner of same bought the piece of ground 16 years ago, paid £50 for it, planted it with the above variety of Willow, and sold them last season as they stood for £2,000. *Jno. Barker, Pishiobury, Sawbridgeworth, Herts.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 23.—The weather on Tuesday last was so cold, and in London, at least, so foggy, that it was surprising that exhibitors had the temerity to make such a good display of Orchids and other plants at the Royal Horticultural Society's meeting in the Hall in Vincent Square, Westminster.

As will be seen from the report printed below, the show of Orchids was unusually good, though the awards made to novelties—three Awards of Merit—were fewer and less important than usual. It has also to be remarked that no exhibit was made in the special competition for Oncidiums which had been arranged for that day.

The FLORAL COMMITTEE recommended one First Class Certificate to Buddleia asiatica, an old species that is not often seen in gardens. No other award was recommended to an individual plant.

The FRUIT AND VEGETABLE COMMITTEE made no awards other than a Medal and two cultural commendations.

At the afternoon meeting Mr. Martin H. F. Sutton read a paper on "The Formation and Care of Lawns and Golf Greens." A number of new Fellows were elected.

Floral Committee.

Present: W. Marshall, Esq., chairman, and C. T. Druery, H. B. May, Geo. Nicholson, Chas. Blick, Chas. Jeffries, Chas. Dixon, H. J. Jones, Chas. E. Pearson, Chas. E. Shea, W. P. Thomson, J. F. McLeod, J. Green, H. J. Cutbush, G. Reuthe, E. T. Cook, R. W. Wallace, E. H. Jenkins, G. W. Barr, George Paul, and R. Hooper Pearson.

Freesia Chapmanni is a name given to varieties of Freesia raised from a cross between F. refracta alba and F. aurea, by F. HERBERT CHAPMAN, Esq., Guldeford Lodge, Rye. The inflorescences as shown were much branched, and the flowers, though smaller in size than those of F. refracta alba, were prettily stained on the lower segments with bright orange colour.

Mr. J. HUDSON, The Gardens, Gunnersbury House Gardens, Acton, exhibited a plant of Haemanthus magnificus in flower.

Messrs. H. CANNELL & SONS, Swanley, Kent, staged a collection of Chinese Primulas. The exhibit, which comprised a very large number of plants, was arranged in batches of various colours, including purple, pink, salmon, red, white, &c. The plants were of a healthy, sturdy type, the trusses of flowers being strong, and the "pips" exceedingly fine; especially commendable were the white and the red varieties. A few plants of a white "stellata" strain named Mrs. R. W. Cannell found a place in the group. Messrs. Cannell also showed sprays of the comparatively new Moschosma riparium. (Silver Flora Medal.)

Messrs. W. BULL & SONS, King's Road, Chelsea, showed a small but choice collection of stove and greenhouse foliage plants. Peliosanthes teta was shown in fruit. Nidularia innocenti striatum and Pandanophyllum humile are two excellent subjects for a warm plant house.

Messrs. JOHN WATERER & SON, Bagshot, Surrey, brought a number of ornamental Conifers, including some of variegated and fastigiated form. The rare Pinus flexilis was noticed. (Silver Banksian Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, set up a representative collection of Davallias in plants of the high quality usually shown by this well-known Fern specialist. (Silver Gilt Flora Medal.)

Mr. A. F. DUTTON, Iver, Bucks, exhibited some excellent Carnations of the popular American or winter-flowering type. We noticed a white "sport" of that sterling variety Enchantress. (Silver Banksian Medal.)

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed a small collection of Carnations of an exhibition standard of quality.

Messrs. HUGH LOW & Co., Enfield, staged a mixed group of flowers and plants. They showed well-grown Carnations in fancy vases, a good batch of Cyclamen, small plants of Lomaria gibba and other ferns, and some neat examples of the beautiful variegated Saxifraga sarmentosa.

Mr. W. SEWARD, Nurseryman, Hanwell, W., put up a batch of Cyclamen that excited much admiration, for they formed one of the finest displays in the hall. The plants were literally crowded with flowers, and seen from either end of the group they presented a sheet of bloom. The individual plants were sturdy, and of the best type of this seasonable florist's flower. The strain is of exceptional merit. (Silver Gilt Flora Medal.)

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, had a showy group of Coleus thyrsoideus, set-off by a back-ground of tall Palms, and relieved with clumps of Gesnera (Nægelia) exoniensis, Primula × kewensis, Jacobinia coccinea, and Eupatorium vernale, the colours of these various flowers enhancing the beauty of the group. Plants of Buddleia asiatica (see awards) and a specimen of Debregeasia velutina, with numerous small orange-coloured fruits, also found a place in the display. (Silver Banksian Medal.)

Messrs. WM. CUTBUSH & SON, Highgate, London, N., showed Alpine and rock-garden plants in a natural manner on a temporised rockery, which gave the exhibit a realistic appearance, this being further intensified by the inclusion of a number of dwarf Conifers, Rhododendron dahuricum, Hamamelis Zuccariniana, Daphne indica, &c., on the higher portions of the exhibit. Irises were shown in plenty, I. histrioides, I. alata, I. stylosa, I. sophemensis, &c., also Christmas Roses, hardy Cyclamen, Primulas, &c. (Silver Banksian Medal.)

Mr. G. REUTHE, Fox Hill Hardy Plant Nursery, Keston, Kent, showed a small number of choice Alpine plants, including many species of Irises, Saxifrages, including the rare S. Frederici Coburgii; Crocuses, Galanthus Ikariæ, &c. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, showed Christmas Roses, Lachenalias, Irises, Crocuses, among which were splendid pans of C. suzianus, C. imperati and C. Sieberi, and many other early flowering hardy plants.

Messrs. JOHN PEED & SONS, West Norwood, London, had many pans of Alpine plants, hardy succulents, a batch of Lachenalia pendula, and some well-grown plants of Primula obconica. (Bronze Banksian Medal.)

Messrs. THOS. WARE & Co., Feltham, Middlesex, also exhibited plants of Primula obconica, in addition to hardy plants and Carnations. Many species and varieties of Helleborus were noticed in this display. (Bronze Banksian Medal.)

The Misses HOPKINS, MERE, Knutsford, showed coloured Primroses, Christmas Roses, crested forms of hardy Ferns, &c.

Messrs. R. WALLACE & Co., Colchester, displayed a large flowering variety of Saxifraga Burseriana labelled S.B. major.

Mr. J. E. LOWE, Shrewley, Hatton, Warwick, displayed some excellent flowers of Chrysanthemum Winter Cheer, a market or decorative variety having bright rosy-pink coloured flowers. (Silver Banksian Medal.)

AWARD.

Buddleia asiatica. This is a tender species from India, introduced into this country in 1874 (*Bot. Mag.* t. 6323). The plants are said to grow about 3 feet high. They have lanceolate leaves finely serrated, and the flowers, though small in size, are pure white and fragrant, and the racemes are of considerable length. Shown by Messrs. JAS. VEITCH AND SONS. (First Class Certificate.)

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair, and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, J. W. Potter, W. Boxall, W. H. Young, H. A. Tracy, A. A. McBean, H. T. Pitt, G. F. Moore, Francis Wellesley, Elijah Ashworth, Jeremiah Colman, J. Charlesworth, W. A. Bilney, H. Ballantine, F. W. Ashton, and Harry J. Veitch.

The worse the weather the better the show of Orchids! With frost and fog outside the hall, and a very wintry temperature inside, the stages were nevertheless richly bedecked with Orchids in bloom.

BARON SIR H. SCHROEDER, The Dell, Egham (gr. Mr. Ballantine), contributed a very fine group for which a Silver Gilt Flora Medal was accorded. In the centre was a very fine display of Lælia anceps, chiefly white varieties, and among which were fine L. anceps Dawsoni, Sanderiana, Stella, Hilliana, Williamsiana, &c. The Cattleyas included C. Trianæ Schroderiana, a handsome white form with rosy-crimson front to the lip; C. T. Russelliana, from the old-time collection of Provost Russell, of Falkirk, and which, like the fine pan of scarlet Sophronitis from the late Mr. Day's collection bearing 40 flowers, tells much for the good cultivation of Baron Schroder's Orchids. Good masses of C. Percivaliana, Lælia acuminata, Odontoglossum Uro-Skinneri album, O. × elegans, Eastwood Park variety; O. crispum, including the neatly spotted variety Lord Selborne; Cypripedium × Lathamianum, with 15 flowers; C. × Leeanum superbum, and other varieties; C. × Maudiæ, C. Mastersianum, Bull's variety, a grand form; Calanthe × Harrisii, Selenipedium × Clonius, Cypripedium insigne varieties, &c.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver-Gilt Flora Medal for a fine group in which were about 80 plants of the rich orange-coloured Lælio-Cattleya × Charlesworthii, one of the best of winter Orchids. The labellums were marked with purplish crimson in varying degree. With them were several plants of their handsome Cattleya × Octave Doin; a fine white Odontoglossum crispum, and the nicely spotted O. c. Clarissa, O. × Harryano triumphans Our Queen, a very large yellow flower heavily blotched with chocolate-purple; Lælio-Cattleya × Andromeda, the new L.-C. × Prospero, and other hybrids.

Messrs. J. CYPHER & SONS, Cheltenham, secured a Silver-Gilt Flora Medal for a very beautiful and tastefully arranged group, rich in the best white forms of Lælia anceps, and including L. a. vestalis, Stella, Dawsoni, Percivaliana, Hilliana, Sanderiana, &c. Among the Cypripediums were several rare hybrids, viz., C. × Cleopatra, a dark-coloured flower with peculiarly long, bright, rose-tinted dorsal sepal; C. × exul × villosum giganteum, a very fine flower of thick texture, C. × Sunray, C. × aureum virginale, C. × triumphans, a varied selection of good C. insigne, and C. × Leeanum varieties, and others. At one end was a batch of good Cattleya Trianæ, &c.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for an extensive and interesting group containing great variety. In the centre was a splendid plant of Angræcum sesquipedale with four of its large wax-like white flowers; a new form of Cymbidium × Ballianum with purple-tinted flowers, C. Tracyanum, Odontoglossum odoratum, a curious form of O. crispum with yellow and rose-tinted flowers; a very handsome O. × Adrianæ with white ground-colour profusely spotted with purple; Galeandra lacustris, some good Calanthes, a remarkable Vanda cœrulea, with white flowers having the labellums purple, the elegant V. Watsoni, and a very fine selection of Cypripediums, including the distinct varieties of C. insigne, named Jewel, ampliatum, and Erin, all of which bore fine markings on the dorsal sepal, &c.

Messrs. HUGH, LOW & Co., Enfield, received a Silver Banksian Medal for a group in which were

three plants of Vanda Amesiana, Cypripedium × aureum Surprise, C. × a. Oedippe, a very pretty C. × Hera Euryades, the delicately tinted C. × Venus, C. × Leeanum Clinkaberryanum, C. × calloso-Charlesworthii, C. × Thompsoni, and the beautiful C. × Mrs. William Mostyn, Chardwar variety.

R. BRIGGS-BURY, Esq., Bank House, Accrington (gr. Mr. Wilkinson), was awarded a Silver Banksian Medal for a select group, including three plants of Cypripedium × Beekmanni, two C. × Maudiæ, C. × Thompsoni, C. × Parkerianum, a fine Odontoglossum × ardentissimum, and the finely blotched O. crispum Mrs. F. Peeters, all splendidly grown and flowered.

M. CHAS. VUYLSTEKE, Loochristi, Ghent, secured a Silver Banksian Medal for a group of very remarkable hybrid Odontoglossums, including a very fine form of O. × Wiganianum, two splendid forms of O. × ardentissimum, O. × Rolfeæ, O. × altum, and some pretty unnamed seedlings, one of them being allied to the finely coloured O. × Vuylstekeæ.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent Brasso-Lælia × Mrs. Gratrix, Westfield variety, a large reddish orange flower, broad in all its parts; Cypripedium × Dicksonianum (villosum × Hera Euryades), with rose-purple dorsal sepal with pure white tip; C. × aureum, Westfield variety, with white dorsal sepal with green base; C. × Cecil Dickson (Niobe × Leeanum), and Lælio-Cattleya × Miss Mary Froude, a delicately rose-tinted flower with reddish purple front to the labellum.

Messrs. STANLEY & Co., Southgate, staged a small group in which were Cypripedium × Leeanum grandisepalum, a remarkable flower with enlarged lower sepals, one side being white, and other Cypripediums; a clear yellow, fiuely-spotted Odontoglossum × loochristiense, &c.

Messrs. HEATH & SONS, Cheltenham, showed a collection of hybrid Cypripediums.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent Cypripedium × aureum Hyeanum.

R. I. MEASURES, Esq., Camberwell, showed Zygopetalum × Max-Iorisi, with green flowers marked with brown and white lip; and Cypripedium × Buchanianum magnificum, a reversion towards C. Spicerianum.

Messrs. WILLIAM BULL & SONS, Chelsea, showed Sophro-Cattleya × Doris, and Dendrobium × Wiganiæ xanthocheilum.

Messrs. JAS. VEITCH & SONS, Chelsea, sent Brasso-Cattleya × Orpheus rosea.

ELIJAH ASHWORTH, Esq., Harefield Hall (gr. Mr. Holbrook), sent the fine Cattleya Trianæi Harefield Goliath.

AWARDS OF MERIT.

Cattleya × *Octave Doin* (Mendeli × Dowiana aurea) from Messrs. CHARLESWORTH AND CO. A charming flower, superior in shape to the best C. Mendeli; sepals and petals white, delicately tinted with rose on the margins of the petals; lip ruby crimson with gold lines at the base.

Phaius maculatus from Messrs. SANDER AND SONS, St. Albans. Inflorescence erect, flowers large, clear yellow with red markings on the lip. A fine form of the species was shown.

Cypripedium × *Bridgei* (Godseffianum × Argus Moensii) from G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page). A very distinct hybrid showing much of the handsome C. hirsutissimum derived through Godseffianum. Dorsal sepal, downy and densely spotted with small blackish spots nearly covering the surface except the white margin. Petals broad rose coloured with a green base bearing black spots.

Fruit and Vegetable Committee.

Present: Mr A. H. Pearson, in the chair, and Messrs. J. Cheal, W. Bates, S. Mortimer, A. Dean, H. Parr, H. J. Wright, G. Kelf, F. Q. Lane, Owen Thomas, J. Willard, C. Foster, H. Somers Rivers, and W. Poupart.

Only two displays were shown in the fruit and vegetable section, one being a collection of Apples and Pears staged by the Dowager Lady HILLINGDON, Wildernesse Park, Sevenoaks, Kent (gr. J. Shelton), the other a number of forced crowns of Chicory and Dandelion grown by Mr. C. FOSTER at University College Gardens, Reading.

The Apples and Pears embraced 42 varieties. A few good dishes of Apples were noticed, notably those of Warner's King, Blenheim Pippin, Striped Beaufin, and Cox's Orange Pippin. (Silver Knightian Medal.)

The two salads shown by Mr. FOSTER looked tempting. The Dandelion was Sutton's Improved Thick-leaved or cabbaging variety. The seed was sown on July 16, 1905, in shallow drills 1 foot apart the plants being thinned to the same distance in the rows. The crowns were lifted in November and forced under a bench in the absence of light. (Cultural Commendation.)

THE LECTURE.

The afternoon lecture was delivered by Mr. Martin H. F. Sutton. His subject, treated with the ease and lucidity gained by experience, was on "The Formation and Care of Lawns and Golf Greens." The lecture was illustrated by an interesting series of specimens, showing seedlings of the various grasses used either singly or in combination for particular purposes. The preparation of the soil, the drainage, the relative advantages and disadvantages of sowing or of turfing, the species to be employed for particular soils and for different purposes, the method and time of sowing were all discussed, and the lecturer then passed on to the special requirements of croquet lawns, tennis lawns, bowling greens, and putting greens for golf. It was pointed out that while cricket grounds were disused for several months in the year the golf greens are in constant use the whole year. The best method of meeting this difficulty was the formation of duplicate "greens," so that one may be rested and allowed to recuperate whilst the other is in use. The question as to the benefit or otherwise derivable from worms was also touched on, Mr. Sutton's conclusion being summed up against the worms, though he was careful to add that if removed some other means must be taken to increase the amount of nutriment at the disposal of the grasses. The chair was filled by Dr. M. T. Masters, F.R.S., and a few remarks were made by Mr. A. H. Pearson and Mr. Alex. Dean.

Obituary.

JAMES MOORE.—There passed away on January 8, after a brief illness, Mr. Jas. Moore, aged 69 years, a good gardener, who for nearly 16 years has been steward and gardener to Lord Langford, at Summerhill House, Co. Meath. Previous to his going to Ireland he had been head gardener at Bray Court, Maidenhead, and the gardens there were laid out under his supervision. When a young man he spent several years in the Royal Horticultural Society's Gardens at Chiswick. Deceased was universally respected in the district. *D. C.*

REMARKS.—A good supply of Grapes is maintained, bunches of exceptional quality making from 1s. 9d. to 2s. 6d. per lb., but prices generally are moderate. Foreign Tomatos are plentiful, in fact the supply exceeds the demand. Pine-apples are making enhanced prices owing to a shorter supply than is usual at this season. Foreign Apples are dearer. Best quality Oranges are scarce, and prices for good fruits have advanced; the major portion of these fruits now arriving are of inferior quality. A large consignment of Egyptian Dates arrived in a bad condition. Two thousand barrels of Nova Scotian Apples were offered at auction on Monday, 22nd inst., and sold readily. Trade generally has not improved. *E. H. Rides, Covent Garden, Wednesday, January 24, 1906.*

POTATOS.

Blacklands, 55s. to 60s.; Bedfords, 65s. to 75s.; Lincolns, 65s. to 75s.; Keuts, 70s. to 80s.; Dunbars, 80s. to 95s. per ton.—*John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

There is little that is new to record this week. Trade continues dull. Not quite so many good pot plants are seen. Plants of Azalea indica in various colours are plentiful, but some are not well flowered. Azalea mollis does not sell readily. Spiræas, though good, do not find much demand. Lilium longiflorum are fairly good. Also lancifolium album and rubrum. Cinerarias are not quite up to the usual standard of quality. The cold weather affects the sale of Poinsettias. Cyclamen are fairly plentiful, but many are not of best quality. Marguerites are good and plentiful. Supplies of Chrysanthemums are not quite finished, but most of the plants now seen are of very poor quality. Callas, although good, are rather tall. Hyacinths are abundant; the majority are grown three in a pot but some are in boxes, and some in quite small pots singly. Tulips are over plentiful, these are chiefly grown in boxes. Some well-flowered plants of Rhododendron Cunningham's White, are seen. Daffodils Golden Spur and Telemonius plenus are good. Begonia Gloire de Lorraine continues plentiful, but some growers do not send it quite up to the best market standard. Among Ferns, Palms and other foliage plants there is little change. Supplies are plentiful and the demand limited.

CUT FLOWERS.

Daffodils are now a prominent feature, the varieties being Golden Spur, Sir Watkin, Princeps, and Telemonius plenus. Owing to large supplies many are cleared at very low figures. Narcissus poeticus is already plentiful, and Soleil d'Or, Paper White, with others of the Polyanthus type, are over abundant. Roses are not numerous and best blooms are making good prices. Supplies of Carnations, except those of specially good bloom, continue in excess of demands. Chrysanthemums are to be had still, but as many spring flowers are now in season the demand for them has fallen off; very late varieties of this flower do not pay so well as those at a more seasonable period. Lily-of-the-Valley has been over abundant for some time. Azalea Fielderi, Camellias, white Pelagonium, and other short stemmed flowers have little demand. Callas, although abundant, appear to be selling rather better. Lilium longiflorum is not so plentiful, but they have not become much dearer. Tulips are seen in immense quantities, and there must be much waste with these flowers. French flowers are sent in large quantities and are cleared very cheaply. All kinds of foliage is well supplied. *A. H., Covent Garden Market, January 24, 1906.*

THE WEATHER.

THE WEATHER IN WEST HERTS.

A change to cold weather. The recent term of warm weather lasted 18 days, during which there did not occur a single cold day or night. On the 20th a change to cold weather suddenly took place, and since then, although the day temperatures have been only slightly below the average for the time of year, the exposed thermometer on one night registered 16° of frost—the greatest cold experienced here this winter. The ground has become colder, and is now at about a seasonable temperature at two feet deep, and about 1° colder than the average at one foot deep. During the first three weeks of the present month rain fell on all but four days, and to the total depth of 3⅜ inches, an inch in excess of the average for the whole month. We have to go back to the end of May and beginning of June to find three weeks equally wet, and even then the rainfall was not nearly as continuous. Since the 21st the weather has been perfectly dry, if a few flakes of snow on one day be excepted. Seventeen gallons, or nearly the whole of the rainfall of the recent wet period, has come through each of the percolation gauges. The sun shone on an average during the week for 2½ hours a day, or for an hour a day longer than is usual at this season. The wind has lately varied greatly in strength. In the windiest hour of one day the mean velocity amounted to 23 miles—direction W.N.W., whereas throughout the calmest day the average rate of movement was less than half a mile an hour. The mean amount of moisture in the air at 3 p.m. was 6 per cent. less than is seasonable for that hour. *E. M., Berkhamsted, January 24, 1906.*

ANSWERS TO CORRESPONDENTS.

BOOKS: *F. B. The American Carnation: How to Grow it,* by Charles Willis Ward (New York: A. T. De La Mare Printing and Publishing Co.). —*C. A. J. The Book of the Rose,* by Rev. A. Foster-Melliar, price 6s. 4d., post free; or *Pictorial Practical Rose Growing,* by Walter P. Wright, price 1s. 2d., post free. Both these books can be obtained from our publishing department.

BRITISH GARDENERS' ASSOCIATION: *F. W., and others.* We are informed that the delay in issuing the pamphlets has been caused by the printers having been swamped with work in connection with the General Election, but they will be ready in the course of a few days. You should address your enquiries to the Secretary, Mr. John Weathers, Talbot Villa, Talbot Road, Isleworth.

CORRECTION. The Boiler mentioned under "Enquiry" in our last issue should have been spelt Menlo not Mento.

GARDENER'S NOTICE: *T. G., Worcester.* If you fill the position of head gardener a month's notice is the least that should be offered you.

GRUBS: *S. C.* The grubs are those of one of the Weevils; trap them with pieces of Carrot or Potato.

HABROTHAMNUS ELEGANS: *W. H. N.* The newer name you refer to is Cestrum elegans. According to your note the situation has been too hot and too dry for a specimen newly planted, and it would have been better to have shaded the glass roof for a time. The sun is sometimes too powerful, on a south aspect, for this plant, and it succeeds best on an east or west position. You will do well to cut the plant hard back, and, by suitable feeding, encourage the development of strong growths next season. The plant should be kept drier at the roots in the autumn and winter.

HYGROMETER: *T. K. S.* The table you require is published in most of the meteorological manuals, but for practical purposes the observation of the wet and dry bulb thermometers is sufficient.

MOSS ON LAWNS: *J. McC.* Remove as much of the moss as is possible by means of an iron rake, after which apply a good dressing of decayed manure or rich compost, spreading the whole evenly about half an inch in thickness. Towards the end of March or in April rake again with the iron rake, removing any rough and unsightly portions of the manure. When there is prospect of rain, sow a suitable mixture of grass seed, and rake and roll in the seed. Allow the grass to grow until the middle or end of May, then mow with a scythe, and afterwards keep under with the mowing machine. If the lawn is wet from stagnant water this must be removed by draining the land.

NAMES OF FRUITS: *J. J.* 1, De Neige; 2, Flower of Kent; 3, Blenheim Pippin; 4, Striped Beefing.—*G. G.* Lamb Abbey Pearmain.

NAMES OF PLANTS: *R. R. Reading.* 1, Doodia lunulata; 2, Adiantum hispidulum; 3, Adiantum Waltoni; 4, Aspidium mucronatum var. laxum; 5, Pteris argyrosa; 6, P. tremula.—*J. W. B.* Bletia hyacinthina, Epidendrum cochleatum —*Head Gardener.* 1, Echeveria metallica; 2, Strobilanthes Dyerianus; 3, Cypripedium venustum; 4 Rhœo (Tradescantia) discolor; 5, Dendrobium nobile; 6, Nephrolepis tuberosa; 7, Eulalia japonica variegata; 8, Epiphyllum Russellianum.—*Caldecote.* Cypripedium callosum.—*J. P.* 1, Daphne indica rubra; 2, Eupatorium petiolare.

NYMPHÆAS IN FOUNTAIN: *R. Sage.* We have submitted your question to Mr. James Hudson, whose success with Water Lilies in Mr. Rothschild's garden at Gunnersbury House, Acton, is so well-known. Mr. Hudson has kindly replied as follows:—"You have not stated what depth of water there is in the tank. Assuming it to be from 12 to 18 inches deep, because less than 12 inches in depth is not sufficient for any Nymphæa excepting such as N. pygmæa and its forms, the best mode of procedure would be as follows: Obtain some clean ordinary building bricks and place these tier upon tier for say 3 or 4 tiers, 5 bricks forming one tier with the corners just touching, and crossing the second over the first tier. Into the space thus formed place some clean drainage material as in the case of a pot plant. Then fill up to the top of the bricks with soil, pressing it down gently. This soil should consist of good loam broken into pieces, as for potting plants in the usual manner, and about as much in bulk of well decayed leaf-soil, with road scrapings or sand in addition up to about one fourth of the bulk of loam and leafsoil. Plant the Lilies into this mixture, just leaving the crown clear of the soil and sufficiently firm to prevent the plants from becoming loosened afterwards. As a finish, and in order to keep the Lilies firm, cover the surface either with spar or gravel stones such as would pass through a sieve with an inch mesh. It is a common mistake to plant these Water Lilies into pots, drainpipes and the like. In so doing the roots are too much confined, and both soil and water must of necessity become stagnant and sour. Under the system advised above, it is always possible to remove the bricks and extend the area of root action without causing any check to the plants, besides which the roots can ramify through the soil in a more natural manner. Any observant grower will note that the roots are predisposed to extension in a horizontal manner rather than downwards. We never use either peat or charcoal here in the cultivation of Water Lilies. It is not stated whether the conservatory is shaded or not. In order to succeed with Water Lilies in such a place no shade should be given, otherwise there would be a tendency to leaf development only.

PINES FOR PLANTING: *T. W. C.* We do not think there is any material difference in point of fragrance for the purpose you mention. Pinus austriaca, Laricio, silvestris, Pinaster, contorta inops, and, in sheltered situations, P. strobus, P. monticola, and the Douglas Fir Pseudotsuga Douglasi. Thuya plicata, the Lobbi of the nurseries, grows rapidly and is very fragrant. It might be mixed with the others. The retention of the leaves in the Oak, Beech, Hornbeam &c., is a matter of variety rather than of soil.

QUICK HEDGE: *J. W.* The quick-thorn Cratægus oxyacantha is very hardy and may possibly survive the application of tar; at any rate we should advise waiting another season to see the result before grubbing the plants. Probably many of the younger shoots will suffer from suffocation. An application of Stockholm tar would have been preferable, as this is a vegetable product, and would not be so likely to injure the plants.

STOVE CLIMBER: *W. T. G. L.* The sudden failure is due to some check; no insect or fungus disease is present to account for it. Strong applications of chemical manure to the roots would be sufficient to cause the injury.

TWELVE GENERA OF PLANTS FOR SUPPLYING CUT FLOWERS OVER A PROLONGED SEASON: *Doubtful.* In attempting to guide you in the selection of choice hardy plants for the supply of flowers for cutting we take the opportunity to emphasise the desirability of growing few varieties, and those in distinct colours. For table decoration, or for vases, it is preferable to have two or three distinct colours in large quantities than to be compelled to carry out the arrangements in numerous small quantities of different shades or colours. For instance, taking Roses, it is preferable, for table work, to have 50 white and 50 pink coloured blooms than 100 in 20 varieties of all shades. This is equally applicable to Tulips, Stocks, Sweet Peas, Carnations, etc. In making this selection it would have been much easier to have named 24 genera than 12, but for your purposes we think the flowering plants in the following list indispensable. Narcissus (the finest of the Magni-coronati, Medio-coronati and Parvi-coronati groups), May flowering Tulips, Anemones (St. Bridgid), Lily-of-the-Valley, herbaceous Pæonies, Ten-week and East Lothian Stocks, Tea-scented and hybrid Tea Roses, Sweet Peas, Carnations, Lavatera trimestris splendens (pink and white), the newer varieties of Montbretia and a selection of the best varieties of Michaelmas Daisy. We are unable to recommend a plant that is known to be objectionable to cats.

VINES: *W. C.* The single rod system is best. If the vines are planted 4 feet apart, supernumeraries may with advantage be planted between them. If the supernumeraries are good canes grown in pots for fruiting this season you could crop them in that position.

VIEWS IN THE GARDENS AT LOCKINGE PARK, BERKS, THE RESIDENCE OF LADY WANTAGE

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C

THE
Gardeners' Chronicle
No. 997.—SATURDAY, February 3, 1906.

CONTENTS.

ILLUSTRATIONS.

LOCKINGE PARK.

(See Supplementary Illustration and Figs. 31, 32, 33, 34.)

THE residence of Lady Wantage, near the small township of Wantage, in Berkshire, possesses most of the characteristics that go to make an ideal country seat. It is somewhat remote, being about five miles from the nearest railway station, which is known as Wantage Road, on the Great Western Railway line, at about sixty miles from London. The Wantage folk have a light railway of their own, which connects their town with this station, but the visitor to Lockinge, if he drives from Wantage Road, will not follow the light railway route through Wantage, but, on the contrary, turn to the left hand and enter a road which was made by the late Lord Wantage, and which traverses private ground all the way. One cannot help being impressed with the vast extent of the Lockinge estate, for on driving from the station, the route passes for 2½ miles through the park. In round numbers the estate consists of 30,000 acres of land, and of this area 14,000 acres are farmed by her ladyship. When it is remembered that this would provide 140 farms of 100 acres each, an idea may be formed of the immense area of land under the management of the home farm.

But our purpose is not to write in detail of the agricultural features of this estate, but rather of the gardens attached to the residence. And it may at once be said that of these the outstanding characteristic consists in the numerous flower-gardens that in summer form so brilliant a setting for the mansion itself. All the illustrations of the place published in this issue have been reproduced from photographs taken late last summer, and on reference to them it will be seen that there were flowers almost everywhere, and the parterres are so near to the dwelling, and they so surround it, that the building appears to be in the centre of a flower garden.

FIG. 31.—LOCKINGE PARK: THE CORRIDOR LEADING FROM THE DWELLING-HOUSE TO THE CONSERVATORY.

(From a photograph by W. J. Vasey, Abingdon.)

The views in the supplementary illustration are of the flower garden on the terrace facing the south front of the house. In the top picture appears the broad path leading towards the church, and the dwelling house, though not apparent, is situated on the right-hand side of the same path. This part of the flower garden has been remodelled by the present gardener, Mr. W. Fyfe, who has had charge of the gardens for 13 years past. The beds are arranged on two levels, those at the forefront of the picture being considerably higher than the pathway. The dark patches on the slope are of Box, and the space between the narrow edging and the Box slope is of red gravel, whilst the spaces around the individual flower beds at the top are covered with white gravel. The slope at one time was of grass, but considerable trouble was entailed in keeping it cut close, and altogether it was unsatisfactory. The present appearance is admittedly formal, but being associated with the mansion, conservatory and other buildings, and bounded with broad, straight paths, it is at least in keeping with its surroundings, and the effect is good. The first flower bed, which in the picture appears rather dull, was last season planted with Calceolaria amplexicaulis, and some standards, five feet high, were interspersed with the dwarfer plants. This old-fashioned plant grew and flowered abundantly—as well as we have ever seen it. In the next large bed were hybrid Verbenas,

which appeared just one mass of flower. The beds on the lower level and opposite the point where the ornamental terrace wall assumes a half-circular shape, can be seen better in the photograph, which is reproduced in the lower picture. Some of the beds contained tuberous-rooted Begonias, and Gladiolus interspersed with them. Large specimens of Agapanthus umbellatus were plunged in small circular beds, and near by Nicotiana Sanderæ grew and flowered well, and was much appreciated. Before turning from the supplement, if the reader looks to the end of the path shown in the top picture, he will see a large specimen plant growing in a tub just behind the white-looking seat. Attention is drawn to this, because it is one of several such specimens of the lemon-scented Verbena (Aloysia citriodora). They are 12 feet in height, and nearly as much in diameter, being the finest plants the writer has ever seen of this fragrant species. Mr. Fyfe said that he raised them from cuttings about 13 years ago. They are so large that quantities of long green shoots may be cut from them without their being missed, and when in bloom their long panicles of pale-lilac coloured flowers have as elegant an effect as those of the Tamarix.

Reference may now be made to Figs. 31 and 32, because the structures shown in them are joined to the mansion, and face to some extent that portion of the flower garden shown in the supplementary illustration.

The gardens at Lockinge are not treated merely as an adjunct to the house, to be kept tidy, because being so near they would be disagreeable if allowed to get into any other condition. On the contrary, they are loved for their own sake; they enter largely into the every-day life of their owner, and every moment that can be spared is spent amongst the plants and flowers. The result of this affection for the garden is seen in the fact that the garden and house are brought into as close association as possible; very much closer association than is common. This is done by bringing, as it were, the garden into the house. Fig. 31 represents the interior of a corridor, and the reader may look towards the opening which leads into the conservatory. But if he turned round and walked in the other direction, he would enter what is known as the "garden room," which intervenes between and joins up the private rooms in the mansion and the afore-mentioned corridor. This garden room is something one is not accustomed to see in such residences. It is neither a conservatory nor a dwelling room, but partakes of the nature of both. The walls are adorned with very valuable paintings, some of which subjects are floral, but most of which are not, being portraits or landscapes, etc. Numerous plants and flowers are placed about the room, and so a person coming from the private sitting or drawing rooms is gradually brought into touch with the garden as he moves towards the gorgeously floral corridor, which last summer contained a quantity of well-grown plants of the chimney Campanula (Campanula pyramidalis), Cannas, Celosias, Liliums, etc.

The conservatory, as seen from the corridor, is shown in Fig. 32. It was a handsome mosaic floor, a square tank in the centre containing a fountain, and is generally an ornamental structure. The ironwork that may be seen at the end is some interesting hammered metal, with mirrors at the back, which appear somewhat meaningless. Cobœa scandens, and many other trailing plants hang from the roof, and, in addition to plants with decorative foliage arranged on the floor, were such flowering species as Lilium speciosum, Cannas, Nerine Fothergilli, Streptocarpus, Campanulas, Crinums, Kalanchoe flammea, etc.

On the walls of the mansion and those of the garden room are some fine specimens of climbing plants, including Vitis Coignetiæ, Ceanothus azureus, Passifloras, and Ipomœa rubra cœrulea. This last-named species has

FIG. 32.—LOCKINGE PARK: VIEW OF THE INTERIOR OF CONSERVATORY.
(From a photograph by W. J. Vasey, Abingdon.)

grown 20 feet in height, and it flowers so freely the effect is brilliant. It may be mentioned here that Ipomœa rubra cœrulea is a favourite material at Lockinge for use in decorating the dinner table, and, accordingly, Mr. Fyfe obtains flowers at all seasons of the year from plants cultivated under different conditions for the purpose.

The photograph reproduced at Fig. 33 represents a broad border with the front broken up into projections of varied form. This border separates the little parish church from the mansion, some ten or fifteen paces north-east of the church. The border last season was planted in some measure as a ribbon border. The front line was composed of Lobelia, and behind it in succession were dwarf Antirrhinums, Ageratum, fibrous-rooted Begonias, and Veronica Hendersoni variegata. In the background were standard plants of the yellow-flowered Marguerite, the double-flowered white Datura (Brugmansia), Heliotropium, Ivy-leaved Pelargoniums, etc. Many of these taller plants were growing in tubs, and are kept from season to season. In the beds that constitute so formal a front to the border, standard Lantanas were associated with Coleus and other plants. Mr. Fyfe has found the varieties of Lantana now obtainable exceedingly useful plants for the flower garden, and owing partly to their habit of blooming continuously over a long period they are used in considerable numbers.

If a line were to be drawn at right angles with the further end of the ribbon border, it would stretch across the west front of the mansion, and here again there are flowers very close to the building. But in this instance they are of perennial herbaceous species, which are cultivated on a border of liberal width that is just on the far side of the terrace wall. Whilst writing of the west front, it may be interesting to explain why the parish church (built in 1564) is so close to the mansion, and has flower borders around it. The circumstances are these. Years ago, when Lord Wantage came first to Lockinge, the village extended to a point very near to the mansion on this, the west front, but during his late lordship's life he acquired considerable ground, and the cottages were removed. In the words of a local inhabitant, the village was "pushed back." But there were difficulties in regard to the church, and therefore whilst this sacred edifice remains in the old position, its environs are quite altered, and it is now, as already stated, surrounded by flowers and pleasure grounds. Nevertheless it is a public place of worship, as of yore, and the parishioners come to the building as freely now as they ever did. On the north side, there was last season a border planted with Antirrhinums facing to the house, and there are three old pyramid Yew trees which Lord Wantage brought with him when removing to Lockinge. A carriage drive leads up to this side, and there are deep rockeries on the banks. Proceeding from the house and walking to the south-west, there is a brook which has been made interesting in several places. A photograph, showing a fern-covered bridge across this water, was reproduced as a supplement to the *Gardeners' Chronicle*, October 28, 1905. Another view of a stream (which contains a large number of trout in the deeper portions) is afforded in Fig. 34, at a point where it winds through a portion of the pleasure grounds, with Cannas and many other species of suitable plants growing on its banks. A circular Rosary is a feature in the grounds, which extend for a considerable distance south of the house. There is plenty of timber in the large park, and some good specimen trees in the pleasure grounds. Indigenous species that appear to grow best are Elm, Buckthorn, Beech, and Oak.

Fig. 33.—Lockinge Park: showing a ribbon border near to the old parish church.
From a photograph by W. J. Vasey, Abingdon.)

Fruit Houses, etc.

It is not possible on this occasion to write in detail of the plant and fruit houses. On the whole, they are of the kind one would expect to be employed at such a place. Vines, Peaches, Figs, Pines, Melons, Cucumbers, and Tomatos are cultivated in considerable quantities, and Strawberries are forced in the house in winter and spring. Mr. Fyfe's system of Vine culture was explained again and again in these columns in 1904, when he was engaged in writing the weekly calendar on fruits under glass. He is a great believer in the sound practice of encouraging the roots to multiply at the surface of the border, and whole

turves are laid down in places to entice them to do this. A very uneven surface is thus left to the borders, but later a little top dressing containing bone meal and other manures is applied, and the results quite justify the methods adopted. When these notes were taken, in September, there were better Muscat of Alexandria Grapes hanging in the Lockinge Vineries than were afterwards exhibited at the Royal Horticultural Society's show in Vincent Square. Excellent fruit of Lady Downe's Seedling and Black Alicante were hanging at the same time, in addition to other varieties. In one of the Peach houses, the system of applying turf each year to the surface of the border has had a surprising effect on one of the trees, for, although it is of some age, and has a stem several inches in diameter, it has been induced to send out a root at a point just above the ground level, and where the wood and bark might have been expected to be too hard. It should be understood that by Mr. Fyfe's methods, the border is raised just a trifle as time goes on, and in some cases the trees adapt themselves to the conditions and make fresh tiers of roots. If Vines and Peaches could do this very easily and continuously, gardeners would have little reason to care much for the deeper roots, which in time would probably perish, just as those of the Poplar trees in the Belgian sand dunes. But they are incapable of doing this to an appreciable degree, and therefore if the covering up of the roots proceeds too hastily, the trees are liable to be suffocated. Thus, some who have imitated Mr. Fyfe in this matter, but have been less careful than he, have suffered from doing so. Melons are cultivated with all the success that could be desired, and in large numbers. The same holds good in regard to Tomatos, and Mr Fyfe having convinced himself that Tomatos care little about the rooting medium supplied, provided it is perfectly well drained and that by some means sufficient nutriment is obtainable, has planted them in mere ashes and clinkers in one of the houses, with just one inch deep of soil over the roots, and they yielded heavy crops of fruit.

Just one word may be said about Rehmannia angulata, one of Messrs. Veitch and Sons' new plants, which is cultivated for furnishing the corridor, conservatory, etc. Mr. Fyfe cultivates specimens 11 feet in height, and one foot in diameter, and they flower profusely in spring in 7-inch pots.

Fortune's Yellow Rose, as most of our readers are probably aware, is one of the features of the plant houses at Lockinge. It grows and flowers abundantly each year.

The kitchen garden consists of 4 acres of land, and is situated on rising ground in the park. The soil there is neither plentiful nor of the best description, and the fruit trees cultivated against the walls have to be lifted every two years, or the leaves become thin and pale in colour, as though possessing no chlorophyll. For this reason, in most cases where re-planting has to be done, cordon trees are selected for the purpose. Good kitchen garden crops are obtained, but they are more the result of the gardener's skill than of suitable conditions in the garden itself. A crop of Onions raised at Lockinge was illustrated in these pages, April 1, 1905. *P. H. R.*

NOTICES OF BOOKS.

"THE FERN PARADISE." Francis George Heath. The Country Press. 7th Edition.

MR. FRANCIS GEORGE HEATH has been so long before the public as the apostle of our native Ferns that it is disappointing to find by this new and enlarged edition that during the 27 years which have elapsed since the first one and the subsequent publication of *The Fern World*, &c., which by their comprehensive title would imply a complete survey of his subject, he has apparently learnt absolutely nothing new to extend the originally limited scope of his remarks. Certainly the title of this volume is justified so far as it applies to the scenic beauties of Devonshire, the author dilating enthusiastically upon these, the references to the common Ferns which contribute thereto being worked in to the utmost. This book, however, like the others on the same subject by Mr. Heath, simply traverses the same ground over and over again, ostensibly telling us all that there is to be told about our native Ferns, while doing nothing more than describe and figure the normal types and their habitats as many cheaper and handier books have previously done. The rest is mere eulogy. As regards the British Ferns proper, it is almost inconceivable, considering the literature extant, that not even the remotest allusion is made to the varietal side of the subject, though many of the more beautiful varieties known were found v&d in precisely the localities he describes. There is consequently not a word relating to the many ardent Fern lovers to whose efforts we are indebted for far more lovely forms than those Mr. Heath treats of, and in the chapters on the Common Polypody and the Hartstongue he does not even mention the Welsh Polypody (P. v. cambricum) or the Frilled Hartstongue (S. v. crispum) which have been known for a century or more. No reference is even remotely made to other instructive literature, and the impression is generally conveyed that Mr. Heath, and none but he, had ever dealt with British Ferns or advocated their culture. We look in vain for any evidence that he really possesses a proper comprehension of what our native Ferns are *as a whole*. On page 154, too, we find the following statement:—"Ferns that grow in wild woods and open spaces are in the free right of all who choose to gather them." This is a distinct incentive to that vandalism against which all true Fern lovers have long protested, and against which the law itself has recently and properly pronounced. We note, too, in this connection that the author himself, in finding a rare Fern (Asplenium lanceolatum), had no hesitation in uprooting it to ascertain what it was. He asserts too that "many Ferns which grow in Devonshire are never seen in other counties" (p. 214), while there is not a single species in Devon which does not grow in many other parts of the country. He also describes Ferns as seed-bearing plants, and seems generally to confound seeds and spores as identical.

ALIEN FLORA OF BRITAIN, by Stephen Troyte Dunn. West, Newman & Co.

THIS work comes to us from far-off Hong Kong. The author, who was at one time an assistant in the Kew herbarium, was unexpectedly appointed to the Botanical and Afforestation Department at Hong Kong. Pressure of official work, therefore, prevented him from arranging his notes on the waifs and strays of the British Flora, but by the aid furnished by his wife he was, he tells us, able to bring the work to a conclusion, so far as the absence of the standard works on the geographical botany of Europe permitted him. The difficulty of determining, in all cases, whether a plant is really native and aboriginal, or whether it has been introduced at some more or less remote epoch is much greater than the ordinary observer would suppose. In the work before us Mr. Dunn gives us some indications of the methods of observation and the deductions from them which enable botanists to say this plant is an "introduction," this is an old inhabitant, and that one a genuine native. A plant found growing on a wall can hardly be considered as a "native." A plant flourishing in a hedge-bank has also doubtful claims to be considered as a native. Out of 924 aliens enumerated in this book 123 are old-established weeds of uncertain origin, 332 are due to horticulture and arboriculture, while 206 are grain-sifting [sifted?] aliens of recent appearance and of little permanence. The plants enumerated are named in conformity with the *Index Kewensis*, and arranged in their genera and orders in the sequence of the *Genera Plantarum*. It is surprising to read that Escallonia rubra grows on cliffs in northern Ireland, evidently as an escape from gardens, and equally surprising to find a doubt entertained of the status of Galium aparine, seedlings of which are at this very time occurring in profusion on the side of ditches and in hedge banks, localities which give rise to suspicion. The hedgerow protects it at this stage, whilst its rampant habits and hooked prickles enable it to shift for itself at a later stage and to dispossess other less well-endowed plants. Ceterach officinarum grows in a locality within eight or ten miles of London, but under circumstances which lead one to think it may have been introduced with stone from the West of England. A similar remark applies to Cotyledon Umbilicus; on looking through Mr. Dunn's book we begin to wonder how many real original natives he would admit. Even the common Groundsel is looked upon with suspicion, and so is the common Tansy, though it grows on river banks in the Thames Valley side by side with Lythrum salicaria and Spiræa Ulmaria, whose claims to be a native are not contested. Arum italicum is, we think, more common in Kent, near the sea, than is generally supposed; it grows in spots far away from gardens and seems as spontaneous as Arum maculatum itself. From the different general appearance it presents as contrasted with the cultivated plant it is a subject for enquiry whether, after all, the Kentish plant may not be a well-marked variety of A. maculatum, with which it often grows in association. From these disconnected remarks it will be seen what a mine of interest Mr. Dunn has provided for those who love our native plants. For our own part we are not disposed to look with disdain upon the "introductions" and "newcomers." There is as much interesting information to be obtained as to their history and as to the how and why they have succeeded in establishing themselves as there is in the study of the conditions which enable us to call others—"wild flowers." A good index completes a book which will be of great service to students of "ecology" and of plant associations.

NEW AND NOTEWORTHY PLANTS.

A NEW CHINESE LILAC WITH PINNATE LEAVES.*

SYRINGA PINNATIFOLIA.—At first sight this new Lilac might be taken for a variety of the Persian, as it certainly resembles Syringa persica, var. laciniata, but on closer examination it proves to be a distinct species. It differs in all the leaves being distinctly pinnate, that is divided to the midrib into separate leaflets; in the lanceolate acute leaflets of much thinner texture, and very minutely fringed on the margin; in the rounded lobes of the calyx; and in the relatively longer corolla-tube. Syringa pinnatifolia, as I propose naming it, was imported by

* *Syringa pinnatifolia*, *Hemsley*; species nova, S. persicæ var. laciniatæ similis, a qua imprimis foliis omnibus pinnatis et foliolis lanceolatis acutis distincte disjunctis differt. *Frutex* 6-8 pedalis, fere omnino glaber, ramulis floriferis gracillimis. *Folia* cum petiolo communi gracili 2-3 poll. longa; foliola 7 vel 9, sessilia, tenuia, infra medium latiora, ½-1¼ poll. longa, apiculata, margine obscure ciliolata, venis subtus sat conspicuis. *Flores* albi, circiter semipollicares, in paniculas axillares sessiles graciles quam folia breviores dispositi, pedicellis brevibus gracillimis. *Calyx* circiter lineam longus, lobis brevissimis rotundatis. *Corollæ tubus* angustus, circiter ½ poll. longus; lobi ovato-oblongi, apice rotundati, circiter 1⅛ lin. longi. *Stamina* paullo sub apice tubi affixa, fere sessilia; antheræ inclusæ. *Stylus* bifidus, quam corollæ tubusdimidio brevior. *Capsula* ignota.

Messrs. James Veitch & Sons, through their collector, Mr. E. H Wilson, who discovered it in the extreme West of China, at an elevation of 9,000 feet. Like many of his discoveries, it appeared to be quite rare, and no seed was collected, but a young plant was brought home safely. Mr. Wilson describes it as an elegant bush, six to eight feet high, with very slender branches and white flowers. It has not yet flowered in this country, so far as I know, but judging from the dried specimens I venture to predict that this new Lilac will prove a welcome acquisition.

I wonder why one so seldom sees the cut-leaved Persian Lilac in gardens? Is it because it is a shy bloomer? Philip Miller, according to whom it was introduced into England upwards of 260 years ago, and before the ordinary Persian, states that "on its first arrival it did not flower for some years, but afterwards it became hardy, and produced its flowers in plenty every year." *W. Botting Hemsley.*

CONIFERS FOR LARGE GROUPS.

The general introduction of ornamental Conifers into our pleasure-grounds dates from about sixty or seventy years. This is rather difficult to realise for those of us at least who are unable to remember the appearance of gardens and pleasure grounds before the middle of the last century. We look upon Cupressus macrocarpa and Thuya plicata (the gigantea of gardens) now rearing their heads 60 or 80 feet high, and assume that they must have been here for a much longer period, yet the former was introduced in 1847, and the latter in 1854. As a matter of fact we are only now in a position to judge of the size to which they are likely to grow, the habit they are likely to assume, the effect they have in relation to one another, and the general aspect they give to the landscape. Their beauty (at least in the young state) we have long learnt to appreciate, and to some extent we have been told by travellers what we might expect regarding their later development, but the information we have had has not always proved trustworthy in this direction, because some plants, which grow to good-sized trees in their native habitat, with us in England do not make anything like the same headway. Sciadopitys verticillata, for instance, is said to grow 50 or 60 feet high in Japan, whilst we have some difficulty to get it beyond 15 or 20 feet.

There must have been some difficulty about the middle of the last century among planters of Conifers who had no matured plants to judge by. Their dilemma is apparent now in many instances where what should have been handsome specimens are so crowded that each is ruining its neighbour. The planter in these days can form a much better conception of the amount of ground each species is likely to require when matured, not from observation of plants growing in exceptional soil or under exceptional shelter, but under ordinary conditions.

The colour of Conifers can be seen, of course, in most instances, at a fairly early age; though perhaps this does not hold good in all. From the dark, glossy, luxuriant green of Pinus radiata [= insignis] there is an almost endless variety of shades to the silvery hue of Abies concolor; and from the gold tint of Taxus baccata aurea to the bronze tint of Cryptomeria elegans.

The outlines of the members of this order are exceedingly diverse, and what is perhaps the most curious feature is the propensity of some to alter their physiognomy during growth. In some cases the form characteristic of youth is completely altered, and there is no trace of it in the matured plant. The mode of growth, too, is very varied; some are columnar, some conical, others broadly conical, and others rounded. They will grow well in well-drained soil of loamy character, but are impatient of cold or sodden soil. They receive dressings of manure kindly, and generally speaking are not difficult to cultivate nor fastidious in their requirements.

The following species are well adapted for planting in groups. To realise the true beauty of a group of Conifers one has to stand in an open space (a small lawn, for instance), around which have been planted Conifers of varied height, colour, and shape; or to walk between these plants when there is room to view each from a short distance. Where there is lack of room, it should be remembered that twenty healthy and symmetrical plants are much more pleasing to look at than a hundred trees crammed together in a space where their proper development is an impossibility.

Some little care is needed when the plants are young to make sure that their leaders are not damaged, or if a leader should be injured to find another shoot and train it up. When they are out of reach this is no easy matter, still it is worth while rigging up a pair of ladders and a pole rather than to leave the plant to spoil or become contorted. The loss of a leader may not only throw a plant out of its proper shape at its apex, but its symmetry may be spoiled. A little judicious pruning may be required in any case, but this is not often wanted.

Pinus radiata, better known as *P. insignis*, makes a truly noble tree, growing from 70 to 90 feet high, covering a space 60 feet in diameter, and is of a lovely green colour. The lowest branches are bent upwards, leaving the base of the tree exposed when there is not ample light all round.

P. excelsa grows to about 70 feet in height, is very graceful in appearance; impatient of crowding, though it will admit of closer neighbours than P. radiata. Its colour is silver-grey, shape pyramidal [very variable in this respect.—Ed.] covering a space 50 feet in diameter.

P. Ayacahuite.—A little-known but handsome Mexican tree, the cones of which measure a foot or more in length; height 50 feet. It covers a space 50 feet through.

Cedrus sp.—Cedars are uncertain; the Deodar at least has not fulfilled in its maturity the promise of its early and middle life. C. libani is too well known to need description; it is not well fitted for a group. C. atlantica makes a good specimen, with a height of 70 feet, covering a space 60 feet through.

Sequoia gigantea (*Wellingtonia*) is a magnificent tree, conical in shape, 80 to 100 feet high. It covers a space 50 feet through.

Abies Webbiana grows 80 feet high, is conical in shape, and bears handsome purple cones; the foliage is dark green with glaucous lines on the under side of the leaves. It covers a space 30 feet through.

A. Nordmanniana.—This is a handsome species, broadly conical in shape, attaining a height of 80 feet, and covering a space 50 feet through.

A. religiosa is a tree which grows 60 feet high, with long pendent branches; it is somewhat impatient of overcrowding, and is liable to be injured by wind. Where it is sheltered it makes a magnificent specimen.

A. concolor.—In this the foliage is glaucous green; it is a handsome plant, and will probably make one of the best when matured; it is said to grow 100 feet high in its native habitat.

Picea Morinda Smithiana.—A noble, broadly conical tree, the colour of the foliage light green. It grows 70 feet in height, covers a space 30 feet through, the branchlets drooping fountain-like.

P. excelsa, the common Spruce, may be planted for protection, but is not a great favourite for ornamental work.

Araucaria imbricata.—A tree attaining a height of 50 feet, and covering a space 30 feet through. If the soil is such as to admit of this plant having enough water without being stagnant, it forms the handsomest of all Conifers either for a group or as a specimen.

Cunninghamia sinensis.—This is something like Araucaria imbricata, but is much more delicate. It suffers greatly if exposed to wind. I have seen a specimen about 30 feet high covering a space 25 feet through, but even in the most favoured situation it is a risk to plant it.

Cryptomeria japonica makes a handsome tree 60 feet high, covering a space 25 feet through.

Cupressus macrocarpa grows 70 to 80 feet in height, and 25 to 30 feet through. It forms a splendid tree to plant for shelter or in an ornamental group; near the sea, or inland if planted in an exposed position, it is liable to lose its leader rather quickly.

C. Lawsoniana.—A free grower, conical in shape; height 30 feet and upwards, and 10 to 12 feet through. Some of the varieties are remarkably beautiful.

Juniperus communis may be anything from a trailing plant upwards, to a height of 20 feet.

Pseudotsuga Douglasi, the Douglas Fir.—A handsome Conifer which in good soil and situation reaches 100 feet in height and 40 feet through.

Cupressus (Retinospora) pisifera grows 20 feet high and about as many through. A most desirable plant for a group, as are also C. filifera, C. obtusa (about the same for size), while C. ericoides is dwarfer and exceedingly attractive. [These are all juvenile stages of species of Cupressus, and are liable to revert to the specific form.]

Sciadopitys verticillata, unfortunately, does not do well with us. It grows 15 to 20 feet in height and 7 or 8 feet through, and is a very curious-looking plant, but rather fastidious.

Sequoia sempervirens, the Redwood, grows to a great height; it does well on most soils, but shows a brownish-red on its dead leaves if not well suited. A large tree, but not covering a great space.

Taxus baccata var. fastigiata, the Irish Yew, is a dark-green foliaged tree, 25 feet high, columnar, and will stand any amount of pruning.

Thuya dolobrata, a very beautiful plant, 20 feet high, 12 to 15 feet through; it loves a warm, well-drained soil.

T. plicata [= the T. gigantea or T. Lobbi of gardens] grows to a height of 60 feet and is about 7 or 8 feet through, columnar. A very striking effect is produced by grouping this remarkable plant judiciously. Sometimes this plant assumes quite a conical shape. [Few Conifers bear the knife so well as this.—Ed.]

Podocarpus andina.—A Conifer of great beauty, with dark-green, shining leaves; it grows 20 to 23 feet high and 15 feet through.

There are a number of plants in cultivation which are members of this Order that have been well known for a much longer period than those named above, but to give their names is unnecessary. On the other hand, there are many handsome Conifers whose constitution is now being tested in many parts of this country and in Ireland about which it is hardly safe to say anything yet regarding their fitness to withstand our climate. If the appearance of their youth is any forecast of that of their age, then Abies brachyphylla and other Japanese kinds, as well as Pinus Montezumæ and P. ponderosa, and many others, will add to the beauty and interest of the pleasure-ground. *H. W., Trevince, Redruth, Cornwall.*

ORCHID NOTES AND GLEANINGS.

ONCIDIUM AURIFERUM.

A COMPACT branched inflorescence of this pretty and uncommon species is sent by Messrs. Hooley Bros., Bitterne Park, Southampton, who received it with an importation of Odontoglossum luteo-purpureum from New Granada. It is an ally of O. panchrysum, and like that species the light green stems of the flower-spikes have a delicate bloom. The flowers, which are about ¾ inch in length, are of light yellow colour, with some reddish brown markings on the sepals, petals and base of the lip. It is a cool-house Orchid and an attractive plant on account of its bright yellow flowers and compact habit.

LÆLIO-CATTLEYA × EXONIENSIS.

A FLOWER of this fine Veitchian hybrid comes from Mr. W. T. Hurlstone, Parkfield Gardens, Worcester, whose remarks on the plant are interesting. "Our largest plant has 21 bulbs and three leading growths. The bulbs and leaves together are nearly 2 feet in height. The plants have been here since 1876." It is interesting to find that such fine specimens exist of the original stock which first flowered with Messrs. Jas. Veitch and Sons in 1866, and was described by the late Professor Reichenbach in the *Gardeners' Chronicle*, 1867, p. 1,144, as Cattleya exoniensis. The flowers are 6 inches across, with pale lilac-tinted sepals and petals, the front of the lip being of a rich crimson-purple colour. Despite the large number of hybrids recently raised it is well worthy to rank with the best.

VANDA AMESIANA.

A CLEAR white variety of this pretty and fragrant Orchid is sent us by D. Campbell Brown, Esq., Bank of Scotland House, Oban. The flowers which are 1½ inch across are pure white with three thickened light rose-coloured lines forming the crest of the lip. The species was imported in considerable quantity in 1887 by Messrs. Hugh Low and Co., from the hills of the Southern Shan States, India, and it has been found to thrive well in a cool intermediate house. It is winter flowering, and active growth commences in spring, from which time an increased amount of warmth and moisture should be afforded the plants until growth is completed. The flowers are usually tinged with pale rose colour, but, as in the present instance, are occasionally pure white.

COLONIAL NOTE.

NICOTIANA SANDERÆ IN CANADA.

I HAVE read with interest the different experiences of cultivators of Nicotiana Sanderæ recorded in the *Gardeners' Chronicle*. My experience in this country is that as a bedding plant it is a partial disappointment, as the flowers close during bright sunshine, when the whole plant looks half dead. In Britain it may possibly behave better, owing to the more humid atmosphere.

As a pot plant, I have not experienced the same result as Mr. Etherington, p. 331, November 4. I sowed my seed in February, and the plants, in ten-inch pots, were in bloom during July and August. They all showed their flowering spikes within three weeks of each other, and developed into magnificent plants.

Nicotiana Sanderæ is seen at its best grown as a pot plant, for the colour of the petals varies little, and the flowers appear to develop to their best. The only fault I find with it as a pot plant is its variation in habit, for while one plant is perfect in form, another will throw up a long spike 5 or 6 feet in length, with strong straggling side shoots.

If the type generally seen in illustrations could be firmly fixed, I consider it would be one of the best plants introduced of recent years for conservatory decoration. As a plant for winter decoration in the conservatory, it gives great promise. I had a batch flowering splendidly in a cool conservatory about the first week in September, and with another later batch I hope to maintain a succession of flowers all through the winter. For cut purposes the flowers are splendid, the colour showing well in artificial light. *Chas. Craig, Gardener to A. Joyce, Esq., Rockland House, Outremont, Montreal.*

The Week's Work.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Muscat Grapes.—The structure containing these should be got in readiness for forcing the vines without delay, in order to allow a sufficient period for the proper development and finish of the bunches before Autumn. The Canon Hall variety of Muscat requires great attention to detail in order to develop it to perfection. If the vines are young, say, three, four, or five years of age, the rods should be brought down to a horizontal position, in order to obtain an even "break" on the leading shoots, but the buds on the spurs or side growths will generally start away satisfactorily. The leading shoot of the main rod is often not cut sufficiently short at pruning time, with the object of furnishing the vinery with permanent bearing canes in as short a time as is possible. When this is practised the canes will often "break" with great vigour at the top of the rod, leaving the lower buds of the shoot very feeble. Two to three feet of new growth, according to the strength and the ripeness of the young wood, is ample to allow each year. The night temperature of the vinery when forcing is begun should be about 50° or 52°, and during the daytime 55° to 57°. Well syringe the rods with water, as this will tend to make the buds swell and burst into growth.

Early Cherries form an agreeable adjunct on the dessert table. A few trees should be introduced into a cool house, and forcing very slowly commenced, as these trees are most impatient of fire heat, 40° to 45° at nights, with 5° degrees higher in the day, being all they require. The trees should receive a rich top-dressing of loam and bone-meal prior to forcing in order to encourage the feeding roots near to the surface. Abundance of ventilation should be given, and if the ventilators are allowed to remain open a trifle at night time it will be beneficial. A sharp watch should be kept for green and black fly, which are amongst the chief enemies of the Sweet Cherry.

Grapes in bottles.—These should be examined daily, and any decayed berries on the bunches removed. The end of the stem should always remain in water, and by keeping the bunches in the dark as much as is possible the berries will retain their colour for a long time. An equable temperature of 45° should be maintained. Lady Downes and Black Alicante are two excellent late keeping varieties.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to F. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Clivias (*Imantophyllums*).—Where sufficient plants are grown for the purpose, they may be had in flower during the next three months by introducing a few plants at intervals into an atmospheric temperature of 55° to 60°. If grown in six inch pots they are useful for house decoration, their richly coloured flowers and graceful foliage rendering them very effective. The present is a good time to increase the stock either by sowing seeds or by division. Provide perfect drainage and pot the bulbs in rich loamy soil with the addition of bone meal. An abundant supply of water is essential during the growing season.

Plants for Table Decoration.—Any of these which may have been used for decorating the dwelling rooms will now need attention. Codiæums (Crotons) will have lost some of their lower leaves, and in consequence they are of no further use as table plants. The tops, however, may be rooted by the method known as "ringing." Take a sharp knife and make two or three cuts upwards in the bark, and a little into the hard wood immediately under the lower leaves, afterwards binding some moss around the portion which has been cut. Keep the moss in a moist condition always. When roots have been made, the stem may be severed and the rooted plants again potted. Thus treated they will soon prove useful again.

Acalyphas.—Cuttings of young wood of Acalyphas should now be inserted singly in small pots, and if placed in heat they will soon make roots, and become useful plants for furnishing in a small state. The foliage will have a much better colour if the plants are grown in a somewhat cool atmosphere, and are fully exposed to the influence of the sun; especially should this treatment be afforded in summer. The foliage will then be comparatively hard, and, apart from the improved colour, be capable of withstanding the adverse conditions in the dwelling-rooms. A. Macafeeana and A. musaica are two of the best varieties for the purpose mentioned above.

Fittonias.—Where large vases or the base of screens have to be filled with plants and edged with dwarf growing species, Fittonias will be found to be very useful. Shallow pans may be used for propagating the cuttings, and when the latter have made roots tie them round with damp moss and place them together in shallow boxes, and they will be convenient for use when required. This is a much better method than that of growing them in pots. Large quantities can be accommodated in boxes and be kept within a limited space.

Hydrangea paniculata grandiflora.—Some of the plants growing in pots and having well-matured their growths may now be pruned hard back before they commence to make new growth. If very fine heads of bloom are required it will also be necessary to thin out the young shoots after growth has commenced, leaving four or six of the strongest to each plant. If medium-sized trusses of bloom are preferred all that is necessary is to allow a greater number of shoots to develop. Place the plants in an atmospheric temperature of 55° to 60°. Apply occasional waterings with liquid manure during the growing season. Though the above is often spoken of as Hydrangea paniculata there is a considerable difference between H. paniculata and the variety grandiflora.

Violets in frames should now be yielding a wealth of flowers. Keep them free from decayed leaves and lightly stir the surface soil occasionally. If the soil is at all dry afford a good soaking with soot water and diluted liquid manure from the cowsheds. On fine, warm days remove the lights entirely for a few hours. Free ventilation at all times is essential for Violets growing in frames.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Zygopetalums.—The present is a good time to repot Zygopetalum Mackayii, Z. crinitum, Z. triste, Z. Protheroeianum, Z. brachypetalum, Z. Clayii, Z. Murrayanum, Z. Perrenoudii, Z. Burkei, &c., if any of the plants require to be moved. Good fibrous loam, chopped sphagnum moss, and plenty of broken crocks, if well mixed together, will form a suitable compost for them to root in. The atmosphere of the Cattleya or intermediate house will suit them, and they will require plenty of water at the root when growing and rooting freely. Z. maxillare thrives best when fastened to an upright piece of Fern stem and allowed to climb around it. A shaded part of the cool house will suit this species.

Masdevallias.—The present is a good time to divide old plants, or to afford more root room to the Chimæra section of Masdevallias, which includes M. Chimæra, M. bella, M. Backhouseana, M. Wallisii, M. Winniana, M. Houtteana, M. radiosa, M. trinema (Lowii), and M. erythrochæte. These plants should be grown in shallow teak-wood baskets, and as their flowers are produced from descending stems, no crocks must be used for drainage, but a few tough, well-dried pieces of fern rhizome may be placed across the bottom bars of the baskets to prevent the compost from falling through. A moderate quantity of peat and sphagnum-moss well mixed together, but not compressed very tightly, will afford a suitable rooting medium. During the next two or three months

repotted plants should be suspended well up to the roof glass in a shaded position in the intermediate house. Afford water with the fine sprayer whenever the surface of the compost appears to be in the least dry, and frequently sponge the under-sides of the leaves to prevent the lodgment of red spider. The pure white flowered M. tovarensis may also be repotted, and for cultural directions the reader may refer to p. 14 in the *Gardeners' Chronicle* for January 6, where a description was given of a method of culture which has been attended with great success. Any plants of the M. Harryana and M. Veitchii sections, or of the dwarf growing species that require fresh compost to root in, should be given attention at once. Well-rooted specimens in a healthy condition that were repotted last autumn should be given increased supplies of water, but not kept in a saturated condition at the root. Allow the compost about each plant to become properly dry previous to affording more water. The warmer end of the cool house is the best place for them. Do not damp between the pots when the weather is dull and wet, because an excess of atmospheric moisture at this season often causes black markings and spotting on the foliage.

In the intermediate house plants of Platyclinis glumacea are fast pushing up their rosy-coloured growths, and they should be elevated as near to the light as possible. From the present time until the pseudo-bulbs are thoroughly matured, afford the plants plenty of water at the root, and on all bright mornings well syringe the under sides of the leaves. It is also well to sponge them occasionally, as red-spider is very apt to make an appearance. The proper time to repot plants of this species is when they commence to grow, or as soon as the flowers fade. They will root and grow freely in the ordinary Orchid compost.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

Herbaceous Plants.—Though September is undoubtedly the best month in the year in which to undertake the work of making new borders for herbaceous plants, and the renovation or the rearrangement of old ones, circumstances often make it necessary to postpone these operations until a later date. Failing the autumn there is no better time than the present to carry them out. The weather in February is usually open and mild, which will enable the plants to get sufficiently established in their altered position before the advent of the keen March winds, which otherwise might be detrimental to them. It is essential to prepare the soil in a thorough manner when making a new border, for once made it should remain undisturbed for a number of years. If the ground is not naturally drained, artificial drainage must be provided, as it is impossible to cultivate herbaceous plants well unless the soil is in the very best condition. Trench the border to the depth of three feet, and remove and replace with rich loam any soil of poor quality. When doing this add a dressing of basic slag, and a plentiful supply of well-matured farmyard manure. Where new borders are made in front of strong growing trees and shrubs, precautions must be taken to prevent the roots of these trees getting into the border. This can be done to a certain extent by providing a space between the shrubs and border, which can be deeply trenched every year and all roots removed.

Although much might be said in favour of borders on which the effect of the flowers is enhanced by the dark green foliage, and the bold appearance of shrubs as a background, yet when the opportunity offers itself, almost equally charming effects can be obtained by a flower border against a wall. Whether of stone or brick the wall can be quickly clothed with appropriate growth in such a manner that it will soon become an excellent background, and there will be no danger of encroaching roots, which, no matter the precautions taken, are always a menace to the best interests of the inmates of the border. In planting, avoid what is termed the "dotting" system of arrangement, and in preference adopt that of boldly grouping, but not stiffly, the plants in numbers, ranging from three to twenty or so, according to the habit of the plant and the size of the border. Borders are often spoilt by the use of too many kinds of plants. It is better to plant in groups, and limit oneself to fewer kinds. The habit, and the height of the plants must be considered in arranging them, and though generally the taller growing ones should be placed towards the back of the border, do not be afraid to allow some of them of medium height to approach the front and *vice versa*, groups of lesser growth to recede amongst the taller ones. A free and natural style is far more effective than a stiff "banking" arrangement graduated in regular heights from back to front.

Arrangement of colour.—In the matter of colour, very much depends upon the individual taste, but still there are certain rules regarding colours that cannot lightly be disregarded. As, however, it is intended to return to this subject in a future note (probably in September) it will suffice for the present to simply state that it is preferable in bringing colours together in a border of herbaceous plants to endeavour to create harmonies, and leave formations of contrasts to beds by themselves. There are certain colours like red and yellow, which retain their intensity, no matter from what distance they are regarded, and again colours like blue, which require to be viewed close at hand to be appreciated fully—facts to be remembered when arranging them. In arranging and planting the "herbaceous border," no one now thinks of merely including plants that strictly come under the category of hardy herbaceous plants. They of course predominate, but as the object is to achieve the best possible effect, Roses, tender bedding plants, hardy and half-hardy annuals, and bi-annuals are all used, and with decided advantage. Even many of the numerous flowering shrubs can be employed provided the border is of sufficient size to accommodate them. Therefore spaces should be left in appropriate positions in the border for planting at the proper time such plants as Dahlia, Hollyhock, Pentstemon, Antirrhinum, Salvia patens, S. splendens, S. farinacea, S. Horminum, Lobelia (the Cardinalis type and L. pumila), Gladioli in variety, Carnation, Pink, Marigold (African and French), Delphinium "Queen of the Blues," Phlox Drummondii, Scabious, Canna, Calceolaria amplexicaulis, Nicotiana Sanderæ, and Pelargonium, and also for sowing Lavatera splendens, Love-in-the-Mist, &c.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Planting.—January has been wet enough in this locality, over 5½ inches of rain having fallen. Any planting that has still to be done should be pushed forward in the event of the weather becoming suitable. Obtain some dry soil if possible, such as that from the potting bench, and mix it with mortar *débris* from old buildings, and with a mixture of this nature the work of planting may be carried on pretty comfortably. Work this dry soil in among the roots as much as possible, in order that the soil about the roots may be made firm, but on no account should wet soil be rammed.

Espalier Trees.—Examine the supports of espalier trees, and renew any that have become defective. Straight young Larch poles make admirable supports, and should be driven in straight with a mallet, and not closer together than is necessary for the support of the tree. If these stakes be dipped in creosote before use they will last much longer in good condition. Cut off the upper ends level by means of a saw. Bamboo canes may be tied to these with tarred string, in horizontal positions. When the work has been well done trees trained in this manner have a very good appearance. When pruning and training are done rake over the surface ground, dress the trees to kill insects or fungi, and then fork in a little manure if necessary, and leave the ground as tidy as possible. Let the label denoting the variety be placed in a position where it will be easily seen.

Apricots.—Wherever there are worn-out trees of Apricot, young trees should be planted in some position in the same garden, for the fruits are among the most delicious of those available for dessert. Apricot trees require a free loam, and plenty of lime rubble, which mixture should be very often renewed. The wood of Apricot trees may be very easily damaged, and if this occurs "gumming" very often follows. Nearly all the necessary pruning (stopping and disbudding) should therefore be done by means of the thumb and finger, in the early stages of growth. Many mistakes are made in cropping these trees too heavily, and another mistake is that of allowing the roots to become dry. Established trees should now be pruned by reducing the old spurs if necessary, leaving several flower buds and a leading wood bud. Lay in a good supply of young growths and take care they are not tied taut against a nail or wire, nor bruised with a hammer during the operation. Young trees that have made strong growths must be reduced in order to get a well-balanced start; these trees are generally trained on the fan system, and should a branch die, the branches left can be unfastened and redistributed; stop all holes and crevices in the wall in order to destroy vermin. Let the protective material be held in readiness for use when the flowers commence to open.

The Loganberry, Wineberry, and American Blackberries may still be planted.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Potatos.—Do not lose any favourable opportunity that may occur for planting the earliest crop out of doors, on a warm border sloping to the south, and if possible in front of vineries or other hot-houses. It is assumed that the soil has been well trenched and liberally manured with well rotted material, in order that the young tubers may acquire size as early as possible. Cover the sets with light soil, procuring some if the natural soil is of a heavy nature. May Queen, Ringleader, and Sharpe's Victor are three reliable and good varieties, and providing they have sprouted well in the usual way should give a return towards the end of May. Protection from frost at night will be necessary, as the young growths are very tender at the time they push through the soil. Loose, dry bracken or straw will protect them materially, but it is safer to make a temporary frame work and run down a blind over this at night time.

Peas.—The earliest sowing of Peas may now be made on a warm border, but as in the case of Potatos the soil must not be interfered with until it is dry enough to be worked without it sticking, or more harm than good will result. In late localities, or in others where the soil is of a heavy nature, it will be advisable to sow a round-seeded variety at this date to make certain that rotting of the seed will not take place through excessive damp. The marrowfat varieties, which are far and away the best, need to be sown in boxes, and started into growth indoors, and if such are transplanted early in March, they should come into bearing as early as the others. Sutton's Ringleader is an excellent variety of the former type, while Early Giant, growing also about 4 feet in height, is amongst the best early marrowfats. Chelsea Gem and Green Gem are two excellent dwarf-growing varieties that may be sown at less than 2 feet apart between the lines. On small narrow borders, when the lines are drawn, cover the seed with leafmould or other light soil.

Spinach.—A sowing of Spinach should be made as soon as possible on an exposed border. Like all other early vegetables Spinach succeeds best where the soil has been thoroughly prepared, and is in good condition to receive the seed.

Jerusalem Artichokes.—The tubers being perfectly hardy, the crop may be planted without delay. Assuming the soil to be in good heart, and that it has been deeply worked, let the tubers be planted in lines 3 feet apart, and allow 1 to 2 feet between them. Use good-sized sets in preference to small ones. The newer white variety is an improvement on the old purple one, and should be planted in preference to the latter.

Carrots.—It is rather early yet to sow carrots, but a sheltered spot, if available, may be made use of for raising a bed of the earliest variety at hand. Dig the ground well and sow the seeds in lines drawn at 6 inches apart, being careful not to cover the seeds too deeply. Use light soil for covering, and gently press it down with the back of a rake as a finish. Paris Market is a good type to sow at this date, together with Inimitable Forcing, which also turns in very quickly, to be followed with Early Nantes and Early Gem, all of which are first-rate varieties. If a rough frame can be spared for this crop a gathering will be obtainable at least a fortnight earlier. Make successional sowings of Peas, Potatos and Carrots in frames as required.

General Remarks.—As fast as the ground is cleared of Broccoli, &c., make every effort to get the same prepared for a future crop by trenching if possible, or at least digging the soil and manuring it to suit the next crop. The greater surface that can be exposed to the influence of the weather the better it will be for the crops.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Feb. 3	Société Française d'Horticulture de Londres meet. German Gardeners' Society meet.
TUESDAY,	Feb. 6	National Amateur Gardeners' Association meet.
FRIDAY,	Feb. 9	Annual Meeting of the Royal Gardeners' Orphan Fund and election of Candidates at Simpson's Restaurant, 101, Strand, London, at 3 p.m.
SATURDAY,	Feb. 10	Dutch Gardeners' Society meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—39·3°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Jan.* 31 (6 P.M.): Max. 46°; Min. 33°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 1 (10 A.M.): Bar., 30·3; Temp., 47°; *Weather*—Slight rain.

PROVINCES.—*Wednesday, Jan.* 31 (6 P.M.): Max. 50° Ireland East; Min. 43° Cambridge.

SALES.

WEDNESDAY NEXT—
Sale of Roses, Shrubs, Perennials, 100 cases of Japanese Lilies, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY NEXT—
Hardy Border and Herbaceous Plants, 1,800 Roses, Lilies, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Herbaceous and border plants, Liliums, Hardy plants at 1; 3,000 Roses, Palms, Azaleas, Rhododendrons, &c., at 3, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY NEXT—
1,800 Roses, Liliums, Hardy border plants and bulbs, Azaleas, Greenhouse plants, &c., by Protheroe & Morris, at 67 and 68, Cheapside, E.C., at 12.

FRIDAY NEXT—
Imported Odontoglossum Crispum and Cattleya Trianæ, choice established Orchids, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

Nomenclature.

WE have from time to time had occasion to notice the vagaries of some of the American botanists who have of late years been employed in executing permutations in nomenclature. These changes have been made for reasons which doubtless seem valid to some naturalists, and so long as they were confined to strictly botanical books, we could look on with amazement, perhaps, but as horticulturists we were not justified in making any protest. If the botanists liked to indulge in such vagaries it was no concern of ours, and, however erratic their methods, the rules of synonymy and of publication render it easy to trace any particular plant under whatever name it may be masquerading. The cyclone is now, however, approaching our own territories.

Our valued correspondent, Mr. Smith, of Newry, writes:—

"Much has been said, from time to time, about the mischievous practice of multiplying names. The following have been taken from a current American catalogue, and I imagine are for the most part quite new, and inasmuch as they are given without any synonyms, further comment would appear to be unnecessary:—

Veronica virginica	is now called	Leptandra
Liatris	,, ,,	Lacenaria
Gillenia stipulacea ...	,, ,,	Porteranthus
Lysimachia	,, ,,	Steironema
Dielytra	,, ,,	Bicuculla
Goodyera	,, ,,	Peramia
Amianthemum ...	,, ,,	Chrosperma
Spiræa aruncus ...	,, ,,	Aruncus Aruncus
Darlingtonia	,, ,,	Chrysanthera
Hales a	,, ,,	Mohrodendron
Magnolia	,, ,,	Adelia
Calycanthus	,, ,,	Butneria
Ilex verticillatus ...	,, ,,	Decodon
Andromeda ligustrina	,, ,,	Xolisma
,, calyculata	,, ,,	Chamædaphne
Ledum buxifolium ...	,, ,,	Dendrium
Ampelopsis	,, ,,	Parthenocissus
Laurus Benzoin ...	,, ,,	Benzoin Benzoin"

It is now time to protest, and to proclaim our allegiance, as we have done often before, to the nomenclature adopted in the *Index Kewensis* and in the works, such as the *Kew Hand-lists*, which have been framed in accordance with it. It is not that the Index is infallible—it does not pretend to be. But as a general standard it is the best that we are ever likely to see. No alterations in it should be lightly tolerated, and only monographers and specialists dealing at first hand with particular groups should be allowed to tamper with its pronouncements. The Botanical Congress, held at Vienna last summer, revised the "Lois" put forth by the late Alphonse de Candolle, and generally adhered to by European botanists. The Congress, we believe, negatived many of the proposals of the extreme neo-American school. But until the Report is issued we cannot say which of the names mentioned by Mr. Smith will be put under the ban.

A garden-catalogue is not drawn up with the precision and accuracy of a botanical monograph, so that there is no means of ascertaining in an ordinary garden-list who is responsible for any particular name and where and when it was published. In those matters the botanist has a great advantage over the gardener.

But there are worse grievances than changes of nomenclature consequent on differences of opinion on matters of technical detail. There are, we are told, names which may be found in certain catalogues, and in certain gardens, which have nothing to justify their existence. They do not occur in the *Index Kewensis* or its Supplements, nor, so far as appears, in any monograph.

In one case a correspondent tells us he found in English gardens the same species of Daphne under seven different names.

We have before us a marked catalogue containing scores of names which are not in the *Kew Hand-lists* nor in the *Index*. Such names, if genuine, should be authenticated by the name of the author, the place and time of publication, and other details such as botanists are accustomed to give when they describe what they believe to be new plants, otherwise they are open to suspicion.

ROYAL HORTICULTURAL SOCIETY. — We would remind readers that there will be no meeting of the Committee on Tuesday next, but that the annual general meeting will be held on the following Tuesday, February 13.

FLOWERING OF THE HAZEL. — Our record showing the expansion of the male flowers is earlier than usual, viz., January 22. The earliest date for several years is January 22, the latest February 21. The bushes observed are the same each year, and are in proximity one to the other.

NATIONAL CHRYSANTHEMUM SOCIETY. — We are informed that the annual general meeting of the members of this society will take place at Carr's Restaurant, 265, Strand, W.C., on Monday, February 5, next, at 7 o'clock in the evening. CHARLES E. SHEA, Esq., president, in the chair and the usual business pertaining to the annual meeting will be transacted. The General Secretary (*pro tem.*), is Mr. G. R. DEAN, 8, Avonwick Road, Heston, Hounslow.

THE LATE MR. O. T. HEMSLEY. — The funeral of Mr. O. T. HEMSLEY, Superintendent of the Government Gardens, Lahore, who died at the Mayo Hospital on January 6 last, took place the same afternoon. It was, says a Lahore paper, a military one, Mr. HEMSLEY having belonged to the Punjab Light Horse, of which he was Quartermaster-Sergeant. The Corps paid a worthy tribute to a devoted Volunteer. The Commanding Officer, Lieutenant-Colonel GREY, the Adjutant, Captain CHEYNE, Major PEASE and Lieutenant PERCY BROWN attended; and Major ROBERTSON, Private Secretary to His Honour the Lieutenant-Governor, and Captain WRIGHT, of the 1st Punjab Volunteer Rifles, were also present. The charger of the deceased was led behind the remains, and the Police Band supplied the solemn music for the procession to the grave. The Rev. K. G. FOSTER conducted the service, and the firing party consisted of Light Horsemen. Sir CHARLES and Lady RIVAZ sent a cross and wreath, and similar floral offerings were brought by Colonel GREY, Major ROBERTSON, Captain CHEYNE, and many others, including Mr. A. PINTO, the Acting Superintendent, and the native staff of the Gardens. We are requested to insert the following note:—"Mr. and Mrs. BOTTING HEMSLEY and Miss HEMSLEY are deeply grateful for the appreciative and sympathetic announcements in the gardening Press relating to the great loss they have sustained in the death of their only son and brother. These notices have brought them so many letters of condolence and expressions of sympathy from friends far and near that it is impossible to reply to them individually, and they avail themselves of this means of conveying their heartfelt thanks to one and all.

THE FRUITERERS' COMPANY.—At a dinner given by this company at De Keyser's Hotel, Blackfriars, on the 25th ult., Mr. G. BUNYARD, the Master, presided. In the course of his remarks he stated that he was the first Master of the Company who understood the art of fruit-growing! Mr. EAGLETON, the secretary, said the Fruiterers' Company, in its desire to advance the art of fruit-growing, had come to the conclusion that it was of no use to try to teach new methods to grown-up people. Their efforts in the future were to be in the direction of instilling into the young mind new ideas and up-to-date plans whereby fruit could be grown to perfection in this country and a satisfactory profit made. Pamphlets had been issued, but now, on the suggestion of the Master and his greatly-gifted daughter, Miss BUNYARD, they were about to venture out in a new direction. A series of five charts, or diagrams, was about to be issued, illustrating the culture of fruit, and these would be hung in elementary schools. The idea had already been approved by upwards of a dozen county councils, and, later, they hoped to issue some thousands of sets.

ALL ABOUT SWEET PEAS.—Mr. ROBERT SYDENHAM has lately published the third edition of *All About Sweet Peas*. It is a booklet with a useful description of every known variety and instruction how to grow it. It contains a list of the best varieties for exhibition and other purposes, as well as information for the amateur or general grower. The newest varieties of Sweet Peas are, of course, mentioned.

CALATHEA ALLOUYA.—This is a disappointing plant. An excellent figure in the *Tropical Agriculturist* for December last naturally suggests that it would form a good substitute for the Potato in tropical countries. If the foliage were concealed the observer might fancy he had to do with

"Northern Star," so close is the resemblance in the mode of growth, but Mr. MACMILLAN, who furnishes the description, reports the results of several trials, which were all unsatisfactory, and so long as we have, says he, the "Sweet Potato" (Batatas) there is no need to trouble about the Calathea or even the ordinary Potato.

CELEBES.—Little is known in this country of the vegetation and productions of this island. We may, therefore, call attention to the "Reisen in Celebes," by PAUL and FRITZ SARASIN, recently published at Wiesbaden (Kreidel), in two volumes. The text is in German; it is copiously illustrated by excellent illustrations (some coloured), which show the nature of the country, the general character of the vegetation, the appearance of the inhabitants, their dress, and their weapons. There is no separate list of plants. The book may be had of Messrs. WILLIAMS & NORGATE.

NYMPHÆAS.—The catalogue, in Swedish, of Mr. M. P. ANDERSEN, of Jönkoping, contains details of some new hardy Water Lilies such as the miniature flowered N. fennica of Mela, and others, which would interest cultivators of these plants.

A FRENCH AGRICULTURAL JOURNAL.—The first number of the eighth yearly volume of *Le Mois Scientifique : Le Mouvement Agricole*, includes a review of MM. DE RIVIERE & LECQ's book on Agriculture in Algiers and Tunis; of that by DE M. KAYSER on Agricultural Microbiology, and of various publications on allied subjects. These reviews are valuable, being written by specialists in the various branches of agriculture under consideration.

THE ENGLISHWOMAN'S YEAR BOOK AND DIRECTORY FOR 1906.—Miss JANES is again the editor of this volume, which has become practically indispensable to every working woman. The subject matter includes Education, Employments and Professions, Industrial Pursuits, Science, Literature, Art, Sports, Philanthropy, &c.; all from the standpoint of woman's employments and interests. We note that in addition to agriculture and horticulture and florists' work the question of Settlements for women is carefully considered; in fact every effort has been made to keep the Year Book up to date. The publishers are Messrs. ADAM and CHARLES BLACK, Soho Square, London.

DENDROBIUMS AT GATTON PARK. — It is rumoured that the Dendrobiums in the collection of JEREMIAH COLMAN, Esq. (gr. Mr. BOUND), are better than ever this season, and it is intended to make a fine display at the Royal Horticultural Society's meeting on February 13. The annual general meeting of the society at Vincent Square will be held on the same day. Diplomas are also offered on the same date for Lælia anceps (white varieties), Cattleya Trianæi and hybrids, and Cypripedium villosum (including Boxalli), and hybrids of that section, consequently, with incidental exhibits, the show should be a good one.

THE WRITERS' AND ARTISTS' YEAR-BOOK.—This is a directory for 1906 for the use of writers, artists, and photographers. It is less bulky than the familiar *Willing's Press Guide*, yet contains not merely addresses of papers and magazines where MSS. and illustrations may be accepted, but many hints for intending contributors. The Year-Book will prove serviceable also to "the ever-increasing host of illustrators," but editors of popular publications who are already surfeited with contributions may not always welcome the additional work this may bring upon them. The publishers of this directory are Messrs. ADAM and CHARLES BLACK, Soho Square, London.

THE GARDENS AT UDAIPUR.—We have received, from Mr. T. H. STORY, the Annual Report on the Gardens of His Highness the MAHARANA FATAH SINGHJI BAHADUR, G.C.S.I., of Udaipur, Meywar, for 1904-5. Plague, rinderpest, and a severe frost were serious drawbacks to work during the season. The frost was particularly fatal to Mangos, Opuntias, Tamarinds, and other plants, and spoiled the lawns. The garden looked in most places like mid-winter in Europe, and sustained a loss that will take many years to repair. At the Observatory from 10° to 12° of frost were registered. This occurred in January, 1905.

APONOGETONACEÆ.—A monograph of these plants has been published by Mr. KRAUSE, with the assistance of Dr. ENGLER. Twenty-two species of Aponogeton were described, including the well-known Ouvirandra fenestralis, which is transferred to that genus. The plants are obviously closely allied to the Potamogetons, Alismaceæ, and Juncaginaceæ. The name Aponogeton is supposed to be derived from the name of an old bath, "Apone," near Padua. The species are mostly South African, with some Australian. They were first raised with a distinct order by PLANCHON.

EIGHT FOR NINE.—The printers of one of the American trade papers have, it is stated, struck because the master-printers do not see their way to accede to the proposal for an eight-hour day for nine hours' pay. There should be give and take in these matters, but the printers seem to prefer taking to giving.

SWEET PEAS.—It is said that the stock of Sweet Peas of the best sorts is rather low this season, and that some of the better kinds will in consequence be difficult to obtain in quantity.

FOREST FLORA OF NEW SOUTH WALES.—Mr. MAIDEN has just issued Vol. II., Part 7, of his valuable work: *The Forest Flora of New South Wales*. This instalment, which forms Part XVII. of the entire work, includes the descriptions and plates of Casuarina stricta (Drooping She-Oak). Eucalyptus numerosa (River White Gum) and Flindersia australis (Native Teak).

SCHOOL OF GARDENING.—Miss MAY CROOKE, F.R.H.S., late Instructor in Horticulture at Lady Warwick College, Studley Castle, and Lady Warwick Hostel, Reading, has obtained a suitable garden for horticultural instruction at Bredons Norton, near Tewkesbury. Miss CROOKE will take a limited number of students, either resident or non-resident. The garden is fully-equipped with glass-houses, mushroom-house, heated pits and a fine selection of fruit trees, and will afford facilities for horticultural instruction in all branches.

THE "BAMBOO" MAGAZINE.—We note the appearance of the first number of "*Le Bambou, son Etude, sa Culture, son Emploi*," founded and issued by M. JEAN HOUZEAU DE LEHAIE, Ermitage, Mons, Belgium. It is proposed to publish the magazine monthly, and its pages are to be wholly devoted to papers concerning the Bamboos, considered from their scientific, horticultural, and commercial aspects. Communications will be printed in Latin, English, French, German, Italian, and Esperanto, and will be contributed by specialists from all parts of the world. Illustrations are included in the pages. The opening number contains an article on Phyllostachys pubescens, on the Japanese method of planting, on the fructification of Bamboos in Europe, and kindred subjects, all connected with this subfamily. We wish success to the enterprising venture, which is addressed to all interested in Bamboos.

W. H. SMITH & SON'S ANNUAL.—A publication for the use of newsagents, containing spaces for a record of orders for various publications, and much information, profitable and interesting, for those to whom it is specially addressed. A portrait of the late Rt. Hon. W. H. SMITH, M.P., serves as frontispiece. The same firm also issue some handsome samples of fancy headings for commercial stationery. For further particulars address to Amberley House, 12, Norfolk Street, Strand, or to the Works, Fetter Lane, E.C.

FLOWERS IN SEASON.—We have, for several seasons past, received from the well-known firm of Messrs. WILLIAM BULL & SONS, King's Road, Chelsea, London, S.W., flowers of a number of named varieties of the florists' Primula. Those submitted to us during the past week showed careful selection, both in regard to colour and type of flower. The colours were of a wide range, from the white alba magnifica to the so-called blue of Imperial Blue, which is, however, more correctly to be described as lavender. There were also double-flowered forms, and still others of the fimbriated type, whose petals are pleasingly crenated. The old double white, or to give it its catalogued name, alba flora plena, is still one of the most desirable of all Primulas, for it is invaluable for furnishing a supply of cut flowers for cutting when white flowers are scarce. There are also blush rose, and still deeper coloured varieties of this useful type. Comet (carmine crimson), Countess (blush pink), Fulgens (scarlet), and Ruby Queen (magenta crimson) are four good varieties of the ordinary florists' strain.

HORTUS VILMORINIANUS—an appendix to the volume for 1904 of the *Bulletin de la Société Botanique de France*—is devoted to the systematic enumeration of the trees, shrubs, and herbaceous plants cultivated in the garden of M. PHILIPPE DE VILMORIN and in the trial grounds adjacent, at Verrières le Buisson, near Paris. The catalogue fills, with the index, over 371 pages—a detail we mention for the purpose of giving some idea of the richness of the collection. The list has been very carefully drawn up and richly illustrated, and abounds in relevant annotations. The preface contributed by Prof. FLAHAULT, of Montpellier, is a very interesting autobiographical sketch, introducing some account of DECAISNE which will be read with interest by those who were fortunate enough to be acquainted with that great botanist. The book before us, says M. FLAHAULT, is "the work of a VILMORIN. . . . He [the author] is the successor of those who for a century and a half have never ceased to associate the requirements of practice with scientific truth." M. PHILIPPE DE VILMORIN contributes in an introduction some account of the collections which he traces back to the 18th century, and sketches the additions made by successive members of the VILMORIN family. The collections of Conifers and of Alpine plants are very rich. Their nomenclature is according to the *Index Kewensis*, and their arrangement in accordance with the *Genera Plantarum* of BENTHAM and HOOPER. The catalogue was prepared as a consequence of the visit of the members of the Botanical Society of France to Verrières on the occasion of the fiftieth anniversary of the Society in 1904; and is in every way worthy of the occasion and of the present representative of the family which has done so much for horticulture and agriculture. The assistance of M. MOTTET is gracefully acknowledged.

TO HELP THE CHARITIES.—The tenth annual Bohemian concert organised by the Geo. Monro Ltd. Concert Committee will be held in the Queen's Hall, Langham Place, on Thursday, February 22, 1906. The proceeds of these concerts are devoted to charities. The amount given last year to deserving institutions was £35 14s., and of this sum the Gardeners' Royal Benevolent Institution received ten guineas. Tickets may be obtained from the Hon. Sec., Mr. H. Baker, 42, King Street, Covent Garden, London, W.C.

SEED LISTS RECEIVED.—We have received the list of seeds offered in exchange from the Botanic Gardens, Paris. Applications for any of the items should be addressed, as soon as possible, to M. le Directeur du Museum d'Histoire Naturelle (Service de la Culture), Rue Cuvier, 57, Paris.—*Catalogue des Graines Recoltées en* 1905, Villa Thuret, Antibes. Many interesting seeds are offered for which application should be made before March 1, to le Jardinier en Chef, M. B. Texier, or to the Directeur, M. Georges Poirault.

LEGISLATION WITH RESPECT TO PLANT DISEASES CAUSED BY FUNGI.

(Concluded from page 53.)

WITH regard to the well-known potato disease (Phytophthora infestans), it may be that the special difficulty mentioned by Mr. Massee exists in this case. But the matter is not so hopeless as to justify this writer's words as to the impossibility of legislation in connection with the disease. It would be the duty of the Government of a country where this disease is unknown to endeavour, by passing a law prohibiting the importation of potatos from a country where the disease was known to exist, to preserve their country's immunity. This duty has just been performed by the Government of New South Wales, who are trying to protect potatos in their country from this very disease by a law passed in March, 1905, prohibiting the importation of potatos from New Zealand, where the potato disease has lately appeared.

Turning now to the general question of legislation and the control of plant diseases caused by fungi, it must of course be admitted that in very many cases, as Mr. Massee says, legislation cannot, at all events at present, be called into operation. This is no new view, however, but was put forward very clearly by Prof. B. T. Galloway (then Chief of the Division of Vegetable Pathology) at the National Convention for the Suppression of Insect Pests and Plant Diseases by Legislation, held at Washington, U.S.A., in 1897. Prof. Galloway expressed his opinion then that the greater portion of our plant diseases and insect pests cannot be reached by legislation: "A vast number of fungus diseases are almost as universally distributed as the host-plants themselves." Among such diseases rust is mentioned. "It would be manifestly as impossible to control such enemies by legislation as it would be to control the dust of the air."

But Prof. Galloway goes on to say: "Of course, there may be special cases where laws would be an advantage. It may sometimes happen that a dangerous pest is imported, and, although established in one or more places, might be quickly and easily eradicated by prompt and intelligent action supported by proper legislation."

I contend that the Gooseberry disease mentioned above is eminently a case where legislative action by the authorities is required. As a general principle, too, whilst ready to admit that with our present imperfect knowledge of the life-history of many fungi, it is impossible in many cases to control, by legislative means, the diseases they cause, I maintain that each disease requires the most careful consideration by itself to ascertain whether its control or prevention lies within the scope of legislation.

For a demonstration of the economic importance of vegetable pathology, and the use of legislation in safeguarding the interests of agriculturists and horticulturists, we have to turn in the first place to the United States. Other countries are now following the example set by the United States in controlling the spread of fungus plant diseases by legislation; we may mention the "Orchard and Garden Pests Act" of New Zealand, and the laws passed recently by New South Wales, Sweden, and Finland. From an article by Prof. E. F. Smith, of the U.S. Department of Agriculture, Division of Vegetable Physiology and Pathology, on the subject of "Legal Enactments for the Restriction of Plant Diseases," we find that in 1896 no fewer than 14 States possessed legal regulations for the prevention of plant diseases. The same high authority, in his exhaustive governmental report on the fungus disease known as "Peach Yellows," spoke strongly in favour of employing inter-State legislation to prohibit strictly the importation of peach trees from the Eastern United States into California. The remarks made here* by Prof. E. F. Smith, on the subject of "Restrictive Legislation," may be commended to the readers of this journal.

The following is an instance of the good effects brought about by the passing of a State law in connection with fungus plant diseases. The following words are contained in a report made by the Secretary of the Californian State Board of Horticulture: "Prior to 1880, California had no State legislation for the protection of the horticultural interests, and the Eastern and Southern nurserymen found our State a convenient dumping ground for all their pest-ridden trees, until we became alive to the danger before us through yearly loss, and secured the creation of the State Board of Horticulture and the enactment of protective horticultural legislation. . . . What was the result? Each nurseryman pays strict attention, and sees that his stock is clear before shipment, else it will be quarantined at destination, and a certificate of inspection before shipment must accompany each shipment."

Mr. Massee, in the concluding part, asks that his article may not be taken as a tirade against legislation. Except for this warning, there certainly might have been this danger. If all the assumptions made by Mr. Massee were warranted scientifically, and if, as Mr. Massee apparently believes, the serious epidemic fungus diseases are seldom in evidence or capable of detection at the time of introduction into a new country, and that therefore it would be necessary for the Government to plant out and supervise for a year all imported living plants (surely a *reductio ad absurdum* of any proposed legislative action), the authorities might indeed have reason to believe legislation impracticable.

In conclusion, with reference again to the question of dealing with the American Gooseberry mildew—at the present moment a vital and pressing question—I cannot help expressing my regret that Mr. Massee should have published statements calculated to dissuade the Authorities from employing legislative measures to stamp out this disease. It is the more regrettable, since at the present time there is a movement on the Continent to establish an international bureau of plant pathology, in connection with an international institute of agriculture.† If our Government will support this movement, we may hope that at length the question of legislation and the control of plant diseases will receive the careful and scientific attention it has received in other countries. *Ernest S. Salmon, South-Eastern Agricultural College, Wye, Kent.*

* Bull. 9, U.S. Department of Agriculture, Section of Vegetable Pathology.

† See my previous article in this Journal, Oct. 1905; also *Fortnightly Review* for November last.

CULTURAL MEMORANDA.

ACHIMENES, TYDÆAS, &c.

THE time of the year has arrived when a commencement may be made in the preparation of a small quantity of the stolons of Achimenes for early flowering in the stove and other warm houses. Providing the last season's masses are still undisturbed in the pots and pans in which the plants flowered, and this is always the best practice, a few of such varieties as may be desired should be shaken out of the soil, and the stolons collected and sized, the larger ones of about an equal size being reserved for starting into growth and treating as flowering plants, and the weaker to grow on as stock plants, which may or may not flower satisfactorily, but will certainly increase in size, becoming useful stolons the next year, Achimenes being mostly natives of tropical South America need a considerable amount of artificial warmth at the beginning of the year, and a free and porous soil, together with ample drainage, much water at the root being essential at the height of their growth. The best receptacles in which to start the stolons are pans or boxes of not more than 2 inches in depth, nearly half of which may be occupied with crocks, and the upper half with a coarsely-sifted mixture of leaf-mould and peat in equal proportions, together with a fair quantity of sharp sand. Having pressed down the soil evenly and firmly, place the stolons at about an inch apart, and rather more if these are of large size. In the case of A. picta, a pretty scarlet-flowered species, these are less than ½-inch in the longer diameter, and require a correspondingly smaller space. The stolons being duly placed on the soil, should then be covered with the compost to the depth of ½-inch, this being likewise pressed slightly and made smooth and level, the pans, &c., placed on a shelf in the stove, stove-pit, or propagating house, in which a night temperature of not less than 60° *Fahr.* is maintained, no water being afforded unless the soil should have become very dry, till the shoots have pushed through the crust; even so, a slight dewing over with a fine rose syringe is better than an application with a watering can. In this connection it may be stated that overhead syringings need not as a rule be indulged in with any of this family of tropical herbs, and are as a rule positively injurious to the velvety leaves of Gesneras, to Tydæas, &c.; indeed a dry, rather arid atmosphere suits these plants much better than a moisture laden one.

As basket plants for summer flowering Achimenes are excelled by few others, and by none having the same colours in their flowers. They succeed in the ordinary greenhouse after June is out, and in the southern parts of the country can be employed in open verandahs and balconies. Those which lend themselves to basket culture the more readily are such as possess long trailing stems as A. longiflora, A. l. alba, and A. patens, A. Rollissoni, a cross between A. gloxiniæflora and A. Scheeri and A. Gibsoni. Several varieties are of more stocky growth and are in consequence well adapted for cultivation in pots and pans, being supported by means of thin twigs and sticks. All the species may be rendered bushy in habit by having the points of the growths nipped out once or twice during the early season of growth, these points rooting readily in heat if an increase of stock be necessary.

TYDÆAS.—These plants, which inter-cross readily, need much the same sort of treatment as Achimenes in the early stages, and more warmth to flower them successfully. There are now many varieties due to the efforts of Continental hybridists, more especially of M. Roezl, who raised numerous crosses in M. Van Houtte's nursery at Ghent. These plants seem to be dropping out of cultivation in this country, although handsome in flower and foliage, and of easy cultivation. The starting of the stolons is better done at the end of February and in the months of March and April, the method being the same as in the case of Achimenes. *F. M.*

AZARA GILLIESII.

(For Illustration see p. 77.)

THE Azaras are very attractive evergreen shrubs, natives of Chile, and hardy in most parts of England. A. microphylla is remarkable for its leaves, which are of two different sizes on the same branches. A. Gilliesii has larger leaves, not unlike those of a holly. The small yellow flowers are borne in axillary spikes. We are indebted to Messrs. Paul and Son for a specimen. In their nursery at High Beech, the home of many rarities, the plant is quite hardy and is now showing flower. The Azaras are included among the Bixaceæ.

JOINT RAILWAY AND PARLIAMENTARY COMMITTEE.

The following Copy of a Memorial presented to His Majesty's Ministers in the Cabinet has been sent us for publication :—

Tavistock Hotel,
Covent Garden,
London, W.C.
January 10th, 1906.

WE, the undersigned, representing the Producers and Distributors of Perishable Foods on the above "Joint Railway and Parliamentary Committee," beg to call your attention to the fact that the Industries we represent, although of National importance, are becoming more and more at the mercy of the Railway Companies.

This arises, partly from the Railway Companies acting in concert, as though the Legislature had sanctioned a vast Parliamentary Monopoly or enormous Trust or Combine, partly from the Railway Companies refusing to recognise the enormously increased volume and altered conditions of traffic in our trades, and the necessity for lower rates and increased facilities, and more especially from the gradual nullification of the safeguards the Legislature intended to provide for Traders.

The result of this is, that our industries are crippled in many instances by the increase of rates and the withdrawal of facilities, when lower rates and increased facilities should in justice be given.

We, therefore, ask you to do all in your power to help us to obtain by Act of Parliament, a Tribunal with powers :—

1.—To alter and amend the already out-of-date Classification.

2.—To deal as intended by the Legislature with increases in rates and withdrawal of facilities.

3.—To deal with claims for reductions in rates and increase of facilities.

We ask that the Tribunal be so constituted as to give Traders an inexpensive and practical procedure.

As matters stand now, we are powerless to obtain redress even by fighting the combined Railway Companies of the Kingdom in the Law Courts at enormous cost, and admittedly the time has arrived for new Legislation.

We feel sure you will agree with us that the fostering and development of Home Industries is, at the present moment, a far more vital question than many others that may be brought before you, directly affecting, as it does, the prosperity of the whole Country.

We also claim that better Railway facilities for these trades will materially help to solve the Unemployed question, and by still further increasing the volume of traffic will substantially benefit the revenues of the Railway Companies themselves.

If you can conveniently appoint a time for a Deputation from our Committee to wait on you and lay our views before you, we should esteem it a favour.

(Signed) :—Colonel Charles Wigram Long, M.P., D.L., President, The National Fruit Growers' Federation; H. Isaacs, President, The Green Fruit Section, The London Chamber of Commerce; David Rose, President, The National Federation of Meat Traders' Associations, Incorporated; William Cooper, President, the Central Markets' Meat and Poultry Association; P. J. Chirgwin, President, the Federation of Grocers' Associations of the United Kingdom; W. Poupart, President, The Market Gardeners', Nurserymen and Farmers' Association; Stuart H. Low, President, The Horticultural Trades' Association of Great Britain and Ireland; The Hon. and Revd. A. C. Baillie Hamilton, President, the Guernsey Growers' Association; H. Becker, President, The Jersey Growers' Association; E. Rochford, President, The English Grape Growers' Association; Geo. Monro, President, The National Federation of Fruit and Potato Trades' Associations, Incorporated, and of the Joint Railway and Parliamentary Committee.

THE WEATHER AT ROTHAMSTED IN 1905.

According to the meteorological records at the Rothamsted Experiment Station, Hertfordshire, for the year 1905 just past, the year as a whole has shown a temperature slightly above the average of the past twenty-seven years. The only cold months were August, September, October, and November, the two latter being the most unseasonably cold, while the months of February, March, and July were the most unseasonably warm.

The total rainfall for the year 1905 amounts to very nearly 26½ inches, which shows a falling off from the average of the past 52 years at this station of about 1¾ inch. There were no very wet months, March and June showing the greatest excess, while October and December recorded the most deficiency. The sun shone brightly throughout the year for a total of 1,579 hours, which is 10 hours less than the average in this neighbourhood for the past twelve years. The sunniest months were May and July, while the greatest deficiency of bright sunshine was experienced in April.

The following table shows the rainfall of each month for the past year at Rothamsted, with the average amount of rainfall for each month of the previous 52 years (1853-1904), and the difference of 1905 above or below the average record :—

Rainfall at Rothamsted, Herts, for each month of the year 1905, the total for the year, the average rainfall of 52 years, 1853-1904, and 1905 above or below the average.

Months.	Rainfall 1905	Average Rainfall of 52 years	1905. Above or below the average (1)
	Inches	Inches	Inches
January	1·34	2·38	— 1·04
February	0·95	1·81	— 0·86
March	3·57	1·81	+ 1·76
April	2·22	1·85	+ 0·37
May	1·13	2·22	— 1·09
June	4·05	2·36	+ 1·69
July	1·47	2·58	— 1·11
August	3·46	2·66	+ 0·80
September	2·25	2·49	— 0·24
October	1·67	3·12	— 1·45
November	3·23	2·56	+ 0·67
December	1·10	2·31	— 1·21
Yearly total	26·44	28·15	— 1·71

(1) The sign in the last column (+) signifies above the average, and the sign (—) below the average.

The rain gauge, which is one-thousandth part of an acre in dimension, stands two feet above the surface of the ground, and is about 420 feet above sea level. The above data shows a total of 26.44 inches of rain for the twelve months of the year 1905, against an average of 28.15 inches, which is 1.71 inch less than the average record for this district extending over a period of 52 years. In other words, the deficiency of rain for the year amounts to 172¾ tons of water on each acre of land, and taking the rainfall for the last four months of the year, there is a falling off of the average for the same period in the last 52 years by 2¼ inches, which is equivalent to a loss in our underground water supply of 50,450 gallons on each acre of land.

The next table shows the mean temperature in the shade for each month of the year 1905, with the excess or deficiency at the Rothamsted Station during the past 27 years, 1878-1904; also the number of hours of bright sunshine recorded for each month in the past year, and the number of hours above or below the average for the past 12 years, 1892-1904. Mean temperature and bright sunshine, at Rothamsted, Herts, for each month of the year 1905 :—

Months	Mean Temperature		Bright Sunshine	
	1905	Above or below Average	1905	Above or below Average
	Degrees	Degrees	Hours	Hours
January...	37·4 +	+ 0·8	84	+ 37
February	41·2	+ 3·0	78	+ 10
March	44·1	+ 3·3	126	+ 14
April	45·6	0	101	— 70
May	51·4	+ 0·2	244	+ 48
June	58·5	+ 1·1	169	— 34
July...	64·2	+ 3·4	265	+ 43
August	58·7	— 1·2	180	— 25
September	54·7	— 1·1	129	— 31
October...	44·5	— 3·5	114	+ 8
November	40·1	— 2·4	60	+ 2
December	39·2	+ 1·5	30	— 13
Yearly mean or total	48·3	+ 0·4	1579	— 10

The mean temperature for the year is 48.3°, or 0.4° above the average record. Seven months gave an excessive amount of warmth, while four months gave a deficiency.

The month of April was neutral, giving exactly the temperature of the past 27 years, viz., 45.6°. There were 66 nights when the minimum temperature fell below the freezing point of water, the aggregate amount of frost for the year being 216°. January recorded 18 nights of frost, with an aggregate record of 102°, November 14 nights with an aggregate amount of frost of 49°, and December 10 nights with 19°. In fact, December was exceptionally dry, calm and warm, with no cold worth mentioning. There was one night of frost in May, which cut down all the Potato haulms to the ground. There was frost in eight months out of the twelve. There was probably an aggregate depth of about 8 inches of snow recorded in this neighbourhood throughout the year. The bright sunshine was in excess from the average record during seven months, and under the average for the other five months. The sun shone on an average about 4 hours 19 minutes each day throughout the year, which is a few minutes per day below the average record for this open country district. *J. J. Willis, Harpenden.*

KEW NOTES.

Jacobinia Penrhosiensis ×.

When first exhibited some 50 or 60 years ago, this garden hybrid was of more botanical interest than it is to-day. At that time the two parents were known under different generic names, so that the hybrid was considered to be a bi-generic one. It was obtained by crossing Libonia floribunda with Sericographis Ghiesbreghtiana. Modern botanists having included the two parents in the same genus Jacobinia, the hybrid is now of less scientific interest. Several years after it was exhibited under the name of Libonia penrhosiensis, M. Linden made the same cross, and not being aware of its previous introduction gave it the name of Sericobonia ignea, a name indicating its generic origin. He withdrew his name on learning of the earlier one, but even now it is more generally known on the Continent by Linden's name.

The plant is more robust than the seed-bearing parent, the leaves are larger, the corolla of the flower longer and brighter in colour, there being a greater preponderance of red in proportion to the yellow, showing distinctly the influence of the pollen parent.

As a plant for greenhouse decoration in winter it is very useful. It may be readily propagated by cuttings inserted in spring, and old plants may be cut back after flowering and grown on, affording them a little extra heat until new growth has been made. In a few years by this method good bushes may be obtained. Plenty of fresh air and sunlight are necessary to ripen the wood for flowering in the following season. A small group of plants have been flowering in No. 4 greenhouse. *A. O.*

Interesting Orchids in Flower.

Amongst the numerous well-known species of Orchids now flowering are many that are less well-known, some of which are very beautiful, and others that are of exceptional interest. None more so, perhaps, than Dendrobium capituliflorum, which is very distinct from the typical Dendrobium. It is a species from New Guinea, with a growth about a foot in length, rather stout at the base, tapering to the apex; the flowers are borne in dense globular heads, containing about 20 small creamy-white blossoms. The Burmese D. luteolum is also worthy of note; the large pale-yellow blooms are very pleasing. Tainea viridi-fusca attracts attention with its erect spike of yellow-brown Dendrobium-like flowers. One of the most charming hybrids now in flower is Lælio-Cattleya Lydia of a delightful shade of pale-yellow colour. Amongst the Masdevallias, the hybrid M. Rushtoni is one of the best. M. abbreviata and M. polysticta are very charming with their numerous small white-speckled flowers. Seraphyta multiflora and Octadermia serratifolia represent two genera that are rarely seen. Mystacidium (Angræcum) sesquipedale is represented by a good specimen

carrying seven of its remarkable large white waxy flowers. Phalænopsis rosea, P. gloriosa, P. denticulata, and P. Luddemanniana are amongst the species of this beautiful genus, now in flower. Saccolabium bellinum is a species which excites the admiration of all; a healthy little specimen is now carrying ten blooms. Vanda Watsoni is a pretty little species with slender, terete leaves and pure white flowers, having a large fringed lip. It was recently introduced from Annam by Messrs. Sander & Sons. The elegant Epidendrum Endresii has three growths, with a total of 36 flowers. It is undoubtedly the pearl of the genus, and all too rare. E. Wallisii is also very fine, with a tall, stout growth, having nine clusters of blossoms. E. polybulbon is a pretty and distinct species with Bulbophyllum-like growths. The flowers are about 1 inch in diameter, linear sepals and petals, and a pure white cordate-shaped lip. E. Allemanii belongs to the E. fragrans type, and has white, vanilla-scented blooms of good substance, lasting for a considerable time in a fresh condition. Cynorchis compacta is a pretty little terrestial Orchid from South Africa, with erect spikes of violet-spotted white flowers. Small pans of a dozen flowering growths are a welcome addition in the cool house at this season. C. Lowiana is a larger growing species from Madagascar, having a prominent magenta-coloured lip. Xylobium corrugatum is a curious small-growing Orchid, with slender, erect scapes, bearing usually four rather small yellow-red flowers. Pleurothallis Roezlii is now very fine, and is without doubt the best of the large genus to which it belongs. Brassavola Martiana is a free-flowered species with a prettily fringed lip. Listrostachys hamata is a very distinct species, having a short spike of large pearly-white flowers, in which the sepals, petals and the lip are exactly alike in shape, giving the flower a "regular" appearance. The very rare Odontoglossum retusum is represented by a small plant bearing two erect spikes; it is a small bulbed species with long, narrow leaves. The flowers are rather smaller than those of O. Edwardi, and are of an orange-red shade of colour. *W. H.*

FRUIT REGISTER.

APPLE CHARLES ROSS.

Now that many gardens contain trees of this variety of a fruiting size growers will be able to judge of its merits. From five small pyramid-shaped trees grafted on the Paradise stock I gathered last season some 50 very fine quality fruits of excellent flavour, but of much too large a size for dessert purposes. I think the Fruit Committee of the Royal Horticultural Society would do well to class this variety with Blenheim Pippin, Gascoyne's Seedling, and other varieties of that type, in order that it may be exhibited both as a culinary and a dessert variety at the autumn exhibitions. It is doubtless a very fine Apple and well worthy to perpetuate the name of the veteran fruit grower who raised it. I am forwarding two fruits. *Chas. Page, Dropmore Gardens, Bucks.*

[The fruits were exceedingly handsome, but they possessed no flavour, and the flesh was dry and mealy. They had undoubtedly been kept too late in the season.—ED.]

FIG. 34.—LOCKINGE PARK: A GLIMPSE OF A STREAM IN THE PLEASURE GROUNDS.

(See page 67.—From a photograph by W. J. Vasey, Abingdon.)

FORESTRY.

CLIMATE AND FORESTRY.

FOR me, who have had to do with the question of naturalisation of exotic forest trees during the last quarter of a century, there can be no doubt as to there being a great difference between our climate and that of the British Isles; but it turns out to be quite in favour of the latter. And so I can only corroborate Sir Herbert Maxwell's statement, as well as that of Dr. Augustine Henry's, published in the *Gardeners' Chronicle*.

Let me add a few words. A good many of the north-west Conifers, as for instance the Douglas Fir, grow in a most remarkable way with us—better than our own indigenous trees—but this is because the geographical range of this tree is so very large. It extends, according to Professor Sargent, over 30 degrees of latitude.

But to give in a few words the principal difference between the English climate and our own (and that in these cases it is not a matter of soil, but solely one of climate) I may state that you will never see in Germany such splendid avenues of Cedrus deodara and Araucaria imbricata as those at Bicton and Dropmore, nor such specimens of Taxodium sempervirens and the Mexican Conifers as Pinus Hartwegi, nor the beautiful Abies morinda. I could easily make up a list of 100 plants, trees, and shrubs which grow luxuriantly in England and which will never stand our Continental climate. I know the British Isles pretty well and the wonderful growth of trees in those islands. There is nothing on the Continent to be compared with the growth of trees in England. *John Booth, Corresponding Member of the R.H.S., Gross-Lichterfelde, near Berlin.*

THE ROSARY.

ROSARIUM.

WE have before us the first number for the year of a journal devoted to Rose Culture and to the interest of the society known as "Nos jungunt Rosæ" (Roses unite us all). The title of the society is, as is customary in Holland, expressive of its aims and objects. The editorship is confided to Mr. P. L. Baudet, of De Bilk, and Mr. J. K. Budde, of Utrecht, whilst the publisher is M. E. E. M. I. Kromme, Hartingstraat No. 24, Utrecht. The subscription price for foreign countries is 3 florins (5 shillings).

The Rose exhibition is to be held at Zeist on July 25 and 26. A photographic illustration of Rose Souvenir de Jean Ketten H. T. is given with the present issue. The text is in Dutch. What matter? "Nos jungunt Rosæ."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

NICOTIANA SANDERÆ.—This proves to be a valuable plant for flowering in the winter months. Some plants that were late in commencing to flower were lifted about the middle of October and put into pots. They were given a little care and attention, and soon recovered from the check. They have flowered ever since, and at the present date, January 6, they are still in full bloom and likely to continue so for some time to come. The plants have been kept in an atmosphere of the temperature of 45° to 55°. Air has been admitted to the structure whenever the weather was favourable. The colour of the type is useful in winter, when bright flowers are none too plentiful. The colour improves under artificial light, and the plants have a light and graceful appearance when used for the decoration of the dinner table. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

CLEANSING HARDY FRUIT TREES.—Owing to the exceptionally mild weather experienced this season, fruit buds of all kinds are in a very forward condition, making it imperative that all cleansing operations should be taken in hand forthwith. In many gardens and fruit-orchards one still sees trees infested with moss and lichen, which form a hiding place for all kinds of insect pests. No better winter-dressing for fruit trees can be applied than the caustic soda and pearl-ash wash, which substance can now be obtained from the horticultural sundriesmen in tins ready for mixing, and with instructions for using. Persons desirous of mixing the components themselves can use the following quantities with safety:—1 lb. caustic soda, ¾ lb. of pearl-ash, 10 oz. of soft soap, and 10 gall. of water, the last-named at a temperature of 120°. This mixture will destroy all insect pests with which it comes in contact. I strongly urge all fruit-growers in whose plantations winter moth and scale insects are troublesome to use alkali dressing at the present time, as the benefit of the labour entailed now will be apparent in the coming summer. It may be necessary in the case of trees on which the woolly aphis, American blight, has obtained a footing to dress the affected parts two or three times at intervals of a week, working the solution well in with a stiff painter's-brush. Rubber gloves must

Fig. 35.—Azara gilliesii: A, young flower from the side; B, flower further expanded; C, corolla from below (magn).

be worn by the operator to protect the hands, as the mixture is very caustic, and the use of an old coat and a sack apron are recommended. The Abol syringe is an excellent tool for applying the mixture to dwarf trees, but for standard trees a garden engine should be used, choosing a still day for the operation. *C. Page, Dropmore Gardens, Bucks.*

THE HERB GARDEN.—In order to make certain of a continuous supply of herbs, a plantation should be made of all varieties that are likely to be required. These should be properly labelled so that there will be no excuse for anyone making a mistake in gathering a particular herb. Many of the species can be divided in the same way that herbaceous plants are treated in order to form fresh stock. The ground should first of all be trenched and given an application of manure. More often than not, some out of the way spot is selected for herbs, and they afterwards suffer neglect, but a good herb border should be an interesting feature of any garden. Seed may be sown later, of all varieties, and especially of such sorts as sage, &c., that cannot be divided. There is no hurry to sow just yet. *Jas. Gibson, Welbeck Gardens, Worksop.*

SHOW OF FLOWERING CARNATIONS.—With reference to previous correspondence on this subject may I say that February 13 has been fixed by the Council of the Royal Horticultural Society for this show? Three classes of exhibits have been suggested, viz., those occupying 5, 15 and 30 feet of tabling respectively, thus providing for the requirements of small, medium and large growers. Exhibits, which may be either Tree Carnations, or Malmaisons, or both, may consist of cut bloom, plants, or both together, with Carnation foliage, or other small foliage plants, The Council will grant medals, etc., to any of the groups, classes or exhibits which they may think worthy of that distinction. They will also give certificates to blooms of new varieties of Tree Carnations or Malmaisons, of sufficient merit "not yet in Commerce." Not fewer than six blooms to form an exhibit. Notification of intention to exhibit and of space required should be sent on or before Thursday, February 8, to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W. *Hayward Mathias, Thames Ditton, Surrey. January 19, 1906.*

FIFTEEN POUNDS ANNUAL RENT PER ACRE FROM TIMBER CROPS.—It is curious reading the opinions of doubters about the unsuitableness of our climate for growing timber with such certified examples to be seen as that furnished by Dr. Nisbet, in his recently published *Forester*, regarding the Douglas Fir at Scone. It is stated that a Perth timber merchant offered to buy the whole Taymount plantation at £200 per acre when the trees were 40 years old from seed; and that from 1888 up till quite lately the annual increment alone, per acre, amounted to 400 cubic feet of timber—merchant's trunk measure—worth £15 per acre at 9d. only per foot. I would like to hear of a regular rent like this from any other crop in any climate. *J. Simpson.*

IRIS TUBEROSA.—When I was a boy living in Devonshire I grew this well in a shaded and sheltered situation. I have it now in this garden in a somewhat similar condition, but much the oldest group is in a wood, greatly overrun with ivy and shaded by trees. I have known this group for more than 60 years, and it must then have been there many years. The plant evidently requires shade, shelter, and good loam to succeed well. This delicate and interesting plant is not, however, a very free bloomer. *W. S. L. Pinwill, Trehane Probes, Cornwall, January 29.*

EARLY SPRING OR LATE AUTUMN?—At present Rosehill garden at Falmouth has, in addition to the ordinary spring plants, the following in flower in the open air:—Acacia dealbata, A. longifolia and A. lophantha, Abutilons megapotamicum, Boule de Neige, Crusader, and Prince of Wales; Auricula, Anemone, Berberis Darwinii, Camellias, Chrysanthemums, Chionodoxa sardensis and C. Lucilliæ, Clematis balearica, Cyclamens coum, ibericum and persicum; Daphne vera indica, Desfontainea spinosa, Diosma ericoides, Diplacus glutinosus, Eccremocarpus scaber, Erica carnea, E. codonodes; Erysimum, Erigeron, Eryngium pandanifolium, Eupatorium micranthum, Everlastings, Fuchsias, Fragaria indica, Geraniums, Grevillea rosmarinifolia, Hydrangeas and Hellebores in variety, Iberis sempervirens, Iris stylosa and I. reticulata, Lithospermum prostratum, Musa japonica (Banana), five plants in flower and fruit; Melianthus major, Marigold, Marguerites, Nasturtiums, Narcissus, Nicotiana Sanderæ, Olearia Gunniana Omphalodes verna, Polyanthus, Pansies, Pittosporum Tobira, Roses in variety, Schizostylis coccinea, Spiræa ericoides, Squills, Stocks, Saxifraga crassifolia, Skimmia japonica, Sparmannia Africana, Senecio grandifolius 8 feet high, with flower heads from 12 to 18 inches in diameter, S. Petasites, Thalictrum, Triteleia uniflora, Tritoma, Vinca, Wallflowers and Yuccas. The following have been in flower all the year round:—Cestrum (Habrothamnus) fasciculatum, Coronilla glauca, Escallonias, Genistas, Teucrium fruticans and Veronicas. *Howard Fox, January 27, 1906.*

PLANTS FOR ASSOCIATION WITH RHODODENDRONS, &C.—I have found the Iceland Poppy (Papaver nudicaule) one of the best plants for this purpose, especially in the case of newly-planted narrow beds or borders in which the Rhododendrons have a clear stem of 1½ to 2 feet in length. The Shirley Poppy is also suitable, but this plant will not succeed in the shade, and is more likely to be affected by drip from the Rhododendrons after rain than are Iceland Poppies. For larger beds giant annual Poppies can be used. Salpiglossis is also very useful, and makes an effective combination. Tree Lupins, providing the soil is a loam and of not too light a nature, are in some cases very good subjects for planting in beds of Rhododendrons. Iceland Poppies and Salpiglossis should be raised in early springtime, and be planted out when the general bedding work is undertaken. Sow the giant Poppies where they are intended to flower. Tree Lupins transplant much better from pots than from a seed bed. *C. Ruse, Munden Gardens, Watford.*

THE PLANTING OF VINES.—Vines intended for planting should be dealt with as soon as they show signs of growth. Carefully remove all the soil from their roots by washing them in tepid water. Make the holes intended for their reception wide enough to allow of the roots being spread in a horizontal position from the stem, placing them so that the topmost roots are just below the surface of the ground. When an inside as well as an outside border exists place most of the roots in the direction of the inside border. Water will, as a rule, not be required until the vines are growing freely, neither should any artificial heat be given until the young growths are at least 1 foot in length. The vines should not be cut back, and all the buds should be allowed to break into growth. Select the strongest "break" for the leading shoot and pinch out all above it, but preserve all shoots below the leader. When the auxiliary growths develop eight leaves they should be stopped. Most of the growths below the wires will need securing to sticks placed in the border. Plenteous side growths will not be detrimental, but, on the other hand, will be a material aid in strengthening the stem, for abundance of healthy, exposed foliage means plenty of roots, and consequently a strong and healthy vine. As the season advances admit, in fine weather, plenty of outside air. Remove all bunches of fruit that appear, and in warm weather syringe the vines and close the house about 4.30 p.m. that the atmosphere of the vinery may remain damp during the night. When all the leaves have fallen prune the side shoots close to the stem, leaving the rod, if strong and well ripened, some 6 or 8 feet in length, but should it be weak cut back to a good plump bud. After being pruned tie the vines in a horizontal position, and allow them to remain in that position until the following spring. *C. Ruse, Munden Gardens, Watford.*

EARLY FLOWERS.—In the American Garden here that bright coloured Rhododendron Nobleanum is now in full bloom, and is a charming sight. R. præcox, that delightful little hybrid between R. ciliatum and R. dauricum, of rosy purple colour is opening its flowers, and in one or two extra warm spots has been in flower for several days; it makes a very charming bush from 2 to 3 feet in height, and is well adapted for cultivation in warm positions in the S.W. counties. If it is necessary, the plants may be easily protected, by means of a few stakes stuck in the ground in tripod fashion, and a mat or piece of stout tiffany wrapt around them at night. Primrose Miss Massey, bright red, has been in flower in the Alpine garden for some time past—as have several other white and purple varieties. Iris stylosa is flowering very freely, and Narcissus minimus is giving a touch of colour. Erica carnea and alba are also flowering freely; while towering above them is the lovely Erica codonodes—plants of these, 6 feet in height, are beautiful and well worth the notice of all lovers of out-door gardening. Grevillia rosmarinifolia has been in flower for a considerable time, its pretty red flowers are very attractive, and it is now a conspicuous figure in the American Garden. Chimonanthus fragrans has been perfect this season. Jasminum nudiflorum, with its pretty yellow flower, is charming upon walls and growing around trees and over other bushes. Anemone blanda is flowering freely. *W. A. Cook, Leonardslee Gardens, Horsham. January 27.*

CANKER IN APPLE TREES.—The variety Ribston Pippin is liable to this disease no matter what the locality, or the kind of soil the trees are growing in, but the conditions are much worse where the roots of the trees come into contact with an unsuitable subsoil, or if there is only imperfect drainage. All badly affected shoots or branches should be cut clean out, but slight attacks may have the cankered portion removed with a sharp knife or chisel and the wound be painted over with Stockholm tar, keeping it away from the bark as much as possible. We use this tar for all Conifers when a branch of any size has to be removed, and the bark quickly begins to heal over. Out of about 60 varieties of Apples grown here only four exhibit signs of canker, namely, Devonshire Quarrenden, Bismarck, Gascoyne's Scarlet Seedling, and Ribston Pippin. *J. Mayne, Bicton.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 23.—*Present*: Dr. M. T. Masters, F.R.S. (in the chair); Messrs. Massee, Saunders, Gordon, Bowles, Michael, Nicholson, Holmes; Rev. W. Wilks; and F. J. Chittenden (Hon. Sec.).

Apples with ring-like split.—Mr. MASSEE said that the cracks and markings on the surface of the Apples shown by Mr. SPENCER PICKERING, F.R.S., at the last meeting, were caused by the well-known parasite Fusicladium dendriticum. This fungus, however, was not at all concerned with the abnormal constriction of the fruit.

Clematis stem cracked.—Mr. MASSEE also reported that in the Clematis stems shown by Mr. G. S. SAUNDERS, F.L.S., there was an excessive development of callus excited by the rupture of the stem. Such rupture is not caused by a fungus, and the origin is not apparent. It was suggested that frost was the cause of the splitting.

Holly leaves blistered.—Some Holly leaves with the well-known disfigurement of blisters were received from Milverton, N.B., upon which Mr. SAUNDERS reported as follows: "The coloured blotches on the leaves are caused by the grubs of the Holly fly (Phytomyza aquifolia), a very common insect, which lays its eggs just underneath the skin of the leaf. The young grubs at once begin to feed on the inner substance of the leaf, and cause the blister-like blotches. When the grubs become chrysalides their heads are partly pushed through the skin, so that when the fly emerges it at once does so into the open air. It is almost impossible to recommend any remedy, no insecticides can be made to reach the grubs or chrysalides, and it is a hopeless task to try to catch the flies. Spraying the leaves with a solution of paraffin emulsion at the time when the flies were wishing to lay their eggs would probably deter them from doing so. This operation is performed in May or June, according to the season, and it is very difficult to know when to spray. Picking off and burning the infested leaves is the most practical remedy. The minute pustules and depressions which are present on many of the leaves are not caused by this insect." Members of the committee considered that the small depressions were due to the puncturing of the leaves by the spines of other leaves in windy weather.

Beans poisonous.—Mr. HOLMES, referring to the cases of poisoning by roots of Runner Beans, recently brought to the notice of the committee, mentioned a case where a herd of 26 cattle had been poisoned by beanmeal, and said that it could not be too widely known that uncooked beans of the genus Phaseolus contained prussic acid, and should on no account be eaten.

PLANTS EXHIBITED.

Debregeasia velutina.—Dr. MASTERS drew atten-

tion to a fruiting shoot of this plant shown by Messrs. VEITCH. The plant is a native of the Himalayas, and bears numerous small orange yellow Mulberry-like fruits in small clusters. The plant belongs to the Urticaceæ, and the fruits are edible, but "are not much appreciated." It was figured in the *Revue Horticole*, 1896, p. 321.

Hæmanthus magnificus.—This plant, with a large head of pinkish flowers, was shown by Mr. HUDSON.

Tulip Proserpine.—Mr. HORNE, of Thurstaston, near Birkenhead, sent two examples of this Tulip, each of which bore three flowers, one, as usual, terminal, and one springing from the axil of each of the upper two foliage leaves. The production of more than one flower on a stem of Tulip is not very unusual.

MANCHESTER & NORTH OF ENGLAND ORCHID.

JANUARY 11.—There was a good display of plants at the meeting held on the above date.

E. ASHWORTH, Esq., Wilmslow (gr. Mr. Holbrook), staged a nice collection of Lælia anceps, in variety. Noticeable among these were L. a. var. Ballantineana, L. a. var. grandiflora Chamberlain's variety, L. a. var. Schröderiana, and L. a. Bull's alba. (Silver Medal.)

A. WARBURTON, Esq., Haslingden (gr. Mr. Raven), exhibited several good Cypripediums. C. × Germain Opoix was one of the best, and received an Award of Merit; C. × Victor, and a distinct form of C. × aureum were also noted. (Vote of thanks.)

J. LEEMANN, Esq., Heaton Mersey (gr. Mr. Smith), sent some good plants, amongst which were Cypripedium × Winston Churchill, a supposed hybrid between C. insigne × C. Sallieri var. Hyeanum. (First Class Certificate.) Cypripedium × luminosum, from the same owner, received an Award of Merit.

O. O. WRIGLEY, Esq., Bury (gr. Mr. Rogers), staged some good Cypripediums, viz., C. × Kitty, C. × Ajax, and C. × Lathamianum, Wrigley's variety, each of which obtained an Award of Merit. (Vote of thanks for group.)

G. W. LAW-SCHOFIELD, Esq., Rawtenstall (gr. Mr. Shill), obtained an Award of Merit for Cypripedium × Edmond Lord, and a Silver Gilt Medal for a very nice group, principally of Cypripediums.

Messrs. CHARLESWORTH & Co., Bradford, staged a charming group of plants, consisting of good Odontoglossums, Cypripediums and Lælio-Cattleyas, Brasso-Lælia "Mrs. Gratrix var. magnifica" was given an Award of Merit, a similar award being voted for Lælio-Cattleya × Wellsiana.

Vote of thanks were awarded to Messrs. STANLEY & Co., D. MCLEOD, M. CH. VUYLSTEKE, H. Low & Co., and KEELING & SONS for exhibits. *P. W.*

JANUARY 25.—A capital exhibition was made on the above date.

A group was contributed by Messrs. CYPHER & SONS, of Cheltenham, to which a Silver Gilt Medal was awarded. Cypripedium × Charlesianum Cypher's variety was one of the best in this group, but was not shown for Certificate; C. × villexul, a cross between C. villosum × C. exul, obtained an Award of Merit.

G. W. LAW-SCHOFIELD, Esq., Rawtenstall (gr. Mr. Shill), obtained a Silver Medal for a group of Cypripediums and Odontoglossums, and an Award of Merit for Cypripedium × Euryades Low's variety.

Messrs. CHARLESWORTH & Co., Bradford, were awarded a Bronze Medal for a small and very select group of Lælio-Cattleya hybrids and Odontoglossoms.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Cypher), obtained Awards of Merit for two good Cypripediums, viz., C. × Rex and C. × Headlandianum, the latter a richly-coloured flower of great size.

A. WARBURTON, Esq., Haslingden (gr. Mr. Raven), obtained a First Class Certificate for Cypripedium × Mrs. Mostyn Chardwar variety, and C. × Watsonianum. C. × Germain Opoix was also shown.

E. ASHWORTH, Esq., Wilmslow (gr. Mr. Holbrook), exhibited Cattleya Trianæi var. Harefield Goliath, a wonderfully fine form. (Award of Merit.)

M. CH. VUYLSTEKE, Ghent, obtained a Silver Medal for a choice lot of Odontoglossum hybrids, including some very distinct forms of O. × ardentissimum, also O. × Wiganianum, a choice hybrid which obtained an Award of Merit.

Messrs. Low & Co., Enfield, obtained an Award of Merit for Cypripedium Venus Low's variety.

Messrs. H. J. CRAVEN and Messrs. KEELING & SONS received votes of thanks for exhibits. *P. W.*

SOCIETE ROYALE LINNEENNE ET DE FLORE, BRUSSELS.

JANUARY 21.—The first meeting, held on this date, by the conjoint Societies of Brussels, the Linnéenne and the Flore, was an unequivocal success.

Two hundred and thirty-one plants were exhibited. The jury awarded four diplomas of honour, 58 certificates, and 23 commendations. The jury was divided into four sections.

The principal awards on this occasion were made to Orchids from MM. Lambeaux, Vuylsteke, J. Hye de Crom, Duchesne, Lanthonie, Putzeys, Pauwels, Draps-Dom, Van de Putte, Madame Madoux, and others,

Botanical certificates were awarded to Habenaria procera, a species from the Congo, flowering for the first time in Belgium, and to Satyrium odorum from the Brussels Botanic Garden.

Chinese Primroses, Cyclamens, were shown, as well as Anthurium Rothschildianum Pteris metallica, Hymenodium crinitum, Eugenia myriophylla, Selaginella Africana, and Codiæum "Norman MacLeod," which all received recognition, as did also a collection of Pears, including Olivier de Serres, Besi de Chaumontel, Beurré Rance, Passe Crassane, Josephine de Malines, Bergamot Espèren, besides others less familiar to English readers.

The next meeting will be held in the Forestry Museum of the Brussels Botanic Gardens on February 18.

IRISH GARDENERS' BENEVOLENT.

JANUARY 25.—The members of the above society held their annual meeting on the above date, Mr. F. W. Moore, A.L.S., presiding over a good attendance. The annual report stated that the year 1905 would rank as one of the most successful experienced. The amount paid out in benefit (£30) was the largest on record; yet by economy of working expenses the balance showed a substantial increase. Numerous papers on gardening topics were read during the year, including those by Mr. Houston, of the Department of Agriculture. The members also enjoyed some profitable outings. The accounts showed a balance on hand of over £141, as against £121 the previous year. On the motion of the chairman, seconded by Mr. Longmuir, the report was unanimously adopted, after which Mr. Moore delivered a lecture on Palms.

BRITISH GARDENERS' ASSOCIATION.

At a recent meeting of the Ealing Gardeners' Mutual Improvement Society, Mr. J. Weathers, secretary of the British Gardeners' Association, delivered an address to the members upon the aims and objects of this association.

Mr. Weathers said one of the main objects of the association was to persuade all trained gardeners in the United Kingdom to unite into one strong association instead of remaining as powerless units isolated from each other all over the country.

Although the association had been instrumental in filling situations, Mr. Weathers maintained that, if the association only succeeded in weeding out from the ranks of the gardening profession all those who had no claim whatever to the title of gardener, it would have accomplished a work that would confer a lasting benefit upon real gardeners throughout the length and breadth of the land.

The question of wages and hours of labour were at present not of such paramount importance, and any attempt to make them the cardinal points in the association's programme would be likely to result in disaster. There would be a natural, and almost automatic, improvement in these directions in the course of time when trained gardeners of all grades agreed to work together for the common good.

No one could possibly object to gardeners uniting into combination for the protection of their common rights in the same way as doctors, lawyers, teachers, and members of many other professions.

Indeed, employers, and the public generally, should look upon the British Gardeners' Association as their best friend. At present hundreds of gardens were being ruined because the owners had no means of knowing whether the men they employed were really qualified gardeners or not. Even the person who employs a jobbing gardener one or two days a week should ascertain whether the man employed understands his business, otherwise, as is at present often the case, the ignorant individual who poses as a gardener will do as much mischief in half an hour as a bull would do in a china shop in the same time.

Eventually it was decided to form a branch of the association at Ealing, the members to decide upon a secretary at their next meeting.

GARDENERS' DEBATING SOCIETIES.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' MUTUAL IMPROVEMENT.—The annual meeting of the above association was held at the Athletic Institute, John Bright Street, Birmingham, on Monday, January 15, when the balance sheet was presented and the committee for the present year elected; it was also decided to hold a social gathering at the Colonnade Hotel, New Street, on February 21, to celebrate the 20th anniversary of the association. The balance sheet showed that the expenses for the year amounted to £68 4s. 2d., and the receipts to £56 9s. 8d. The assets amount to £366 15s. 4d. and include the Guthrie Investment £274 11s. 9d. Books in library are valued at £76 5s. 1d., etc., etc. The show of early Chrysanthemums was successful, and being helped by donations and a contribution from the general account of £2 19s. 6d. the expenses were covered. The following papers will be read during the present sessions: February 12—"The Primula." Mr. C. H. Herbert, The Nurseries, Hazelwood Road, Acocks Green; February 26—Discussion on the advisability of holding a Summer Excursion and Question Night; March 12—"The Dahlia." Mr. G. W. Kerr Manager to Messrs. Baker & Sons, Old Hall Nurseries, Codsall; March 26—"Alpine Plants." Mr. R. Cock, F.R.H.S. Horticultural Lecturer to the Staffordshire County Council; April 9—"The Carnation." Mr. W. H. Parton, Kingswood Grange, Hollywood; April 23—"The Pruning of Hardy Trees." Mr. E. Burden, The Nurseries, Billesley Lane, King's Heath. An Early Flowering Chrysanthemum and Dahlia Show will be held at the Botanical Gardens, on October 3 and 4. Schedules will be sent out in due course.

BOURNEMOUTH GARDENERS'.—At the meeting of the above Society, held on Tuesday, January 16th, at the Avenue Restaurant, Bournemouth, Mr. C. Nippard in the chair, Mr. J. Stevenson, Gardener to the Duke of Hamilton, Wimborne, gave a lecture entitled "Some Notes on Peas." The lecturer gave the results obtained from different varieties, and demonstrated the value of an intelligent selection of sorts best suited for particular localities. Mr. Stevenson exhibited a fine collection of Apples in 18 varieties.

CROYDON AND DISTRICT GARDENERS'.—This society opened their new session on Tuesday, 16th ult., when a paper on "Primulas" was given by Mr. G. Gumbrell, the Lodge Gardens, Widbury, Herts., from which the following extracts are taken. Sow the seed thinly about March and April, or it may be sown in August, and covered with sand or finely sifted soil. Place the seed pans in a temperature of 55 to 65 degrees, and cover them with glass to prevent evaporation. Constant care in watering must be exercised at all times. When the seedlings are vigorous place them on a shelf near the glass, and when big enough prick them off into boxes, where they may be allowed to gradually harden off. They may then be planted into 3-inch or 4-inch pots. When good root growth is made remove them into 5-inch or 6-inch pots for flowering, using a mixture of two parts loam, one part leaf soil, one part spent mushroom bed and sand, and a little mortar rubble or charcoal, with the addition of a small quantity of bone meal. A slight sprinkling of water night and morning should be given, and when the plants are well established give abundance of air, whilst protecting them from strong sunshine. Remove the flowering spikes till good root action is made. By the end of September they may be removed to the greenhouse and placed near to the glass, in which position they may be given plenty of ventilation but must not be allowed to experience cold draughts. Double varieties are best propagated from cuttings and should be treated in a similar manner to the seedlings. A good discussion by the members followed.

Close upon a hundred members and friends of the above society assembled at the Greyhound Hotel, Croydon, on Wednesday, 24th ult., on the occasion of the society's sixth annual dinner, which function invariably proves one of the most enjoyable of its kind. The Vice-chairman, Mr. G. J. Ingram, in submitting the toast of "The Society," said:—During the past year they had had 19 meetings, but only two discussions, and had also held a very successful spring show. He congratulated the society upon having a very capable working committee. They were also fortunate in having at their head a gentleman who always took a keen interest in horticultural matters. The secretary and the treasurer also received a word of praise. Mr. Boshier, Hon. Sec., on rising to respond, met with a cordial reception. He asked the members to attend in as large numbers as possible, and so encourage the lecturers and committee in their endeavours to make the society a success. After a good deal of consideration the committee had found it advisable to make provision for a microscope, which could be used at meetings and by the members.

REDHILL, REIGATE AND DISTRICT GARDENERS'.—A meeting of the above society was held on Tuesday, 16th ult.; Mr. W. P. Bound in the chair. A paper on "Vine Culture," written by Mr. C. E. Salter, was read in the writer's absence by his father, Mr. C. J. Salter, of Woodhatch Lodge, Reigate. The paper dealt in an able manner with propagation, pruning, ventilation, and the formation of vine borders. A discussion followed the paper. *F.C.L.*

EGHAM AND DISTRICT GARDENERS'.—At the meeting of this society held on January 17, Mr. A. Sturt in the chair, Mr. W. Swan, of Thornecote Gardens, Staines, read a paper on "Orchids." The essayist described the habits of growth, and the flowering and resting period of many species and varieties of these flowers. He also stated the most suitable temperatures in which to grow them, proper materials for potting and basketing, hints on hybridisation, &c. A discussion followed. A group of Freezias was exhibited by W. A. Stearns. *T. J. W.*

BIRKENHEAD AND DISTRICT HORTICULTURAL.—The members of the above association assembled on Thursday, 18th ult., in the Gordon Hall, Birkenhead, when Mr. R. Horne, The Gardens, Dawpool, Cheshire, delivered a lecture on the "Cultivation of Calanthe Veitchii." The lecturer gave full cultural details. He recommended the potting of the pseudo bulbs singly, in 5½-inch pots during the month of March, in a compost of three parts loam, one part moderately dry cow manure, and one part woodash, with charcoal and fine gravel incorporated as the potting proceeds. The plants should be fed with Clay's Fertiliser when the new growths have attained a length of a foot, and be watered occasionally with a solution of Ichthemic Guano. Never syringe the plants with water overhead. Stand the plants on inverted pots over a bed of coal ashes, and shade them when bright sunshine appears. Maintain a temperature of 70° to 80° all through the growing season, and withhold all stimulants from the time the first flowers open. Maintain a drier atmosphere during the flowering period, and also lower the temperature to 58° or 60°. Mr. Horne exhibited well-grown plants of this decorative Orchid. *Herbert May.*

CHESTER PAXTON.—The opening meeting of the present session was held in the Grosvenor Museum, on Saturday, the 20th ult., under the presidency of Mr. Robt. Wakefield. Mr. J. D. Siddall was the lecturer, and he took for his subject "South and West Cornwall." By the aid of lantern slides, prepared from photographs taken by the lecturer himself, and dried specimens of the principal plants, he described in an interesting manner the flora of these districts. The beautiful and rugged scenery of these districts was well portrayed in many of the lantern slides. Amusing anecdotes bearing upon the habits and characteristics of the seafaring population of Cornwall were also related.

CARDIFF GARDENERS'.—The annual dinner of the members of the above society was held at the Sandringham Hotel, St. Mary Street, Cardiff, on Wednesday, 24th inst. Mr. E. H. Battram presided, and a company of about 60 members and friends passed a very enjoyable evening. The function was declared to be the most successful gardeners' dinner ever held in Cardiff. The arrangements were carried out by Mr. John Julian, the Hon. Secretary.

PANGBOURNE & DISTRICT GARDENERS'.—The fortnightly meeting of this association was held on Wednesday, January 24, in the New Hall, Pangbourne. Mr. D. Harris, Mapledurham, presided over a record attendance of members. After the formal business of the association was concluded, the chairman called on Mr. W. E. Dix, Gardener to Sir B. Baker, K.G., Bowden Green, Pangbourne, to read a paper on "Sweet Peas and their Culture." The essayist gave the history of the Sweet Pea, and also the cultural details necessary for the production of good plants and handsome blooms. He also explained the many uses of this popular flower, both in the garden and also for table decoration.

CHELMSFORD & DISTRICT GARDENERS'.—At a recent well attended meeting of the above association an essay on "Deciduous and Evergreen Flowering Shrubs," was read by Mr. Chandler, who dealt exhaustively with the subject, and gave a long list of suitable subjects for planting. *W. C. S.*

At the meeting held on Friday, January 26, before a large gathering of the members, Mr. W. W. Bull read a paper on "Bush Fruits." The essay dealt in a thoroughly practical manner with the propagation, planting, and general culture of these fruit trees. Special reference was made to birds in the orchard.

TRADE NOTICES.

J. W. MOORE, LTD.—Mr. W. MANSELL (for the last 12 years with Messrs. CHARLESWORTH & Co.) has taken over the management and the principal proportion of the shares of Messrs. J. W. MOORE, Ltd., Orchid Importers, Rawdon, nr. Leeds.

SCHEDULES RECEIVED.

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY'S Summer Carnation and Autumn Exhibitions to be held on June 27, July 20, and November 6 and 7 respectively.

ENQUIRIES.

WHAT IS PINUS MALLETTI? Where is it described? It is not in the ordinary lists. *X.*

LOUGHBOROUGH BOILER.—Can any gardener who has been using the Loughborough Boiler give his opinion as to how long a No. 3 size should last? We have had one here in use for nearly nine years, and now it has cracked in several places. I may say the boiler is embedded in cement, which cannot allow gradual contraction. It is suggested the boiler ought to have lasted at least ten years longer. *H. H., Kerry.*

ANSWERS TO CORRESPONDENTS.

*** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BOOKS: *W. E. A.* We are unable to tell you what the books you mention would be likely to fetch at a sale. The edition of Miller's Dictionary (the eighth), which you have, is the only one of much value nowadays, as it is the first in which the Linnean system was adopted. We should advise you to consult some second-hand bookseller.

CYMBIDIUM LOWIANUM: *T. B.* This Orchid is practically a greenhouse plant, and the atmospheric temperature you give as the minimum is in excess of that required. Especially should this cool-house section of Cymbidium be subjected to a lower temperature at night than in the day, and when expanding their blooms a rather dry atmosphere is necessary. The flower spikes you have sent us seem to indicate that the atmosphere of the house containing the plants has been too warm, moist and imperfectly ventilated.

CYMBIDIUM TRACYANUM LOSING BUDS: *A. E. B., Gravesend.* Protracted, dull weather, and fogs often cause the loss of flowers in winter in the manner you describe. But your Cymbidium has probably been kept in a too warm and moist atmosphere. See answer to *T. B.*

FLANNEL FLOWER OF AUSTRALIA: *J. G. G.* The name might be applied to several genera indigenous to the Colony, and remarkable for possessing tomentum, such as Ammobium, Helipterum, and Helichrysum.

FRUIT TREES: *W. P.* If the tenant is a nurseryman or market gardener he may remove them, but otherwise the tenant should not take away or destroy the trees he has planted on the ground. This is, of course, after notice of termination of tenancy has been given by one or the other parties to the contract. Consult a solicitor.

GRUBS IN VALLOTA PURPUREA: *A. J. Bliss.* The specimen you sent is undoubtedly the larva of the Narcissus fly, Merodon narcissi. Your record is interesting, but the larvæ do not confine their attacks to the various species and varieties of Narcissi; they have been found to be destructive to many rare and beautiful Hippeastrum hybrids, &c.

JASMINE: *W. B.* The white Jasmine is a shy flowering plant in many places. Encourage free growth and preserve the long trailing shoots, pruning sufficiently only to admit the necessary light and air. Remove the tree's fastenings in the autumn in order to allow the air and light to circulate freely amongst the shoots, that they may become well ripened. Jasmines require plenty of space over which to ramble at will.

MENDEL'S THEORY: *Correspondent.* It is difficult to compress an account of this theory into the space at our disposal for Answers to Correspondents. Mendel crossed certain varieties (not species), with marked contrasting characters; for instance, smooth skinned Peas and wrinkled seeded Peas. In the first generation the offspring was uniform, the "dominant" character asserting itself over the "recessive," which was latent. On crossing them again, a mixed progeny made its appearance, the "dominant" character appearing in the proportion of three to one of the recessive so that the hybridiser has first to find out what is dominant and what recessive, and then to arrange that the dominant, if that is what he wants, shall assert itself in the proportion of three to one. The dominant character may, under certain conditions, lose its predominance and become recessive and *vice versa*, and so by careful study and experiment hybridisation, instead of being a haphazard procedure, may gradually be regularised and its results obtained with something like numerical precision.

MOSS-FIBRE FOR BULBS: *X. Y. Z.* You will probably be able to obtain particulars concerning the cultivation of bulbs in moss-fibre by writing to Mr. R. Sydenham, Seedsman, Tenby Street, Birmingham. We do not know of a book upon roof gardening.

NAMES OF PLANTS: *C. W. S.* Psidium Cattleyanum, the Guava.—*A. D.* The specimen sent is a form of Cypripedium × Leeanum. It is a form which has reverted towards C. villosum, or it may have a touch of an allied form, but in effect it is as stated above.—*W. K.* 1, Abies bracteata; 2, Juniperus virginiana var.; 3, Abies cephalonica (?); 4, Abies Pinsapo; 5, Abies nobilis; 6, Sequoia sempervirens.

PEACH SHOOTS: *C. B.* The appearance of the shoots shows that the real cause of trouble is the root. Too much water and imperfect drainage. There is no fungus disease present.

PERENNIAL FLOWERING PLANTS: *F. F. S.* The following will be found suitable for your purposes: Anemone japonica, Antirrhinums, Michaelmas Daisies, Campanula pyramidalis, Red Valerian, Carnations, Pinks, Doronicum, Lathyrus latifolius, Lupins, Lychnis chalcedonica, Oriental Poppies, Scabiosa caucasica, Trollius europœus, Solidago, Rudbeckias, Sunflowers, Saponaria, Yeratrum album, Silene acaulis, and Saxifrages in variety.

PLANTS SUITABLE FOR A NORTH BORDER: *W. H. N.* Christmas roses, Petasites fragrans, Delphiniums, Aconitum, Agrostemma coronaria, Anemone fulgens, Antirrhinums, Epilobium angustifolium, Snowdrops, Narcissi, and many other bulbous plants, Polemonium cœruleum, Primulas and Polyanthus, Vinca major, Violets, Pyrethrums, Perennial Asters (Michaelmas Daisies), Solidago, Hypericums, Chrysanthemum maximum, Saxifragas, Campanula pyramidalis, Chrysanthemums, &c. The foregoing species are all perennials, but not entirely herbaceous. With regard to the other question you ask, we have not read the pamphlet in question, and can offer no opinion on the subject.

POTATOS: *J. B., Carlisle.* You should send your specimens to the Royal Horticultural Garden. Wisley, Surrey, or to the Secretary of the National Potato Society, Postling Vicarage, near Hythe, Kent. To allow tubers to heat or sweat in heaps would no doubt greatly facilitate the growth of the fungus, but such a practice was certainly not the first cause of the Potato disease.

PRIVET ATTACKED BY GRUBS: *C. F. M.* The twigs are apparently injured by the larva or caterpillar of a Noctuid moth; but the specimen you sent was dead and shrivelled, therefore we cannot fix the species. If you will forward us living examples we will endeavour to rear the perfect insect.

SCALE INSECTS ON PALMS: *A. W.* Aspidiotus dictyospermi on Kentia Belmoreana. This species is fairly common on various species of Palms in this country. Ischnaspis filiformis, or black-thread scale, on Areca lutescens, together with a few examples of Diaspis boisduvalii. Both insects are common greenhouse pests in this country.

SEDGES ON POOR LAND: *W. F. P.* No. 1 is the creeping underground stem of a species of Carex. The other specimen is a grass—probably a species of Agrostis. Sedges are usually associated with poor, wet land, on which grass will not succeed well. If your land is waterlogged it should be suitably drained, and receive a heavy dressing of farmyard manure in order to encourage the growth of grasses, which will in time crowd out the sedges. Road sweepings, old potting soil, or any similar materials form a valuable top-dressing for poor grass land. Before making the application use the wooden rake freely over the surface, and afterwards drag the grass with a brush-harrow.

VIOLETS DISEASED: *W. B.* The plants are attacked by a fungus, Ascochyta violæ. Spray them with a solution of potassium sulphide, using one ounce of this chemical to three gallons of water every fortnight. If the disease is rampant, plant a fresh bed in another part of the garden, using new stock obtained from a healthy bed, but do not neglect to burn all the diseased plants and the surface soil from the ground in which they are growing.

COMMUNICATIONS RECEIVED.—T. H. C.—C. J.—G. P.—Pink—G. L. H.—J. M., Totnes (Photograph) can you send us a few twigs and an old leaf?—T. C.—C. B.—H. H. T. W. G. B.—Cayeux and Le Clerc—H. L. & Co.—D. KNIPHOFIAS AND THEIR CULTURE.

RECENT introductions of species of Kniphofia, or Tritoma, as they are more frequently called, and the good products of skilful hybridists who have raised new colour varieties from species already well known, have increased the garden value of this genus. Many of the older species, such as K. Aloides, are undoubtedly coarse plants both in flower, colour and habit of spike—they are plants to be used, massed for distant effect, for the better furnishing of large belts of shrubbery, where flowers are desired, and for kindred uses in the garden landscape, but their utility in the flower garden was never very great.

Kniphofias have kept pace with the improvement manifest in many hardy plants of value for borders, and they can now be had in many fascinating shades of colour, ranging from creamy white through all shades of yellow, apricot, coral, red and crimson, either self-coloured or in the two or three contrasting shades peculiar to the group. In stature they vary from slender, multi-flowered, grassy tufts a foot in height that would grace any rockery, to noble plants that have been rendered still more unfit for small gardens, but which have a grand effect in large borders and in the garden landscape. In the older K. Aloides the plant was far too large, and the stems much too thick for the size of spike; in these newer forms the inflorescence is proportionately much larger, but the greater gain is in the elimination from the newer hybrids of the glaucous grey colouring of the buds of the old species, and in the production of much longer spikes. Forms that are intermediate in stature often give us the refined, shapely inflorescences in sheaves, and here we find the very best border plants in a great variety of new colours such as would astonish one who is accustomed to regard Kniphofias as "red hot pokers."

FIG. 36.—SHOWING ADVENTITIOUS BUDS ON THE FLOWER STALK OF A KNIPHOFIA, BY MEANS OF WHICH PROPAGATION MAY SOMETIMES BE EFFECTED.

Practically all the best Kniphofias are quite hardy in Britain, a few of the broad-leaved, Agave-like species are a little tender, and two of the small-flowered grassy species are not hardy; but as the former group has good hardy representatives, and the latter group is of limited garden value, they cannot be considered much loss. In most cases the slender, grassy Kniphofias winter well in a light, well-drained soil, and are not otherwise difficult to manage, but all varieties are benefited by a mulch of strawy manure placed over the roots should frost threaten when newly planted.

Many of the species have well-marked characters that render their identification easy, but with those species that have been in cultivation for some considerable time difficulties arise owing to a natural variation from the given type. Seedlings vary from the parent plant in a remarkable manner, too, and where red-flowered forms and species are grown together, bees and other insects, by interpollination, render it impossible to carry a species through more than one generation without obtaining remarkable variation in the shape and colour of the flowers, as well as in the habit of the plants; detailed descriptions of such plants, therefore, are more an embarrassment than help to the grower who seeks to cultivate an acquaintance with them, and in the following notes on the species and varieties of Kniphofia, the chief characters from the gardener's point of view are dealt with mainly.

Early winter and early spring are the best seasons for moving and planting Kniphofias, and it is preferable in naturally retentive soils to cover the crowns with but 3 inches of soil, or decay may ensue; their own contractile roots will pull the plants deeper into the ground as growth goes on. Firm planting is desirable, and the roots should be spread apart to ensure good anchorage and thus prevent frosts lifting the plants above the ground level and exposing the rootstock. If the plantation is a new one and the plants have to be purchased, only those should be chosen whose leaves and roots are uncut. Many nurserymen still follow the unfortunate practice of trimming the roots and leaves of Kniphofias close to the rootstock, treating the plants as though they were deciduous bulbs—nothing can be more detrimental to the plant's welfare than this. The shortened leaves form a perfect funnel to conduct water to the rootstock in the depth of winter, and the mutilated roots are in a soddened state and quite inactive for months afterwards; the wounds cannot heal, and decay ensues as a matter of course. A well-rooted plant, having plenty of good leaves, can protect itself from excess of wet and thrive where a mutilated stump would quickly die out. I have several times had occasion to condemn this practice, and I have noted with satisfaction that others have entered their protests in these columns from time to time.

All Kniphofias are quite hardy save those species which flower in winter. K. modesta, K. multiflora, and K. longicollis are the least hardy, but these winter well if they are able to perfect their flowers before severe frosts occur. The frost-stricken flower stems decaying to the base cause the plants more harm than that resulting from frosts. One cannot, however, recommend these species for general planting except in the south-western counties. K. Rooperi, K. Northiæ, and K. Leichtlinii are often "hit" badly, but survive and flower freely in dry soils and in naturally warm positions. The hybrid race of garden Kniphofias are generally quite hardy once established, but need covering in cold counties in winter.

SPECIES AND VARIETIES.

K. aloides (Uvaria).—The old-time species, which, in conjunction with K. Burchelli, Leichtlinii, foliosa and Macowani, has given us a host of garden forms of hybrid origin, varying greatly in every detail. The type plant has dark-green leaves in tufts, and stout spikes of flowers 4-6 inches long, the buds of which are of glaucous grey colour, and the developed flowers of dull red, passing to a dingy yellow at the throat as they mature. The spike is only twice as thick as the stem at its base, and the flowers are closely packed together. There are five distinct varieties

and these are as follows:—*glaucescens*, a glorified aloides with spreading glaucous foliage two or three yards across, and stout spikes of deep red flowers produced in October; *grandiflora* (longiscapa), the spike of which is massive, the florets distended at the throat and poised at right angles with the stem; the free lobes are very long and reflex fully; colour a deep glowing coral red passing to orange. A wonderfully free-flowering variety which blooms in August and September; *nobilis*—massive spikes 7 to 8 feet in height, bearing distended orange-red coloured flowers 2 inches long, closely packed together to form a cone-shaped inflorescence a foot in length. The buds are crimson and devoid of any glaucous tint, and the flowers are canary yellow. At its best during September. *Pfitzeri*.—A showy, almost self-coloured form with very large long spikes of orange scarlet flowers, crimsoned buds, and yellowish tinted throat internally. There is no yellow colouring at the base of the inflorescence. It flowers regularly from August onwards, and the plant is not too coarse for planting in the smallest garden. *Saundersii*.—A vigorous form introduced twenty years ago, with stout spikes of rich red flowers passing to brick-red with age. Every flower stands at right angles with the stem. Octobgr.

K. breviflora.—A rare species that might

FIG. 37.—KNIPHOFIA NELSONI; COLOUR, BRIGHT CORAL-RED.
(The section through the flower and the fragment of the leaf are magnified 2 diameters, the pollen grains 200 diameters.)

be treated as a rock plant. The leaves are narrow and grassy, produced in tufts 2 feet high and through. The flower spikes develop in quantity during October, and they have short cones of lemon yellow-coloured flowers an inch long, tubular in outline and with reflexed lobes. Sixty spikes from a small clump are not an unusual number, and the plant appears to be exceptionally fitted for cultivation in a rockery. It is figured in *Bot. Mag.*, t. 7,570. An apricot-coloured, and a white form are in cultivation. A charming species, totally unlike the majority of Kniphofias.

K. Burchelli.—A showy and valuable species that differs but little from some forms of K. aloides in habit and colouring. It is a sturdy, compact plant, producing throughout summer a series of showy spikes of deep orange-scarlet-coloured flowers, generally more than one foot in length of spike and of uniform colouring throughout, except that the spent flowers show more orange than red in their colouring. A refined Torch Lily whose brilliant flower spikes can be singled out of a collection by their symmetry and the glowing flame-like depth of colour both inside and outside the expanded flower tubes. K. aloides var. Pfitzeri too often does duty for this species in gardens, but K. Burchelli may always be recognised by its reddish orange base and longer spikes produced two or three together.

K. caulescens.—A distinct plant producing stout fleshy stems, which branch dichotomously at intervals of a foot or thereabouts, forming a stout tree several feet in height, bearing huge rosettes of thick glaucous green, Aloe-like leaves, 2-3 feet long in well-grown specimens. The flowers are borne in stout spikes 2 feet in height, the actual inflorescence being 6-8 inches in length, coloured brick red with a glaucous sheen throughout, the flowers passing to a greenish yellow as they age. The inflorescence lacks refinement, and the plant always has an untidy mass of dead foliage clinging firmly to its stems, yet it is valuable for association with the larger order of rock plants, Yuccas, Eryngiums, and other evergreen plants of kindred types. Its flower spikes are produced in June, and they invariably show traces of injury by frosts in a nascent state if the season is late and the position devoid of shelter.

K. citrina.—A pretty plant of garden origin, whose neat habit and quaint flowers are very pleasing. The leaves are produced in Eulalia-like tufts 2 feet across, and are an ornament in any border. The spikes appear in quick succession from August onwards, and bear cones of pale canary yellow flowers, the buds of which are greenish, changing to straw yellow as they open, and the spent flowers are tinted dull white. The spikes are symmetrically cone-shaped, and they rarely exceed 3 feet in height when bearing flowers. Many people appreciate the delicate colouring and pretty habit of this choice plant. Its hybrid descendants are even more beautiful.

K. comosa.—A charming little Kniphofia from Abyssinia, forming grassy tufts 2 feet in height and producing elegant, attenuated spikes of lemon yellow-coloured flowers with short tubes and exserted anthers. It proves to be a hopeless plant for the English climate, and is at present exceedingly rare. K. recurvata I have sometimes seen labelled K. comosa splendens in gardens.

K. corallina.—The prettiest Kniphofia for small gardens. It forms an elegant tuft of narrow leaves 2 feet long, and produces sheaves of coral-red flowers of exceptional richness; no glaucous-grey or yellow colouring finds a place in this charming plant. It is among the first to flower and maintains a rich display throughout autumn. The flowers being mainly sterile, the plants suffer no tax in respect to seed production. K. Macowani is one parent and K. Burchelli is probably the other.

K. longicollis.—A tender species from Natal flowering in early winter. It is a slender-growing plant, growing 3 feet in height and having grassy leaves and long spikes of pretty deep yellow flowers. It is likely to prove of value to the hybridist as a means of introducing refinement into the coarser species, and may yet prove amenable to cultivation in the open borders when reared from seeds in the open, as was originally done with K. breviflora.

K. Macowani (see Fig 38).—A remarkably pretty plant that one can recommend confidently. It is of tufted growth, rarely exceeding

2 feet in height. The scapes are produced in great numbers throughout autumn, and they bear small and few flowered but pretty inflorescences coloured a deep coral red with darker tips. It is a choice little plant, and very easy to grow. The flowers are small and tubular, with reflexing lobes, and they are closely pressed to the scape, forming a very neat cone. Many seedling forms are now grown, but most of them lack the pretty habit of the type. *Brilliant* is the only variety I can recommend. It is twice as large as the type and equally choice.

K. modesta.—A somewhat tender Natal species that I have not tried in the open. It resembles Nelsoni in leafage, and bears long tapering scapes studded at intervals of half-an-inch with ing September. Old-established clumps thriving in light sandy soil, give from 30 to 60 spikes in a season. The inflorescense is comparatively few-flowered, but very graceful—each flower is seen in perfect outline. They measure about 2 inches in length, are quite tubular, coloured a ruddy coral tint, and have reflexing petal lobes. It should have a place on the rockery where shelter can be given, and it has a splendid effect if massed among choice plants in borders. It is preferable to start newly acquired plants in pots before planting them out, or loss may result. I have seen splendid plants in the colder parts of Scotland thriving well in gritty soils without protection. *G. B. Mallett.*

(To be continued.)

Fig. 38.—KNIPHOFIA MACOWANI; COLOUR OF FLOWERS YELLOW, PASSING TO DEEP CORAL-RED.

short-tubed, distended, white flowers, whose stamens and styles are much exserted. The inflorescence is quite 2 feet long and closely resembles that of Gasteria in habit. Useful only as a parent in improving the hybrid race. Although the plant possesses several pretty features, its comparative rarity and reputed tenderness are against its ever becoming much sought after. It flowers in September in a cool house.

K. Nelsoni (see Fig. 37).—Few plants are more admired than goodly tufts of Nelson's Kniphofia. It is in many respects the gem of the genus. Its Eulalia-like leaves are produced in dense, yet graceful, tufts 2 feet in height, and as much in diameter; the remarkably pretty spikes are yielded in considerable quantity dur-

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT ROSSLYN, STAMFORD HILL.

The famous collection of H. T. Pitt, Esq., is one of the richest and most varied in the London district, and one of the few in which rare species and varieties of pretty and curious plants are now to be found. Cattleyas, Lælias, and Cypripediums are great favourites, and the best procurable in each section have been obtained, and all have been cultivated well by Mr. Thurgood, the gardener at Rosslyn. But of all the specialities there the Odontoglossums, although the most costly, have proved to be the most satisfactory, and the collection embraces many grand blotched forms of Odontoglossum crispum which are not yet in any other collection. These have often been admired, and some have secured awards at the Royal Horticultural Society, in whose list of awards, by a coincidence, three of the best known forms of Odontoglossum crispum, viz., Persimmon, Pittiæ, and Pittianum are enumerated together as each having secured a First-Class Certificate when shown by Mr. Pitt, the next line recording O. c. Prebendary Bevan, another of the Rosslyn varieties which secured an Award of Merit. These four alone cost the price at which many a good collection of Orchids has been got together.

The Odontoglossums are housed in a range of houses specially constructed for them, and despite their proximity to the great Metropolis, they grow vigorously and flower well. Many are sending up strong flower-spikes, and some few are in flower. Among other varieties coveted by the Odontoglossum specialist were noted O. crispum F. K. Sander, known to be a marvellous blotched variety, but which Mr. Pitt thinks has never yet been seen at its best; O. c. Annie, O. c. Abner Hassall, O. c. xanthotes, Snow Queen, and others which had gained honours. Of fine varieties of species O. Hallii, King Edward VII. and the purple-spotted O. Pescatorei, Pitt's variety, take the lead in their sections, as do O. × Wilckeanum Pittiæ, and Pitt's variety in that class. Odontoglossum × Adrianæ Cobbianum, with its pretty flowers

heavily blotched with chestnut red; O. grande citrinum Pitt's variety, of a clear canary-yellow colour; O. cirrosum, Pitt's variety, with its large heavily-blotched flowers, and the best forms of O. crispum, give pointed examples of wisely selected unique plants still holding their own, notwithstanding the large number of each of the species from which they were selected having flowered since those varieties appeared. Such experience gives the best excuse for the enthusiasm of first-class Odontoglossum collectors, as it plainly tells that the best forms will always be rare.

The smaller Odontoglossums occupy another house, and in one corner is a small batch of store pots of young seedling Odontoglossums raised from the best blotched forms of O. crispum and others in the collection. The object here is rather to perpetuate and increase the best blotched forms of O. crispum than to obtain hybrids.

Another range in three divisions contains a good selection of fine varieties of Lælia anceps, L. a. Amesiana, Crawshay's variety, and L. a. Schroderiana, Rosslyn variety, a fine white variety which closely approaches L. a. Waddoniensis, being two of the best. The plants are not allowed to make large masses with a number of old back pseudo-bulbs, but are divided and freed from such pseudo-bulbs, which make vigorous plants in due time. In the next division is a pretty specimen of Sophro-Lælia × Psyche, with nine light scarlet flowers; and an equally good plant of Sophro-Cattleya × eximia, together with other hybrids of Sophronitis grandiflora. A batch of seedling Sobralias, raised at Rosslyn, is showing flower for the first time; a specimen of the rare Phaius tetragonus, and an interesting collection of Mormodes, Catasetums, Cycnoches, &c., are also in this range, a part of which is fitted for the raising and perfecting of some promising hybrid Cattleyas, Lælias, &c.

The third division is filled with Dendrobiums, some in bud and flower. The next range, also in three divisions, has a fine collection of rare Cypripediums, the hybrids of C. bellatulum, and C. niveum being specially good. The difference in the vigour of plants of the same cross is shown by two plants of C. × Chapmani growing side by side. The older plant is still a comparatively small specimen, while its neighbour is probably the largest plant of its kind in cultivation. Extra constitutional vigour in the larger specimen appears to be the only explanation. The delicately-tinted C. × Felicity, a yellow form of C. × Barteti, C. × Ajax, a very large and distinct flower; C. × tessellatum porphyreum and some others are in bloom; and among curious and rare plants noted were Eulophia pulchra, with four spikes; E. virens, with three spikes; Trigonidium spatulatum, Epidendrum polybulbon, a large mass of Bulbophyllum barbigerum, a flowering specimen of B. occultum, and other Bulbophyllums, and Cirrhopetalums; a singular Maxillaria of the Dicrypta section with primrose-coloured flower; a batch of Ada aurantiaca, good masses of Sophronitis grandiflora, Ornithidium Sophronitis; a collection of the best Cymbidiums, and a great variety of species not often seen in private gardens.

The span-roofed Cattleya house has a fine collection of the best varieties of species and albinos as well as hybrids, most of which were selected in flower. The show of flowers at present consist of the varieties of Cattleya Trianæi and a nice batch of the beautiful Oncidium splendidum, which is seldom seen in such perfection. The position which it occupies in the house suits it admirably, as the plants are in a good light, and the atmosphere around them is not moist. Several of the plants have three spikes of flowers on each, their large, clear, yellow blooms making a fine display. Specially interesting plants are Lælio-Cattleya × Canhamiana, Rosslyn variety, of a bright purplish rose colour, and of great size; C. Schroderæ, Pitt's variety, with dark maroon colour on the lip, and which constitutes one of the unique varieties of the collection; a good collection of Brassavola Digbyana hybrids, one of them B. Digbyana × Lælia majalis, approaching maturity, being very promising.

The old warm house, which had been a Pine-stove, has always suited the Phalænopsis which are suspended from the roof, the bed being occupied by a good stock of Eucharis amazonica, which also thrives well. P. Schilleriana is in flower. Another house contains a good collection of varieties of Cypripedium insigne, including the best yellow forms; a fine lot of Cælogyne cristata well furnished with sprays of white flowers. Here a large specimen of Aerides Vandarum has several spikes of white flowers, and Lælia × Latona, and some others are in bloom.

In the other house are many uncommon stove and greenhouse plants, and a well-grown collection of coloured Codiæums, Dracænas, and other decorative plants.

FOREIGN CORRESPONDENCE.

MEXICO.

PROFESSOR J. G. Lemmon and Mrs. Lemmon, the well-known botanists of Oakland, California, write that they have been in Mexico for about seven months. Some portion of their time has been spent in the city, the remainder having been passed in an exploration of the forests about Orizaba, from which place they returned a few days ago.

While in Orizaba they gathered a good many specimens of Mexican trees, which they intend to study closely after their arrival in California. All their time while in Mexico has been devoted to the study of trees, shrubs and flowers, and it is their intention to return next year and continue this study.

They were much impressed with the beauty of the forests about Orizaba. According to their statements, it would require many months to exhaust the possibilities of that section in regard to botanical exploration and classification of trees.

The oaks collected are very numerous, as was to be expected, and among the pines were Pinus Montezumæ of several forms, including the great macrocarpa with cones 8-14 inches long; P. Hartwegi, in several forms; P. pseudostrobus, in several seemingly distinct forms; P. leiophylla, in beautiful condition, showing especially its cones of three years' growth; P. oocarpa, in beautiful condition; P. Arizonica and P. Mayiana and P. Chihuahua, with a form perhaps of P. Ayacahuite were re-collected on the way in fine form in the Catalina Mts. of Arizona.

ENGLISH GARDENERS IN THE UNITED STATES.

IN the *Gardeners' Chronicle* for January 6th last a note appeared in the "Answers to Correspondents" column under the heading, "Situations in the United States."

I should like to inform *E. J. H.* that the condition of gardening here is much better than in England, and there is no difficulty in young, well-trained gardeners getting good situations in this country.

Head gardeners and superintendents experience some trouble in securing good men, and New York seedsmen are always glad to hear of men coming from England, and are ready to answer any inquiries, although they offer no temporary employment.

March and April are the two best months to arrive here.

The general wages for journeymen (or assistants, as they are termed here) is about 50 to 55 dols. per month, without board, or 30 to 35 dols. with board, board and lodging being worth about 20 dols. per month. The English value of one dollar is 4s. 2d.

It would be no use to attempt to advertise in the American papers, because they would not publish such an advertisement, it being contrary to the law of the U.S.A. for anyone to become engaged before landing, and the parties who do so are subject to a very heavy fine, besides the probability of being deported.

I am sure many young gardeners in Great Britain do not know of the advantages this country offers or they would leave England without hesitation.—*T. E. R., New Jersey, U.S.A.*

CULTURAL MEMORANDA.

ACHIMENES, TYDÆAS, &c.

(Continued from page 74.)

THE stolons of these plants having commenced to grow in pans, they should be left undisturbed till they have reached a height of 1½ to 2 inches. In the meantime prepare the pans, baskets, or pots in which the plants are to flower, by using as drainage materials a few large crocks with a 2-inch layer of small ones above them, and above these a layer of from 3 to 5 inches of soil similar in its composition to that recommended for starting the stolons, with a quarter addition of light loam, finely sifted and well incorporated with the other materials, not omitting plenty of silver sand. The young plants must be carefully lifted with as much soil as will cling to them, and set out in the new soil at from 2 to 3 inches apart, burying the stolons 1 inch deep, and making the compost moderately firm about them, then applying enough warm water to consolidate the soil, and returning the pans to the stove or other equally warm structure. Early started plants seldom need shade, and in a few days after replanting growth will recommence. Plenty of atmospheric moisture is better than spraying, either by means of the watering-can or syringe. When the soil has become dry and it is necessary to afford water to the roots, be careful not to wet the leaves.

GESNERAS.

These plants are among the handsomest stove herbs, possessing a more erect habit than either Achimenes, Nægelias, or Tydæas, and a sturdiness which in most cases does away with the need of artificial supports. Some of the best known species and hybrids in our gardens are G. zebrina, and the fine variety G. z. splendens, G. cinnabarina, and several hybrids obtained from G. amabilis and G. zebrina splendens. The plants possess velvety, dark green or bronzy leaves, and grow to a height of 1½ feet to 2 feet, forming pyramids of brilliantly coloured flowers. One of the most strikingly beautiful hybrids, the seed parent being G. discolor and the male or pollen parent Gloxinia rubra, is Gesnera Donklarii. This hybrid springs not from a stolon, but from a hard, woody sort of tuber of a perennial character, which increases in size slowly from year to year; the leaves are large, and when the treatment is of the right kind these furnish the stem quite down to the soil. In G. macrantha we have a cross between G. bulbosa and G. b. Cooperi. Provided a warmth of from 60° to 65° as a minimum be afforded during the season of growth, and bottom heat at the start of 75° to 80°, Gesneras are not difficult of cultivation. Those species and varieties which propagate themselves by stolons should be afforded the same kind of general treatment as that advised for Achimenes, although in order to avoid any

check one stolon per small 60 pot is preferable to starting them together in pans or boxes, and several small repottings should be afforded whilst the plants are in full growth and previously to the flowers appearing. The tuberous species and hybrids require a slightly loamy porous compost, together with peat and half-decayed leaf mould and a fair amount of drainage material, whereas the stoloniferous species are the better for being afforded a lighter mixture. Those with velvety leaves should not be wetted overhead or their beautiful appearance will soon suffer. For an eight inch flower pot 5 plants are ample for forming a handsome object; and in order to secure uniformity of height and time of flowering, these plants should be of equal strength and height when planted in the flowering pots. G. Donklarii should be given a pot or pan to itself; and G. bulbosa and its varieties also. In order to cultivate Gesneras properly and flower them at their best, a place apart from the other inmates of the stove should be found for them, and failing a pit, heated with hot water, frames placed on a mild hotbed composed of tree leaves, and surfaced with spent tanners' bark, cocoanut fibre, or coal ashes finely sifted, would answer admirably; for in such conditions, ventilation, shade from strong sunshine, and provision of moisture, are matters quite under the gardener's control. It will conduce to healthy development of the foliage and flower spikes if very weak liquid manure be applied to the soil as soon as it is found to be well filled with the roots of the plants—not before. The plants form nice objects for furnishing vases and *jardiniers* in apartments that are not too cool, and in which they are not exposed to draughts from windows, doors, or ventilators. As materials for dinner table decorations *à la Russe*, when grown in 4½-6 inch pots, they are admirable. *F. M.*

THE ROSARY.

ROSES AND HOW TO GROW THEM.

New York: Doubleday, Page & Co.

No author's name appears on the title page of this little volume, but from the preface we gather that the compiler has availed himself of the work of several experts. In any case, from a glance at the book we can endorse the general statement that all that is really necessary for the amateur Rose-grower to know, in order that he may intelligently make a Rose garden, select his varieties, and grow the harvest of bloom, is told in this volume. The chapters are devoted to the questions when, where, and how to plant, the routine of work, pruning, diseases and their remedies, Roses for cut flowers under glass, types or races, Roses for special purposes, Roses of American origin. The book is written from an American point of view, and hence allowance must be made for differences in climate, when an attempt is made to follow out the author's precepts on this side of the Atlantic. At the same time it must be remembered that the climate of the United States is very far from being uniform. The conditions in Florida, Arizona, and California are widely different from those prevalent in the Eastern States, for instance. We have the advantage in some things, as we read that the term "perpetual," applied to Roses, is a misnomer in the Eastern States, where a season of bloom beginning in mid-June and ending in the following month is all that can be reckoned on with certainty, even for H.P.'s, what second bloom is produced being but scanty. As giving some idea of the commercial importance of Rose-growing near New York City, it is stated that about two millions of square feet are used in houses devoted exclusively to the production of Roses for the cut-flower market in one large "Rose factory" within twenty-three miles of New York. This may be very nice commercially, but it will hardly appeal to Rose-lovers. There is, however, no room for sentiment in business. The book before us is essentially practical, and well suited for the amateur, to whose notice we therefore commend it.

VAPORISING WITH HYDROCYANIC ACID GAS.

I HAVE made good use of hydrocyanic acid gas for vaporising purposes during the last 12 months, and am very pleased with the result. I had plenty of material to experiment with, i.e., bug and scale, but now I have practically none.

The first house I fumigated contained Orchids, Ferns, Ardisias, and Gardenias, whilst Stephanotis occupied the wires overhead; the Stephanotis and Gardenias were badly infested with bug.

The first difficulty here was to lower the temperature sufficiently; the valves of the hot-water pipes were closed the first thing in the morning, but it was next to impossible to get the temperature below 59 degrees, and in order to reach this the plants had to be exposed to much draught. Secondly, a quantity of water had been thrown about up to the evening previous to the day of operation, so that I could not get a dry atmosphere. Nevertheless, bug was so numerous, and it had occupied so much time in sponging, etc., that I was determined to vaporise at 3 p.m. I used less than the prescribed quantity, i.e., 2½oz. of potassium cyanide per 1,000 cubic feet, and closed the house for 40 minutes, then opened it for an hour, when I thought it was quite safe to enter. I was naturally anxious to examine everything. The first thing noticed was a quantity of bug on the floor, and on the foliage under the Stephanotis, and all the bug remaining on the Stephanotis and Gardenias appeared to be quite dead. The plants, so far as I could judge so soon after the exposure to the gas, appeared all right. Next morning, however, I found a few bugs still alive; the scale was all killed. Further, I noticed some of the Orchid leaves were showing signs of injury.

In the course of a week I was able to form an opinion of the results of the experiment as regards damage, etc. The cyanide had either been too strong, or there had been too much heat, or moisture, or both; certainly the damage was not great, but it was desirable to avoid it in the future, if possible. Therefore, I decided to try again; this time the valves were closed the night before. The temperature next morning was just below 60 degrees, and it happened to be a dull morning, so that by opening the ventilators the temperature was quickly lowered to 55 degrees. An excess of moisture was avoided as much as possible. I used the same quantity of potassium cyanide, but closed the house for an hour, and afterwards opened it for an hour before going inside. The next morning an examination proved that the cyanide had been insufficient. I could find odd bugs still alive, and in the course of time I could not detect any ill-effects of the acid fumes upon the foliage. I tried a third time, practically in the same way as the last, but used more cyanide. This was in November, 1904; the results were entirely satisfactory, and I have not had occasion to repeat the operation since in the same house. A few plants have been brought out once or twice for scale, and exposed to the cyanogen fumes in other houses; that was not to be wondered at, as the plants are constantly changed from one house to another.

The plant stove was the next house to be treated: that was in June, 1905. I thought first thing in the morning would be the best time, the temperature being unavoidably high in the evening at that season of the year. The fire was allowed to die out during the afternoon prior to the morning of operation, so that the temperature at 6 a.m. was 57 degrees. The ventilators were thrown open for a short time to reduce the temperature and allow the moisture to escape, though efforts had been made the day before to prevent moisture. I closed the house and exposed the contents to the fumes for three-quarters of an hour, afterwards opening the doors at either end of the house, and finally the top ventilators. It was noticed that the temperature had risen considerably during the time the house was closed, the sun having shone a little on one end of the house. In the course of a day or two, it was found that practically all the bug, and scale, had been killed. At the same time some small Palms, Kentias, and Rondeletia had suffered. Undoubtedly this was due to the increase of temperature during the exposure. The house was again treated in October, but this time the fire was put out the first thing in the morning. No water was thrown about, the ventilators were opened towards evening, and the temperature was reduced below 55 degrees. The same quantity of cyanide was used as before, the exposure was the same, and the results were entirely satisfactory. Begonia, Gloire de Lorraine, and Cypripediums in flower showed no trace of injury.

The late Vinery was another house fumigated in this way after the Grapes were cut. It was the only fruit house infested with bug. I used rather more than the prescribed quantity of cyanide to make sure of destroying all the bugs. The temperature was low, 45 degrees, and the atmosphere dry. There were bug and thrips on the Vines, and scale on certain plants in the house. On examination, both immediately afterwards, and since while the Vines were being cleaned, not one live bug was found, although several dead ones were concealed under the bark. The thrip, scale, and, unfortunately, a good cat, previously unobserved in the house, were destroyed. The only plants to suffer from the stronger application were the Clivias; it was certainly too much for them. The vaporising has saved us a great amount of labour in one year; every gardener knows what it means when men have to spend their time sponging repeatedly for bug, and removing scale from Asplenium, Ferns, etc., with the point of a stick.

I use 2½oz. of potassium cyanide 95 per cent., 2½ fluid oz. of the strongest commercial sulphuric acid, and 10 fluid oz. of water per 1,000 cubic feet. My method is the following: I mix the acid and water in an earthenware bowl. Note: The acid must be added to the water, and not the water to the acid, or very serious results may follow. The affinity between the concentrated acid and water is so great that if a little water is added to a quantity of the acid, the action is so vigorous that it is quite likely the bulk of the acid and water might be forced out of the vessel over the person mixing them, and burn him severely, or even blind him. The requisite amount of acid and water in the bowl is placed upon the floor in the house, and the weighed quantity of cyanide is rapidly transferred from another dish to the one containing the dilute acid. I lock the doors and leave the house for three-quarters of an hour. In those houses where the ventilating gear will allow, I leave it so that I can open the top ventilators from the outside, but in most of the houses the apparatus consists of iron rods and worms, so that it is impossible to open the top ventilators from the outside without unscrewing and so liberating them. In some cases this would be very difficult, the

screws having rusted in the wood. In cases of this sort, after the time of exposure, I open the doors at either end of the house, and leave it for perhaps twenty minutes or so, then take a deep breath, rush in and open the top ventilators as quickly as possible, and out again; then go back in the same way to open the front ventilators, and leave the house for an hour, when one may go in safely. I know this is a very dangerous performance, and one that is not to be recommended. If I had no knowledge of chemistry I should devise some other means of opening the house from the outside, and this is what I should strongly advise others to do, because cyanide is a most DEADLY POISON. We must never forget that.

I have seen in the *Gardeners' Chronicle* at different times that sodium cyanide 130 per cent. has been recommended. How is it possible to get more than 100 per cent. absolute purity in a chemical compound? [This is a commercial term meaning that the sodium cyanide contains 130 parts of cyanide to every 100 parts of sodium.—ED.] I think I am right in saying sodium cyanide is more difficult to obtain than the corresponding potash compound. We find it so here. I am aware there is one thing in favour of the sodium cyanide, i.e., according to the chemical formulæ of the two compounds, 1lb. of sodium cyanide pure yields as much gas as 1¾lb. of potassium cyanide pure. I don't know the price of the sodium cyanide, therefore do not know the cheaper source from which to obtain the hydrocyanic acid gas, but, supposing they were both 1s. per lb., the sodium compound would be the cheaper, because it would yield the most gas. *W. H. Dobson, The Gardens, Stapleton Park, Pontefract.*

[Those who try this most effectual, but most dangerous remedy, should contrive some means of lowering the cyanide into the acid from without so as to avoid the necessity of being in the house at the time the cyanide is dropped into the acid.—ED.]

THE HARDY FLOWER BORDER.

TWO MONTBRETIAS.

Two varieties may be noted here. Neither belongs to the large-flowered section, some of which, by the way, are not such effective border plants as the best of the older small-flowered type. M. Vulcan is one. The plants grow tall for Montbretias, this being by no means its least charm. The colour in a mass is good and effective, and the plants are among the earliest to flower, which will increase its value in late districts. The other is M. "fleurà jaune," a clear and good yellow. I think the best of the colour. The plant belongs to the dwarf section, but is not as dwarf as either Eldorado or Matador. I am hopeful that "Tigridie" will prove a splendid border plant, but one has to see Montbretias in groups of one to three hundred plants to gain a good idea of their effectiveness as garden flowers.

GIANT HELIOTROPES.

By sowing early, large standard in pots may be had in flower in July, or in the open, if required for borders. But strong floriferous plants for borders are produced with less trouble by sowing and growing on in the same manner as tender annuals. The flowers are either whitish or blue in several shades, some of which are distinct and pretty. These originated with M. Lemoine, of Nancy, but seeds are now procurable in England. M. Lemoine grows a select few by name, and these, of course, are true to colour, but they are so easy to produce from seeds that for ordinary purposes those who care to try them as border plants should be advised to propagate a stock in that way. *R. P. B., Prestonkirk, N.B.*

KEW NOTES.

SOLANUM INTEGRIFOLIUM.

This plant is a native of Asia and Africa; its chief beauty is afforded by the fruits, which resemble small corrugated Tomatos. The attractiveness of the plants in the greenhouse and conservatory does not depend entirely on the proportion of brilliant colour they supply, but rather on their variety. The flowers of S. integrifolium are small, and the leaves vary in size from 5 to 8 inches in length and 4 to 5 inches in width.

Propagation is effected by seeds, sown preferably in February or March in a warm house. Prick the seedlings off into small pots or boxes when large enough to handle, and cultivate them in an atmosphere of intermediate temperature for a time. When affording them the final potting if pots measuring 6 or 7 inches in diameter be used they will be large enough. The plants may be hardened off and plunged outside for six or eight weeks, if the weather is favourable, in July and August. Failing this grow them in a house where they will get abundance of light and air.

A number of plants in No. 4 house are bearing both red and green fruits. This winter the shoots were not stopped, and the plants flowered a second time in December. They will last in good condition all through the winter. *A. O.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Plants of Odontoglossum crispum and hybrids that have been obtained from this species that were repotted last autumn have now become well rooted in the new compost and have their growths well advanced. Where it is found desirable to increase the stock of any special variety, the rhizome of the plant may be partially severed with a sharp knife, and in a few weeks should be cut quite through. My practice has been to cut the rhizome just behind the second pseudo-bulb, leaving the two front bulbs to support the leading growth. In time old pseudo-bulbs will produce one or more new growths, and by the autumn they will have made some roots, when they may be removed from the front portion of the plant and be potted up separately. By adopting this method young plants are produced more freely and with less trouble than by the old plan of cutting the pseudo-bulbs off entirely and suspending them in the house,

The Mexican Lalias as L. albida, L. autumualis, L. Gouldiana, L. anceps, and its numerous varieties will now be commencing to make new roots, and immediately these are observed the plants, if necessary, should be supplied with fresh material about their roots. Well established plants, that do not now require larger receptacles, should have any old worn out material carefully removed from about the roots and fresh compost substituted for it. These Lælias may be grown in pots, shallow pans, or teak-wood baskets, but, whichever receptacle is chosen, it is imperative to provide good drainage. The compost should consist of a mixture of one-half fibrous peat, one quarter sphagnum-moss, and one quarter leaf soil, to which may be added some small crocks and coarse silver sand. In the course of re-potting press the materials firmly together, and keep the rhizome of the plant about on a level with the rim of the pot. Until the plants have become re-established and are again growing freely, merely keep the surface of the compost moist to encourage the new sphagnum-moss to grow. The atmosphere of the house should still be kept at a temperature of about 55° at night, but during the day it may rise as high as the sun beat will raise it if ventilation is afforded with discretion. When the new growths appear the degree of warmth and moisture should be gradually increased. Such species as L. albida, L. autumnalis, and L. majalis should be suspended in a light position in the cool house. Cockroaches and woodlice are very fond of the roots of these plants, and therefore every means should be taken to eradicate them.

Heating and Ventilation.—The weather being very mild, each division should be given a thorough damping down every morning; the paths and the surface beneath the stages will require to be sprinkled again in the afternoon. The temperatures at night need not be raised above those given in the issue for January 6, The day temperatures should also be kept the same so far as fire-heat is concerned, but when the sun causes the temperature to increase, admit air to every department through the bottom ventilators. In the Phalænopsis-house and Dendrobium-house, where many plants are now in bloom, a "chink" of air should be admitted through the top ventilators whenever practicable, so as to allow any over-abundance of atmospheric moisture to escape, and thus prevent the flowers from becoming spotted.

THE FLOWER GARDEN.

By HUGH A. PETTIGREW, Gardener to the Earl of PLYMOUTH, St. Fagan's Castle, Glamorganshire.

The Rosary.—All renovations and improvements must be completed as early as possible, and any planting left over from November can now be proceeded with as soon as the weather permits of the ground being worked properly. Though November is the safest month of the year in which to plant Roses, many prefer to do the work in February, and even March, and excepting cases where the soil is of a light nature there is not much to be said against doing so. There is one decided advantage, however, that November planting has over that in February which cannot be overestimated, and this is, that in purchasing from Nurserymen the best plants naturally are selected first, therefore growers who defer planting until February often have to be satisfied with indifferent quality in the varieties they particularly desire. When about to plant Roses, too much stress cannot be laid upon the urgency of trenching deeply, and of supplying to the soil abundance of farmyard manure. In the management of the Rosary the best results are obtained by providing beds to contain each its own particular variety, and they should be large enough to hold from 20 to 30 plants each. Larger beds might be planted with a number of varieties, taking care that the flowers will not only agree in colour, but also that the plants will be of the same habit of growth. In these larger beds half-standards could be used with advantage for planting amongst the dwarfs, and this would relieve the effect. Where practicable exclude Hybrid Perpetuals from the Rosary, and also the rampant-growing Polyanthas, and grow principally the recognised decorative Roses of the Tea-scented, Hybrid Tea, China, Noisette and Dwarf Polyantha types, because of their perpetual blooming habit. The season of blooming of Hybrid Perpetuals is comparatively so short that it is generally desirable that they should be grown in the "garden for cut flowers," and also that the strong growing Polyantha Roses should be restricted to the Rosary in the wild garden.

Varieties to Plant.—For beds devoted to one variety, or for the larger beds to be associated in colours, the following varieties occur to one as being a few of the very best for the purpose:—Caroline Testout (H.T.), Bardon Job (H.T.), Grüss an Teplitz (H.T.), Hon. Edith Gifford (T.), Madame Lambard (T.), Préfet Monteil (T.), Corallina (T.), Madame J. Dupuy (T.), Madame Berkeley (T.), Madame Antoine Mari (T.), Dr. Grill, Souvenir de Catherine Guillot (T.), Ma Capucine (T.), Anna Olivier (T.), Lady Roberts (T.), and Laurette Massimy (C.). A very pleasing feature could be made in the Rosary by devoting a bed or group of beds to those varieties possessing the sweetest scent. In a bed of this description such fragrant roses as La France (H.T.), Madame de St. Joseph (T.), and Zéphyrine Drouhin (B.), should unbesitatingly be placed.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

The Stove.—The longer days and the increase of light and sunshine will soon set the machinery of plant life in motion. The atmospheric temperature of stoves should be gradually raised to promote active growth. At night it may now range from 65° to 68°, allowing an increase of 10° or more on bright days. More moisture should be maintained in the atmosphere, and such plants as need it may be gently syringed overhead with tepid rain water. The propagation of plants in general should now be given attention. Before inserting any cuttings let them be examined, and if there are any insects present dip the cuttings in a solution of XL-all insecticide.

Allamandas.—Plants that have been resting for the past two months may now be started into growth. Potting may be done either while

the plants are in a dormant state, or after they have commenced to grow. Whilst they are still dormant is perhaps the most suitable time, inasmuch as there is then no risk of breaking the young shoots. Reduce the old ball by one-half, after which soak the remaining half in tepid water and allow it to drain thoroughly before repotting. Fibrous loam, with a little sand and dried cows' manure added, will be found to be a suitable compost. Avoid over-potting the plants. Cultivate them in a position close to the glass in full sunshine, and afford free ventilation.

Clerodendrons require similar treatment to that advised for Allamandas, with the exception that the roots should not be disturbed more than is necessary. These plants succeed well in the same pots for two seasons or more, provided a top dressing of dried cow manure, leaf mould, and soot be given; also frequent supplies of liquid manure during the growing season.

Eucharis.—Plants that have flowered should be given copious root waterings, and if the pots are well filled with roots and have not been repotted for some time, afford them liberal supplies of manure water. Clear soot water may be applied to the roots at any time, and if the plants are syringed with it occasionally they will be benefited.

General remarks.—Pits and frames containing miscellaneous plants should be examined. Any plants that may require to be propagated should be placed near to the light to make strong growths for use as cuttings. If not already done, have the water cisterns cleaned out, for the winter rains will have carried a deposit into them from the roof glass, and as the syringe will soon be coming again into use it would convey the deposit on to the plants and wood-work in the houses. There is no better safeguard against any serious attacks of insects than that of keeping the plants in a vigorous state of health, and of maintaining strict cleanliness in the structures in which they are grown. Any bulbs that are still plunged in ashes should not be allowed to remain there very long. Let Cinerarias and Calceolarias be kept close up to the glass, and be afforded free ventilation, also liberal supplies of liquid manure. The application of water to the roots of plants should be very carefully studied, especially so immediately after plants have been repotted and the young roots are just advancing into the new soil. Carelessness in affording water often ends in the constitution of a plant being deranged for the whole season.

FRUITS UNDER GLASS.

By T. W. BIRKINSHAW, Gardener to Lt.-Col. Sir CHAS. HAMILTON, Bart., Hatley Park, Bedfordshire.

Early Melons.—Where hotbeds, composed of leaves and long litter, have already been made up, as was advised in a former Calendar, and provided the soil has been got into the house and warmed, the plants may be put out at once or as soon as they are sufficiently rooted that it is possible to turn them out of the pots without breaking the balls of soil. The compost should consist of turfy loam, lime scraps, wood ashes, soot, and about 1 lb. of bone meal, also 1 lb. of ½-inch bones to each barrow full of compost. The compost should be made up into a ridge and beaten down firmly. It is a good plan to make little mounds of loam and wood ashes in positions on the ridges where the plants are intended to be grown, for such mounds act as a preventive of too much water reaching the stems of the plants, and so helps to keep the plants free from canker. Some gardeners prefer to grow and fruit their earliest batch of plants in pots, which should not be less than 11 inches in diameter. These are plunged into the hot-bed up to their rims, and filled with the same kind of compost already described. When the plants are first put out in their permanent positions, and provided there is strong sunshine, they may require to be shaded for a few days whilst becoming established in the soil. The atmospheric temperature of the house should range from 65° to 68° at night, and maybe 10° higher during the day. Maintain considerable moisture in the atmosphere by frequently damping down all available spaces in the house. Syringe the plants and close the house early in the afternoons to economise fire heat.

Cucumbers.—Plants which have been in bearing since last October are probably almost exhausted, but if given very careful treatment, and rich top dressings of fresh horse manure are applied to the roots, they may be encouraged to yield a few more fruits, and thus be of use until the successional plants begin to bear. It is not very difficult to obtain Cucumbers during the last three months in the year, but in order to have plenty during the first three months in the year much attention must be given, and suitable houses where the plants can obtain all the light possible are necessary provisions. The atmospheric temperature should be from 65° to 68° at night and 75° by day. Let the foliage be syringed on all favourable occasions to prevent red spider.

Vine "Eyes."—It is convenient to have a few young Vines growing on for the purpose of inarching them on to other varieties, or for use in planting out in permanent borders. Select plump "eyes" from well-ripened wood, leaving about 1½ inch of wood to each eye. Cut the wood on the under side in a slanting direction, and place each "eye" in a 3½ inch pot which has been filled with sandy loam. Plunge the pots in a mild bottom heat, when they will soon make roots if kept in a uniformly moist condition.

THE KITCHEN GARDEN.

By J. GIBSON, Gardener to His Grace the Duke of PORTLAND, Welbeck Abbey, Notts.

Celery.—Those who require to have Celery fit for consumption in August should now sow seeds in moderately rich soil in shallow boxes. Let the soil be watered after it has been pressed down in the boxes and just before sowing the seed. Finish off with a slight sprinkling of finely sifted soil only just sufficient to cover the seeds. Celery seeds sometimes come up very irregularly, therefore do not throw away a box-ful simply because a few seedlings only first appear; others will come up in all probability a little later on. Veitch's Early Rose and Sutton's Dwarf Gem are very suitable varieties for early crops. I do not recommend the so-called self-blanching varieties, of which White Plume is one that is mostly grown. For early exhibition purposes Dobbie's Invincible White is one of the best, with Standard Bearer as a first-rate red variety.

Early Cauliflower.—Young seedlings from last month's sowing will require to be pricked off in frames, and preferably over a slight hotbed. A few may be potted up also with a view to cultivating some early "heads" under glass, using pots 8 inches in diameter, and though the "heads" will not be of large size they will be very early, and consequently much appreciated. Make another sowing in boxes to form a succession, and a third sowing in a cold frame.

Winter Onions.—Towards the end of the month transplant these into lines 15 inches apart, and allow 6 inches space between each plant. Rich soil is essential in the cultivation of very fine bulbs. Thin out the seedlings in the lines at the same time, but take care not to thin them too severely, as there is always the danger of loss caused by some of the plants running to seed, which is much more prevalent in some seasons than others, even with the same variety.

Shallots.—The present is a good time to get in this crop, for if planting is done late, the subsequent crop is always of less amount. Plant them in rich soil which has been deeply worked. This remark applies to nearly all vegetables. The small Cluster variety is very serviceable when grown for pickling, and the Red Dutch, which is large, is the most useful for slicing for flavouring purposes. There are several selections of this latter variety, which are improvements on the type, and a good one should be secured. Seed may now be sown in the same way as that of onions, and many cooks prefer the young seedlings to Onions for use in flavouring.

Turnips.—If seeds are not sown until the end of the month there will be less fear of the crop being spoiled through "bolting." But if a frame can be spared let a sowing be made now on a slight hotbed, followed by another sowing made in a cold frame. A succession of nice tender roots may then be anticipated before there are any fit for use out of doors. Turnips require a light, firm soil, and a sprinkling of soot mixed with it. Thin out the seedlings as early as it is possible to do the work, and before they get "leggy," which is the ruin of many young plants. Early White Milan is one of the best varieties for cultivation in frames, and may be followed by Snowball. The latter is the better Turnip, being deeper in the flesh, but it is later in coming to maturity. A small sowing may be made out of doors shortly on a sheltered and warm border, employing the same varieties. The loss will not be great if they fail, and there is the possibility that they will succeed.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Pruning Apple and Pear Trees.—If this work has not been completed, let it be hastened as much as possible, for the buds are beginning to push. Prune the spurs somewhat severely in order to induce them to "break back," but favour those buds which are most suitably placed. Thin the spurs out as much as is practicable, in order that those which remain will be the better exposed to the influence of light and air. Young shoots in a vigorous condition should be cut back more severely than others. Thin out the branches of any standard trees that may still remain to be pruned, and shorten the longest growths.

Vines should now be pruned; Raby Castle is a fine variety for affording decorative foliage, being of a dark port wine colour and often called by that name. It is suitable for cultivation on old or unsightly buildings.

Strawberries.—Beds that have not been mulched may have the surface soil between the rows lightly pricked over with a fork, and a good mulch of manure placed over it. Prepare a piece of ground by trenching it and adding manure, that the soil may be ready to receive plants next month. Royal Sovereign, if wintered in pots, succeeds very well under this treatment, and is capable of producing fine fruits. A system that may be recommended as a good one for producing an early crop of fruit outside, is that of planting strong crowns on a south border and covering them with frames.

Crab Apples.—These fruits are very nice, and they answer a double purpose. The trees are beautiful when in flower; they continue to be showy all through the summer and the fruits make an agreeable preserve. The Siberian Crab is one of the best. Others to be recommended are John Downie, The Dartmouth, Mrs. John Seden, and The Langley, which are newer and very showy. They form very beautiful standards.

Blackberries, &c.—Good plants of these can be procured in pots, therefore planting may still be done. Wilson's Early is very productive, and Wilson, Junr., a large fruited variety. The parsley-leaved Bramble, Rubus laciniatus, is one of the most serviceable. The Logan Berry, a hybrid from the Raspberry and Blackberry, is grown extensively. The fruit is of large size and rich in colour, possessing a fine flavour which makes it of use for dessert or for culinary purposes. This hybrid makes a robust growth, and should be trained to strained wires, or be supported on poles or stout stakes.

Filberts and other Nuts.—Thin out the wood of these bushes and remove all suckers from the base.

THE APIARY.

By CHLORIS.

Its Position.—Very few people seem to realise how necessary it is to choose a suitable site for the hives. Many of my acquaintances place them under hedges, in spots sheltered from the sun, and even in a very weedy portion of the garden. Last year I was requested to overhaul some bees by the head gardener at a large establishment, and I could scarcely see the hives for tall weeds.

What then is a suitable place?—It should not be where there is much traffic, e.g., near a path or croquet ground. It will be well to choose a low position on rising ground, sheltered from north and east winds. It will be well to let the entrances face to the south-east, so that the inmates may feel the warming and rousing influence of the early morning sun. The stands of the hives should not be very high, for the bees returning heavily laden often have a difficulty in reaching a high alighting board. There is also another drawback, and that is the hives are in greater danger of being blown over in a gale when they stand too high above the ground. The land in front of the hives should always be kept free of all plant life for a space of 2 or 3 feet.

Distance between the Hives.—If two or more lines of hives are kept, there should be a space of from 12 to 18 feet between the lines and a distance of 6 feet between the hives in each line.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* EDITOR, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Feb. 10	Dutch Gardeners' Soc. meet.
TUESDAY,	Feb. 13	Ann. Meet. Roy. Hort. Soc. at 3 p.m. Committees meet at 12 p.m. Hort. Club Ann. Meet. & Dinner.
THURSDAY,	Feb. 15	Linnean Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—39·0°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Feb.* 7 (6 P.M.): Max. 45°; Min. 37°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 8 (10 A.M.): Bar., 29·9; Temp., 45°; *Weather*—Dull.

PROVINCES.—*Wednesday, Feb.* 7 (6 P.M.): Max. 47° Ireland West; Min. 39° Colchester.

SALES.

MONDAY NEXT—
Thousands of Hardy Border, Herbaceous and other plants, Lilies, Roses, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—
Sale of Roses, Lilies, Rhododendrons, &c., at Stevens' Rooms, King Street, Covent Garden, London.

WEDNESDAY NEXT—
The Freehold Property, the Exotic Nurseries, Heritage Road, Coalville, Leicestershire, with Dwelling-house, Greenhouses, trade buildings, &c., at Railway Hotel, Coalville, by Protheroe & Morris, at 4.

WEDNESDAY NEXT—
Herbaceous and border plants, Gladiolus, Begonias, &c., at 12; Roses at 1 and 3, also Azaleas, Palms, plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY NEXT—
Roses, Azaleas, Hardy plants and bulbs, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY NEXT—
Choice imported and established Orchids, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

Variation in the Potato Tuber.

M. Edouard Heckel contributes a paper to a recent issue of the *Comptes Rendus* on variation in Solanum tubers, which is of great interest to Potato raisers and to botanists. He mentions the rapid and important changes in the vegetative system as also in the reproductive organs of Solanum Commersoni reported to have been observed by M. Labergerie at Verrières. This plant had been cultivated by M. Heckel at Marseilles for six years without any such variation in the specific type having been observed. In these specimens it was the tuber that was especially modified in size, in colour, taste, and the nature of the skin. It became edible and, finally, developed four varieties: violet, yellow, rose, and white, which all sprang from a tuber supplied by M. Heckel that was originally yellow. It was remarkable that variation in the tubers affected first the colouring of the skin and even of the flesh as in the case of Oxalis crenata, the Jerusalem Artichoke, and the Yam.

The violet variety is the most remarkable, and some growers, as we have already stated, conjecture it may be the same as a variety of Solanum tuberosum known as *géante bleue*, a view which M. Labergerie strongly disputes. M. Heckel also has no doubts as to its origin, for he reports that he has seen, in the Botanic Garden at Marseilles, tubers of the violet variety yield plants that afforded a reversion to the purest type of S. Commersoni, whilst at Verrières M. Labergerie found all intermediate stages between the cordiform fruit of S. Commersoni and the round fruit of S. tuberosum. Having grown Solanum Commersoni, S. Maglia, S. Fendleri, S. Ohrondi, and S. stoloniferum unsuccessfully in Provence, M. Heckel resolved to start afresh under different conditions, and to commence with S. Maglia. In 1905 he received from MM. de Vilmorin, who had long grown this species, and from Messrs. Sutton and Sons, of Reading, violet and yellow tubers of S. Maglia. Planted in a warm house, supplied with the usual manures (super-phosphate, potassium chloride and nitrate of potash), the tubers yielded fine plants, and their flowers were identical with those of S. Maglia. At the end of April many of them ceased forming tubers, and M. Heckel resolved to turn them out of their pots and put them in the open ground in a bed where the preceding year he had grown some plants of Sutton's Discovery, North Star, and Edward VII. These are all varieties of the common Potato S. tuberosum selected, on account of the abundance of pollen they yield, for hybridising (successfully, as it proved). S. tuberosum was used as the pollen parent, and S. Commersoni as the female. Mole crickets and various accidents eventually left only one plant of the yellow S. Maglia alive. Last November this plant bore at its base, without stolons, five tubers very varied in character, but all red-violet in colour.

While the tubers planted weighed 4 grammes and 5 grammes, and measured 2 cent. 5 long, those which M. Heckel gathered measured between 5 and 9 cent. and weighed from 30 to 130 grammes. The lenticels had disappeared, the flesh was no longer watery and bitter or tasteless, but was firmer, contained more starch, the eyes were developed, and the tuber was now edible. In a word, this variety of S. Maglia behaved in the same way as that raised at Verrières in 1901 from Solanum Commersoni, of which yellow tubers were sent to M. Labergerie. This result induced M. Heckel to think that the vicinity of S. tuberosum and its influence on the surrounding soil was responsible for the variations. Evidently these results were not due to cultural causes, but were probably due to the same phenomena recently observed by M. Bonnier in the ordinary Potato. Clusius, it is stated, was only able to obtain tubers on plants raised from seed by the aid of a little earth surrounding the tubers. M. Heckel is repeating, on all the wild tuber-bearing species that he can procure, the same experiments which were carried on with the tubers in a state of variation, and he desires that growers of these same varieties should repeat his trials, as the importance of the subject demands careful checking by several observers. In any case, M. Heckel's experience serves to confirm the opinion of A. de Candolle that the S. Maglia of Chili and Peru was the wild species whence our cultivated Potato originated. The fact admitted of no doubt historically, and M. Heckel has now proved it experimentally. It is possible that the tuber which was the subject of the variation here described resembles some known and cultivated form of the common Potato, as it sprang from the violet variety of S. Commersoni. This is not surprising, since most writers who have studied the matter agree that S. Commersoni and S. Maglia had a share in yielding the numerous varieties of the Potato in cultivation that are classed indifferently now as S. tuberosum.

It would seem from the results published by M. Labergerie and M. Heckel that we have here to do with a process analogous to what De Vries calls "mutation." It is equally evident that the observations of the two gentlemen above-named require to be repeated in various localities before their inferences can be accepted as free from doubt.

With regard to the identity of the tubers gained by M. Labergerie with those of "Blue Giant," there is, as we have already stated, considerable difference of opinion. M. Labergerie is convinced that his tubers are different from those of Giant blue. M. Heckel, as we have seen, shares M. Labergerie's convictions. M. Gaston Bonnier says, from trials made at Fontainebleau, that in dry soils it is impossible to confound the two sorts, but that in damp soils the difference is not so perceptible, although, even then, careful examination reveals points of distinction. M. Labergerie's plant, says M. Bonnier, differs from the Blue Giant in the greyish violet colour of the tubers, the abundance of lenticels, and its earlier ripening. Moreover, the Blue Giant cultivated in soils of the most varied character, neither develops the great variability of the sport derived from S. Commersoni, nor the reversions to the wild form which have been observed in the last mentioned.

Incidentally, M. Philippe de Vilmorin contributes an interesting addition to this discussion. In the Bulletin of the Botanical Society of France, No. 7, 1905, p. 535, M. de Vilmorin expresses a doubt as to the origin of M. Labergerie's variety, and goes on to allude to the not infrequent production of tubers on the haulm. In his experience this production of aerial tubers is more common in violet coloured Potatos than in any other, and occurs especially in cases where the vegetative growth is rendered excessively luxuriant by the humidity of the soil. In our own experience we have thought that the production of tubers on the haulm was sometimes due to some injury to the underground tuber by a digging fork, wire-worm, or other source of injury to the subterranean parts of the stem. But this is a point which demands investigation. The instance described and figured by M. de Vilmorin is specially remarkable in that the aerial tubers were not produced on the haulm but on the inflorescence. It would seem, from M. de Vilmorin's figure that certain branches of the inflorescence which, under ordinary circumstances should be short, slender, almost thread-like, and terminated by a flower, have developed into stout herbaceous, leaf-bearing shoots like those of the ordinary haulm, but even thicker. From the axils of the leaves on these modified shoots aerial tubers have been formed.

The problems to be solved then are these:—Are we to consider Solanum tuberosum (our ordinary Potato), S. Commersoni, and S. Maglia, leaving others for the time being out of consideration, as separate and distinct species, or can we believe that the one may develop from the other by "mutation" or otherwise? If this latter view is proved to be

the correct one, may it not be that S. tuberosum itself is only a derivative from some other species? In that case it might be of the greatest practical importance to know the conditions which have brought about these changes. And so it comes about that variations which are sometimes rather disdainfully called sports or "freaks of Nature" (as if there was ever any caprice in Nature!) become of the highest importance scientifically and practically. The exhibit of species of Potato which Messrs. Sutton tell us they will display at the meeting of the Royal Horticultural Society on Tuesday next will, in view of the circumstances just mentioned, be scanned with unusual interest.

OUR SUPPLEMENTARY ILLUSTRATION.—The group of Chrysanthemums shown in our supplementary illustration was exhibited by Mr. H. J. JONES, Ryecroft Nurseries, Lewisham, at the exhibition of the National Chrysanthemum Society held at the Crystal Palace in December last. This group was greatly admired, and it received one of the highest awards given at the Show, in the form of a large gold medal. All the various sections of this popular flower were represented in the group, a feature being the single-flowered and the smaller decorative sorts, which were arranged among the larger specimen blooms. Among the latter, Mrs. Swinburne, a pure white variety, received a First Class Certificate on account of its beauty and for its value as a late variety. Mrs. Beech, a yellow sport from the last-named variety, was also shown in good form. Mrs. W. Elliott, a large, white flower with very long, drooping florets, Crimson Gem, a medium-sized bloom rich in the colour indicated by its name, Market Gold, and Glory, a new golden-yellow decorative flower, are other worthy varieties included in the display. Of the singles, Silver Star was one of the most prominent. The large specimen blooms seen in the foreground were arranged among Ferns, which manner of staging was more effective than if the flowers had been arranged stiffly on boards. It has been remarked for several years past that some of the trade growers, particularly Mr. H. J. JONES and Mr. NORMAN DAVIS, have arranged groups of Chrysanthemum blooms and decorative foliage plants in a manner that has won admiration by reason of the bold effect obtained. Mr. DAVIS' group in the Royal Horticultural Hall in November last was a good instance of this.

THE BOTANICAL MAGAZINE.—The contents of the February number, edited by Sir WILLIAM T. THISELTON-DYER, comprise coloured illustrations and descriptions of the following plants:—

EULOPHIA NUDA, *Lindley*; tab. 8,057.—A terrestrial Orchid found wild from Nepal and Burma to Ceylon, as well as in the Chinese province of Yunnan. The leaves are plicately folded; the flowers borne in erect scapes; perianth segments ascending, rose-pink; lip—trowel-shaped with a yellow disc margined with deep rose, and a rather long conical spur. The variations in colour are said to be very great.

SAXIFRAGA SCARDICA, *Griesbach*; tab. 8,058.—A sturdy species which "may be expected to supersede, to some extent, the well-known S. Burseriana, as it is more showy and stands damp weather better." It is a native of the Balkan Peninsula.

IRIS SIEHEANA, *Lynch*, in *Gardeners' Chronicle* (1904), p. 282; tab. 8,059.—Closely allied to I. persica, but differs in its stiffer leaves and the colour of its perianth, which is silvery-grey, striped with reddish purple.

LONICERA PILEATA, *Oliver*; tab. 8,060.—A low-spreading shrub with hairy branches, ovate evergreen leaves and pale yellow flowers in the axils of the leaves. The flowers are in pairs, united at the base, and the calyx-tube is provided with a sheath-like outgrowth directed downwards. The plant was introduced to the Veitchian nurseries by Mr. E. H. Wilson.

PRUNUS TRILOBA, *Lindley*, in *Gardeners' Chronicle* (1857), p. 268; tab. 8,061.—A charming spring flowering species, the leaves of which are often three-lobed. Very often, too, the flowers contain three, or even five, carpels in place of the ordinary single pistil.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the lecture hall of the Institution on Monday, February 12, 1906, at 8 p.m. when the discussion on Mr. MARSHALL'S paper will be resumed.

NURSERY EMPLOYEES AT DINNER.—The well-known nursery firm of Messrs. CYPHER and Co., Cheltenham, recently entertained the whole of their indoor staff at dinner. The older members, numbering 20, met on Wednesday, 31st ult., and the remainder on the following evening. Mr. JOHN CYPHER said it gave him pleasure to meet them under such pleasant circumstances, and referred to the good feeling that existed between them, mentioning that some of those present had been connected with the firm for upwards of a quarter of a century.

BRITISH GARDENERS' ASSOCIATION.—At the last meeting of the Executive Council held at the R.H.S. Hall, Westminster, the Secretary reported that 38 new members had joined the Association since the last published report, bringing the total up to 835. One candidate for membership was not accepted by the council. Since the last meeting was held the rules, list of members with addresses, branches, &c., have been issued to all members of the Association. Certificates have also been issued to those who have paid their subscriptions for the year 1906. The Secretary, Mr. J. WEATHERS, 7, Talbot Road, Isleworth, Middlesex, will be glad if members when remitting their subscriptions will be good enough to acquaint him with any changes of address.

THE STAFFORDSHIRE COUNTY COUNCIL AND GARDEN EDUCATION.—The Education Committee of the Staffordshire County Council has published a pamphlet respecting its scheme for gardening in public elementary day schools. It is intended to provide suitable practical teaching for country boys; and two years' experience having proved its value in some places, it is hoped that the scope of the scheme will now be enlarged. A general garden, or single plots are used, according to circumstances, and all are supervised by certificated teachers. The boys are encouraged to note the weather, birds, insects, and other surroundings, as well as the crops before them. The satisfactory results already obtained encourage the committee to continue their work. The report is drawn up by Mr. GRAHAM BALFOUR, Director of Education, and by Mr. A. W. BROWN.

POTATOS.—Messrs. SUTTON & SONS inform us that on Tuesday next, February 13, on the occasion of the annual meeting of the Royal Horticultural Society, they will exhibit a collection of Potatos containing features of special interest. Included in the collection will be specimen tubers of many original wild species and types, some of which, so far as they are aware, have never been exhibited in this country.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are informed that Lord BALFOUR OF BURLEIGH (President of the Royal Caledonian Horticultural Society, Edinburgh, and Member of the Council of the Royal Horticultural Society) will preside at the 67th anniversary festival dinner at the Hotel Metropole on Wednesday, June 13, in aid of the funds of this institution.

MANURING OF HOPS.—Dr. BERNARD DYER obligingly furnishes us with a summary record of his experiments on the manuring of Hops during the last ten years at Mr. SHRIVELL'S farm near Tonbridge. The general results of the experiments appear to justify the conclusions already expressed, namely, that even when the soil is otherwise liberally manured by autumn or winter dressings of dung, rape dust, fish guano, etc., 4 cwt. per acre of nitrate of soda, applied early in the spring, may be regarded as a safe and profitable dressing for Hops, even in a wet season; phosphates, of course, being used liberally at the same time, and potash salts if the land requires them. Such a dressing (4cwt. per acre) of nitrate of soda, it would perhaps be better not to exceed in the case of the more delicate varieties of Hops. If, however, neither dung nor any other nitrogenous fertiliser has been recently applied, there appears to be no reason to anticipate that 6 cwt. per acre of nitrate of soda would be otherwise than safe, even for delicate Hops; while for freely growing and heavily cropping varieties as much as 8 cwt. per acre might be used. But a more miscellaneous manuring, including moderate dressings like 4 cwt. per acre of nitrate of soda would probably commend itself to most growers. It is not desirable that nitrate of soda should be put on late in the season, as is sometimes done, since this appears to tend to delay the ripening of the Hops.

SUGAR IN QUEENSLAND.—An old correspondent writes in a letter received a few days ago that "the young cane (sugar) and ratoons are looking well, and if we get rain about the usual time there will be another grand season; but drought may upset all our calculations. A farmer close to me is cutting 45 tons to the acre. The sugar mills are all busy, and will have a very profitable season."

MUSA.—From the Royal Botanic Gardens, Kew, has been issued what we take to be a reprint of certain articles previously published in the *Bulletin* and elsewhere, on the species and principal varieties of Musa. Mr. BAKER'S monograph of the species, 35 in number, has been incorporated to a large extent. In addition, there is a great variety of miscellaneous information relating to varieties, their culture, uses, geographical distribution, and the like. The volume is, in fact, an encyclopædic summary of what is known concerning Musas, and will be very useful for reference. A few illustrations and a sufficient index are provided.

"ELECTROS."—We are very frequently asked to sell, or to lend, electros from our blocks, but, unless under special circumstances, we do not sell or lend our blocks if they are to be used for commercial purposes. The next question asked is where can I procure the electros I want? This question has hitherto been difficult to answer. It is rendered much more easy now by the publication, by Messrs. WATKINS and SIMPSON, wholesale seed merchants, of Tavistock Street, Covent Garden, of an "electro album" devoted to the illustration of types of vegetables and hardy or half-hardy flowers. Those desirous of illustrating their catalogues with accurate representations will find this album very serviceable. County Council lecturers and others engaged in educational work will also find it of value to them.

"L'ART DE FORCER."—M. VAN DEN HEEDE supplies for the benefit of French readers a handy little treatise on the "Art of Forcing." It is to be had from M. CHARLES AMAT, Rue Cassette 11, Paris. It deals with forcing in general, its importance and value, the best methods of carrying it out, the processes of retarding by cold, the application of ether or chloroform, an enumeration of the most useful

plants for forcing purpose, and a variety of details of importance to those who engage in this work. In his preface M. Van den Heede gives some interesting particulars of the practice of forcing in France from the time of Olivier de Serres (1513-1619) to the present time, when forcing not only supplies luxuries for the rich as in bye-gone times, but is a commercial industry on a vast scale, in the benefits of which the poorest have their full share.

Gloire de Lorraine.—We have received a photograph from Mr. C. P. Lamb, the gardens, Pinkney Park, Malmesbury, showing three excellent plants of Begonia Gloire de Lorraine, cultivated there for Lieut-Col. Turnor. The specimens measured 3 feet in height and 3½ feet in diameter. We should have been tempted to reproduce the photograph but for the fact that his popular Begonia has been already figured on several occasions in these columns.

A New Propagating House.—In the current number of *Revue de l'Horticulture Belge* is an account of a new propagating house erected by M. Buyssens at Vilvorde. It is simply a glass box, raised on three layers of bricks. The roof is nearly flat, with only just sufficient slope from the ridge to carry the water off. The lights at the ends, as well as at the sides, are 1·50 metre (5 feet) long by 0·81 in breadth (about 32 inches), so that a maximum of light is ensured. The stages on which the plants are placed can be raised or lowered at will by appropriate mechanism so that the plants on an upper stage can be placed as near the glass as necessary, and lowered when watering or other operations are required. At the same time there is abundance of room and light for a second stage beneath the upper one. The lights, being inserted in grooves without putty, can easily be removed for painting, cleansing, or repairing the rafters, or they can be removed altogether during the summer. We are not told what provision is made for ventilation.

A New Vegetable.—M. Barial, of 3, Boulevard de l'Ouest, Le Raincy, Seine et Oise, France, announces a new vegetable under the name of "Helianthi," or American Salsafy. According to the illustrations which have reached us, this is none other than the tuberous stolons of some species of Helianthus unnamed, but evidently akin to H. rigidus. The foliage is also recommended for forage.

Botanic Gardens.—We have received a copy of the exchange seed list issued by the Imperial Botanic Garden, St. Petersburg. In addition to the general enumeration there are special lists containing the names of plants obtained from Turkestan, the Caucasus, and various Russian provinces. The names are in Latin. The Director is Prof. Dr. Fischer de Waldheim, to whom application should be made before March 1.

Linnean Society.—The next meeting will take place on Thursday, February 15, 1906, at 8 p.m., when the following papers will be read:—"The Structure of Iris hippuris" (Linnæus), by J. J. Simpson; "Note on the Geographical Distribution of the Genus Shortia" (Torr. and Gray), by W. B. Daydon Jackson, Gen. Sec. L.S.; "Exhibitions": Dr. H. Charlton Bustian, F.R.S., F.J.I.; "Developmental Changes in Zoogloea" (with lantern slides).

The First County Park System.—A book, written by Mr. Frederick W. Kelsey, claiming to be a complete history of the inception and development of the Essex County parks of New Jersey has lately been published. The author was a member and vice-president of the first Board of Commissioners selected to lay out the parks, and in ten years has seen them succeed and develop to a most satisfactory extent. The facts are candidly stated, and should interest all who know the grounds, and be of use to future workers in similar fields. Illustrations brighten the pages, and afford evidence of the attractiveness claimed for these recreation grounds and gardens. The book deals with the inception of the enterprise, and reflects the smooth course of progress "until the blighting influence of special interests and of practical politics were injected into the undertaking."

Flowers in Season.—From Messrs. Webb and Sons, Stourbridge, we have received some flowers of their strain of florist Primula. Avalanche is white, of large size, and possesses frilled florets. Meteor is also large, and the colour is of pale salmon-rose. Others sent are Ruby Queen (ruby), Eclipse (purplish-crimson), and a rose-coloured seedling.

Horticultural Club.—The annual dinner of the Club will be held on Tuesday, February 13, at 6 p.m., at the Hotel Windsor. Ladies are specially invited. After dinner there will be music by the "Quavers" Vocal Quartette, under the direction of Mr. Wilfred Kearton, of St. George's Chapel, Windsor Castle. The annual meeting will take place at 5 p.m., and it is hoped that all interested in the club will be present.

National Rose Society.—A meeting of the General Purposes Committee will be held at the Westminster Palace Hotel, Victoria Street, Westminster (not at the Windsor), on Tuesday, the 13th inst., at 2 p.m. Agenda: To draw up Schedule for the Royal Botanic Gardens Show, "The Rose Annual" and other business.

Messrs. Protheroe & Morris.—The Central Cricket Club (in connection with the firm of Messrs. Protheroe & Morris) held their second annual smoking concert at "Stone's," Ludgate Hill, on Monday evening last. Mr. J. B. Slade was in the chair, and there was an attendance of about 85, including Messrs. Carter, James, and Seymour (former members of the staff), the employees, and their friends. The programme lasted for 4½ hours, the chief items of interest being songs, musical sketches, &c., by Mr. Wyatt, Mr. George Pritchard, Mr. Cox, Mr. Alf. Amis, Mr. H. Bowers, Mr. Goddard, and Mr. Seymour. The toast, the "C. C. C.," was given by Mr. Slade, who presided in his well-known genial manner, and was replied to by Captain Humphrey in suitable words. The entertainment was a great success.

Royal Horticultural Society.—The society's annual examination in the Principles and Practice of Horticulture will be held on Wednesday, March 28, 1906. Candidates should send in their names not later than March 1. Full particulars may be obtained by sending a stamped and directed envelope to the Society's Offices, Vincent Square, Westminster, S.W. Copies of the questions set from 1893-1905 (price 1s. 9d. or 10s. a dozen), may also be obtained from the office. The society is willing to hold an examination wherever a magistrate, clergyman, schoolmaster or other responsible person accustomed to examinations will consent to supervise one on the society's behalf. In connection with this examination a scholarship of £25 a year for two years is offered by the Worshipful Company of Gardeners, to be awarded after the 1906 examination to the student who shall pass highest if he is willing to accept the conditions attaching thereto. The main outline of these conditions is that the holder must be of the male sex, and between the ages of 18 and 22 years, and that he should study gardening for one year at least at the Royal Horticultural Society's Gardens at Wisley, near Ripley, Surrey, conforming to the general rules laid down there for students. In the second year of the scholarship he may, if he like, continue his studies at some other place at home or abroad approved by the Master of the Worshipful Company of Gardeners, and by the Council of the Royal Horticultural Society. In case of two or more eligible students being adjudged equal, the council reserve to themselves the right to decide which of them shall be presented to the scholarship.

The Forest Flora of New South Wales.—Mr. J. H. Maiden has now completed part 8 of the second volume of this useful work (part xviii of the complete publication). The species herein considered are the following:—Flindersia Schottiana, Eucalyptus regnans, or Giant Gum Tree, and Casuarina tuberosa, or Black She-Oak.

Publications Received.—Select list of works prepared at the Royal Botanic Gardens, Kew, &c., &c.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Hippeastrums (Amaryllis) at Tring Park.—The Right Hon. Lord Rothschild has for some years past taken great interest in perfecting the fine strain of Hippeastrums in his gardens at Tring Park (gr. Mr. Arthur Dye). As each successive batch of seedlings has flowered marked improvements have been disclosed until at the present time the magnificent show of flowers in the Tring Park Gardens seem to indicate that in some of the sections the best quality possible has been obtained. The production of large flowers of considerable substance and equally broad segments were the first objects in developing the strain, preference being given to the forms which displayed but little green in the centre, and to those which produced four flowers on a spike all open at the same time. The batch now in bloom came chiefly from two of the best of the Tring Park strain, viz., King Edward VII. and St. Frusquin. There are several distinct sections, the favourite being one with massive flowers of a brilliant dark scarlet. The lighter strain has very large white flowers variously striped with scarlet, and a very attractive class has the bright red flowers with a broad white margin. Two of the finest pure white varieties were obtained a few years ago, and two or three good white forms raised from them now in bloom will develop into better flowers than the parents. A large number of bulbs in another house are just sending up their spikes, so the display will continue for a long time. *J. O. B.*

The Flannel Flower of Australia (see enquiry by J. G. G., p. 80).—This is Actinotus Helianthi. *C. Bennett, Hall Green, Birmingham (late of Sydney, N.S.W.).*

The Late Harrison Weir and Bullfinches.—The recent death of Mr. Harrison Weir reminds me of some correspondence that passed between us some years ago respecting the Bullfinch. I had sent a note to the *Gardeners' Chronicle* describing the nuisance that these birds occasioned, and complaining that they had visited the gardens of which I had charge. I stated that on the choicest trees, every fruit bud had been carefully dissected, and that, owing to the Bullfinches' audacity, I had been enabled to "pick off" a large number of them. A few days later I received a gentle chiding from Mr. Weir for employing such measures against the birds, and he assured me they did a vast amount of good in destroying innumerable insects. That was their mission, they instinctively knew that these pests lurked beneath the scales, &c. My reply was that no one took greater interest in birds than myself, and that for years I had kept a number in a spacious aviary, but I utterly failed to comprehend what advantages accrued from their visits to the bushes when they removed every fruit bud. Most gardeners in the country are well aware of their destructive capabilities. In some gardens they are but seldom seen, and doubtless the presence of extensive woodlands and game coverts in close proximity to the gardens under notice would account for their unusual numbers. The gardener in an adjoining estate found it necessary to cover all his fruit trees with wire netting, a perfect square being formed round each tree. *Walter H. Aggett, Supt., Public Gardens, Bermondsey, S.E.*

Apple Charles Ross.—It is disappointing to learn from some growers of this new Apple, one that at the outset gave such rich promise of excellence, that with them the fruits have been of inferior merit. But whilst there could be no question that the fruits first exhibited to the R.H.S. Fruit Committee by Mr. Ross, and probably from the seedling tree, were of rich flavour

and undoubted excellence, so also were the fruits to which the first prize was awarded in the class for any other dessert Apple at the great show of British fruit held last October. In that case the fruits were not exceptionally large, but were so richly flavoured and good as to evoke from myself and my fellow judges the highest praise. These two instances show that the Charles Ross Apple has qualities that growers, so far, have largely failed to bring out. It would be interesting to learn from the grower of those first prize fruits the conditions of their production. My impression is that as the variety being new has so far fruited on young trees only (except perhaps in a few cases where worked on old trees), the fruits have suffered in quality because the trees have been rather overfed, resulting in the production of large fruits. The more they approached in size those of one parent, Peasgood's Nonsuch, they naturally lacked the richer flavour and excellence found in the fruits of the other parent. It will be no matter for surprise to find Charles Ross producing from elderly trees, and especially orchard-standards, fruits of that rich excellence which, though smaller in size, marks the fruits of Cox's Orange Pippin so grown. From such trees I have invariably found the fruits to be of richer flavour, just as is found also in fruits of Blenheim Pippin. It will then be found that in granting Charles Ross a F.C.C. the Fruit Committee did not make the mistake usually charged upon it.—*A. Dean.*

Winter-flowering Carnations.—There being much interest shown in winter-flowering Carnations at the present time, and particularly in the newer American varieties, I am sending a few blooms with this note. My experience with them has shown these varieties to be valuable acquisitions to our winter-blooming Carnations. Enchantress, perhaps one of the best known of the group, is a lovely variety of a popular shade of pink colour. Halowarden is a very large crimson flower and a strong grower. Lady Bountiful, pure white, is magnificent; the flowers are of large size, and the plants b oom very freely. Royalty is of salmon-pink colour, a good variety, but not so robust here as most others are. Nelson Fisher is a most effective colour after the manner of Mrs. T. W. Lawson, but deeper in shade. Reliance, pure white, at present is not so good with us as Lady Bountiful. Dorothy Witney is quite a new colour in the tree section, being yellow, striped with pink, very rich indeed; the flowers are of perfect form, but hardly so large in size as those of some other varieties. Her Majesty, white with faint rose stripes, is a beautiful bloom, but is not a very strong grower with us at present. Of the older varieties, Mrs. T. W. Lawson is one of the very best, strong and healthy in its growth, producing plenty of good blooms on long, stiff stems. Mrs. S. J. Brooks, pure white, is a splendid companion for this, and succeeds remarkably well here. Floriana, another fine variety, is of a pleasant shade of pink colour; the flowers are of good size, and the plants grow well. Alpine Glow is also a good shade of pink colour. A point in favour of the newer varieties is the long, stiff stems, which make them doubly valuable for decorative purposes, and I believe that they will be much favoured where the best Carnations are grown. *J. G. Weston, Eastwell Park Gardens, Kent.* [The flowers sent by our correspondent are exceedingly bright and pleasing.—Ed.]

Chrysanthemum Baron de Vinols.—I noticed the remarks of *C. H. P.* under the above heading on p. 51. This variety is synonymous with Caprice du Printemps, which has been largely grown for decorative and market purposes in this country for several years past. A sport from it, Kathleen Thompson, received an Award of Merit from the Royal Horticultural Society in the autumn of 1904, and judging from the description of Mme. George Barré in a French catalogue, I think this variety is synonymous with Kathleen Thompson, thus showing that the parent, Caprice du Printemps, has given similar sports on both sides of the Channel. *I. G.*

To Brighten Beds of Azaleas and Rhododendrons.—*F. M.*, according to his note on p. 46, would, if permitted, make a good jungle planter; for his style of planting is in very bad taste, as all plants such as he names have a beauty of their own at all seasons of the year. Azaleas are crimson and gold in the autumn. Fancy Rambler Roses and Scotch Roses in a Rhododendron bed! A Scotch Rose, like a Scotchman, once well planted, wants plenty of room and a lot of shifting. *R. M., Garden City, January 22, 1906.*

Cystopteris fragilis sempervirens.—By the courtesy of Mr. Somerville of Glasgow I have recently received several fronds of a form of Cystopteris fragilis, found in Scotland by Mr. William Young of Kirkcaldy, which appear to answer to the description of the sempervirens form of the species described by Mr. Britten in page 23 of his "European Ferns" as being a native of Madeira, except perhaps as regards the greater size of the anterior basal pinnules "and the glandular hairy vestiture of the indusium which is conspicuous in the fresh plant." The sempervirent character, however, is abundantly shown by the fact that I have just received (Jan. 31) perfectly green fronds taken by Mr. Young from his plant under glass, while the ordinary C. fragilis is deciduous, dying down entirely in the autumn. Mr. Young's plant is furthermore distinguished by its very robust growth, the fronds attaining 18 inches in length as is shown by the accompanying specimen, while as a rule I have never seen the fronds more than half that size. Under the above circumstances I consider that Mr. Young is perfectly justified in considering his find to be really C. fragilis var. sempervirens, of which previous finds in this country appear to have been doubtfully recorded. *Chas. T. Druery, V.M.H. F.L.S.*

Iris tuberosa.—The snake's-head Iris, mentioned by Capt. Pinwill in his note on page 78, is apparently not very exacting in its requirements in the south-west. Capt. Pinwill writes of an old group doing well in a shady wood. With me this Iris prospers under very different conditions, for a colony growing in the full sunshine in the open on a southern slope, that becomes dust dry in hot summers, never fails to flower well. That it does not flower freely in all portions of the Kingdom may be gathered from the notes of correspondents resident in divers localities in England and Scotland. In South Devon it is, in one place, to be found growing in a quasi wild condition in the hedgerow. It is a quaint and soberly pretty flower with its pale green standards and velvet-black falls, and has the additional merit of fragrance. The quadrilateral foliage is also curious. In Italian gardens it goes by the name of La Vedovina, the Little Widow. *S. W. Fitzherbert.*

Fifteen Pounds Annual Rent per Acre from Timber Trees.—I believe that a crop of houses in any large manufacturing town will give a bigger return than that which Mr. Simpson quotes (for forest land) on page 78. But *The Forester*, by Dr. Nisbet, states that by a judicious selection of exotic forest trees and also by manuring the ground thoroughly, these trees will pay. Will, however, the extra cost in plants above that of the native or semi-native species pay as well for what seems to be the uses to which timber will in future be put, namely, for the making of sleepers, wood-wool, etc.? *Alec. D. Berney, Stanwix, Carlisle.*

Nicotiana Sanderæ.—In reference to Mr. W. H. Diver's note on p. 76 respecting Nicotiana Sanderæ continuing to flower in so low an atmospheric temperature as 45° to 55°, I may say that I have at the present time plants that have been in flower since September last, and they have still flowers of a good shade of colour and satisfactory foliage. I intend growing more of this plant another season, as I have a house 130 feet long to keep filled with flowering plants. The atmospheric temperature averages from 45° to 55°. It is quite possible to have Nicotiana Sanderæ in flower all the year round. *W. G. Edwards, Plymouth.*

Hazel in Bloom.—With reference to your record on p. 72 I noted a nut bush, "Prolific Cob," had expanded female flowers on December 27 last. It was planted on January 29, 1905, and flowered after, so this plant has flowered twice in one year. The plant is fully exposed to the weather in an open orchard, not even a line fence to screen the wind. I noted several male flowers in the bedgerows prior to this. *Cymru, Castle-Caereinion, Welshpool.*

The Fern Paradise.—As the criticisms of your reviewer of my "Fern Paradise" are, perhaps unconsciously, unfair, I ask you to favour me with a brief reply. The writer of your "notice" has missed the "point" or object of the book, which is to serve as "a plea for the culture of ferns." This, in fact, is its plainly-written sub-title. It is not intended for expert botanists; it is not designed to convert those who are already converted; it has a "mission" which has been very largely accomplished. Special mention of detailed "varieties" was purposely excluded, as no one knows better probably than your contributor that the simple purpose of the volume would have been largely defeated had it been overloaded with descriptions of the multitudinous number of departures from normal forms. That is the purpose of another book now preparing. With due deference to your contributor, I maintain that "ferns are seed-bearing plants." Spores are seeds, though seeds are not always spores [?]. I also maintain that "many ferns" (I do not say species of ferns) "that grow in Devonshire are never seen in other counties." *Francis George Heath, Underwood, Kew Gardens.*

SOCIETIES.

ROYAL HORTICULTURAL.

The following extracts are taken from the report of the Council to be presented at the one hundred and second annual meeting on Tuesday, February 13, at the Hall in Vincent Square:—

The One Hundred and Second Year.

The year 1905 has been one of development and steady progress in every direction of the Society's manifold operations. The new hall and the new garden at Wisley have both demanded much and careful consideration, and it is satisfactory to note that each of them has far exceeded the most sanguine expectations of their suitability for the Society's purposes.

The Finances.

The attention of the Fellows is directed to the satisfactory position of the Society, not only as regards its present resources and the number of Fellows, but also in respect to the largely increased privileges of the Fellows and the greatly augmented general work of the Society for the promotion of practical and scientific horticulture. As will be seen from the balance-sheet, the Society has invested £18,430 in public securities; the hall, with its equipment and furniture, represents at least £41,000; and the works already executed at Wisley have cost over £5,600. All these are genuine assets to the credit of the Society; and, despite the increased necessary expenditure at Vincent Square compared with that at the Drill Hall, the credit balance on the year's working is £6,203.

[The financial statement, we may mention, shows a credit balance for the year of £6,203. The Temple Show was a great success; the Chelsea Show, in spite of the attractiveness of the locality, entailed a loss of nearly £500. The receipts for letting the hall, when not required for horticultural purposes, amounted to over £700. The sale of the Chiswick lease brought in £4,673. The new hall has cost about £38,924; dwelling-houses at Wisley, £2,236; glasshouses at Wisley, £3,295. The approximate value of the investments is £16,811.]

Deputations.

The Society was represented at the great International Horticultural Show at Paris in May, 1905, by Sir Albert Rollit, Bart., Major Holford, C.I.E., C.V.O., Mr. J. Gurney Fowler, Mr. Harry J. Veitch, F.L.S., and the secretary, who were empowered by the Council to award the Society's medals to exhibits of conspicuous excellence. As a slight acknowledgment of the gracious reception accorded to the deputation by the President of the Republic and Madame Loubet, the Council presented him with the Society's Flora medal in gold suitably inscribed, with which Monsieur Loubet expressed himself as being much gratified.

Another deputation consisting of the President, Mr. George Bunyard, V.M.H., Mr. James Hudson, V.M.H., Mr. A. H. Pearson, Mr. H. B. May, Mr. H. J. Veitch, F.L.S., and the secretary, visited the International Horticultural Exhibition at Edinburgh on September 13th, when medals were also awarded, and the deputation met with every kindness and attention.

The Council.

In the spring of 1905, the Council heard with the deepest regret that, owing to the state of his health, Baron Schröder was unable to continue to occupy his seat on their board. As this decision was definite, the Council would, had it been possible, at once have invited the

Fellows to put so honoured a name on the list of vice-presidents of the Society, but as it was found that this could only be done at an annual meeting, they had no choice but to postpone it till the present occasion when they are confident that the heartiness of the vote of the Fellows will be in no way affected by the unavoidable delay. Baron Schröder's services to the Society and to horticulture generally are such as will ever make his name respected and beloved by all gardeners and plant lovers who will, one and all, join in wishing that he may enjoy many years of rest in his retirement.

A very heavy loss to the Council and to the Society—as indeed to many other public institutions—was experienced towards the close of the year by the death of the Rt. Hon. the Earl of Ilchester, who took the liveliest interest in the welfare of the Society, and only quite recently he had again given permission for the show to be repeated on July 10th and 11th, 1906, a privilege which has since been most kindly confirmed by the Dowager Countess of Ilchester.

Retiring Members of Council.

Under bye-law 60 the three members of Council who have been longest in office retire each year but are eligible for re-election. The three thus retiring this year are Major Holford, C.V.O., C.I.E., Mr. H. B. May, and the Hon. W. F. D. Smith, M.P., who was appointed by the Council to sit in the place of Baron Schröder; there is also the vacancy caused by Lord Ilchester's death to be filled.

Victoria Medal of Honour.

During the past year five of the oldest and most respected holders of the Victoria Medal of Honour in Horticulture have passed away in the persons of Mr. William Paul, of Waltham Cross; Mr. Richard Dean, of Ealing; the Rev. H. Honywood D'Ombrain, of the National Rose Society; Mr. F. W. Burbidge, of Trinity College, Dublin; and Mr. Henry Eckford, of Wem, to whom we owe so many of the most beautiful Sweet Peas.

Annual Progress.

The following abstract will show the Society's progress in regard to numerical strength during the past year:—Loss by death in 1905, 94, £113 8s.; loss by resignation, etc., 485, £573 6s.—total, 579, £686 14s. Fellows elected in 1905, 1,330, £1,964 0s. 6d.; deduct loss, £686 14s.—nett increase in income, £1,277 6s. 6d. New Fellows, etc., 1,330; deduct resignations and deaths, 579; numerical increase during the year 1905, 751. The total number of Fellows, members, associates, and affiliated societies is now 9,111.

Journal.

The *Journal* continues to maintain its position in the esteem of the Fellows, and its high rank among the publications of the scientific societies of Europe and America.

Editorship.

The rapid increase in late years of the general work of the Society has rendered it impossible for the secretary to continue to act also as editor of the *Journal*, and the Council have pleasure in announcing that they have secured the services of Mr. George S. Saunders, F.L.S. (son of that staunch supporter of the Society, the late Mr. Wilson Saunders, F.R.S.), to take over the superintendence of this part of the Society's work.

Pamphlets.

The second edition of that most useful pamphlet on "Rules for Judging and Hints to Schedule Makers" which was first published in 1896, having become exhausted, a third, and greatly amended edition has been issued. A newly revised edition of the popular pamphlet on "Varieties of Fruits for Cottagers, Small Farmers and Private Gardens" has also been published with additional notes on root-pruning, etc., and the whole has been brought up to date. A new edition of the list of Orchid awards given by the Society from 1859 to December 31st, 1905, has also been prepared, and Fellows can be supplied with it on application at a cost of 5s., which is much less than the cost of production.

Examinations.

The Society's thirteenth annual examination in the Principles and Practice of Horticulture was held on April 12th, 1905, when 160 candidates entered, and the result will be found in the *Journal* (Vol. xxix., pages 688-692).

The examination will be again held on Wednesday, March 28th, 1906, at as many centres as may be necessary to suit the convenience of candidates.

The examination in cottage and allotment gardening for elementary and technical school teachers only, which was held for the first time in 1904, was repeated on April 5th, 1905, when 139 entries were received as against 124 in 1904. In order to further encourage the candidates in this examination, the Council have decided that those who pass in the first class, and desire to become Fellows of the Society, shall be exempted from the payment of the entry fee, a privilege hitherto confined to working gardeners earning their living thereby, and Fellows permanently resident outside the United Kingdom. This examination will again take place in London and at other centres in the provinces on Wednesday, April 11th, 1906.

In compliance with a request from certain county council authorities, the Council of the Society consented to hold a special examination on January 11th, 1906, for gardeners employed in the London and other town public parks and gardens.

Local Societies.

A scheme for the affiliation of local horticultural and cottage garden societies was put forward in 1890, and more than two hundred local societies have availed themselves of it. They have caused a new medal to be struck which is only to be used by affiliated societies, and which is supplied to them at cost price. The affiliated societies have also many other privileges, particulars of which may be obtained from the office.

Information.

The Council note with much satisfaction that the number of Fellows seeking information from the Society's officers continues to increase rapidly, and some thousands of answers have been given to enquiries of every description.

The Society's Hall.

The new hall has exceeded the most sanguine expectations of the Council and Fellows, both in respect of its suitability for the Society's purposes and of the demand for hiring it by other societies and individuals. The past year has been one of completion, improvement, and development. Various minor defects and faults have naturally been discovered, and these have been, or are being, corrected. A stepped platform-superstructure has been made for orchestral performances, which is almost identical with that formerly used at St. James's Hall.

Legacies and Gifts to the Hall.

Two very welcome bequests have been received during the past year, one of £250 under the will of the late Mrs. Begley, of St. Peter's Square, Hammersmith; the other of £50 under the will of the late Mr. J. Cohen, of St. Mark's Crescent, Regent's Park. The Council venture to remind Fellows of this way of handing on the benefits and enjoyment of the Society to future generations.

Various other gifts have been received, including a handsome clock for the Council chamber from Lady Macleay, in memory of Sir George Macleay, of Pendell Court; a microscope, for the use of the Scientific Committee, from Mrs. H. H. France-Hayhurst; and another for use at Wisley from General Sir Henry Yorke, K.C.B. Sir Trevor Lawrence, Bart., President of the Society, has also presented two additional high power object lenses for each of the microscopes.

Letting.

In issuing the regulations for letting the hall and other parts of the building, the Council adopted a liberal policy. They further decided to make considerable reductions to charitable institutions and horticultural societies. This policy has resulted in the hall becoming popular with lessees, who have in several cases desired to hire it annually, and have recommended it to their friends, so that no less than £700 has been received during the first year 1905.

The Library.

The whole of the books in the library have been cleaned and put in order at the sole charge of Baron Schröder, V.M.H., and the Council have caused a brass tablet recording the fact to be erected in the Library. The Veitch Memorial Trustees have also made a donation of £50 towards the funds of the [Lindley] library.

Shows in 1906.

The shows during the past year have numbered 27, occupying 36 days in all; and already 33 shows have been arranged for 1906, lasting over 42 days. These include 24 fortnightly meetings, one Home-Grown Fruit Show, three Colonial-Grown Fruit Shows, one Special Show of Table and other Decorations, and the Annual Shows of Sweet Peas, Carnations, Autumn Roses, and Potatos, to which the Council have arranged for Fellows' tickets to admit.

The Temple Show.

By the kindness of the Master and Benchers, the Society was able to hold its great show of flowers, for the eighteenth year in succession, on May 30th and 31st and June 1st in the gardens of the Inner Temple, and, despite the extremely unsettled weather, both the exhibits and the attendance exceeded the average of the last few years. Arrangements have been made for the show to be held on May 29th, 30th, and 31st, 1906.

The Summer Show.

By the kind permission of the Lords Commissioners the Great Summer Show of 1905 was held in the grounds of the Royal Military Hospital, Chelsea. Only a short time before his death the late Earl of Ilchester again most kindly placed Holland House Park at the Society's disposal for the 1906 Summer Show, on July 10th and 11th.

Fruit and Vegetable Show.

The Society's twelfth Annual Show of British-Grown Fruit was held in the Hall on October 10th, 11th and 12th; a Show of Home-Grown Vegetables on October 24th; and a special exhibition of Home-Grown Bottled and Preserved Fruits on December 5th and 6th.

Colonial Fruit Shows.

Two further shows of Colonial Fruit and Vegetable products in succession to that on December 13th and 14th, 1904, have been held, on March 30th and 31st, and December 5th and 6th, 1905. The interest taken in these has led the Council to arrange for similar shows on March 22nd, 23rd, and 24th, June 6th and 7th, and December 4th and 5th.

Kindred Societies.

The following shows were held by kindred societies in connection with certain of the Society's fortnightly exhibitions in 1905:—April 25th.—National Auricula and Primula Show. May 23rd.—National Tulip Show. July 4.—National Sweet Pea Show. July 18th.—National Carnation and Picotee Show. Sept. 26th and 27th.—National Autumn Rose Show.

These societies will continue to hold their shows at the Hall, but they will not in future take place on days fixed for the Royal Horticultural Society's own exhibitions. The Council have, however, made arrangements by which R.H.S. tickets will admit to these Kindred Societies' Shows.

Conference of Fruit Growers.

In connection with the show of British-Grown Fruit, a conference on fruit growing was held by the Society in conjunction with the National Fruit Growers' Federation on October 10th, 11th, 12th. The conference attracted considerable attention and was well attended. The papers read, and a complete illustrated report of the discussion, will be published as a separate volume of the Society's *Journal* early in the spring of 1906.

Special Orchid Classes in 1906.

At the suggestion of the Orchid committee the Council have adopted a scheme, which they hope will have the effect during the ensuing year of including Orchid growers, both large and small, amateur and professional, to exhibit their already certificated and other choice varieties at the fortnightly shows of the Society. Without in any way wishing to alter or curtail the exhibits as at present shown, *which they hope will be continued exactly as they are now*, they propose to award additional

diplomas to plants of exceptional merit staged in one group. This group will be composed of all the exhibits duly entered for this special competition in accordance with the schedule. They hope that by this means groups may be brought together representing as far as possible all the varieties of the particular species decided upon for exhibition on each occasion, together with the hybrids having that species as one of their parents. At the same time the Society's paintings of the species, and hybrids therefrom, to which awards have already been given, will be exhibited. They believe that these exhibits will have a great educational value to hybridists, orchidists, and the Fellows generally, and they rely upon all Orchid growers to assist them in making the exhibit as complete as possible.

International Conference on Plant Breeding.

Very successful conferences on plant breeding, whether by hybridisation or by cross-fertilisation, have been held already, one in London under the Society's auspices in 1899, and a second in New York under the auspices of the Horticultural Society of New York, U.S.A., in 1902. A third has now been arranged by the Council to take place in London, commencing on July 30th, and concluding on August 3rd, 1906.

It is felt that such conferences afford an unusually good opportunity for scientific and practical men to become acquainted with each other's methods and ideas, and it is hoped that representatives of both classes of students will respond to this invitation to take part in the proceedings.

Wisley.

The new garden, which was so generously presented to the Society by Sir Thomas Hanbury, V.M.H., K.C.V.O., is gradually getting into thorough working order. Fine collections of flowering shrubs have been received from the Director of Kew Gardens, and from the leading nurserymen; and representative collections of Roses have also been given by the principal Rose growers. Much, however, still remains to be done as soon as the state of the finances will permit.

Mr. George Massee, V.M.H., has kindly undertaken some original research work in the garden, especially regarding the possible transference of the Hazel-bud-mite to the Black-currant, which, when completed, will be published in the Society's *Journal*. The want of a properly-equipped research station is becoming daily more acutely felt.

The number of visitors to the Gardens admitted by Fellow's tickets during the year 1905 amounted to 5,250. This number is exclusive of horticultural parties, which were admitted by special arrangement, and would bring up the total to over 6,000.

Students.

Students are admitted to Wisley for a period of two years, and are trained in practical horticulture. Some of them also attend the Society's lectures and shows in the new hall and elsewhere. A small horticultural library is attached to the Gardens for their use. Every opportunity and encouragement is given to students, who use application, to master the whole of the general subject of practical horticulture, and as soon as a scientific department can be established, elementary science as it affects horticulture will be added to the curriculum. More than 90 per cent. of the old garden-students are doing well. The Council are quite unable to meet the applications for energetic, trustworthy young men, but they *must all be workers*. During the past year applications were received for 34 head gardeners, 7 single-handed gardeners, 12 foremen, 9 journeymen, and for many miscellaneous men, such as nursery foremen, landscape gardeners, propagators, &c. In the great majority of cases the applicants were supplied with suitable men.

The Meteorological Station.

The meteorological observations which were initiated in 1825 at the Chiswick Gardens, and are, therefore, the oldest series in the metropolitan area, are now being carried on at Wisley with a station which is regarded as one of the finest in the kingdom as regards both its situation and its equipment. The annual records are published in the Society's *Journal*.

Gifts to the Garden.

Besides the microscopes already mentioned, Mr. J. Willings has given a most useful waggonette.

Conclusion.

In concluding the report for the past year and the forecast for 1906, the Council feel that they may justly congratulate the Society on being the most prosperous Royal Scientific Society in the kingdom, the privileges of whose Fellows are in excess of those of any similar institution. At the same time they feel that what has been done in the past will be surpassed in the future, provided the Fellows do not relax their exertions, but rather make a renewed effort to wipe off the debt still remaining on the Hall, to complete the equipment of Wisley by the erection of a horticultural research station, and to increase the roll of Fellows to 10,000 by the end of the 102nd year of the Society, which closes on March 6th, 1906.
—By order of the Council,

W. WILKS, *Secretary*.

NATIONAL CHRYSANTHEMUM.

Annual Meeting.

FEBRUARY 5.—The annual meeting of the members of the National Chrysanthemum Society took place on Monday evening last at Carr's Restaurant, Strand. Mr. C. E. Shea (President) occupied the chair, and there were present about 50 members. The report of the executive committee was presented, and on the suggestion of the chairman it was taken as read. We extract the following paragraphs:—

Extracts from the Report of the Executive Committee.

"Three exhibitions were held at the Crystal Palace in 1905. At the October Show the trade exhibits of early flowering Chrysanthemums and the floral decorations were most attractive features. Some very pretty exhibits of Dahlias, Begonias, etc., were staged in the Miscellaneous Section. In many classes at the November Show the competition was exceptionally keen. In the Decorative Classes some very fine exhibits were put up; and the Miscellaneous Section, consisting of groups of Chrysanthemums, retarded plants, etc., and some tables of Carnations made a very attractive exhibition. The December Show was a highly satisfactory one, the entries in some classes being considerably above the average.

"A Conference on Early Flowering Varieties was held in connection with the October Show, papers being read by Messrs. D. B. Crane, C. Harman Payne, J. W. Moorman, E. F. Hawes, G. Gordon, V.M.H. and E. F. Such. The attendance was highly satisfactory. The papers will be issued as a separate report by the Honorary Secretary, Mr. C. H. Curtis.

"Arrangements have been made with the Crystal Palace Company to hold three Exhibitions at Sydenham in the present year on the following dates:—October 3 and 4, November 7, 8 and 9, December 5 and 6.

"Following the success of the Exhibition of Market Crysanthemums at the Essex Hall in 1904, your Committee held a repetition at the French Flower Market, Covent Garden, by kind permission of his Grace the Duke of Bedford, which proved a great advancement, both in quality of the exhibits and in its arrangement. From a financial point of view it has also been successful, there being a satisfactory balance in hand.

"Six meetings of the Floral Committee were held during the season, three at the Essex Hall and three at the Crystal Palace. The number of novelties submitted to the committee has been largely in excess of that for many years past, and a higher standard of excellence has been maintained. Thirty-six First Class Certificates were awarded. The number of meetings for the present year is increased to seven.

"The Annual Dinner was held at the Holborn Restaurant on November 28, the President occupying the chair. A most enjoyable evening was spent by those present, who numbered over 100. Fruit and flowers were contributed by several members.

"In November the National Chrysanthemum Society received a special invitation to attend the International Autumn Show of Chrysanthemums, Fruit, &c., held in Paris by the National Horticultural Society of France, and several members attended, being honoured with prominent positions on the jury. A report of this visit will be found in the schedule.

"In recognition of the valuable services rendered by Mr. G. L. Caselton, Superintendent of the Crystal Palace, at the various shows, your committee, on the occasion of the annual dinner, presented him with the society's Gold Medal suitably inscribed.

"The society is in a satisfactory financial condition. The reserve fund amounts to £119 11s. 4d., of which £115 is on deposit.

"It is to be hoped that members will use their utmost endeavours to increase the membership during the present year."

On rising to move the adoption of the report, the President referred to the services rendered by the late Secretary, Mr. R. Dean, and said that as time continued to pass, and it became possible to make a retrospect, it would be more clearly seen how valuable Mr. Dean's services had really been. The committee invited criticism of the report, for it was necessary the society should advance, otherwise it must suffer, for in regard to such institutions there could be no standing still. Then Mr. Shea again referred to the subject of literature which he mentioned on the occasion of the annual dinner, and recommended that the society should publish a Year Book, or something of that nature, that would constitute a good return for the subscriptions obtained from country members who were not necessarily exhibitors. The effect of the adoption of such policy had very greatly benefited the Rose Society during the past three years. In regard to the schedule he would recommend the committee to have some new feature at their shows every year if possible. Mr. J. H. Witty seconded the motion for the adoption of the report and balance sheet, and the subject became open for discussion. Mr. Moorman did not wish to cause any alarm by the sounding of a pessimistic note, but he drew attention to the fact that the society owed a sum of about £119 7s. to its exhibitors, and he hoped an effort would be made to discharge this liability soon, even if the sum had to be taken from the society's deposit account.

The Crystal Palace Company owes the society a considerable sum of money, and Mr. T. Bevan (chairman of committee) and Mr. Taylor, treasurer, stated that they expected to receive this shortly, although all their efforts to obtain it had failed up to the present. In any case the exhibitors would be paid soon. The president recommended that the Crystal Palace Company should be threatened with proceedings. Mr. Taylor (an exhibitor) drew attention to the fact that a sum almost equal to the amount offered in prizes at the December Show had been spent in luncheons and refreshments for the committee and friends. He thought that the sum was larger than it should be. Mr. Bevan explained that non-competitive exhibitors were invited to lunch on the Show day, and he thought the policy a good one.

Mr. Williams (Ealing) complained that amateurs were pitted against tradesmen in the class for a decorated table, and that the committee still looked for its judges amongst members of the society rather than select persons who were not members.

After a vote of thanks had been passed to the auditors, Mr. C. Harman Payne, referring to the conference on early flowering Chrysanthemums which was held in October, said that much of the success of that event was due to Mr. C. H Curtis, who had acted in the capacity of honorary secretary. The committee therefore recommended that a Silver Medal be given to Mr. Curtis as a souvenir of the conference. This medal was then handed by the President to Mr. Curtis.

The Question of General Secretary.

The following motion was proposed by Mr. T. Bevan, and seconded by Mr. Hawes—"That this meeting, at its rising, stand adjourned until April 30 next at 7 p.m., and that the committee be empowered in the meantime to retain the services of Mr. Gerald Dean as general secretary *pro tem.*, until a permanent secretary is elected at the adjourned meeting." This was carried unanimously.

Election of Officers.

The president, Mr. C. E. Shea; treasurer, Mr. A. Taylor; chairman, Mr. Thos. Bevan; vice-chairman, Mr. J. H. Witty; and hon. foreign corresponding secretary, Mr. C. Harman Payne, were re-elected. Including retiring members of

the executive committee and resignations, there were fourteen members to be elected that night. Election was by ballot, and the following gentlemen were elected:—G. Castleton, E. F. Hawes, D. Ingamells, E. Jones, R. E. Reeve, C. Want, J. Windibank, G. Gover, F. G. Oliver, W. Harrison, W. Wells, H. J. Jones, J. B. Riding, and Percy Cragg.

SPECIAL PRIZES.

During the time occupied in counting the votes, a little discussion took place, which turned largely on the question of decorative exhibits at the shows, and, eventually, the president offered a Silver Cup, value three guineas, for a table decorated with small flowers of Chrysanthemums. Any number of vases or other receptacles might be employed at the discretion of the individual exhibitor, but no large flowers should be used. The prize should be awarded for general effect only. A second prize of two guineas was offered by the firm of Messrs. Cragg, Harrison, and Cragg, and a third prize of thirty shillings by Mr. Williams, Ealing.

THE LATE JAMES LYE, AND ONE OF HIS PRIZE GROUPS OF FUCHSIA.

Obituary.

JAMES LYE.—On Saturday last, at a ripe age, a victim to paralysis, there passed away at Market Lavington, Wilts., a gardener in the person of James Lye, who had the warm esteem and regard of a wide circle of friends, and who had made for himself a good name in horticulture. For very many years he was gardener at Clyffe Hall, Market Lavington, and there gave his attention largely to the raising and growing of Fuchsias and Potatos. Whilst the varieties of the latter which he raised have been elbowed out of commerce by newer ones, many of his Fuchsias to-day still rank amongst the very best in cultivation—indeed, none are more beautiful, have better habits, or flower more abundantly. Mr. Lye was a very capable raiser and first-class grower of specimens, and the noble pyramids he grew at Clyffe Hall, 9 to 10 feet in height, and referred to in an article in the *Gardeners' Chronicle*, February 14, 1885, were never excelled out of the West of England. He had retired from active life for several years, but still retained his love for Fuchsia-raising to the last. *A. D.*

THE WEATHER.

THE WEATHER IN WEST HERTS.

A change to cold weather. After ten days of unseasonably high temperatures the weather became cold on the 3rd, and since then low readings have prevailed. On the warmest day of the past week the temperature in the thermometer screen rose to 49°, whereas on the coldest day it did not rise higher than 38°. On the coldest night the exposed thermometer registered 16° of frost. Although this is by no means an exceptionally low reading for February it has only once before been equalled during the present winter. The ground is now at about a seasonable temperature at two feet deep, but nearly 2° colder than the average at one foot deep. Rain or snow fell on four days, but the total fall amounted to only about a tenth of an inch. On the morning of the 5th the ground was nearly covered with snow, but as the day advanced this slight layer quickly melted. This was the heaviest fall of snow as yet this winter. For four days there has been no measurable percolation through either of the soil gauges. The sun shone on an average for 3¼ hours a day, or for over an hour a day longer than is usual at this season. The wind has been variable both in strength and direction. On the windiest day the highest record for any hour was 18 miles—direction W.N.W.—whereas on the calmest day the average rate of movement was only about a mile an hour. The mean amount of moisture in the air at three o'clock in the afternoon was as much as 9 per cent. less than a seasonable quantity for that hour. Narcissus minimus first came into flower in my garden on the 1st, which is 15 days earlier than its average date in the previous eight years, and earlier than in any of those years.

JANUARY.

A remarkably warm, wet and sunny January. In the last 20 years there have been only three warmer Januarys. On the warmest day the temperature in the thermometer screen rose to 53°, and on the coldest night the exposed thermometer registered 16° of frost—both unusually high for the time of year.

Our underground water supply. Since the winter half of the drainage year began in October the total rainfall has fallen short of the average for those four months by three-quarters of an inch, equivalent to a loss on each acre in this district of 16,740 gallons. At the same time last year the deficiency amounted to 107,200 gallons per acre. *E. M., Berkhampsted, February 7, 1906.*

REMARKS.—The first Strawberries of the season were seen on the 2nd inst.; we may now expect a regular consignment of these fruits. Over 2,000 cases of Cape Plums arrived on the 5th inst., but the cold weather prevents their sale. Cape Peaches are now arriving in better condition than when first received. A large quantity of fruit from the Cape is due to arrive on Monday next. Grapes from this colony were received last week. These met with a poor demand owing to their unripened condition. Prices for Mushrooms are inclined to be firmer. Trade in foreign Tomatos has improved. Business in vegetables is very dull. Pines are a short supply, consequently prices have advanced. The fruit trade generally is somewhat better than is usual at this season of the year. *E. H. Rides, Covent Garden, Wednesday, February 7, 1906.*

COVENT GARDEN FLOWER MARKET.

WITH colder weather flowering plants are not quite so plentiful, but supplies are still more than equal to all demands. Hyacinths are very good, but, although prices are low, it is impossible for the salesmen to clear their stands. Tulips also are over abundant, and returns are much lower than at the corresponding period of last year. Azaleas are not quite so plentiful. Some fine plants of A. mollis are seen. Lily of the Valley in pots is very good. Cinerarias are soon spoiled by the cold winds. Cyclamen are numerous and have sold rather more freely. Good plants of Begonia Gloire de Lorraine are now becoming scarce. Narcissus plants do not sell readily owing to a superabundance of cut flowers. Nice examples of Lilium lancifolium rubrum are noticed; there are also some fairly good L. longiflorums, but the latter are rather tall. Good plants of Spiræas are not abundant, but there are plenty of second quality. Marguerites can be had in quantity. Supplies of Solanums have fallen off somewhat. Dielytra spectabilis never sells readily in this market. Erica gracilis and E. melanthera can still be had in abundance. Coleus in all sizes, from those in 60-size pots up to large specimens, are plentiful. The supply of Ferns varies but little; it is, perhaps, not quite so large as that of the past week or two. The cold weather has stopped the sale of hardy flower roots.

CUT FLOWERS.

Narcissi of various sorts are extremely plentiful. The most prominent varieties are Emperor, Sir Watkin, Princeps, Golden Spur, Obvalaris, Ornatus, and the double Von Zion, or Telemonius plenus. There are also seen large quantities of the Polyanthus type, mostly imported flowers. Tulips are also abundant. A few of the finest double varieties make good prices, but "singles" are very cheap. Liliums are now making rather better prices, especially L. longiflorum. There is still a glut of Lily of the Valley. Roses do not sell well. General Jacqueminot is now marketed by several growers. Liberty is bright in colour, but the blooms are rather small. I find some florists prefer General Jacqueminot on account of its fragrance. Best quality Carnations sell readily, but flowers of second quality are over plentiful. Among Orchids are noticed free supplies of Dendrobiums, Cypripediums and Odontoglossums. Good Cattleyas are not so abundant. Of Eucharis there is no lack, and Callas are cheaper. The old double white Primula does not sell as freely as it formerly did.

In the French Flower Market this morning large supplies were at hand. While much remains unsold from day to day, it requires great care when buying imported flowers, especially in the early morning, for I find on inspection by daylight much of the cut bloom is past its best. *A. H., Covent Garden, Wednesday, February 7, 1906.*

SCHEDULES RECEIVED.

TORQUAY DISTRICT GARDENERS' Association's Spring Show to be held at the Bath Saloons, Torquay, on Thursday, March 29, 1906, and Chrysanthemum Show to be held on Thursday, November 8, 1906.

KENT AND SUSSEX DAFFODIL AND SPRING FLOWER SOCIETY'S First Annual Show to be held at the Great Hall, Tunbridge Wells, on Friday, April 20, 1906. Secretary, Mr. F. H. Chapman, 101, High Street, Rye, Sussex.

ENQUIRIES.

CARNATION. — Can any reader inform *R. F.* where he can purchase plants of Carnation "Coronation"?

EXCELSIOR BOILER.—Can any gardener tell me if this boiler is economical in the consumption of fuel, easily managed, quick in action, and generally satisfactory? *W. J. S.*

ANSWERS TO CORRESPONDENTS.

APPLE FRUIT WITH SPOTTING THROUGH THE FLESH: *X. Y. Z.* We can offer no suggestion as to the cause of the spotting beneath the skin. There is no trace of a fungus present.

BOOKS: *Hobbies.* Mendel's Principles of Heredity, translated by W. Bateson. London: J. Clay & Sons, Cambridge University Press, Ave Maria Lane.

CAMELLIA LEAVES: *T. A. G.* The black sticky substance present on your leaves is often found on these plants. It arises from a sugary secretion formed by aphides. Dirt from the atmosphere and the surroundings collect on this substance. It can be loosened by a mixture of soft soap and paraffin in hot water, and may be removed by sponging. Place a goodly-sized handful of soap in a bucket and pour on this a very small quantity of paraffin. Knead the two substances together until all the paraffin has been taken up by the soap. This will readily dissolve in water, and the petroleum does not rise to the surface to the same degree as when the two are used separately.

CHEMICAL MANURES: *E. E. S.* The package labelled No. 1 is nitrate of soda. The other appears to be a compound containing nitrogenous and other manures, but we cannot undertake to analyse it. Nitrate of soda is a very soluble manure, and should be applied to the plants with care when they are growing actively, especially in the spring. For pot plants it is advisable to apply it in a soluble state in the water when affording water to the roots. The other substance will be best applied as a top-dressing, using a pinch or two to each pot.

CHOICE HARDY PLANTS SUITABLE FOR PRODUCING FLOWERS FOR CUTTING: *Pink. H. P. Roses:* Mrs. John Laing, Frau Karl Druschki, Margaret

Dickson, Ulrich Brunner, and Louis Van Houtte. *H. T. Roses:* Caroline Testout, Lady Battersea, Killarney, Papa Gontier, and Catherine Mermet. *Carnations:* Raby Castle, Cecilia, and Herbert Cutbush. *Delphiniums:* formosum, nudicaule, and Cardinal. *Montbretia:* Pottsii, Etoile de Feu, rosea, and elegans. *Monarda:* purpurea and didyma. Eremurus robustus, Incarvillea grandiflora, Linum flavum, Hydrangea paniculata. *Liliums:* candidum, L. croceum, and L. tigrinum. *Chrysanthemums:* Marian and Mrs. Heal. *Campanulas:* persicifolia and the varieties alba and flore pleno. Heuchera sanguinea and H. gracillima. *Hollyhocks:* Kniphofia (Tritoma) aloides and K. glaucescens. *Perennial Phloxes:* Brilliant, Comtesse Jarnac, Archie Forbes, Boule de Feu, and Mrs. Jenkins. *Pyrethrums (Double):* Aphrodite, Captain Nares, and King Oscar. *(Single):* H. M. Stanley, and Captain Strachan. *Pæonies (Double):* Baroness Rothschild, Edward André, and Caroline. *Single Pæonies:* Beatrice, Duchess of Portland, candida, and Milton. *Potentillas:* La Nuit and Victor Lemoine. English and Spanish Iris, also I. Kæmpferi and I. Lorteti. *Michaelmas Daisies:* Amellus Darkness, A. bessarabicus, Hon. Vicary Gibbs, and Fairy Queen. *Sweet Peas:* Dorothy Eckford, Miss Willmott, Lady Grisel Hamilton, Lord Rosebery, Gladys Unwin, and Captain of the Blues. *Climbing Roses:* Dorothy Perkins and Crimson Rambler.

EMPLOYMENT IN CANADA: *W. C. A.* There should be plenty of openings in Canada. Apply to the Government Emigration Office, 31, Broadway, London, S.W., also to the Canadian Government's Information Office, Parliament Street, Westminster. See also the note on p. 84 referring to English gardeners in America.

FRUIT TREES: *F. M.* The bands round the main stems are known as grease-bands, and are applied for the purpose of preventing the wingless females of the winter moth from reaching the branches. Cart grease made from fat or oils, and without tar, is recommended as the best and safest composition to use for banding fruit trees. Grease banding must be performed early in October, and the bands must be kept soft and serviceable. The white coating you mention was probably lime, with which the trees are largely washed in the Kent fruit plantations. The practice of dusting the trees with slaked lime is also adopted by many fruit growers. Probably the best wash to apply to fruit trees is the caustic-alkali wash, as it destroys all manner of insect pests, and removes moss and lichens from the branches. This wash, which can be applied at the present time, is made by dissolving 1 lb. of commercial crude caustic soda in water and, separately, 1 lb. of crude potash (pearl ash) in water. When both are dissolved mix the two well together, adding ¾ lb. of soft soap or agricultural treacle. These proportions are sufficient for ten gallons of the mixture. Handle the wash carefully owing to its caustic nature.

FUMIGATING WITH HYDROCYANIC ACID GAS: *H. H. T.* See our correspondent's article on p. 85, also previous notes in the issues for April 23, 1904, p. 241, and December 9, 1905. p. 416.

HYACINTHS: *A., Bros.* We have often seen this condition. It is due to irregular growth: the central spike grows very fast, but the outer scales do not grow in proportion, and so they constrict and nip off the flower spike. If you could detect it in time a surgical operation would liberate the spike.

LOCKINGE: *Correspondent.* The glass houses at Lockinge, we are informed, were built by Mr. James Gray of Chelsea.

MEALY BUG ON VINES: *R. M.* Our own experience is that the mixture recommended on p. 48 is perfectly harmless to the vines, provided that it is not smeared over the young buds, and that in other respects ordinary care is used in making the application.

NAMES OF FRUITS: *G. B.* 1, Gooseberry Apple; 2, Langton Nonsuch.—*S. A. G.* 1, D'Arcy Spice; 2, Lord Lennox.

NAMES OF PLANTS: *F. E. G., Haywards Heath.* The flower is not a species of Crinum, but is now known as Clivia miniata; its previous name was Imantophyllum miniatum. It is a greenhouse plant, and should not at any time be subjected to the hot atmosphere of the stove. Do not disturb the roots more than once in two years. The plant often succeeds well for three or even four years without re-potting.—*Rex.* 1, (pinnate leaf) Nandina domestica; 2, (coloured do.) Trachelospermum jasminoides; 3, Teucrium fruticans. Why not number your specimens?—*A. Y. L.* The flowers were dried up owing to having been placed in cotton-wool (the worst material in which to pack flowers). 1, Appears to be Epidendrum verrucosum; 2, Bletia verecunda. The variation in colour and form of the lip is not unusual. 3. Cymbidium sinense.—*A. C. P.* Gesnera (Dolichodeira) tubiflora.—*J. O. C.* 1, Codiæum (Croton) Countess; 2, C. Aigburthiensis; 3, C. nobile; 4, C. Earl of Derby; 5, C. Laingi; 6, C. variegatum.—*Subscriber,* 1, Blechnum braziliense; 2, Nephrolepis tuberosa; 3, Ophiopogon Jaburan; 4, Polygala Dalmaisiana; 5, Gnidia pinifolia; 6, Bæckia frutescens; 7, Azalea amæna; 8, Pernettya sp. (?).—*Subscriber,* Acacia armata.—*W. H. B.* 1, Blechnum polypodioides; 2, Blechnum occidentale; 3, Pteris umbrosa; 4, Nephrolepis pectinata.—*C. A. N.* Pittosporum Tobira.—*E. M.* 1, Rosa rugosa; 2, Potentilla fruticosa.—*F. B.* Salvia leucantha.—*A. W. T.* 1, Chlorophytum elatum variegatum; 2, Anthericum Liliastrum variegatum; 3, Stenotaphrum americanum variegatum.

PEACH-BUDS: *A. H. E.* Growth went on favourably for a time, but then came a check, and the buds shrivelled and died. Without knowing all the circumstances we cannot say why. Much correspondence on this subject took place in our columns during the early months of 1905 (see pp. 106, 125, 139, 156, 170 and 234 for that year), when the consensus of opinion was that excessive dryness at the roots during autumn and winter, and a too sudden change in the temperature of the atmosphere in the house when forcing is commenced, were the principal causes of bud-dropping.

PEACH SHOOTS: *Essex.* The shoots are attacked by a species of Botrytis, a fungus commonly attacking imperfectly-ripened wood or young shoots that have been injured by chill. All diseased shoots should be cut off and burned, otherwise the disease will spread to others. After pruning has been done spray the trees with a rose-red solution of permanganate of potash or diluted Bordeaux mixture.

PEARS FOR GROWTH AS CORDONS AGAINST A WALL TEN FEET IN HEIGHT, FACING THE SOUTH: *G. L. H.* For ripening in September: Triomphe de Vienne, Marguerite Marillat or Fondante d'Automne. For ripening in October and November: Conference, Louise Bonne of Jersey, Durondeau, Doyenné du Comice. For ripening in December, January and February: Josephine de Malines and Le Lectier. There are several other varieties equally good as those named above, but we have always had good results from these sorts. Le Lectier is but little known, but it is a grand Pear of excellent quality, and grows satisfactorily.

POTATOS: *T. T. T.* We know of no main crop Potato or any other of recognised merit which produces pollen in the flowers freely and later seed-berries. Nothing seems to be more rare now than to find even a single seed-berry produced naturally. New varieties are obtained by extracting, with much difficulty, the tiny deposits of pollen found in the pollen-cases in the centre of the Potato-flowers, of certain varieties, and conveying it to the pistils of the flowers of other varieties, but rarely indeed is there found pollen sufficient to produce natural fertilisation. That this state of things is very different from what existed some 30 to 40 years ago is certain, for many varieties at that time produced pollen and seed berries in abundance. The change is probably due to the constant in-breeding by intercrossing that has been practised for the purpose of raising varieties that yield heavy crops of tubers, hence the force requisite to produce pollen has been largely exhausted or diverted. Varieties that produced pollen freely never yielded more than moderate crops of tubers.

ROSES: *G. L H.* Turner's Crimson Rambler, Lady Gay, Mrs. F. W. Flight, are all excellent ramblers, and the fourth may be Cheshunt Hybrid, or climbing La France.

ROYAL HORTICULTURAL SOCIETY: *Tooting.* The minimum subscription is one guinea each year. Those who elect to subscribe one guinea only are called upon to pay in addition an entrance fee of one guinea, unless they are professional gardeners.

SITUATION IN UNITED STATES OF AMERICA: *A. N.* See note on page 84 from a correspondent residing in America.

STEPHANOPHYLLUM "LONGIFLORUM": *E. B.* The genus Stephanophyllum is now included under Pæpalanthus. P. longifolius may be the plant you refer to. There is no such plant as Stephanophysum longiflorum. You probably mean S. longifolium, which is now called Ruellia amœna. This last-named plant is more likely to be found in a nurseryman's catalogue than is P. longifolius, a plant of little garden value and having a sedge-like habit.

STRAWBERRIES FAILING: *Perplexed.* The diseased condition is not due to a fungus nor to the presence of insects in the soil as you suggest, but the failure has probably resulted from some adverse conditions of culture. Too much water at the roots, or the excessive use of chemical manures, would be sufficient to cause rotting in the crown. Did you bring the plants into the forcing-house when they were in a frosted condition? The potting compost appears to be suitable.

THE HEATING ARRANGEMENTS IN DALKEITH GARDENS: *C. B., Guernsey.* In reference to our remark on p. 33 that the late Mr. Malcolm Dunn had effected a rearrangement of the heating system of Dalkeith, for the purpose of heating all the houses from one centre, we have received additional information, owing to the courtesy of Mr. Jas. Whytock, the Duke of Buccleuch's head gardener at Dalkeith Palace. Mr. Whytock writes as follows: "I had a conversation on this subject with the Duke of Buccleuch quite recently, who said that there were previously 21 fires and boilers to heat the glasshouses that are here at present, excepting the large new vinery, containing 10 rows of 4-inch pipes, and which has been built since. These 21 boilers were thrown out, and we have now instead one stokehole containing three steel Cornish or Trentham boilers, each 12 feet in length. During six of the warmest months in the year one of these boilers easily supplies all the heat needed, and in winter two boilers supply it just as easily. We commence to force all hothouse fruits in December, and therefore require to maintain high temperatures in the coldest weather. One man is able to attend to the fires, and this in itself is a great saving. On looking through the books containing the details of garden measurement I find that under the old system of heating as much as 600 tons of coal were burnt in some years, and an extra man had to be kept to wheel coal to and from the numerous stokeholes. At the present time we burn from 300 to 350 tons per year, according to the severity of the winter. Taking everything into consideration I believe Dunn's improvement has resulted in saving the labour of two men, and besides the economy effected in fuel and labour, the heating is incomparably more satisfactory, than it was previously." Such are the circumstances that led us to make the remarks to which you have drawn our attention.

VINES: *H. W.* A fly, quite different from the Phylloxera.

WHITE GRUBS IN FLOWER-POTS: *J. L.* The insects are allied to the mealy-bugs, and are known as Ripersia terrestris. They can be destroyed by small quantities of bisulphide of carbon. To apply this liquid, make a few holes in the soil with a 4-inch wire nail, and pour the liquid into the holes, applying two table-spoonfuls to a 6-inch pot. Take care that no light is brought near the liquid.

WILLOWS INJURED BY BEETLES: *J. W.* The insect is the common *Phratora vitellinae.* Try scraping with Paris Green (poison), at the rate of 1 ounce to 20 gallons of water. If the foliage will stand a greater proportion of Paris Green you will find it more effective; but you had better make a few experiments on a small scale first in order to ascertain this. The solution must be used with great care, as it is highly poisonous. Apply it as soon as the insects appear on the foliage. The larval stage of this insect is also destructive. They feed in colonies and are very conspicuous.

THE CARNATION IN FRENCH LITERATURE.

TO Mr. Douglas, of Great Bookham, I am indebted for a perusal of two early French books on the Carnation, the one *Le Jardinage des Œillets*, à Paris, MDCXLVII, the other, *Nouveau Traité des Œillets, la façon la plus utile and facile de les bien cultiver, leur noms, leur couleurs, and leur beauté. Avec la Liste des plus nouveaux. Par L.C.B.M.*, à Paris, MDCLXXVI. Both are interesting, the latter especially so, because every page bears evidence of its having been written by someone intimately acquainted with the Carnation. We have nothing like either in England, the best early treatise on the Carnation being that of John Parkinson embodied in his *Paradisus*, but nothing like so full.

Le Jardinage des Œillets was written by *L. B.*, whose address to the reader is a verselet telling how the Carnation came to wear the sceptre in the Kingdom of Flowers. L. B. was perhaps less an authority on the Carnation than an elegant writer who was as happy in filling pages of his book with philosophical remarks as in discoursing on cultural matters. Some 70 names of Carnations are given, and it is interesting that among these are some also named by Parkinson, whose "Gray Hulo" appears as "le Hulot gris." "Le sauvage" may be accepted as identical also with the "Sauadge" of our John. Instead of the public flower-shows there seem to have been private exhibitions, for the writer remarks on the pleasure there was in rearing some beautiful and rare sort; over and above the profit it brought to its master, and to see it inspected by gardeners who came to examine all its parts, to observe its petals, to distinguish its colours, and, according to the spirit by which they were animated, to show up its good qualities or discover its faults.

Carnations were cultivated solely in pots, and when in flower the blooms were supported by round pieces of cardboard, white or black according to the colour of the flower. Bloom was produced nearly the whole year round; during winter, from early layers which had spindled in autumn and from old plants which pushed new growth late in the year, these flowers being used in the composition of winter bouquets. The little structures in which the plants were kept during winter were freely ventilated, and no artificial heat was applied unless in very cold weather, when a fire of charcoal was lighted.

In a chapter on seedling-raising it is advised to leave one or two pods only on each plant; and seedlings, like the others, were cultivated in pots. Propagation was effected by various methods, in addition to that of sowing seeds; a method of splitting up the end of the stem of cuttings into four strips being recommended as infallible. Layering by splitting the stem seems to have been a usual practice, but the common method of making layers is also described. The book concludes with "Christian Reflections on Flower Growing."

The writer of the *Nouveau Traité* goes about his business in a more workman-like manner, in the preface remarking that several people raised objections to him for divulging his secrets and making his experience public, narrow views which he combats with vigour. Chapter I. treats of layering, the best time for doing this work being from July 20 to the month of August, the method of layering being detailed clearly and with fulness. The soil used for layers was composed of two parts thoroughly decayed horse dung, and one part black or marsh earth. Small pots or funnels of tin are recommended to be used for the layers. Those failing to emit roots were put on a hot bed and covered with bell glasses, by which means splendid plants were produced. Otherwise cuttings were not relied upon. Chapter II. is about pots, which it would appear reached the gardener in an unfinished condition, as the remarks on making holes for drainage show. Soils are the theme of Chapter III., those too heavy, too light, too moist and too dry being condemned. For "Incarnats" a soil of one-half horse dung thoroughly decayed and old, the other half to be composed of black soil, material from elevated tufts on marshes, and one-sixth yellow loam is noted. For other sections and Picotees two-thirds black soil and one-third horse dung with one-sixth yellow loam. Chapter IV. tells how the Carnation is to be potted. The peg having been removed from the layer the latter has the connecting piece of stem severed quite close to its junction with the layer, so that roots may push from it as well as from the tongue. The bottom of the pot was next fitted with horse dung for drainage. The compost was then added till it reached nearly the rim of the pot, and decayed dung level to the brim, and one layer set in the material. Most growers, it is remarked, planted three or four in each pot, but the author preferred to put one only, and this was planted directly into the flowering pot. Up till the beginning of December the plants were kept in the open air, but protected from inclement weather. Then they were transferred to the greenhouse, from which frost was kept by means of paper and mats in preference to fires. In many gardens the usual method of protection consisted in placing the plants in cellars. During winter water was only applied when the plants flagged, and sometimes saucers were used as a means of conveying water to the roots, each plant being placed in a saucer into which just a little water was introduced when the soil required moistening. In Passion week the plants were returned to the open, and numerous recommendations are given as to the aspects to be chosen during the different stages of the plant life.

Chapter IX. is devoted to water and its application, the writer disapproving of the practice of supplying manure water lavishly, his own experience being that cow-manure was best, and three or four applications sufficient during summer. Chapter XV. is all about seed-saving, sowing, &c. Plants which naturally were free seed bearers were chosen as mothers. Some sowed the seeds in autumn, others in spring, a time which he himself preferred, and favoured the Holy Week," because of the full moon." Rea, or was it Gilbert, used almost exactly the same words when writing of the same subject.

In Chapter XXIII. the qualities of a good Carnation are thus given: The flowers ought to be of large size, furnished with numerous petals, round, well-striped and without spots. They were to be large, because small blooms were not esteemed unless very fine indeed; well furnished with petals, because a flat flower had not the beauty of the dome-shaped, that is to say, one in which a kind of dome forms in the centre of the flower. (This type of flower is portrayed in *Parkinson's Paradisus.*) A circular outline is the form required in a perfectly striped Carnation, for the Carnation without stripe (or bar) is little to be esteemed, the stripe forming its chief beauty when it is large, and when it extends from the base to the edge of the petal. Lastly, the flower was to be spotless, because a spotted Carnation lacks purity, is confused; and being confused, should be thrown away. A capital catalogue *raisonné* of the best sorts then in cultivation is given. It is divided into sections, e.g., Violets in which purples, brown (or black-brown) were placed); reds of all shades; Incarnats, pale, bright, and flame-coloured; Roses, flesh, pure whites, and "pignetez," the latter being all spotted. With the exception of these the others were all flakes with white grounds. There are also tricolours, in which "a bar of purple followed one of pale rose on a white ground." Another variety had a "milk" ground cut with large brown, nearly black bars and rose colour. A "bizarre" is mentioned composed of seven colours. In addition to the description of the flower of each variety, its habit, the number of blooms to be left on its plants, their healthiness, or liability to disease, and the place it was raised, are all given.

This very keen florist also thought it was proper to dress blooms to the best advantage, by which they were made larger and more shapely, and disposes of the objections that it would appear were even then brought against the practice as being opposed to nature. *R. P. B.*

SOUTH LODGE, LOWER BEEDING.

Our illustration at Fig. 40 represents a view of South Lodge, the residence of F. D. Godman, Esq., F.R.S. It is situated about four and a half miles from the old town of Horsham, on the Brighton road. The owner is a very enthusiastic plant lover, his especial favourites being Orchids and Carnations. During the past few years, many alterations and additions have been made in the gardens. A batch of Cyclamen, showing good cultivation, is accommodated in one of the houses; while Primulas, among which the Duchess forms a conspicuous feature, are seen in excellent condition. Carnations are extensively cultivated, a succession of these beautiful winter flowering plants being maintained. Most of the better varieties of these flowers are grown, including Enchantress and Yuletide, which are favourites at South Lodge. In still other houses plants of Souvenir de la Malmaison Carnations are looking in perfect health, while a number of plants of Begonia Gloire de Lorraine almost fill another glasshouse. Salvias brighten the conservatory with their brilliant flowers, the plants being exceedingly well grown. Other houses are filled with stove and greenhouse plants, such as are useful for decorative purposes and for furnishing cut flowers. At the time of my visit a good crop of black Alicante Grapes was still hanging in one of the vineries. Muscats, Peaches, Melons, etc., are also cultivated. In the Orchid houses Cypripediums furnish an abundance of flowers, many choice varieties being included in the collection. Example: C. Leeanum giganteum, C. L. magnificum, C. L. virginale, C. L. Keeling's var., C. L. aureum, C. L. Clinkaberryanum, C. insigne Saundersii, C. aureum Hyeanum, C. Acteus, C. Milo, etc. The Cattleya house contains some fine plants of C. Bowringiana, some of which have been in these gardens for upwards of 20 years. Other plants noticed were Brasso-Cattleya Mossiæ-Digbyana, B.-C. gigas-Digbyana, C. Mrs. Pitt, C. Iris, L. C. Fascinator, L. C. luminosa, L. C. Canhamiana, L. C. alba, L. C. Charlesworthii, L. C. Hypatia, L. C. Gottiana, etc., all of which are doing well. In another house a batch of Lycaste Skinneri and its varieties were in flower, the plants exhibiting extraordinary vigour, the white variety being especially noteworthy. A system of staging is adopted in the Odontoglossum house whereby each plant is surrounded with fresh air. Over a bottom staging of shingle is placed another stage made of iron rods running from end to end of the house. On these rods are placed obliquely small strips of teak wood. The flower pots are stood upon two of these strips of wood, and as a result the air circulates freely among the plants. Amongst the choice plants are Odontoglossum Ruckerianum, O. triumphans, O. Harryanum × crispum, O. excellens, O. Halli, O. Edwardsii, O. grande, O. crispum aureum, and O. Andersonianum. The Calanthes have made some fine pseudo-bulbs, and are throwing up very strong flowering spikes. Large and well-grown plants of Cineraria were in frames, several of which also contained Violets La France and Princess of Wales. I also noticed Hippeastrum (Amaryllis) bulbs of a large size.

The pleasure ground contains a good border of herbaceous plants, at the end of which is a well-furnished rock and an Alpine garden. Tubs containing Agapanthus and Hydrangea are arranged around the mansion in the summer time, and when I saw them in flower they were very handsome. The plants, I should think, must be among the finest in the country. Large Rose beds adorn the lawn; also beds of Narcissus in variety, some of which contain several thousand bulbs (see Fig. 41). Lilies and several species of Rhododendrons also find a home in this quarter. I noticed R. Falconeri, R. cinnabarinum, R. Thomsoni, R. Royli, R. campylocarpum, etc. A little shelter is obtained from some large Beech-trees above them, and all appear healthy. The kitchen garden was very prim. In small ornamental lakes are aquatic plants, with Azalea Mollis and other useful flowering plants arranged on the slopes and banks. A cool greenhouse contains specimens of half hardy Rhododendrons, R. argenteum grande, R. Aucklandii × Fortunei being the more conspicuous. Flowers from these plants have been exhibited at the meetings of the Royal Horticultural Society. Some grand views are obtained from the terrace in front of the mansion, and above the tops of a wood can be seen the South Downs and the Devil's Dyke, near Brighton, which is 16 miles distant. Mr. Moody, the head gardener, has been entrusted with the care of these gardens for upwards of 28 years, during which time he has formed one of the most interesting gardens in Sussex. *W. A. Cook.*

Fig. 40.—South Lodge, Horsham, the residence of F. D. Godman, F.R.S.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM WARDIANUM.

This is still one of the handsomest of Dendrobiums, its profusion of large white flowers tipped with purplish-rose and having the disc of the lip dark yellow with two maroon blotches rendering it a charming flower and unlike any

other hybrid or species. The main Orchid house in the Right Hon. Lord Rothschild's gardens at Tring Park has the end of the central stage filled with a fine display of splendidly grown plants, whose 3 to 4 feet long pseudobulbs are plentifully set with fine flowers varying in tint but always beautiful. The plants are grown and the buds produced in the warm moist atmosphere, where some ornamental stove plants are also cultivated. As the flowers expand they are removed to the drier conditions of the Cattleya house, where they are at the present time. When the flowers have passed the plants will be returned to the growing house until the new growths are fully made up, when they will be rested in a cool, well-ventilated atmosphere. Under such treatment D. Wardianum does not deteriorate, but if the growing and resting seasons be not observed it is shortveining. It is an elegant and distinct species not often met with in gardens, although it was collected by Libon, on the peak of Itabira, Minas Geraes, Brazil, in 1847, and has since been imported occasionally. It is grown in the intermediate house without much difficulty.

THE MAKING OF ORCHARDS.—II.

(Continued from page 37.)

In the last article the preparation of the ground for the contemplated orchard was dealt with, and reference was made to some of the most common faults committed in the matter of planting the trees. The old-fashioned method of "dumping" the tree into a square-cut hole has been referred to, and one or two personal instances of observation in this direction pliable nature, the hole-digging plan, provided that the holes are dug large enough, so that the roots can be stretched out naturally, is not so absolutely fatal to success as when one has heavy land with a holding subsoil to deal with; but it stands to reason that if you go right through the soil, or nearly through it, planting your trees actually on or just above the subsoil, the chance of a healthy growth is very remote, and no wood means no fruit. For a time trees thus planted may succeed moderately well, for they will feed to some extent on the good soil thrown back into the hole upon the roots, but very soon the evil effects of the sour soil below will become evident, canker and decay will set in, and the trees will gradually, or perhaps quickly, perish.

Surface Planting.

The alternative to this antiquated and entirely

Fig. 41.—"Emperor" narcissus flowering on the lawn at south lodge. (See page 98.)

lived. A number of plants of Calanthe Regnieri, a fine Lælio-Cattleya ×, between L. purpurata and C. Trianæi Reine des Belges, the pretty Lælia rubescens (acuminate), some hybrid Lælias, Lælia superbiens, and other showy Orchids were in flower in the same house.

ZYGOPETALUM BRACHYPETALUM.

This pretty and uncommon evergreen species has flowered with Mrs. R. A. Mitchell, Mayford House, Woking (gr. Mr. Gittens). The flower sent is nearly as large as that of Z. Mackaii. The sepals and petals are of purple-brown colour, with a slight greenish base and a few irregular, thin, transverse green lines. The lip, which is longer and narrower than in Z. Mackaii, is nearly covered with a broad irregular veining of a light blue colour, the white ground colour showing through at the margin and between the

were cited to show the impossibility of obtaining satisfactory results under such rough-and-ready systems of planting. It would be quite profitless to go into further details concerning a practice which has nothing to recommend it even on the score of cheapness, for the hole-digging plan is an expensive one; but it will be interesting to give an example, by way of contrast, to show what the trees, had they been properly planted on prepared soil, might have done. It so happened that a couple of Apple trees were left over after the orchard had been set out, and these two single specimens, of much the same quality as the rest, were put in in the corner of the farm garden in a good piece of prepared soil. These two trees are now some 15 feet in height, and bear fair crops, while the others, planted in holes in the grass, are, as already stated, dead or dying.

In a good deep soil, well drained and of a

wrong method of planting is to be found in the system known as "surface-planting," which, as its name implies, consists of putting in the trees so that they actually stand on the surface of the original soil, as far as possible, that is, from the subsoil below. It must not be supposed, however, that planting flat upon the ground is recommended, for to do so would amount to asking the tree to spread its roots in a directly lateral position. This, it need hardly be explained, is not a natural proceeding, and the difficulty is overcome by the simple process of taking the surface soil, at some distance from the proposed position of the tree, and forming a gently sloping mound, at whose rounded apex the tree is set in position. In order to make the process more simple it is better to set out one's ground throughout in a businesslike manner before planting begins, and a sufficient number of stakes, to which the trees will afterwards

be secured, should be at hand for the purpose. When these have been firmly driven in the planting can proceed, and the stakes will not be disturbed in the planting process, since no digging is necessary in their vicinity. The stakes fixed, the mounds already mentioned will be thrown up around them to a depth of six or eight inches at the centre, care being taken that the soil thus used is brought from a spot as far away from the tree's actual position as possible. How far this soil for the mounds will have to be transported depends on the distance between each row of stakes; but in any case it will come from a spot about half-way between each row. It now remains only to place the tree in position, tie it loosely to the stake, and lay out its roots naturally and evenly around in their original positions, remembering at the same time to cut away with a sharp knife all broken or bruised portions of root up to a sound point. Some more soil is then thrown lightly over the roots, so that all are covered to a depth of three or four inches, and the tree is for the present left to settle. Later on it will need a little more attention.

The advantages of this method of planting will be apparent to anyone who cares to consider the question for a moment. Firstly, because the stakes are set in position first of all, and absolutely straight rows of trees are thereby secured. Under this system no damage is possible to the branches, but when stakes are put in after planting the bark must inevitably be injured, fruiting spurs knocked off, and twigs broken. Secondly, one gets the full advantage of the depth of the original soil in addition to the extra depth of soil thrown up around the tree, both under and above its roots. Thirdly, the main roots begin their fresh growth in a sloping, natural, and uncramped position, with a good depth of mellow soil below, and no sour material anywhere within reach for many years to come. Fourthly, the formation of the mound provides a natural system of surface drainage. And fifthly, the smaller roots of the tree are encouraged to keep near the surface, and so form plenty of fibre (which corresponds to the fruit spurs above), instead of wandering downwards in the forlorn hope of finding something to feed upon.

The planter, when following this method of orchard-making, must, of course, modify his procedure to some extent, according to the depth of the soil he is dealing with, but even this plan of surface planting is not to be recommended on a very shallow soil, which is not suitable for fruit trees unless one is prepared to pay pretty heavily for the manuring which will be necessary in the future. It is far better to pay more rent in the first instance for a better and deeper soil than to take a piece of poor and shallow land, which will cost much to get into good order before the trees are planted, and will need much "mending" from time to time afterwards. The directions given above refer to an average soil, say, of a foot in depth, and if deeper, so much the better. On such a soil the trees will have a good 18 inches to start upon, in addition to the 3 or 4 inches above the roots. Ground which is in fair heart and has been well cultivated will need no manuring in the first instance, and, indeed, even if the soil is poor, any manure used should be thoroughly rotten, and none of it should come in contact with the roots. The application of manure before planting is an expensive method, because it is difficult to put it in so that the tree will get the full benefit of it, and it is not so easy to regulate the quantity as when it is applied after planting from the top of the ground. Besides this, top dressings serve a threefold purpose: they feed the trees from above, thus keeping the roots near the surface, where sun, light, and air can work their good effect; they protect the roots of the tree from cold winds and frost in winter; and keep off the fierce and drying rays of the sun in summer. Trees planted in the autumn should be dressed with manure, which for top application need not be very rotten, so soon as they are "settled," that is to say, within about a month or so after planting. It may, however, be advisable, if severe frost is feared, to cover up around the stem before this; but as newly-planted trees require a little attention around their roots within the first few weeks after being put in, it is as well, if possible, to defer manuring until this extra attention has been given, and the tree is left to itself. The work necessary simply amounts to patting the soil gently over the roots with the back of a spade, so as to make all firm, and tying the stem firmly to the stake, not forgetting to bind a wisp of straw around the tree to prevent chafing. A fortnight or so should elapse between the time of planting and these last finishing touches, so that the tree may have time to settle naturally to some extent, and it should be particularly observed that when all is finished the stem of the tree is just so far underground as it was when lifted from the nursery. The mark round the stem will show this. The manure is now shaken lightly around the stem, and spread out over the roots to a distance of about 2 feet all round. This will cover all the roots in the first instance, but subsequent dressings will have to extend as the roots go farther afield. By the time that the winter is over the nourishment in the manure will have been washed down to the roots by the rain, and the remaining litter will be lightly forked in at the end of summer, ready for a fresh dressing to be applied before the frost sets in in the autumn. These light annual dressings are better than heavy applications of manure once in two or three seasons, for they nourish the trees more gradually, besides protecting the roots more effectively, and it will be found more easy, when only a little manure is applied at a time, to keep down the growth of weeds. Trees planted in the winter or early spring may be manured in the same manner, but in this case it will be as well to do so very lightly, and to add further dressings annually in the autumn. The chief advantage of this procedure is that the heavy rains of autumn will send all the goodness of the manure into the soil, whereas if the dressing is applied in the spring it may be there for months before rain comes, much of its virtue being exhausted by cold March winds and summer sun. *East Sussex.*

(To be concluded.)

KNIPHOFIAS AND THEIR CULTURE.

(Continued from page 83.)

K. foliosa.—An Abyssinian plant of great vigour, but one requires to be careful as to the type of plant acquired, for most K. foliosa grown in this country are poorly-coloured forms probably raised from plants grown with other species, for they shew, in addition to marked worthlessness, traces of hybridity with K. caulescens and K. præcox. The best forms of K. foliosa are noble plants, handsome both in flower and foliage, whilst the richness of the flower heads is not surpassed by any other early flowering species. It has giant leaves—broad and sturdy—arranged in handsome Bromelia-like tufts, and produces stout scapes of reddish scarlet flowers, which pass to lemon yellow as they age. The spikes are cylindrical and about 3 feet in height, and last long in good condition. It has been called K. Quartiniana, and the plant now known as Quartiniana in gardens is the best form of K. foliosa known to me. This form is of bold habit and a splendid plant for large rockeries and for borders. The plants are quite hardy, and are easy to cultivate.

FIG. 42.—KNIPHOFIA NORTHIÆ, MUCH REDUCED.

K. Leichtlinii.—Another Abyssinian species of doubtful hardihood everywhere, but which can be grown very successfully if the roots are lifted in cold districts for storing during the winter. It is a moderately vigorous and, in this climate, deciduous plant, whose spikes are cylindrical

and very long, commencing to flower from near the top or the middle of the inflorescence; the anthers and styles are much exserted. The root-stock has few fleshy roots, and a limited number of semi-prostrate, twisted pale-green leaves. The spikes are produced in late summer, and are 3 feet in height, bearing a brush-like inflorescence coloured dull vermilion externally, yellow internally, each flower-spike developing a yellowish tint as it ages by reason of the multitude of apricot-tinted stamens that survive the perianths. *Aurea*, an orange-yellow variety with scarlet stamens, and *distachya*—a twin-spiked variety, whose flowers are of orange scarlet colour, and whose stamens are scarlet, are splendid plants for the choice flower border in warm districts. Distachya is the taller and, I think, the most effective plant of the three.

K. Northiæ (see Fig. 42).—A stately plant of noble proportions, forming a stout stem 3-4 feet in height, the broad, glaucous leaves forming a huge Agave-like rosette which measures a yard across. The flower scapes are as thick as a man's wrist, and the inflorescence is coloured dark brick red with yellow base. The plant is really a glorified K. caulescens, much larger in all its parts and with darker flowers. A grandly effective species for warm and sheltered corners where its huge leafy rosettes may reach their finest development. It is more hardy than people imagine, and many grand plants thriving in the open without protection are known to me, which produce spikes 6 feet in height regularly every year. It is a rare plant of slow growth, yielding but few offsets unless injured. Propagation should be effected by means of seeds. Most K. Northiæ I have met are not quite true to type, showing evidence of hybridity with common species.

K. pauciflora (see Fig. 43).—A low-growing, sedge-like plant whose flower spikes are poor individually, but which are effective when massed. It is suitable only for cultivation on rockeries and the forefront of herbaceous borders. The spikes are arching, 2 feet in height as a maximum, and they bear pendant yellowish, short-tubed flowers from May onwards. Crossed with breviflora and others it has given me a race of nodding Kniphofias that resemble giant Lachenalias of singularly beautiful colouring, and which flower in two relays annually, once in mid-summer and again in September.

K. recurvata (præcox).—A sturdy species with handsome, erect-growing, arching leaves and flowers that resemble a very poor K. aloides in early summer. It has the misfortune to flower too early in the season, and the spikes are frequently damaged by late frosts in a nascent state.

K. Rooperi.—A very hardy and free-growing plant, forming handsome sheaves of broad, dark green foliage that is an ornament all the summer long in a sheltered position. The spikes are handsome, but are produced from September throughout winter, hence many of the best are spoiled by frosts. This is a grand plant for cultivation in warm counties, but on the East Coast, in the Midlands, and the colder parts of Scotland it rarely reaches its best condition, although flowers are produced in moderate quantities in mild winters. It grows about 3 feet in height, but is capable of much finer growth in warm districts. The scapes may be likened to those of a crimson K. foliosa.

K. rufa.—A delightful, new species that flowers all the summer long. It has the slight tufted growth of K. Nelsoni, and bears quantities of slender scapes supporting a refined inflorescence of long-tubed, elegant flowers coloured canary yellow in the lower series and coral red at the top of the spike. There are not many flowers on each scape, but the number of scapes and their elegant habit render this the most charming of Kniphofias for planting in borders. It appears incapable of producing seeds, and the pollen is often sterile. It is very hardy, and thrives in any soil.

K. Tuckii.—Another plant of the K. caulescent type whose glaucous, serrulate leaves are arranged in handsome Aloe-like rosettes, and whose flowers are produced in June and July. The inflorescence resembles that of K. caulescens, but is less hoary in appearance, the colouring being of brick red, with vermilion tips and Primrose yellow at the base. There are several beautiful colour forms in cultivation, and the plant appears to be capable of further improvement by selection of the best seedlings for perpetuation.

K. Tysoni is a kindred plant to the last-named species, but it shows greater refinement in the closely-packed inflorescence coloured a fairly bright shade of scarlet with yellow basal colouring. The foliage is arranged in splendid rosettes of a dark bluish green, with glaucous tips, and the spikes, which appear in June, are 6 feet in height. *G. B. Mallett.*

Fig. 43.—Kniphofia pauciflora, flowers yellow.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from page 60.)

"TATIEN-LU AND THE QUEST OF MECONOPSIS INTEGRIFOLIA."

The town of Tatien-lu is situated in long. 102° 18′ E., lat. 30° 3′m., at an altitude of about 8,300 feet. By the most direct route it is 12 days' journey from the city of Kiating, and a similar distance from Cheng-Tu, the provincial capital, the routes converging at Yachou-Fu.

The first Britisher to visit the town of Tatien-lu was the late Mr. T. T. Cooper in 1868. Since that time it has been visited by many travellers —probably more than any other town in Western China. Much has been written, yet much remains to be told. The late Captain Gill, who visited the place in 1877, has given us a very good description of the town and its people.* More recently an American traveller, Mr. W. W. Rockhill,† and an English naturalist, Mr. A. E. Pratt,‡ have considerably increased our knowledge. The present town is built in the narrowest of valleys at the head of a gorge, down which the River Lu tumbles, falling some 4,000 feet ere it joins the River Tung, 20 miles distant. This torrent bisects the town, being crossed by means of three wooden bridges, and is joined immediately below the North Gate by another river, which flows from the north. The town is hemmed in on all sides by steep, treeless mountains, whose grassy slopes and bare cliffs lead up to peaks which culminate in perpetual snow. On the whole, the situation is about the last in the world in which one would expect to find a thriving town.

Formerly the town occupied a site about half a mile above its present one, but about a hundred years ago this was totally destroyed by a landslip, caused by a moving glacier. The old town was surrounded by a wall, fragments of which remain, and was evidently much larger than the present town. Tatien-lu is peculiar in that the only wall it possesses runs *across* the town near the South Gate, and in that many hundreds of blocks of stone with which the streets are paved are of the purest marble.

Tatien-lu is a small and filthily dirty place; it boasts a large mixed population of Chinese and Tibetans. Being on the highway from Pekin to Lhassa, officials are constantly passing and re-passing. This makes it a highly important place, both politically and commercially. Although Batang, 18 days' journey to the west, is the actual frontier town, Tatien-lu is really the gate of Tibet. The country between Tatien-lu and Batang is physically purely Tibetan. Politically, it is of a nondescript character, and is ruled by native chieftains. At Tatien-lu itself, there dwells a Tibetan chief of no mean standing. He is styled King of Djiala, and possesses much land and immense herds of yak. He has power of life and death within his own territory. His palace is spacious, and about 6 miles to the south-west of the city he has a country residence, fitted with stone baths, into which water is led from thermal springs.

This local king and the head Chinese official, styled Kiung Liang Fu, are supposed to be colleagues, but, in reality, the King is very much the subordinate. In my dealings with both, I found them very willing to assist, but suspicious and jealous one of the other.

Commercially, Tatien-lu is a most important entrepôt. It and Sungpan, in the north-west, have a monopoly of the trade between this part of China and Tibet. The Tibetans bring in wool, musk, hides, gold, and medicines, and exchange them for coarse brick-tea, tobacco, and trinkets, such as beads of inferior turquoise, coral, etc. Indian and Chinese rupees are the current coin, but much of the trade is done by barter.

The Roman Catholic fathers have been working in this neighbourhood for very many years. Since their expulsion from Tibet proper, about 1867, their Bishop (Vicaire Apostolique de Lhassa) has resided at Tatien-lu. In 1896, the so-called Tibetan band of the China Inland Mission, despairing of being able to enter Tibet from the Indian side, opened a station here. So far, they have not been able to enter Tibet any more from this side than they could from the Indian.

With these introductory remarks on this interesting border town, we will now turn our attention to things botanical. *E. H. Wilson.*

NURSERY NOTES.

THE ALMA NURSERIES, FARNHAM.

THESE nurseries, belonging to Mr. S. Bide, are mainly devoted to the cultivation of crops for wholesale supply. For instance, here can be seen 50 acres of Seakale, and such crowns, too, that one cannot imagine anything but success for those who make use of them. The natural soil here is specially well suited for the growth of this vegetable, and with Mr. Bide's system of deep digging and liberal manuring the growth is all that could be desired. Several span-roofed houses are being utilised for the forcing of surplus Kale under the most favourable conditions. Fruit trees are grown in large numbers. Worcester Pearmain, Mr. Gladstone and Cox's Orange Pippin Apples are favourites. A high opinion is being formed of Norfolk Beauty, which promises to be one of the most popular of kitchen apples. Mr. Bide has also quantities of shrubs and trees, many acres being occupied with Spruce Firs, ranging from 3 feet to 6 feet in height. There are Laurels in large numbers and breadths of Larch suitable for immediate planting. An additional nursery of some 20 acres of land a few miles away has recently been acquired to act as a feeder for the home nursery.

The range of glass is extensive. In addition to the cut-flower trade done here, many thousands of Roses in pots are grafted. Grafting commences in November, and continues until March. The batches of such varieties as Caroline Testout, Mrs. W. J. Grant, Dorothy Perkins, Kaiserin Augusta Victoria, and Lady Gay, appeared to be remarkably good. Great care is taken to keep them true to name and in the best of health.

Many thousands of Chrysanthemums are grown to meet the demand for cut flowers. Quite one of the best of late, yellow-flowered sorts here is Mrs. J. S. Fogg, of deep yellow with a tinge of bronze in it and a flower possessing much substance. As an extra late variety no better white flower than L. Canning has yet been found. Bulbs are a feature — 150,000 Narcissus being flowered annually. Emperor, Horsefieldii, Empress, Golden Spur, H. Irving, and Princeps are grown in quantity. A new variety of Ornatus, named Ornatus Grandiflorus præcox, was most promising. It is fully three weeks earlier than the type—and has more orange colour in the cup. It was introduced, I believe, by Mr. Baylor Hartland. N. Cervantes, with but little forcing, is also a desirable variety. House after house is filled with Palms, Begonias, Richardias, Ferns, &c., all in good health. Mr. Bide has the advantage of having three sons and a brother, all of whom take a deep interest in the business. Of Potatos many absolutely new varieties are on trial. Mr. Bide is a large Hop grower, as well as a farmer, and keeps 70 dairy cows of a choice description. *E. Molyneux.*

CULTURAL MEMORANDA.

ZONAL PELARGONIUMS.

THERE is nothing at the present season more cheerful in appearance than a span-roofed house filled with flowering Zonal Pelargoniums. Their bright and variously coloured flowers are delightful, while the suitability of the latter for table and other floral decorations render them almost indispensable subjects. Now that the time has arrived when their propagation may be commenced a word in reference thereto will be appropriate, for the sooner the cuttings are inserted now the better. For the purpose of furnishing cuttings a stock plant of each variety is usually kept, but this is not imperative, as cuttings can generally be procured from shoots of ordinary plants after the flowers have been cut, or they can be taken later—at the time the plants are cut back in February or March. Insert the cuttings singly in thumb pots in a soil containing a goodly proportion of sand, and plunge the pots in gentle bottom heat near to the glass. Keep the soil in which the cuttings are rooting, on the dry side, and afford a little ventilation. In March they may be shifted into 4-inch pots, using a rather heavy soil with which some well-rotted manure has been incorporated. Hoof filings from the smithy form an excellent manure for Zonal Pelargoniums, and they are also benefited by applications of manure water from the byres, as this will dissolve hoof and horn filings, especially when the manure water is fresh. Active growth must be encouraged in the plants throughout the season, and when June arrives they will have filled their pots with roots, when another shift becomes necessary, again giving them a rich compost. After the plants have fairly settled in their new pots they may be placed outside on an ash bottom, there to remain until about the last week in September. Never allow the plants to suffer from the want of water, and be careful not to let them root through the bottoms of their pots into the ashes. Constant removal of the flower buds and discreet pinching of the stronger shoots is essential to success. When housing the plants, and for about a month afterwards a sharp look-out should be kept for the green caterpillars, which destroy the leaves. The plants should be placed in an airy, somewhat dry house where plenty of light is obtained, and allowed heat sufficient only to keep the atmosphere moving. The plants will flower in profusion for several years in succession, provided they are allowed a period of rest, but one year, or at most two year old plants will be found the best. During the winter season watering must be performed with care, and a little soluble phosphatic manure may be added with good results. *H. W., Trevince.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Preparations for Shading.—The blinds or shading used on the Orchid houses should be at once fixed in their places to be in readiness for immediate use. It may happen that for a week or two there will be no need to use them, but the sun is becoming too powerful for some Orchids, especially when it shines forth in the middle of the day on such plants as Phalænopsis, Cypripediums, Bolleas, Aerides, Vandas, Angræcums, Odontoglossums, small seedlings, &c. At this particular time of the year every care should be taken to shade rare and delicate plants, as often irreparable damage is done before the grower is aware of it. After passing through several months of dull weather the plants generally are not in such condition to stand direct sunshine, as they are during the autumn months. The blinds on the East Indian, Cattleya, and Mexican houses may be fixed so as to roll down on the glass. As much sun heat as is possible without scorching is required in each division. Those on the intermediate and cooler houses should be raised by means of supports fixed to the roof to five or six inches above the glass. If arranged in this way a current of air will pass between the blind and the glass, which helps to preserve a suitable atmospheric temperature for the plants during hot weather. At Burford we use the lath roller shadings for all the houses, with the exception of the Phalænopsis and Masdevallia houses, these being covered with the ordinary canvas blinds.

Phalænopsis.—In the warmest house such plants as Phalænopsis Schilleriana, P. amabilis, P. Aphrodite, P. Rimestadtiana, and the supposed natural hybrid P. leucorrhoda are now in bloom. It is a critical time with these plants, great care being needed in supplying them with water. If kept too wet at the root, or if water be allowed to lodge in the centre of the growths, the leaves are liable to become spotted and diseased. Water should be afforded from a fine rosed watering can, or the fine sprayer, merely sprinkling the roots that are clinging to the baskets or pans often enough to keep them just moist, the sphagnum-moss that is near to the collar, or base of the plant, being allowed to remain on the dry side. Phalænopsis are often seriously or even permanently injured by carrying their flower spikes for too long a time. It is necessary to cut the spikes off after the flowers have been open for a reasonable period. It sometimes happens that the leaves of a plant will shrivel slightly before the flowers have opened, but if the spike is removed immediately the blooms are expanded, the leaves will soon become plump again when the plant is placed in a shady position and water afforded with judgment. The gradual increase of sun heat, and therefore of atmospheric moisture, will also greatly assist them to recuperate their strength.

PLANTS UNDER GLASS.

By B. CROMWELL, Gardener to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool.

Gardenias.—These are useful to supply flowers in the winter and spring months, but they are very accommodating, inasmuch as their flowering season can be advanced or retarded as required. If the plants are wintered in an atmospheric temperature of 55°, a few plants may from time to time be introduced into the warmer house, and if afforded an increased amount of moisture they will soon commence to expand the flower buds. Stimulate the plants by applying liquid manure and occasional dressings of Clay's Fertilizer to the roots. Keep a sharp look out for insects. G. florida intermedia is the best variety to grow for affording flowers for cutting, and should be given a place in every collection of stove flowering plants.

Gloriosas.—The old soil should be shaken from the tubers of these stove climbers, and the plants repotted in a mixture of light loam, good leaf mould, well decomposed manure and fibrous peat, with fine siftings of crocks and some sand to keep the whole porous. If the potting soil is in a suitable condition the plants will require no water until they commence to grow, after which a moist and heated atmosphere, with increasing supplies of water and frequent applications of weak liquid manure, will be found to favour their growth. These plants are trained up the rafters at Cleveley in a house in which Codiæums (Crotons) are grown. In this situation they are exposed to the full sunshine, the colour of the flowers being much improved with this treatment, and they also last much longer when used for dinner table decorations, for which purpose they are much admired.

Hard-wooded Plants.—Plants of Epacris that have finished flowering should be cut back, but not too severely, and be placed in a warm pit to induce them to break into new growth. When the young shoots have grown about two inches or so in length repot firmly any plants that require it. The same remarks and treatment apply to Ericas of the hyemalis and Wilmoreana type. At this season of the year mildew often attacks Ericas, and causes much mischief before it is discovered. As a preventive apply a light dusting of flowers of sulphur.

Mignonette.—Plants raised from seeds sown in the autumn, and that have been steadily growing, will now need to be repotted; but in doing this work do not disturb the roots more than is necessary. Good drainage is all-important, as the careful application of water is one of the principal items in the successful growing of Mignonette. These plants are very much benefited by lime, consequently a few pieces of old mortar rubble can with advantage be used in the drainage of the pots, while a sprinkling of fine siftings of the same material used in the potting compost will tend to keep the roots in a healthy condition. Good turfy loam, with dried cow manure that has been rubbed through a sieve, and a little soot, will form a suitable potting material. If grown as standards, restrict the plants to one straight stem until they reach the required height, when the side growths may be allowed to branch on to the trellis, after which frequent stopping and tying of the shoots will be necessary. The plants will be greatly benefited by occasional dressings of Standen's manure.

General Remarks.—A considerable number of flower seeds should be sown this month. See that

the pots or seed pans are thoroughly clean, and provided with perfect drainage, after which partly fill them with some rather rough fibrous compost, and complete with a layer of finer soil, which must be made firm. Examine the seed pans at least once each day, preferably in the morning, as negligence when seeds are germinating may end in failure. Should the soil in the seed pans become dry after the seeds are sown, the safer plan will be to soak the soil, being careful not to float the seeds. Increase such plants as Dracænas, Bouvardias, &c., by cutting the stout roots into short pieces, or the stems into lengths containing an eye or two, and inserting them in soil in pots, which must be placed in bottom heat.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Late Vines.—In houses containing such varieties as Black Alicante, Lady Downes, and Gros Colmar, the work of pruning should be already completed. The wood-work should be thoroughly washed down with water containing soft soap and paraffin in order to kill or dislodge any insects that are lurking in the crevices of the wire-work and rafters. If the Vines were attacked last season with red spider, let the rods be washed with the same solution. Prick up the surface of the border with a fork, and apply a similar top dressing as was recommended in a previous Calendar for early fruiting Vines. The Vines may be started gently into growth towards the latter end of the present month, as very little saving in fuel can be made by postponing this until later in the spring. In such circumstances, should the following autumn be dull and sunless the Vines would require more artificial heat to ripen them. A Vine or two of the variety West's St. Peter's are very useful, especially for "invalids," as the fruits have very thin skins and are rich and juicy. They ripen in October, and will keep in good condition until March. It sometimes happens that with the grapes being kept on late Vines until January, the borders become rather dry, and if this be so water should be applied to them before forcing commences.

Tomatos.—If the winter-fruiting plants are clean and in good health, they may yet be encouraged to yield a few more fruits. Apply a top dressing of turfy loam and bone-meal, and now that the days are lengthening and the sun is gaining more power, a little extra air may be admitted to the house during sunny days. Plants raised from seeds sown in the last week of December are now ready for the final shift into 8 or 9 inch pots. Use a compost consisting of three parts rather strong loam, adding some manure from an old mushroom bed, wood-ashes, lime scraps, and a sprinkling of bone-meal. These plants when repotted should be placed on a shelf not far from the glass, placing a grass turf under each pot, which will help to keep the roots in a moist condition and form a bed for them to ramify in after the pots have become full. The plants require an atmospheric temperature of 60° at night, but a rise may be permitted during the day. Leave a space of fully two inches in each pot to allow of a top dressing being applied when the first bunch of flowers have set.

Early Peach Trees.—Continue to disbud these trees, taking care to leave a shoot at the base of each bearing shoot, and another at the extreme end. Those which are retained for supporting the fruit should be pinched back to the third leaf, but the basal growth must be trained in for next season's bearing wood. Exercise care in ventilating the house, so that there will not be currents of cold air. Where there is very much bloom, some of the flowers may be taken off, and those remaining will thereby be benefited.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Annuals, and tender bedders in the Rosary.—Despite a prevalent prejudice against planting amongst the roots of roses, or in fact growing anything but roses in the Rosary, it is now generally admitted that the use of any light-rooting annuals or bedders to hide the bareness of the bed is conducive of little harm to the roses, while the improvement in effect is incalculable. There is no doubt that Rosaries in the past lost much in effect by the beds being too thinly planted, and the display of flowers marred by the appearance of the unsightly manure and bare ground beneath the plants. The Rose beds should be planted in April or May with whatever it is decided to cover the surface of the ground, so that by the time the roses come into bloom the soil will be hidden. By the end of September, or whenever circumstances permit, the beds can be cleared again of these decorative plants, and a heavy dressing of manure applied to make good the additional drain which has been put upon the soil's resources during the summer months. Dwarf plants similar to Lobelia pumila, tufted Pansy, and Phlox Drummondi are admirably adapted for use as surface bedders. Of the Lobelia, the dwarf compact growing blue varieties are best, and they can be easily raised by thousands from seed. The seed should be sown now in heat, in shallow boxes and very thinly to avoid "damping off." In a few weeks' time the seedlings can be pricked out singly into slightly deeper boxes, and by the end of March, or beginning of April they will be ready for transferring into boxes of still larger size in which they will remain until planting-out time. In putting them into these last boxes give sufficient space between the plants to allow of them making a "tufted" habit of growth. The blue of the Lobelia harmonises effectively with orange yellow coloured Roses, or with such copper coloured Roses as L'Idéal or Ma Capucine, so should be used as a foundation or surface plant for beds filled with Roses of this colour. A purple variety of "tufted Pansy" harmonises with yellow roses. As a contrast, white Roses and blue Lobelia go well together. For planting below the different shades of red Roses, Phlox Drummondi, in the desired shade of colour to harmonise, is an excellent subject, but it requires constant attention. It will be necessary to go over the beds containing the Phlox Drummondi at least twice a week, as soon as the plants are established, to thin out the growths, and peg them down, otherwise their vigorous growth would prove detrimental to the Rose by completely smothering those of weakly habit. The white "tufted Pansy" makes a good contrast for a bed of red Roses, and so does any green-foliaged carpeting plant.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Standard Apple and Pear Trees.—The present is a good time to prune and cleanse these trees. The pruning is necessary for relieving the trees of superfluous wood, such as dead and decaying branches, and for cutting back all weak growths. Scrape away as much as possible of the lichen on the trees, and afterwards spray the trees with the XL-all wash. Those contemplating making a new orchard would do well to plant the ground with Potatos. It will not then be unproductive all the season, but will be made clean ready for planting in next October and November. Choose a site on moderately high ground where there is some available shelter from winds; the soil should be of clayey loam and be well drained, either by natural or artificial means. Select the varieties of fruits carefully, choosing some that will ripen early, in mid-season, and late, but, above all, select those varieties that have proved themselves to be most useful and serviceable in the locality. For use at the present season we have no better Apple than Dumelow's Seedling (Wellington), an Apple of moderate size and good flavour and cooking quality. It is also a good cropper. For some time past the fruits have been quoted in the markets at from 8s. to 14s. per bushel, and at a quarter of this rate they would be very remunerative. In order to obtain satisfactory crops it is necessary to treat the ground well and leave nothing to chance.

Pear Trees prove very remunerative when good and suitable varieties are planted on well-drained ground. I have seen bushels of Pears lying on the ground in country places, the owners not knowing how to dispose of them, and thinking the Pears worthless because they were hard.

Standards of Plum, Damson, etc.—Thin out the shoots of these trees and shorten the strong growths.

General Work.—Proceed with the pruning and nailing of trees generally. Take advantage of wet days to get shreds cut, stakes sharpened, covering material overhauled and repaired. Protect Pear, Gooseberry, and Currant trees from birds. Remove all decayed fruits from the fruit room. Admit a little air at all times to dispel damp. Apples and Pears are keeping well this season. Pear Olivier de Serres is in capital condition just now.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Onions.—Failure in this crop, owing to the attack of the Onion fly, are more frequent in the north, especially in cold districts, than in the south of the country, which is owing to the young plants being in a less advanced stage of growth at the season when the fly is breeding. The plants are not so readily attacked when they are older, therefore no better system can be practised in these districts than that of sowing the seed thinly in boxes in gentle heat, growing them on steadily and hardening them off by the end of April, when they can be planted out of doors in lines drawn at 15 inches apart, putting each plant six inches distant from its neighbour. There is no necessity to prick off the seedlings into other boxes or to cultivate the plants so highly as would be necessary to grow exhibition Onions, but they may be transferred direct from the seed boxes to the open ground. A far greater weight of produce will be the result, and the bulbs will not be so large in size as to injure their keeping qualities. They will be earlier and much more likely to be immune from the attacks of the fly. In more favoured districts Onion seeds may be sown out of doors towards the end of February or early in March, according to the condition of the weather and soil. Young Onion plants are not readily injured by frost, but are more easily ruined by excessive moisture, therefore those who have light soil can sow before those having soil of the opposite character. In any case it should be deeply worked and contain plenty of manure. Choose a fine day and fork over the space to be sown, adding at the same time a heavy dressing of soot. Let shallow lines be drawn at distances of 12 inches apart, just allowing a sufficient depth that the seed may be covered a quarter of an inch deep. A sowing of wood ashes on the seeds before covering them is an excellent practice. The old variety James' Keeping is still one of the best to keep in good condition a long time, together with Veitch's Main Crop and Sutton's A1, all of these being most suitable for this method of culture. Silver Queen is an excellent variety for use in pickling, and a few rows of these should always be sown, as the bulbs are better for the purpose than the small ones picked from the other varieties mentioned would be.

Leeks.—The main sowing of Leeks should be made at the same time and in lines in the same manner as the Onions. Make sure of a good tilth in order to get strong plants to transplant as early as possible. More often than not this crop is not transplanted sufficiently early to yield the best results. Musselburgh is still one of the hardiest and best to stand the winter. Sutton's Royal Favourite has intense green leafage and is thoroughly hardy; it has the advantage of thickening early, is of medium length, and becomes ready for use in advance of many other varieties.

Garden Paths.—Now that all the wheeling and heavy traffic incidental to winter is nearly done, attention should be given to the edgings. If Box requires relaying it should be done at once. Do not allow this edging to become overgrown, and thus afford a harbour for slugs, etc. Box, if well laid and trimmed annually, is, I think, the best form of garden edging, but in soils where Box will not succeed, ornamental tiles may be recommended. These should be laid deeply in concrete, otherwise they may be easily broken by accident. Gravel paths are improved in appearance by an annual sprinkling of fresh material. This will cost no more expense than is entailed by a heavy dressing every third year. Attend to the edgings of grass paths and returf any bare patches. A top dressing of very rotten dung if put through a sieve and applied to the turf will effect much good.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

FRIDAY,	Feb. 23	Roy. Botanic Soc. meets.
SATURDAY,	Feb. 24	Dutch Gardeners' Soc. meets.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—39·3°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Feb.* 14 (6 P.M.): Max. 46°; Min. 29°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 15 (10 A.M.): Bar., 29.6; Temp., 44°; *Weather*—Much rain.

PROVINCES.—*Wednesday, Feb.* 14 (6 P.M.): Max. 45° Cornwall; Min. 36° S.E. Scotland.

SALES.

MONDAY—

Thousands of Hardy Border and other plants, Roses, Lilies, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—

Lilies, Hardy Border plants and perennials, Gladiolus, &c., at 12; 3,000 Roses also Fruit Trees at 1 and 3. Greenhouse plants, Ferns, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Clearance Sale of Nursery Stock, Greenhouses, &c., at the Nursery, Castle Road, Southsea, by Protheroe & Morris, at 12.

Sale of Palms, Roses, Lilies, &c., at Stevens' Rooms, King Street, Covent Garden, London.

THURSDAY—

945 cases Japanese Lilies received direct, also Lily of Valley, Palm Seeds, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 3.

FRIDAY—

Herbaceous plants and perennials, Hardy bulbs, Pink Carnations, Roses, Azaleas, &c. Imported and established Orchids from various sources, Orchids in flower and bud, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

The Royal Horticultural Society.

IN the face of the Report—the greater part of which was given in our columns last week—it is not wonderful that a tone of satisfaction prevailed at the annual meeting of the R.H.S. on Tuesday last. What was there to do but to express gratitude to Baron Schröeder, the veteran who persisted that we must have a hall, and kept on persisting till, largely through his generosity, the hall is an accomplished fact, and everyone is praising its commodiousness and convenience? What was there to do but again record our acknowledgments to Sir Thomas Hanbury, to whom we owe the delightful garden at Wisley, with all its potentialities? What was there to do but recognise thankfully the services of Mr. Wilks, Mr. Wright, Mr. Reader, and of the staff generally? No less imperative was the duty of showing our appreciation of the services of the President, so long and so unwaveringly given, through bad times as well as in the present state of prosperity.

Sir TREVOR LAWRENCE commented on the report in terms that we need not here repeat, and Mr. GURNEY FOWLER, the treasurer, made one of those excellent, lucid statements as to the financial condition of the Society which inspire so much confidence. The amount of profit made in 1905 was, he told us, no less than £6,203, and then he went on to say how the money had been spent on the hall, and at Wisley—and clearly well spent too. The fly in the pot of ointment was the heavy loss entailed by the summer show at Chelsea. The show was a good one, the weather unexceptionable, the site beautiful, but the attendance of the public very unsatisfactory. This may have been because sufficient publicity was not given. In any case, the public lost a fine opportunity, and the Society suffered a loss which was, as far as they were concerned, quite unmerited.

Mr. ELWES, in supporting the motion for the adoption of the report, suggested the advisability of a publication committee to assist the editor of the journal. Whether the editor would care to be hampered in this way is doubtful, but, at any rate, the practice of other societies of appointing expert referees to report confidentially to the council or to a publication committee as to whether certain articles should, or should not, be inserted might, if adopted, relieve the editor of some responsibility and tend to reduce the present bloated volumes to more reasonable dimensions.

The distribution of plants to the Fellows from Wisley also came under discussion. The present system involves an amount of trouble wholly disproportionate to the benefit to horticulture and, to some extent, perhaps, is inimical to the interests of the trade. There are certain plants not generally in commerce, or of special interest, which might advantageously be propagated for the benefit of the connoisseurs—and, for the rest, the society should not compete with the members of the trade.

The most interesting feature of the day was the election of four new Victoria Medallists of Honor in place of a similar number deceased. When we say that the new recipients of the honor included Mr. Harry J. Veitch, Mr. William Marshall, Mr. R. I. Lynch, and Mr. J. Smith, of Newry, we feel that our readers will add their plaudits to those which made the room ring on Tuesday last. It will doubtless occasion some surprise to realise that some of these gentlemen have not long ago been entitled to write V.M.H. after their names, but as they were members of Council, they may have thought it right to waive their claims. Be that as it may, their rights will be recognised universally.

The Right Hon. Lord Balfour of Burleigh and the Right Hon. the Earl of Tankerville were elected members of Council, and Major Holford, C.I.E., C.V.O., and Mr. Henry B. May were re-elected.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue affords a view of a portion of the Royal Gardens at Sandringham that has not been previously illustrated in these columns. It is known as the Queen's "Wild Garden," and being situated only a very short distance from the mansion, affords a very pleasant contrast to the more formal flower garden, and an agreeable retreat from bright sunshine. In our Coronation number published in 1902 reference was made to this feature of the Sandringham gardens, and though certain modifications in the planting have since been made, and various improvements carried out, as in the substitution of an irregular stone path for the much worn path of turf, the general effect is of the same character. In the view photographed, some of the principal objects include the great Thistle, huge Lavender bushes, Rosemary, and herbaceous flowering plants that help to brighten the more sombre effect afforded by the many trees and shrubs. It is worthy of remark that, apart from any dissimilarity there may be in the colours of the numerous shrubs, there appears to be an infinite contrast in the forms of leaf and habit of growth of the various plants.

THE FACTORY ACT AND THE FLORISTS' SHOPS.—It appears from an advertisement in our last week's issue that an attempt is being made to bring florists' shops under the provisions of the Factory Act, and thereby to subject the proprietors of those establishments to regulations and restrictions which would "practically make the business of a florist impossible." It is to be hoped that the real state of the law will be speedily determined. For this purpose the Florists are combining among themselves to assist any one who may be prosecuted under the Factory Act. The names of the following well-known Florists are appended to the document:—Messrs. GOODYER, PIPER & SON, STRUDWICK, TAVERNER, WILLS & SEGAR, BROOKS & SON, BUTLER, and ROBERT GREEN.

MATS ON GARDEN FRAMES.—Mr. F. G. BREWER, of Bryntirion Gardens, Dolgelly, Merionethshire, N. Wales, sends us a sketch of an iron appliance for fixing mats on garden frames. One end of the iron is fixed to a corner of the frame, and a strip of board passed through on the top of the mats makes the covering secure.

AMERICAN CARNATIONS.—The great improvement of these in recent years is attributed by the President of the American Carnation Society to increased size of flower, longer duration, and greater variation of colour—we think we may add, greater length and stiffness of stem, and hope that no further increase of size will be looked on with favour, but that enhanced fragrance may be ensured.

THE LATE SHIRLEY HIBBERD.—It may be remembered that on the death of this genial and much respected member of the horticultural fraternity a subscription was raised for the benefit of his only daughter. The sum originally subscribed was £232 16s. 9d., which was invested in the hands of trustees for her benefit. Now that the lady has attained a majority steps are being taken to transfer to her the sum of £324 7s. 6d.

THE NATIONAL POTATO SOCIETY.—The annual report for 1905 is very interesting and very suggestive. The reports of shows are only of passing interest, but the carefully-compiled records of experiments made in various counties are of permanent value. The experiments have reference to the trial of newly introduced varieties, to the determination of synonymous forms, or, at least, of such that are so like some others, as, for practical purposes, to be treated as identical. The relative powers of resistance to disease are also tested, and the advantages of "change of seed" brought to light. The trials in any one year, however accurately conducted, cannot be accepted as absolutely satisfactory, but a series of such trials in the same localities spread over a number of years will certainly elicit most important results. The report can be had from Mr. W. P. WRIGHT, Postling, Hythe, Kent.

PACKING SEED FOR THE TROPICS.—The need of proper packing for seed intended for transmission to tropical countries is one that should receive full attention from those concerned, yet is but too often neglected. Mr. J. H. HART, writing in the Trinidad *Bulletin of Miscellaneous Information*, mentions this important matter, which has lately been the subject of discussion in our columns:—"While in England, from May to July, 1905," he says, "I interviewed one of the principal officers of the firm of Messrs. SUTTON and SONS, of Reading, with reference to suitable seeds for tropical use, and was successful in showing

him the need for better packing when sending them from temperate climes. What are required are sealed packages after the form of biscuit tins to secure the seeds from damp and small insects. This enterprising firm are now packing seed in small quantities for immediate use in fine or thin metal containers, which are hermetically sealed in dry air. The packages cost one penny each more than the ordinary paper envelopes, and the seeds are preserved in a fine growing condition some 100 per cent. longer than by the old method, and will not perish while in the hands of the seedsman who undertakes their sale locally. The firm, I am informed, has arranged with Messrs. Stephens & Scott, of Port-of-Spain, to distribute for them as local agents in Trinidad, and it is now certain that growers can obtain seeds of fine quality and reliable vitality. This method of packing will enable growers to keep their seeds until required quite free from the attack of insects and secure from the effects of climate. The packages can be readily opened when necessary and should obtain a ready sale in this colony."

Scottish Horticultural Association.—The inaugural address by the President, Mr. David W. Thomson, was mainly devoted to the subject of change—change in fashion, change in taste, change in material, change in circumstances. The lecturer alluded to the comparative decline in the culture of stove and greenhouse plants, and to the rise in favour of hardy herbaceous plants, of Narcissi, of Chrysanthemums, and Carnations. With Grapes to be bought at 1s. a lb. the lecturer predicted the gradual decrease in the culture of the Vine, just as imported Pines have in many cases caused the disappearance of Pine stoves. Mr. Thomson strongly urged upon the young gardeners that they should watch the signs of the times, keep pace with the fashion, and devote more of their attention to outdoor gardening. Change also was observable in the climate, for lately it had been as warm as or warmer at Stornoway than at Nice. We remember the late Mr. McNab making a similar remark many years ago, but since then we have been subjected to two of the most rigorous winters known even to the oldest inhabitant, so that prognostications as to climatal change need to be made with hesitancy. One point was alluded to by Mr. Thomson in which there had been little change, and that is in the wages paid to gardeners. The gardener's position and remuneration are not adequate to the forethought, responsibility, and intelligence required of him. In all these points the gardener is at a disadvantage as compared with other workers from whom less is expected. Lastly, progress and efficiency were pointed out as the objects to be aimed at in the future. Mr. Thomson's address will doubtless be published in full in the Transactions of the Society. In the meantime we call attention to it as full of interest and sound advice to young gardeners.

Gardeners' Royal Benevolent Institution.—We are informed that the Liverpool Auxiliary of this Institution has arranged to hold its fourth annual concert, in aid of the funds, on February 24. Dr. G. W. Mc Fall, M.B., lecturer on Botany, will preside, and a good programme of music will be carried out. The secretary is Mr. R. G. Waterman.

Royal Gardeners' Orphan Fund.—We are glad to note that the report and balance-sheet presented by the committee at the annual general meeting of the subscribers to this institution held on the 9th inst. was generally satisfactory. The receipts from all sources—and from each source (excluding legacies) — showed an increase over those in previous years, and the help that it had been found possible to afford to necessitous orphans was greater than ever before. At the same time, we cannot help remembering that whereas several years ago the Fund was able to meet all applications for relief, it is quite unable to do so at the present time, for if the receipts are larger the demands for assistance are much more numerous. And in connection with this lamentable fact, it has been pointed out again and again that if gardeners could be brought to recognise their responsibilities in respect to the Fund, and would subscribe but five shillings each year, it would not be necessary to turn empty away a single child who needs assistance. Let our readers remember this, and also that, however unlikely it may appear at the present time, there is the possibility that at some future period their own children, or the children of some friend, may be among those for whom help may be asked from this same Fund. Therefore, whilst it should be only necessary to appeal for annual subscriptions on the highest ground, and by awakening in gardeners a practical sympathy for those among them who may suffer misfortune, the further fact can be stated that in many cases the sum subscribed will prove to have been well invested. Subscribers will be sure to approve of the election by resolution of three candidates who in peculiar circumstances had been unsuccessful at the poll, and also agree with the announcement in the report in respect to the acceptance of two candidates at one time from one family.

Horticultural Portraits. — It is well known that the late Mr. Richard Dean had made a very extensive collection of portraits of horticulturists, without doubt the most considerable one in the kingdom. This collection it is much to be desired should pass into the hands of some individual or of some body willing to preserve them for their intrinsic interest and value. The Royal Horticultural Society did some time since, yet subsequent to Mr. Dean's death, endeavour to secure the collection as likely to make an interesting addition to the Lindley Library. The offer was made, but was unfortunately declined. That leaves open to anyone desirous of possessing this unique collection the opportunity to make an offer for it. Mr. Dean was far from being a rich man. His was a life of indomitable industry and hard work to the last, yet it was one that did not enable him to accumulate wealth. Hence the necessity of asking a substantial sum for the collection of portraits. Enquiries may be addressed to Miss Dean, 7, Marlborough Road, Ealing, W.

Winter Flowering Carnation Society.—On the 13th inst. a meeting of Carnation growers and others was held at the R.H.S. Hall, Westminster, to discuss the advisability of forming a Winter Flowering Carnation Society. A provisional committee was formed, to make enquiries amongst growers and to report to a general meeting, to be held in May. The following are members of committee:—Messrs. W. E. Boys, Leicester; J. S. Brunton (Chairman); H. J. Cadman (T. S. Ware, Ltd.); H. J. Cutbush, London; A. F. Dutton, Iver, C. E. Engelmann, Saffron Walden; Low (Hugh Low & Co.); S. Mortimer, Farnham; and Hayward Mathias, Thames Ditton (Honorary Secretary).

Publications Received.—*Native Guano.* Results of its practical Application in the Farm and Garden.—*Agricultural Bulletin of the Straits and Federated Malay States*, October. Edited by H. N. Ridley. Contents: Position of Rubber among Cultivated Plants, Rubber Diseases, Rubber Notes by the Editor, &c.—From the University of Illinois, Agricultural Experiment Station, Urbana, November. Bulletin 104: *Field Experiments on Insects Injurious to Indian Corn*, by S. A. Forbes.—From the United States Department of Agriculture, Bureau of Plant Industry. Bulletins: 84. *Seeds of the Blue grasses*, by Edgar Brown and F. H. Hillman.—85. *Principles of Mushroom Growing and Mushroom Spawn Making*, by B. M. Duggar.—87. *Disease Resistance of Potatos*, by L. R. Jones.—89. *Wild Medicinal Plants of the United States*, by Alice Henkel.—No. 90. Part II. Crowngall & Hairy.

Exchange Seed List Received.—Delectus seminum ex horto Cantabrigiensis Academiæ ad mutuam commutationem propositorum. Application should be made to the Curator, Mr. R. Irwin Lynch, M.A.

NOTICES OF BOOKS.

Gardening in India.

Mr. Johnstone, the manager of the Himalayan Seed Stores, Mussooree, has published a "Guide for Amateurs." The book is arranged alphabetically, beginning with Artichokes and ending, so far as vegetables are concerned, with Vegetable Marrows, Potatos being conspicuous by their absence. Flowers are treated in the same way. Brief general descriptions are given and hints afforded as to the best method of cultivating each variety named. In addition, monthly calendars of operations for the plains, as well as for the hills, are given. The illustrations are, some of them, venerable friends that did duty in seedsmen's catalogues half a century ago, but others are more "up to date." A general index and an index of vernacular names add to the utility of this unpretentious little book.

THE ALPINE GARDEN.

"GALANTHUS GOTTWALDI."

Under the above name bulbs of a Snowdrop were received at Kew from Mr. W. Siehe, of Messina, during last autumn. When the plants flowered in the Alpine house at the beginning of the year they proved to be identical with G. byzantinus, although the examples in flower were very weak as compared with this usually robust species. The bulbs, however, were small when received, and the flower may improve another season. The plant possesses the distinct plicate leaves peculiar to both G. byzantinus and G. plicatus, but in the marking of the inner segments of the flower it agrees with the former species. These two species resemble each other to a great extent, the chief difference being in the green markings on the inner segments. In G. byzantinus the apex, as well as the base of the inner segments, is marked with green, as in G. Elwesii. In G. plicatus the apex only is marked with green, as in our native G. nivalis. The origin of G. byzantinus is somewhat obscure. It was introduced in the year 1893, and was said to have been found near Constantinople. Mr. Baker described it and gave it its name. G. plicatus, the "plaited Snowdrop," is a better known plant, and is found in the Crimea and in the Caucasus. G. byzantinus appears to be intermediate between G. plicatus and G. Elwesii, with the leaves of the former and the flowers of the latter species. Whether a natural hybrid or a species remains to be proved, as the origin of both G. byzantinus and G. Gottwaldi is doubtful, Mr. Siehe stating that he received the latter from Holland under that name. *W. I., Royal Gardens, Kew.*

VEGETABLES.

WEBB'S JEWEL TOMATO.

I consider this variety as the best red Tomato for general use and for exhibition purposes. It is almost round in shape, of medium size, and of a lovely red colour. I am still gathering fruit from plants raised from seeds sown last June; and having to furnish a supply of these fruits all through the winter months, I find this by far the best variety for the purpose. I can also recommend it for its free setting and heavy cropping qualities, the plants being literally covered with large bunches of fine, well-flavoured fruits.

WEBB'S MASTERPIECE ONION.

As the season is now at hand when the main crop of Onions should be sown, it is advisable, if not already accomplished, to thoroughly trench the ground 2 feet or more in depth, as the soil for this crop cannot be too rich, nor in too fine a condition. The seed bed should be made quite firm by treading or rolling previous to sowing the seed,

whether broadcast or in drills. If grown in rows, the lines should be 12 inches apart, and the young Onions, when large enough, thinned to about 6 inches apart, according to the variety grown. During long periods of dry weather a good watering is most beneficial. Growers of Onions for exhibition purposes usually transplant the seedlings, and this is almost a sure means of checking the Onion grub, so prevalent in some districts. Having grown all the leading varieties, both for exhibiting and for culinary purposes, I find Webb's Masterpiece one of the best. It is a handsome globe-shaped variety, growing quite as large as Ailsa Craig. The flesh is white, of mild flavour, with a pale yellow skin. *R. Milner, Margam Gardens, S. Wales, February 1.*

Fig. 44.—Buddleia asiatica, flowers whitish.

BUDDLEIA ASIATICA.

We publish the following note on this species, from Mr. Alwin Berger, La Mortola, Ventimiglia, Italy :—

"Mr. E. W. Wilson has published in the December number of *Flora and Sylva*, a full account of the Buddleias now in cultivation. He says much in favour of this species, B. asiatica. It was cultivated in England as long ago as 1874, and was figured in 1877 in the *Botanical Magazine*, tab. 6323, but was lost again until its re-introduction by Mr. Wilson.

We received a young plant here last spring, which was planted about May, in a sunny place. It is now a bush over 2 feet high, having every shoot terminated by its long flowering racemes. It is not so much for the beauty of these flowers that the plant deserves to be recommended as for its general appearance, its flowering season, and fragrance. Moreover, plants flowering about the end of the year and continuing for a long time cannot fail to be welcome.

All this makes the plant a valuable addition to our garden flora, chiefly for the south or in other favourable situations, where it can be grown in the open. The species will certainly make its way into every garden along the Riviera and not again be lost."

Our illustration at Fig. 44 is reproduced from a sketch made by Mr. Worthington G. Smith, of specimens exhibited by Messrs. Jas. Veitch & Sons, at the Royal Horticultural Society's meeting held on January 23 last.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Examinations in Horticulture.—It is doubtful whether such examinations as those held by the Royal Horticultural Society are of much value as a means of training in professional horticulture, or even as a test of knowledge of the principles and practice of the art. Would any practical gardener attach any importance to the success or failure of a young man at an examination in which he is asked to explain or describe the structure and growth of cells, the process of impregnation of the ovule and similar academic questions? And even the more practical questions, such as the description and use of implements, manures and their application, are worthless as tests of anything except perhaps memory. This sort of thing has about the same bearing on gardening as questions on the varieties and special uses of saucepans, the origin and chemical constituents of salt, or the effects of heat on vegetable and animal tissue have on cooking. Of course the college students who know little or nothing of gardening do well at the Royal Horticultural Society's examinations, whilst intelligent, experienced young men of proved ability in the garden rarely get into the first class. Take, for example, the result of the 1905 examination. Of the 160 candidates 76 were from horticultural schools, and the whole of the 20 that obtained firsts were school-students, chiefly from Swanley and Studley, which are for girl students only. This class-room gardening may be of some use, but it is no proof of real gardening ability, or even aptitude. It is impossible to devise a scheme of examination to be conducted in a class-room that would be a satisfactory test, and I rather fancy the examiners know that as well as I do. A gardener requires just that kind of knowledge of his art, and skill in its practice, as will enable him to obtain the best results as a cultivator. He may not be able to give satisfactory answers to any of the 24 questions asked and yet be a champion gardener. I am only concerned to protect the gardener from the imputation of ignorance or want of skill in his profession because he fails in class-room questions, and that things are tending in that direction is to be seen in the action of the London County Council in making the Royal Horticultural Society examinations a test for promotion among its gardeners. Would any responsible gardener or nurseryman select the members of his staff on such lines? I have had many years

experience in sorting men for all kinds of positions in horticulture, and I know the danger of being too much influenced by tongue or pen work. In horticulture we want men who are able to *do* things, and if we are going to prefer the training of the schoolmaster and lecturer to that of the gardener we shall get into the same mess as those military leaders found themselves in when well-schooled officers were pitted against field-made men in the Boer war. If we are to have tests in horticultural training they should be real and not sham. The horticultural colleges may be doing useful work, though one wonders where it reveals itself; so far as I can see it is not in any practical field; still, the training they give may be at least as useful as other things taught in schools; but this output should not be confused with the genuine article, much less considered superior, and that is the danger which I see. *W. Watson, Kew.*

Mutual Improvement Societies. — The federation of the numerous Horticultural Mutual Improvement Societies into one body having a central depot would be a means of furthering the objects which the individual societies have at heart. If such a scheme meet with the approval of the members of these various bodies I suggest the adoption of the following proposals by the Federation:—(*a*) An interchange of lecturers in districts within a given radius. (*b*) The formation of societies in districts in which no society exists. (*c*) An affiliation to a recognised federation would create the *locus standi* of each of the societies affiliated. (*d*) To bring before employers and employees the advantages of these improvement societies to both. (*e*) To institute a labour bureau for gardeners, with a registration of situations vacant and wanted. [Is not this work already carried out by the British Gardeners' Association?] (*f*) The meeting of delegates from each society at a conference, held annually, or oftener if desired, when matters relating to their separate societies could be brought forward and discussed. The society I have the pleasure to serve as honorary secretary is in unison with my views. *Hon. Sec. of the Croydon and District Society, 62, High Street, Croydon,*

Carnation "Coronation."—[See enquiry on p. 95.] This variety was shown by Mr. A. Smith, of Enfield Highway, at the National Chrysanthemum Society's Exhibition at the Crystal Palace on November 1, when it received an award of merit. I have not seen it in any other collection. Mr. Smith stated that it was one of his own raising, but I do not know if he has put it into commerce or not. I have since seen a large stock of "Liberty" in another nursery. This variety also was shown by Mr. Smith on November 1, and gained a first class certificate. *A. H.*

A good Cattleya.—I send a spike of Cattleya Trianæ delicata which is flowering in the collection here. The plant from which it was cut has ten pseudo-bulbs, the largest of which produced this enclosed spike. This spike measures with leaf combined 22 inches, the bulbs in the thickest part being 3 inches in circumference. The spike originally had four flowers. *F. C. Puddle, gardener to W. H. St. Quintin, Esq., Scampston Hall, Yorks.* [A capital specimen. Ed.]

Conifers for Large Groups.—*H. W.*, p. 69, directs attention to Conifers for grouping, and also mentions the mistake of planters of sixty years ago in not giving each tree sufficient room for full development. The former lack of knowledge in this respect is apparent to-day in many private grounds, where one may often see examples that would have been far finer trees, if, at planting time or later, sufficient space had been afforded them. Planters of to-day have a knowledge of the probable space such Conifers will cover, and therefore such errors should not be repeated. That a group of the Conifers "H. W." mentions presents a grand and beautiful appearance is without doubt, but they must have ample room for their true beauty and fine proportions to be seen. And "H. W." omits one important point in not saying what amount of space should be allowed between each specimen. A most beautiful effect is produced by a group of Thuia gigantea and Cupressus nootkatensis, but these two species do not require so much room as groups of Pinus excelsa or Pinus insignis. At Poltimore examples of these last-named cover a space of 64 and 61 feet respectively, and for trees which have attained to these dimensions 40 feet between each specimen is not too much to allow. It is doubtful if Araucaria imbricata will cover a space of more than 36 feet through, as by the time this size is attained the lower branches will begin to die off. Picea Smithiana at 50 years of age covers a space of 36 feet. The Deodar, with a diameter of 60 feet at a similar age, affords another example. Close planting of Conifers will restrict the spread of the branches, while the provision of ample room between the specimens will encourage branch extension. *T. H. Slade, Poltimore.*

To Brighten Beds of Azaleas, Rhododendrons, &c.—Your correspondent *R. M.* at p. 91 makes a curious remark with regard to the plants which I named on p. 46, as being suitable for the purpose required, in that they have, as he states, "a beauty of their own at all seasons of the year." Why should that be an objection to their use to brighten shrubs when the latter are not in flower? Besides, there are beds of Azaleas and Rhododendrons that contain hundreds of plants, as at Dropmore and Bagshot Park; and others which are filled with a few dozens of small plants. The person who asked the question of the editor omitted, as I take it, to mention the size of beds; and I named a number of plants of various species as being suitable and of which an intelligent gardener could select one, two, or more, as seemed to him best for the purpose. There are positions in pleasure grounds and semi wild gardens where Roses, and even Scotch Roses, would not be incongruities in the vicinity of Azaleas &c. *F. M.*

Dangerous Insecticides. — After reading carefully all that Mr. W. H. Dobson has written (see page 85), about hydrocyanic acid gas, its troubles and grave dangers to both human and plant life, one is tempted to ask whether the game is worth the candle. Were some gardener encouraged to use this dangerous gas after reading Mr. Dobson's article, and to be poisoned in consequence, its doom as an insecticide would be sealed. But I rather infer that no one of good sense would be disposed to dabble with such an eminently dangerous article, and especially because it needs such exceeding care in its preparation and use. We have plenty of patent insecticides that are dangerous to neither man nor plant. With these, gardeners have been enabled to keep hot-house or greenhouse plants, Vine-Peaches and other fruits perfectly clean and free from insect pests, and what they have done they can do. That Mr. Dobson had need to employ drastic remedies in his plant houses is evident when he states that he had plenty of "material." That was his misfortune; where gardening is well done drastic remedies are not required. *A. D.*

Legislation and the Spread of Fungus Disease.—In my article on this subject I distinctly stated that in certain instances a fungus known to attack a given plant at home followed that plant when the latter was introduced to new countries, and followed it in such a manner as to elude detection by legislative methods. Mr. Salmon appears to have missed this point, and replies as if I denounced legislation entirely, and has consequently introduced controversy extending outside my delimited sphere. With this portion I shall not deal. There are, however, a few points bearing on my remarks which Mr. Salmon considers to be impossible or doubtful that may be briefly considered. We are told that Klebahn, an acknowledged authority on rusts, does not know how the Hollyhock rust reached Europe. Quite so; but I fail to see what this has to do with my statement that the rust did come: on this point, I suppose, we are all agreed, and if Klebahn does not know how it came, surely this is proof that it came in a manner that would have eluded legislation. Next Mr. Salmon points out that I have advocated a point that is impossible of realisation. Wheat taken to Australia could not have been inoculated by spores conveyed with it, as uredospores lose the power of germination so quickly. This contention is derived from ancient history, and only an assumption at best. Mycology is a progressive science, and if Mr. Salmon will turn up *Science*, Vol. 22, p. 50, he will learn much relating to the modern study of rusts; among other things, he will learn that the uredospores of many cereal rusts, including Puccinia graminis and P. rubigo-vera—both wheat rusts—remain quite uninjured and capable of producing infection, after being exposed on bits of dead leaves and straw to the drying winds of autumn and the intense cold of a North Dakota winter. This point, however, has no direct bearing on my statement that the rust fungus did reach Australia, and in a way that no practical act of legislation could have prevented. Other points challenged turn simply on a difference of opinion. I instanced a case of Broad Beans sent to Central Africa, where they were promptly destroyed by the same fungus that proves so destructive to Beans at home. I assumed that the fungus went along with the seed; Mr. Salmon assumed that the fungus was there already, and simply attacked the Beans. Either assumption may be correct. Mr Salmon is convinced that the Gooseberry fungus was introduced into Ireland; there is not a scrap of direct evidence on this point; it is a conviction. Now, suppose I adopt Mr. Salmon's line of reasoning with regard to the Bean fungus, and assume that the Gooseberry fungus was not introduced at all, but that it was already in Ireland; would Mr. Salmon even admit the bare possibility? I imagine not, neither would I; but is it more foolish to assume one case than the other, and, if so, why? It might be asked, Why did not the fungus attack the Gooseberry before? I don't know. I don't know why the Potato was with us so long before it was attacked. I am charged with scientific inaccuracy respecting the life-history of the Gooseberry fungus. I intentionally abstained from using scientific terms, but spoke of spores only as fully explaining my contention. I was fully conversant with the difference between spores, perithecia, etc., for some time past, in fact, for many years before I imparted to Mr. Salmon the information that the group of fungi including the Gooseberry mildew existed, and suggested that he should study the group. Fortunately, he acted on my advice, and the result has been an unqualified success. At the present moment we are in possession of much valuable information respecting these mildews, due entirely to Mr. Salmon's accurate and painstaking investigations. However, the mildews number only about 50 out of the 55,000 known species of fungi, and it may be that Mr. Salmon's knowledge of the remaining 54,950 species is not sufficiently exact to justify the position of the all-round censor he has assumed. Potato disease is stated to be absent from New South Wales, and, as an instance of prompt legislation, it is pointed out that measures are in force for preventing the introduction of Potatos from countries where the disease exists. If the New South Wales people in reality have no Potato disease I should strongly advise them not to import from anywhere, but to remain content with what they have, unless Mr. Salmon can indicate a country where Potato disease does not exist, as I am afraid no one else can. I am not at all prejudiced against legislation; in fact, I should like to see it applied in the case of our wilfully neglected orchards and gardens that are centres of infection from which disease spreads in every direction. So far as this country is concerned, nursery stock and seed cleaned by machinery are practically free from disease. I am quite open to conviction, but must say that I am not convinced by Mr. Salmon's arguments, and still consider that a very large share of disease caused by fungi is conveyed from one country to another in ways that no legislation could meet. *Geo. Massee.*

Dressing Fruit Walls in Winter.—A few years ago my attention was attracted by the freedom from insect pests on the upper parts of Peach and other fruit-trees growing on a wall, the upper half of which had been pointed during the previous winter, while on the lower parts of the trees, against the unpointed portion of the wall, the leaves were badly infested with aphides and other insects. The effect was most marked, for while the fruit in the one case attained to a considerable degree of perfection, in the other it was very inferior. Since that time I have made a point of bestowing extra attention on the walls, in the matter of winter dressing, using preferably a solution of caustic soda and potash, applied with a knapsack spraying machine, which, by the way, is one of the most useful appliances for use in the garden, as by its use the mixture can be made to go very much farther than with an ordinary garden engine, and it can be forced into every nook and cranny of the wall, destroying any insects or eggs that may be harbouring therein, the work being got over very quickly. Where this is carried out thoroughly during the resting season, much less trouble will be experienced with insects generally during the season of growth. *R. W. Dean, Wainsford.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 13.—On the occasion of the annual meeting of the Society, we have become used to witnessing large exhibitions and the attendance of numerous visitors, but on Tuesday last the display was fuller and better than ever. The fine hall was replete with gay flowers and well-grown plants; the Committees were unusually well attended, and there were numerous visitors from the body of Fellows.

Before the ORCHID COMMITTEE an exhibit from Major HOLFORD was of outstanding merit, and its effect was better than we have seen in any previous exhibit of Orchids staged in the hall. The collection of Dendrobiums from JEREMIAH COLMAN, Esq., was comprehensive and of great excellence. The ORCHID COMMITTEE recommended awards to novelties which included three First Class Certificates, twelve Awards of Merit, and one Botanical Certificate. Diploma Awards were also made for plants previously advertised, particulars of which are given below.

The FLORAL COMMITTEE recommended three Awards of Merit to novelties, and nineteen Medals for groups of plants and of cut flowers, including a Gold Medal for Carnations.

The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty, and only four Medals for exhibits.

In the afternoon, at the annual general meeting, nearly one hundred new Fellows were added to the Society's list.

Floral Committee.

Present: W. Marshall, Esq., chairman, and Messrs. C. T. Druery, H. B. May, R. C. Notcutt, Geo. Nicholson, Jno. Green, G. Reuthe, C. J. Salter, Jas. Douglas, J. F. McLeod, Chas. Jeffries, W. Howe, Jno. Jennings, C. Blick, Chas. Dixon, W. Bain, W. P. Thomson, R. C. R. Nevill, A. R. Goodwin, C. E. Pearson, Chas. E. Shea, W. Cuthbertson, E. H. Jenkins, W. J. James, F. Page Roberts (Rev.), Geo. Paul, H. J. Cutbush, R. W. Wallace, R. Hooper Pearson, and James Hudson.

Messrs. H. CANNELL & SONS, Swanley, Kent, made a very fine display with Chinese Primulas, most of the plants being at their best stage of development. The flowers of this strain are of unusually large size and of great substance, with brilliant colours. Cannell's Blush Pink, Carmine, White, Swanley Giant, and others were prominent varieties. In addition to the strain already noticed, there were many varieties of the "star" type, in which the lax and free-blooming habit, combined with rich colours, were greatly admired. (Silver Gilt Banksian Medal.)

Messrs. SUTTON & SONS, Reading, exhibited a collection of Primula sinensis that furnished the whole of one long table. The plants were arranged in rows running from the back to the front, there being five plants in each row, and in all over fifty varieties were represented. These plants were as nearly alike in size and habit as possible, and they presented a level surface of floral colour which varied a little in each row. It is obvious we cannot enumerate such a number of varieties, but it may be pointed out that the influence of "The Duchess" Primula, which Messrs. SUTTON first brought to our notice a few years ago, is becoming more and more evident in the varieties that constitute the major portion of the strain. There is just one plant of a Giant Duchess, the flowers being nearly two inches across, and having all the colour and "halo" that characterised the first plant. Its appearance was remarkable, and there is little doubt but others of the same excellence will be forthcoming. The "double" Duchess is now two years old at least, and the "fern-leaved" Duchess is becoming equally well known. The semi-double varieties were grouped by themselves, and represented flowers of salmon, Carnation-flaked, pink, scarlet, and blue colours, as well as pure white flowers. The "Star" Primulas were also shown, and among these there are now double-flowered varieties. In addition to the Primulas Messrs. SUTTON & SONS exhibited a group of Cyclamen of the variety Sutton's Cerise. The numerous plants had prominently marbled or mottled foliage, and every one was true as possible. In this variety a very successful effort has been made to develop to its fullest the silver or white markings on the foliage, which in some Cyclamens are much less prominent than was formerly the case. (Silver Gilt Banksian Medal.)

From Lady TATE, Park Hill, Streatham Common (gr. Mr. W. Howe), came a group of forced bulbs. Mr. Howe had probably rather less space than he required for the plants, for they were somewhat thickly placed, but they constituted a capital evidence of good management, the flowers being of very large size and perfect development. There were Tulips, Prince of Austria, Queen of the Netherlands, Pink Beauty, Van der Neer, Duchess de Parma, &c., Narcissus, Golden Spur, Henry Irving, Princess, Van Sion, &c., Italian pink-flowered Hyacinths, &c., &c. (Silver Gilt Banksian Medal.)

Messrs. W. & J. BROWN, Stamford and Peterborough, exhibited plants of Eupatorium petiolare in flower [see fig. in *Gardeners' Chronicle, March 12, 1904*], also cut flowers of a strain of zonal Pelargoniums that has been described as a "Cactus" strain.

Messrs. WM. PAUL & SONS, Waltham Cross, Herts., exhibited a collection of Camellias in 40 varieties. Many plants were included in the display, some being specimens of a large size; all were flowering freely, and all looked the picture of health. Many seedlings, chiefly single-flowering varieties, found a place in the group—Mercury and conspicua tricolor, the latter, having red-striped flowers on a rose ground, being conspicuous. Another good flower is Pride of Waltham. This is a double form, the well-shaped flowers being of a lovely shade of rose pink colour. (Silver Gilt Flora Medal.)

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, put up a magnificent group of forced flowering shrubs. The plants were shown in splendid condition, and displayed in a manner that excited admiration. The design was made up of three bays, the intervening groundwork being composed of Azaleas. The central and taller bay was furnished with grand specimens of Magnolia speciosa and M. alba superba, set off by the bright foliage of Abutilon Thomsoni, while on either side were clumps of Lilac and the yellow Rhododendron (Azalea) Anthony Koster respectively. Standard trained plants of Wistaria, Laburnum, Prunus triloba, &c., were interspersed throughout the group, which was finished by an edging of Spiræa Thunbergi and small Ferns. (Silver Gilt Flora Medal.)

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., showed a collection of forced flowering plants: Lilacs, Azaleas, Staphylea colchica, Viburnum Opulus, Prunus triloba, Spiræas, &c.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, displayed a group of forced flowering shrubs: Lilacs, Azaleas, Viburnum Opulus Forsythia suspensa, Deutzia, &c. (Bronze Flora Medal.)

Messrs. PAUL & SON, Cheshunt, staged a dozen varieties of Lilacs and a new hybrid Tea Rose named Cherry Ripe.

Messrs. JAS. VEITCH & SON, LTD., King's Road, Chelsea, showed Clianthus puniceus albus, Coleus shirensis, C. thyrsoideus, Eupatorium vernale, and Rhododendron (Azalea) Early Gem. (Bronze Flora Medal.)

Messrs. WM. BULL & SONS, King's Road, Chelsea, exhibited a collection of Aralias. The species included the strong growing A. triloba, the elegant A. Veitchi, with its handsome pedate leaves, A. elegantissima, and A. Chabrieri [Elaeodendron], with simple, linear leaves.

Mr. W. PALMER, Andover Nurseries, Andover, had a number of Primulas in 60-size pots, adaptable for table decoration. The variety was Queen Alexandra, a double form with blush rose petals.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, staged a miscellaneous group of plants, including Ferns, Camellias flowering well in small pots, Thyrsacanthus rutilans, with its long pendulous racemes of red tubular flowers plentifully developed, Primula × kewensis, and a batch of the scented leaved Pelargonium Clorinda, which formed the subject of our supplementary illustration in our issue for April 15th, 1905. (Bronze Flora Medal.)

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, exhibited a group of large specimen Ferns. The exhibit was staged in the East Annexe, one end of which it completely filled. Splendid specimens were shown of Dicksonia squarrosa, Davallia fijiensis elegans, Aspidium nidus avis, Polypodium glaucum giganteum (magnificent specimen), Asplenium inequale, &c. (Silver Flora Medal.)

Messrs. JOHN WATERER & SONS, LTD., Bagshot, Surrey, set up a group of Evergreens, principally Hollies, among which was the small-leaved Ilex crenata. Several other good things were included, Osmanthus myrtifolius, Andromeda japonica, &c.

Mr. H. HAYWARD, Fife Road, Kingston-on-Thames, showed sprays of ornamental foliage: Conifers, Cassinia fulvida, and other shrubs, and two large bowls containing Garrya elliptica, with its long pendulous catkins well developed.

Mr. JOHN R. BOX, West Wickham, put up a batch of Begonia Gloire de Sceaux and a few of the Rex type interspersed with others of the semperflorens class.

Messrs. BARR & SONS, 11, 12, 13, King Street, Covent Garden, London, W.C., showed many choice Alpine and hardy flowers—Irises, Daffodils, Adonis amurensis, Lachenalias in several species, including L. Wrightii, with erect greenish-white flowers tipped with deeper green, Eranthis cilicica, Saxifragas, &c.

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, staged a number of hardy and rock-garden plants in flower, prominent among which was a batch of Saxifraga burseriana major, and three splendid specimens of Lachenalia Nelsoni.

The Misses HOPKINS, Mere, Knutsford, Cheshire, showed a small group of Alpines. We noticed a specimen of Daphne Blagayana in flower.

Messrs. THOS. WARE, LTD., Feltham, Middlesex, set up a number of pans and boxes of hardy and Alpine plants, among others Tropæolum tricolor, Canarina campanula, and Orobus vernus purpureus. Some good Carnations were also staged by this firm. (Silver Flora Medal.)

Messrs. JOHN PEED & SON, West Norwood, also presented a display of Alpines: Hepaticas, Primroses, Lachenalias, Hellebores, &c.

Mr. G. REUTHE, Keston, Kent, showed hardy and rock-garden plants in flower: Irises, including I. Bakeriana, Galanthus Ikariæ, Hepaticas, many species of Crocus, &c. (Bronze Flora Medal.)

Sir E. G. LODER, Bart., Leonardslee, Sussex (gr. Mr. W. A. Cook), displayed a number of flowers from the open that testified to the mildness of the past winter: Azara microphylla, A. Catesbei (with handsome foliage), and A. integrifolia.

Lady CHESTERFIELD, Holme Lacy, Hereford (gr. Mr. W. Humphries), showed several varieties of Violets, all exhibiting good culture.

Mr. ROBT. SYDENHAM, Tenby Street, Birmingham, brought bowls of Narcissus grown in moss fibre. The plants were flourishing in this material.

The GUILDFORD HARDY PLANT CO., Millmead, Guildford, exhibited a small group of Alpine plants in pots and pans. Cyclamen coum was very bright in several pans, also Anemone blanda, Iris reticulata, &c.; but other species, though good specimens, were not in flower.

CARNATIONS.

The effort to make a special show of these flowers met with success. The groups were arranged in various parts of the hall, and each was more or less a replica of another, owing to the similar style of staging adopted, and to the repetition in each stand of similar varieties. The largest display was shown by Mr. G. ENGELMANN, Horneybrook Nurseries, Saffron Walden, Essex. This collection made a brilliant show, and all the flowers were in first-class condition, and embraced a very large number of the finest sorts in cultivation, such as Flamingo (scarlet), Mrs. T. Lawson (and its white variety), The Belle (white), Enchantress, Fiancée (salmon pink), Prosperity, The Cardinal (scarlet), Lady Bountiful, &c. (Gold Medal.)

Messrs. CUTBUSH & SONS, Highgate, London, N., set up a very pretty group of Carnations. The flowers, which were principally of the American or free-flowering type, showed to

advantage against a groundwork of green baize, fancy vases and bamboo epergnes being requisitioned for their display, which was further enhanced by sprays of Asparagus medeoloides (Smilax) entwined around the receptacles. The varieties embraced most of the popular kinds. We also noticed some excellent blooms of Souvenir de la Malmaison, Princess of Wales, and Duchess of Westminster. On an adjacent table Messrs. Cutbush arranged an exhibit of hardy early-flowering plants. Two interesting plants were Corydalis rutæfolius and Dondia epipactis. (Silver Gilt Banksian Medal.)

Mr. A. F. Dutton, Iver, Bucks, displayed an attractive exhibit of Carnations having excellent flowers of many of the latest and most beautiful of the American or tree-flowering type. Christmas Eve is a comparatively new scarlet variety of good shape. The fine dark clove-coloured Harlowarden was shown well. (Silver Gilt Flora Medal.)

Mr. Hayward Matthias, Medstead, Hants, arranged a small exhibit of these flowers, having The Belle (white), Nelson Fisher, Harlowarden, &c. (Bronze Banksian Medal.)

Mr. S. Mortimer, Rowledge, Farnham, Surrey, contributed an excellent group of these flowers, having well-grown specimens neatly arranged with small Palms, Ferns, and Smilax. The brightness of the exhibit was remarked, and the selection of varieties of the best. We noticed a flaked variety named Mrs. H. A. Patten, the ground colour being white and the marking of bright red colour. (Silver Flora Medal.)

Messrs. Hugh Low & Co., Bush Hill Park, Enfield, showed many vases of Carnations, and they had in addition a number of Cyclamen plants with flowers of white, red, salmon and other shades of colours. (Silver Banksian Medal.)

Mr. H. Burnett, St. Margaret's Vineries, Guernsey, displayed a collection of Carnations, including two new varieties, Mrs. H. Burnett (see Awards) and Mikado, the latter being a flower of pleasing form, but the mauve colour is dull. A vase of Mrs. Lawson and another of unnamed seedlings were also noticed. (Silver Flora Medal.)

Messrs. Dodd & Lancashire, Guernsey, staged half-a-dozen vases of these flowers, but although the collection was small, the quality was excellent. The varieties were Mrs. T. W. Lawson, The President (dark clove colour), Enchantress, &c. (Silver Banksian Medal.)

Messrs. T. S. Ware, Ltd., Ware's Nurseries, Feltham, also displayed some excellent Carnations, as already stated above.

Awards of Merit.

Asparagus Colmanni.—This is a variety of Asparagus exhibited by Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. W. P. Bound). It forms a dwarf bushy plant hardly one foot in height, and throws a number of growths from the base. The growths are similar to those of A. Sprengeri, but more delicate and slender in appearance.

Lachenalia "*Brightness.*"—This is one of the fine crossbred varieties raised by Mr. Moore, Glasnevin Botanic Gardens, Ireland. The flowers are of considerable size, and coloured deep yellow with crimson margins, but the Award of Merit was recommended mainly on the ground that this variety is an extra good grower, and has an excellent habit. Shown by Mr. F. W. Moore.

Carnation Mrs. H. Burnett.—This winter-flowering or "tree" Carnation is of excellent quality, and very attractive. The flowers are of considerable size, and have petals only very slightly fringed, of rosy salmon colour, with somewhat slender stems. Shown by Mr. H. Burnett, Guernsey.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (Hon. Sec.), Major G. L. Holford, Harry J. Veitch, Francis Wellesley, F. Menteith Ogilvie, R. Brooman-White, H. Little, W. Boxall, H. A. Tracy, H. G. Alexander, Arthur Dye, F. J. Thorne, H. Ballantine, W. H. White, S. Briggs-Bury, J. Charlesworth, A. A. McBean, R. G. Thwaites, H. G. Morris, H. T. Pitt, F. Sander, W. Cobb, E. Ashworth, G. F. Moore, W. A. Bilney, J. Colman, and De B. Crawshay.

Major G. L. Holford, C.I.E., C.V.O., Westonbirt, had an exhibit which was generally conceded to be the most extensive, varied, and beautiful, as well as the best arranged group which has yet appeared in the new hall, and it was deservedly awarded the Society's Gold Medal, with the addition of the Lindley Medal to Mr. H. G. Alexander, the Orchid grower at Westonbirt, as a mark of appreciation of the excellent culture he had exercised on the plants of all classes. It is impossible to enumerate the scores of rare Orchids shown, and a general description of the arrangement must suffice. The group occupied the first section of the main staging at the entrance of the hall. At the back were massive Kentias and dwarfer Cocos Weddelliana, two noble specimens of the last-named species being also placed in the group, the centre of which was composed of a fine lot of white Lælia anceps with fine pans of scarlet Sophronitis arranged in front of their gracefully arching spikes. On each side of the central block of white Lælia anceps were groups of rare Cypripediums which were continued by elegant arrangements of white and coloured Odontoglossums, the white O. crispum being specially beautiful. Then followed, on each side, selections of good Cypripediums flanked by richly coloured Cattleya Trianæ, C. Percivaliana, &c., the ends being of orange and crimson coloured hybrids of Lælia cinnabarina, Lælio-Cattleya × luminosa, rose-coloured Pinguicula caudata, Masdevallias, some fine pans of white Cœlogyne cristata being interspersed along the front line, the whole admirably set up in fresh green Moss and Maidenhair Fern. Among the Cypripediums noted was a fine selection of C. aureum varieties, the noble C. Scipio, raised at Westonbirt, C. Maudiæ, &c.

Jeremiah Colman, Esq., Gatton Park (gr. Mr. W. P. Bound) secured the Gold Medal for a very beautiful and varied group of Dendrobiums, many of them raised at Gatton Park, the whole occupying nearly 700 square feet. Thirteen distinct varieties of D. nobile were present, the pure white D. n. album contributing 165 flowers. There were also several plants of the handsome D. n. Colmanianum, a pretty white flower with lilac disc to the lip, and the rare D. tortile album. With these were about 70 distinct Dendrobiums of the type for which Gatton Park is noted, including varieties of D. Artemis, D. Cybele, D. rubens, D. Othello, &c. D. × rubens, Gatton Park variety, was a noble and richly-coloured flower; so also D. rubens Colmani, of a bright reddish purple. D. Othello colossus was large, finely formed, and with rich, claret-coloured disc to the lip; D. Ainsworthii Colmani, a beautiful and dark-tinted bloom, and all the others grown to surpass even their fine form of last year. Others noted were a very fine D. Wardianum album, white with orange disc, and no dark marking as usually seen; D. crassinode album, D. melanodiscus Aurora, D. Schneiderianum, &c. Arranged with the Dendrobiums were some nice hybrid Calanthes and Phaius, white Lælia anceps, the orange-coloured Epidendrum Boundii, varieties of Spathoglottis Aureo-Veillardii, the rare Arachnanthe Cathcartii, Masdevallias, Cymbidium Hookerianum punctatissimum, Cattleya Trianæ alba, C. T. Purple King, Lælia Mary Colman, &c. The whole was most tastefully arranged by Mr. Bound.

J. Bradshaw, Esq., The Grange, Southgate (gr. Mr. Whitelegge), was awarded a Silver Gilt Flora Medal for an excellent group composed chiefly of fine varieties of Lycaste Skinneri, Cattleya Trianæ and Odontoglossum crispum, in all of which Mr. Bradshaw excels. The best of the Lycastes were L. Skinneri alba, 20 flowers of which appeared; L. S. Jewel, with large rose-tinted flowers; L. S. Enchantress, blush white and fine in shape; L. S. Eros, L. S. Apple Blossom, L. S. Beauty, and other fine varieties were equally good, and the hybrid L. Balliana bore many rich claret-rose blooms. The varieties of Cattleya Trianæ, the best of which were shown for Diplomas, ranged from white to the best coloured forms.

Messrs. James Cypher & Sons, Cheltenham, secured a Silver Gilt Flora Medal for a fine, varied, and excellently arranged group in which the white forms of Lælia anceps and good hybrid Cypripediums were conspicuous. Cypripedium aureum Hyeanum is a grand flower, and it has never been seen in so good a condition as in Mr. Cypher's group. C. aureum virginale, and other varieties of C. aureum; C. Leeanum and C. insigne varieties and many others were also well shown. Varieties of Lycaste Skinneri, Cattleya Trianæi, Dendrobiums, Phalænopsis, Odontoglossums, including the rare O. aspidorhinum, a pretty Phaio-Calanthe, scarlet Ada aurantiaca, Sophronitis grandiflora, and various Masdevallias were also noted.

G. F. Moore, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page), received a Silver Flora Medal for a fine group of Cypripediums, a large proportion of them being hybrids of C. villosum and C. Boxalli, and entering into the Diploma competition of the day, the whole being a most remarkable series too varied and excellent to admit of adequate enumeration in the space at our disposal.

Messrs. Sander & Sons, St. Albans, were awarded a Silver Flora Medal for an interesting group of good things, the best of which, Cymbidium Holfordianum, secured a First Class Certificate. (See Awards.) Cypripedium Pallas (Godefroyæ × Hookeræ) was a very distinct purplish red spotted flower; C. Leeanum Niobe, showy and distinct; C. × Rajah (triumphans × callosum), a good, dark flower; Odontoglossum Loochristyense nobilius, yellow prettily spotted. Among good Cattleyas C. Trianæ Purple King merited the name; of species Platyclinis valida had a profusion of white fragrant sprays; Eulophia Saundersiana represented a rare and pretty species.

Sir Trevor Lawrence, Bart., Burford (gr. Mr. W. H. White), was awarded a Silver Banksian Medal for a pretty little group of finely-flowered yellow hybrid Dendrobiums, including two fine D. Wiganiæ xanthocheilum, and two of the better known Burford hybrid D. Melpomene; also D. Ophir, D. xanthocentrum, D. Aspasia, and the finely coloured Cypripedium Watsonianum.

Messrs. J. and A. A. McBean, Cooksbridge, received a Silver Banksian Medal for a neat group of white Lælia anceps varieties, good Odontoglossums, etc., arranged with the pretty reddish scarlet Epiphronitis Veitchii, etc. Odontoglossum crispum Anak was a noble white flower.

Messrs. Hugh Low and Co., Enfield, were awarded a Silver Banksian Medal for a group composed of Miltonia Bleuana, varieties of Cattleya Trianæ, of which The Don was a very large self rose coloured flower with orange coloured disc; Dendrobium heterocarpum, D. superbiens, with three spikes; D. crassinode, a nearly white Vanda Amesiana, and various Cypripediums, of which C. chrysotoxum, a large yellowish flower with white to the dorsal sepal, was the best.

M. Chas. Vuylsteke, Ghent, secured a Silver Banksian Medal for a group of hybrid Odontoglossums: O. ardentissimum, O. Wiganianum, and others.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent Cattleya Miranda, three good forms of C. Trianæ, Cypripedium aureum Surprise, C. a. Hyeanum, C. a. virginale, and C. Mrs. Wm. Mostyn, the last two securing Diplomas.

Mr. Whateley, Kenilworth, showed several pretty Odontoglossums.

H. Druce, Esq., The Beeches, Circus Road, St. John's Wood (gr. Mr. Walker), staged a small group of Cypripedium villosum and hybrids.

Messrs. Heath & Sons, Cheltenham, showed a small lot of Cypripediums, Dendrobiums, &c.

Messrs. Jas. Veitch & Sons, Chelsea, showed two Sophro-Lælia Psyche, two Sophro-Cattleya Saxa, and Sophro-Lælia Valda—all of pretty tints of yellow and red.

Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins), sent Cypripedium Miss Marian Sillem, a pretty white flower densely spotted with purple; a very fine form of C. Mons de Curte, C. W. E. Dickson, C. Boxalli nigricans (see Awards), and Cattleya Chocoensis, Westfield variety, fine in form, white with orange disc and small purple spot on the lip.

Mr. A. A. Peeters, Brussels, showed three forms of his fine hybrid Odontoglossum Lambeauianum, illustrated in the *Gardeners' Chronicle* (see Awards).

W. Parmenter, Esq., Braintree (gr. Mr. Buckland), showed a nearly white form of Lælia Jongheana.

C. L. N. Ingram, Esq., Elstead (gr. Mr. T. W. Bond), sent Lælia canariensis (harpophylla × anceps) and Cattleya rubens.

W. M. Appleton, Esq., Weston-super-Mare, sent several hybrid Cypripediums.

R. I. Measures, Esq., Camberwell (gr. Mr. Smith), showed an interesting collection of cut Cypripediums.

R. G. Thwaites, Esq., Streatham (gr. Mr.

Black), showed two varieties of Lælio-Cattleya Oriens (L. Cowanii × C. Trianæi).

H. T. Pitt, Esq. (gr. Mr. Thurgood), sent Lælia anceps Schroderiana and Cypripedium Ajax.

Messrs. Charlesworth & Co., Bradford, showed Lælio - Cattleya harpo - aurea, Odontoglossum Adriano triumphans and O. Hallio Adrianæ.

F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed Lælio-Cattleya Myra imperialis, very fine in colour; Lycaste Skinneri Fascinator, Cypripedium aureum Surprise, and C. insigne Bohnhoffianum.

C. K. Wild, Esq., New Eltham (gr. Mr. Usher), sent a good Cattleya amethystoglossa.

From the Royal Botanical Gardens, Dublin, came a spike of a fine variety of Odontoglossum cirrosum, Oncidium pubes, and Gongora atropurpurea.

Messrs. Sutton & Sons, Reading, showed a pan of a pretty terrestrial Orchid from China, reported to be allied to Pleione pogonioides. It was awarded a Botanical Certificate by the Scientific Committee.

AWARDS.

First Class Certificate.

Cymbidium Lowio-grandiflorum, from Major G. L. Holford (gr. Mr. H. G. Alexander). It is the plant raised by Messrs. Jas. Veitch and Sons, and who formerly received an Award of Merit for it. Flowers large as those of C. grandiflorum, sepals and petals emerald green, lip creamy white with reddish spots.

Cymbidium Holfordianum (eburneum × grandiflorum), from Messrs. Sander & Sons. A charming and delicately tinted hybrid with flowers partaking much of C. eburneum, but large as C. grandiflorum. Present inflorescence four-flowered, sepals and petals ivory-white, slightly tinged with emerald green. Lip, cream-white with a row of purple spots inside the margin and at the base.

Odontoglossum Lambeauianum, from Mr. A. A. Peeters, Brussels, two of whose varieties of this noble hybrid have been illustrated in the *Gardeners' Chronicle*. Flowers large, much like one of the best spotted O. crispum, but of firmer substance (see illustrations in *Gardeners' Chronicle*, Nov. 4 and Dec. 23, 1905).

Award of Merit.

Lælio-Cattleya Myra, Burford variety (Trianæ × flava), from Sir Trevor Lawrence, Bart. (gr. Mr. W. H. White). The finest of its class. Flowers bright yellow with dark crimson lip.

Dendrobium Brodici (Dominianum × Wiganiæ), from Jeremiah Colman, Esq. (gr. Mr. Bound). Flowers white shaded with rose, disc light purple.

Spathoglottis Colmani (aureo-Veillardi × aurea, Gatton var.). A very pretty yellow flower spotted with crimson. Shown by J. Colman, Esq.

Dendrobium Othello Colossus, from Jeremiah Colman, Esq. Like a very broad-petalled rubens, and with a large maroon disc to the lip.

Cypripedium Boxalli nigricans, from Francis Wellesley, Esq. (gr. Mr. Hopkins). The darkest form of C. Boxalli. Dorsal sepal blackish purple with narrow light margin. The rest of the flower very dark.

Cattleya Trianæ, Westonbirt variety, from Major G. L. Holford. A charming form of typical richly-coloured C. Trianæ.

Lycaste Skinneri Fascinator, from F. Menteith Ogilvie, Esq. (gr. Mr. Balmforth). One of the finest of the delicately-tinted white and rose forms which has yet appeared.

Lycaste costata, from H. G. Goodson, Esq. Putney (gr. Mr. Day). The fine old species with ivory-white flowers was well shown.

Cymbidium eburneo - giganteum, from Messrs. Charlesworth & Co. Flowers large, cream-white with reddish brown markings.

Cypripedium × G. F. Moore, variety punctatissimum, from G. F. Moore, Esq. A fine flower with dorsal sepal densely spotted with blackish-purple.

Cypripedium Edithæ Rowena (Chamberlainiana × bellatulum), from W. M. Appleton, Esq. Flowers densely spotted with dark purple.

Lælia anceps Fascinator, from Messrs. J. & A. A. McBean. A grand flower, resembling the fine L. a. Chamberlainiana, but with a purplish feather on the segments.

Botanical Certificate.

Maxillaria arachnites, from Sir Trevor Lawrence, Bart. A fine plant with many pretty light yellow flowers.

Diploma Awards.

Cattleya Trianæ.—*1st Diploma:* Cattleya Trianæ "The Premier," from J. Bradshaw, Esq. *2nd Diploma:* C. T. Westonbirt var., from Major G. L. Holford.

Lælia anceps (white).—*1st Diploma:* L. anceps Schroderiana, from Baron Schroder, Major Holford, and Jeremiah Colman, Esq. *2nd Diploma:* L. a. Hollidayana, from De B. Crawshay, Esq.

Cypripediums (Species).—*1st Diploma:* C. Boxalli nigricans, from Francis Wellesley, Esq.

Cypripediums (Hybrids).—*1st Diploma:* Cypripedium aureum virginale, from J. Gurney Fowler, Esq., and G. F. Moore, Esq. *2nd Diploma:* Cypripedium Mrs. Wm. Mostyn, from G. F. Moore, Esq., and J. Gurney Fowler, Esq.

A large collection of the Society's paintings of certificated Orchids bearing on the Diploma exhibits was arranged, and proved very useful and instructive.

Fruit and Vegetable Committee.

Present: A. H. Pearson (in the chair), and Messrs. Jos. Cheal, James Gibson, W. Bates, Geo. Woodward, S. Mortimer, A. Dean, H. Parr, W. Fyfe, Ed. Beckett, W. Pope, R. Lye, H. J. Wright, Jas. Vert, Geo. Kelf, W. Barnes, Jos. Davis, J. Lyne, Chas. Foster, P. C. M. Veitch, J. Willard, J. Jaques, J. McIndoe, Owen Thomas, and W. Poupart.

Six good bunches of Black Alicante Grapes in an excellent state of preservation were shown by G. C. Raphael, Esq., Castle Hill, Englefield Green (gr. Mr. H. Brown). (Silver Banksian Medal.)

The small table in the Annexe contained several dishes of Apples, and two Broccoli, named respectively Snow's White and Brydon's Peerless, were shown for award, but were passed by the Committee.

Mrs. MacCreagh, Thornhill, Stanton-in-Peak, Bakewell, Derby, showed six dishes of Oranges and two of Lemons. The Oranges were well coloured, and ornamental, but appeared hollow and of little value for dessert. (Silver Banksian Medal.)

Messrs. Sutton & Sons, Reading put up a magnificent stand of Potatos. The collection numbered 150 dishes, besides many species and types. Among the ordinary varieties were the very latest and best, and shown in first-class condition. More interesting than the culinary varieties were the numerous species and types, as showing from what apparently insignificant origins the fine tubers exhibited on either side of them have been obtained. The tubers of Solanum tuberosum were about the size of small marbles; those of S. Maglia were of the size and shape of cob-nuts; the skin being almost black; the tuber S. Commersoni was much larger, and the skin was very pale. S. polyadenium resembled Pea-nuts in shape, and were not much larger than these fruits. Then there were the different varieties of the type known as Fir Apples, the small white Fir Apple somewhat resembling a Fir Cone. Blue Giant was staged in juxtaposition to the large variety said to have originated from S. Commersoni, and the resemblance was seen to be very great. We have no space to name the interesting commercial varieties with which the exhibit abounded. (Gold Medal.)

Mrs. Denison, Little Gaddesden, Berkhampstead (gr. Mr. A. G. Gentle), staged about 30 dishes of Potatos in 17 varieties. They formed a remarkably even, clean lot of tubers, and embraced several of the latest novelties. (Silver Knightian Medal.)

The Annual Meeting

was held in the lecture-room upstairs, under the chairmanship of Sir Trevor Lawrence, President. Nearly one hundred new Fellows were elected at the commencement of the proceedings.

Sir Trevor Lawrence moved the adoption of the annual report and balance-sheet, and the motion having been seconded by Mr. Gurney Fowler, remarks on the subject of the report were made by Mr. H. J. Elwes and Surgeon-Major Ince, after which the report was adopted unanimously and with acclamation.

The President, Treasurer and Secretary were re-elected. Major Holford, C.I.E., C.V.O., and Mr. Henry B. May were re-elected members of Council, and Lord Balfour of Burleigh and the Earl of Tankerville were elected new members of Council. The Rt. Hon. J. Chamberlain, M.P., Earl of Ducie, Lord Rothschild, Baron Schröeder, Sir J. T. Dillwyn-Llewelyn, Bt., and Sir Frederick Wigan, Bt., were elected vice-presidents of the Society. Mr. Alfred C. Harper was appointed auditor. Remarks on this meeting will be found on page 104.

ROYAL GARDENERS' ORPHAN FUND.

Annual Meeting.

The annual meeting of the subscribers to this deserving institution was held at Simpson's Restaurant, Strand, London, on February 9, Mr. H. B. May presiding. About thirty supporters comprised the company, but the smallness of the assembly may be taken rather as an indication of the confidence reposed in the management than to lack of interest. The report of the Executive Committee was presented to the meeting, and was as follows:—

Report of Executive Committee.

"The Committee, in presenting their eighteenth annual report, congratulates the subscribers once more upon the continued steady progress which the Fund is making, though the annual income is still far from sufficient to meet the many claims now made upon the charity. The revenue for the year (exclusive of legacies, &c.), shows an increase of £186 16s. over the receipts for 1904; while having regard to the special objects for which the Fund was established, the expenditure in weekly allowances and grants in aid of the sum of £1,438 15s., an increase of £108 15s. over the previous year's total, the Committee believes will be accepted as an assurance that they are administering the means at their disposal with a due regard to the beneficent policy of doing the greatest good to the greatest number. That the number of claims for assistance has considerably outgrown the Committee's resources, may be seen by a reference to the list of candidates seeking election and the relatively small number of ten only which the Committee feel justified in recommending the subscribers to elect. That the Committee would be glad to see the position reversed is obvious to all, and reversed it could be easily enough if only the great body of gardeners in the country would afford the support which such an institution surely deserves. With such a small subscription as 5s. per annum, there are hundreds of gardeners who could, if they would, render solid aid, and the Committee again most earnestly appeals to the better nature of the many who have hitherto neglected their obvious duty.

"The number of orphans who have been elected to receive the benefits of the Fund during the 17 years of its existence is 204, and the total amount expended in allowances during the same period is £14,961 12s. 6d. At the commencement of the year, 88 children were receiving the full weekly allowance, and 15 were added to the list at the annual meeting. On December 31 the number on the Fund was 90, and 23 of the candidates waiting for election were receiving grants in aid.

"The question raised at the last annual meeting as to the advisability of permitting two members of one family to seek election at the same time, has been well considered by the Committee, and they have come to the conclusion that, having accepted the nominations of the children whose names appear on the voting list, they had no option but to allow them to appeal for election; but that, until further notice, the nomination of only one child at a time from any family will be accepted unless in very exceptional cases, when the dire necessities of a family may properly justify the acceptance of two.

"The Committee records the fact with much gratification that, under the genial presidency of the Earl of Mansfield, the annual festival held on May 11 proved from every point of view an unqualified success, the entire proceedings giving the liveliest satisfaction to all present. Lord Mansfield's kindly appeal for the support of all interested in the welfare of the Fund met with a most generous response, the subscription list amounting to the handsome sum of £889 4s. 8d., which amount has only once been exceeded at any previous annual dinner. The Committee most heartily thanks Lord Mansfield for his great kindness on that occasion, and invites the subscribers to join them in unanimously adding his Lordship's name to the roll of Vice-Presidents.

"The next annual festival has been arranged to take place at the Hotel Cecil on Thursday, May 10, when the esteemed treasurer of the Royal Horticultural Society, J. Gurney Fowler, Esq., has

most kiudly consented to preside. Mr. Gurney Fowler's keen personal interest in gardening and influential position in the horticultural world will, the Committee feels assured, insure for him a most cordial reception as well as a very generous measure of support on that occasion.

"The supporters of the Fund will learn with as deep regret, as the Committee feels in making the announcement, that, in consequence of ill-health, Mr. Sherwood has felt compelled to resign the office of Treasnrer, which he had held for nine years. Than Mr. Sherwood the Fund has had no more generous supporter. From the first inception of the movement which led to its establishment none bas more whole-heartedly watched over its interests, and his munificent benefactions and ready counsel and advice in promoting its best interests will cause his name to be remembered with sincere gratitude and affection. The Committee congratulates the subscribers on the acceptance of the office, at their nnanimous request, by Mr. Edward Sherwood, in snccession to his father.

"With due regret the Committee records the loss which the Fund has sustained by deaths of valued supporters, including two of the Vice-Presidents, Sir Reginald Hanson, Bart., who presided at the annual dinner in 1889, and Mr. Richard Dean, one of the fonnders of the Fund and for some years an active member of the Committee. From the late Mr. David P. Laird the Fund received constant support from its foundation. He was ever most energetic in bringing its claims under the notice of his Scottish friends, and by his death the orphan children of Scottish gardeners have lost one of their best friends.

"The Committee have with sincere regret been called to accept the resignation of their valued colleague Mr. George Cuthbert, in consequence of his severe accident. In recognition of the warm interest taken in the Fund by Mr. Cuthbert and his family his son, Mr. George H. Cuthbert, has been unanimously elected to the vacant seat. The members of the Committee who retire by rotation are Mr. H. B. May, Mr. W. Bates, J.P., Mr. G. Caselton, Mr. H. J. Jones, Mr. J. W. Moorman, Mr. W. Nutting, Mr. G. Reynolds, and Mr. J. H. Witty; and Messrs. May, Bates, Caselton, Moorman, Nutting, Reynolds and Witty being eligible, offer themselves for re-election. For the seat vacated by Mr. Jones, who retires, the Committee recommend the election of Mr. Charles Dixon, Holland House Gardens, Kensington, W.

"The Committee again desire most cordially to record their appreciation of the valued services rendered by the anditors, Mr. M. Rowan and Mr. P. Rudolph Barr. Mr. Rowan is the retiring auditor and is nominated for re-election."

The balance-sheet showed that the total income from all sources was £3,037 os. 4d., including a balance from the last account of £1,306 15s. 6d. The magnificent sum of £889 4s. 8d. was raised in connection with the annual dinner, which amount, less £149 19s. 9d., for expenses in connection therewith, formed by far the largest contribution to the fund yet made. Invested funds furnished £336 19s. 9d., while subscriptions and donations realised £551 14s. 5d. On the debit side of the balance-sheet the total expenditure, including investments, reached a sum of £2,339 19s. 6d., and a substantial balance of £697 os. 10d. remains on hand. The total grants expended in allowances and relief amounted to £1,438 15s.

The Chairman, in the course of his remarks, expressed his pleasure at the increased income, all sources of which are augmented save that of legacies. Still he was not satisfied, and he appealed for more subscriptions, especially from the general body of gardeners. He instanced one large county in which four children were receiving allowances, and which had two candidates on the present voting paper, yet that county contributed last year only the small amount of £28. Another county sent but £24, and of this amount £15 came from one town, there being only two gardeners who had subscribed direct. The Committee have carefully considered the question of allowing two candidates from one family to be nominated for relief, and while they do not recommend that any alteration be made in the rules in order to render such applications impossible, because in some cases it might become an absolute necessity, still the Committee will not ordinarily accept after this date the nomination of a second candidate from one family until the first has been elected. The Chairman also referred to the success of the last annual festival, and congratulated the subscribers on securing Mr. Gurney Fowler to preside at the next similar function. The retirement of Mr. N. N. Sherwood from the present post of treasurer was deeply regretted, as no better friend of the fund than that gentleman existed, but they were happy in the fact that Mr. Sherwood's son had consented to take up the responsibilities his father had felt compelled to relinquish. The adoption of the report having been seconded by Mr. Bates in a few well-chosen words, Mr. Alex. Dean rose to support the motion. He advocated the co-operation of the numerous Gardeners' Mutual Improvement Societies throughout the country to swell the funds. At the Kingston Gardeners' Society, of which the speaker was a member, a collection was taken at every meeting, with the result that £4 had been forwarded to the secretary. This, in itself, was not a large amount, but if other bodies did likewise an appreciable sum would be realised.

The Election of Officers

was next proceeded with. The president and vice-presidents were all re-elected, and The Earl of Mansfield was unanimously elected a vice-president.

As above stated, Mr. Ed. Sherwood was installed in the office of treasurer, *vice* Mr. Sherwood, sen. The auditors were re-elected and thanked for their past services. All the retiring members of the committee were re-elected to serve, and the name of Mr. Chas. Dixon, gardener at Holland House, Kensington, substituted for that of Mr. H. J. Jones, who retired. Mr. Brian Wynn was re-appointed secretary.

Result of the Ballot.

The chairman announced the names of the successful candidates and the number of votes they received as follows:—

Name.	Votes.
1. Josephine Inglis	533
2. Edith Clare Harvey	439
3. Albert Leslie Day..	318
4. Arthur Reid	297
5. Doris Evelyn Stride	287
6. William Allan Seaman	284
7. Ena Mary Tilbury..	241
8. Harold Ingersoll Hayes	237
9. Thomas Arthur Hardes	213
10. Olive Gertrude Bundy	205

After the declaration of the poll the chairman said that it was a matter for regret that two children for whom third applications had been made were still unsuccessful, also that a third candidate, whose father had subscribed regularly to the funds for 17 years, had also been unsuccessful. If some one would move that these three children, Albert Edward Page, Arthur Richard Sparkes, and Edward Lee be added to the list by resolution, the committee would be glad to give the resolution its support. Mr. W. Marshall thereupon moved that the children be elected, and the motion was carried unanimously.

The Friendly Supper.

In the evening the members of committee and friends, to the number of 35, assembled at the friendly dinner at the same hotel. Mr. H. B. May presided, supported by Mr. Edward Sherwood and Mr. W. Marshall, and a pleasant evening was spent.

HORTICULTURAL CLUB.

Annual Meeting.

FEBRUARY 13.—The annual meeting of the members of the Horticultural Club took place on the above date in the club room at the Hotel Windsor, Westminster.

The Committee, in the annual report, announced that it had the pleasure to record an interesting year in the history of the club, and the reading of excellent papers after the monthly dinners. During the year seven members have resigned, all owing to the distance at which they reside from London. The number of members is now 127. The Committee deeply regrets to have to record the death of the founder of the club, who was also the first secretary—the Rev. Honywood D'Ombrain, whose interest in the club was maintained until the last. Mr. Harrison Weir had been an honorary member for many years, and by his death an interesting personality has gone from among us. The general meeting of the club was held on February 14 (1905), and was followed by the annual dinner under the presidency of Sir John Llewelyn, Bart., about eighty members and guests being present.

At six o'clock p.m. the members and friends assembled for the annual dinner. Sir John T. Dillwyn-Llewelyn, Bart., presided over a company which numbered rather more than seventy. Mr. George Paul proposed the toast of "The Royal Horticultural Society," and referred humorously to the "great surplus" the Treasurer of that Society had declared earlier in the afternoon to those who attended the annual meeting. In the presence of such profits he would suggest to the Council that whilst letting the Vincent Square Hall as profitably as possible to others than those engaged in horticultural work, that they should let it for next to nothing to the smaller horticultural societies who were less prosperous. There was no wonder that the annual meeting had been a satisfactory one, and it was certain that in the hands of the present Council the interests of the Royal Horticultural Society were safe. Mr. W. A. Bilney responded, and in the course of his speech said it was desirable that an institute for scientific research should be established at Wisley.

The toast of the evening, that of the "Horticultural Club," was proposed by the President, who made kindly and sympathetic reference to the decease of the Rev. H. H. D'Ombrain and Mr. Harrison Weir. Sir John Llewelyn was sure that the club served a very useful purpose, and was glad that it continued to succeed. Mr. George Monro responded, and stated, amidst laughter, that if the Royal Horticultural Society had been able to show a surplus on the year's working, so also had the club, for the auditors had declared a balance that day of 2s. 8½d.! The club was a social centre for horticulturists, the members were very fond of the institution, and it could not be denied that the papers read at the monthly meetings were of a very high order of merit. Many of them had been accepted for publication in the Royal Horticultural Society's "Journal." The club had 127 members, and a sum of between £400 and £500 invested at the bank.

Mr. Harry J. Veitch proposed the toast of "The Chairman" in very appropriate terms, and remarked upon the affection Sir John Llewelyn is known to entertain towards the club. He always attends a meeting when it is possible for him to do so, and arranges many of his visits to London in accordance with these meetings. Sir John has a delightful garden at Penllergaer, in South Wales, but it is distant from London abont 200 miles. In response, the President said that the club had nothing to thank him for, but he had himself to acknowledge indebtedness to the club and to members of the club. He felt that it was a great privilege when coming to London to be able to meet horticultural friends in snch a social manner as they did there.

The next toast was that of "The Visitors," proposed by Mr. W. J. Jefferies, and responded to by the Rev. C. J. Smith, B.A., Dr. Augustine Henry, and Mr. Rawlings. The toast of "The Secretary, Mr. Cook," proposed by the Chairman, and received with musical honours, concluded the list. A good programme of music was rendered by the "Quavers" Vocal Quartette, and the dinner tables were very prettily decorated with flowers by Messrs. James Veitch & Sons.

LEEDS PROFESSIONAL GARDENERS' BENEFIT.

THE thirty-ninth annual report and statement of accounts of the above society expresses great satisfaction at the continued improvement in the financial position of the institution.

The amount of sickness experienced among the members during the year has been particularly small, entailing an expenditure of £33 14s. 2d. only, or just over 5s. per member.

Six members (and one member's wife) have died during the year, and of these four had been members since the society's formation in 1867. The total income for the year amounted to £195 18s. 11d., and the total expenditure to £138, which leaves a profit on the year's account of £57 18s. 11d., and this gives a grand total of

£1,348 8s. 2d. as the available funds, representing a value to each member of £10 15s. 6d., a gain of £1 per member during the year. The number of members at the present time is 126. The committee deeply regret the loss by death of Mr. Robert Featherstone, a senior trustee. At the special meeting held on December 5 it was resolved to adopt the committee's recommendation to make application to become a Branch of Grand United Order of Oddfellows.

CARDIFF AND COUNTY HORTICULTURAL.

JANUARY 30.—The annual general meeting of this society was held on the above date, under the presidency of Mr. J. Grimes. The statement of accounts for the past year showed the receipts to be £1,028 12s, 3d., with an expenditure of £950 5s. 7d., leaving a balance of £78 6s. 8d. in hand. The payments included the amount of the adverse balance of £175 due on the 1904 account. The dates for the next show were fixed for July 25 and 26.

SOUTHAMPTON ROYAL HORTICULTURAL.

FEBRUARY 5.—The annual general meeting of this society was held in the Council Chamber at the Municipal Offices on the above date. The Mayor, H. Cawte, Esq., presided over a small attendance.

The statement of accounts showed a total income for the past year of £707 11s. 4d. and expenditure and liabilities amounting to £729 1s. 9d., leaving a deficit of £21 16s. 1d. on the year's working, but as the society has a reserve fund amounting to £75 and stock valued at over £50, it possesses a total of assets over and above liabilities of £103 3s. 8d.

The report shows that, notwithstanding the improved excellence of each of the exhibitions, the gate receipts at both the Rose and the Autumn Shows were the lowest recorded for many years, unpropitious weather and counter attractions being credited with the cause. An urgent appeal is made for increased and additional subscriptions.

The society's Rose Show for 1906 is to be held on June 27 at the County Cricket Ground, and the hope is expressed that the holding of the show on this date will induce the trade growers to exhibit, The Carnation Show is to be held on the Pier as is usual, while the Autumn Show is to take place at the Artillery Drill Hall. The report and statement of accounts were adopted, after which the following officers were elected:—President, Sir Samuel Montagu Bart.; Chairman, Mr. H. J. Blakeway, together with the other retiring members of the Council, and the Secretary, Mr. C. S. Fuidge, who now enters upon his 34th year of service and who has been associated with the management of the society for over 40 years.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 12.—On this date the Executive Committee held a meeting at Carr's Restaurant, Strand, Mr. Thomas Bevan presiding.

It was resolved that the acting Secretary's salary for the ensuing year be fixed as before at the rate of £100 per annum.

The election of the new Committees excited considerable interest and, in some cases, competition. One-third of the Floral Committee retires annually in rotation, and this election was the first item on the agenda. The ballot resulted as follows:—J. B. Riding, A. W. Seabrook, C. J. Ellis, W. Harrison, E. F. Hawes, W. Wells, H. J. Jones.

A Sub-Committee, consisting of Messrs. D. B. Crane, C. H. Curtis, and Harman Payne, were appointed to compile the necessary list of last season's novelties for inclusion in the schedule now in preparation.

Messrs. Ingamells, Hawes, and Moorman were elected as the new Financial Committee, and out of the various nominations for the Schedule Sub-Committee Messrs. John Green, W. Howe, P. A. Cragg, Ingamells, Oliver, G. Prickett, Simpson, Crane, Hawes, and Moorman were appointed.

Mr. C. H. Curtis, the secretary of the Publication Committee, made a brief informal report concerning the proposal to issue a Year Book, and promised a detailed report on the subject for the next Committee meeting.

Several new members were elected.

PLANT PORTRAITS.

REHMANNIA ANGULATA.—*Garten Flora*, t. 1547.

ROSE, MADME. ABEL CHATENAY, H. T.—*Revue Horticole*, February 1; a "Gold Medal" Rose raised by M. Pernet-Ducher, of Lyons, and said to be the product of a cross between Dr. Grill and Victor Verdier. The flowers are rosy carmine, shaded with orange and salmon.

TRADE NOTICE.

Mr. H. MARSLEN has been appointed manager at Mr. L. R. Russell's, Wood Lane Nurseries, Isleworth, in succession to his late father.

ENQUIRIES.

TIMBER FOR USE AS FIREWOOD.—I should feel obliged if any of your readers could refer me to a book on timbers from the firewood point of view. I want a comparative view of different woods, showing: (1) length of time required between cutting down and burning, (2) readiness of ignition, (3) endurance, (4) heat evolved, and (5) freedom from sparks and sputtering. *B., February 13.*

TRANSPARENT PAPER.—Can any reader inform *S. F.* where to obtain transparent paper used for the protection of plants.

ANSWERS TO CORRESPONDENTS.

ADDRESS: *G. B. The American Florist*, 324, Dearborn Street, Chicago, U.S.A. We know of no work on the subject you mention.

BASIC SLAG FOR LAWNS: *Tooting.* Basic slag contains free caustic lime, and it is the presence of this lime which renders the manure so useful as a fertilizer for strong soils or those which contain large quantities of humus, and hence are naturally acid by nature. Slag is very useful for any soils deficient in lime, but experience has shown that it is less good if used on light soils that contain little natural potash or not much humus. Therefore, when it is proposed to apply slag to lawns one has to be guided by the character of the soil. For strong, clayey soils 10 cwts. per acre may be used, or 4 ozs. per square yard. For sandy and the higher class of soils 7 cwts. per acre, or 3 ozs. per square yard, will be sufficient, to which must be added 2 ozs. of kainit, or 1 oz. sulphate of potash, per square yard. These manures should be applied during the month of February, if possible.

BASIC SLAG OR LAWN SAND: *W. S.* These two substances are quite different in character, and are used for very different purposes. Basic slag is applied to add both lime and phosphoric acid to the soil, and therefore is of little use for very poor lawns. It must have natural potash and humus to act upon, otherwise no good effect will be apparent. Lawn sand is used especially to destroy moss on lawns, and to give a stimulus to the grasses. If your lawn is infested with moss it shows poverty of soil, and basic slag would be of no service. In this case use for the area you mention 10 lb. superphosphate, 4 lb. nitrate of soda, and 1 lb. sulphate of iron. These may be mixed together and sown any time within the next month. If your lawn is in fairly good condition and contains a moderate quantity of humus (decaying root-fibrils), and does not suffer from drought, then apply 20 lb. of basic slag to the area mentioned. Slag is of no use to very dry soils. There must be a certain amount of moisture to combine with the acid of the soil, and this slightly acidified water acts directly upon the phosphate present in the basic slag. During the month of April apply to the lawn which has had the slag 5 lb. of soot or finely sifted fowl manure, to be sown during damp weather.

CARNATIONS DISEASED: *C. L.* The name of the fungus responsible for the disease is Helminthosporium echinulatum. The fungus vegetates between the two membranes of the leaf, and it is difficult to destroy it by external remedies. Pick off and burn all the diseased leaves and destroy any plants badly affected. Spray the remaining plants and their surroundings with weak Bordeaux mixture, or dilute permanganate of potash (Condy's fluid).

CORRECTION.—Our correspondent, *Mr. A. D. Burney*, points out that the word "manuring" in the seventh line of his note on page 91, should have read "knowing."

CYCLAMEN: *A. B.* The unhealthy appearance is due to thrip. Soak the foliage in a solution of tobacco water.

CYPRIPEDIUM: *R. W. Rickards.* The original record of C. × Leeanum is insigne × Spicerianum, and doubtless that was correct worked both ways for the earliest batches. But later batches were raised in many gardens with what were called varieties of × C. insigne viz., C. i. Chantini and × C. i. punctatum violaceum. Some of these were, however, the natural hybrid C. nitens, imported freely with some true insigne, and in some of the forms not distinguishable from true C. insigne, although study has shown that they are natural hybrids of C. villosum and C. insigne, In batches where such so-called C. insigne has been used as a parent the latent C. villosum comes out in some of the hybrids in a most extraordinary manner. There is no blame to the raisers of the varying seedlings, for even an expert cannot be certain in all cases, but in the progeny you get a clearer view in reverting forms. You may say, then, why call them Leeanums? The answer is that they cannot be called anything else.

FRENCH GARDENING PAPERS: *G. H. Le Jardin*, 6, Rue de l'Abbay, Paris; *Revue Horticole*, Rue Jacob 26, Paris 6e.

GRUBS AMONG FERN ROOTS: *H. G. P.* The grubs are those of one of the weevils. These are disastrous pests and must be removed or they will in time kill the plants. Turn the ferns out of their pots and soak the "balls" in a weak solution of extract of quassia. A plan of capturing the beetles is to place slices of Potato or Carrot on the soil in the pots.

HYACINTHS: *H. H.* For some reason or other the bulbs did not develop flowering spikes last autumn, although they have since grown very well and have rooted freely. That the bulbs were incapable of flowering may be due to imperfect ripening last season, or to the bulbs being too young. Your system of cultivation appears to have been the proper one.

NAMES OF PLANTS: *W. G. S., Lancaster.* An imperfectly developed specimen of Cattleya Trianæ.—*A. E. M., Bristol.* 1, Cypripedium Boxalli; 2, appears to be intermediate between C. Boxalli and C. insigne; 3, C. insigne. If all were imported together the variation of No. 2 would be explained as suggested.—*E. C. C. D.* Euonymus radicans variegata, Cotoneaster Simonsi. — *I. T.* Cypripedium nitens. The Cattleya bulb shows disease and such plants rarely recover. It would be better to burn all badly affected.—*F. B.* 1, Begonia hydrocotylæfolia; 2, Begonia fuchsioides.—*E. H.* Iris japonica, syn. Iris chinensis; commonly known in gardens as Iris fimbriata.—*A. H.* 2, Tsuga Hookeriana; 3, Picea Morinda; 4, Pinus Cembra (probably); 5, Cupressus (Retinospora) obtusa; 6, Arbutus Unedo; 7, 8, 9, 10, 11, Your specimens were so badly labelled and packed that we are unable to name the others as the labels were mostly detached.—*F. S.* Boussingaultia baselloides.

POTATO, POTATOS: *H. S. W.* Very many years ago, when the *Chronicle* was young, by some oversight the "e" was, on one occasion, left out of the plural noun. The then editor, recollecting that the word was often spelt without the final "e" in the singular, determined that in future the "e" in the plural should, in the *Chronicle*, also be deemed superfluous. The present editor found the system in use and has retained it. In order, however, to obtain support for the practice, he submitted the case to the late Dr. Latham. In reply the great scholar said that our version, if unusual, was correct, and that we were merely anticipating a usage which would become more and more general, as indeed time has proved in the case of other nouns ending in "o" in the singular. The lexicographer complimented us on being up-to-date, and we hope to continue so.

ORCHIDS AT WESTONBIRT.

(See Supplementary Illustration.)

MANY of our readers had the privilege of inspecting the superb display of Orchids made by Major Holford in the Royal Horticultural Hall, Vincent Square, Westminster, on February 13th, and all who did so will agree that never was the gold medal of the Royal Horticultural Society more deservedly awarded than it was on that occasion. All the specimens shown were examples of unusually successful cultivation, and they were grouped together and relieved in such a manner that the general effect of the display was as good, or even better than, has previously been afforded by an exhibit of Orchids in the new hall. The public spirit shown by Major Holford and other amateur exhibitors in their willingness to incur the trouble and expense of bringing so many choice and valuable plants considerable distances, in order to make these meetings so attractive as they are, is beyond praise.

The following account by Mr. James O'Brien of the conditions under which the Orchids are grown at Westonbirt may be of interest to many of our readers, in consequence of the excellence of the plants so recently exhibited from that collection.

"The collection of Orchids in the gardens of Major G. L. Holford, C.I.E., C.V.O., at Westonbirt, Tetbury, Gloucestershire, is contained in fifteen modern Orchid houses, the greater number of which constitute a recently-constructed block erected by Messrs. Mackenzie and Moncur, of Edinburgh. This range of buildings is complete in every detail, and nothing likely to aid in the successful culture of the plants appears to have been omitted. The heating of the block is perfect, and to this feature Mr. H. Alexander, the Orchid grower at Westonbirt, attaches great importance, for, in his opinion, irregular temperature, either from faulty heating apparatus or from bad management, is one of the most common causes of unsatisfactory results. The houses are chiefly span-roofed structures running at right angles to the connecting corridors. The floors of the houses are formed of the natural earth surfaced with clean shingle or some other moisture-holding material, a neat trellis covering the walk. The light but strong stagings are generally of open teak wood in two tiers; on the higher the plants are placed, the lower being covered with cocoa-nut matting and leaves, kept damp for the purpose of evaporating moisture. In some instances a temporary wire-work is placed about a foot above the hot-water pipes and between them and the lower stage. This is also covered with some moisture-holding material similar to that on the lower staging. Thus a suitable but not excessively warm temperature is maintained, which accounts greatly for the robust condition in which all classes of Orchids are seen at Westonbirt, the Odontoglossums especially, which have pseudo-bulbs, superior to any seen in their natural habitats.

Potting Material.

"Another important question which seems to have been finally settled at Westonbirt is that of the best material for potting. Good peat of Bracken fibre more or less mixed with sphagnum moss, was always believed in and used with fair success. But good peat was not always obtainable, so when the 'leaf-soil' prescription was commanding attention elsewhere, a careful use was made of it at Westonbirt, but for many reasons it was soon abandoned. Ultimately, American Osmunda fibre was tried, and with such marvellously good results that it has almost displaced the use of peat. As to the benefit from the change, a glance at the Westonbirt Orchids, individually and collectively, gives the best of all testimony. With Osmunda fibre, however, as with other materials, care in watering is the leading point to be observed. Cypripediums and terrestrial Orchids are still potted in the material formerly used generally.

"Orchid growing at Westonbirt has been carried on for many years, and although most of the old favourites have disappeared under the old methods of culture, there is still a small collection of Vandas, and some other plants known to have been in the gardens for more than fifty years. An interesting example is a small plant of Cattleya Hardyana, which nearly died, but which is now, like the other older inhabitants, rejuvenated. This plant is believed to have been the first C. Hardyana to flower in Europe, as it bloomed before the specimen which the late Mr. George Hardy showed before the Royal Horticultural Society in 1885. Evolution has resulted in the present-day collection being composed very largely of hybrids raised at Westonbirt during the time Mr. Alexander has had charge, and the countless plants of all sizes, and the size and vigour of a large proportion of them, which either have flowered or will soon do so, are almost incredible, in view of the short space of time in which the work has been accomplished. Some of the methods under which such good results have been attained may here be mentioned, such as the allowing of fairly liberal pot-room to all plants as soon as they are rooting vigorously in the first small pot; the absence of any set time for repotting the plants of any house, or stated class of Orchids, each plant being repotted when necessary, that is at the time when the roots begin to push strongly on the last growth, for by so doing the new roots at once take advantage of the fresh material. Thus managed, the small hybrid Cattleyas and Lælio-Cattleyas in their early stages have, in some cases, pseudo-bulbs as broad as they are high, and a relatively sturdy condition is maintained up to their flowering periods and onwards. Some two hundred crosses of Cattleyas, Lælias, and Brassavolas in which none but the best parents, albinos, and rare varieties have been used, have been effected.

"The corridor connecting the houses contains a large quantity of these hybrids, both on the stage and suspended from the roof. Some are in flower and a great quantity in sheath.

Odontoglossums.

"Referring to the principal classes in the houses connected by the corridor, mention may be made of a magnificent lot of Odontoglossums, the O. crispum in flower being of the fine broad-petalled type. With these in bloom are some good forms of O. Andersonianum and other showy varieties, while suspended overhead is a number of well-flowered plants of O. Rossii majus, and O. Cervantesii. In another house is a fine collection of the largest type of O. crispum, and other Odontoglossums, many being in flower. All show the same remarkable vigour, among them being O. crispo-Harryanum, with fleshy leaves nearly three inches in width, and another fine Odontoglossum, which, from a single pseudo-bulb in 1904, made five leading pseudo-bulbs in 1905, and is now a great mass of growth, with twelve strong leading shoots. Some fine things in bloom are O. loochristiense, and its remarkable variety, 'Lord Howick'; handsome plants of O. Adrianæ, O. Wilckeanum, etc. Next follow several houses containing hybrid Cattleyas, Lælias and Lælio-Cattleyas, with a collection of white forms of Cattleya labiata, C. Mossiæ and other large-flowered Cattleyas. Some of the crosses are interesting, among them Cattleya citrina × Brassavola Digbyana and Lælia anceps Schroderiana × Cattleya aurea. Sophronitis gradiflora forms large masses, and a number of specimens, each with from ten to fifty large, brilliant scarlet flowers, makes a fine show. This plant is here grown under cool treatment, and appears to double the number of its flowering growths every year.

"Lælio-Cattleya Charlesworthii, L.-C. Cappei, and other crosses of L.-cinnabarina present a fine show of orange-coloured flowers with crimson and purple lips.

"Phalænopsis Rimestadtiana and P. Schilleriana are finely in bloom, some of the latter bearing flowering spikes with nine branches and about eighty flowers.

Cattleyas.

"The Cattleya houses present a fine sight, the plants in flower being principally C. Trianæ. C. T. Westonbirt variety is a handsome form. An instance of what may be done by good culture is given by another pretty light form of C. Trianæ, which from a small plant has, in a short time, multiplied into several strong specimens, bearing between them 26 flowers. C. T. Russelliana and other old favourites are in bloom. A

singular circumstance is noted in the case of two plants bought from collections widely separated, and under different names, although evidently from the same original plant. Both are bearing badly developed flowers (the only instance in the collection), doubtless an occasional peculiarity with the plant. Cattleya Percivaliana is well in bloom. A grand specimen of Lælio-Cattleya elegans has produced nearly 100 flowers, while other smaller plants are also in bloom.

"Dendrobium Wardianum, with its pure white variety ochroleucum, and some hybrid Dendrobiums brighten the houses with their flowers; a grand specimen of Epidendrum radicans, trained over the end of a house, has over 120 heads of its large orange-scarlet flowers.

The Span Range.

"In the three-quarter-span range is a fine display of white varieties of Lælia anceps, and another long house is literally filled with the fine and varied flowers of favourite Cypripediums. Many of those in bloom are new crosses raised at Westonbirt, and some of these have outstripped all others in their classes, such as, for instance, C. Alcibiades magnificum, C. Milo Westonbirt variety, and C. Niobe Westonbirt variety. C. Sallieri has been found a very satisfactory parents, and many of its hybrids are very choice varieties; for example, C. Scipio, the result of C. Sallieri × Mrs. Tautz, while a fine type of C. Boxalli crossed with the Westonbirt C. Euryades has resulted in a grand flower heavily marked with rich mahogany red. Some of the specimens of C. Lee-anum varieties, and others, have 20 or more flowers, and are beautiful objects. Two houses containing hybrid Cypripediums, many approaching the flowering stage, serve to ensure a supply of fine novelties for some years to come.

"A batch of Miltonia vexillaria is in excellent condition, even small plants have five or six flowering spikes. [See supplementary illustration to this issue.—Ed.] The large specimen plants of Cymbidium have numerous inflorescences, some already in bloom, including the rare C. Lowio-grandiflorum, and C. eburneum. C. eburneo-Lowianum has eight spikes, some with seven

[Photo by E. T. Lamb.

Fig. 45.—Cattleya Bowringiana, from Major Holford's collection.

flowers, and others are gigantic specimens. With them is a grand clump of Ada aurantiaca, good Odontoglossum Edwardi, Oncidium macranthum; a nice batch of showy Masdevallias, and, in the collection of Sobralias, a large specimen of the original Sobralia Holfordi, by far the largest rose-purple Sobralia of the macrantha section. Vanda Kimballiana is grown in very large masses, and V. teres, including the blush white variety Aurora; a strong specimen of the carmine scarlet Sophro-Lælia laeta Orpetiana, Sophro-Cattleya Chamberlainiana, and other hybrids, with Sophronitis grandiflora; Cattleya The Czar, C. Berthe Fournier, Westonbirt variety, and a host of other rare things were passed in review.

"Major Holford takes the greatest interest in his Orchids, and knows every plant in his collection. Seeing the wonderful state of perfection to which his collection is brought, his enthusiasm is easy to understand.

"The famed collection of Amaryllis is about to be plunged in leaves in a gentle bottom-heat. Such large bulbs as are seen should produce flowers even better than previously, if that be possible. One bulb weighed 2lb. 6oz., and was but a fair sample of the best."

Fig. 46.—The Rosary at Loft's Hall, Essex.

NEW AND NOTEWORTHY PLANTS.

PLEIONE YUNNANENSIS, ROLFE.*

A charming little novelty was exhibited at the last R.H.S. meeting, held on February 13th, by Messrs. Sutton and Sons, Reading, as "Orchid sp. from China." It also appeared at the meeting of the Scientific Committee, and received a Botanical certificate. I recognised it as one of several species of Pleione which I had described from dried specimens, and now that Messrs. Sutton have sent flowers to Kew I find that it is Pleione yunnanensis, a species discovered by Mr. W. Hancock, F.L.S., in the province whose name it bears, the locality being given as Mengtsz, in mountain pastures at 6,000 to 7,000 feet, flowering in March. It was also collected there by Dr. A. Henry, on grass mountains at 5,500 feet. It is an elegant little plant, like several of the Indian ones, flowering in advance of the leaves, but having rather smaller flowers. These are produced on erect scapes, three to four inches high, and bear a certain resemblance to those of P. lagenaria. They measure about two and a quarter inches in diameter across the petals. The sepals and petals are oblong in shape, gracefully recurved, and light rosy purple in colour. The lip is beautifully fringed, less than an inch broad in front, and lilac, with numerous irregular bright purple blotches, while the disc bears five deep, slightly undulate keels The side lobes of the lip are striped with purple toward the base. Messrs. Sutton have had the plant three or four years, and the pan exhibited by them had three expanded flowers and several buds. It is an interesting addition to the genus. *R. A. Rolfe.*

* Pleione yunnanensis, Rolfe in *Orch. Rev.*, 1903, p. 292. Cœlogyne (? Pleione) yunnanensis, Rolfe in *Journ. Linn. Soc.*, xxxvi., p. 23.

A NEW SPECIES OF RODGERSIA WITH PINNATE LEAVES.*

In the *Gardeners' Chronicle* of August 23, 1902, p. 131, Dr. A. Henry gives a synopsis of the four species of Rodgersia then known. A fifth species was discovered by Mr. E. H. Wilson in June, 1904, growing at elevations of 9,000 to 10,000 feet, in the Yalung Valley, about 100 miles west of Tatien-lu. It was just coming into flower at the time, and it is from a very young specimen that I have drawn up the accompanying description. As in the case of the Lilac I recently described in these columns, no seed being obtainable, the discoverer brought away a few roots, and the plant is now growing in Messrs. James Veitch and Sons' nursery at Coombe Wood. The dried specimens before me are between 2 and 3 feet high, the simple stems bearing one large pinnate leaf, and an entire one just below the inflorescence. The largest leaf, including the long petiole, is nearly 2 feet long, and it is probable that under cultivation all parts of the plant will attain larger dimensions. Somewhat unfortunately the appropriate name pinnata has been given to another species which has quasi-pinnate leaves, as may be seen in the figure accompanying Dr. Henry's description. However, the name given to the new species is quite appropriate, the leaves being very similar to those of the common Elder, as well as to those of Sambucus javanica. The leaflets are 9 and 11 in number respectively in the two fully-grown leaves under observation, and they are thin, oblong, serrated, and 4 to 6 inches long. The only inflorescence is about 3 inches long, and the flowers unexpanded. At present I am unable to say anything about its relative merits as an ornamental plant, but it is very different from the four previously described species. *W. Botting Hemsley.*

* *Rodgersia sambucifolia*, Hemsley; ab omnibus speciebus hucusque cognitis foliis vere pinnatis 9-vel 11-foliolatis recedit.

Herba 2–3 pedalis, sparsissime arachnoideo-hirsuta. *Folia* radicalia non visa; caulina solitaria vel bina, imparipinnata, 9-vel 11-foliolata, longe petiolata, cum petiolo communi 1–2 ped. longa; foliola subsessilia, membranacea, subopposita, oblongo-lanceolata, 4–6 poll. longa, 1–2 poll. lata, acuta, basi cuneata, per totam longitudinem serrulata; venæ subtus sat conspicuæ; petiolus basi pilis longis arachnoideis brunneis vestitus. *Inflorescentia* pubescens, parva, terminalis, dense cymoso-paniculata, cum pedunculo elongato circiter pedalis; pedunculus folio unico simplici instructus. Bracteæ et bracteolæ omnino deficientes. *Flores* parvi inconspicui. *Sepala* 5–7, carnosa, ovata, sesquilineam longa, subacuta. *Stamina* 10–14, quam sepala breviora (immatura?). *Styli* 2 carnosi, stamina æquantes. *Fructus* ignotus.

ROSARY AT LOFT'S HALL, ESSEX.

The Rosary illustrated at figs. 46 and 47 forms part of an old kitchen garden walled in on three sides, and bounded on the fourth by an evergreen hedge, and was made and planted by Mr. George Paul. The north wall was taken down and rebuilt with panels of open lattice work, through which the Roses can be seen from the drive up to the house, and when festooned with Wistaria, which it will be in a year or two, it will form a very pretty picture. The beds for the Roses have been cut out on grass, and a width of bed has been adopted which enables almost every plant to be reached for cutting purposes without trampling on the beds. The Roses were planted in March last, and the photograph was taken in June. Under the care of Mr. George Jordan, whose successes from Hawksted at the National Rose Society's Exhibitions are so well known, it is needless to say the Roses did exceedingly well. The garden was planted in the following manner:—

In the border next to the front court there are two rows of Standard Teas to show through trellis and a row of Dwarf Teas, edged with border Carnations.

The corresponding border on the other side contains masses of Provence and garden Roses, edged with Dwarf Polyantha varieties. Each of the four round beds has one Weeping Wichuriana Rose and twenty dwarf yellow-flowered plants. The two outer corner beds are planted with rose-coloured varieties; the two corresponding outer corner beds with crimson varieties; the two inner angled beds with pink Roses; and the two corresponding inner angle beds with blush and white-flowered varieties.

Along the herbaceous border at intervals of 10ft. Penzance Briars were used as pillars, and the pergola was planted entirely with Roses, so that the whole garden was encircled with Roses.

It is not necessary to enumerate all the varieties used, but of crimson varieties there were Victor Hugo, Madame Victor Verdier, Dr. André, Bruce Findlay, and Liberty. In rose colours, Countess of Rosebery, S.M. Rodocanachi, Rev. A. Cheale, and others. In yellows, Marie van Houtte, Madame Hoste, Madame Ravary, Francisca Kruger, Madame C. Guinoisseau, etc. In pinks, Caroline Testout, Mrs. J. Laing, Killarney, and others. In blush and white, Frau Karl Druschki, Viscountess Folkestone, Augustine Guinoisseau, Paul's Early Blush, etc.

The old manor house, Loft's Hall, is the seat of Sir James Bayley, situated about four miles from Audley End Railway Station, on the Great Eastern Railway. It is a charming old house, with gables and old-fashioned chimney stacks, and the gardens are on ascending slopes from

the front to the back of the house. One of the chief features of the place is its very fine fish ponds, one of about an acre. The church, though not seen in the picture, is to the right-hand of the house, and, as in many old-fashioned parks and gardens, seems a part of the estate.

LATE DESSERT PLUMS.

Late varieties of Plums are useful for extending the season when choice dessert fruit is available, and are worthy of more extensive cultivation, especially in gardens where wall space can be afforded them, for wall-trained trees undoubtedly produce fruit of the highest flavour and best quality. With care and attention trees planted on walls of various aspects will furnish delicious fruits until quite late in the season. I have heard of some growers who have been enabled to keep these fruits in good condition until Christmas, but although I have taken all the necessary precautions and have excellent means of storage I have not been able to keep them so late as Christmas by four weeks.

In many gardens room might be found for a few late Plum trees to take the place of some of the many Peach trees, whose fruit arrives at maturity rather inconveniently at the same time. Walls facing west present a most suitable aspect for the planting of Plum trees. In some gardens Peach trees fruit very unsatisfactorily on walls with this aspect, and much time and labour is unprofitably expended on these trees and valuable wall space is lost. Given good cultivation Plum trees will yield fine crops with much less attention than is required for Peaches.

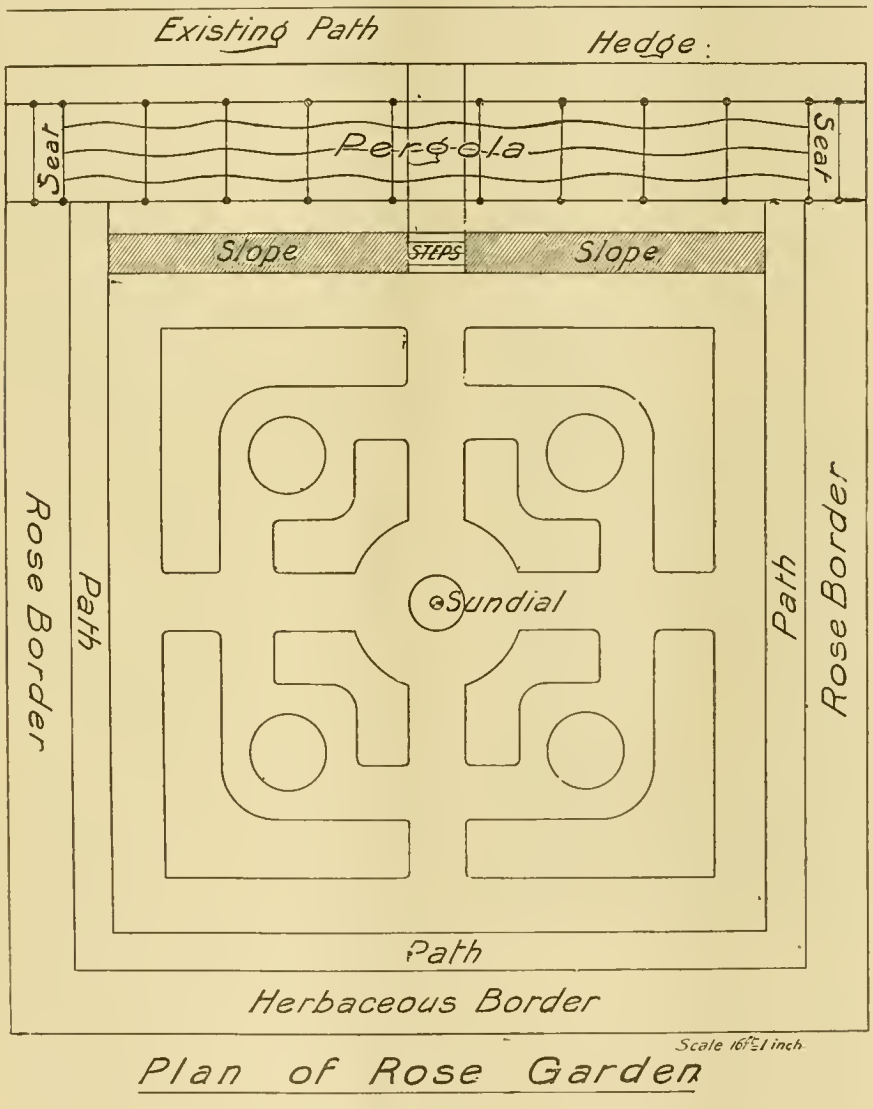
Some varieties of Plums are much improved in flavour when shrivelled, and should not be gathered until this has taken place. The Plums when gathered should be perfectly dry, and it is most important to allow the stalks and fruit to remain intact, otherwise many of the fruits will decay. I usually gather my crops by cutting the individual fruits from the tree with a knife or with a pair of scissors. They are then very carefully laid on cotton wool and carried to the fruit room, and not allowed to become bruised in the process. Wrapping each fruit separately in tissue paper has no advantage; they should rather be laid out thinly on paper in a cool fruit room. A sharp eye should be kept for any fruits that are inclined to decay; these should be removed immediately. Coe's Golden Drop is the leading favourite with the majority of growers, and although of excellent quality, whether procured from north, south, east, or west walls, there are other varieties equally serviceable. Angelina Burdett, classed by some authorities amongst the Gages, is a variety ripening about the middle of September, and by allowing the fruits to hang and become shrivelled the saccharine matter is so increased as to make it a perfect sweetmeat. Ickworth Impèratrice, although not a "gage," remains serviceable for a long time when treated in the same manner as the last-named. The fruit is of medium size, roundish-oval in shape, and of a purple colour, and when shrivelled is rich and juicy.

Bonne Bouche Gage is of excellent flavour and of the same type is Bryanston Gage, and Reine Claude de Bavay, the former ripening at the end of September, while the last-named will hang during a dry autumn well into October. Guthrie's Late Green is also a valuable late Plum of good flavour. I have seen this variety hanging on the trees in good condition, in the Midland counties, in November. Braby's Greengage is much later maturing than the old type, and is a most delicious variety.

The Transparent Gages are all delicious fruits, and the trees possess a vigorous constitution. Transparent, Golden Transparent, and Late Transparent are valuable Plums, keeping in good condition some time after the fruits have reached maturity. Reine Claude Comte d'Althann, a variety introduced from Bohemia, comes with a good reputation as a valuable late red Plum. Up to the present time I have not fruited this variety.

Low walls can be planted with trees trained horizontally, which are the best for this purpose.

Young trees require to be carefully root-pruned about every third year in order to keep them in a fruitful condition. By this means coarse, strong growth is checked, and the energies of the tree are directed into producing fruit-bearing wood. Cordon trained trees of the varieties named produce fine quality fruit, and by this system of training many varieties may be planted against one wall. The distance between each tree should be 2 feet, the roots should be well restricted until the trees have arrived at a fruit-bearing age. *W. H. Clarke, Aston Rowant, Oxon.*



Plan of Rose Garden

(See text, page 115.)

CULTURAL MEMORANDA.

HIPPEASTRUMS.

These plants resent frequent disturbance at their roots, so that whenever practicable top dressings of soil and the liberal use of manure-water should be afforded rather than the repotting of the plants, but should a larger-sized pot become absolutely necessary take great precautions not to damage the roots. A suitable soil consists of a mixture of firm loam, rotten manure, leaf-mould and a liberal quantity of sharp sand. Start them into growth in a temperature of 65° to 70°. It is not necessary to plunge the pots in tan or cocoa-nut fibre. Very little water will be needed until the growth commences. As the plants advance in growth admit air to secure strong and healthy foliage. Hippeastrums (Amaryllis) are useful decorative plants, both for use in the mansion and in the conservatory. After the flowers have faded place the plants in the greenhouse for the purpose of completing their growth, after which dry them off slowly, but never allow the roots to become dust-dry, even when dormant. When raising Hippeastrums from seed use 60-sized pots, placing one seed in each pot. Use a rather lighter soil than that advised for potting, and pass the same through a half-inch sieve. A shelf in a warm pit, near the glass, is a suitable place for the seeds to germinate. The seedlings should not be dried off until after they have flowered. *C. Ruse, Munden Gardens, Watford.*

POINSETTIAS AND EUPHORBIAS FOR USE AS CUT FLOWERS.

It is a common occurrence to find cut flowers of Poinsettias and of Euphorbia Jacquiniæflora when used for decorative purposes droop and wither a few hours after being cut. To prevent this it is necessary to subject the plants to a lower temperature with less moisture, a week or so before cutting. A temperature of 50° is all the plants require after they have developed their inflorescences, and the dryer the condition of the house the better will the flowers or plants be enabled to withstand the draughts and dry air of dwelling rooms. Equally important is the manner in which the flowers are handled when being cut. To prevent bleeding, it is necessary to have ready a pail of very hot water in which

to insert the stalks after cutting them the required length and removing all unnecessary leaves. The hot water will prevent further bleeding and will quickly heal any wounds. A hot iron answers the same purpose, but its manipulation is not so simple or simultaneous as that of hot water. Various other methods have been tried for preventing bleeding, such as dipping the stems in sand, sealing the wounds with pitch or hot clay, but I regard the hot water plan as the simplest and safest. As decorative plants these subjects remain in much better condition if they are placed in stands or in baskets, but as plants they are not so adaptable for effective use as in a cut state. When used for dinner table decoration the stalks should be cut of the length required, all unnecessary leaves removed, and the same method to prevent bleeding adopted. Euphorbia Jacquiniæflora cannot be used for sprays or button-holes for the reason that if only a flower or a leaf becomes broken, the milky substance would stain the dress, *C. J. E.*

KNIPHOFIAS AND THEIR CULTURE.

(Concluded from page 101.)

HYBRID KNIPHOFIAS.

Much confusion exists in the nomenclature of hybrid Kniphofias, and it is no uncommon circumstance for a plant to bear half-a-dozen names. Most of these hybrids are improvements on the specific types, but several are coarse, ungainly, badly coloured and unworthy of garden room. More recent hybrids have K. Macowani, K. Burchelli, and K. citrina as parents, and these are a great gain, being of neat tufted habit, marked floriferousness, and the spikes bear inflorescences that may be described as marvels of delicate colouring and symmetry when compared with the older hybrids such as Star of Baden-Baden and others whose stamens are much exserted. No good purpose can be served by detailed enumeration of all known hybrids, but a selection of those which are most showy and refined, made over a period of several years from a complete collection, will doubtless be helpful to planters, together with brief descriptions of their height, habit of growth, and colour of flowers.

Chloris.—A vigorous pale green-leaved plant 6 feet in height and as much in diameter, flowering in August. Spikes cylindrical, of apricot yellow colour throughout.

Chrysantha.—A small plant 2 feet in height and in diameter. Flowers of canary yellow colour, the spikes tipped with green and produced in sheaves from August onwards. A seedling from K. citrina.

Diana.—A strong grower, with towering spikes of bottle-brush-like flowers coloured scarlet, suffused with buff. Anthers much exserted.

Excelsa.—A giant plant 6 feet in height, bearing enormous spikes of light crimson flowers, fading to orange colour. The spikes often have three apices.

Golconda.—A broad-leaved, sturdy variety of rapid growth, yields symmetrical spikes of apricot-tinted flowers in foot-long cylinders. Anthers slightly exserted. Very showy and free-flowering.

Heroine.—Resembles Golconda, but with coral-tinted anthers much exserted, giving the inflorescence a hairy appearance.

Henry Cannell.—Plants 3 feet in height and in diameter, bearing long inflorescences of a uniform rich shade orange scarlet colour, slightly yellowed at the base. A capital border variety.

John Waterer.—Resembles Henry Cannell, but more coral than scarlet, and the spikes are cone shaped.

J. Sallier.—A new hybrid of rich scarlet, very strong and stately in habit.

John Benary.—An old-time hybrid with loose cylindrical spikes of deep red flowers, passing to orange, then to yellow. As nearly flame-coloured as is possible. Flowers in August.

Lachesis.—Pretty and refined spikes of deep yellow flowers, the anthers of which are coral-tinted and slightly exserted. Height, 6 feet.

Leda.—Produces cylindrical inflorescences half the length of the spike in July and August. Flowers coral red with orange anthers slightly exserted. Foliage sub-prostrate and pale-green, giving the plant the outline of an Eremurus.

Lemon Queen.—Hybrid seedling of K. citrina. Plant neat habited, free-flowering, producing in August cone-shaped inflorescences of a canary yellow tint, greyish white at the base and greenish yellow-tipped. A very choice and showy form which, in my view, is the best of the smaller habited plants.

Matador.—Resembles Leda, but flowers in September. Bears cylindrical spikes of dark-glowing crimson flowers entirely self-coloured. Plant prostrate, spikes 6 feet in height.

Meteor.—Of straw-yellow colour, the perianths lined with coral, the anthers also coral-tinted and exserted. A good variety of the bottle-brush type and very vigorous. Inflorescences 18 inches long, in September.

Obelisk.—A noble plant 6 feet in height, leafage broad and lustrous. Inflorescence 18 inches long, of golden yellow colour, symmetrical and wonderfully clear in colour. A refined, chastely-coloured "Star of Baden-Baden."

Ophir.—Resembles Obelisk, but has coral-tinted exserted stamens and perianth tubes much distended at the throat.

R. C. Affourtit.—This is best described as a glorified corallina. Flowers continuously throughout summer. The inflorescences are distinctly cone-shaped with reflexing perianth lobes, and several are produced together.

Rufus.—A selection from Lemon Queen. Flower heads cone-shaped, canary yellow below orange scarlet above, rarely exceeding 3 feet in height.

Sirius.—Has attenuated inflorescences of reddish orange colour with scarlet anthers much exserted. Grows 6 feet high, and generally has one to three subsidiary spikes at the base of the central inflorescence.

Seraph.—A compact plant 2 feet in height, bearing cylindrical saffron-coloured inflorescences. Its habit is similar to that of Macowani. Flowers in August.

Solfaterre.—Has quaintly coloured spikes of a short and sturdy character, grows about 2 feet in height and bears yellow inflorescences with orange-coloured base and greenish tips. The sunny side of the spike is of orange-red colour, and the shady side greenish-yellow. Pretty and distinct form for planting in borders.

Stella.—A tall and stately variety bearing bronzed scapes 3 feet long, and maize-yellow coloured inflorescences of great beauty. The spikes are a long time developing, and the resemblance of the spikes to "cobs" of maize is very marked till the flower lobes reflex.

Tricolor.—Is a dwarf variety of Lemon Queen, and has quaint, bluntly cone-shaped inflorescences that are coloured straw-yellow at the base, red at the top, and canary yellow about the middle. A neat variety whose spikes are produced in considerable quantity in late summer.

Triumph.—A showy and popular plant coloured deep yellow, with much exserted coral-tinted stamens. Before the flowers expand the yellow is very soft and pleasing, but the anthers change the colour scheme to coral red with the yellow showing here and there. Grows 5 feet in height, and invariably has two or three subsidiary spikes partially developed at the base of the main one. Two new varieties, *Henry A. Drecr* and *R. Wilson-Ker*, are of much promise. Both varieties flowered when others of the same type were in a condition to admit of comparison. The former resembles K. Macowani Brilliant, the latter the hybrid excelsa, but the spikes are simple and possibly a little richer in colour.

Another series of hybrids, marking a distinct break from the usual run of Torch Lilies I have reared from the following parents:—Nelsoni × Macowani; pauciflora × Macowani; breviflora × pauciflora; tricolor × Nelsoni; modesta × citrina; Macowani × citrina; modesta × Lemon Queen ×. The seedlings are pretty border plants with refined inflorescences more resembling K. Nelsoni and K. Macowani in habit, but flowering from May onwards, starting with the pauciflora hybrids, which have quaint pendulous Lachenalia-like inflorescences in various colours; the others carry the display onwards till the taller Kniphofias show spikes.

Singularly, the pauciflora ♀—Macowani ♂ seedlings are all typical K. rufa, whilst Macowani ♀—pauciflora ♂ seedlings are very varied and of K. Nelsoni habit, the colours embrace all shades of yellow and coral. Breviflora ♂ × pauciflora ♀ yield pendulous flowers mainly. *G. B. Mallett.*

NOTICES OF BOOKS.

"The Book of Cut Flowers."—A Complete Guide to the Preserving, Preparing, and Arranging of Flowers for Decorative Purposes. By R. P. Brotherston. With preface by J. Martin White. [Published by T. N. Foulis.]

This work is written in simple readable style, being thus equally acceptable either to the employer who keeps his gardener, the gardener himself, his assistants, or to the amateur. Including the preface, the book contains 316 pages. It is freely illustrated, and includes in its earlier chapters a few examples of decorative art in the 17th century, and later, up to the 19th century, dealing also with the methods and styles adopted by the Japanese. From these latter highly artistic people we may all learn something to our own advantage. Examples of free arrangements are given, some of which are good, notably a bowl of China Roses, and one of Chrysanthemums, Michaelmas Daisies, etc.; whilst some are not so good by reason of the mixed arrangements. These are, we think, too freely illustrated. From these latter, however, one may learn what to avoid. Examples of suitable vases and glasses are illustrated, and due prominence is given to those of glass, than which, all points considered, there is nothing better either from the point of effect when complete, or of utility and simplicity in the arrangement. One of the illustrations—that of a bouquet—shows the flowers of a Cattleya upside down, an error that any critical observer may see perpetrated by inspecting the arrangements set up in florists' windows, and even in our leading exhibitions. By carefully inspecting some of the illustrations one may see the evil of overcrowding clearly defined; also the bad effects of bringing together flowers and foliage of incongruous detail, showing a want of harmony. Simplicity in the arrangement of cut flowers prevails more perhaps at the present day than it has ever done. Of this fact scarcely enough is made in the illustrations.

The text embraces floral arrangements in the widest sense, both for home uses and in churches. In the retrospect, note is made of the "decking of chimnies with moss, flowers, and pot-plants in 1600." The author also states that "Flower services in church for children were instituted by the Rev. Mr. Whitmill, who held the first in 1853." This commendable practice does not appear to have been generally adopted until later years, but it is now a frequent custom. When treating of the relative value of flowers (chap. 2) the author does well in commending those of a so-termed commoner nature. He says: "Common flowers, however, possess a beauty of their own, and it is conceivable that the person who has the capacity to display common flowers to advantage places them on a plane equal with flowers intrinsically of more value, but arranged less artistically. Moreover, it is well to disabuse our minds of

the feeling that the exotic vegetation of our hothouses is merely, on account of its rarity, to be preferred to flowers that are hardy in our climate." He could not have written truer words than these. Would that some of our gardeners, and others too, would place more value on "common flowers," and less upon the choicer exotics.

Upon the subject of fashion the author adds in pertinent words, "Unlike the Chinese and the Japanese, whose floral tastes reached, centuries ago, a high development, which has never since changed, ours is constantly in a state of flux." Extravagances are justly condemned, in support of which the methods adopted by the Japanese are quoted. Warning is given against the too free use of flowers that emit a fragrance, such as Liliums, for however agreeable they may be in the open air they are not in rooms or apartments so commendable. The practical experience of the author is exemplified in his notes upon the time of gathering flowers, cutting whilst still young, placing in water before packing, preparing for large supplies, etc., and packing for transit. The use of waxed paper for packing, however, does not appear to have been noted. The decorations of rooms, environment, colours of paper, and detailed ornamentations are dwelt upon in a common sense manner. One recommendation we cannot, however, agree with, viz., to first place the flowers in a vase, then add the foliage afterwards. After years of experience we prefer the opposite method both for economy and effect. Choice of colours is treated upon in a practical and suggestive manner, but upon this point there will always be some divergence of opinion. Upon such adjuncts as "coloured silks, chiffons and be-ribboned tables," the remarks are pertinent, and rightly so, "not calling for remark here."

Church decorations are separately treated upon in a short but comprehensive chapter. Personal adornment is considered in a similar fashion. Speaking of bouquets, the author says quite correctly: "The bouquet of the florist is so entirely artificial that all would hail with pleasure a return to the simple posy or nosegay." In like manner the decorations of graves, the uses of wreaths, etc., are described in a rational way. Chapters are devoted also to suitable flowers such as annuals, biennials, and hardy perennials, tuberous-rooted plants, etc. The uses of Orchids are treated upon; so also are everlasting flowers and grasses. Japanese methods are considered in detail, and this chapter affords some interesting reading. Literature dealing with floral decorations concludes what may be fairly described as a well considered and carefully written work, which may be confidently recommended as an addition to a gardener's library. The book can be obtained from our publishing department.

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Miltonia vexillaria grows rapidly at the present season, and the young roots are very active. Those plants that were repotted into small pots last August should now be shifted into pots of a larger size. When repotting do not disturb the roots or the compost more than is unavoidable. Afford plenty of drainage materials and a shallow compost which should consist of one half sphagnum-moss, one quarter fibrous peat, and one quarter leaf soil, mixing with the compost some small crocks and coarse sand. Place plenty of living heads of moss on the surface of the compost, and subsequently afford enough water to keep these in a growing condition. Stand the plants well up to the light at the cooler part of the intermediate house, and where plenty of fresh air can be afforded when practicable. If kept for long together in a close atmosphere, the leaves are apt to decay at their points and the plants become unsightly. Black spot will sometimes appear on the young leaves if the plants are wet and the atmospheric temperature of the house falls a few degrees below the average. Examine the young growths several times each week, as occasionally some of the leaves stick together so firmly as to check the youngest leaves and cause them to crinkle. These should be liberated by passing a thin piece of smooth wood or the handle of a budding knife between them, and at the same time carefully liberate any flower spikes that may have become fixed in the axils of the leaves. These cultural remarks apply also to M. Bleuana and its distinct variety—nobilor. M. Endresii having passed out of flower should be kept rather on the dry side until growth has re-commenced. M. Phalænopsis, now growing freely, should be well supplied with water at the root. A moderately light position near to the roof glass of the Mexican house will suit its requirements admirably. Unlike its congeneric species, M. vexillaria, it prefers a small space to root into, and the plant may be repotted now if repotting is found to be necessary.

Odontoglossums.—In the cool house there are many plants of O. crispum and various other kinds that are now producing their flower spikes. These should be tied, or looped up to neat sticks. It is not advisable to tie them up straight, but to arrange them so that when in bloom the spikes will have an arching appearance. Slugs are sometimes troublesome at this season, and valuable plants of rare species and hybrids should have their young succulent spikes protected by a ring of dry cotton wool. Some of the smaller plants may be suspended to the rafters of the house, and large specimen plants may be elevated on inverted pots that are standing in pans of water. These latter precautions are sometimes of little use if slugs have been introduced with the sphagnum-moss used for potting, as they are often found lurking in the compost for several months after the plants have been repotted or top-dressed. No trouble should be spared to banish these pests from the house; baits of potato, young lettuce leaves, cabbage leaves, etc., are always useful for this purpose. The same remarks are applicable to such species as Oncidium macranthum, O lamelligerum, O. serratum, O. Loxense, O. monachicum, O. tetracopis, O. zebrinum, and others of that section. Nearly all of these plants are now showing new roots, and if slugs are about they will soon be destroyed if not carefully protected. Any of these Oncidiums that require to be repotted should be attended to at once. They prefer rather large pots for their roots to ramble in, and they will root freely in a compost of peat and sphagnum-moss in equal parts, adding a little leaf soil and some broken crocks. Those plants that have their flower spikes already well advanced should not be disturbed by repotting, but if the old compost has become sour and decomposed it may be carefully picked out down to the drainage, and fresh material substituted for it. Stand the plants in the coolest part of the Odontoglossum house, and where the atmosphere is very moist. Syringe well between the pots several times each day when the weather is bright and warm. They all delight in a free circulation of air at all times. Oncidium Marshallianum is now sending forth both roots and strong flower spikes. This plant should be grown in the same house, but if possible it should be placed in a drier position, though plenty of root moisture is necessary until the flowers expand, when the quantity should be considerably reduced. Plants of O. varicosum that have just passed out of bloom should be placed alongside the last-named species; they will require but limited supplies of water at the root until growth recommences. O. ampliatum majus will now be sending up flower spikes, and the plants should be placed in a shady part of the warm house, and water afforded often enough to keep the roots moist. Plants of O. Cavendishianum that have their spikes well advanced should also be placed in the East Indian house until the flowers open, when they may be returned to the intermediate house.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Palms always take a leading part as decorative subjects. Any plants that require to be repotted should now be attended to. If treated skilfully, Palms may be kept of a useful size for many years without being disturbed at the roots by repotting, provided the drainage is kept in good order. The common error made in the cultivation of these plants is that of overpotting. As a rule Palms grow under ordinary circumstances so easily that one is apt to treat them carelessly in the matter of affording water; being free rooting subjects there is little left in the pots but roots after they have occupied the pots for some time. Any inattention to supply a sufficient amount of water to a plant under such conditions would cause a check and the leaves to assume a yellow and sickly appearance, thus destroying the health of the plant. A good compost that will last for a long period is one composed of good fibrous loam three parts, peat or good leaf soil one part, some coarse bone meal, and coarse sand. The best fertiliser for Palms I find to be liquid manure and soot water, and occasionally nitrate of soda at the strength of 2 oz. to a gallon of water. Spray the plants once a week with a solution of soft soap and nicotine to keep them free from scale insects.

Hanging Baskets, containing Asparagus Sprengeri and other varieties of Asparagus, will need to have the material in which the plants are growing renewed. If it is necessary to increase the stock this can be done by division. By this early attention the baskets will become furnished with young growing shoots early in the season. A few ripe seeds of A. Sprengeri may be sown, and any young plants raised from last year's sowing will, if put in baskets, make very useful material for cutting from in the autumn and winter months. The durability of the fronds when cut is a sufficient reason for growing this plant in large quantities. The baskets should be lined with moss to give them a neat appearance. Asparagus deflexus and A. decumbens are two very useful varieties in addition to that named above. A humid atmosphere, free use of the syringe to keep red spider in check, a very porous compost for the roots, and liberal feeding, are details necessary to success.

General Remarks.—Take notice of your plants from day to day. Keep in mind the treatment to which you have subjected them; note the slightest change in their appearance, and the cause of the same. You will then have made a start in the right direction, for the man who errs and recognises the true cause of his failure has learned something, but he who attributes his failure to the wrong cause has not. By constant observation one may soon learn to judge a plant by its appearance, and after a time become sufficiently expert to be able to tell at a glance to what treatment a plant has been subjected, whether too warm or too cold, too wet or too dry, or just right, and be guided accordingly. Observe the appearance of plants in perfect health, strive to keep them in this condition, and never be satisfied until you can do so. Persevere and you will achieve success in the end.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Plum Trees in Pots.—It is not convenient to every grower to have one or two houses entirely set apart for the cultivation of permanent trees planted in borders. Therefore a few early fruiting varieties in pots may be brought on gradually in any unheated structure, such as the latest Peach-house, if frost can be excluded. The present is a good time to introduce a few trees which will yield ripe fruits before there are any ripe out of doors. Plenty of air must be admitted during the day and night on all favourable occasions. When the trees are in flower the blooms will need to be pollinated every day by means of a camel's-hair brush or rabbit's tail until the small fruits are seen to have formed. Syringing should afterwards be recommenced and carried out twice each day. If any aphis are seen notwithstanding these syringings, the most effectual method to employ against them is that of vaporising with the XL-all compound. The trees should not be allowed to become dry at their roots at any time. When the "stoning" period is past, the atmospheric temperature of the house may be increased with safety, and the trees be given a weak application of liquid manure twice each week. A few varieties specially adapted for pot culture are Purple Gage, Transparent Gage, Washington, Bryanston Gage, Coe's Golden Drop, and Jefferson.

In order to force Plums in pots successfully

it is important to have the trees well established beforehand.

Queen Pineapples.—If a batch of suckers were rooted last summer, preparations should now be made for affording them a shift into 10in. or 12in. pots, according to the extent each plant is furnished with roots. The compost most suitable to promote the growth of these plants is one of good turfy loam with the fine soil riddled out of it, adding about 3lb. of half-inch bones and a liberal quantity of soot to each barrowload of soil. If a little charcoal be broken up and mixed with the soil it will be all the better. Use clean pots, and provide them with perfect means of drainage. Make the soil firm with the rammer as the work of potting proceeds. A hot-bed should be in readiness for receiving the plants, the hot-bed being of the temperature of 85 to 90 degrees. Now that the sun-heat is becoming stronger and the days are lengthening, attention must be given to plants that require to be repotted, so that they may have a full season of growth. They will not require much water at their roots for some time after being disturbed and until the roots get established in the new compost. Use the syringe freely amongst the plants.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Dahlias.—For producing autumn effect in the borders, or for massing in isolated beds, the Dahlias—especially some varieties of the Cactus and pompon sections—are almost indispensable. Combining stateliness of growth with a wealth and beauty of exquisitely varied colour, they never fail to attract attention in the brightest of gardens. Easily propagated, there is little real difficulty in their culture, as unlike many of our best flowering plants, the Dahlia enjoys a remarkable immunity from disease of any sort. Neither mildew nor, in fact, any of the fungus scourges appears to affect it. It is true that in common with most herbaceous plants it is liable to suffer from attacks of snails and slugs, and also from earwigs, which ruin the growing points of the young shoots, and later attack the flower buds, but these excepted, the plant, practically speaking, is exempt from enemies. As the stem and growths of the Dahlia are succulent and brittle, precautions to prevent their being broken by violent winds must be taken—conjointly with proper staking—by growing them in sheltered positions. In the herbaceous borders, shelter to a great extent exists always, but in selecting the beds in which they are going to be grown by themselves it is important that the matter be borne in mind. The ground should be prepared at once. The position they are to occupy in the border should be determined, and holes 18 inches deep dug out according to the number it is intended to plant. Manure should be placed at the bottom and the hole refilled, taking care to keep the manure sufficiently deep to allow of the future planting being done, without the roots at once coming into actual contact with it. Prior to refilling the holes, strong stakes should be placed in position in the centre of each, so that when planting time arrives there should be nothing to prevent the work being done easily and expeditiously. The distance to be allowed between the holes will depend upon the variety of Dahlia it is intended to use in the particular position, but let each plant have ample room to develop. Beds, or ground that will be devoted entirely to Dahlias, should be trenched through, and if the soil is poor let a liberal amount of manure be added. In the back of herbaceous borders, and in large beds by themselves, the best of the bedding varieties in the Cactus section are effective. To furnish the fronts of borders, or small beds, varieties of the dwarf pompon section are especially adapted. Of bedding varieties in the Cactus section the following are amongst the best: Coronation, Floradora, the Queen, Britannia, Charm, Eva, Florence M. Stredwick, J. H. Jackson, Harbour Lights, Mabel Tulloch, Mary, Mrs. Ed. Mawley, Mrs. Winstanley, Sirius, and Vivia; and in the pompon section: Early Sunrise, Nerissa, Bacchus, Buttercup, Darkest of All, Guiding Star, and Phœbe.

Propagation.—The tubers should now be removed from their winter quarters, and placed in a mild bottom heat, covering them with loose leaf-mould but leaving the crowns exposed. Gentle syringing overhead to induce growth is all the moisture requisite. In the course of a week or so, which is quite early enough, there will be a number of growths ready from which to make cuttings. These should be taken with a small portion of the tuber attached, and inserted singly in sandy soil in small pots, and placed in bottom heat to make roots. When rooted they should be rapidly hardened off as far as atmospheric temperature is concerned. The young plants should not be left too long in the small pots in which they were "struck," but as soon as they appear to be rooting freely, let them be transferred to pots 5 inches in diameter, using a compost consisting of two parts loam and one part leaf-mould. In these pots they should, if practicable, be again plunged over a slight bottom heat, but in a cool atmosphere. By the beginning of May they will be ready for removing to cold frames, where every attention must be given to them in respect to ventilation and watering, and care taken to protect them from injury by late frosts.

The proper time to plant them out will depend upon the locality, but it is never wise to undertake this until the weather is warm enough to allow the plants to continue growing without the risk of a check. Dahlias from cuttings are much to be preferred to plants obtained by dividing up the old tubers, as they are not only better plants, but they have also the advantage that in the early summer when in pots they require much less room than the others.

Raising Seedlings.—This mode of propagation is only to be recommended for obtaining new varieties, and not for ordinary garden-decoration. If the seed is sown at the present time the seedlings will grow freely and quickly, and form good flowering plants by the autumn. The seed can be sown in shallow boxes or pans in ordinary light compost, covering them merely with a sprinkling of fine soil, and placed in heat. When the plants are up, they must be potted carefully into small pots and kept near to the glass. Their after care is similar to that already described for plants grown from cuttings.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Peach and Nectarine Trees.—The principal point in training the peach is to obtain an equal distribution of vigour amongst all the branches, so that there will be an equal flow of sap over all the tree. Assuming the trees were partially pruned late last summer, very little cutting will be required at the present time beyond shortening some of the long branches and cutting weak ones out or to a fruit bud at the base. As much old wood as can be spared should be taken away, as Peach trees bear on shoots made last year. Nail up the centre branch perfectly straight, using soft twine for this and other large branches. Train the two bottom branches right and left nearly horizontally, and let the others radiate at their different angles until a perfect fan-shape is obtained. The shoots should not be placed closer together than four to six inches. One of the essential points in Peach-growing is to allow plenty of room for the young growths that they may be enabled to mature thoroughly. Of young maiden trees, the shoots need to be pruned back half their length. Shoots will get up the wall soon enough, and if these are allowed to do so prematurely the tree will be ruined, it being essential to have a good base. Do not allow such trees to ripen any fruits during the first season after planting. Established trees that were lifted early in the autumn are of a different nature, and may bear a moderate crop; but should the tree show any signs of debility after starting into active growth do not neglect to remove the fruits. Assuming the walls have been given the necessary cleansing, the trees, after pruning and training has been done, should be sprayed with petroleum emulsion, the fumes of which will be effective in helping to prevent an attack of aphis when the trees are in blossom. Clear the surface of the ground of all rubbish and make it of tidy appearance. The following varieties of Peaches generally succeed well and ripen over a long period:—Waterloo, Amsden June, Hale's Early, Early Alfred, Early Silver, Noblesse, Royal George, Barrington, Sea Eagle, and Dymond. Nectarines: Lord Napier, Cardinal, Early Rivers, Victoria, and Pine Apple. The protection afforded these trees in spring varies in different localities. I do not advise the use of heavy coverings at any time; the coverings, whatever they may be, should not be of a dark, permanent nature, such as spruce branches. Have some means or other in readiness to protect the bloom at the right moment.

Stocks for Fruit Trees.—Let these be cut back for grafting, and retard scions by placing them in ashes under a north wall.

Affording Stakes.—Newly-planted trees that require support should be attended to at once, or the prevailing winds of March may sway them about and hinder root action.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Parsnips.—The end of the present month will be a good time to sow the main crop of Parsnips. The seeds require a long time in which to germinate, but are quite hardy, and a moderate frost seems to have but very little effect on the young plants. Parsnips need deep soil in order that the roots may penetrate easily and continue straight. If obstructions are present through the ground being untrenched, the crop will be materially lessened and forked growths will result. Select a piece of fairly rich ground, but do not add any green manure; merely make an application of wood ashes or of refuse from the burning heap which is a common feature in most gardens. The soil should be trenched to the depth of 3 feet, and the mould finely broken up. Sow the seeds in drills at distances of 2 feet apart, and later on the seedlings may be thinned out to 1 foot apart in the lines. It is seldom that the finest exhibition Parsnips can be had from the ordinary method of culture because of the little obstructions in the way of small stones, etc. For such a purpose it is necessary to make holes with an iron bar quite a foot deeper than you expect the root to grow. These holes may be made 6 inches wide and filled in with finely sifted soil, adding a little soot to help to prevent insect attacks. Then the seed can be sown, and later the seedings be thinned out to one plant in each hole. These long roots are often the subject of comment when seen at exhibitions, and the length of the tap root is objected to, but in defence of them it may be said that one straight root affords far finer texture of flesh than is obtained from an accumulation of several: therefore the quality of the edible part is higher in the long roots. For shallow soils where no trenching is possible, there is a stump rooted variety of Parsnip on the market which should be sown, but otherwise Hollow Crown is a fine main crop variety. Sutton's Tender and True, and Dobbie's Selected are improvements because of their whiter skins, and which are also much smoother.

Main Crop Potatos.—Preparations should now be made for this, the most important crop of the kitchen garden. Although at present it is too early to plant by three weeks, the soil should be fully prepared by being dug over, and as far as possible exposed to the morning frosts. Assuming that the ground was trenched in the autumn, the soil should now be thoroughly broken over with the fork, incorporating with it at the same time a dressing of lime or wood ashes to sweeten the surface, and increase the weight and table quality of the crop. Make no attempt to prepare the soil in wet weather, but wait until the return of a drying wind and sunshine. The seed tubers should now be finally prepared by having their sprouts reduced to one, or at the most two, on each tuber.

Earlier Potatos.—The advancing crops in frames or in pots will require to be top-dressed or earthed-up when they have reached the height of 9 inches, and as the sun advances in power so must more air be admitted to the frame, otherwise the haulm will soon become leggy and tumble over.

Peas.—Such varieties as Early Giant, Duke of Albany, and Alderman may now be freely sown. When shelled these varieties yield a splendid return, and are of the best quality when cooked. Another variety, which is a prodigious cropper—Senator, a variety raised by Messrs. Webb at Wordsley—is worthy of much attention, whilst Edwin Beckett and the new one named Quite Content should not be overlooked by cultivators for exhibition.

French Beans.—A sowing should be made in small pots with a view to planting them in frames when the Potato crop is cleared out later on.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR MARCH.

THURSDAY,	Mar. 1	Linnean Soc. meet.
SATURDAY,	Mar. 3	Ann. meet. Wakefield Paxton Soc. Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.
TUESDAY,	Mar. 6	Roy. Hort. Soc. Coms. meet. Nat. Amateur Gard. Assoc. meet. Complimentary Dinner to Mr. W. Marshall, at Hotel Windsor, Westminster.
SATURDAY,	Mar. 10	Dutch Gard. Soc. meet.
MONDAY,	Mar. 12	Ann. meet. Unit. Hort. Ben. & Prov. Soc., 8 p.m., at the Roy. Hort. Hall, Westminster.
THURSDAY,	Mar. 15	Linnean Soc. meet.
TUESDAY,	Mar. 20	Roy. Hort. Soc. Coms. meet.
WEDNESDAY,	Mar. 21	Roy. Bot. Soc. Show, Regent's Park.
THURSDAY,	Mar. 22	Roy. Hort. Soc. Exh. of Colonial-grown fruit (3 days).
WEDNESDAY,	Mar. 28	Liverpool Spring Hort. Show (2 days).
THURSDAY,	Mar. 29	Torquay Gard. Soc. Show.
FRIDAY,	Mar. 30	Roy. Bot. Soc. meet.
SATURDAY,	Mar. 31	Dutch Gard. Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—40·2°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Feb.* 21 (6 P.M.): Max. 45°; Min. 30°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, Feb.* 22 (10 A.M.): Bar., 30.1; Temp., 41°; *Weather*—Fair, with occasional sunshine.

PROVINCES.—*Wednesday, Feb.* 21 (6 P.M.): Max. 45° Ireland, South; Min. 37° N.E. Scotland.

SALES.

MONDAY NEXT—

Herbaceous plants, Hardy bulbs, Lilies, Roses, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY NEXT—

Hardy border and herbaceous plants, Lilies, Begonias, &c., at 12; Roses, Azaleas, &c., at 1 and 3, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

Sale of Roses, Azaleas, Liliums, &c., at Stevens' Rooms, King Street, Covent Garden, London.

THURSDAY NEXT—

Double-fronted Freehold House and Building Land, Six Greenhouses, Stock, Household Furniture, &c., in lots at the Exotic Nurseries, Hermitage Road, Coalville, Leicestershire, at 2, by Protheroe & Morris and H. M. Bertenshaw.

FRIDAY NEXT—

Hardy border plants and perennials, Lilies, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Law of Inheritance.

WE are frequently asked for information concerning the so-called Mendelian law, which is so important as regards the practice of cross-breeding, whether of animals or of plants. The subject is too intricate for satisfactory treatment in the course of an article, consequently for the fullest details we must refer the enquirer to Mr. Bateson's *Principles of Heredity*, published by C. J. Clay and Sons. Less easily obtained is Mr. Bateson's address before the Cambridge meeting of the British Association (Zoological Section), 1904. An admirable summary, but one we fear even more difficult to procure, is contained in a lecture delivered by Mr. C. C. Hurst before the Leicester Literary and Philosophical Society in 1904. A translation by Mr. Druery of Mendel's original paper was printed in the *Journal* of the Royal Horticultural Society, and is incorporated with Mr. Bateson's volume just mentioned.

The terminology and the algebraical formulæ made use of by some writers are, of course, essential to the student, but they prove embarrassing to the reader who only desires to secure a grasp of the general principles involved.

Gardeners and hybridists are familiar with plants that breed "true," i.e., in which a particular character, or characters, becomes "fixed," and with others which cannot be depended on to breed true, but yield a mixed offspring. Whether apparently "true" or "mixed," the offspring always contain, in varying degree, certain features or characters derived from their parents. These "characters" are either apparent—that is, "dominant"—or latent—that is to say "recessive." Where they are dominant we get, so far as those particular characters are concerned, "thoroughbreds" or pure offspring. Where they are mixed we get the heretofore "recessive" or latent characters manifesting themselves in varying degree. This predominance of certain characters and this latency of others are found, when carefully investigated, to manifest themselves in accordance with certain definite numerical proportions, such as 3:1. Each "gamete"—that is to say, each individual plant or animal—is, as we have said, made up of certain characteristics which are associated together, but which, whilst on the one hand they never truly blend or mix any more than cards do when shuffled, yet on the other hand frequently become more or less dissociated or "segregated," and thus give rise to variations or sports. The "gamete," according to Mendelian views, is made up of pairs of contrasted characters; for instance, in the case of the Pea, of smooth or wrinkled seeds, as well as of many other similar contrasts. Of these contrasted characters one is found, as we have said, to be numerically dominant—the other recessive. If the "gamete" is pure the plants will breed true. If the "gamete" is impure or mixed, the dominance is upset and the offspring becomes varied. It is not only the seeds that vary in this way, but many other parts of the plant are seen to present contrasted characters which behave in like manner. To avoid complication, however, one pair of characters is studied at a time, though it is obvious that to get at trustworthy results all must eventually be studied and compared one with the other in the same way, so as to get at the sum total of resemblances or differences.

The occasional appearance of purple Sweet Peas when two white-flowered varieties have been crossed, or of purple-flowered Stocks with hoary leaves, raised from plants with white and cream-coloured flowers and glabrous leaves, as explained by Mr. Bateson, is due to reversion.

Reversion itself is described as a "simple and orderly phenomenon," the explanation of which as given is, however, too abstruse to be made readily intelligible in this place. It will be interesting to Sweet Pea raisers to know that not only are there colour-variations in the flower, but also co-relative differences in the size and shape of the pollen-grains, which may account for some of the phenomena witnessed in the breeding of Sweet Peas.

Other workers have attacked the solution of these problems from different quarters—Mr. Bateson himself, by practical experiments with poultry and with insects, as well as with Primroses and other flowers. Mr. Hurst has investigated the phenomena in rabbits and mice as well as in Orchids. Quite lately he has communicated to the Royal Society a paper in which he shows, from an examination of the Stud Book, that the inheritance of coat-colour in thoroughbred horses is in accordance with Mendelian principles. The Stud Book contains fairly complete records of the age, colour, sex and parentage of British thoroughbreds from the earliest accounts down to the end of 1904. A critical examination of these records shows that bay and brown colours are "dominant" and chestnut "recessive." Thus from the union of several pure bay and brown sires with numerous chestnut mares, 370 foals were produced, all of which were bays or browns. The sires were themselves, in all but one instance, the offspring of bay or brown parents or grandparents. In other cases, wherein the bay or brown sires were "impure" (that is, less markedly dominant as to inheritance of colour), and were mated with chestnut mares, then the offspring numbered 702 foals, of which 355 were bays and 347 chestnuts.

The general results go to show that, contrary to the opinion of Prof. Pearson, the inheritance of particular colours in horses is subject to definite numerical laws, as pointed out originally by Mendel in the case of Peas.

The matters treated of are naturally of great importance to breeders and raisers, so that we look forward with much interest to the publication of the Orchid Stud Book, which cannot fail to throw light on this obscure subject, and to suggest further matters for enquiry. The subject will also naturally come under consideration at the Hybridisation Conference on July 30th-31st.

HORTICULTURAL EXHIBITIONS AT BIRMINGHAM.—Many of our readers are aware that several important exhibitions, including those of the Midland Daffodil and Carnation Societies, are held each year in the Botanical Gardens, Edgbaston, Birmingham. With a view to the promoting of further exhibitions in those gardens, which are admirably suited for such a purpose, the committee of the Birmingham Botanical and Horticultural Society has sent a circular to exhibitors and prominent horticulturists in the Midland Counties asking for their support. We make the following extracts from the circular:—

"DEAR SIR,—Owing to the increased interest now shown in the pursuit of gardening in the Midland Counties, the Birmingham Botanical and Horticultural Society has considered a proposal to hold monthly flower shows in the Botanical Gardens, Edgbaston, during the Summer months. The Daffodil and Auricula Shows, held at the Gardens in April, the Carnation Show in August, and the exhibition of Border Chrysanthemums and other Autumn flowers, held under the auspices of the Gardeners' Mutual Improvement Association, are well supported by exhibitors and visitors. It is now proposed (as an experiment) to hold two extra Shows during the coming Summer—one in June and the other in July. It is proposed to award medals to meritorious exhibits, and certificates to individual plants, etc., of superior excellence. A meeting to consider the project and to elect representatives of intending exhibitors and supporters to serve on a sub-committee to deal with the arrangements, fix dates of Shows, etc.,

will be held at the Botanical Gardens, Edgbaston, on Thursday, March 1, at 5.30 p.m. NEVILLE CHAMBERLAIN, Esq. (hon. treasurer of the society), in the chair.—THOS. HUMPHREYS and W. H. WHITELOCK, hon. secs."

We trust that the movement will meet with support, and that Birmingham may become a centre of greatly increased horticultural activity.

"FLORA AND SYLVA."—The third volume of this elegant publication is before us, and in paper, typography, and illustrations is equal to its predecessors, which is about as high praise as can be bestowed. The present volume has a painful significance, inasmuch as it contains some of the last—and, we may add, some of the best—work of the late H. G. MOON. The volume is dedicated to his memory, and there is at p. 346 an appreciative account of his life and works. The figure at p. 62, taken from Loudon's Arboretum, p. 2,075, is by some mischance stated to represent the "Buckland Yew, recently destroyed." The Buckland Yew is, or was till lately, flourishing exceedingly in spite of its transportation. In a notice prefixed to the December number we are informed that *Flora and Sylva* will henceforth be published in the form of a yearly volume.

THE PRESIDENT OF THE ROYAL HORTICULTURAL SOCIETY.—Sir TREVOR LAWRENCE completes this month the 21st year of his presidency of the Royal Horticultural Society. The council has resolved to have his portrait painted to place in the society's new building, and also to establish in perpetuity a large gold medal to be called the "Lawrencean Medal," to be awarded to exhibits of a specially deserving character at the society's meetings. *Times*.

SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, February 26, 1906, at 8 p.m., when a paper by the late Mr. JOHN LEANING, entitled "The Assimilation of the Practice of Quantity Surveyors," will be read by Mr. H. J. LEANING (Fellow).

ROYAL GARDENERS' ORPHAN FUND.—A concert under the patronage of Lord and Lady BELPER was held in the Kingston-on-Soar Reading Room on Friday, 16th inst., in aid of this excellent charity. The Rector, the Rev. H. B. HAMILTON, occupied the chair, and a large and appreciative company was present. The concert resulted in a profit of £6 10s.

GARDEN POTS.—We have received from the SCREMERSTON COAL CO., LTD., Berwick-on-Tweed, two flower pots, with an indication of the size of each stamped into the clay at the base. This information may be of value in some gardens, for it can hardly be denied that, owing to the practice of describing pots as of so many inches in diameter at one time, and at other times as of so many to the "cast," some confusion has arisen. It may be remarked that the diameter of the pot before us marked 3½ inches is at least one-eighth of an inch in excess of the marked measurement, and the other marked 3 inches is equally above the standard. The pots are exceedingly well made, and of good material, their smooth finish being very praiseworthy. The base is slightly hollowed and grooved.

NAME, NAME!—PARKINSON seems to have had a poor opinion of the honesty of the nurseryman of his day. Speaking in the *Paradisus* of the "Arch-Duke Cherrie" he says, "Scarce one of twentie of our Nurserie men doe sell the right but give one for another; for it is an inherent qualitie almost hereditarie with most of them to sell any man an ordinary fruit for whatsoever fruit he shall aske for: so little are they to be trusted. . . . The true Gascoign Cherry is known but to a few; for our Nurserymen do so change the names of most fruits they sell, that they deliver but very few true names to any." We are happy to think that there has been a great improvement in this respect, as nowadays no nurseryman with a reputation to lose would resort wilfully to such practices.

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—Not many changes in the personnel of these bodies is seen in the lists of membership recently issued. The Council's policy now seems to be to retain, so far as possible, the experience of the old and efficient members. The Fruit Committee, the senior body, loses Sir ALBERT ROLLIT and Mr. BALDERSON as vice-chairmen, Mr. JOSEPH CHEAL being the only new appointment to that position. New members are Mr. ALLAN, Hillingdon Court Gardens, Uxbridge; Mr. W. BARNES, Bearwood, Wokingham; Mr. J. DAVIS, Glebelands Gardens, Woodford; Mr. R. LYE, Sydmonton Court Gardens, Newbury; Mr. JAS. VERT, The Gardens, Audley End, Essex; and Mr. CHARLES NIX, Tilgate, Crawley. The first four, as will be seen, are gardeners, making of gardeners and ex-gardeners no fewer than 30, a material preponderance. The total membership now is 42, as is also that of the Floral Committee, the new members of which body are three—Mr. JAS. DOUGLAS, V.M.H., Great Bookham, transferred from the Orchid Committee; Mr. A. R. GOODWIN, Kidderminster; and Mr. R. C. R. NEVILL, Chislehurst. The new additions to the Orchid Committee—the total membership of which is 39—are Major HOLFORD'S able grower Mr. ALEXANDER, Mr. BRIGGS-BURY, Accrington; Mr. A. DYE, The Gardens, Tring Park; Mr. LEEMAN, Heaton Mersey; Mr. C. J. LUCAS, Horsham, and Mr. F. M. OGILVIE, Oxford. The Narcissus Committee also number 39, and shows a few changes in its composition. The Scientific Committee, the largest body, has increased its membership from 76 to 81, one of the chief additions being Lieut.-Col. PRAIN, the new Director of Kew Gardens. This Committee does not, as a rule, show the largest attendance at its meetings, the members acting as referees when required. The total list of names on the five committees reaches 243, but allowing for a few duplicates it is thus seen that the Council calls to its aid this year, as members of these important bodies, no fewer than 230 Fellows, all of whom render gratuitous and willing service to horticulture and science.

MANURING OF POTATOS.—The Midland Agricultural and Dairy Institute publishes the following summary of the results of experiments made in Lincolnshire in 1905. 1. Where farmyard manure alone is applied to the Potato crop, moderately heavy dressings (up to 20 tons per acre) may profitably be given. 2. The largest profit was realised by Plot 4, where a small dressing of dung was supplemented with a moderate dressing of artificials, as follows: 10 tons farmyard manure, 2 cwts. nitrate of soda, 4 cwts. superphosphate, and 1½ cwts. sulphate of potash. 3. Artificials alone give considerable profit when applied in moderately large dressings, but are not so good as artificials and dung together. 4. The dressing of artificials only, which gave the best results, was the following (Plot 5): 1½ cwts. sulphate of ammonia, 4 cwts. superphosphate, 1½ cwts. sulphate of potash. 5. It pays better to supply nitrogen to the Potato crop in the form of sulphate of ammonia than as nitrate of soda. 6. Dissolved bones do not give such good results as when the same amount of phosphoric acid is applied in the form of superphosphate. 7. When equal amounts of potash are used, sulphate of potash has a more beneficial effect upon the potato crop than either muriate or kainit. 8. Very heavy dressings of artificials may give a heavier crop, but are not so profitable as moderately large applications, and are, therefore, not to be recommended.

"PIPS."—Dr. MURRAY, in a recent number of *Notes and Queries*, seeks information as to the date of the first employment of the word "pips" to designate the seeds of Apples or Pears. He tells us that up to this time he has not found an instance of the use of the word in this sense earlier than the beginning of the 19th century. So familiar are we with "Pippins" that we not unnaturally thought "pips" would be contemporaneous with them. A search through *Parkinson's Paradisus* (1629), however, showed that in his time the seeds of Pippins, as well as other Apples, were called "kernels," a term we now confine to the seeds of stone fruit. In *Miller's Dictionary* (ed. 8, 1768), the word "pip" finds no place, the seeds being called as by Parkinson "kernels." It is interesting to note, with reference to seedless Apples, lately brought prominently under notice, that in *Parkinson's Theatrum* (1640) mention is made of a sort "which hath no kernels within the core." *Gerard ed. Johnson* (1636), *Evelyn Pomona*, p. 345 (1678), and *Grew Anatomy*, p. 40 (1682), all use the word kernel. Some of our readers who may have access to garden books of old times may be able to trace the early use of the word "pip" in the sense of seed, as well as in its application to one flower out of a cluster, as in the Auricula.

COUNTRY IN TOWN.—The object of the Exhibition proposed to be opened in the Whitechapel Art Gallery during the summer of 1906 is to show East Londoners what can be done to bring into that neighbourhood something of the beauty, freshness, and inspiration of nature. The Exhibition will contain:—I. Living things: (*a*) Plants which have been grown in London. Plants which have been grown in London Schools. (*b*) Plants, suggested by experts, which might be grown in London. (*c*) Such plants fitted into models of windows, gardens, or roofs. (*d*) Aquaria, Vivaria, Beehives, &c. II. Pictures and Models; (*a*) Parks and Open Spaces. (*b*) Playgrounds. (*c*) Open-air Swimming Baths. (*d*) Children's Gardens in London and other cities. (*e*) Town Gardens. (*f*) London Back Gardens. (*g*) Foreign Towns, showing planting in the streets. (*h*) Garden Suburbs. (*i*) Country Cottages. (*j*) Railway Embankments and Stations. (*k*) London Trees. III. Materials and appliances: (*a*) Specimens of soils and suitable methods of planting for London. (*b*) Window Boxes. (*c*) Fern Cases. Flower Tables for Schools, &c. (*d*) Hives. (*e*) Nesting Boxes and methods of feeding wild birds. Prizes may be offered for Window Boxes *in situ* in crowded neighbourhoods, and for arrangements of cut flowers. Railway Companies will be asked to send photographs of suitable places to which town children could be taken, and to suggest comfortable and economic methods of conveying them. Nurserymen will be asked to make displays of flowers under 1. (*b*). A Committee was formed last year, but not early enough to complete the preparations for an Exhibition in the summer of 1905. The Committee is being reconstructed, and in the meantime offers of co-operation and suggestions will be received by Canon and Mrs. BARNETT, Toynbee Hall, Whitechapel, E.

FRUIT GROWERS' GUIDE.—According to the title page, this little pamphlet is intended for growers not only of fruits, but of flowers, vegetables and Potatos, but it was not convenient to get all that information into a headline. The Guide is intended to assist growers, especially in the Wisbech district, in placing their produce to advantage in the populous towns of the north. The directions given are, however, so practical and so excellent that we commend the pamphlet to the notice of all who grow for market, wherever it may be. The recommendations made are not new, but they are so lucidly and tersely set forth that growers will have themselves only to blame if they do not, as far as circumstances permit, carry out the directions for picking, grading, and marketing their produce. It is issued by the Newcastle-on-Tyne Fruit and Potato Merchants' Association, of which Mr. T. PRINGLE, of Pringle's Buildings, St. Andrew's Street, Newcastle-on-Tyne (and elsewhere), is the Honorary Secretary.

FLORA OF TROPICAL AFRICA.—Another instalment of this important publication, edited by the late Director of the Royal Gardens, Kew, Sir W. T. THISELTON-DYER, has been just issued. It contains a detailed account of the Convolvulaceæ by Messrs. BAKER AND RENDLE, continued from a previous part, as well as the Solanaceæ by Mr. C. H. WRIGHT, and part of the Scrophulariaceæ by Mr. HEMSLEY and Mr. SKAN.

ILLUSTRATIONS OF PLANTS.—The garden of M. VAN DEN BOSSCHE, at Tirlemont, Belgium, continues to furnish illustrations and descriptions of new or interesting plants. In the *Icones Selectæ* are given representations of cultivated plants which have produced flowers in M. VAN DEN BOSSCHE's garden. These are enumerated in another column under "Plant Portraits." In another publication of a similar character, called *Plantæ novæ vel minus cognitæ*, M. DE WILDEMAN describes and figures several new plants collected in Mozambique by M. LUJA, and now preserved in the herbarium of M. VAN DEN BOSSCHE. The plants described by M. DE WILDEMAN are Ottelia latifolia, Asparagus Lujæ, Gladiolus affinis, Oxalis morrumbalensis, Triumfetta morrumbalana, Plectronia stipulata, and Pavetta appendiculata. The drawings by M. APREVAL are excellent, and the critical dissertations by M. DE WILDEMAN most instructive.

BORDEAUX MIXTURE AND THE POTATO DISEASE.—The Midland Agricultural and Dairy Institute have lately issued the result of some field trials carried out in Lincolnshire to determine the effect of Bordeaux mixture and solutions of sulphate of ammonia, respectively, in preventing the Potato disease. Summarising, the results may be stated as follows:—1. The application of Bordeaux mixture is effectual in reducing the amount of disease and increasing the yield, and results generally justify its application being recommended, provided the details of mixing, &c., are strictly attended to. 2. Three times spraying, at intervals, gives better results than either one or two applications. 3. Solutions of sulphate of ammonia are not to be recommended for the spraying of Potatos, for they increase the amount of disease, and reduce the crop to an alarming extent.

THE BEST MANURES FOR MANGELS.—Among the several bulletins useful to agriculturists issued by the Midland Agricultural and Dairy Institute is one on the manuring of Mangels. Field trials of various preparations were made during several years, and Mr. J. F. BLACKSHAW deduces the following conclusion:—That the following dressing per acre (in addition to farmyard manure) is what farmers should apply in order to get the most profitable crops of Mangels: Sulphate of ammonia (at seeding) 100 lb. (or such an amount as contains 20 lb. nitrogen). Nitrate of soda (at singling) 130 lb. (or such an amount as contains 20 lb. nitrogen). Superphosphate (at seeding) 715 lb. (or such an amount as contains 90 lb. phosphoric acid), Sulphate of potash (at seeding) 127½ lb. (or such an amount as contains 60 lb. potash). Common salt (at seeding) 280 lb.

THE SOUTH AFRICAN FORESTRY SCHOOL.—We learn that a South African School of Forestry is being established by the Government of Cape Colony for the scientific training of forest officers, and for research in South African forestry. The aim of the School is to provide a thorough course of instruction in forestry with special reference to South African conditions. According to the programme from which we quote, the Tokai arboretum, which now comprises the largest collection of timber trees in South Africa, affords unique opportunities for practical instruction in silviculture. To this will be added the pineries and sand-reclamation planting in the Cape Flats, together with the fine arboreta and forests at Ceres Road, comprising forest estates of 20,000 acres. Such instruments as are required for practical forest work, including plane tables, barometers, chains, dendrometers and calipers, will be provided. The course of training proposed covers a period of two years, preceded by a preliminary scientific course of one year, specially arranged for those students who are not qualified to enter the regular course. Further particulars can be obtained from the Chief Conservator of Forests, or from the Registrar, South African College, Cape Town.

LINNEAN SOCIETY.—At a meeting to be held on Thursday, March 1, at 8 p.m., the following papers will be read:—1, Dr. D. H. SCOTT, F.R.S., F.L.S., "On a new type of Stem from the Coal Measures." 2, Dr. H. C. TORBY, F.R.S., F.L.S., "Notes on Some Species of Nereis in the District of the Thames Estuary."

THE "JOURNAL OF THE JAPANESE HORTICULTURAL SOCIETY."—This publication has been in existence since 1889, and its New Year's volume for 1906 shows no falling off in size nor in illustrations. The letterpress, contributed by native authorities, is in Japanese, and includes articles on fruit-tree blossoms, a proposed Alpine garden in Shinano, and similar subjects. The pictures, black and white and coloured, are formed with a few effective strokes of the brush. Some of them show the results of increasing intercourse with Western nations.

NATIONAL FRUIT GROWERS' FEDERATION.—A meeting of the Council took place on Tuesday, the 20th inst., at the Royal Horticultural Hall, Westminster, Col. C. W. LONG, M.P., president of the Federation, in the chair. There were also present Messrs. F. S. W. CORNWALLIS, G. E. CHAMPION, E. VINSON, S. BOCRMAN, F. SMITH, A. H. H. MATTHEWS, W. IDIENS, C. H. HOOPER, T. WAGHORN, and A. T. MATTHEWS (secretary). Major A G. BOSCAWEN was appointed president elect in the room of Mr. CORNWALLIS, whose duties as president of the R.A.S.E. prevented him from retaining the office. Mr. T. WAGHORN, legal adviser to the Federation on railway matters, made important statements in connection with the claims of Kent growers for rebates due to them on large consignments, and it was decided to send a communication on the subject to all members. Mr. C. H. HOOPER's appointment as delegate to represent the Federation on the Joint Railway and Parliamentary Committee was confirmed, and that gentleman reported what was being done by that important body; including the drafting of a Bill to be introduced this Session dealing with the classification of goods, owners' risk rates, powers of the Boards of Trade and Agriculture on railway questions, &c., &c. The President called the attention of the Council to certain grievances affecting growers, in which they might take action, including the present mode of assessment for the Income Tax. He also pointed out that something might be done to simplify and improve the present system of taking valuations for outgoing fruit-farmers, by urging the adoption of certain recommendations of the Departmental Committee on Fruit Culture. The next meeting will be held on March 12 at 2 p.m.

AMERICAN CARNATIONS.—We are indebted to Mr. A. DIMMOCK for the opportunity of inspecting a bouquet of Carnations, the flowers having been cut in America and imported here in this condition. Mr. DIMMOCK has previously shown us Roses which have crossed the Atlantic in a cut state, and were brought to this office in a good state of preservation. The interest in the present instance lies in the fact that the Carnations are of a new variety named "Victory." The flowers are crimson coloured, of considerable size, moderately fragrant, and the petals are less fringed than American varieties are usually. Whether it is of better quality than some varieties which have already been imported of the same colour will have to be determined after cultivation here. In the meantime, we could not conceal our admiration for the excellent "grass" on the stout, wiry, perfectly rigid stems. Certainly, Carnation culture is practised with extraordinary success on "the other side."

LAW NOTES.

A SINGULAR ACTION.

A singular action affecting Rhubarb was lately heard at the Leeds District County Court, before his Honour Judge Greenhow. The plaintiffs, fruit brokers of Birmingham, claimed £50 from the defendant for damages to 2,500 roots of Rhubarb. It was stated that defendant used the ground adjacent to Rhubarb beds for sporting purposes. The plaintiffs claimed damages for nuisances alleged to have been committeed by crowds of people who visited the defendant's grounds to see sporting events. Defendant had been in occupation of the field for some years. People got on to the plaintiffs' land and trampled down the roots. On August 9 last there was a race between a horse and a man for £100 a side, and other events, which drew a big crowd, and the crops of Rhubarb were much injured. During the race rain fell, and the Rhubarb was pulled up by the crowd, who used the leaves as umbrellas. Plaintiffs applied for an injunction.

His Honour said there was nothing objectionable in the sports themselves. The only possible charge that could be brought against the defendant was that he had presented such attractive sports that the crowds which gathered were uncontrollable. He held the crowds were not large or bad enough to constitute a nuisance, and therefore gave judgment for the defendant.

IN BANKRUPTCY.

At the London Bankruptcy Court, on February 16, before Mr. Registrar Brougham, an application was made for the discharge of Dick Edwards Radclyffe, described as an horticulturist and seedsman, lately carrying on business at Wraysbury, near Staines. The statement of affairs filed by the debtor disclosed liabilities amounting to £714, but, as a matter of fact, proofs of debt had been admitted for £1,715. The debtor returned his assets at nil, but £50 2s. 6d. had been realised, and a first and final dividend of 2½d. in the £ had been paid to the unsecured creditors. The debtor's failure appeared to have been caused through his embarking in enterprises of a speculative character without sufficient capital. Eventually the discharge was suspended for two years.

UROPHLYCTIS ALFALFAE, A FUNGUS DISEASE OF LUCERNE, IN ENGLAND.

A FEW weeks ago some plants of Lucerne (*Medicago sativa*) were sent to the College from a farm near Herne Bay, Kent. The piece of Lucerne from which the plants were taken had been sown in the spring of 1899, and it was noticed during 1905 that many of the plants were beginning to die away. On examining the plants sent several superficial, warted, gall-like outgrowths, about three-quarters of an inch across, were found on the crown of the root. These "galls" proved on microscopic examination to be of fungus origin and due to the attacks of *Urothlyctis Alfalfae* (v. Lagerh. *olim*), P. Magn., a fungus not hitherto reported as occurring in England. The "galls," which consist of the hypertrophied tissue of the host-plant, were found on being cut across to contain a number of minute cavities or chambers filled with a crowded mass of brownish spores. These spores, which measure about 40 μ. in diameter, are the resting-spores of

the fungus. From the appearance of the plants sent it was evident that they had been infested for some time, and the injuries caused by the fungus had induced the plants to throw out fresh or extended crowns. Some of the plants were almost killed. This piece of Lucerne has now been ploughed up.

The present disease was first observed (in 1892) in Ecuador, where it causes considerable loss in certain districts. It is not improbable that it occurs in other countries of South America. The fungus was observed to be most destructive to plants sown on damp ground, and in such spots many old fully-grown Lucerne plants were killed. In these cases "galls," much warted or coralloid externally and often reaching the size of a tolerably large Apple, had been formed in considerable numbers on the crown of the root. These "galls" closely resemble externally those found on the roots of Alder.*

In 1902 the disease was recorded from Colmar, in Alsace, Germany, where it occurred destructively on cultivated Lucerne. It is now reported as being not uncommon in Alsace and in certain localities in Switzerland, and it has quite lately been observed in Italy, where it has caused considerable damage to the Lucerne.

A detailed account of the disease, with illustrations, will be given in the Journal of the Wye Agricultural College. One of the most important points in connection with the present disease is to ascertain whether the fungus can attack other cultivated crops, and investigations on these lines are being carried out in the botanical laboratory and experimental grounds of the College. I should be glad if anyone meeting with the present disease would kindly forward examples to me at the address given below. *Ernest S. Salmon, South Eastern Agricultural College, Wye, near Ashford, Kent.*

* Excellent photographs showing these galls (natural size) on diseased plants are given by von Lagerheim in the *Bihang k. svenska vet. alsad. Handl.*, XXIV., Afd. III., 3–12, Taf. I., II. (1898). For an account of the first appearance of the fungus in Europe see Magnus in the *Ber. d. deutsch. botan. Gesellsch.* XX., 291–296, Taf. XV (1902).

MONTANOA BIPINNATIFIDA.

This is a handsome shrubby Compositæ, native of Mexico, with boldly cut pinnate foliage and yellow flower-heads. In this country it is used as a "sub-tropical" on account of its handsome foliage, but where the summers are hotter the flower-heads are produced abundantly, as may be seen from our illustration taken from a photograph by Mr. D. E. Peto of a plant in the garden of Dr. Hubbard, Casa St. Monica, Bordighera.

Fig. 48.—Montanoa bipinnatifida flowering at Bordighera.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Return of Income Tax.—It has occurred to me that the following list of grounds upon which a reduction or return of Income Tax should be claimed might interest readers of the *Gardeners' Chronicle*. The list hereunder is by far the most complete which has ever been issued to the public. Any advice I can give to a reader it will be a pleasure to give without any fee. Claims may be prefered by any :—(1) Who pay bank interest *whatever the income may be*. (2) Who pay Insurance premiums *whatever the income may be*. (3) With incomes not exceeding £700 per annum. (4) Minors (sometimes even for 20 years). (5) Who have come of age within the last three years. (6) Beneficiaries under wills or trusts. (7) Femes soles, widows or spinsters. (8) Executors, &c., of deceased persons' estates. (9) Who have been over assessed. (10) Who have suffered business losses. (11) Whose profit during the last year has decreased. (12) Who have been doubly assessed. (13) Who have discontinued their business. (14) Who have received capital which has been assessed as income. (15) For set-off of loss against profit or against private income of self and wife. *F. Lodge Rosser, Secretary, The Income Tax Reclamation Association, Ltd.*

Winter-flowering Carnations.—Having read with interest the note on p. 91 of the winter-flowering American Tree Carnations from Eastwell Park Gardens, I should like to add to Mr. Weston's excellent list the following varieties :—Prosperity, white overlaid with pink, a strong grower; Cressbrook, white; Lewis Bradbury, cerise; Miss Clibran, scarlet; Mrs. G. M. Bradt, flesh colour; Julian, dark crimson, a strong grower; Duchess of Portland, pink; and Bronwen Lewis, yellow, tipped with pink. The above varieties are not all strictly American, but have the long, wire-like stems so desirable, and should be in every collection. *Henry Butcher, Wheatley Park, Doncaster.*

Excelsior Boiler.—In respect to the enquiry in the *Gardeners' Chronicle* for February 10, I may say that I have had an Excelsior Boiler in use here for over 17 years. It is economical, easily managed, quick in action, and generally satisfactory. *W. H. Lewis, Tythrop House Gardens, Thame, Oxon.*

Azalea Beds.—I planted an Azalea bed here two years ago in a conspicuous position on the lawn, and one of the first things that occurred to me was that the Azaleas must be planted reasonably thickly to afford the desired effect when they were in flower. Secondly, I wanted a flower bed, so to speak, after the Azaleas were over. This is how I contrived to overcome the difficulty. Some bushy plants of the best coloured varieties of Japanese Acers were mixed with the Azaleas. Afterwards, two arches were made of stout iron, and put over the bed, crossing each other in the centre. On these I planted Dorothy Perkins Rose. Last season each Rose plant made about nine growths 10 feet long. These I intend to tie to temporary irons which will be placed over the bed after the Azaleas have flowered. The margins of the bed are planted with Veronica rupestris, and there are good clumps of Daffodils in the centre. In March I planted Gladiolus Nanceianus, and lifted them after they had flowered. In June all bare places were planted with pink and white flowered Pelargoniums. The effect was very satisfactory. *T. G., Sulop.*

Plants in Flower at Culzean Castle, Ayrshire.—The following list of plants in flower in the gardens of Culzean Castle, Ayrshire, on January 31, 1906, testifies not only to the mildness of the season and the mild climate of the Ayrshire coast, but also to the wealth of shrubs and other plants cultivated at Culzean, where the Marquis of Ailsa has for some time been forming a magnificent collection of plants, many of which are hardy there and only half-hardy in the greater part of Scotland :—Shrubs: Rhododendron Nobleanum, R. præcox, Nuttallia cerasiformis, Berberis repens, B. aquifolium, B. nepalensis (japonica R.Br.), B. Darwinii, Escallonia macrantha, E. exoniensis, Garrya elliptica, Jasminum nudiflorum, Pieris (Andromeda) floribunda, Viburnum Lantana, Correa speciosa alba, Ceanothus Veitchianus, Arbutus canariensis, Veronica parviflora, V. speciosa variegata, &c., Pyrus japonica, P. Maulei superba, P. M. alba, P. Simoni, Arundinaria (Bambusa) Simoni, Cytisus albus, Clianthus puniceus, C. p. albus, Erica carnea, E. vagans, E. stricta, E. arborea, Clematis calycina, Hamamelis arborea, H. japonica, Rubus spectabilis, Ulex europæus. Herbaceous plants: Colchicum hydrophilum, C. cilicicum, Scilla bifolia, Eranthis cilicicus, E. hyemalis, Iris reticulata, I. Krelagei, I. histrioides, I. alata, I. Histrio, I. persica purpurea, I. taurica, I. Vartani, I. Danfordiæ, Anemone blanda, Primula veris, P. elatior, P. casbmeriana, P. denticulata, P. d. alba, Leucojum vernum, Galanthus nivalis (single and double), G. Elwesii Cassaba, G. E. præcox, G. E. ochrospeilus, G. plicatus, G. cilicicus, Arabis alpina fl. pl., Aubrietia purpurea, Sternbergia Fischeriana, Schizostylis coccinea, Nymphæa odorata (?) in bud, Bellis perennis (double and single), Calceolaria amplexicaulis, Crocus aureus, C. Imperati, Vinca major elegantissima, Cheiranthus Cheiri in quantity, Lunaria biennis, Myosotis, Petasites japonicus, P. fragrans, Narcissus scoticus, Helleborus colchicus. The Marquis of Ailsa kindly informs me that Clianthus puniceus, which is on a south wall, and has its stem of the thickness of a man's wrist, was only a small plant when planted about two or two and a half years ago. It now covers a large space of the wall, and at the date mentioned was covered with large buds. *S. Arnott.*

Montbretias.—These plants are very effective if grown in the following manner. Take up the bulbs early in spring every year, and separate them, removing all the offsets from the bottom of each bulb. Afford the ground a liberal dressing of well-rotted manure, and plant the bulbs at 6 inches apart, burying them 2 inches deep. Given this treatment, I find Montbretias to flower very freely, and the bulbs increase in size, and produce two or three spikes of bloom.

A long border planted with them and backed by a row of Japanese Anemones, affords such an effect in August and September as could hardly be forgotten. *G. Buckley, Tarporley, Cheshire.*

HIGH PRICE FOR WILLOW TIMBER.—At the sale held last week on Sir Walter Gilbey's estate Willow timber suitable for bat-making fetched 11s. 6d. per foot. Through the medium of papers connected with the timber trade I have for long advocated the extended culture of Willow timber suitable for the manufacture of cricket bats, but although a few plantations were formed some ten years ago, yet not one tithe of the area that our ever-increasing demands warrant has been brought under cultivation. When we consider that the Willow succeeds best on damp land that would be considered unsuitable for agricultural purposes generally, that it is of the freest growth and may be readily propagated, and that the price of the timber is far ahead of that of any other tree grown in this country, the wonder is that it is not more generally cultivated. For planting in marshy ground by lakes and streams—and there are hundreds of acres of such land throughout the country—the Willow is peculiarly suitable, whether viewed from an æsthetic or an economic point of view. *A. D. Webster, Regent's Park, February 17, 1906.*

PLANTS FOR ASSOCIATING WITH RHODODENDRONS.—This is a very difficult question to solve, many persons strongly objecting to any other plants than Rhododendrons in the beds, while others dislike bare ground, however small. Those with the latter taste have ample subjects to choose from, and in gaps or open spaces between large specimens, providing there is no overhead growth, Foxgloves will grow to perfection. A mass of these plants in full bloom in such a position is a sight not easily forgotten. In beds of younger plants, where space is left for their future development, there is plenty of plants to choose from, and these may be selected to harmonise with any position. If a cool effect be desired, Periwinkle, ground Ivy, and Ferns, planted either separately or in combination, will make a splendid carpet, and they each have the advantage of choking all weeds, a consideration where labour is limited. Where a brighter effect is desired, Pelargonium Flower of Spring is excellent for the purpose, its white leaf against the dark foliage of the Rhododenrdons producing a pleasing effect. In a position where plenty of bloom is desired bulbs could be planted, preferably Snowdrops, to be followed by Tagetes, which plant does well in such a position, and is one of the most continuous bloomers of all the annuals, commencing, as it does, to bloom at the beginning of June and continuing until cut down by frost. Some varieties of Rose are also suitable, especially the variety Hermosa. This is almost a perpetual bloomer, and its lovely pink flowers are among the best for table decoration. With this latter combination a few Larch posts, to which are trained some rambling Roses, would much improve the effect, especially when seen at a distance. *Jno. Barker.*

SMALL HOLDINGS AND WHAT MAY BE GROWN ON THEM.—The happenings in the political world are likely to be followed by alterations for the bettering of the conditions of the peasantry, farmers, and small cultivators as a class. Taking it for granted that endeavours will be made by those in authority to keep as many people as possible on the land, by granting long leases, free from irksome restrictions as to manuring and rotation of crops, sale of produce off the land, and other matters of importance to holders, it will become a part of the duty of parish and county councils, to a much greater extent than at present, to teach the new tenantry better methods of cultivating the land than those hitherto in vogue. Not the least important of these relate to the laying down of fruit plantations, the utilisation of walls of every sort of aspect in the cultivation of the choicer kinds of fruits, the raising of vegetables for town consumption, these including such rare commodities as Asparagus, Sea Kale, Mushrooms, Gourds, French Beans, and the white seeded varieties, the Haricots of the shops, a far superior food to the potato when eaten in the ripe state, while the more common kinds of vegetables are certain to be grown in abundance on almost all sorts of soils. Still thinking of the culinary side of things, there ought, in a few years after the system is inaugurated, to be no scarcity in any part of these islands of Strawberries; and common, Japanese and American species, and varieties of Brambleberries; Quinces, common and ornamental Crabs, which make such excellent jellies. No peripatetic lecturer holding forth in the village is worth his salt who does not, or is unable to, teach the rustic how to raise fruit trees from seeds, and how to treat them afterwards, and the best methods of grafting and budding stocks thus raised. This applies to all of our commoner kinds of fruits without exception. Budding and grafting should always be insisted upon, the trees coming into fruit at an earlier age, and the produce being finer and of greater value than that from the usual run of seedlings. We are acquainted with parts of the Continent where farmers raise Peaches, Apricots, Plums of sorts, from seeds, but it is extremely rare to meet with a truly nice, delicious fruit. But then, these people have never tasted one, and have no knowledge of anything better than their own. We have an idea that the Peaches sent us from the Cape are seedlings, and unselected at that. The various productions of the garden and farm that would come under the purview of the small holder cannot be enumerated here, but enough has been said to show there is a wide choice of subjects from which to select. Bee keeping should not be overlooked. *F. M.*

FIRST EARLY DAFFODILS.—It is the early bird that catches the worm. It is the early bloom that makes the profit for the market-grower. Here at Ard Cairn, Cervantes, a pale straw-coloured form, not unlike the well-known Irish Princeps, has been in flower under glass since the middle of December, and now out of doors it is full of flowers, and when this letter is published it will be in the fullest state of perfection. Large, late sorts will never get plentiful enough to remunerate the grower who wants to make ends meet. What we want is early varieties, with good constitutions, such as Princeps, Golden Spur, etc. I am sending some of the flowers of Cervantes. Poeticus præcox grandiflorus is also one to be noticed. It flowered here under glass at Christmas, and is now in full promise out of doors. As a fine, sweet-scented large-flowering sort it has no equal. Personally I have been working up stocks of all early sorts, the aim being that in years to come, not only in England, but all over the Colonies, the grower shall get his reward. There is another good early trumpet variety that I must mention, viz., Early Bird or North Star. It has a rather small bloom, but is a good grower, and flowers even earlier than Cervantes. I should like the Daffodil Committee to get together a collection of early sorts, no matter how small the flowers, provided the constitutions of the plants be good, and the petals still and imbricated. I have one of this class, but only a few bulbs of it. It promises to be the best thing in the market. It is now in flower out of doors, and is all that can be desired. *William Baylor Hartland, Ard Cairn, Cork. February 10, 1906.*

EXAMINATION IN HORTICULTURE.—The question of the value to gardeners of the examination of the Royal Horticultural Society has been put to me over and over again. Mr. Watson is perfectly right, and if the L.C.C. is making it "a test for promotion among gardeners," irrespective of any previous test for practical experience, I, for one, unhesitatingly say it is a wrong one. My reply to all questioners is, they must apply to whomsoever has superintended the examiners' practical work in the garden for a second certificate, independently of that of the Royal Horticultural Society. The examinations have great value in securing mental cultivation in the subject of horticulture; but they are unquestionably of little, if indeed it may be of any security, for skill in practical work. It is obviously impossible for the Society to undertake to estimate a young gardener's proficiency. Such is only possible after having seen how he has worked through each season of the year. *George Henslow.*

FUMIGATION WITH HYDROCYANIC GAS.—Having seen *A. D.*'s remarks on Mr. Dobson's article headed "Vaporising with Hydrocyanic Gas," and whilst agreeing with him as to the danger of the operation, I think that his query as to whether "the game is worth the candle" is premature. He should reserve his judgment until this method of fumigation has been given a fair trial, so that the relative conditions of temperature and atmosphere, and also the quantities of acid and cyanide required to obtain the best results, may be ascertained. *A. D.* states that "we have plenty of patent insecticides that are dangerous to neither man nor plant," but I question if any one of them approaches in either cheapness or efficacy the method described by Mr. Dobson. As to his statement that "what gardeners have done they can do," surely this is not the spirit in which to meet any attempt to lessen and facilitate the numerous and arduous duties of the gardener. If *A. D.* were to ask any gardener of advanced age and life experience whether he would like to do without the appliances and innovations that have come into use during the last 40 or 50 years, I don't think he would be answered in the affirmative. The experimental efforts of Mr. Dobson are surely deserving of encouragement, not of the hasty criticism meted out by *A. D.*; at least, that is the humble opinion of *B. M. H.*

CYANIDING.—All who desire to try this fumigant should write to Strawson's, Queen Victoria Street. Mr. Strawson knows more about cyaniding than any man living, and his treatise as published is extremely simple. *T. A. Weston.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 13.—*Present:* Dr. M. C. Cooke, V.M.H. (in the chair); Dr. M. T. Masters, F.R.S.; Sir John Llewelyn; Messrs. Massee, Douglas, Saunders, Worsley, Keeble, Michael, Gussow, Nicholson, Lynch, Cuthbertson, Druery, Sutton, Rolfe, Hemsley, Bowles, and Chittenden (Hon. Sec.).

Apples with Median Lateral Groove.—In reference to these shown at previous meetings by Mr. SPENCER PICKERING, Mr. G. S. SAUNDERS showed figures of some fruits collected some time ago at Cheltenham deformed in a similar manner, except that the groove ran round the Apple in a spiral manner.

Grubs in Stem of Common Laurel.—From R. W. BOURNE, Esq., of Bishopstoke, came specimens of insects taken from the stem of the common Laurel, and branches showing aerial roots from the surface similar to those so frequently found in this shrub when grown in damp, close situations. Mr. BOURNE stated that the grub, which was small and white, but later brown, "appeared to work upwards and to kill the branch by destroying the inner part of the bark, the leaves on the attacked branches turning yellow, and dying. Branches about 1½ inches or more in diameter are usually attacked." Mr. G. S. SAUNDERS reported that the Laurels are "attacked by the larvæ of a small moth, one of the Tortricinæ, most probably Semasia wœberiana, but the insects cannot be the direct cause of the outgrowths, as they are found on pieces of the shoots that are not attacked by the caterpillars, but they are probably formed indirectly from this cause. The burrows of the larvæ may weaken the branches by to some extent cutting off the food and water supply, and they may in self-defence, as it were, start these adventitious roots.

Galls on Ash.—Mr. G. NICHOLSON showed terminal growths of Ash which had been malformed and caused to produce numerous lateral and adventitious buds through the attacks of the mite, Eriophyes fraxini. This particular gall appears more rare than many caused by the attacks of other members of the genus.

Vines Attacked by Weevils.—Dr. MASTERS drew attention to some young shoots of Vine which had just started, but which had been bitten completely through by a weevil, probably Otiorhynchus sulcatus.

Pelargonium Diseased.—Mr. WORSLEY showed leaves of a zonal Pelargonium which were spotted with numbers of small, brown, dry spots. Mr. WORSLEY said that the disease spreads rapidly, and that eventually the plant died as a result of the attack. Mr. MASSEE took the leaves to examine further. Mr. WORSLEY also showed some mealy bugs which had come from Jamaica with Bananas. Mr. SAUNDERS took them to examine.

Galls on Birch.—Mr. HANS GUSSOW showed some of the large malformed growths which are so common on the silver Birch, where the buds are injured by mites, and as a result produce numberless lateral and adventitious buds forming a confused mass of growths similar to those shown by Mr. NICHOLSON on the Ash. The mite in this case is Eriophyes rudis.

Scale on Willow.—Mr. LYNCH, who was heartily congratulated by the committee on the occasion of his receiving the Victorian Medal of Honour,

showed shoots of Willow badly attacked by a scale insect, a species of Chionaspis salicis, Linn.

Variation in Potatos.—Dr. MASTERS commented on the remarkable exhibit of Potato varieties shown in the hall by Messrs. SUTTON. Mr. A. SUTTON drew special attention to Solanum Commersoni and to a specimen of the tubers raised by Mons. LABERGERIE, which that gentleman called S. Commersoni Violette, as he considered it to have originated as a sport from S. Commersoni. Mons. P. VILMORIN, who had grown S. Commersoni for many years (and, like others, had never found any sporting proclivities in that species), regarded the alleged sport as a tuber of the Blue Giant, which has been in cultivation for a long period, and which had by some accident got mixed with the tubers of S. Commersoni. Mr. SUTTON showed *Blue Giant* and the alleged sport side by side, and pointed out that the slight differences between the two were only such as might be expected when two examples of the same variety grown in widely separated districts were shown side by side. Mr. WORSLEY pointed out that Mons. HAECKEL claimed to have obtained intermediate forms between S. Commersoni and the alleged sport, and Mr. SUTTON said that M. LABERGERIE considered that he had seen the sport reverting completely to S. Commersoni.

PLANTS EXHIBITED.

1. Mr. R. I. LYNCH, V.M.H., of Cambridge, showed a flowering specimen of *Alpinia officinarum*, Hance, the "radix galangæ minoris" of the pharmacologists, a plant that very rarely flowers in this country.

2. He also showed some specimens of *Rosa lævigata*, a large-flowered species of Rose, which he thought useful in corridors.

3. *Crocus veluchensis* (Herb). — This Grecian species now for the first time seen in cultivation, was shown by Mr. A. E. BOWLES, F.L.S., who compared the actual specimens with the published figures. The present species differs from C. vernus and C. banaticus in its diphyllous proper spathe and in the absence of basal spathe; from C. Sieberi (specimens of which were also shown) in the absence of the yellow spots in the throat and in the small corm.

4. Dr. MASTERS showed flowering specimens of *Daphne odora*, which proved perfectly hardy in the open. *Prunus Mumé*, one of the Japanese Plums, and *Jasminum primulinum*, a newly introduced Chinese species, all cut from the open ground, and sent by Mr. VEITCH, of Exeter.

5. Mr. A. SUTTON, F.L.S., showed specimens of a species of *Pleione*, *P. yunnanensis* (Rolfe), which had been sent to them by a missionary from China, and had been grown on by them. The greater number of species of this genus are native in the mountains of India, but this came from further to the north-west, and was taller than the majority of the Indian species. On the motion of Dr. MASTERS, seconded by Mr. DRUERY, a Botanical Certificate was unanimously awarded to this plant.

American Blight on Apples.—From L. L. SAVILL, Esq., came shoots of Apple badly attacked by the well-known American blight. He remarked upon the fact that the tits seem particularly fond of pecking the swellings and canker-like growths produced by this pest on the branches, and presumably devouring the aphides.

Celery Woody and Spotted.—F. A. GREGSON, Esq., of Cranleigh, sent Celery, complaining that the plants were always woody, and lacked the nutty flavour which is desirable, this being specially the case when the crop was grown on sand, less so when they were grown on clay. The members of the committee considered that in all probability the defect was due to lack of water during the hotter part of the year.

Orchids with Spots on Leaves, &c.—E. F. CLARK, Esq., of Chamonix, Teignmouth, sent parts of Orchids, chiefly Cattleyas, which were spotted and deformed in growth. While fungi were certainly present in some of the spots, it was thought that the primary cause of the trouble lay not so much with the fungus as with a too wet compost and lack of air to the roots, and possibly a too damp atmosphere.

THE SOCIETY FOR HORTICULTURAL SCIENCE.

This society held its fourth annual meeting in New Orleans, beginning December 29th.

THE PRESIDENT'S ADDRESS.

The address of the president, Prof. L. H. BAILEY, dealt with the recent progress in American horticulture, covering the period since 1902. This progress, the Professor holds, has been largely along the line of further development of work already established rather than in the projection of entirely new lines. The most active agents in the progress of horticulture along educational, scientific, and literary lines are the horticultural and agricultural colleges and experiment stations, and the U.S. Department of Agriculture. Through these agencies there have been published during the past three years nearly 600 bulletins on horticultural subjects.

In technical horticulture plant-breeding is occupying unusual attention. The work of Mr. Burbank was stated as remarkable and significant, but often sensationalised and overstated. In commercial horticulture there has been a remarkable development in various directions.

Very valuable work has been done by the Division of Pomology of the U.S. Department of Agriculture by showing the relation of cold storage to the handling of fruits. Green or unripe fruit is undesirable for storing. It is not matured, remains unpalatable in quality, and is liable to "scald." Ripe fruit, carefully handled and put directly into proper cold storage, will keep a very long time. Investigation of the Californian methods of picking and handling Citrus fruits has shown that carelessness in clipping stems, in handling the individual fruits, and delay in putting the fruits into storage, result in a relatively short life and a high percentage of decay.

In fruit growing there appears to be a marked tendency toward better grading, smaller packages, and dessert quality.

The wholesale cut-flower trade is increasing. Increased attention is being given to the adornment of home grounds and to the use of native plants for this purpose, particular attention being called to the genus Cratægus. Attention was called to the valuable work of the Office of Seed and Plant Introduction of the U.S. Department of Agriculture, in the introduction of thousands of new species, strains, and varieties of plants.

THE INFLUENCE OF COLOURED LIGHT ON PLANT GROWTH.

In a comprehensive paper on light as a factor of plant culture, V. A. CLARK discussed the effects of various coloured lights, of direct and diffused sunlight, and of various artificial lights on the growth of plants. Light rays of different wave lengths have very different effects on plant organisms. The red rays of the spectrum in general promote vegetative growth, particularly that of the leaves, while the more refrangible blue rays act upon the molecular structure of the plant giving rise to mutations. In arid regions direct sunlight is injurious to many plants, and the successful culture of such plants depends upon furnishing them with partial shade. The composition of light was stated to be of much greater importance than its intensity. The electric arc light, being very rich in chemical rays, should prove of special advantage where vegetative growth is sought. Roots and stems require no light. Tender stem growth in the case of Celery is secured by the exclusion of light. Rhubarb stems also develop best in darkness when forced, and some plan of excluding the stems from light in field growth should be found. Leaf growth is largest and tenderest in light of rather low intensity, a fact which suggests the desirability of growing salad plants in partial shade, or, better still, in red light. The use of the blue light inhibits leaf growth. This might have particular application in regions of intense sunlight in the growth of seedlings. Seedlings with normal leaves transpire too rapidly when transplanted, and often succumb. Growing them in blue light would reduce their size, and hence better adapt the plant to growth under arid conditions where transpiration from large leaves would be excessive. From observations in Arizona, it is believed that the intensity of direct sunlight is greater than the intensity most favourable to bud formation, and that better results would be obtained with very light shading on the south and south-west sides of fruit trees. The suggestion is made that in flower growing the plants should be grown in red light until the flowering period, and then grown in blue light, which favours flower development. Volatile oils appear to develop best in red light. Flowers grown for fragrance might be grown in a combination of red and blue light.

The growth of plants in normal white light was stated to be a kind of compromise between conflicting interests. Instead of thus growing plants under one unvarying condition, they should be grown in the kind of light most suited to the particular stage of development and the use to which the crop is to be put. Strong light has been found in some instances to inhibit the growth of the pollen tubes. This is thought to be the reason why Tomatos and Cucumbers do not bear fruit in midsummer in Arizona. Strong direct sunlight in summer also prevents the formation of chlorophyll. Thus, Strawberries are yellow for about three months in summer, even when grown under the shade of cheese cloth. When grown on the north side of a dense shade of Sorghum or cotton, the plants remain green and dense all summer, and are the most vigorous in the garden. It is believed that the matter of shading is of greater horticultural importance in arid regions than fertilisation is in the East.

HORTICULTURAL BOTANY.

Mr. L. C. CORBETT presented a paper on horticultural botany. He stated that horticultural botany commenced where systematic botany left off. Horticultural botany should give us uniform, detailed descriptions of our cultivated varieties of fruits, vegetables, and ornamental plants, together with a systematic classification and arrangement of such varieties. In a description of horticultural varieties, such matters, in addition to the usual descriptive notes, should be included as the history of the variety, parentage and line of descent, and its behaviour in breeding experiments—whether possessing a dominant or recessive character, etc. The matter of botanical and scientific nomenclature being still unsettled, Professor Corbett recommended that horticulturists should follow some standard guide as the Cyclopædia of American Horticulture.

ORCHARDS IN THE WESTERN STATES.

The Irrigated Orchards of the Western States formed the subject of a paper prepared by Mr. M. B. WAITE. The paper pointed out the increasing importance of orcharding in the Rocky Mountains Plateau and the adjacent arid regions of the western half of the United States, and called attention to some of the differences between these sections and the humid eastern United States.

POTATO SCAB.

Some interesting observations were forwarded to the Society by Prof. W. PADDOCK, of the Colorado Agricultural College and Experiment Station. From experiments carried out at the station, Professor Paddock questions whether eastern potato scab may not be due to Rhizoctonia rather than to Oospora. He suggests that Oospora may often be a parasite upon Rhizoctonia and not actually concerned in the scab at all. It is believed that the whole subject of potato scab is very much in need of investigation.

MR. BURBANK AND HIS WORK.

Prof. N. E. HANSON reported the results of a visit to Luther Burbank, in which he stated that some of our scientific workers are in danger of criticising Mr. Burbank's work too much, and suggests that before they criticise more they should produce one single seedling from their own work that in a measure approximates to the achievements of Mr. Burbank. Burbank makes constant use of the principle laid down by Darwin that excess of food causes variation. Top-grafting is extensively resorted to in his work, one Apple tree being cited which contains 526 kinds of Apples top-grafted upon it. The recent notoriety to which Mr. Burbank has been subjected in periodicals has resulted in thousands of people visiting his place and occupying his time, to the detriment of his work and health.

SOIL-HEATING.

Prof. U. P. HENDRICK presented the results of an experiment designed to test the effects of superheated soils on plants. The work was carried out in a greenhouse on Cucumbers. The bottom heat was supplied in bench beds, the soil of one section being kept at an average temperature during the experiment of 70.8°, of a second section at 73.8°, and of a third section

at 83.3° F. The plants kept in the soil at the highest temperature came up about three days earlier than those kept in the bed at medium temperature and six days earlier than those in the bed kept at the low temperature. There was about the same difference of time in the formation of true leaves. The plants bloomed in the hot bed in 35 days, in the medium hot bed in 39 days, and in the cold bed in 44 days. The first mature fruits were picked from the hot bed in 74 days, from the medium hot bed in 77 days, and from the cold bed in 82 days from seeding. The average number of fruits was slightly more in the medium hot bed, and they were a little larger than in either of the other beds.

Commenting on these results, Professor Hendrick stated that they represented but one experiment; the number of plants used was but 12 in each bed; much variation occurred in the behaviour of individual plants in the same bed; and that there was a slight difference in the position of the beds, but, so far as he knew, they represented the first recorded work along this line, designed to secure definite data regarding the best soil temperature in which to grow our various greenhouse crops. All that is available at present is the dogmatic assertion of gardeners to avail themselves of brisk or mild heat or none at all. Something more definite is needed, and he expressed the hope that others might take up work along similar lines.

Fruit Surveys.

H. P. Gould sent a paper on "The Significance of Fruit Surveys." He considered a fruit survey as involving "a study of varieties with special reference to their requirements; a study of conditions with special reference to this influence on varieties; a correlation of the factors brought out in these two lines of investigation with regard to cause and effect." A fruit survey of this character should assist growers in the selection of varieties for their conditions. The history of the American Pomological Society is that of a study of varieties and their adaptation to different localities and conditions. A commercial fruit grower no longer asks for the best variety, for, in its broad sense, such a one is known not to exist, but he requires a variety which will best serve a particular purpose under definite known conditions. A fruit survey should furnish information along these lines.

Scientific Problems in Louisiana

was the title of a paper presented by F. H. Burnette. Foremost among questions demanding attention in a scientific way in the growing of fruits is the late-frost problem. This is most serious perhaps in late February, when most of the trees are in bloom or have even formed small fruits. In addition to the usual methods of warding off frosts, he suggested the desirability of breeding up later varieties and more hardy varieties in the case of Citrus fruits. Breeding experiments with Apples seem to indicate that by this means varieties will be secured adapted to the home needs of Louisiana growers. Much improvement has been made in the case of Pecans, but other varieties are needed which will come into bearing earlier. Some trees also are self-sterile. The control of fungi is a serious problem in Louisiana, and resistant varieties are needed. This has been partially met in the case of New Orleans market Cantaloupe and New Orleans market Cucumber. Among Pears, Smith shows by far the greatest power of resistance. Some Oaks have been found upon which Mistletoe has not been able to gain a foothold. Seedlings of these are being grown to see if this character can be perpetuated.

Persimmons.

A paper by Mr. David Fairchild was presented on the "Japanese Method of Ripening Persimmons," from which it appears that ripe Persimmons, grown according to the Japanese method, are as firm in texture as a Northern Spy Apple, free from astringency, and of a delicious flavour. Investigations as to methods of curing ripe Persimmons show that the Japanese put the Persimmons in sake (Japanese beer) casks as soon as the casks are emptied. The heads of the casks are immediately replaced, and the package made air tight. In from 5 to 15 days, according to weather conditions, the Persimmons are cured and can be removed and marketed, keeping in a firm, edible condition for a long period of time. It is believed that if Americans wish to cure Persimmons according to the superior Japanese method, it would be advisable to make casks of southern Cypress and saturate them with first-class sake imported from Japan.

Forcing Rhubarb.

A paper entitled "Forcing Rhubarb in the Dark" was presented by W. R. Lazenby. Rhubarb roots grown from seed planted early in the spring are pulled out the following fall and allowed to freeze. The roots are then put in beds in the cellar, and covered from 2 to 3 inches deep with dirt, and kept in total darkness. With a temperature of 70° F., marketing the crop can begin within 20 days, and cuttings can be made for about four weeks. At a temperature of 55°, about 30 days are required before the first cutting can be made. Drying the roots was found to have about the same effect as freezing. Either drying or freezing serves the same purpose as a long rest, which is otherwise required, and the growth is more vigorous. When thus grown in darkness the leaf blade is greatly reduced; the green colour is wholly absent; the texture is more crisp and delicate, due to a lessened development of woody fibre; the skin is much thinner than when grown in light; the water content is increased 6 to 10 per cent.; and the flavour generally improved. The first two or three cuttings give the finest stalks. Two crops can be grown in the same space during the winter. By double cropping, $35.55 worth of stalks was sold from an area of 185 square feet.

Horticulture in France.

Mr. C. B. Smith gave a review of "Horticultural Progress in France," in which he summarised the experimental data that had appeared in that country during recent years on such subjects as the etherisation of plants, the methods of pruning by disbudding, and the results secured in the culture of the Uruguay Potato (Solanum Commersoni).

American Grapes.

Mr. T. V. Munson presented a paper on "Improvement of Quality in Grapes," considering the subject from the standpoint of improvement by cultivation, by selection of kinds, and by breeding or hybridisation. *C. B. Smith, Department of Agriculture, Washington.*

Obituary.

Mr. John Forrest.—We regret to announce the death of Mr. John Forrest, late head gardener to the Earl of Aberdeen at Haddo House, Aberdeenshire, which occurred after a few hours' illness at Craiglea, Culter, Aberdeenshire, on Friday, February 16. Mr. Forrest, who was in his 73rd year, retired from his position at Haddo House only last year, and had since resided at Culter, a beautiful spot on Deeside, some seven miles from Aberdeen. Previous to becoming head gardener he was foreman at Haddo House, after which he was for a time head gardener to the late Mr. Thompson, Banchory House, near Aberdeen. Mr. Forrest returned to Haddo House as head gardener in the year 1871, so that altogether he had been in the service of the Aberdeen family at Haddo House for nearly 40 years. On the occasion of his retirement in June last year Mr. Forrest was entertained by Lord and Lady Aberdeen at a garden party, to which were invited a large number of ladies and gentlemen residing in the district around Haddo House. On that occasion Mr. Forrest was presented with a number of valuable gifts from the Aberdeen family, the servants on the estate, and from neighbours, testifying to the esteem in which he was held. In making the presentations, Lord Aberdeen spoke in terms of cordial appreciation regarding the manner in which Mr. Forrest had not only devoted himself to the duties of his position as head gardener, but had also identified himself with all the interests and concerns of the family at Haddo House. Lord Aberdeen went on to say also that, beyond the immediate circle with which he was concerned, Mr. Forrest had been a most acceptable and desirable personality and influence in the district. The funeral took place at Methlick churchyard, near Haddo House, on Monday, February 19. Deceased had been a widower for some years.

William Chamberlayne Breese. — The loss of another good and respected gardener has to be mourned in the death on the 12th inst. of Mr. Breese, head gardener to Mrs. Ackers, Moreton Hall, near Congleton, in Cheshire. Deceased was sent to Keele Hall, Staffordshire, as a journeyman in 1859, by Messrs. Dicksons, of Chester. After four or five years he became head gardener on an estate in Ireland, and subsequently, after a further time spent at Keele, removed to Moreton Hall in 1872, where he succeeded to Mr. Mounsden. Mr. Breese was gardener at Moreton for nearly 34 years, and during the whole time was remarkable for growing excellent crops of grapes, particularly of the variety Muscat of Alexandria. But he was a generally good, all-round gardener, and the Moreton Hall gardens were kept always in an exemplary condition. A man of high character, kind heart, and good professional experience, deceased was well qualified to judge at horticultural shows and was frequently invited to do so. Mr. Breese was in the 69th year of his age, and succumbed after a few days' illness to an attack of pneumonia. His name has appeared year after year among those correspondents who have contributed to our annual report on the condition of the fruit crop.

THE WEATHER.

GENERAL OBSERVATIONS

The Following Summary Record of the weather throughout the British Islands, for the week ending February 17, is furnished from the Meteorological Office:—

The *weather*. The general character of the weather was changeable. Several very bright intervals were experienced in almost all districts, but few days passed without a fall of rain or showers of hail, sleet or snow. The snow was heavier and more general in the north than elsewhere. Lightning was observed at Fort William on Wednesday and Thursday, thunder and lightning occurred at Newquay on the former day, and thunder at Swanaton on Friday.

The *temperature* was again below the average, the deficit being least (1·2°) in England and greatest (about 4°) in Ireland. The highest of the maxima were recorded late in the week, and ranged from 51° in England and the Channel Islands to 45° in Scotland N. The absolute minima, which were read during the earlier half of the period, were as low as 11° or 12° in Scotland E. and N., at Balmoral and Fort Augustus respectively, but elsewhere varied from 22° in Scotland W. and 23° in the Midland Counties to 27° in Ireland N., and to 32° in the Channel Islands.

The *rainfall* was in excess of the average over the Kingdom generally, but below it in Scotland E. and England N.E. In Scotland W. and England N.W. the amount for the week agreed very closely with the normal. The excess was greatest in the south and south-west of England and the Channel Islands.

The *bright sunshine* exceeded the mean in all districts except England N.E. and the Channel Islands, the excess in most instances being large. The percentage of the possible duration ranged from 43 in Ireland S. and 42 in Scotland W. to 29 in the Channel Islands and England N.W. to 26 in England E. and the Midland Counties and to 23 in England N.E.

THE WEATHER IN WEST HERTS.

Sunshine after rain.—The spell of wintry weather lasted only a few days, when a return to somewhat less inclement conditions took place. During the past week there were only two unseasonably cold days, and only one unseasonably cold night. On the other hand, there were no really warm temperatures for the time of year. The ground is now at both one and two feet deep at about an average temperature. The most noteworthy feature of recent weather has been the frequent falls of rain and snow. In fact, since the present month began there have been only two days on which no rain at all fell—the total fall for the three weeks amounting to two inches, or about the average for the whole month. To show how persistent the rainfall has lately been, I may state that during two consecutive days of the past week there were only 15 rainless hours. As during the greater part of the week the atmosphere remained damp nearly the whole of the rain, as shown by the percolation gauges, must have gone permanently into the ground. The first and last days of the week were particularly sunny, but during the intervening five days the sun shone for altogether only 1½ hours. The wind has been, as a rule, moderately high, and on one day the mean hourly velocity for the 24 hours was 14 miles, and in the windiest hour 18 miles was recorded—direction west. The mean amount of moisture in the air at three o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent. Vegetation is not now as forward as it was at the beginning of the month A selected patch of yellow crocuses first showed an open flower on the 20th, which is three days earlier than its average date of flowering in the previous 19 years. *E. M., Berkhamsted February 21, 1906.*

MARKETS.

COVENT GARDEN, February 21.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Remarks.—Fruit received this week from the Cape include Williams' Bon Chrètien Pears and Kelsey Plums, both of which arrived in splendid condition. Peaches from the Argentine Republic are also in fine condition, and are carefully packed in trays containing 15, 18, and 30 fruits. Good culinary Apples are scarce and in consequence dear. The vegetable and fruit trade generally is quiet. *E. H. Rides, Covent Garden, Wednesday, February 21, 1906.*

COVENT GARDEN FLOWER MARKET.

The trade in plants shows little improvement, and supplies are still in excess of all demands. Indian Azaleas are now of very good quality, the clear pink and the bright scarlet varieties being in most demand, although good "whites" also sell. Azalea mollis is seen in soft shades of colour, but the demand for these plants is always uncertain. Erica Wilmoreana is now in the market, the plants being fairly well flowered. E. hyemalis are now getting past their best condition. E. gracilis is still very good, also E. fastigiata. Cyclamen are plentiful and good. Supplies of Hyacinths continue excessive, and are disposed of for low figures. Tulips in pots are also abundant, while the stock of these plants grown in boxes is so large that many remain unsold at closing time. Daffodils in pots are good. Boronia megastigma and Acacia Drummondi are seen in various-sized plants. Orange plants in fruit, and others in flower, can be had. Solanums are plentifully berried, and have good foliage. Cinerarias from several growers are very good. A few plants of Deutzia gracilis are seen, but Spiræas have supplanted these plants, so that there is little demand for the old favourite. The Spiræas are plentiful and fairly well flowered; some are, however, of poor quality. Among Ferns are well-grown specimens of Nephrolepis, Pierson, Asplenium nidus, Davallias, Adiantums, and the usual sorts of Pterises, Cyrtomiums, Polypodium aureum, &c. Trade in these plants is not brisk. Palms in all sizes are well supplied. Some very small, useful-sized plants of Kentia Belmoreana are seen. Aralia Sieboldi is sent in good condition by some growers, but there are other weakly, drawn plants. There is no lack of Asparagus tenuissimus and A. Sprengeri, but not many good A. plumosus.

Cut Flowers.

There seemed a prospect of better trade last week, but things were again quiet all round this morning. The growers are still sending Chrysanthemums. I saw some very nice blooms this morning, but there appears little demand for them. Daffodils, including many of the Barri section, still flood the market. Carnation Madame Therese Franco (syn. Mrs. Leopold de Rothschild) is extensively grown, but the American varieties are fast taking the place of the winter flowering English Carnations. In Roses not many large blooms on long stems are seen. A few fairly good flowers of Kaiserin Augusta Victoria are to be had; also some of Liberty and Bridesmaid, but most of the Roses are only of medium size. General Jacqueminot is coming from several growers, and prices for this variety are low, but after the first crop prices may increase again. In Tulips the double varieties have made the best prices, especially the deep yellow Coronne d'Or, which has been very fine. Crimson, pink and white varieties are all good. A few of the finer sorts of single Tulips have also made fair returns, but generally Tulips have realised far less than did last season's crop. Liliums are in demand. Best quality Callas are plentiful and vary but little in value. In Orchid blooms are seen Dendrobiums, Cœlogyne cristata and Odontoglossum. Freesia refracta is sent by both home and foreign growers. Violets continue very plentiful. Anemone cardinalis and other varieties of the coronaria type are very bright. Mimosa is still plentiful. Roses are imported in fair condition but, with the exception of Safrano, their petals drop soon after being exposed. Ornithogalum (Star of Bethlehem) is now seen. Jonquils and other Narcissus of the polyantha type arrive in large quantities. *A. H., Covent Garden, Wednesday, February 21, 1906.*

TRADE NOTICE.

The Shepherds Bush Exhibition.—We are informed that Mr. John Russell, of Haverstock Hill, N.W., has been entrusted with the laying out of the grounds, and planting of same of the new Exhibition, Shepherds Bush.

ANSWERS TO CORRESPONDENTS.

Books : *L. W.* A single volume of Sweet's *Flower Garden* would not be of much value.

Buttonhole : *C.* We do not know that the term "Buttonhole" as applied by florists can be held to mean only a single flower with suitable relief. Your suggestion that a "gentleman's buttonhole" should not consist of more than one flower is, however, in accordance with the general idea on the matter, and when such a flower as for instance an Odontoglossum is selected, more than one specimen might very reasonably be considered to be superfluous. But that it is difficult to make any absolute rule is apparent when it is remembered that, whilst in the case of the Odontoglossum one flower from a spike is sufficient, it Lily of the Valley be used a whole spike of flowers would certainly be chosen. In drawing up the schedule therefore, it would be best to say "flower or flowers arranged for a gentleman's buttonhole," and leave the judges to determine whether or not individual exhibits are larger or smaller than good taste would approve.

Emigration to New Zealand : *R. H. T.* We have not the means of knowing what are the exact wages obtained by gardeners in New Zealand. Several young gardeners of our acquaintance who emigrated to that colony some 15 years ago have succeeded well. There can be no doubt but New Zealand, with its good climate, offers excellent prospects for young men, whether gardeners or not, of sound constitution, who have a small capital, and who will be content to work at whatever may come in their way. Naturally enough, professions and trades are not specialised to the extent they are here, and it is therefore the "handy" man who succeeds best.

Employment in Private Garden or Nursery : *J. B.* We are not quite sure that we fully understand your question. The conditions of a

"head" gardener in a private establishment are not quite similar to those of manager of a market growing establishment, because in the former case he is regarded as a domestic servant, and is therefore subject to the conditions governing domestic servants.

ERICA HYEMALIS: *C. D. H.* Your plants were cut back much too late to flower last season, and everything will now depend upon their condition at the present time They may only require to have the tops taken from the strongest shoots. Under any circumstance they should not be cut back severely. In order to get the plants to flower well they should be grown throughout the summer in the open air in a position where they will be fully exposed to the rays of the sun. Applications of soot-water and a little liquid manure may be made to the roots early in the summer, but such applications must be discontinued after August, or the plants would continue to grow, but fail to flower. Even plants that are well furnished with bloom buds may fail to expand them if improper treatment is afforded after they are taken under glass. Ericas require plenty of light and air, and must be subjected to only sufficient artificial heat to exclude frost. Owing to the prevalence of dull weather many market-growers failed to flower this Erica well last season.

GARDENING SITUATIONS IN AMERICA: *W. J. G. and many others.* It was pointed out by *T. E. R.* on p. 84 that no situation can be legally filled by advertising from this or any other country outside the States, or by becoming engaged before landing. If you have sufficient means for the purpose, your better plan is to proceed to some large centre—New York or Boston for preference—and then advertise in the papers, or offer yourself for employment to a nurseryman. According to *T. E. R.*, New York seedsmen are always willing to give advice to young men from this country even though they can offer them no employment in their own nurseries; and he further states that March and April are the best months to arrive there. With regard to the wages of head gardeners and foremen in the United States, they vary greatly, as they do also in this country. They are higher in the States than here, but this advantage is in some measure discounted by the extra cost of living in America. You should be able to judge somewhat from the prices mentioned by *T. E. R.* as paid to journeymen. His letter is certainly encouraging to intending emigrants. For securing a situation in Canada *H. D.* should advertise in a Canadian horticultural paper, such as the *Canadian Horticulturalist*, whose address is Grimsby, Ontario, Canada. The restrictions covering the question of labour in the United States do not, of course, apply to Canada. Many of our correspondents on this question have enclosed stamps for reply by post; but, as we have stated on many former occasions to do so would seriously interfere with our primary duty of preparing the weekly issues of this journal, and we are therefore obliged to make it a general rule not to reply to such communications except through these columns.

GREENHOUSE HEATING: *V. C., Paris.* Apply to one of the horticultural builders in Paris, who will be much more conversant with the requirements of the district than we can be.

GROS COLMAR GRAPES: *Grape.* This is a late-ripening Grape, and as such is not generally forced to ripen early, either in private or market establishments. The earliest ripe bunches that we have known were ready about the beginning of August, but fruits could be ripened earlier if desired by applying a considerable amount of heat, and this would probably improve the flavour.

HOME FOR GARDENERS: *Excelsior.* There is no home exclusively for gardeners who have become unable any longer to follow their employment. But as you are in a position to pay ten or twelve shillings each week we think it should not be difficult to find a philanthropic institution of a general character that would meet your requirements.

LANDSCAPE GARDENER: *N. L.* We cannot help you in this matter. Advertise the fact that you require a situation as improver.

LIMEWASH ON WALL: *Correspondent.* Scrape off as much as you can by means of an iron or steel scraper, then scrub the wall with vinegar or a weak dilution of sulphuric acid. Do not use the sulphuric acid if there are fruit trees near to the wall, or you will injure or destroy the roots, and mind you do not scald your own hands.

NAMES OF FRUITS: *Gardener, Norfolk.* We still think the Apple is of the variety "Sam Young." The specimen you forwarded was compared with others of that variety. The following description of "Sam Young" is taken from Dr. Hogg's *Fruit Manual*:—"Flesh yellow, tinged with green, firm, crisp, tender, juicy, sugary and highly flavoured. A delicious little dessert Apple of first quality." We do not consider this very old variety large enough for market purposes. Twenty dishes were exhibited at the Apple Congress at Chiswick in 1883. Do not plant either Rymer Pippin or Brabant Bellefleur. There are newer sorts equally attractive and of better cropping qualities, and very few nurserymen now stock Rymer or Brabant Bellefleur.—*X. Y. Z.* Pear Bellissime d'Hiver; Apple French Crab.

NAMES OF PLANTS: *H. C.* Brunfelsia latifolia. —*H. K.* Senecio Petasitis.—*A. L.* Jasminum Sambac, double flowered form.—*X.* Cypripedium Fitchianum (venustum × Hookeræ Bullenianum). The Dendrobium is a variety of Wardianum.—*J. G.* 1, Aralia trifoliata; 2, Kalmia latifolia; 3, Andromeda floribunda.—*J. D. M.* 1, Dracæna nigro-rubra; 2, Dracæna Reginæ; 3. Dracæna hybrida; 4, Dracæna intermedia; 5, Dracæna terminalis. The insects are the common cockroach. The sooner you get rid of them the better for your plants. Use Phosphor paste which is Poison.—*J. P. R.* 1, Abutilon megapotamicum variegated form; 2, Abutilon Savitzii; 3, Reineckea carnea; 4, Ophiopogon Jaburan; 5, Pteris cretica; 6, Acacia dealbata.—*R. E.* Lopezia racemosa, *Bot. Mag.*, t. 254.—*J. S. and Sons.* Rhododendron (probably) Veitchii.

ONION: *W. H. S.* We believe there is no record of the introduction of the Onion to this country. The wild plant is indigenous in central Asia, and probably cultivated Onions were known in Britain in Anglo-Saxon days.

PLANTS AT KEW: *A. T.* The indoor plants in the Royal Gardens, Kew, are cultivated as well as it is possible to have them with the means at present available, and considering the enormous number of species contained in the collection. The commercial growers, and the private gardeners in some instances, are able to devote a whole structure to a single species, or even variety, and are thus enabled to afford the exact conditions that are most suitable for that particular plant. In a botanic garden of such importance and richness as that at Kew this special grouping is generally impossible, for it is only in connection with the cultivation of the smaller decorative plants that frames can be used in any but the early stages of growth. Recognising these important factors, we believe it will be generally conceded that the plants in the houses at Kew are a credit to all concerned in their management, though we cannot assert that they "represent the highest state of culture of which they are capable in this country." It is now mid-winter, but we believe that economic plants in fruit include Oranges, Lemons, Bananas, Guavas, Dates, Vanilla pods, Granadillas and Prickly Pears. Many other economic species, owing to the conditions of cultivation they require, could not be fruited in this country except at very great expense, which is prohibitive. We agree with you that if they could be it would be an advantage. Probably you have heard the statement that it cost the Duke of Northumberland £1,000 to fruit the Mangosteen?

PLANTS RECEIVING INJURIES FROM FUMES: *G. H.* The injuries are doubtless caused by the fumes from the heated pipes which have been coated with so many substances. There are only two methods of preserving the plants open to you. (1) Remove them to another house, and freely ventilate this one for a period, or (2) if this be impracticable employ a little ventilation by day and night, and keep the water pipes sufficiently hot to maintain the temperature needed by the plants. After a time the injuries will cease.

ROSES AFTER GRAFTING: *R. M.* The cause of the scions turning black as described may be due to various reasons. When performing the operation of grafting it is necessary to use a very sharp knife, and the bark of the scion and stock should be made to meet at least on one side. The same angle at which the stock is cut should be reproduced on the scion, that a perfect fit will result between the two, and there will be no space for air. This latter condition is a very necessary one, for an attempt to bring the two surfaces into contact by means of raffia where they did not fit properly would bruise the scion and consequently cause it to become black. Unripened wood or wood which has been injured by frost would, if used as grafts, become discoloured when taken into heat, although to all appearance sound when cut. It is necessary to use firm, hard wood to ensure success at this season, and if it is taken from pot plants, or from plants growing under glass, so much the better. The atmosphere of the frame should be kept close, and be kept at the temperature of 60°. Very little water should be given the stocks whilst they remain in the frame, and when water is necessary each stock must be watered individually from a spouted can, that no more moisture will be caused in the atmosphere than is unavoidable. When the lights are taken off each morning let the glass be wiped dry, and if it is noticed that much moisture has condensed on the glass again before evening, again wipe it dry. Carefully shade the frame from all sunshine, and cover the raffia binding with a little painter's knotting or French grafting wax rubbed on with the forefinger.

SOOT: *Enquirer.* On analysis an average sample of soot will be found to contain 43 per cent. of organic matter, in which is about 5 per cent. of ammonia, 10 per cent. of carbonate of lime, 6 per cent. iron oxide, and 15 per cent. insoluble silicious matters. From some experiments by Johnston and Cameron it was found that 56 bushels of soot mixed with 6 bushels of common salt and sown on an acre of land produced larger crops of Carrots than 24 tons of farmyard dung with 24 bushels of ground bones. Applications of soot to Onions, Asparagus, Celery, Peas and other vegetables have been followed by remarkable success. Few manures are so effective for fruit trees and bushes as soot, and it has been found in practice that hardly any manure has the effect of colouring fruits so highly as a liberal dressing of soot. It forms a capital dressing mixed with leaf-mould for impoverished lawns when moss is prevalent. For outdoor work soot should always be applied during damp weather. The most important conditions in regard to soft-wooded plants are the provision of a suitable medium for the formation of roots, with abundance of moisture, but without stagnation. Hence it is that many of the successful propagators use soil only in the lower portions of the cutting-pot, the upper part being filled with clean sand. To the soil previous to use may be added 2 lbs. of soot to a bushel of loam; this will be conducive to health and vigour of root-growth. A little bone-meal may also be added. As soot contains so large a proportion of carbonate of lime, a direct application of quicklime is never necessary or advisable when soot is used.

TEAK: *U.* We do not know of any special work on this subject.

TWIN TULIPS: *R. W. R.* The appearance of more than one flower on the inflorescence of Tulips is not uncommon. Both are derived from separate growths, but fusion takes place later, resulting in an apparently branched peduncle. If you make a transverse cut of the stem at the point where the flowers branch you will clearly see indications of the two stalks.

VIOLETS DISEASED: *Anxious.* Your plants are attacked by the disease so prevalent among Violets at the present time. It is caused by a fungus—Ascochyta violæ. If your plants are badly affected, the better plan is to burn them and plant new healthy stock obtained from a distance. Choose a fresh site in the garden for the new plantation. If you do not wish to destroy the old beds try spraying with potassium sulphide. Use 1 oz. of the chemical to 3 gallons of water, and apply at intervals of a fortnight. See our issue for November 5, 1904, p. 328.

POTATOS.

AMID the piles of picked Potatos which were displayed by Messrs. Sutton at the Royal Horticultural Hall a short time since, there was a little glass case whereon reposed, like so many gems in a jeweller's shop, a collection of tiny tubers which might well have been overlooked by the indifferent spectator. The picked samples were for the public eye—they represented what has been accomplished; they appealed to the cultivator, they aroused the attention of the consumer. But the "gems" reposing on their velvet cushions had a different value. They were the forerunners of what is to be; they attracted the attention of the botanist, they whetted the curiosity of those interested in the progress of the Potato; they excited the hopes of those who are on the look out for a Potato which shall prove more or less immune to the attacks of the Potato disease. Already by the production of Discovery Messrs. Sutton have made a great advance in this direction, and they may do more. By the courtesy of Messrs. Sutton we are enabled to give representations of some of these treasured tubers, drawn for us by Mr. Worthington Smith. The first we shall mention is the fir-cone Potato, fig. 49, which is a mere curiosity, but a very interesting one, as proving to the ordinary observer what has been always known to the botanist that the tuber is merely a shoot, just like any other shoot except in its subterranean habit and its thickened fleshy consistence. Gardeners speak of the tubers as "seeds," though, of course, such an epithet is as incorrect as is the use of the word "apple"

FIG. 49.—EXAMPLES OF THE FIR CONE POTATO.

to denote the fruit or berry, which has absolutely no resemblance whatever to an apple. The fir-cone Potato, with its thickened leaf-scales spirally arranged, is obviously nothing more nor less than a leaf-shoot, every bud or "eye" of which, if detached, might serve to propagate the variety. This Potato is not only curious to look at and interesting morphologically, but it is of good flavour when cooked. The colour of the tubers varies.

The tuber marked "tuberosum" in the upper left-hand corner of fig. 50 shows what the original Potato was like, and is interesting to compare with the Magnum Bonums and Sir John Llewellyn of our present time. Next to it a tuber of Solanum Maglia, a Chilian species, growing naturally in damp places. The tubers are sub-globose, deep purple-skinned, with sunken eyes. In August 1886, when we first saw this species at Reading, we noted a tendency to revert to the wild condition, and to the formation of stolons of considerable length, tuberous at the end, or, in other cases, upturned, and producing a tuft of leaves.

There seems little doubt that S. Maglia is the parent or one of the parents of our ordinary Potato. Messrs. Sutton have succeeded in effecting a cross between this species and an ordinary Potato.

The globose tuber labelled Papa d'Amarilla came originally, we believe, from the neighbourhood of Lima. It is a yellow-fleshed variety of delicate flavour, and in the hands of Messrs. Sutton we may look for some remarkable developments in the future. We have not seen the haulm or the flower. We may here mention that whilst the haulm and the foliage are very variable, and consequently of little value for purposes of determining one species or variety from another, the flowers, and especially the calyx segments, are much less subject to variation, and thus offer better differential characters. The last figure, in the lower right-hand corner of our illustration (fig. 50), represents a tuber of S. Commersoni, a distinct species which has been in cultivation for some time. It has lately attracted attention from the statement made by M. Labergerie that from this yellow-skinned variety he has obtained a sport of large size and the skin purple. Messrs. Sutton showed, side by side with some tubers of M. Labergerie's variety, some of the variety known as Blue Giant, and not even the experts could distinguish any difference between the two sets of tubers as shown. That there may be differences in the manner of growth, haulm, &c., is quite conceivable, indeed good witnesses affirm that there are such differences, so that the matter must for the present be left open. Other Potatos exhibited in this group were the Black Congo, in which both skin and flesh are of a rich purple colour. This is described as excellent in flavour, and is used in salads like beet-root, for ornamental purposes. Whether the Potato, as we now know it, originated from one species like S. Maglia or whether, as M. Andre thinks, several species have concurred in its production, is a matter that cannot with certainty be determined at present, but the experiments made with so much care by Messrs. Sutton for so many years may very likely lead to the solution of this and other problems connected with the Potato, whilst their value from an economic point of view is already incontestable.

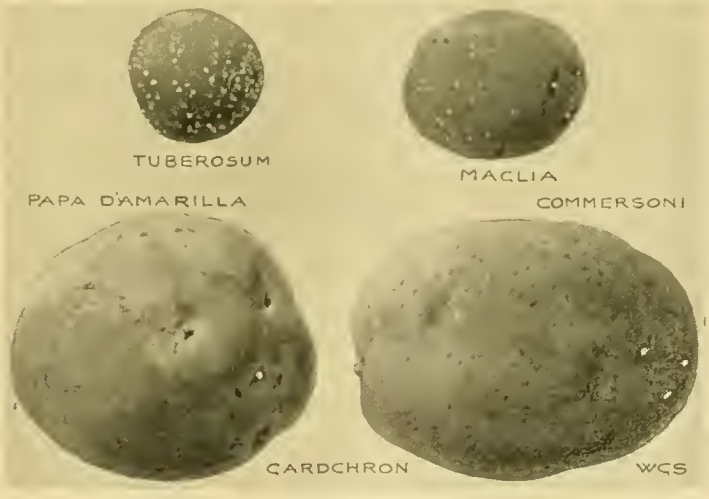

FIG. 50.—SPECIES OF POTATO.

NEW AND NOTEWORTHY PLANTS.

ALOE LAXIFLORA, N. E. BROWN (*N. Sp.*).

This new Aloe belongs to the same group as the well-known A. ciliaris, A. tenuior, and A. striatula, to which latter it is perhaps most nearly allied and similar in habit. It was sent by Mr. P. G. Griffiths, of Port Elizabeth, Cape Colony, in 1897, to Kew Gardens, where it flowered in December, 1902. Its distinctive features are the very lax arrangement of the flowers, horizontal bracts and pedicels, and long, vertically pendulous perianth, with brownish margins to the inner segments. The leaves, too, although straight in their general direction, are yet slightly but distinctly sinuous, both laterally and vertically, in their upper part, in a manner difficult to express in words.

Stem of the Kew plant about 4 feet high, erect, about ½ inch thick, leafy along the upper 2 feet. Leaves very lax, ½-1 inch distant, 4½-10 inches long, ½-1⅓ inch broad at the base, ⅛-⅛ inch thick, almost horizontally spreading, nearly straight, neither deflexed nor recurving, of nearly equal breadth almost to the middle, then gradually tapering to an obtuse, denticulate apex, slightly sinuous at their upper half, soft, concave above, except at the flat base, convex beneath, rather dull deep green, without spots, not in the least glaucous. On the upper side of the basal part near one margin are usually one or a few minute tubercles in a line, none on the underside; marginal prickles minute, ⅓ line long, ½-1½ line distant, cartilaginous, white, numerous, almost obsolete near the apex; sheath quite entire, indistinctly marked with green lines. Peduncle simple, erect, about 16 inches long, ⅛ inch thick, naked below the flowering part, two-edged at the base. Flowers 20 to 30, in a very lax raceme, 3-4 inches long, 1¼ inch in diam. Bracts 2 lines long, ¾-1 line broad at the base, where they embrace the pedicels, thence tapering to a very acute point (deltoid-acuminate), horizontally spreading, pale brownish-white, submembranous. Pedicels 4 lines long, horizontally spreading, green. Perianth vertically pendulous, 1⅓ inch long, 2½ lines in diameter at the base, and slightly less at the apical part, trigonous, straight, orange-red on the basal ⅔, light yellow on the apical part, with a greenish keel to the outer segments, and a sienna-brown margin to the inner ones; tips of the segments erect, not at all spreading, obtuse, the outer slightly hooded. Stamens just reaching to the mouth of the perianth; filaments pale yellowish; anthers with reddish-brown margins, pollen yellow. *N. E. Brown.*

THE ROSARY.

RELIABLE ROSES.

At this season of the year, when Roses are being carefully selected by cultivators to add to their collections, it is of the highest importance to know what varieties are best suited for garden cultivation. For it cannot be denied that Roses which are brilliantly successful at our annual exhibitions are not always best adapted for the special purpose to which I have just referred. Such varieties, for example, as Mildred Grant, Alice Lindsell, and Mrs. Edward Mawley, from which great achievements, or, at least, very considerable artistic effects might naturally be expected, I have found most disappointing when compared with many of their much less renowned predecessors and contemporaries. I much regret to say that most modern Roses, where weighed in the impartial balance of ordinary garden culture, are found terribly lacking in effective floral capability. There are, however, outstanding exceptions, and Florence Pemberton—perhaps the very finest of modern introductions—is one of these. This, in my estimation, is the grandest Rose that has come to us from Newtownards since the beauty and luxuriance of Margaret Dickson first dawned upon the horticultural world. It has the same marvellous capability of growth, and nearly as great a profusion of exquisite bloom. Dean Hole and Lady Ashtown I have not found quite so accommodating to our somewhat variable Scottish climate; I find them occasionally eulogised by fervent English cultivators; but I can only say that, even under the most favourable atmospheric conditions during last summer they did not succeed. It was only by the most careful attention, indeed, that I could induce them to grow in situations where older Roses of greater vitality have grown and flowered admirably for the last ten years. Nor was I very successful, notwithstanding all my efforts, with Earl of Warwick and Countess Cairns; but as these, and some of the Irish Roses to which I have alluded were planted somewhat late in the season, I anticipate that they will be much more effective this year. I have good hopes of Charles Grahame, Countess of Annesley, J. B. Clarke, and my fragrant namesakes from Newtownards and Waltham Cross, the former of which was quite a success last season, even when planted in somewhat too shady situations.

But as I have perhaps sufficiently indicated, the most reliable Roses, with one or two notable exceptions, are to be found chiefly among the older varieties; and are for the most part either Hybrid Perpetuals or Hybrid Teas. Margaret Dickson I have already eulogised as a magnificent garden Rose; Clio, one of the many beautiful varieties raised by the late Mr. William Paul, is equally fine. I may perhaps add that these two varieties are among the most aspiring climbers I possess; here the former rivals, if not transcends, its Australian and American aspirations, attaining on the walls of this manse to a height of nearly 13 feet. Another Hybrid Tea of remarkable achievement in this direction is Caroline Testout, one great plant of which, climbing up a venerable Apple tree, produces enormous blooms at an equally commanding elevation. Viscountess Folkestone, La France, Clara Watson, Papa Gontier, and Madame Pernet Ducher are also vigorous growers, which, unlike some of our modern varieties that require to be grown by the hundred for exhibition, can always be relied upon to produce splendid floral effect in the garden. Such glorious Roses as these will not soon be superseded, for they are immensely superior to any of their successors. Nor do I hesitate to assert that even among the so-called Hybrid Perpetuals the older varieties are unquestionably the best. Duke of Edinburgh, Charles Lefebvre, Duke of Teck, and Horace Vernet—such venerable Roses as these will not easily be surpassed, though doubtless some grand crimson varieties have recently been introduced, such as J. B. Clark and Charles Grahame.

Many of the finest Noisettes and Teas, notably the far-famed Marechal Niel (the queen of the Conservatory), are, chiefly owing to the possession of a delicate constitution and an intense susceptibility to atmospheric influences, wholly unsuited for garden cultivation. Among the most reliable for this special purpose are Madame Alfred Carrière, a sweetly fragrant and profusely flowering Hybrid Noisette; Madame Pierre Cochet, a lovely derivative from Wm. Allen Richardson; Bouquet d'Or, an exquisite daughter of Gloire de Dijon; Anna Olivier, Devoniensis, Papa Gontier, Corallina, and Enchantress, a charming hybrid between the Chinas and the Teas; Souvenir d'un Ami, and Souvenir de S. A. Prince.—*David R. Williamson, Wigtownshire*

NOTICES OF BOOKS.

The French Flora.

M. Léveillé has recently published a pocket flora of France, which will be very serviceable to tourists and others. The plants are arranged in analytical tables in which a series of alternatives are presented to the enquirer. By continuously selecting the appropriate alternative, and eliminating the other, the student is, with the plant before him, by the exercise of patience, gradually led to the determination of its name, having incidentally picked up on the way a great deal of information relating to the plant itself. Of course, if the student has a good knowledge of the natural orders to begin with, his labours are rendered much less irksome. We notice in this volume that even the minor sub-divisions of the genus Rubus are thus analysed; various directions as to the collecting and preservation of specimens are given, whilst a glossary and an index complete a very useful little publication. It is published by M. Charles Amat, 11, Rue Cassette, Paris, and may be had from Messrs. Williams and Norgate.

The Book of the Winter Garden By D. S. Fish. John Lane.

The object of this little volume is to call attention to those hardy plants which flower in the winter, or which from the form and colour of their foliage are conspicuous in the winter season. The author passes in review the principal "berried" trees and shrubs, the winter-flowering shrubs, shrubs notable for the colour of their bark, and plants suitable for winter bedding. Another chapter deals with herbaceous plants flowering in the open in winter and early spring. The Alpine house next receives attention, and, considering the small expenditure of time, trouble, and expense that it demands, it is surprising that it is not more often met with. Mr. Fish's directions for its management are simple and to the point, and will, we hope, induce many to take up a department of gardening specially suitable for amateurs and those with little space at command. The latter half of the book is taken up with details relating to the plants that produce their flowers under glass during the winter months with the aid of a little artificial heat. It is surprising to see how many plants there are which will follow on after the Chrysanthemums are past their best. The book is illustrated with several appropriate photographic reproductions, and has an index. When a second edition is called for, greater attention should be given to the names of plants and to the reading of the proofs. At p. 3 the author, alluding to artificial light, is made to say the exact opposite of what he intended. Mr. Fish's book will be serviceable as a reminder to many, and will furnish valuable hints to the inexperienced.

ORCHID NOTES AND GLEANINGS.

LÆLIA × NEMESIS, "TRING PARK VARIETY."

(L. anceps white variety × L. superbiens.)

A very interesting hybrid raised in Tring Park Gardens from a cross effected by the Hon. Walter Rothschild, M P., is flowering in the collection of the Right Hon. Lord Rothschild. In the early stages the plant very closely resembled Lælia anceps, even the growth made before the flowering pseudo-bulb appeared being exactly like a white Lælia anceps. From it proceeded two growths, one of which, with one leaf, closely resembled Lælia anceps, while the other, with two leaves, closely resembled Lælia superbiens. In the flowers the

characters of L. superbiens are the most apparent, especially in the strong, wavy purple ridges extending down the lip. The inflorescence, which is 3 feet 6 inches high, bears 3 flowers, each 6 inches across. The sepals and petals are silver-white, delicately tinted with light rose colour, darkest on the outer halves of the segments. The margins of the side lobes and the broad front lobe of the lip are of a bright shade of rose purple colour. The base of the lip is white, with numerous narrow, dark purple lines extending into the side lobes; the disc is bright yellow with five raised wavy-edged keels, along the edges of which a dark purple line extends. It appears to be very floriferous, and in that and other respects it is a marked improvement on Lælia superbiens. The original form was raised by De B. Crawshay, Esq., Rosefield, Sevenoaks, between L. anceps Crawshayana and L. superbiens.

Fig. 51.—Lælia × nemesis, "tring park variety."

ORCHIDS AT THE GRANGE, SOUTHGATE, N.

It has been my privilege to visit a large number of large and small Orchid collections at home and on the Continent, but seldom have I inspected such a choice and healthily grown collection as that belonging to J. Bradshaw, Esq., at "The Grange," Southgate. Like many another gentleman who commenced in a humble way, and being content for a time with Orchids simply because they were Orchids, the above-named cultivator has now reached the stage when nothing but the best of the different species and hybrids therefrom will satisfy him. The consummation of this desire, however, requires considerable assistance from an obliging banker, but when, as in the present case, the cultivator is more than ordinarily successful in growing and propagating the plants, it is, in most instances, a profitable investment, as well as a pleasurable indulgence. The collection principally consists of most that is good in three or four genera, and is contained in several houses divided into half a dozen compartments, each and all well situated to receive the full benefit from sunlight.

On entering the first compartment the feeling peculiar to a well organised Orchid house was borne in upon me, and afterwards it came as no surprise to find that in each structure the inmates were almost without exception in the pink of health. This is largely attributable to having the paths and floors beneath the stages made up of such porous, clean, and yet moisture-holding material as coal ashes, also to the provision of ample hot water piping, and efficient means of ventilation. In this first division are many of the fine forms of Cattleya labiata that were exhibited at the Royal Horticultural Hall last autumn, and the grand series of white-segmented varieties which are such a feature in this collection. Of the latter section there are no fewer than forty-five healthy plants, many of which have been certificated, notably C. l. G. G. Whitelegge (award of merit, October 29, 1901), and C. l. glauca, given an award of merit on the same date. Just prior to my visit they had all been set in order for the coming growing season, evidence of an early start being even then visible in some. Following the above are a couple of dozen plants of Cattleya × Mantini, C. × Mrs. J. Whiteley, and C. × John Bagguley, these derivatives from C. Bowringiana being greatly favoured and exceedingly well grown, one particular plant having over half a dozen leads.

The main Cattleya house was next entered, where my attention was first directed to a large batch of C. Trianæ, several of which were in flower. The first to claim attention was the one which, since my visit, was accorded (on February 13) the Orchid Committee's 1st diploma for the best C. Trianæ shown. It is aptly named C. T. The Premier. It is represented here by two strong plants, the one then in bloom having a massive flower almost eight inches in diameter, the sepals being an inch and a half

in width, and the petals three and three quarters, the whole flower being of a beautiful shade of rose purple colour. The lip is large, and has a deep orange coloured throat, a bright purple front lobe, and delicately white, frilled margin, altogether a surprisingly perfect flower. Another good form in bloom was C. T. Mrs. de B. Crawshay, an almost perfectly round flower, with very broad petals and highly coloured lip. A white form—of which there are many present—in flower is named C. T. albo-violacea, the segments being white, and the front lobe of the lip of a pale violet tinge. Amongst the many notable varieties particularised was a thriving plant—part of the original old and distinct form known as C. T. Leeana, which gained a F.C.C. so long ago as March 25, 1884. An excellent example of C. Schröderæ alba, thirty vigorous pieces of C. intermedia alba, a dozen or more of C. Skinneri alba, C. Percivaliana alba, and other "albinos" were admired. The central stage is filled with a number of fair sized specimens of many of the more showy Cattleya and Lælio-Cattleya hybrids, several being instanced as being the original plants, and all of superior merit. The chaste flowered L.-C. Digbyano-Schröderæ-alba which gained an award of merit on April 5, 1904, is doing well. L.-C. Haroldiana John Bradshaw, given a F.C.C. on October 27, 1903, is probably the finest variety of this gorgeous hybrid yet seen. Many other specialities were pointed to with evident pride, but considerations of space precludes their enumeration. The north side of the central stage is given up to a very fine batch of Phalænopsis grandiflora, known as Rimestadtiana, which from the bristling spikes give promise of a good show of flowers later on.

Dendrobiums are not favoured here, yet two well-flowered examples of D. splendidissimum grandiflorum, and another of D. nobile Cooksoniæ, gave a touch of colour to the sombre green of the Cattleya foliage. Another species, more modest than the above two, viz., the new and rare D. bellatulum, bore a couple of its quaintly coloured blooms. The north side stage is occupied with such species as C. Mendeli, Mossiæ, etc., whose qualities lie more in their merit than in their flourishing condition, though given a few more years of their present treatment and that reproach will be removed, as is evidenced by a couple of twenty-year-old plants of C. Mossiæ Wageneri, which had reached a very low standard of health, yet have now so far recovered as to be allowed to carry sheaths. The roof is not much obscured with hanging plants, but several nice pieces of L.-C. Ingrami and Lælia anceps Sanderiana are suspended over the path.

A third compartment is a span-roofed structure, the south side stage of which is filled with green leaved, massive-bulbed plants of Lycaste Skinneri, a large number of which were in flower at the time of my visit. It came as a complete surprise to me to find such a collection of this somewhat neglected species, and as nothing but the best are included, it was indeed a feast. L. S. Enchantress is a magnificent form, with large solid blush white flowers, as also is L. S. Lady Gladys, which gained an award of merit on December 17, 1901. Fourteen plants of L. S. alba were in flower, some of which carried nine glistening white blooms. A large plant of L. × Balliæ bearing eight flowers, large in size and highly coloured, also commanded admiration. The opposite stage is occupied by some very healthy plants of Cymbidium Lowianum, C. Tracyanum, C. eburneo-Lowianum, with five developing spikes, C. Ballianum sending up a strong scape, and in flower, a plant of the rare C. Wiganianum (C. Tracyanum × C. eburneum); other plants present being some good masses of Maxillaria Sanderiana, etc., and overhead some resting plants of Odontoglossum citrosmum. Squeezed between this range and the Odontoglossum house are two small houses, one of which is devoted to the propagation of offshoots from the special Cattleyas and Lælias and hybrids, and the other is partly filled with an importation of Cattleya Trianæ numbering over a hundred plants, all except two of which are guaranteed to be white. What a speculation!

The Odontoglossum house is a long, narrow, span-roofed structure, fully exposed to the sunlight during the long dull season, but amply provided with shading appliances when the occasion demands. That this is the proper position for an Odontoglossum house, or any other Orchid house for the matter of that, is evidenced by the massive bulbed, strong, bronzy-green foliaged plants inside, and also by the vigour of the pushing spikes, as well as by the thick substanced and highly coloured blooms of those plants in bloom. Better plants no one could wish to see, and now the fact of their successful cultivation is assured, Mr. Bradshaw is replacing those of inferior merit with more costly specimens. A good commencement has already been made, as is seen by some grand pieces of O. Harryano-crispum, Harryano-triumphans The Queen, recently given an award of merit, O. × Bradshawiæ (O. Andersonianum × O. Harryanum), given a first-class certificate on January 27, 1903, O. excellens Lowiæ (award of merit, April 27, 1894), a very pretty O. × Rolfeæ named Kathleen, an almost white form, and a form of O. × ardentissimum, spotted in the way of the well-known O. crispum Starlight.

Several grand spikes of O. triumphans carrying numerous highly coloured flowers were next admired, along with some O. × Adrianæ, O. × Ruckerianum, and several dozen spikes of good ordinary O. crispum, not forgetting a fine plant in flower of the new O. × Wiganianum (O. × excellens × O. Rolfeæ). O. luteo-purpureum and O. Hallii were showing numerous flower-spikes, and in most instances, where sufficiently advanced, two spikes from each bulb were seen on the O. crispum. Hard work, high aims, tireless energy, with a consistently correct cultural policy, backed by an enthusiastic and encouraging master, have gained for Mr. G. G. Whitelegge, the gardener, such a large measure of success as I have only faintly described. *W. H. Young, East Sheen.*

TREES AND SHRUBS.

PINUS INSIGNIS, OR PINUS RADIATA.

In a note in the *Gardeners' Chronicle* for December 23, 1905, "H. W.," Trewince Gardens, remarked that the specimen illustrated on page 435, which is 75 feet high and has a girth of 12 feet at 3 feet from the ground, is the largest of that species that he knows. There are several finer trees than this in the Pencarrow collection. The tallest is 97 feet 6 inches high, and measures 14 feet at 5 feet from the ground. This tree has a magnificent trunk, but, unfortunately, it has got up into the wind zone, and the upper branches have suffered. Another tree, which is a perfect specimen, is 88 feet high, and its girth 15 feet 6 inches at 3 feet, and just a foot less at 5 feet from the ground. This is the finest example of the Montery Pine that I have seen, although I have heard of even finer ones elsewhere. Both of these trees were planted in 1844. Two others, planted in 1849, are very beautiful specimens, 69 feet high, girth 14 feet 6 inches, and 70 feet high, girth 17 feet 7 inches at 5 feet up. They are well furnished with lustrous foliage and clothed to the ground.

The Monterey Pine is so generally known as Pinus insignis that it is a great pity Mr. Kent, in the 2nd Edition of Veitch's *Manual of the Coniferæ*, has tried to depose this name in favour of the lesser known P. radiata; and is it not quite possible that the name radiata was given to a tree which differs in some particulars from the general form of P. insignis? Sir William Molesworth, who founded the Pencarrow Pinetum, bought trees in 1844, and again in 1849, as P. insignis. Later, in 1851, he bought as a distinct species a pine under the name of P. radiata. I do not know from whom it was bought, but the bulk of the trees which he planted at that period were bought from Knight and Perry, the predecessors of the Chelsea firm of Veitch and Sons.

This P. radiata is growing in the avenue, and throughout his lifetime Sir William is said to have made a point of stopping his carriage every time he returned to Pencarrow to examine this tree, which he greatly valued. He had planted P. insignis seven years previously to this P. radiata, which he bought as a distinct and rare tree. Of its characteristics as a young tree I know nothing; but at maturity it differs in many respects from P. insignis. It is a flat-topped tree, with nearly horizontal branches; the lower ones are very long, making the tree unusually broad at the base, whereas P. insignis has a more or less rounded top; the bulk of the branches are ascending, and the broadest part of the tree is at a point nearly half-way up. The leaves of P. radiata are of a paler green than those of P. insignis. The cones are smaller, rounder, and more prickly. When mature they are more uniform in colour, which is a very light shade of brown. I feel inclined to say that the cones of P. radiata are also paler than those of P. insignis, but on even the same tree of the latter one finds extraordinary variation in shades of colour.

As "H. W." remarks, the cones of P. insignis—and this applies to both forms—are remarkably persistent; some on the trees here must be more than 30 years old. I have opened many cones, but have found only a small proportion of good seeds. Neither of the two forms here are "spring-tender," but I find that young trees continue to grow till very late in the autumn, and the soft growth is very susceptible to injury from the fierce gales for which Cornwall is noted. The Monterey Pine is a moisture lover, and I am inclined to the opinion that it suffers most from the Pine-beetle, Hylurgus piniperda when growing in a dry situation. It should only be planted on mounds where the rainfall is very heavy—our average of 46 inches does not appear to be too much—or where the land is low and flat. The growth of young trees is very rapid. Seedling trees frequently make shoots 3 to 4 feet long. Although of no great timber value, an occasional tree in a mixed plantation greatly increases its beauty. *A. C. Bartlett, Pencarrow Gardens, Cornwall.*

A NEW HIMALAYAN SPRUCE.*

MR. REHDER described in 1903 a new species of Spruce, Picea morindoides, from a specimen which is growing in the arboretum of M. Allard, at Angers, in France. This Spruce strongly resembles in habit Picea morinda, having similar pendulous branches. It is, however, entirely different, as the leaves, which are shorter than in that species, bear bands of stomata on their dorsal [? ventral] surface only, and show that the species belongs to the section Omorica. In fact, this Spruce is very closely allied to P. Omorica and to P. Breweriana. M. Rehder knew nothing of the origin of M. Allard's Spruce; but it is evident now that it must have been raised from Himalayan seed. In 1877 a native collector found in Chumbi, between 9,000

* In Sargent, *Trees and Shrubs*, L. 95, t. 48.

and 10,000 feet, a Spruce, which is identical with the Angers tree. It was lately again collected by Mr. E. H. Walsh, who accompanied the late military expedition to Tibet.

The occurrence of a Spruce belonging to the section Omorica in the Himalayas is of the highest interest. In its restricted habit, occurring only so far as is known in Chumbi, the new Spruce resembles the Servian Spruce and Brewer's Spruce.

Seeds of this Spruce were sent to various botanical establishments in Europe in 1877 or 1878 by Sir George King; and it is possible that other examples of it occur in cultivation on the Continent or in this country. As it strongly resembles Picea morinda in habit, it may be confused in collections with that species. The writer would be much obliged if owners of reputed Picea morinda would kindly examine any trees of that

PORTRAIT OF JOHN EVELYN, WHO DIED 200 YEARS AGO LAST TUESDAY.

name which differ in having short flattened leaves, conspicuously marked with white bands on the dorsal surface (simulating in appearance a silver Fir) and send specimens for identification, with particulars of the height and girth of the tree, and the provenance of the seed, and date of planting. *Augustine Henry, Kew.* [Among Mr Wilson's Chinese specimens are flat-leaved Spruces which will be described later on. *M. T. M.*]

JOHN EVELYN.

Among the pioneers of scientific horticulture, John Evelyn held a foremost place in the troubled reign of Charles I., and in the not altogether creditable reign of his successor. Evelyn was a good example of a learned, a genial, and a practical country gentleman. He died on February 27, 1706, just two centuries ago. In spite of much that was humiliating in the reign of Charles II. there was an awakening, and a real progress in literature, in art, and in science, and it is only right that the "merry monarch" should have the credit of having fostered and encouraged the movement. In 1662 the Royal Society was definitely incorporated. John Evelyn was one of the Fellows, and he had among his colleagues Christopher Wren, Nehemiah Grew, Samuel Pepys, and others. Evelyn makes mention of the first anniversary meeting on St Andrew's Day, November 30, 1663. To the general public Evelyn is best known by his charming Memoirs, a singular contrast to that of his contemporary Pepys. But interesting and valuable as that publication is, his papers contributed to the Royal Society have had more far-reaching effects. His famous "Silva" first saw the light in the shape of a contribution to the Royal Society, and it was, as he tells us, "the occasion of the propagation of many millions of useful timber trees." His *Gardeners' Kalendar* (1666) was scarcely less influential. In our Volume for 1895 (November 16 and December 28) is an exhaustive article on Evelyn and his work by Mr. W. Roberts, to which we may refer the reader, whilst the occurrence of the bicentenary of his death gives us an opportunity of publishing the portrait of one than whom no one is deserving of more reverence among horticulturists.

CULTURAL MEMORANDA.

DEYEUXIA ELEGANS VARIEGATA.

This decorative greenhouse grass is a native of Bolivia. From its stout rootstock are produced numerous arching, deep green leaves, each about a quarter of an inch in breadth, and ornamented with a clear, creamy-yellow margin.

The plant is easily increased by division of the crown, which consists of numerous suckers or off-shoots. These, with a few roots attached, should be potted singly into well-drained 3-inch pots, in a compost consisting of about three parts sandy loam, one of leaf-mould, and a sprinkling of sharp sand. Pot the crowns fairly firm, and afford an application of tepid water to settle the soil about the roots. Keep a close atmosphere about the plants for a week or ten days, until the roots have pushed into the new soil, after which the plants may be subjected to the ordinary greenhouse treatment. The plants should be shifted into 4½-inch, and again into 6-inch pots, as they require more room at their roots. Plants in the latter pots are of a size best adapted for decorative purposes.

MARANTA INSIGNIS.

This is a very distinct and beautiful foliage plant. The long, semi-erect, lanceolate leaves are of a light green colour, darkly shaded on their margins, and ornamented on the central portion with dark green oval blotches, arranged alternately with a small round bloth placed on each side the midrib. These markings, viewed in connection with the clear maroon colour of the under surface of the leaves, give to the plant a very handsome appearance.

The plant is easily increased by division, or by off-shoots taken from established plants with a few roots attached, and potted singly into 3-inch or 4½-inch pots, according to size of the portions. Use fine peaty soil and silver sand, and pot firmly. Place the pots in the plant stove and afford tepid water to settle the soil about the roots. The moist, warm atmosphere of the plant stove will suit the requirements of this Brazilian plant in every respect. *H. W. Ward, Rayleigh.*

HIPPEASTRUMS.

I think the majority of growers at the present time repot their stock annually. Unlike Mr. Ruse (see p. 116), I find no ill effects from disturbing the roots; but, on the contrary, I consider it is most beneficial to plants started from the new year onwards. When batches are introduced to a warm atmosphere during October or November to supply flowers in mid-winter, it is probably better not to repot them, the days being short and comparatively sunless. Any plants that are still dormant at the present date should be placed in an atmosphere of 60° at night until growth commences, when repotting should be carried out. As a rule it will be observed when shaking away the exhausted soil there are many decayed roots, hence the value of repotting annually or biennially. Robust plants after a few years' growth usually have their pots filled to the rim with fleshy roots, which renders it almost impossible to apply a top-dressing. Bottom heat may not be absolutely necessary, but when plunged to their rims in a bed of fresh leaves root action is much increased, and in an atmosphere of 60°, with fire heat, the flower spikes, as well as the foliage, are respectively stronger and firmer. I am not a believer in using any kind of manure in the soil, believing that it fosters disease, but rely on diluted manure water, which is applied as soon as the roots are seen to have reached the bottom of the pots. Some growers place their plants out of doors and expose them to sunshine in the month of June, and I adopted this practice one summer, but could not see that the bulbs ripened up any better, neither did they flower more satisfactorily than when treated under glass the year through. After they have passed out of flower I stand the plants along the front stage in an early vinery or peach-house, where they get all the light and sun possible. *J. Mayne, Bicton, Devon*

KEW NOTES.

Senecio Petasitis.

This Mexican plant, the Butterbur-leaved Senecio, is not often met with in gardens, although it was introduced into this country as long since as 1812.

It is a useful plant for the cool greenhouse or conservatory in January and February, and more especially for large structures. A number of plants, from 2 feet to 6 feet in height, are flowering in No. 4 greenhouse. The smaller plants were raised from cuttings inserted last spring, the larger being plants that were cut back after flowering a year ago, and grown on again.

The large terminal panicles of yellow flowers are freely produced. The leaves are petiolate, rounded, cordate at the base, fairly thick, dark green on their upper surfaces, and paler beneath, When planted out in a large house it develops a thick stem, and grows into a large bush.

It is figured in the *Botanical Magazine*, tab. 1536, under the name of Cineraria Petasitis.

Garrya elliptica.

On the west wall at the end of the Duchess border, the catkins on the male form of this evergreen shrub have formed a conspicuous feature during the past month, with promise to continue attractive for some weeks to come. The plant was introduced from California by the Royal Horticultural Society in 1828, through their traveller Douglas. Its value for planting for winter effect is not fully appreciated. In sheltered positions, not necessarily against a wall, the greyish-green catkins render it a conspicuous feature. The pendulous catkins on the upper shoots can be used very effectively in vases either by themselves or in conjunction with flowers. Propagation may be effected by means of layers, or by cuttings. If possible, place the plants in their permanent positions when they are small, as large plants suffer badly when transplanted.

Growing by the side of the male plant at Kew is a smaller female plant, whose flowers are very small and not so attractive as the catkins.

Epacris.

These Australian plants, the analogues of the Heath family at the Cape, are not so popular in gardens as they were a few years since, although they are eminently suitable for the decoration of a cool greenhouse in late winter and early spring. Between 40 and 50 of these plants are now a feature in No. 4. There are two distinct sections, the one being strong and upright in growth, the other lax or pendulous. The growths, many of them 18 inches or more in length, are thickly clothed with tubular wax-like flowers, arising from the axils of the leaves.

From 20 to 30 distinct species have been described, but very few are in cultivation. Only four species are given in the Kew *Hand-list of Tender Dicotyledons*, published in 1899. Of these, E. impressa, with its variety alba, and E. longiflora are flowering at the present time. E. purpurascens and the double-flowered variety E. densiflora and E. hyacinthiflora are included, but these are garden varieties.

A considerable number of beautiful hybrids have been raised, whose flowers embrace a variety of shades of colour, ranging from pure white to dark red. The following is a selection of those in flower, with their colours:—Ardentissima—reddish-terra-cotta; Alba odoratissima—white, the small flowers are sweetly scented; Fireball—bright red; hyacinthiflora—soft pink; hyacinthiflora rosea—deep pink; Model—pale pink; Princess Beatrice—rose-pink; Rose perfection—rose, the flowers are long and thin.

A large bush of E. longifolia var. superba, planted in one of the beds, is 5 feet in height. Being one of the lax-growing varieties, it has to be supported by stakes. A few flowers are usually to be found on the plant throughout the year. During the recognised flowering season it is clothed with red flowers tipped with white. *A. O.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Dendrobiums.—A large number of species and hybrids of Dendrobium are in bloom at the time of writing, and some of the plants having already started to grow, it may be pointed out that these tender young growths are very liable to be injured if the atmospheric temperature of the house falls several degrees below the average and is permitted to continue so for some length of time. They are especially liable to become spotted and diseased if not carefully protected from cold or boisterous winds, which are more or less prevalent during the months of March and April. In order to guard against the plants receiving any such injury during the night, it is a good plan to fasten mats of double thickness along the sidelights and ends of the house, also to roll some mats along the lower part of the roof, which is the coldest part of the house, putting them on at dusk and taking them off early in the morning if the atmospheric temperature in the house will permit. In order to make these coverings secure we let down the lattice wood blind over them, tieing the blinds to small iron fixtures made for the purpose. Should the atmosphere in the house feel at all close or stuffy when the coverings are all on, a very little air may be admitted through the ventilators. When removing the coverings in the morning it may not be advisable to take them all off at one time, as sudden fluctuations in the conditions of the atmosphere should be avoided as much as possible.

Arachnanthe Cathcartii, &c.—The singular and handsome A. (Vanda) Cathcartii is now in bloom with five flowers on a spike. It is a plant that is rather particular as to position and treatment, but if fastened and trained up a Teak-wood raft and placed in a moist, shady part of the East Indian house, it will thrive luxuriantly. The present is a suitable time to examine such beautiful Orchids as Aërides, Saccolabium, Renanthera, Angræcum, Sarcanthus, Arachnanthe Lowii, and the warm-growing Vandas, to ascertain the condition of the plants as regards the rooting medium, &c., for with the increase of sunshine the young, tender points of the roots will commence to grow, and a slight touch would injure or break them. Plants that have lost a number of their lower leaves and that have a sufficient number of roots above to support them should be cut down, so that when the plant is placed in position in the new pot the leaves will be on a level with the rim. Afford plenty of drainage materials and use a compost of clean sphagnum moss and broken crocks, pressing it down firmly among the roots. For such large, fleshy-rooting species as Aërides crispum and its varieties Lindleyanum and Warneri, also A. crassifolium, A. Fieldingi, A. maculosum, and its rare variety Schroderi, Angræcum Kotschyi, and some of the stronger growing Saccolabiums, something different from sphagnum-moss appears to be necessary, as the thick, succulent roots do not thrive satisfactorily in such close, damp material. At Burford these plants are being placed in pots which are filled with moderately-sized pieces of well-dried elm bark, and some of the plants have been in this material for over a year, and are growing exceedingly well. The varieties of Aerides enumerated above thrive better in an intermediate temperature than when placed in great heat.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Ferns.—Examine the stock of Ferns, and if it is necessary to increase any by division there is no better time than the present to carry out the operation. Dispense with as many of the old fronds as is practicable, for by so doing thrips, if present, will be destroyed. Adiantums which were treated as advised in my Calendar for January 20 should be given frequent waterings of weak liquid manure and soot-water. Most Ferns, but especially Adiantums, thrive wonderfully if given a few doses of *Le Fruitier*, and also if a small quantity is used in the potting mixture. Ferns which have creeping rhizomes require a lighter compost to grow in than the crown or tufted species. Rough fibrous peat, chopped sphagnum-moss, small lumps of charcoal, and red sandstone rock, with a proportion of sand, forms the compost in which all the surface rooting Ferns are grown at Cleveley. For exhibition the six followings Ferns are worth growing: Davallia Fijiensis, Nephrolepis davallioides furcans, Goniophlebium appendiculatum, Davallia tenuifolia Veitchiana, Nephrolepis rufescens tripinnatifida, and Adiantum tenerum Farleyense. Apply water sparingly until the young roots have obtained a good hold on the new soil. Maintain an atmospheric temperature of 60° to 65°.

Primula verticillata.—This lovely sweet-scented species flowers from now onwards till the end of May. The plants are most useful for placing at the fronts of stages in the corridor or conservatory, also if associated with Tulips, Lily of Valley, or other bulbs they are very pleasing. A packet of seed if sown at once in an atmospheric temperature of 50° will soon germinate. A successional lot of plants may be raised by sowing new seed which will ripen in the course of a month or six weeks hence, on plants now going out of flower. The plants need to be cultivated in a cool greenhouse or frame.

Chironia ixifera.—Cuttings of this lovely free-flowering greenhouse plant may be inserted at the present time, and they will make nice plants if grown on for another year. Pot them in a compost of good sandy loam and leaf-soil, and feed the plants liberally when the pots have become full of roots. Pinch the shoots occasionally to induce a bushy habit in the plants.

General remarks.—Examine blinds used for shading, and take steps to have them put into good order so that when required they may be in readiness. The syringe must now be brought into use morning and afternoon on bright days to encourage growth in Codiæums (Crotons), Ixoras, and other stove species. The temperature of the water used for syringing purposes should exceed that of the atmosphere of the house by 5°. Continue to increase by cuttings, Fuchsias, Coleus, Petunias, and all soft-wooded plants which may be found useful in furnishing the houses when most hard-wooded plants will have been removed out of doors. Tuberous Begonias should be placed in shallow boxes containing a little leaf mould and sand. A suitable place and atmosphere may be found for the same in a Peach house or Vinery which has been just started. Give strict attention to cleanliness in all departments, and adopt every means to make the plant houses as attractive as possible.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Strawberries in Pots.—The earliest Strawberry plants that were started in January have made considerable progress during the past fortnight, and will now require daily attention in order to keep the roots in a moist condition. Cut off all weak and deformed fruits in order that those which remain may grow stronger. The fruits will now need to be supported by thin stakes about 8 inches in length, two of which should be placed in each pot and a piece of strong raffia tied to each stake for the fruits to rest upon. As the fruits approach the ripening stage, they would soon bruise if left to hang over the pot sides. Waterings with diluted liquid manure and a little guano dissolved in water may be applied to the roots alternately twice or three times each week until the fruits commence to colour, when it must be discontinued, and only clear water used. The best position for the plants at the present time is on a shelf close up to the glass in the Melon house or Pine stove, where there is plenty of atmospheric moisture, and exposure to full sunshine. Syringe the plants twice each day when the weather is favourable, for if red spider becomes prevalent the fruit will have a dingy appearance, and possess but poor flavour. When the fruits are ripe, remove the plants to a cooler atmosphere for a few days before sending the fruits to the table or packing them to travel. Place a large number of plants in an atmosphere of moderate warmth, so

that there may be no break in the supply of fruit later on. Select the best plants with the most promising crowns, and as they begin to show their flower-scapes move them to a warmer atmosphere in numbers as may be required. Any plants that would be "blind" can be detected before bringing them into the houses from the cold frames.

Cape Gooseberry (Physalis peruviana).—This fruit is very attractive when ripe, and it makes an additional dish to the dessert. Seeds should be sown at once, putting them thinly in a pot or pan of light soil and placing them over mild bottom heat. When the plants are about three inches high pot them into three inch pots, keeping them near to the glass, and when they have filled these pots with roots they may be planted out in a warm greenhouse or vinery in turfy loam, leaf-soil and lime scraps. If only a few plants are required 10 inch pots will be suitable to fruit them in, using the same kind of soil. When they become established they make much growth, and this will require to be thinned out regularly. The fruits ripen in August and September, and they are useful for dessert or for the making of jam.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

The Hollyhock from Seed.—Owing to the almost universal prevalence of the disease to which this beautiful flowering plant is subject, it is generally recognised that the only way to enjoy the colour of its splendid spikes, so essential to the boldness of a mixed border, is to raise fresh stock every year from seed. The seedlings, though not exempt from the fungus, still, in comparison to old plants and plants raised from old stock, enjoy an appreciable degree of immunity for a few years. It is almost hopeless for individuals to try to eradicate it entirely, and it is questionable whether united action on the part of all growers would do so, owing to the fact that all the mallows are subject to the same disease. The Hollyhock comes very true to colour from seed, so that when sown in distinct colours the seedlings can be relied upon for border decoration. Many prefer the autumn for sowing, and then grow on the seedlings through the winter in cold frames, but it will be found that sowing now, and growing the seedlings on quickly, is far better than keeping them throughout the winter, the prey of damp and slugs. Sow the seeds in well-drained pans or seed boxes filled with moderately rich soil, afterwards place the pans or boxes in a warm atmosphere and cover the seeds lightly with a sprinkling of fine soil. When strong enough to handle, the seedlings must be potted into small pots, using a good porous compost, and then when rooting freely they should be potted again into 5 inch pots, in which they can be hardened off by employing increased ventilation. As soon as they make sturdy growth the plants can be transferred to cold frames, where merely protection from frost and cold winds need be provided. By the end of the month of May they will have formed sturdy-growing plants fit for planting out. Treated thus, Hollyhocks flower the first year, though the spikes produced in the following year are much stronger and freer. It is interesting to note that one or two firms of seedsmen are supplying as a novelty seeds of what they term an "annual type" of Hollyhock. It is in mixed colours, and if sown in the middle of March and planted out in the first week in May the plants are said to bloom from the middle of July until late in autumn. According to the catalogue descriptions the habit is branching, semi-tall, with double flowers of graceful, loose petals.

The St. Bridgid Anemones.—Where the climatic conditions are comparatively dry, these roots are best planted in the autumn, but in localities where the ground is wet it is better to defer doing so until February or early in March. They ought to be planted at once, and to obtain the best results the ground should have been previously manured, but they succeed well in any good garden soil.

The Persian and Turban Ranunculuses.—These are also beautiful flowers for the garden, and afford a charming effect, particularly if grown in masses. It is even more advisable than in the case of the Anemones that the roots of the Ranunculuses should not be planted until the latter end of February or early in March, because they are even more susceptible to danger from being exposed in wet soils during the winter. It is essential that the Ranunculus should be given liberal treatment. The beds in which it is intended to grow them should be well prepared before planting by incorporating some manure and leaf-mould with the soil. If the soil has a tendency to be heavy, sand can be added. Draw drills about 6 inches apart and 1 inch in depth. Then place the roots in them about 4 inches between each, and press them firmly into the soil. A top dressing of good loam to the thickness of 3 inches should be applied, and then raking the bed smooth is an appropriate completion to the planting.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Gooseberry Bushes.—Complete the pruning of these as soon as possible. If large fruits are desired the branches must be well thinned out and the spurs cut back to three or four eyes on each. In cases where a large quantity of green fruits is desired the shoots may be left nearly their whole length. Gooseberries are first-rate when bottled properly whilst green. Protection from birds may be provided by the use of netting as was advised on p. 38. Sprinkle a good dressing of lime under the bushes, and if there is any lichen on the branches spray them with an alkali solution. Richards' XL-All Winter Wash is a good non-poisonous wash for fruit trees. It destroys all kinds of pest and lichen, and leaves the bark bright and clean. When this work has been done, lightly fork over the ground, and apply a good mulch of long strawy manure. The value of mulching to fruit trees cannot be over-estimated. These latter remarks apply with equal force to Red and Black Currants.

Raspberries.—If the growths have been tied to strained wire, the tops may now be pruned back. Let newly-planted canes be cut to the ground level. Autumn fruiting varieties, such as Belle de Fontenay, etc., should be pruned hard, half now, and the remainder about two or three weeks later. The whole of the Raspberry plot should then be given a liberal mulch of manure.

Alpine Strawberries.—Sow seeds of the variety called Sutton's Improved Red, the fruit of which is twice the size of that of the ordinary Alpine Strawberry. For this purpose employ boxes containing finely-prepared soil, and afford an atmospheric temperature of 55°. Sow the seed thinly, and when the young plants are large enough to handle prick them off into other boxes, and subsequently plant them out in a well-prepared border of fine, medium soil.

Planting must be finished without delay. Apply a mulch over the roots of all trees planted after this date. Have material ready for protecting fruit tree blossom from frost.

Morello Cherries.—Thin out the wood thoroughly and lay in good shoots their whole length all over the tree. This system needs to be repeated year after year, the young wood being the bearing wood. Leave plenty of room for young shoots to be laid in, and still have the advantage of exposure to light and air. Spray the trees with XL-All or Petroleum Emulsion just before the flowering stage.

Pruning should now be brought to a completion as soon as possible.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Onions in Boxes.—Young Onion plants raised from seeds sown early in January will now be in good order for pricking off into other boxes. They must be encouraged to grow to their fullest extent in order to get the greatest size possible if they are intended for exhibition purposes. Plant the seedlings 3 inches apart each way in a compost of rich soil and keep them in an atmospheric temperature of 55° until they have made considerable growth, and are ready for hardening off in the first week in April.

Vegetable Marrows.—Marrows are much appreciated early in the season, and a few seeds should be sown in pots at this date if means will allow a crop to mature in frames. One of the small varieties should be selected, such as Pen-y-byd, or Moore's Cream, and the Custard Marrow should not be forgotten; these latter are very fruitful and make a splendid dish. Sow the seeds in pots on a slight hotbed, or in a propagating pit, when they will soon germinate. Good crops should be secured by the latter end of May.

Early Peas which have been raised in boxes, and are now from 2 to 3 inches in height, should be hardened off in readiness for planting in the open. Thorough hardiness when first put out is essential to success. Some of the plants may profitably be planted in cold frames where space can be spared. In cold districts another sowing should still be made in boxes to succeed the others, using some of the varieties already mentioned in a previous Calendar. Those already established under glass will require considerable water at the roots, and should be syringed with tepid water in the afternoon on fine days.

Celery.—The main crop of plants remaining in the open may now be lifted and stored closely together behind a shady wall. This will allow the trenches to be levelled and the ground dug in readiness for the next crop. If time can be spared it is best to trench over the land, as the manure left in the trenches will then get better incorporated with the whole soil and the succeeding crop be more regular.

Seakale.—Plant out the main crop, and be careful to plant the best cuttings obtainable. A deep, rich soil that has been well manured is necessary. Seeds may be sown also, but good crowns are not so readily produced in one season from seeds as from cuttings, neither is the crop so regular. The variety Lily White is certainly an improvement as far as colour is concerned, but is not so vigorous in growth as the more common variety.

Spring Cabbages.—Slightly loosen the soil between the lines as soon as the plants begin to grow freely, and afford a sprinkling of nitrate of soda, which will hasten the crop towards maturity, as well as increase the size of the heads. Make up any blanks there may be by lifting plants from the old seed-bed, choosing a day when the weather is damp for this purpose. Young plants from seeds sown at the beginning of the year will now be ready to be pricked off into frames. These, when well grown, succeed immediately after those mentioned above.

Cauliflowers.—These young plants also will be in condition for pricking off, and should be encouraged to grow as fast as possible, but they must not be coddled or they will damp off. Use a compost of some good holding materials that will be sure to form good "balls" when the plants are being transferred to the open garden. Those wintered in frames should be finally hardened off in readiness for planting, and when this is done afford protection by hand lights, inverted flower pots, or anything that will secure them from damage on frosty nights. Scatter a little lime round each stem to protect them against slugs.

THE APIARY.

By Chloris.

How to Spread Brood without Danger.—Most of those who make a practice of spreading brood do so by inserting a comb in the centre of the brood chamber, and by placing the feeding bottle above it. By adopting this plan, we run a great risk of chilling the brood, and thus retarding the increase which is so desirable. During the past season I found another plan which, my informant told me, had not been attended in practice by any mishap. It was as follows: When the frames, occupied by the bees, are well filled by the cluster, another frame is added on one side, the cappings having first been removed or bruised, then the feeding bottle of syrup is placed over the frame, and, in about nine days, the operation is repeated on the other side. By adopting this method I was assured that no misfortune could follow, and the bees are soon in a very strong condition.

Buying Bees.—If the bees bought be in a skep, place them in their permanent position immediately on receipt, with the opening towards the south-east. It will be well to feed in order to stimulate breeding. It is awkward to feed bees in a skep, but the best way is to cut a hole in the top not less than 2 inches wide and place the bottle over it. Cover the whole up warmly and make it watertight, and also secure it against being blown over. It is a good plan to add a sheet of stout brown paper between the quilts, as brown paper is a bad conductor of heat, and will thus help to maintain a higher temperature within the hives during the cold weather which often prevails before the month of May or even June.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Mar. 3	Ann. meet. Wakefield Paxton Soc. Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.
TUESDAY,	Mar. 6	Roy. Hort. Soc. Coms. meet. Nat. Rose Soc. Com. meet. Complimentary Dinner to Mr. William Marshall.
SATURDAY,	Mar. 10	Dutch Gard. Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick 41·3°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, Feb.* 28 (6 P.M.): Max. 46°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 1 (10 A.M.): Bar., 29.8; Temp., 48°; *Weather*—Dull, with occasional sunshine.

PROVINCES.—*Wednesday, Feb.* 28 (6 P.M.): Max. 49° Ireland, South-east Coast; Min. 35° Scotland N.

SALES.

MONDAY—

Hardy border plants, Perennials, 1,800 Roses, Lilies, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—

Perennials, Herbaceous plants, Lilies, Hardy Bulbs, Roots, &c., at 12; 3,000 Roses, at 1 and 3; Azaleas and other plants following, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

Sale of Roses, Fruit Trees, Lilies, &c., at Stevens' Rooms, King Street, Covent Garden, London.

THURSDAY—

820 cases Japanese Lilies, Thousands of Gladiolus, Davallias, Iris, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 3.

FRIDAY—

Collection of Orchids, 30 Cypripedium Lawrenceanum, received direct, Disas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Pedigree Sugar Canes. In an interesting article in the *West Indian Agricultural News* the history of raising Sugar-canes from seed is briefly given. At a time well within the memory of the present generation seedlings of Sugar-canes had not even been seen, and even Roxburgh had never seen seeds.

Rumphins, as cited by Alphonse de Candolle, in his *Origine des Plantes Cultivées*, stated that the Sugar-cane never produced seeds until it was allowed to remain some years in a stony locality. The possibility of raising Sugar-canes from seed was discussed in the West Indies between 1858 and 1888. Since that time seedling varieties have been raised which are found capable of resisting the attacks of disease, which destroyed the older forms, as well as of increasing the yield of sugar. By means of a system of rigorous selection both in the field and in the laboratory several good varieties have been raised, but, at the same time, even more rigorous elimination has been found necessary, for the great majority of the seedlings so raised were found to be no better than the old ones. In any case it takes several years before a seedling cane is sufficiently tested under varying conditions to deserve to be recommended to planters. Moreover, the variety that is found suitable for one locality is useless in another. Cross fertilisation has also been attempted, but, as it would seem, with doubtful results. Some varieties it is found do not produce fertile pollen. Cross fertilisation has been effected by emasculating the flowers while still young—a delicate operation obviously—and transferring by means of a camel's hair pencil the pollen of another variety to the stigma of the emasculated flower. The resulting seedlings raised by Mr. Lewton Brain are the first, observed in the West Indies, whose parentage on both sides is a matter of certainty.

Further experiments on a large scale are in progress under the superintendence of Mr. Stockdale, so that it is hoped in a few years that experimenters will be as successful as raisers of Wheat and other cereals have been in England, and, like them, will be able to produce pedigree Sugar-canes as well as pedigree Wheat or Oats.

OUR SUPPLEMENTARY ILLUSTRATION—SNOWDROPS AT HOME.—There are certain flowers which only look happy when their surroundings are Nature's, or a good copy of them, such are Snowdrops, Primroses, Cowslips, Anemones, Daffodils, Heaths, Furze, Ferns, and many more. One might express it differently and say that no plant looks happy unless its surroundings are natural. Use is second nature, and we certainly have got used to a great deal in gardening that wants reforming, but reform moves slowly. Meanwhile we are getting on. We have wild gardens, water gardens, grass glades, woodland walks, natural grouping, and other improvements in the garden, and plants which not many years ago were only seen in pots and pans and formal beds are now planted to run wild, as it were, whilst the hand of the gardener is cunningly veiled. The view of Snowdrops in a wild garden at Kew, reproduced in the Supplementary Illustration, should make every gardener decide to grow Snowdrops in future only in Nature's way. A bed of such things is as natural as a waggon-load of monkeys; pots and pans filled with them as artistic as the contents of a sardine tin. Of course, it is not every lover of the Snowdrop who, desiring to have some of his own, can give them a big stretch in a wild garden three acres or so in extent, as is done in the Royal Gardens, Kew. But our public parks and gardens might do a great deal more of this sort of thing. Some day, perhaps, we shall be so far "reformed" as to have turfed over all our formal flower-beds and got into the habit of copying Nature's best work in everything. Someone remarked recently that the flower-bed was a proof of civilisation, just as are the top hat, tight lacing, and shaving! Maybe he was right; at any rate, as things are at present we must go in for them all, although some of us would like to abolish them. Fashion and what we like to call convenience control our gardening efforts; but let us, just to show that we are masters of our own actions, now and then break the bonds, as was done when we started "wild" gardening. *W. W.*

SMALL HOLDINGS.—The departmental committee appointed by the President of the Board of Agriculture and Fisheries to inquire into the subject of small holdings resumed their sittings on the 21st ult. Evidence was given by Mr. J. W. WILLIS BUND, chairman of the Worcester County Council, and Mr. F. SMITH, F.S.I., chairman of the Small Holdings Committee, Worcester County Council.

GEORGE MONRO, LIMITED, CONCERT COMMITTEE.—The tenth annual Bohemian concert arranged by this committee was held at the Queen's Hall, Langham Place, W., on Thursday last, the 22nd ult., and was again a great success, both numerically and financially. The vast hall was filled to its utmost capacity, and it was computed that 1,800 persons were present.

The secretary, Mr. H. BAKER, informs us that the sale of tickets exceeded any previous record, and therefore the various gardening charities for whose special benefit these concerts are arranged will in all probability receive a larger amount than in any previous year.

The programme was indeed a monster one, and where the artistes engaged were of all-round excellence, and included such well-known society entertainers as Miss MARTHA CUNNINGHAM, Miss EDNA THORNTON, Messrs. ALFRED HEATHER, CHARLES TREE, MCCALL CHAMBERS, WILL EDWARDS, R. H. DOUGLAS, and JAMES GODDEN, it may seem invidious to mention any one specially; but we cannot refrain from saying that Miss EDNA THORNTON's singing of "Land of Hope and Glory," accompanied by the Coldstream Guards' band (Conductor, Lieut. J. MACKENZIE ROGAN), was a musical treat well worth a long journey.

During the evening the Chairman, GEO. MONRO, Esq., who was supported by many of the leading men in the horticultural world, was presented by the Committee with a handsome brass and copper table gong, suitably inscribed, and we noted he used it with great success during the evening.

ITALIAN GARDENS.—Messrs. LONGMANS, GREEN & Co. have just issued a prospectus of a very fine work they are about to publish, entitled "The Art of Garden Design in Italy," by H. INIGO TRIGGS, A.R.I.B.A. It is dedicated by special permission to H.M. QUEEN MARGHERITA of Italy, and will consist of a handsome volume folio with 128 plates, 17 inches by 13 inches, of which 73 are reproduced in collotype. The first part of the work consists of an historical essay on garden planning from the days of the Roman Republic through the Imperial Age to the Middle Ages down to the early Renaissance. The second part is a series of descriptive accounts of the principal villas still remaining—Isola Bella, Villa d'Este, Villa Carlotta, Boboli Gardens, Villa Campi, the Quirinal, the Vatican Gardens, Villa Borghese, Villa Pamphili, Villa Medici, and Villa Lante.

DISHONEST TRADE MARKS.—A Canadian fruit grower was convicted in January last of having in his possession 50 barrels of apples marked XXX., but which were below the standard required. The case was proved, and the chief of the fruit division said that the man who deliberately marked packages falsely committed a crime against society. The magistrate imposed a fine of 50 dollars and costs, or imprisonment for 30 days in the common jail.

"GARDENING YEAR-BOOK AND GARDEN ORACLE."—Mr. George Gordon, editor of the *Gardeners' Magazine*, has again issued this annual, now so well appreciated. It includes an almanack and diary, many gardening articles and notes, and plenty of pictures. The frontispiece is a pretty coloured plate of the hybrid Wichuriana Rose, Pink Rambler.

THE MAGAZINE OF FINE ARTS.—The February number contains an illustrated account of the famous illustrated manuscript bought by Mr. QUARITCH at the sale of the Earl of CORK'S library. The price paid was no less than £2,600, but the book is unique. In this volume, the title of which is *Le Livre de Rustican des Prouffits Champestres*, the people and the life of the fields of 500 years ago are represented with a beauty and care that is charming and instructive. We see the

castles, farms, fields, gardens, implements, the manner of working; in fact, everything relating to country life in mediæval times; and in more than one occupation the method practised then is similar to that in use to-day. By way of illustration a figure is given showing some men engaged in grafting. In another plate the process of house-building and thatching is depicted; in others various agricultural and gardening operations. Nothing is known of the author of the book nor of the illuminator whose art is so highly estimated by our contemporary.

"The Year-Book of New South Wales."—This annual, issued under the auspices of the Agent General in London, is as usual full of useful information concerning New South Wales and its resources. There is a short article on forestry, and the agricultural industry is also dealt with. As the Year-Book bears reference to the whole Colony, its government, history, present status, products, industries, and even the postal regulations, it will be understood that each subject can be but briefly dealt with. It should prove as valuable for reference as previous issues have been.

Railway Reforms.—At present a committee, presided over by Lord Jersey, is enquiring into the question of preferential rates given by railway companies to foreign produce. It is expected that a report will be presented to Parliament at an early date. To tackle the question of reform in connection with many other railway matters a most influential committee has recently been formed, known as the Joint Railway and Parliamentary Committee. It consists of representatives from the National Fruit Growers' Association, the London Chamber of Commerce (Green Fruit Section), the Federation of Grocers' Associations, Meat Traders' Associations, the Horticultural Trades, the Potato Trades, and others. The president is Mr. George Monro, and meetings are held every week at the Tavistock Hotel, Covent Garden, W.C. The necessity for action has been brought about by a huge combination among the railway companies and the formation by them of a Joint Claims Committee. Nothing was ever devised by the railway companies of Great Britain which has been, and is, such a source of irritation to traders as this Joint Claims Committee. The railways have, in many cases, two classes of rates, a "company's risk" rate and an "owner's risk" rate. The former means that the railways carry the goods as ordinary carriers, and are responsible for damage and loss. "Owner's risk" used to mean that the companies at least were responsible for delivering the goods in some shape or form, but since the combination and the advent of the Joint Claims Committee they do not even undertake that liability. Cases are on record where they delivered several parcels less than they received; where they delivered them to a wrong station; where they set fire to a truck of bananas and some cases of plants and offered the consignee the charred remains. In all these instances when claims for damages were sent in the Joint Claims Committee said: "No liability; goods consigned at owner's risk." To contest these decisions of the Railway Companies' Committee the trader has to fight the combined railway companies of the kingdom in the Law Courts at enormous cost. In the report of the Departmental Committee on Fruit Culture it is stated that "this action of the railway companies may not be illegal, but it has caused great irritation among growers all over the kingdom." The difference between "company's risk" rates and "owner's risk" rates varies from something like 7½ per cent. to 50 per cent., but even the greatest difference should not imply that the railways are at liberty to do what they like with the goods entrusted to them. Compensation claims used to be entertained, too, for loss of markets, but that also is a thing of the past, unless the sender can prove "wilful misconduct." It was shown before the Departmental Committee just referred to that if the *owner's* risk rates were slightly raised, say, by 5 per cent. (which Mr. Vincent Hill suggested was the proper difference between them and company's risk rates, though the actual difference is generally much more, and varies enormously), and if all fruit, both by passenger and goods trains, was carried at company's risk in future, growers would gladly pay the small extra amount. The development of *petite* culture in all its branches is one of the most hopeful lines along which to look for help in the solution of the "unemployed" and "back to the land" problems, and better railway facilities would go a long way to help such development. It is singular that exactly the same questions affecting railway management are attracting the serious attention of traders in the United States. There, the strenuous President, Mr. Roosevelt, is interesting himself in the matter. It is hoped that Mr. Lloyd George, M.P., President of the Board of Trade, will emulate President Roosevelt in this, and tackle the subject. In an article in the February *Century Magazine*, the following appears: "This is what has happened, and is happening, in all parts of the States. Where there is not absolute identity of ownership in the railways serving different markets, that ownership is so concentrated that it has become possible for the owners of different properties to sit down in conference and determine that 'suicidal competition' shall no longer prevail. With notable exceptions, market competition can no longer be relied upon either to reduce rates or to prevent their advance. . . . As a result, rates upon almost every staple article have, within the last five years, been materially advanced. . . . If the railway imposes upon me an unjust charge for the transportation of my person or my property, it violates the law, precisely as I should do if I declined to pay a reasonable charge for that transportation," says the American writer. So says the British trader, and to get a more accessible tribunal, a less costly tribunal, and a tribunal more in touch with commercial methods, he means to go to Parliament.

Sugar Beet Experiments.—The high price of sugar in 1904, and the exclusion of bounty fed sugar from the English market have had the effect of again bringing into prominence the question which has for many years been much discussed as to the advantage of manufacturing sugar in this country from home-grown Sugar Beet. The Essex Education Committee have therefore conducted certain experiments in order to find the yield and quality of the Beet grown on typical soils and to compare some varieties. The results show that Beets have been grown equal to and in some cases better in quality than those produced in sugar-making countries. It would seem, therefore, that a new and profitable industry has been but too long neglected. The business side of the question—the cost of production and the consideration of the local conditions prevailing in the Eastern counties, the cost of working a factory, and a host of similar points, need, however, careful and experienced consideration. Mr. George Clarke, who has assisted in preparing the Report from which we now quote, issues the warning that nothing would be more disastrous both to farmer and to capitalist investing his money in the erecting of plant, than for the former to embark on the cultivation of Sugar Beet on an extensive scale without a proper knowledge of the best methods of cultivation, the varieties best suited to his particular neighbourhood, and the amount it would cost him to grow the crop. Still, there seems to be no reason, if due consideration be given to all these details, why a properly initiated undertaking should not be remunerative both to the farmer and the manufacturer. As regards an unsuccessful effort in this direction started some 30 years ago, it is noted that the mean percentage of sugar in the Beet used was 10.0. The mean of over 80 samples from different plots grown in Essex in 1905 is slightly over 16½ per cent. of sugar. This is a striking illustration of the improvement in the quality that can be brought about by careful selection along the right lines. Cultivation is a matter fully as important as the choice of the best varieties of Beet, and the subject of manuring also requires careful study. In the experimental plots it was found that the sugar content was considerably increased by the use of sulphate of potash. For further details of these important trials readers should consult the pages of the Report, which is fully and instructively illustrated. It may be had from the County Technical Laboratory, Chelmsford.

Mythical Plants.—The astonishing stories that are occasionally reproduced in the lay journals are a source of amusement to botanists and gardeners who are apt to wonder whether the information supplied on matters outside their own department is as untrustworthy as that relating to the subjects of which they have first-hand knowledge. Dr. George A. Grierson writes from Camberley under date of January 6th:—"In *The Times* of to-day your Calcutta correspondent, in describing the visit of the Tashi Lama to Bôdh (not Buddh) Gayâ, says—'One can imagine the feelings with which he solemnised the mysteries of his religion under the spreading branches of the same venerable Bo tree of Buddh Gayâ, beneath which, according to Buddhist tradition, Gautama himself received enlightenment.' I was for five years magistrate of Gayâ, and probably know the temple and tree at Bôdh-Gayâ as well as most people. In the interests of historical accuracy permit me to point out that the existing Bo tree, or Bôdhi-drnma as it is called in India, has not spreading branches, is not venerable, and is not the same tree as that under which Gautama is said to have received enlightenment. The existing tree was planted in 1876, being a seedling from its predecessor. When I last saw it, some eight years ago, it may have been 20ft. high, and had no spreading branches. It is a 'peepul' (Ficus religiosa), a quick-growing, short-lived tree, and, even if its history were not perfectly well known, it could not possibly be the identical one under which the Buddha sat. According to tradition, the original tree was cut down by the Emperor Asôka (say, 250 B.C.), and is said to have been destroyed a second time by his Queen after it had been miraculously restored. The Chinese pilgrim Yuan Chwang tells of another persecuting monarch, by name Sasanka, who cut down its successor of the seventh century A.D., and dug up most of the roots. 'Then he burnt it with fire and sprinkled it with the juice of the sugar-cane, desiring to destroy it entirely, and not leave a trace of it behind.' Shortly afterwards, a pious local Râjâ, 'with the milk of a thousand cows again bathed the roots of the tree, and in a night it once more revived and grew to the height of some ten feet.' Dr. Buchanan Hamilton saw the tree about the year 1811. According to him:—'The tree is in full vigour, and cannot in all probability exceed 100 years of age; but a similar one may have existed in the same place, when the temple was entire.' The penultimate Bôdhi-druma, which was the one seen by Dr. Hamilton, was blown down by a storm in 1876, and its successor, the present tree, was planted in its place by Mr. Beglar,

who was then in charge of the restoration of the temple. At this time it was worshipped both by Hindus and Buddhists. I believe that I am correct in stating that Mr. Beglar planted two seedlings, one on the original site for the Buddhists, and another a short distance off for the Hindus, and that both trees are now in existence. General Cunningham was of opinion that there must have been 'a long succession of fresh trees raised from seed, from the time of Asôka down to the present day. Perhaps as many as 12 or 15, or even 20, to meet the frequent destruction to which it was exposed.'"

The Fixation of Nitrogen.—Professor Silvanus Thompson, in lecturing at the Royal Institution on this subject, began by emphasising the enormous practical importance of the question in connection with the wheat supply of the world. The demand for wheat by the white races increased every year with increase of population. But the acreage of land devoted to wheat-growing did not increase at an equal rate, and in any case, being limited by climatic conditions, would all be taken up in a comparatively small number of years, perhaps less than 30. When that condition of affairs was reached there must be a wheat famine, unless, as Sir William Crookes pointed out to the British Association in 1898, the world's yield per acre (at present about 12.7 bushels) could be increased by the use of fertilisers. Wheat required some fertiliser containing fixed nitrogen, and the chief substance of the kind now available was nitrate of soda, obtained from the nitre beds of Chile. The demand for this had practically doubled since 1890, and in 1905 was over a million and a half tons; at the present rate of consumption the supply would be exhausted in less than 50 years. Then the only chance of averting starvation from the races for which wheat was the staple food would be, as Crookes pointed out, through the laboratory, through chemists discovering some method by which at a sufficiently cheap rate the free nitrogen of the atmosphere could be fixed in a form that could be utilised by the wheat plant. Experiment showed that the nitrate of lime produced by electric means by Birkeland and Eyde, of Christiania, was as good a fertiliser as Chile saltpetre. The conditions in Norway were exceptionally good for furnishing cheap electric power. Hence the new "Norwegian saltpetre" could compete with the imported saltpetre from Chile, and would every year become more valuable as the demand for nitrates increased and the natural supplies became exhausted.

Costa Rica.—The ninth volume of the *Anales del Instituto Fisico-Geographico Nacional de Costa Rica*, of which Dr. Pittier is the Director, has been published. It contains detailed meteorological observations on climate for the year 1896, which are important for cultivators of plants. A partial enumeration of the flowering plants by Captain Donnell Smith follows, together with a monographic sketch of the Piperaceæ by M. Casimir de Candolle. The Acanthaceæ are enumerated by M. G. Lindau, the Euphorbiaceæ by Prof. Pax, and the Araceæ by Dr. Engler. The general character of the flora shows a closer relation to the flora of Northern South America than to that of Mexico.

The Uses and Misuses of Manure.—The Dorset County Council has published a report on the Soils of Dorset, by Professor John Percival, that contains some valuable information concerning plant foods and manures. In 1898 the University College, Reading, undertook to analyse 100 samples of soil from various parts of the county of Dorset and to report upon them. This was done partly by Mr. Jeffreys and Dr. Luxmoore, as well as by Professor Percival (Director of the Agricultural Department of the college), who now issues this summary of the results obtained, which should have an immediate interest to farmers in the county and elsewhere. Briefly, manures are applied to soil to supply constituents lacking from it and necessary for certain crops. Such plant-food, therefore, must be given as is naturally deficient in the land to which it is applied, and, further, such as is required and can be assimilated by the crops to be grown thereon. To apply manures whose effect is to neutralise each other, or which are unsuitable to the soil and to plants, is unnecessary labour and a waste of resources. The details concerning the use of nitrogenous, phosphatic, and potassic manures are very valuable, and should be carefully studied by all who are contemplating the employment of artificial manures.

Commercial Research in the Tropics.—An institute has been formed in connection with the University of Liverpool for the purpose of collecting and co-ordinating information of all kinds relating to commercial products, or substances used in manufactures, and of supplying scientific information to all interested in commerce. These objects are carried out by means of scientific explorations, research work in the laboratories and museums of the University and of the city. The Department of Economic Botany is under the direction of Dr. Eric Drabble, that of Economic Zoology has Mr. Newstead on its staff as Economic Entomologist, and there are numerous other experts dealing with chemistry and other sciences. The first part of a journal, which is to be issued quarterly, is now before us. It contains full details as to the work of the Institute. The experiments of Messrs. Garton on the improvement of Cereals and other plants will be subjected to exhaustive examination, and a report thereon is announced as nearing completion.

The almond.—The first flowers on an Almond tree in a favourable position in Wandsworth, south-west of London, expanded fully on Wednesday last, February 28, as against March 7 last year, and March 21 in 1904.

Sugar-cane Experiments in the Leeward Islands.—We note the publication of the first part of the report on Sugar-cane experiments conducted at Antigua and St. Kitts in 1904-5. Trials were made of varieties of Sugar-cane to prove which were of most value for certain districts. Good results were obtained, though very severe drought, particularly in Antigua, was a serious drawback. The report is drawn up under the superintendence of the chemist in charge of experiments, the Hon. Dr. Francis Watts, and contains a brief introductory letter by Sir D. Morris.

United Horticultural Benefit and Provident.—The annual general meeting of this society will be held at the Horticultural Hall, Vincent Square, Westminster, S.W., on Monday, March 12, 1906, at 8 p.m. Mr. H. B. May will preside. The committee hope that as many members as possible will endeavour to be present.

The Royal Horticultural Society is forming a collection of the best varieties of Grape vines at Wisley. All that are wanted have been met with except Diamant Traube and White Nice, and for these the secretary and the superintendent have inquired in many quarters but failed to find them. The society would be most grateful to anyone who can supply information of their being still in cultivation, and from whom they may be obtained. It is a thousand pities that two such varieties should perish off the earth. Will foreign and American Horticultural papers be so kind as to copy this note? *W. Wilks, Sec. R.H.S.*

Bird-Lime for Catching Rats.—Mr. C. Drieberg, Superintendent of School Gardens, Colombo, writes as follows in the *Tropical Agriculturist* for January:—"It is not generally known how readily rats may be caught by means of bird-lime. If it is desired to make a colony desert their burrows it is only necessary to smear a little round the entrances. If it is desired to catch them, the best way is to dress plenty of straw and spread this thickly on the ground around the burrows. Among the straw throw some attractive bait. When the spot is visited next morning the straws will be found gathered up in little bundles, and in the centre of each will be found a rat, alive or dead, according to the extent of its entanglement. If the bird-lime is to be used indoors take a piece of stiff brown paper and put the sticky stuff in the centre. Bird-lime can be easily made by boiling down linseed oil. Put the oil into a tin, place the tin in a saucepan of water, and let it boil slowly till it is of the right thickness or stickiness."

Para Rubber in Singapore.—We have received the first annual report by Messrs. H. N. Ridley and R. Derry on experiments in rubber-tapping made in the Botanic Gardens, Singapore. Certain important facts as to the growth of trees, yield of rubber, best methods of procuring and preparing latex were ascertained, and the records form a valuable basis for continued researches. The work was most sedulously carried out, and the rubber obtained fetched on sale in all cases the highest price in the market at the time, showing the care taken in its preparation.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from page 101.)

The Flora of the District.

Our knowledge of the flora of this neighbourhood is considerable, thanks to the labour of Père Soulie, Mr. A. E. Pratt, Prince Henri d'Orleans, Père Fanrie, Père Mussott, and the Russian traveller, Potanin. Hemsley, in his "Flora of Tibet or High Asia" (Journal Linn. Soc., Vol. xxxv.), speaking of the flora of this neighbourhood, says: "In character it is essentially Himalayan or Indo-Chinese, and is quite distinct from that of Tibet proper." Anyone who has had the opportunity of botanising in this region, or of examining the collections made there, must certainly agree with this statement. The Sikkim-Himalayan element is very striking, even to a casual observer. In point of numbers, two of the commonest plants are Primula sikkimensis and Podophyllum Emodi, both of which are common in Sikkim.

Tatien-lu, it may be said, is situated on the extreme edge of the Himalayan highlands, and less than a day's journey in a westerly or north-westerly direction brings one to the luxuriant pastures of the Tibetan uplands. These pastures support huge herds of yak and sheep. Around the town, an occasional field of wheat, barley, or Irish potato is all the cultivation one sees. These fields are usually fenced by hedges composed almost entirely of the wild Gooseberry. The only trees are Populus euphratica, with an occasional Spruce Fir and Walnut.

It was on the evening of July 14, 1903, that I arrived at Tatien-lu after a circuitous and arduous journey of 20 days. I took up quarters in the same dilapidated Tibetan inn that had lodged all travellers from the time of Gill and Baber downwards. Two days later I left for a trip to the snowy range south-west of the town. On this journey I was accompanied by Mr. Edgar, of the China Inland Mission, in whom I found a delightful companion. To this gentleman and his colleague, Mr. Moyes, I am much indebted, and it is with feelings of deep gratitude that I recall the many acts of kindness I received at the hands of these estimable gentlemen.

Leaving by the South Gate, we followed the main road to Lhassa—a broad, well-paved road. Crossing a stone bridge, situated a short distance above the site of the old town, we entered the nondescript country of Djiala. Soon after-

wards, sheltered beneath magnificent groves of lofty Poplar (P. euphratica), we passed two large Lamaseries and a building containing many prayer cylinders, each with numerous prayer-flags flying from their roofs. Large cairns of stones, surmounted with tiny prayer-flags; slabs of slate or marble, and tiny cones of dried mud, all with prayers inscribed thereon. These, to mention nothing else, were sufficient to remind us that we were in the hierarchy of Lamaism. Herdsmen, with their yak and sheep; women and children gathering fuel, harvesting grain, or performing ordinary household duties, all chant, in a not unmusical voice, their universal prayer, "*Om mani padmi hum.*"

About two miles from Tatien-lu we left the main road and followed the left bank of the River Lu, crossing over to the right bank soon afterwards by a rickety wooden bridge. A little above this bridge the stream bifurcates—one branch rising in the Cheh—To pass over which the road to Batang crosses; and the other in the snow-clad peaks flanking the Ya-chia-kang, our destination.

Our road was through lovely grassy country, with a very steady rise. A wealth of many-coloured herbs enlivened the path; various species of Pedicularis, with white, red, pink, and golden flowers, were particularly abundant, more especially where the country is marshy. In these same marshy places, Primula vittata, P. Poissoni, Lilium Duchartrei, and a species of Parnassia abound. In less marshy, but by no means dry, meadows, a Primula (P. Cockburniana), with wonderful *orange-red* flowers, occurred in thousands! (See *Gardeners' Chronicle*, May 27, 1905, Fig. 137.) In fairly dry places, clumps of a yellow-flowered Cypripedium (C. luteum) were conspicuous. The flowers of this fine Cypripedium are nearly as large as those of C. macranthum, and of a clear yellow colour throughout, though occasionally an odd flower or two is seen in which the lip is brownish. In addition to these, we saw Morina Delavayi, with white, pink, or purple flowers, Pæonia anomala, and various Composites and Labiates in abundance. Bushes of Lonicera, Spiræa, Hydrangea, Berberis, Rhododendron, and Viburnum, stunted and scrubby in appearance, are common; and over these trail two species of Clematis, with a wealth of yellowish-white fragrant flowers.

Passing the king's summer palace, a very unregal looking place, with a filthy exterior, we reached a tiny stream, and lunched there. Thermal springs are common hereabouts; in some of these the water is naturally boiling. Near our luncheon place were several huge prayer cylinders fixed to horizontal wheels, and turned by the water of the stream.

On restarting, we continued through similar country, with a fine snow-clad peak straight in front of us, and another to our left, and soon reached two or three Tibetan farmsteads (alt. 10,000 feet), where a little barley is cultivated. Just beyond this tiny hamlet we commenced a steep descent of a thousand feet, through a dense thicket of Rhododendrons, dwarf evergreen Oaks, Berberis, Hippophae rhamnoides, with a few trees of Larch, Silver Fir, and Spruce interspersed. Herbs abound: a species of Iris, with large, dark, violet-blue flowers, Trollius yunnanensis, Podophyllum Emodi, Parnassia sp., various Composites and Umbelliferæ being perhaps the more striking. Less conspicuous, but none the less interesting, were Primula deflexa, and two other species, Fragaria filipendula, with luscious fruits, Ajuga ovalifolia, with lovely blue flowers, various species of Pedicularis, and many terrestrial Orchids.

On clearing this interesting belt, we soon reached a house, or, rather, the remains of one, for fully half of the roof was missing, tenanted by an old drone and her idiot daughter. We had agreed to make this point our base, and made arrangements accordingly. The old woman having agreed to accommodate our followers, we selected a convenient spot near by on which to pitch a tent for ourselves. Our baggage coolies and men not having arrived, we thought we would beguile the time by having a look around. Rain, which had fallen in fitful showers during the whole day, commenced again as we set out, and we were less than half a mile from the house when it fell in torrents, quickly drenching us to the skin. It was more of the nature of hail than rain, and hurt as it struck one's face. My poor dog howled and shivered with cold. The yak and their hardy herdsmen did not seem to mind the raging elements in the least, but we were benumbed with cold. Hurrying back with all speed to our shelter, with visions of hot tea and dry clothing, we were far from anticipating what really awaited us. The altitude had affected our men, and they were in a sorry plight, only two being in any sense fit to do anything. Our cook—the most important man for the moment—lay stretched out on a plank with his head swathed in bandages. With difficulty we managed to get out of him what was wrong. He said "his head was swimming and throbbing, his heart palpitating sixteen to the dozen, and that a general paralysis had seized his legs, and more particularly his knees." Lifting him up on his

Fig. 53.—DOUBLE FLOWERS OF THE WINTER ACONITE.

legs, we gave him a stiff dram of brandy, but the moment we loosed him he sank into a heap on the floor. It was hopeless to expect anything from him, so for the moment we let him go. Whilst I acted as family doctor, my companion and the two men in good health attempted to fix up the tent outside—meanwhile rain, hail and sleet descended in torrents. After half-an-hour's struggle, the rain and wind conquered, and the task of rigging the tent outside had to be abandoned. There being no possible place to sleep inside, free from rain, the only thing left was to fix the tent up inside the house, the floor of which, owing to the absence of part of the roof, being already a quagmire. At length it was put up somehow, our beds were arranged beneath it, and oil-sheets placed over the top, as the thin cloth did not pretend to be waterproof. Next we built a fire in the driest part of the house we could find, and all huddled around it to get warm and dry. After a time, we managed to get some hot tea, and with this and ship's biscuit and cheese made a hearty supper.

Having done all we could for our men, and lent them what spare clothing we had, we sought our beds about 11 p.m. By this time our tent was soaked through, in spite of the oil-sheets; the wind and rain continued without mercy, and did not cease in violence until 6 o'clock next morning. Having at length got rid of our soaked garments—a difficult enough task under the circumstances—we eventually got between the blankets. No sooner had I lay down than drip came a spot of rain into my eye; I turned over, and drip came another into my ear. I twisted this way and that way, but there was no escape. Like evil genii these rain-drops pursued me turn which way I would. I could not move my bed, since this was longer than the tent was broad, and my feet already exposed, and we were sorely afraid the whole thing might collapse, it being anything but secure. My companion was in a similar plight, and there being no escape, we buried our heads beneath the blankets and tried to get to sleep. Our sleep was fitful and disturbed. About 2 a.m. I awoke to find that my blanket had slipped over on to the floor; pulling it over me again I disturbed four half-drowned chickens whom my thoughtless men had tied to a post alongside my bed. These chickens resenting the loss of the blanket tried to follow it, and succeeded in nearly blinding me with mud.

About 4 a.m. our firewood gave out, and things assumed a very dismal aspect. However, all things have an end; day at length dawned, and all were devoutly thankful. On getting up, we found that our beds were soaked through and through, and our blankets plastered with mud. With what fire remained we managed to boil some water and make some tea. We breakfasted on ship's biscuits and cheese, and felt none the worse for the night's experience. *E. H. Wilson.*

(*To be continued.*)

THE DOUBLE WINTER ACONITE.

One of the most delightful of our Spring visitants is the winter Aconite, Eranthis hyemalis, with its frill of green leaves surrounding its yellow petals. The double form in which petals take the place of stamens is not so commonly met with. Nevertheless, it amply deserves to be more fully known, on which account we give an illustration of it, taken from a photograph by Mr. H. A. Smith, of Lewisham.

THE ST. LOUIS EXHIBITION.

The official report of His Majesty's Commissioners for this exhibition has been published. It gives the history of the undertaking, and details the steps taken by our own Government to secure that British products should be (as far as the Customs regulations would permit) adequately represented. One great hindrance alike to the exhibition and to trade in general lies in the most oppressive fiscal regulations which the United States Government deems desirable in the interest of its own manufacturers and producers. These effectually prevented some of our manufacturers from exhibiting as they would have done. It is doubtful whether the advantages to the citizens of the U.S. outweigh the annoyances to which, not only foreigners, but they themselves are subjected by the vexations of their Custom House regulations.

These are dealt with at p. 15 and p. 167 of the Report, and again in the Report of the Art Committee, from which we extract the following remarks:—

"The great difficulties resulting from the stringent nature of the regulations of the United States Government in regard to works of art and industry from foreign countries are fully dealt with in a separate report by Sir C. M. Watson. It may, however, be mentioned in this connection that before the packing of our works of art could be commenced no less than ten separate forms, containing miscellaneous information, had to be examined and approved in various departments of the U.S. Custom House.

"It is, however, satisfactory to note that, in the face of very exceptional obstacles, Great Britain was the first to

complete the dismantling of her Art Section, and it was well on its way to New York before permission had been obtained by some of the other foreign art departments to begin the work of packing."

The Departments of Horticulture and Forestry were officially represented by Mr. H. J. Elwes, F.R.S., from whose report we extract the following particulars:—

"Cannas were the only group of plants which really made a great show at the time when the jury was sitting, and these, favoured by the warmth of the climate, were much superior to what I have seen in England, though the individual varieties and novelties were perhaps not finer than what have been raised and grown in the South of France.

"The one striking exception to the general uniformity of the ornamental bedding was an extremely fine collection of Water Lilies and other aquatic plants exhibited by Messrs. Dreer, of Philadelphia, which filled a large pond, and were, in my opinion, by far the most meritorious exhibit in this section.

"The foreign exhibits in these classes mostly took the form of gardens surrounding the pavilions and buildings of their respective countries, and though they contained fairly representative collections of annuals, lawn-grasses, Roses, shrubs, and trained fruit-trees, in which latter the French were supreme, I saw nothing, except a fine collection of Cacti from Mexico, which calls for any special remark.

"The British garden was designed by one of our most able landscape gardeners, Mr. Goldring, of Kew, and his designs were carried out by his representative, Mr. T. W. Brown, in a manner which did the greatest credit to his horticultural skill and taste. The materials at his disposal, which consisted, with few exceptions, of common bedding plants and annuals, were made the most of under extremely difficult and trying conditions of soil and climate. The general effect of the British garden was good, and quite in keeping with the style of architecture of the Royal pavilion. The trained Yew trees and other examples of the topiary art sent by Messrs. Wm. Cutbush and Son, of Highgate, were much admired.

"The French garden, which was of great size, and admirably laid out by M. Vacheraux, of the Municipality of the City of Paris, contained many collections of Roses, fruit trees and shrubs; and was in most respects the largest and best exhibit made in this department by any foreign country.

"The Japanese garden, designed and laid out by Mr. Y. Itchikawa, of the Japanese Commission, was also quite national in its character, and contained a considerable number of dwarf-trained trees, in the cultivation of which the Japanese have such a world-wide fame, but the difficulties of transit over so great a distance had, to some extent, marred his efforts; and coming, as I did, straight from Japan, I was not so much impressed as I should otherwise have been, because the spring and early summer is the time at which Japanese gardens are at their best, and most of the flowering Plants such as Irises, Lilies and Pœonies had lost their beauty in September, whilst Chrysanthemums had hardly begun to flower.

Fruits, etc.

"In the fruit classes the wonderful development of American horticulture was splendidly represented. The Horticultural Building, covering nearly four acres of ground, was in the month of May filled with a collection of fruit, preserved mostly by cold storage from the previous year, of an extent, variety, and quality which no other country could equal. It was arranged in State exhibits, and was constantly replenished by fresh arrivals from time to time as the new season's fruit ripened."

English Exhibitors.

"The following firms contributed selections of plants and seeds in accordance with suggestions which were made to them as to the description of flowers required:—

"Messrs. Cannell & Sons, Carter & Co., J. Cheal & Sons, W. Cutbush & Son, Hobbies, Ltd., Kelway & Son, Sutton & Sons, Sander & Sons, Mr. John Forbes, and Mr. Amos Perry.

"The plants and seeds were forwarded to St. Louis during the autumn of 1903, where arrangements were made for their propagation and display at their proper season. The trees required for forming the 'Pleached Alley' and the outer boundary of the garden, as well as a large number of shrubs, flowering and otherwise, were purchased in the United States, the transportation from England of so large a quantity of growing trees being impracticable in the time. The garden, with its large variety of flowers thus exhibited, throughout the period of the Exhibition was greatly admired, and was a source of considerable attraction to visitors as an example of the methods of treating a garden in accordance with the architecture of the building it surrounded. Sixty large clipped Yew and Box trees (topiary work), which were lent by Messrs. Cutbush and Sons to be placed on the terrace of the pavilion and in other appropriate positions in the garden, were of great interest, this branch of horticulture being almost unknown in the United States. These trees were sent out under special arrangement with the steamship company to St. Louis at the latest possible date to arrive in time for the opening of the Exhibition, as it was feared they would be damaged by the severe frost prevailing in the early spring, and those which remained unsold were, for the same reason, despatched immediately the Exhibition closed.

"At the close of the Exhibition, the garden, with the trees, shrubs, grass lawns, fountains, vases and seats, was handed over to the Washington University of St. Louis, which owns the land, and will be maintained by that body until the ground is required for other purposes.

"In the Horticultural Building a series of photographs and a plan of the Royal Botanic Gardens, Kew, were exhibited by the Board of Agriculture and Fisheries, these being afterwards presented to the Missouri Botanical Garden, St. Louis."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Onions (see p. 128).—Certainly Onions were known in Britain in Anglo-Saxon times. In the 8th century Epinal Glossary we have "ascalonium ynnelaec" (i.e. Onion leek), to distinguish it from "allium-garlec" (i.e. spear leek). See *Gardeners' Chronicle* Nov. 3, 1888, p. 502. *H. N. Ellacombe.*

Foreign Apples.—Being a very bad Apple year we are purchasing foreign fruits in barrels. Although these are tightly packed and are very much bruised and compressed, one seldom finds them rotten. Are they treated with a fungicide before being packed? Because, if an English Apple is stored with the least bruise decay sets in at once. *J. S. Fowley.*

Hydrocyanic Acid Gas.—The use of hydrocyanic gas as an insecticide (see p. 88) requires discussion in order to get at the best means of generating it, the quantities to use, and its effect on vegetation. I am indebted to Mr. Storrie, of Dundee, for practical instruction in its use, but I have not employed it so extensively as he has. At present I am vaporising several houses, vineries at rest, into which a few plants that are subject to mealy bug and to Eucharis mite are placed to undergo treatment. I am using for each 1,000 cubic feet 4 ounces cyanide of potassium at 98 per cent., 8 ounces sulphuric acid, and 16 ounces water. I proceed in the following manner:—Large flat earthenware basins are used as vaporisers, the proper quantity of water is measured into each, then a bottle of acid containing the exact quantity is decanted into the water, and last of all the cyanide, which is tied in brown paper, is popped in one after the other as quickly as possible. The value of the paper consists in its delaying the production of gas long enough to enable the operator to get outside without fear of inhaling it to the least degree, which, if not dangerous, may result in a bad headache. A 3½-ounce strength of cyanide destroys mealy bug, but it is to be borne in mind that it has not been proved to destroy eggs of insects, and though every insect may be destroyed one need not be surprised when vaporing in the season of growth if in ten days or a fortnight a new generation appears. I tried the gas two years ago on a house of Black Hamburgh, on the bunches of which some bug had effected a lodgment. I was rather dubious as to the effect the grapes might have when eaten, but after trying them some days afterwards no bad results followed, and so we may consider the treatment harmless. It would be interesting to know if all kinds of grapes can be safely vaporised. Muscat of Alexandria, for instance, resents insecticides generally. Black Alicante is, of all varieties, one of the most difficult to clean, owing to the downiness of all the parts of the current year's growth. There is a difficulty with the railway people here, as they object to carry sulphuric acid unless at a largely enhanced rate. Where this is pressed it makes it a rather expensive method of getting rid of insects, otherwise it is as cheap as others, and certainly the most effective of all. *R. P. Brotherston.*

Nothing can be farther from my desire than to check in any way the introduction into gardening of cheap and effective insecticides or fungicides. My objection to such a fumigant as hydrocyanic gas is that it is very dangerous to human life. That may be mere sentiment; but as legislation has in so many directions of late tended to the protection of human life from poisonous compounds, and very proper legislation too, it does seem as if there was a tendency to revert to dangerous practices in commanding the employment as a fumigant in plant houses of a gas that is admitted to be of a highly poisonous nature. However, there are plenty of gardeners, and to spare, hence presumably the death of a few can hardly be allowed to stay the progress of fumigation experiment. If the insect life in a plant house be destroyed what matter even if a few human lives be taken also? *A. D.*

Willow for Bat-making.—In reply to several enquiries I may say that the best Willow timber for the manufacture of cricket bats is that of the white or Huntingdon Willow (Salix alba) and the Bedford (S. Russelliana)—the former, in my opinion, is preferable. They are of the readiest culture, as cuttings inserted in autumn or spring grow away freely, while a post driven into the ground emits roots and soon becomes established. I prefer, however, to grow the cuttings in the nursery for two years before planting out permanently. It is well to bear in mind in the cultivation of Willow timber for the making of cricket bats that unpollarded trees, or such as have not been beheaded or pruned too severely, are preferred, and, incidentally, it may be mentioned that such specimens are less liable to the attacks of injurious insects. *A. D. Webster.*

Gros Colmar Grape (see p. 128).—The reply to *Grape* was well worded and to the point, but there is still more to be added from the market side of the question. Gros Colmar is a Grape that, even under the best cultural conditions, requires fully six months to colour, and then another long month to hang before it is fit for the table. The question of when to start the Vines is entirely in the grower's own hand. It is not so much how soon these can be ripened as when they are wanted for market purposes. Provided red spider is kept under, Gros Colmar started in March, and grown as an exclusive crop, without being subject to the consideration of other things in the house, will have the fruit well coloured in the corresponding period of September, and fit for cutting in November and December. This undoubtedly is the safest culture of all, and if the Vines are not overcropped they should prove remunerative. Good Grapes of Gros Colmar, good in bunch and berry, even in a bad market realise 1s. 6d. to 2s. per lb. These figures represent actual facts. Fire heat is a very active factor in producing flavour. No other late crop of Gros Colmar will ever equal that resulting from starting the Vines in March, because they will not get the two months' interval between the cutting of the fruits and the restarting of the Vines. *Stephen Castle.*

The Royal Horticultural Society's Exhibition.—The exhibition of table decorations on June 20 promises to be one of the most interesting meetings in the Vincent Hall. I cannot but think adversely of the lack of enterprise on the part of the Council in offering no other award in any of the 29 classes beyond the Society's medals. This policy cannot but limit competition and therefore interest in the exhibition. The professional florist may regard such an exhibit as an exceedingly good advertisement for the purposes of trade, but for the amateur—male or female—the circumstances are entirely different. Amateurs set little store in obtaining medals as a recompense for time, expense of journey, and possibly the purchase of flowers also. If prizes (in kind if they like) were offered, the display would, I venture to say, be much more worthy of such an exhibition. No class of exhibitors that I am acquainted with think more seriously of the nett results of their labours than do the amateur lady decorators. They prefer to see something much more solid than the possibility of obtaining even a gold medal at the "discretion of the Council." *Decorator.*

The Carnation in French Literature (See p. 97).—In French gardening literature the Carnation has held for centuries past a very prominent place, almost equal to that perhaps which it enjoys in English gardening literature. For if we can find authors like Parkinson, Gerard, Rea, Gilbert and others who have deemed it worthy of their notice we shall probably find that Pierre Morin, Louis Liger, Fuard du Castel, Xavier Mallet and other old French horticultural authors of the 17th and 18th centuries have been equally interested in the Carnation in a general way. One of the most erudite and interesting authors on florists' flowers in the 18th century was the Père d'Ardène. His works are essentially monographs of the subjects on which he writes, and each runs into two or three hundred pages. His *Traité des Œillets*, published in 12mo. at Avignon in 1702, is described by no less an authority than M. Gibault as beyond doubt the best old book on the Carnation. This work is probably as rare as the two by L. B. and L. C. M. B. Another and possibly equally scarce French book on the Carnation is *Nouveau Traité des Œillets*, by Goube of Valenciennes, published in 12mo. at Cambrai in 1769. A few years later a book was published in Paris

entitled *Beauté de la Nature ou Fleuromanie Raisonné*, which, again on the authority of M. Gibault, was essentially a treatise on the Carnation, although it contained chapters on Hyacinths, Tulips, and Auriculas, a kind of French Hogg or Maddock, we may suppose. This is a book 12mo. in size, and it appeared in 1775. After this a great break occurs, and I know of nothing until another writer on florists' flowers undertook the subject. This was the Baron de Ponsort, who in 1841 brought out his *Traité sur la Culture de l'Œillet Flamand*. I have only the second edition, which bears date three years later, and is a very comprehensive treatise of nearly 200 pages dealing with almost every phase of its culture, its diseases, enemies, and classification. In 1845 the same author wrote *Appendice à la Monographie du Genre Œillet*, in which there is a coloured frontispiece of the variety Laure de St. Vincent and ten coloured plates showing the markings of the petals of the various varieties. Ragonot-Godefroy was another of these French writers on florists' flowers, and among his works is one entitled *Traité sur la Culture des Œillets*, published in Paris in 1842. Of this I only know the second edition. It is purely cultural except that he gives a tabular form of classification at the end and two plates (uncoloured) of the distinctive differences of the petals of the different kinds of Carnations. Of *L'Œillet, son Histoire, et sa Culture*, by Dupuis, published in Paris in 1862, I know nothing except the name, for although modern, it seems to be almost as difficult to obtain as some of those published a century before. Most of the remaining French books on the Carnation are much more modern, and little more in many cases than mere pamphlets; but it may be interesting to some of the readers of the *Gardeners' Chronicle* to mention them. There is *Culture et Multiplication de l'Œillet*, par un Amateur, Paris N.D., published probably thirty years ago. Then there is Mottet's *Les Œillets, Historique, Description des Principales Espèces, Races et Variétés, &c.*, published at Paris in 1898, and of which a second edition has recently been issued. *Culture de l'Œillet sous Chassis*, by Francis Orengo Antibes, 1898; and last, but not least, a very excellent treatise in cloth covers by Jules Rudolph, entitled *L'Œillet à la Grande Fleur*, with 22 illustrations, published in Paris in 1903, in which the history of the flower is given at some length, while the subject of propagation by seeds, cuttings, and layers, selection of varieties, culture in pots and in the open, insects, and diseases, all receive an adequate portion of the writer's attention. In addition to the above there is a little Swiss pamphlet, printed in French, called *Culture Pratique de l'Œillet Remontant*, by Auguste Guillot, published in Geneva in 1903. *C. Harman Payne.*

Broccolis at Wisley.—Lest an impression should prevail amongst those persons who send things to Wisley for trial, that such things meet with sparse consideration at the hands of the Fruit and Vegetable Committee, I beg leave to point out that the two Broccoli heads, viz., Snow's Winter White and Brydon's Peerless, mentioned in your report at p. 110, were from Wisley, where, in conjunction with others, they had been grown, but being presented to the committee at the Vincent Square Hall on the 13th in a hard trimmed form both closely resembled each other, and although Mr. S. T. Wright regards Peerless as dwarfer and the heads have better protection naturally than Winter White, and two or three members spoke favourably of it, the Committee thought, as going to Wisley to see the plants at this time of the year was out of the question, to request that at the next meeting plants of each variety just as pulled from the ground, and in no way trimmed, should be sent up for examination. The Committee have the greatest desire to deal justly with every exhibit, whether from Wisley or elsewhere. *A. D.*

Transplanting Early Peas.—I raise my earliest crop of culinary Peas in boxes of my own make, provided with a sliding bottom. When the seedlings are ready for transplanting, a trench is opened the width of the boxes, which are then placed in the trench and the sliding bottom removed. The boxes are lifted and the Peas remain in the trench with their roots practically undisturbed. I withhold water for a day or so previous to transplanting in order that the soil may leave the boxes readily; but after planting, the Peas are given a copious supply of water. I find this system gives excellent results. The plants are 6 inches high when planted out, and sticks are at once placed in position as much for protection in their early stages as for support. The trenches are made sufficiently deep to allow of earthing. The ground is double dug early the previous autumn with a heavy dressing of manure in the bottom of each trench. It is gone over again and thrown up in ridges to receive the full benefit of the effects of the weather. Planting is generally performed about the first week in February, previous to which the ground is levelled. The boxes when empty are washed and dried ready for use again the following season, or they can be used for other crops such as Celery. *S. K.*

Another Ornamental Kochia.—Under the name of Kochia trichophylla I have before me in an Erfurt seedsman's catalogue an illustration of a plant labelled K. trichophylla (Summer Cypress). This appears to be an exact counterpart of the plant that has been grown at Swanley, Hampton Court, Victoria Park, and many other districts during the past three years under the name of K. scoparia. My attention was first directed to the form of Kochia which has been so attractive in our parks, whether K. scoparia or K. trichophylla, by the generosity of Messrs. Cannell and Sons, of Swanley, who sent to me a few plants for trial. They pleased me greatly, and excited the attention of visitors by their symmetrical form and their delicate tint of fine green foliage. These plants were sent out under the name of Kochia scoparia. The following year, wishing to enlarge the stock of such an elegant reintroduction, I ordered seed from a firm of repute, and from the seeds which they supplied as Kochia scoparia developed plants so inferior to those obtained from Messrs. Cannell that I threw them away. Thinking, perhaps, that my treatment of the seedlings in question was at fault, the following year I ordered some more seed of Kochia scoparia from the same source, with the result that I raised a batch of seedlings which, when planted out, grew in such an attractive form, and coloured so beautifully towards the end of the summer, that I am sure, from the numerous enquiries I received, there will be a large demand for seed this spring. Experience has thus taught me that there are two kinds in commerce under the name of K. scoparia, and I should like to know the proper name for the best decorative variety, such as was shown by Messrs. Cannell at the Crystal Palace and at the Royal Horticultural Hall, whether trichophylla or scorpia. Under whatever name it may be recognised, I am sure that the finest form already grown and exhibited in England will not be surpassed by that now being sent out under the name of K. trichophylla. Kochia scoparia was known to Miller, for, in the sixth edition of the abridgement to the *Gardeners' Dictionary*, published in the year 1771, under the name of Chenopodium scoparia, the following details, among others, appear:—"Goose-foot, with narrow spear-shaped leaves, which are plain and entire, commonly called Belvedere, or Summer Cypress." Then follows this description:—"It is a beautiful plant, which is naturally disposed to grow very close and thick as in as regular a pyramid as if cut by art. The leaves are of a pleasant green; and were it not for that, it hath so much of the appearance of a Cypress tree that at some distance it might be taken for the same by good judges, etc., etc." Does not this description of that talented gardener, written more than 135 years ago, apply equally to the form we are now growing as Kochia scoparia, and have not the names of Belvedere and Summer Cypress been handed down from that time also? I trust to be spared through the coming summer to test whether there is any difference between the variety which has been re-introduced by Messrs. Cannell as K. scoparia and the variety now being introduced from Germany under the name of Kochia trichophylla. If no difference is found, which is to be the correct name, K. scoparia or K. trichophylla? *J. W. Moorman, Superintendent, Victoria Park.* [The *Index Kewensis* contains no such species of Kochia as trichophylla. K. scoparia is known to be very variable, and even the same plant varies in appearance according to season.—Ed.]

Horticultural Examinations.—Although I agree with Mr. Watson in the main points of his note regarding examinations in horticulture, yet I do not think it would be wise to disparage horticultural examinations altogether. "Theory without practice" may be useless in any profession, yet "theory" combined with "practice," in gardening, as in other professions, no doubt, is as great a boon as any man can possibly have. I am a "third-class" man myself, and have been a gardener all my life, but the study necessary to gain the third-class certificate more than compensated me for my trouble, by helping me to understand things more clearly, and making me think more about my work than I otherwise should have done. The R.H.S. examinations are too severe for an ordinary young gardener, who starts his career in the bothy, and who has only had a day-school education. Botany may not be absolutely necessary for a gardener, but a knowledge of elementary botany helps him to understand the particular needs of a plant, and makes plain the reason why they require particular treatment. I would like to suggest that the British Gardeners' Association should institute examinations in horticulture, and *only allow young gardeners to enter*. There should not be one severe examination only, but two or three extending over several years. As a boy enters a garden as a garden boy, let him prepare himself for the first examination to take place when he is about 17 years old, the second examination when he is 20, and the last when he is about 23 years old. At that age he ought to be able to take his first foreman's place, and have three or more years as foreman before becoming "head." The first examination need not be severe, but one that should encourage study in elementary botany and the first principles of horticulture, and the others should be gradually more severe. I think by this means the standard of the British gardener might be raised considerably above the present level, and in years to come the gardener would be in a position to hold his own. All successful candidates should be entered on a special register of the British Gardeners' Association, or the B.G.A. might work in conjunction with the R.H.S. in such a matter. *A. E. T. Rogers, Sudeley Castle, Glos.*

I do not imagine the promoters of the examination system ever thought examinations would afford a perfect test of capacity, but I am sure the institution of these examinations is a step in the right direction, and I am pleased to hear that the London County Council think so also, and I should like to hear of other public institutions taking the same view. If so, we might then have a better system of examinations for gardeners adopted by the Royal Horticultural Society, and then our profession would be raised to the level it ought to hold. In my opinion, if such were done it would rid gardening of a lot of superfluous hangers on, and would also afford a guarantee to employers that they were getting gardeners who knew their work from the most elementary portions upwards. I am also sure that a perfect system of examinations would do more to raise the wages of real gardeners than any British Gardeners' Association is likely to do. *W. G.*

Mr. Watson states in a recent issue that young men of proved ability rarely get into the first class. The reason of this is that the majority of gardeners have not acquired the power of close study. In many cases they find this more arduous than their daily work. Many practical gardeners have the idea that the R.H.S. certificate can be obtained without a knowledge of the scientific principles on which his work is founded, but without them how is he to obtain the knowledge of his art? It is true that in horticulture we want men who are able to do things—practical men who understand the principles on which their work is based. No practical gardener who has made a careful study of the R.H.S. syllabus, apart from any examination whatever, will deny that he has received benefit from its perusal. In conclusion, it would be interesting to know how far the Kewites, apart from their practical work, are trained in this "class-room" gardening, and whether or not Mr. Watson owes his position he now holds to practice alone. *G. H. H. W.*

With the general trend of Mr. Watson's remarks upon this subject (page 106) the majority of experienced men will readily agree. Such examinations cannot serve as an adequate test of a candidate's special aptitude as a cultivator, but has such a result ever been claimed for them? I am not aware that any council or any examiners have asserted or implied that those who pass the Royal Horticultural Society's examinations are necessarily fully qualified gardeners. Employers do not engage their men on the strength of such certificates alone, nor do the holders

expect it, so no one suffers in the matter, because no one is deceived unless they mislead themselves. But your correspondent goes farther than this, for he implies that such examinations are almost useless. Against such a notion a protest must be entered. The studying, thinking, and preparing for such ordeals have broadened the minds of many, and have given them a pleasure and intelligent interest in their work which they never before possessed. The disinclination for the labour of gaining a higher education in their business has been one of the chief causes that has retarded the advance of gardeners, especially in the south; in the north the eagerness for knowledge has during a long period been more evident, with substantial results. Examinations offer an inducement to self-improvement, and that leads to progress in the right direction. Personally I would sooner have a man who had tried and failed in any competition than one who had never tried, provided they were equally experienced in their work. One of the great authorities has said: "The rule-of-thumb method of doing anything is pure mimicry . . . without knowing or caring for the reason why." Again he adds: "The man who possesses the greatest range of knowledge relating to his special subject is the one most likely to succeed." Success is a relative term, as fortune does not favour all alike, but even in failure a man who has made the acquirement of knowledge his constant object has a service of pleasure of which even his enemies cannot deprive him. Beyond this a gardener has constantly to deal with well-educated people, who nowadays often include a study of plant-life in their curriculum, and certainly it does not lessen an employer's estimation of his gardener when he finds the latter is duly informed upon the scientific side of his art. In fact, such a knowledge is expected of any man in a good position at the present time. It has always been a difficult matter to induce the young to take a right view of the advantage of study, and if examinations aid in doing this they have their use and justification. In a recent visit to a leading establishment, a hybrid plant was noted which had been raised in that establishment, but not one of the men in the house could tell its history or what its parents were, though to any plant lover it possessed considerable interest. These men may be first-class cultivators—certainly the plants were in admirable condition—but would they have been any less skilful if they had shown an intelligent interest in the plants under their charge? Your correspondent refers to the action taken by the London County Council in desiring their employees in the Parks Department to submit themselves for examination. That is a step in the direction of raising the status of the men, which experience has proved to be not only desirable but absolutely necessary. There are serious defects in the County Council's system, but if they pay wages equal to those given to hundreds of head gardeners they should at least require the men to possess the rudiments of common knowledge. The concluding remarks in Mr. Watson's letter convey a wider meaning than I am willing to believe he intended, but in himself he has a reply to his stricture. As a speaker and a writer, as well as a skilful cultivator, his ability is admitted, and each characteristic has contributed to his success, though it may be difficult to determine their proportionate share in the result. *L. Castle.*

EXAMINATIONS IN HORTICULTURE (see p 124, last issue).—On line ten the printer has put Examiners' for Examinee's! *G. Henslow.*

Obituary.

GEORGE NORMAN, V.M.H.—As these pages are passing through the press we receive the sad intelligence of the death from heart failure, on Wednesday last, of Mr. George Norman, V.M.H., head gardener to the Marquis of Salisbury, at Hatfield. The funeral will take place at Hatfield Cemetery, on Monday next, at 3 p.m. Mr. Norman was a native of Bedfordshire. He has filled the position at Hatfield House, Hertfordshire, for 30 years, having been appointed there in 1876. Previous to that date he had acted as foreman for several years in Linton Park Gardens, Maidstone.

SOCIETIES.

SEVENOAKS GARDENERS'.

FUMIGATING WITH HYDROCYANIC ACID GAS.

At a recent meeting of the above society, Mr. F. H. Westcott, Woodleigh Gardens, Sevenoaks, read a paper on "Cyaniding under Glass." The materials required for this method of fumigating plant houses are cyanide of potassium, sulphuric acid, two pans and a punkah, or fan, for diffusing the gas through the house. One of the pans is fixed to a block of wood, which is hinged, the other pan being placed below, and in such a position that when the top one is tilted by means of pulling a cord, the bottom one receives the contents of the upper. Place the two pans in the middle of the house with the attached string leading to the keyhole of the door through which it is drawn. Place the fan immediately over the pans. The best time for generating the gas is at night, when no person other than the operator is present. When ready for fumigating place the cyanide of potassium in the top pan, and in the lower one put a quantity of water, and mix with this sulphuric acid, stirring them together with a stick. The liquid becomes extremely hot, and this is an advantage, for when the potassium cyanide is put in the heat facilitates the evolution of the gases. [Do not fill the pan with the potassium cyanide until the last possible moment, and when the string is ready to be pulled from the outside.—ED.]

THE LATE GEORGE NORMAN.

Care should be taken not to walk on or entangle the cord when passing out of the house. The ends of the cord being outside, and the doors securely locked, the operation may be put into execution. First work the fan to set the air in motion, and then by means of the string release the cyanide salt into the sulphuric acid, taking care to observe the time.

The punkah should now be well worked, and especially at first, whilst the gas is being rapidly generated. Probably ten minutes will be found quite sufficient to diffuse the gas through the house. Keep the structure closed for 40 or 50 minutes, after which some of the ventilators may be opened from the outside and a little later the doors, the operator using great caution and holding his breath. With moderate ventilation the house should be clear of the gas in about 20 minutes, but operators should keep on the safe side. The odour of bitter almonds is an indication that traces of the gas are still in the house, but a slight smell is not injurious.

Although potassium cyanide has been universally used for the purpose, and may still be used in some cases, sodium cyanide is, in my opinion, preferable. It is smaller in bulk and gives a more convenient effervescence. The amount of cyanide used must be regulated by the heat of the houses and by the tenderness of the plants. For cold houses I have found a remarkably small dose sufficient—namely, 2 oz. sodium cyanide to every 1,000 cubic feet of space. This is a less quantity than has sometimes been used, but it is sufficient to kill mealy bug and all other living pests without causing the slightest injury to any plant. The following plants stood the above quantity without injury:—Tomatos (covering the roof), Fuchsias in flower, Cannas, Chrysanthemums, Heliotrope, Lobelia, Pelargoniums, Asparagus, Azaleas, Adiantum, Primulas, Cyclamens, Palms, Codiæums (Crotons), &c.

DOSES FOR EACH 1,000 CUBIC FEET ENCLOSED SPACE.

Sodium cyanide, full strength.	Sulphuric acid, strength I.S.	Water.
1¼ ozs.	3 fluid ozs.	9 fluid ozs.
1¾ ,,	3½ ,,	10½ ,,
2 ,,	4 ,,	12 ,,
2½ ,,	5 ,,	15 ,,
3 ,,	6 ,,	18 ,,

Two ounces of cyanide is sufficient for a cool greenhouse. The sulphuric acid need not be pure, but should be strong and of a specific gravity not less than 1·8. Commercial oil of vitriol is about this strength, and it requires to be diluted with water in the proportion of one part of sulphuric acid to three parts of water by measure. The plan to follow is to first put the necessary water into the acid dish, next the proper proportion of acid into the water, and stir with a stick, and lastly the cyanide into its metal dish. Sodium cyanide is given at 130 per cent. strength in comparison with potassium cyanide of 98 per cent., and therefore only three fourths of the weight of sodium cyanide is required.

FUMIGATING OUT-OF-DOORS.

The standard for trees out of doors is one ounce cyanide for every 200 feet of space. In introducing this operation to cultivators I am fully aware that in careless hands it is a most dangerous process, but in careful hands the danger is practically nil. I think the lines I have laid down are perfectly safe, and I know they are perfectly effectual. No. 1 house, containing a space of 792 cubic feet, required 1¼ ozs. of sodium cyanide, 2½ ozs. sulphuric acid, and 7½ ozs. water. The plants in the house were Azaleas, Cyclamen, Primulas, Begonias &c., and these were not injured in the least, but on the staging and the floors were dead wood-lice, which had even come out of cracks in the walls. Worms were also expelled from the soil in pots and were shrivelled. No. 2 house, containing 1,471 cubic feet, required 2¾ ozs. of cyanide salt, 5½ ozs. sulphuric acid, and 15 ozs. water. The plants vaporised were Codiæum (Crotons), Streptocarpus, Asparagus, Maidenhair Fern, Pelargoniums, and Palms, &c. The insects affected by the gas were mealy bug, thrip, scale, and green fly; everything living was effectually destroyed.

It should be remembered that the above is the smallest amount of cyanide which has ever been used for the purpose, whilst great damage has been done from overdosing the houses. It now remains to determine what effect temperatures, atmospheric moisture, &c., have upon the action of plant life in the presence of the gas. Cyaniding should not be performed on plants in full sunshine. In winter, however, it may be done at any time, either day or night. The evening is the more suitable time, for several reasons, and fewer workmen will then be found about the place. In the daytime instruct one, or perhaps two, trustworthy men to prepare everything in readiness so that operations can be started directly the staff has finished for the day. The charges of cyanide can be weighed out and put into tins and be locked up until the last moment. The generators should be put into the house and the punkahs hung in position with cords attached leading through a ½-inch hole made in the door. Immediately the workmen have left, the water and acid can be put into the bottom pans, then the cyanide in the top ones, but never allow any cyanide to be between the operator and the outer door. The door should then be closed, the time carefully noted, and the cord pulled. The punkahs should now be kept moving for ten minutes to thoroughly incorporate the gas with the atmosphere. A neat cyaniding battery with interchangeable parts is of great service. The punkahs should be large enough and heavy enough to balance properly. For filling the acid pans a glass measure, which can be obtained at any chemist's or stores, should be used, also a small pair of scales for weighing the quantities of cyanide salt.

Vines which have all the fruit removed and which are infested with various pests should be treated as follows:—All tender plants must be removed and the cubic space of the structure calculated. The pans and the cyanide dishes should be placed in position and the house kept

as dry as convenient. Arrangements must be made for opening the top ventilators from the outside. All means of access to the vineries must be locked, so that there may not be the remotest chance of any person going into the house while the gas is being evolved. For a vinery at this season of the year use 2 ozs. sodium cyanide to every 1,000 cubic feet of air space. The vinery must be kept closed after vaporising for about one hour, when the ventilators and doors must be thrown wide open and allowed to remain so for an hour or two, or until the morning in the case of empty vineries. Next wash the vines with water under high pressure. The cyaniding should be repeated in the spring, but not in such strong doses.

CAUTION.

Death by prussic acid poisoning would be the doom of any individual carrying out these directions without due care, but, if the necessary precautions be taken, there is no danger of fatal consequences.

MANCHESTER & NORTH OF ENGLAND ORCHID.

FEBRUARY 8.—The following Awards were made at the meeting held on this date:—

FIRST-CLASS CERTIFICATES.

Cypripedium × Mrs. Mostyn Chardwar var. (G. W. LAW-SCHOFIELD, Esq., and S. GRATRIX, Esq.); C. × chrysotoxum var. Victor (S. GRATRIX, Esq., and H. Low & Co.); Cattleya Trianæ var. Lady Brunner (J. H. CRAVEN, Esq.).

AWARDS OF MERIT.

Cypripedium × Charles Turner (G. W. LAW-SCHOFIELD, Esq.); C. Adrastus superbum, Vine House var. (A. WARBURTON, Esq.); C. × The Duchess (S. GRATRIX, Esq.); C. × insigne Chantini × C. Godefroyæ leucochilum (J. CYPHER & SONS); C. × aureum var. Mrs. E. Rogerson (E. ROGERSON, Esq.); C. × Rogersonianum (E. ROGERSON, Esq.).

Messrs. J. CYPHER & SONS were awarded a Silver Medal for a good group of plants.

Votes of thanks were given to Messrs. Heath & Sons, S. Briggs-Bury, Esq., E. Rogerson, Esq., and J. Cowan & Co., Ltd., for various groups.

FEBRUARY 22.—There was a good display of plants at this meeting. A group was exhibited by R. LE DOUX, Esq., West Derby, which contained some well-grown Lycastes (Silver Medal). Messrs. J. CYPHER & SONS, Cheltenham, also had a good display of plants (Silver Medal). Messrs. J. COWAN & Co. received a Silver Medal for a good group. W. THOMPSON, Esq., Stone, received a Bronze Medal for a small, choice collection, and a similar award was made to PHILIP SMITH, Esq., of Ashton-on-Mersey. Votes of thanks were passed to Mr. S. Allen and Mr. D. McLeod.

FIRST-CLASS CERTIFICATES.

Cypripedium × Euryades var. magnifica (G. W. LAW-SCHOFIELD, Esq.); C. × Amy Leemann (J. LEEMANN, Esq.).

AWARDS OF MERIT.

Cypripedium villosum × C. insigne Sanderæ (G. W. LAW-SCHOFIELD, Esq.); C. × Beatrice Leake (G. W. LAW-SCHOFIELD, Esq.). *P. W.*

ABERDEEN CHRYSANTHEMUM.

FEBRUARY 17.—The annual business meeting of the members of this society was held on the above date in the Young Men's Christian Association Buildings, Aberdeen, Mr. James Esslemont, Langley, chairman of the society, presiding. The financial report for the past year, submitted by Mr. Magnus H. Sinclair, secretary and treasurer of the society, showed a credit balance of £166 10s. The report, which was considered very satisfactory, was unanimously approved. Thereafter the office-bearers for the ensuing year were elected as follows:—Hon. president, Lord Provost Lyon; chairman, Mr. James Esslemont; vice-president, Mr. A. Kynoch, Clifton Road, Aberdeen; secretary and treasurer, Mr. M. H. Sinclair, 156A, Union Street, Aberdeen; auditors, Mr. William McHattie, solicitor, and Mr. James Terras; and a working committee of 20. It was arranged that the next exhibition be held in the Music Hall Buildings, Aberdeen, on Friday and Saturday, November 23 and 24.

SHEFFIELD CHRYSANTHEMUM.

The address of the new secretary of this society is W. Lewendon, 93, Neill Road, Sheffield. Mr. Lewendon is already known to many of our readers as the secretary of the Sheffield Floral and Horticultural Society.

ROYAL METEOROLOGICAL.

The usual monthly meeting was held on February 21 at the Society's rooms, 70, Victoria Street, Westminster, Mr. Richard Bentley, president, in the chair.

Mr. E. Mawley read his "Report on the Phenological Observations for 1905." He said that, as affecting vegetation, the weather of the phenological year ending November, 1905, was chiefly remarkable for the dryness and mildness of the winter months, the drought and frosts in May, the long spell of hot and dry weather in July, and an exceptionally cold period in October. Wild plants came into flower a few days earlier than usual until about the beginning of May, after which time they were as a rule to about the same extent late. Most of the early spring migrants, such as the swallow, nightingale, &c., reached these shores in advance of their average dates. The best farm crops of the year were those of Wheat, Beans, and Hops, while Barley, Potatos, Turnips, and Mangolds were all more or less over average. But the yield of Oats, Peas, and Hay was almost everywhere deficient, the latter being the worst crop of the year. Apples, Pears, and Plums were in all parts of the British Isles below average, whereas the small fruits as a rule yielded well. Taking the farm crops alone, the past year must be regarded as having been, on the whole, a fairly bountiful one.

THE NATIONAL CHRYSANTHEMUM.

FEBRUARY 26.—The second annual dinner in connection with the above show was held at Hummum's Hotel, Covent Garden, on the above date. The chair was occupied by Mr. R. Ballantine (who with Mr. Prickett, the oldest member of the N.C.S., was the prime mover in starting the "market show"). Copies of the schedule for 1906 and the balance-sheet were distributed to those present. The show will be held in the Foreign Flower Market on December 12. The statement of accounts showed a balance in hand of £11 0s. 11d. The chairman in proposing "The Market Show" expressed satisfaction for the support given, and referred to the great advance the last show was on the first venture, but he (Mr. Ballantine) was still of opinion that the show might be held in January; this, however, was not the opinion of Mr. W. Cull who responded to the toast. Other members also expressed their opinions that it could not be held so late, as it would be unprofitable for growers to keep the flowers over the Christmas season. Mr. Moorman (of Victoria Park) referred to the last show as one of the most instructive and interesting exhibitions he had visited. Mr. Prickett referred to the limited number of exhibitors, and expressed a hope that more growers would be willing to enter into friendly competition.

Mr. T. Bevan in proposing "The Donors of Prizes" referred to the liberality of the chairman and other friends.

Several letters were read from those unable to attend. Messrs. Clay & Son sent 5 guineas towards this year's Prize Fund, Mr. J. Webb manager of Hummum's Hotel) promised a gold medal, Mr. M. Larsen a silver gilt medal, Mr. P. Bunyard (of G. H. Richards) a silver gilt medal, Mr. J. Kinnell (of Kinnell & Co.) a large silver medal, Mr. E. F. Hawes (Royal Botanic Gardens) a silver medal, and Mr. R. F. Felton, of Hanover Square, W., a silver bowl value 3 guineas, for the best collection of single varieties. It is confidently hoped that many more special prizes may be offered.

A pleasant musical programme was carried out under the direction of Mr. D. Ingamells and Mr. Godfrey Woodstock. Mr. D. Ingamells, who has done much towards popularising the market shows, was responsible for the dinner arrangements, which were well carried out in all details.

Schedules and other information may be had from the society's secretary, Mr. G. R. Dean, 8, Avonwick Road, Heston, Hounslow.

GARDENERS' DEBATING SOCIETIES.

CHELMSFORD AND DISTRICT GARDENERS'.—At the meeting of the above association held on Friday, February 9, Mr. Simmonds, of the Elms, Chelmsford, delivered a paper on "Vegetables." A selection of popular kinds was given, and the principal points to observe in their culture were indicated. A discussion on the various methods of forcing Seakale followed the lecturer's remarks.

At the meeting of the above society held on the 16th ult. Mr. W. C. Spruit, of the Nurseries, Moulsham, read a short paper on Palms, including the raising of these plants from seed and their subsequent culture. Several members gave valuable information on various details of culture. Instances were given of successfully reducing the roots of plants which had overgrown their pots, and repotting them into pots of the same size as before. *W. C. S.*

At the meeting held on Friday, February 23, before a good attendance of the members, Mr. F. J. Chittenden read a paper on "The Making of New Plants." The essayist gave a number of valuable hints on hybridising, and mentioned some of the points to be aimed at when raising new plants.

BATH AND DISTRICT GARDENERS'.—The annual dinner of the above Association was held at the Full Moon Hotel, Southgate Street, Bath, on Wednesday, February 14, Mr. R. B. Cater (President) occupying the chair. The company included the Mayor, Mr. Councillor Isaacs. The Mayor submitted "Success to the Bath and District Gardeners' Mutual Improvement Association." He said gardeners stood in a very different position from artizans and mechanics, who had their set hours of work, and who were told they must do so much work and no more. The gardener worked from early morning to late at night, and his ambition was to produce something far better than his neighbour, thereby benefiting the community at large. Gardeners had no trades union, but he hoped they would be able to form an association by which, with a joint effort, they might raise their status, for the wages paid to the gardener were small compared with other trades; indeed, he was a very ill-paid man.

CRAWLEY AND DISTRICT GARDENERS'.—A paper on "Phenomena in the Life of Plants" was given before the members of this association on Tuesday, February 13, by Mr. Wm. Shepherd. The speaker explained the various functions of the leaves, stems, and branches, etc., and showed how the plants assimilate carbon from the carbonic acid gas contained in the atmosphere, absorbing the carbon and returning the oxygen to the air. Many questions were forthcoming at the close of the address, and some valuable information was gleaned from the discussion.

CHESTER PAXTON.—At the fortnightly meeting of this society, held at the Grosvenor Museum on Saturday, the 17th ult., Mr. N. F. Barnes presiding, Mr. E. F. Hazelton, head gardener to Lord Derby, Knowsley Park, Lancashire, read a paper on "Ornamental Flowering Trees and Shrubs." The subject was dealt with by the essayist in a very able manner, and he pleaded for a more extensive use of hardy flowering trees and shrubs for situations adapted to their culture. Mr. Hazelton submitted lists of the best and most suitable varieties, together with cultural methods.

REDHILL, REIGATE, AND DISTRICT GARDENERS'.—A meeting of this society was held on Tuesday, the 13th ult., Mr. W. Seaman in the chair. Mr. H. Hemsley, of Crawley, read a paper on "Herbaceous Plants for Exhibition and Decoration." The paper dealt fully with the formation of herbaceous borders and the planting of the same. Mr. Hemsley also gave a list of plants suitable for furnishing the border. By means of a blackboard, diagrams were shown illustrating the paper. The introduction of a few trees such as Prunus Pissardi and Acers in variety was advocated by the lecturer. *Frederick C. Legge.*

LOUGHBOROUGH GARDENERS'.—The usual fortnightly meeting of the above association was held in the Town Hall, Loughborough, on Tuesday, February 13, Mr. Lane presiding over a good attendance. Mr. Titterton read a prize essay on the Potato, in which he dealt with this useful vegetable from its earliest introduction to the present day. A discussion followed. Mr. Cooke introduced a discussion on the Royal Gardeners' Orphan Fund, and an appeal was made to the members on its behalf, with the result that a goodly sum was raised in the room. It was decided to have an annual collection for the same object, and a committee was formed to carry out the object.

EGHAM AND DISTRICT GARDENERS'.—At a recent meeting of this society, Mr. W. Swan in the chair, Mr. Townsend, of Sandhurst Lodge, Wokingham, gave a lecture entitled "A Ramble Round a Berkshire Garden in Summer." The remarks were illustrated by a series of lantern views. A short description of the views and cultural details of the plants depicted were given. Especially interesting were the Lily ponds and climbing Roses, which are allowed to grow as naturally as possible. The exhibits at the meeting included a well-grown group of Cyclamen and a specimen of Cœlogyne cristata with 54 flower spikes averaging five flowers to a spike. The latter was exhibited by W. A. Stearns, Esq. *T. J. W.*

GUILDFORD AND DISTRICT GARDENERS'.—The members of the above association held their usual fortnightly meeting on February 20, Mr. H. Cook, the chairman, presiding over a good attendance. Mr. Horace J. Wright, the hon. secretary of the National Sweet Pea Society, delivered a lecture on "Sweet Peas." *G. E. B.*

CARDIFF GARDENERS'.—The usual fortnightly meeting of this association was held at the Sandringham Hotel, Cardiff, on Tuesday, February 20, when F. G. Treseder, Esq., presided over a large attendance of members. A lecture upon "Our Resident Birds as Friends and Foes" was delivered by Mr. J. Mountney, taxidermist, Cardiff. The lecture was of considerable interest to the gardener, for it pointed out that though many of the 40 species mentioned in the paper were, to a certain extent, looked upon as foes to both gardeners and farmers, many were desirable friends and destroyed numbers of insect and other garden pests. Mr. Graham opened a discussion in which many took part. Mr. T. Williams won the prize of 5s. offered by Mr. Gillett for the best pot of Cyclamen, his specimen having over 30 expanded flowers. *J. Julian.*

BRISTOL AND DISTRICT GARDENERS'.—The meeting of this association, held at St. John's Rooms, Redland, recently, Mr. Jas. Lee presiding, was set apart for the official visit of the Bristol Amateur Horticultural Association. The good feeling which exists between these two societies speaks well for the interests of Horticulture in Bristol and the district. Owing to the inclement weather the attendance was not as large as it would otherwise have been, but those who did attend were amply repaid in the lecture, illustrated by lantern slides, given by the visitors' president, Dr. Colston Wintle, on "Insects." Dr. Colston Wintle gave many useful hints concerning the pests of our gardens, and at the close of his lecture received the cordial thanks of the Bristol Gardeners. *H. K.*

CROYDON & DISTRICT HORTICULTURAL.—The members of this society assembled on Tuesday, the 20th ult., at the Sunflower Temperance Hotel, to hear a lecture delivered by Mr. T. Crosswell, Eden Park, on "The Culture of Herbaceous Calceolarias." Seeds should be sown between May and August, according to the size of plant

required. It usually takes about eight or ten days for the seeds to germinate, and if the soil appears dry immerse the pots in water till it shows through the surface; on no account water overhead. A little ventilation may be given in about a week, and gradually increased day and night. When large enough pot the plants singly in a compost of equal parts loam, leaf-soil and fine sand. The last potting may take place in February. A little soot-water or weak solution of manure will benefit the plants when they are well rooted. If large specimens are required the central spike should be pinched out. Do not select all the larger seedlings, for the more uncommon colours will often be found in the lesser seedlings. A discussion by the members followed.

ANSWERS TO CORRESPONDENTS.

Abies nobilis: *R. H. S.* Your tree is affected with gouty disease caused by an insect allied to Chermes, which causes American blight in Apples, and which also (or a near ally) occurs

Fig. 54.—Gouty disease of the silver firs.

on the spruce and on the larch (see fig. 54). Petroleum emulsion vigorously applied might do good. Cut out and burn the affected branches so far as you can.

Arrangement of Cauliflowers for Exhibition: *F. L. S., Hants* The usual method is to make a little platform about 9 inches in height, using a board 8 inches wide and as long as is necessary. To this board is fixed a solid piece of boarding, shaped like a triangle, as high as may be necessary for the exhibit of the Cauliflowers. Incline this triangular piece a little backwards and there will then be something to build against. Place on the platform a thick coating of green moss, and on this lay three Cauliflowers, leaving 1 inch between each "head" for Parsley. Make the spaces solid between the Cauliflowers by packing in some moss of any kind to the level of the "flower," then place two more "heads" on the top and repeat the packing, &c., until the whole is finished. After this has been done place some finely selected Parsley between the Cauliflowers and over the whole surface of the moss. Wood-wool is sometimes used instead of the moss, but it is not to be preferred. Be careful to put a wedge or block under each of the outer Cauliflowers in the bottom row to prevent them from spreading, otherwise there is always difficulty in placing them well.

Camellias from the Open: *F. G. B.* We do occasionally meet with gardeners who are not aware that the Camellia will flower in the open air in this country. Those who knew the Royal Horticultural Society's Chiswick gardens, will remember the border near the old Paxton House that contained many good specimens of this plant, which flowered freely annually. From the flowers you send it is evident your plant is in a favourable position.

Dippe, F.: *B.* This botanist visited Mexico in 1828, accompanied by C. J. W. Schiede.

Ficus elastica: *J. S. F.* Ficus elastica in fruit was fig. red in *Gardeners' Chronicle*, September 19, 1874, p. 359. Eucalyptus Globulus, in common with many other plants, possesses a primordial or youth-form of leaf which is quite different to that of the adult stage. The well-known Retinosporas of gardens are but the youth-forms of species of Conifers, principally of Cupressus or Juniperus.

Hyacinths, etc.: *Enquirer.* There is nothing in the specimens themselves to explain why the bulbs have not produced roots. Provided the rooting medium afforded the plants was a suitable one the cause of failure must be in the bulbs, which may have been insufficiently matured last season.

Market Gardening in Guernsey, or in England: *C. B.* We are not surprised to know that, having asked various growers in Guernsey and England which is the better place to establish a nursery, you have elicited contradictory opinions. It is a case in which you will have to decide for yourself, simply because no final and satisfactory answer could be given to the question. Market gardening exists, and has been found to yield a remunerative return in Guernsey and in England. Therefore, make up your mind in which place you would prefer to reside, and having done that go to business with a will and you will deserve to succeed. But having determined the locality in which you will make the start, be very careful in the matter of choosing premises. Carefully examine them from every point of view to see how suitable or otherwise they may be for your purpose. If a lease is to be taken up, let every condition be scrutinised beforehand.

Names of Fruits: *F. T. B.* Claygate Pearmain.

Names of Plants: *M. H.* Dendrobium parcum, a very interesting species, owing to the movable, spring-like labellum. See the illustration and description published in these pages on May, 20, 1905.—*J. J. F.* Osmanthus ilicifolius, but there are no flowers.—*H. S.* 1, Phillyrea angustifolia; 2, Tamarix species, probably T. gallica. —*J. C.* 1, Rhododendron Countess of Haddington; 2, R. Veitchianum; 3, R. formosum: 4, Acacia armata.—*H. W., Trevince.* Photinia serrulata syn. Cratægus glabra.—*J. W.* Stauntonia hexaphylla.—*A. C.* Both species of Euonymus; we cannot tell which without the leaves.—*C., Bridgwater.* Lissochilus streptopetalus.—*W. C. M.* Odontoglossum pulchellum. —*R. C.* Hippeastrum, near to H. equestre. Not indigenous in Burmah, and probably a garden hybrid of H. equestre crossed with H. vittatum.—*A. Y. L.* 1, Scaphosepalum ochthodes, often called Masdevallia; 2, Ornithidium confertum, a native of the West Indies.—*W. W.* Anemone coronaria, double flowered variety.—*F. T., Bourton.* 1, Pinus (next week); 2, 3, 4 and 5, all forms of the common Spruce, Picea excelsa.

Narcissus: *A. K.* The plants that were first placed indoors failed because heat was applied too early. N. poeticus will not respond to hard forcing, though some of the varieties may easily be got into bloom in February. The bad results of applying heat to these plants in November was explained by our correspondent Mr. E. H. Jenkins, in an article published in these pages on October 22, 1904, p. 286.

Notice to Leave: *T. R.* A head gardener is generally considered to be entitled to a month's notice. Consult a solicitor, who will see if there are any special circumstances in your case. Why do not gardeners come to an agreement with their employers at the time an engagement is made?

Peas and Beans during August and September: *T. H. G. Ireland.* To ensure a supply of culinary Peas thus late in the season you will need to sow as for a late crop. Sow a portion of the seeds in May and make other sowings in the third week of the month and at the beginning of June. Of the varieties you mention use Alderman and The Pilot for the earliest sowing, and follow with Gladstone and The Duchess, the final sowing being made with Gradus and Early Bountiful. These should provide a succession through the months you mention, and as the climate of Ireland is more humid than that of this country, the plants will not be so likely to suffer from drought as late crops do here. Late crops of Peas require much attention in the matters of watering and mulching. If these details are neglected the crop will be small and will scarcely pay for the trouble of growing. Sow the Kidney Beans at the beginning of June. For the bog garden it is not advisable to use artificial manures, but such substances as peat, peat manure, decayed leaves, or any substance that will furnish humus to the soil.

Parsnips eaten: *G. B. Marple.* The roots have probably been eaten by voles, which will remove

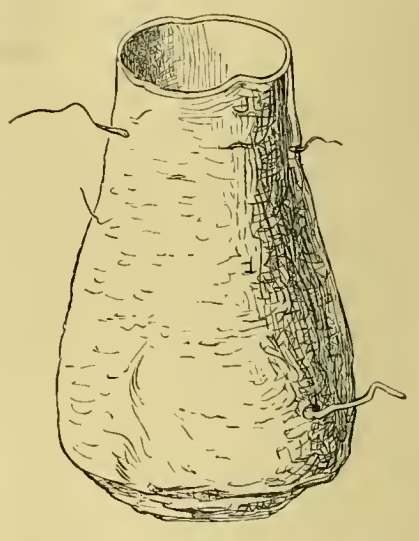

Fig. 55.—Parsnips eaten hollow by voles.

the entire centre portion and leave the skin in the form of a shell. Fig. 55 shows a root that has been thus hollowed by these depredators.

Soot: *R. M. C. L., Nice.* See the remarks on p. 128 of our last issue in the reply to *Enquirer*. You may make the soot water from freshly obtained soot, and if used only in a clear condition, the liquid can be applied to the roots of most pot plants with satisfactory results. If, however, the liquid is not applied in a clear state, it will leave a sticky deposit on the surface of the soil, which will to some extent prevent aeration, which is necessary to the well-being of the roots.

Tuition: *J. R. G. G.* We do not know any particular firm that would take your son for the purpose of teaching him the business, but as you are prepared to pay a premium there should be little difficulty in obtaining the information by inserting an advertisement.

Tulips: *J. W. P.* The shrivelling of the flower buds is doubtless due to the forcing of the plants into flower before their natural season. Some have withstood the strain and succeeded well, but others, being less well fitted, could not adapt themselves so perfectly to the unnatural conditions. In the forcing of bulbs, and indeed of most plants, the gardener must always bear in mind that he is taking liberties with nature, and therefore, in order to avoid causing the plants a check, or hurrying them beyond what they will bear, the forcing must be done very gently, allowing the plants as long a time as possible in which to develop their growth. You may have noticed that varieties of Narcissus poeticus if planted very late in the season often fail, just as the Tulips have done, and this may be due to the plants being unduly forced, owing to the season having further advanced; the sun's rays are much hotter than they were when growth would naturally have been made. In this case, however, it has to be remembered that the bulbs having been kept out of the ground for so long a time have suffered in consequence, and were weaker than otherwise they would have been. We believe that the variety Yellow Prince is often flushed with orange colour, and occasionally even with red as are yours.

THE AMERICAN CARNATION.

AFTER the splendid exhibits seen at the Royal Horticultural Hall on February 13, it is scarcely necessary to say that, for winter flowering, the American raised Carnations are far in advance of our own. When these were first introduced into this country considerable prejudice existed against them on account of their fringed petals. And when first they flowered there was nothing remarkable in the blooms. But they have improved greatly, and some growers who had discarded them have again re-stocked them. The first introductions were not equal to such as were seen at Westminster on the 13th ult., although I find that such early varieties as Daybreak, W. Scott, and others are still grown. It was after the introduction of the variety Mrs. T. W. Lawson that English growers first begun to cultivate them extensively for market. This standard variety did not appear very promising judged by the first flowers seen; but after becoming properly established it improved greatly. Very rapid strides have also been made with other varieties, and from the reports of the American Carnation Society's Exhibition, further advance has been made, and we may expect some more fine varieties next season. English raisers have also been busy, for although few novelties were seen at the recent show, we have some good English sorts which have the vigorous habit and long stiff stems characteristic of American varieties. The exhibit awarded the Gold Medal at the above-named exhibition consisted entirely of American sorts. There were not many varieties, but the exhibit contained upwards of 1,200 blooms, the majority of which were perfect specimens. They were arranged in tall vases, the only garnishing being a few sprays of Asparagus. The exhibitor, Mr. Engelmann, has not been engaged in the culture of these flowers for any considerable period, but he is evidently highly successful with them. Mr. A. F. Dutton was one of the first of the English growers to show Carnations in proper American style. He did not exhibit so extensively as Mr. Engelmann, but his blooms were equally good in quality. Mr. S. Mortimer's display was also noteworthy, especially as he exhibited good plants in addition to flowers. Several Guernsey florists showed remarkably fine blooms of a limited number of sorts. Except in a few instances the same varieties were seen in all the exhibits. It may be of interest if I refer to their relative merits under the different shades of colour.

White Varieties.—There are at least half a dozen good "Whites." Glacier was the first white variety with which I became acquainted. It is still grown, but there are others which are superior. The Belle is a full-size flower, and possesses a very fragrant perfume. Queen Louise still remains a favourite with some growers. White Mrs. T. W. Lawson has stiff stems, although they are not so long as in other kinds. Lady Bountiful I should select as the best white variety, the flowers being of perfect form. I find this variety secured first place among "Whites" in a recent competition in America. A white sport from Enchantress may take the lead later on. Mr. Dutton, with whom this sport occurred, has named it "Iver White," but I find the same sport has occurred in America, where they call it the White Enchantress.

Blush Coloured and Pink.—Enchantress is a long way ahead of any blush coloured variety—in fact, it takes the lead among all American Carnations, and during the past two years I believe blooms have been seen in Covent Garden market almost every morning; it appears equally good for growing in summer as in winter. Alpine Glow is good, and Fair Maid is another most desirable variety; it is deeper in shade than the Enchantress. Floriana is slightly deeper than the last-named. I find it varies in quality, but have seen good specimens of it. Fiancée, which gained high honours in America last year, has not proved altogether satisfactory. Some American growers condemn it unmercifully, and I was inclined to do the same, for, until the recent show, I had not seen satisfactory blooms, although it had been brought to my notice many times. As seen at Westminster, however, in Mr. Engelmann's exhibit in three large vases, it was very fine; all were good, but perhaps a little inclined to split, yet, taking them as shown, one must admit that it is a variety of great merit. Coming to Mrs. T. W. Lawson, which is of a deep cerise pink colour, I need say but little, as it is already well known. I have heard it said that it is not so well grown here as in America; but this was contradicted by an American grower who went through Covent Garden market with me some time since. In Nelson Fisher we have a variety of a deeper shade of colour, with large blooms and strong growth. The plants of this variety shown by Mr. Mortimer were very robust, while the blooms of this from all growers were good (see p. 157).

Scarlet.—Of these there are at least half-a-dozen first-class varieties, and it is difficult to discriminate. Christmas Eve, which recently gained an Award of Merit from the Royal Horticultural Society, is certainly one of the best, perhaps not quite so vivid in colour as some, but very free flowering and having perfectly-shaped flowers. The Cardinal, which also gained an award last November, is of a deeper shade of colour still. It appears one of the most promising. Flamingo is very vivid in colour. It is a fine flower, but is a little inclined to become scalded, while the terminal flowers from strong growths generally burst. Flowers developed from side shoots, however, possess good calyces. Adonis is another fine scarlet.

Crimson.—General Maceo was the first crimson variety I knew. The flowers, though small, are very bright, and it is free in blooming. Harry Fenn is a decided improvement on the last-named, although Governor Roosevelt comes very close, and is preferred by some florists. Harlowarden should, perhaps, take first place in this section. It has been shown in very fine condition by all growers. In Messrs. T. S. Ware's, Ltd., exhibit I particularly noted this as one of the best, and it has been good all through the season.

Striped Varieties.—Variegated Lawson and Mrs. M. A. Patten run each other very close for supremacy, but I should give the first place to the last-named, which has been good from all sources.

Yellow.—At present the demand exists for a good "yellow." Dorothy Whitney, a deep yellow flower with pink stripes, is the only yellow variety I have seen. Although bright in colour the flowers are small. It appears that American growers have nothing much to offer in this colour. The above variety crossed with Miss Audrey Campbell or Cecilia should give good results.

Prosperity should be added to the list. This is a variety with large, sweet-scented flowers, having a white ground-work mottled or splashed with pink. They are developed on good stems. There may be other varieties deserving mention, but the above are those I have noted during the past two years at shows and in the market.

Culture.

A few years ago I cultivated about half a dozen of the American type with others of English varieties, and I found that Mrs. Lawson, in particular, started away much more strongly in the spring than our own type, and made excellent growths suitable for the making of cuttings. When growing actively they require plenty of pot room, and I believe that the American system of planting them out in the summer-time and again on benches when taken under glass in the autumn is a great factor in maintaining a vigorous stock. The planting on benches has been tried in England, and although I have seen them doing well under this treatment, I find opinions of various growers are divided on the subject. It is certainly possible to grow them well in pots, but they require more pot room than is usually given to English varieties. To obtain a vigorous stock the first thing requisite is to see that strong, healthy cuttings are secured; and for this purpose some of the stronger plants should be selected and potted into larger pots, removing all the flower buds as they appear. Another plan, if convenience allows, is to plant a certain number for stock plants. It may not be necessary for the bulk of the stock to be so treated, but some at least should have special attention.

With regard to the best time for propagating, I have always found it is of more importance to wait and secure good cuttings than to take them at any particular time. From January until the end of March the bulk may be secured, and the best cuttings are made from the short, thick, side shoots. I have seen them rooted well on an open bench, but I have succeeded best with a close case frame provided with a moderate bottom heat and a cool surface. The cuttings should never be allowed to become withered. I prefer to take the cuttings early in the morning, and the plants should be looked at on the previous night and well watered if dry.

When the cuttings are rooted in a close frame, they must be removed as soon as the roots form, for they must never be allowed to become drawn or weakened in growth by keeping them in too close and warm an atmosphere. At no stage can Carnations be forced, sunshine and warmth may develop them, but they must have ventilation, plenty of room, and all the sunshine possible. The affording of larger sized pots as the plants require them, and of keeping them quite free from all insect pests and fungoid diseases are important matters. The light, cheaply built houses of modern market growers are far better suited to the requirements of Carnations than are the heavy, expensive structures seen in many private establishments.

In the above notes I have confined my remarks to the American varieties, but I do not mean to infer that we have no good English raised sorts. I hope to refer to these, and to my experience in hybridising them in a later note. *A. Hemsley.*

and even from their decorative character. Some of them, of which Mr. Wilson was fortunate enough to secure seed, are already in cultivation in Messrs. Veitch's nursery at Combe Wood, and of these we propose to publish descriptions and illustrations in these pages. The drawings have been made for us with great fidelity by Mr. Worthington Smith. It must be borne in mind that the drawings have been taken from herbarium specimens, from which many of the leaves have become detached in drying, so that the reader must exercise his imagination and clothe the bare twigs with dense foliage. This is not a difficult matter, as the leaf-scars clearly indicate the position of the leaves. It may here be said that the form of these leaf-scars and the cushions "pulvini" beneath them, especially in the Spruces (Picea), should be carefully examined, as they often afford some means of discrimination when others are not available. *Maxw. H. T. Masters.*

20 to 60 feet, and has the general characters of a Spruce. The older branches are grey, the younger ones slightly setose, and of an orange colour. The buds are broadly ovoid, covered with light brown, oblong-ovate, subcoriaceous scales. The leaf-cushions or pulvini are ascending, straight, constricted near the tips, and symmetrical, not oblique near the apex. The leaves are about 1 cent. long, linear, curved, four-sided, with prominent ridges, stomatiferous on both surfaces, and with an acute or a somewhat obtuse apex bevelled or sloped off on the dorsal side. The male catkins are solitary on the sides of the branches near the ends, each about 2 cent. long, oblong, anther-scales, scoop-shaped, purplish, denticulate. Young female cones terminal erect, with reflexed, purplish-violet, broadly-oblong scales.

The ripe cones, 11 to 12 cent. long, 5 cent. lat., scales subcoriaceous, ascending, oblong, ovate, undulate, light brown, flushed with purple.

The scales of the ripe cone retain something of the purple colour of the young scales, but are completely reversed in direction.

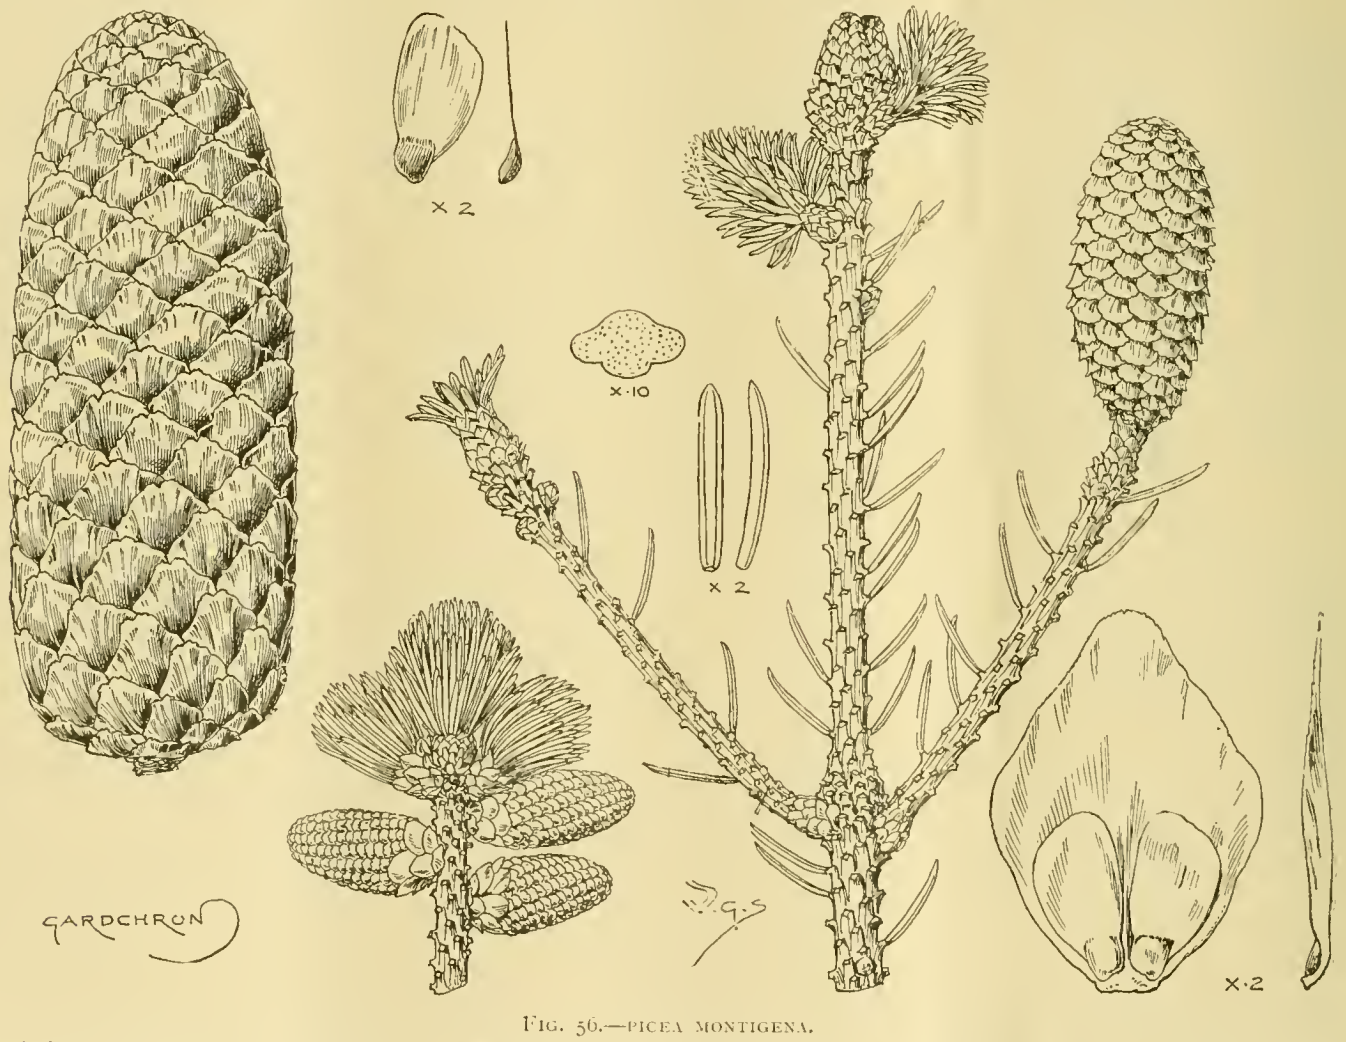

FIG. 56.—PICEA MONTIGENA.

On the left a mature cone, real size; on the right a branch nearly denuded of leaves in drying, and bearing an immature purple cone. Other details show tufts of young leaves and male-catkins, scale with seeds, detached seed, leaves and transverse section of leaf. The figures ×2, ×10 show the degree of enlargement. The young branches are more hairy than shown in the figure.

CHINESE CONIFERS.

SEVERAL species collected for Messrs. James Veitch and Sons by Mr. E. H. Wilson in his first journey to China were described and figured in these columns in 1903, and a complete enumeration of the species was given in the *Journal of Botany*, August, 1903. Mr. Wilson's second journey was even more productive, as will be gleaned from the interesting notes on his journeyings now in course of publication in these columns. Messrs. Veitch have been good enough to place in my hands for identification the specimens of Conifers procured by their zealous and intelligent collector. They comprise many new species, which are very interesting from the point of view of the botanist and the geographer, whilst some may prove of importance from the standpoint of the forester,

PICEA MONTIGENA. (Mast. sp. nov.)* Fig. 56.

This is a species noted by Mr. Wilson as very rare and growing near Tatien-lu, at an altitude of 10,500 feet. It attains a height of from

Judging from its habitat, the species will probably prove hardy. The rich colour of both the male and the female inflorescence gives it an ornamental character. The manner in which the young cone-scales are at first recurved and subsequently become erect is worthy of remark.

PICEA COMPLANATA. (Mast. sp. n.) Fig. 5[illegible].

This is a handsome Spruce Fir discovered by Wilson in Western Szechuan, where it forms forests at an elevation of from 5,000 to 8,000 feet. The timber is used for building purposes. It belongs to the section Omorika, having the blue surface of the leaves uppermost; but the leaves, though scarcely four-sided, are not so markedly flattened as in most of the species of that section. The younger branches are glabrous and of an orange-brown colour. The leaf-cushions or "pulvini" are prominent, oblong, unsymmetrical beneath the apex, so that the

* PICEA MONTIGENA, Mast. sp. nov., fig. 56:—Arbor 20-60 pedalis, *ramulis* novellis hirtulis pallide aurantiaco-fuscis, *ramis* vetulis hirtulis seu glabratis fusco-cinereis. *Pulvini* prominentes parum condensati, ascendentes, recti, oblongi superne constricti.

Gemmæ oblongo-ovoideæ squamis subcoriaceis ferrugineis obtectae.

Folia quadrangulata 10-12 mill. long, 1½-2 mill. lat. arcuata, linearia, dorso prope apicem cartilagineum fastigata, nervo medio utrinque prominente, undique stomatifera. *Amenta* mascula lateralia subsessilia circa 2 cent. long, 1 cent. lat. cylindrato-oblonga, squamæ antheriferæ trulliformes violaceæ ad margines superne laceratæ.

Strobili faeminei juveniles terminales ascendentes rubro-violaceæ, squamæ applanatæ rotundatæ laceræ arcte recurvatæ, *strobili maturi* cylindrato-oblongo-obtusi 10 cent. long., 4 cent. lat. Squamæ appressæ subcoriaceæ oblongæ truncatæ superne undulatæ.

somewhat three-sided cicatrices or leaf-scars seem to be beneath the apex, owing to the greater growth of the upper or axial side of the pulvinus. This is especially noteworthy on the very young shoots, but is less apparent on the older shoots. The buds are ovoid-conic, covered with rich brown, shining, leathery, oblong scales. The leaves are about ¾ inch long, linear acute, not apiculate, somewhat flattened, but with the nerves prominent on both surfaces, glaucous and stomatiferous on the upper surface, and bevelled near the apex on the green dorsal surface. The leaves are thus like those of P. ajanensis in having the glaucous surface uppermost, but are less flattened than in that species. Ripe cone between 4 to 5 inches long, oblong-cylindric. Scales slightly appressed, slightly convex, transversely oblong or rounded, upper border slightly everted denticulate. Seeds with a ferruginous, membranous, oblong wing.†

THE MAKING OF ORCHARDS.

III.

(Concluded from page 100.)

Planting the Trees.

Although the period during which fruit trees may be planted extends from the time when the leaf falls until the spring season has really begun, much depends upon the nature of the season itself, as also upon the kind of weather at the precise moment of planting. For instance, in a winter such as that through which we have nearly passed, orchard planting has been possible in most parts of the country upon five days out of every six, because only now and again has the frost been of sufficient severity to interfere with operations. Frost, however, is not the only thing that interferes with the work at planting time, for an excess of rain in a badly drained or heavy soil renders the ground quite unfit for labour of this kind, making the work far more laborious and unpleasant, and giving the trees a send-off of the worst possible description. A fruit tree which is expected to settle itself in a mixture of soil which approaches more nearly the consistency of a mud-pie than anything else, is very much handicapped at the start, for the wet soil thrown on to its roots will form a cake round them like so much mortar, and so, as it were, suffocate them at the very beginning, if it does not actually destroy many of the more delicate fibres. Treatment of this sort, although the actual health of the tree may not be apparently affected, is causing unseen damage to that very part of the tree's constitution which, from a fruit-bearing point of view, it is most necessary to protect, and the effect will be seen at a later period when the fruit spurs on the branches fail to develop as they otherwise should. Cold, windy weather is also a bad period for tree-planting, not only because it dries up the soil on the surface, but also on account of the damaging influence to the exposed roots of the trees got ready for planting. Mild, open weather is, of course, the best of all; but the planter must be guided by the nature of his soil, remembering that a good start is in this matter, as in many another, more than half the battle. Fruit trees will do no harm if kept out of the ground for a week or so, or even longer, in the case of severe frost, provided that they are well protected in the meanwhile. The best way to do this, supposing that for one reason or another they cannot at once be transferred to their permanent quarters, is to lay them carefully together in an almost perpendicular position against a wall or hedge in some sheltered corner out of the way of cold winds, covering up the roots as one goes along with some dry litter, leaves, sand, or garden mould, to protect them from frost and drying winds. A moderate amount of rain will do no harm, but should spring be approaching it is advisable to keep the roots from getting too moist, as such a condition might excite the trees to premature growth, which will only cause a check when they are removed for planting. If, therefore, trees waiting to be planted can be stored under cover, so much the better, although, under ordinary circumstances, any odd sheltered corner will do. Very late planting in the spring is not to be recommended, because the buds which have already begun to swell upon the trees are apt to be knocked off in the process of removal and replanting; and the trees, in which the sap is already active, will receive a severe check unless very expeditiously handled. In a late spring one can sometimes continue planting a fortnight or three weeks later than in the average season, and there are certain varieties which do not show signs of growth until long after the usual period of budding. Such kinds as these will receive no harm from late planting, and wonderful things can be done even when the trees are very far advanced in the spring. Experiments of this sort are, however, for the amateur who has, perhaps, only a dozen or two trees to handle, and not for the orchard planter who may be dealing with hundreds. It does not matter very much what the weather may be after planting, but the trees should be well settled in their positions (and an extra look round taken to see that all are securely tied to the stakes) against the coming of the equinoctial gales towards the end of March.

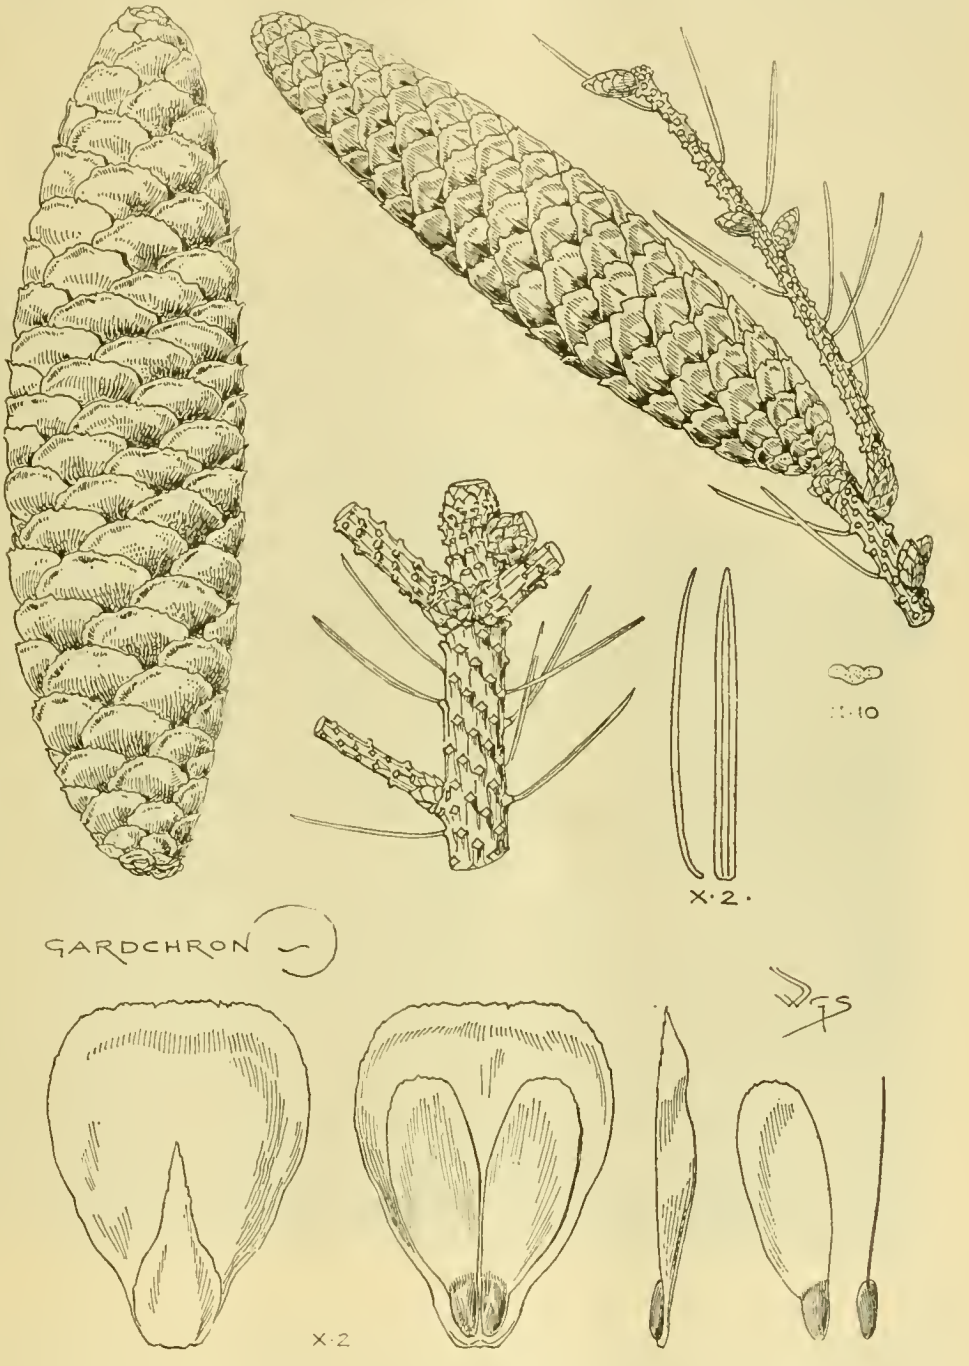

Fig. 57.—Picea complanata (see page 146).

Showing to the left a mature cone, to the right a shoot with buds, but mostly denuded of foliage and an immature cone. In the centre are shown a portion of an older shoot with leaf seen from the front and from the side and magnified two diameters; the cross section magnified ten times shows the flattened leaf. Beneath are views of the cone-scales and seeds magnified two diameters. The bract shown at the back of the scale was observed by the artist.

Drainage.

The question of drainage is an important one in the newly-planted orchard, but it is a matter which can very well be left till the trees are planted. The laying of pipes is always an expensive process, and very often, after considerable time and money have been spent in this direction, the results are not wholly satisfac-

tory. It is, indeed, a mistake to plant trees on any soil which is at times in such a waterlogged condition that drainage by means of pipes is necessary. The money will at all times be better spent in the purchase price or in the annual rent, unless, indeed, in the latter case, one can get one's landlord to share the expense—usually by no means an easy matter. The proximity of pipes in the neighbourhood of fruit trees is, however, not at all desirable. The roots will soon find their way into the pipes, with the result that the former will often be lying in water, and the latter will be displaced or broken, thereby upsetting the whole system and defeating the chief object of the pipes. Drainage may be necessary here and there in orchards which, for the most part, are well drained, and if the water in times of heavy rainfall happens to collect in small depressions on the surface, some means must be taken to carry it away. Usually a few open ditches will do all that is required; but if pipes are really necessary they should be laid so far as possible away from the roots of the trees between the rows. Surface water which only lies about for a few hours will do no harm; it is that which lies below the soil on the top of an impenetrable subsoil which does damage to the roots. The necessity therefore of obtaining at the outset a naturally well-drained soil with a porous subsoil is readily apparent. Thorough cultivation before planting will also do much to keep the ground in good condition for many a long day, and if occasion should require it the use of the subsoil plough will work wonders in a soil which is not over well drained in the first instance.

Weeding.

The trees once planted, very little remains to be done for some time to come, and the planter, if the work has been well carried out and all finished in good time, may rest a while and survey his work with satisfaction. The first thing that is likely to cause him trouble will be the appearance of weeds, and here let it be said that, so soon as they begin to make themselves evident, they should be destroyed whenever the weather is favourable. Many people defer weeding while the plants are yet small, under the mistaken idea that it is waste of time to go all over the ground while only a few weeds are apparent here and there. But it should be remembered that for every small weed visible to the eye there are a thousand which will become apparent within a few hours after the first shower of rain, and that, should a wet period set in, these may in the space of a few days grow to a size greater than the hoe can cope with effectively. When the weeds are only small so that a hoe run lightly through the ground just below the surface will uproot them, one good man can get over a surprising amount of ground in a little time; but if the work be deferred until each individual weed requires a chop of the hoe to itself, the same man will show but a poor result for a day's work, and the job will never be so effectively done. Small weeds soon wither, and the soil falls readily off their fragile roots, so that they quickly die; but the big weeds, which the hoe can seldom destroy unless it be dug deeply into the soil, will start growing again, even in moderately dry weather, nourished, as they are, by the soil clinging to their matted roots. If time presses and labour be scarce, let the work at least be done often in the immediate vicinity of the trees, for it is here that it is of the most importance. The hoe is the best tool for the purpose, for it destroys the weeds, and at the same time keeps the surface in a good friable condition, thus keeping the ground beneath in a moist state during summer, and letting the roots of the trees obtain the full benefit of sun and air. A light fork is useful in the autumn for forking in the remainder of previous top-dressings of manure, but the tool must be in the hands of a careful man who understands the delicacy of the work in which he is engaged, and who will not go deep enough to draw the fibres out of the soil and so destroy them. Horse tackle is best kept out of the orchard altogether, for it is almost impossible to prevent damage to the trees either by the horse or the implement that he draws behind him. Such treatment is only permissible where trees are planted very wide apart, and even then it requires a careful man to undertake the job.

As for pruning, which is a matter too lengthy to be entered into on this occasion, none will be needed the first season, for the trees, whatever their size, should come from the nursery ready pruned before lifting, and it will be better to let them go ahead the first summer as fast as they like, cutting back rather hard the second season after planting, if necessary. Careful and scientific pruning, thorough cultivation, and constant attention to the attacks of blight in its many forms will, for the future, be the chief care of the orchard owner; but all these things come rather under a heading different to that which concerns the original making of orchards. *East Sussex.*

THE ROCKERY AT LEONARDSLEE.

Opuntias succeed well in the rock garden at Leonardslee, Horsham, the residence of Sir E. G. Loder, Bt., where the species cultivated include O. monacantha, O. glauca, and O. Engelmanni. The species last named is represented by a large group which measures 8 feet from front to back and 10 feet long (see fig. 58). It is growing on a rather sharp slope which faces to the south, and having the natural protection of a large piece of overhanging rock. The Opuntias are grown in a specially prepared soil composed of loam, leaf-soil and sand in equal parts with a little lime-rubble added. The photograph from which the illustration has been prepared was taken in January, and shows the plants to be unprotected, as they are during the whole of the winter. There are also several very fine plants of Saxifraga longifolia. The one illustrated at fig. 59 measures 11 inches across, and is grown between two large stones having about 2 inches of soil between them. This soil is composed of light loam with a little wood ashes added, but the plants succeed equally well in any light, sandy soil in several well-drained positions on the rockery. The species flowers at about July, and the illustration at fig. 60 shows how remarkably well it succeeds in the Jardin Alpin d'Acclimatation, Geneva.

ORCHID NOTES.

DENDROBIUM WARDIANUM.

The notes on p. 99 lead me to offer one or two supplementary remarks on this beautiful Orchid. My memory takes me back to the famous collection of John Day, Esq., Tottenham, who cultivated the Assam form, and in several seasons produced flowers of intense beauty and vivid colouring. This plant was known at first as D. Falconeri obtusum, since it was considered a form of that pendent reedy-growing species. When, however, it flowered with Dr. Ward, of Southampton, it was at once recognised as distinct and much superior to D. Falconeri. In the famous collection of S. Mendel, Esq., Manley Hall, was a fine plant of this same form, and, on account of its rarity, it realised a goodly sum when the collection was disposed of by auction. When, however, the Burmese variety, with its stout pseudo-bulbs and thickened nodes, was discovered, vast quantities were imported, and were eagerly purchased by orchidists. And yet, how very few are the large

specimen plants one meets with that have been grown, rested, and flowered, and increased in size, vigour and floriferousness for a number of years. It would almost appear as though large size in plants could not be attained, but that, after a few years, the native vigour was lost, and the strength of the plants continuously diminished.

The reference to treatment in the note already referred to implies that heat and moisture are absolutely necessary to the formation of growth and flowers. It is extremely difficult to say that the treatment given in one house would bring about similar results in another structure, and by a different grower. The practice adopted here for some few years is not quite the same as that in use at Tring Park. I mention this because the result so far has been considerably in advance of anything I have succeeded in obtaining under the heat and moisture treatment.

Our plants are grown in 5-inch pots, with just a bit of peat, sphagnum-moss and crocks jutting from the surface. They are mostly placed on a bed with an ash bottom when subjected to a little heat, and on an ordinary stage when in the greenhouse. We have many in bloom in the conservatory at the present time where the temperature falls sometimes at night time to 50°, and occasionally lower. As the plants pass out of flower they are placed in a warm house, and the growth (which has just started) is stout and vigorous. During the month of May the plants are stood in a greenhouse, where Fuchsias, Zonal Pelargoniums, etc., are grown, some vines in the same house giving shade. The young growths develop clean and strong, and the pseudo-bulbs are much stouter than when grown in heat. This greenhouse treatment is continued all through the summer and autumn, until growth has finished, and the last leaf is developed. Water is then withheld, and by November the buds begin to swell; but it is not until Christmas time that the plants are again put into heat. The result of this method has been eminently satisfactory, for we have them in flower at the present time with 16, 18, 19 and 21 open flowers on a single growth. The blooms are of great substance, and the colours are well developed.

I certainly advise those who have a number of plants to put them in the greenhouse or intermediate house during the summer and autumn; the growth will be more sturdy, will be better ripened, and the flowers will appear far more numerously. Of course constant syringing must be given in the greenhouse, and water must be afforded the roots, but an open soil as I have indicated seems to be the proper medium for the roots, and, since attention must be given to them every day, they will not become sour and soddened through excess of water. *W. Swan, Thorncote, Staines.* [Some excellent flowers produced by this method of treatment accompanied this communication.—Ed.]

(For text see page 148.)

CULTURAL MEMORANDA.

TECOMA SMITHII ×.

This beautiful, free-flowering greenhouse climber was introduced into this country from Australia. The flowers are produced on large panicles, and are of a bright orange colour, with chestnut-brown markings at the base of the lobes, forming a dark ring around the throat. Young growths about 3 inches in length taken off with a "heel" and inserted round the edge of 3-inch pots filled to their rims with light sandy soil, placed in heat, and watered, will soon form roots. Where only a few plants are desired, a simple and efficient method of rooting the cuttings is to plunge the 3-inch pot in another of a 6-inch size partly filled with sawdust or leaf-mould, and cover with a piece of glass, which should not be allowed to touch the cuttings. As soon as the latter become rooted the glass should be tilted for a day or two before finally removing it, in order to inure the young plants to the general atmospheric temperature of the house. They should be potted singly into small 60's, using fine, sandy mould for a potting medium.

BOUGAINVILLEA FORMOSA.

The free growth, and, under comparatively cool treatment, abundant flowering qualities of this semi-scandent plant, combined with a profusion of the richly-coloured bright purplish-mauve bracts, render it a most desirable subject for the embellishment of warm greenhouses and conservatories. The plant is easily propagated from cuttings, about 3 inches in length, taken with a "heel"—that is, with a slice of the wood of the previous year's growth attached—and inserted round the edge of 60-size pots. Use sifted leaf-mould and sandy loam in about equal parts, and surface the whole with silver sand. Place the cuttings in a propagating pit, and water through a fine rose. When the tiny plants have made a little top growth they should be potted singly into small 60-size pots in the same compost as before, which should be made moderately firm. Place the plants in heat, and afford water as recommended above. *H. W. Ward, Rayleigh.*

SALVIA SPLENDENS.

We have a nice batch of plants in flower now that have been grown from cuttings inserted on August 20. The cuttings were procured from plants growing outside; such soft cuttings make roots very readily if plunged in the propagating frame. When sufficiently rooted the young plants were potted off singly into 3-inch pots, and grown on in a cold frame. The compost used was loam and leaf-soil in equal parts, with the addition of a small quantity of well-rotted manure. When the roots began to take hold of the new soil the point of each shoot was pinched out. The final potting took place on September 25, when they were shifted into 5½-inch pots and returned again to a cold frame. At the end of the first week in October the plants were removed to a house having an atmospheric temperature of 55°, and the shoots were then stopped for the last time. They are now in full flower and are much appreciated. These Salvias are very effective when associated with Daffodils, Freesias, and Adiantum Ferns. We always grow a quantity of large plants which flower during November and December, but I find these later flowering plants more useful, although smaller in size. They are about 20 inches in height, and have ten or more flower-spikes upon each. *W. J. Snell, Wimpole Hall Gardens, Royston.*

EUPATORIUM PETIOLARE.

(See Figure in *Gardeners' Chronicle*, March 12th, 1904, p. 163.)

This showy winter-flowering plant, with its pretty, graceful, light, branching stems, is a welcome addition to our greenhouses, especially at this season of the year. It is curious that after a lapse of nearly thirty years this plant should leap into popularity once more. After the normal flowering period is passed, by reducing the shoots to about one-half their length, the new growths will produce a further supply of the fragrant blossoms well into April and May. After this further period of flowering, again cut back the shoots, and the new "breaks" will furnish a supply of cuttings. These should be placed eight or ten in a six-inch pot, in a compost of well-sifted loam, leaf-soil, and road-grit or silver sand. Place the pots containing the cuttings in a small hand-light in a house in which they can be given a little bottom heat. Here they will root readily, and, when rooted, let a little ventilation be given to the propagating light, increasing this in quantity day by day, until the cuttings are robust and strong, when the hand-light may be dispensed

with. After the lights are removed, the plants should be placed on a shelf near to the glass, for the purpose of hardening them off. As soon as the cuttings are sufficiently rooted, pot them into good-sized pots (for they are gross feeders), using the same compost as before. The compost for their next shift would be composed of well-chopped turfy loam, leaf-soil, and decayed horse droppings, with a sprinkling of road-grit to keep the whole open. Pot the plants firmly. As soon as they have established themselves in their new pots, they should be hardened off to such a degree that they may be stood in the open. The roots must never be allowed to become very dry. The plants should be stopped at a height of 9 inches or 1 foot, and again when the new growths are half that length, in order to encourage a bushy habit. When well rooted, they can easily be transferred to their flowering pots, which should consist either of large 24's or large 32's, and some may require even larger sizes than these. Use a compost of soil similar to that used for their previous shift, but it should be coarser in texture, and contain a small quantity of soot. Keep the plants staked whilst growing, allowing plenty of room for their proper development, and, when well rooted, afford weak applications of liquid manure. Throughout the autumn, during the growing period, they will require plenty of water, for they must not be allowed to flag. On the appearance of frost, they should be housed in a temperature just above freezing point. Should green-fly make its appearance, fumigate the plants lightly, and at two or three separate intervals, rather than apply an overdose, as the foliage is very liable to injury from this process. They should be given plenty of light and air. Apparently there are two varieties of this plant, the one flowering in January, and the other in mid-February. The latter kind has larger inflorescences and flowers, and the habit is not so branched as the earlier flowering type. *Torium.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Pleiones.—Now that plants of P. humilis and P. Hookeriana have passed out of flower, and new growths have started, they should be repotted at once into a compost consisting of peat, loam, and chopped sphagnum-moss, with a sprinkling of silver sand, having first mixed these materials well together. Suspend the plants near to a roof ventilator in the cool house, and until the roots have obtained a firm hold on the compost, and the young growths are advancing satisfactorily, afford water but sparingly; afterwards the supply may be considerably increased.

Odontoglossum crispum.—Imported pieces that arrive at this season should at once be thoroughly cleared of all rubbish and decaying parts, and where time will allow, each piece may be placed into as small a pot as can conveniently be used, filling up around the base of the pseudo-bulbs entirely with small crocks. It is not advisable to put in several pieces together with the idea of making a large or specimen plant in the first season, because the plants will differ considerably when they flower, and scarcely can two be found that are alike. Where large quantities are obtained, a good plan is to lay some boards or slates upon the stage and cover these with a thin layer of rough sphagnum-moss, laying each plant separately upon the moss. The pseudo-bulbs will not need to be syringed or damped overhead, as the moisture arising from the usual damping down will be sufficient, and too much damping overhead is often the cause of decay occurring in the pseudo-bulbs. These freshly imported plants should be frequently examined, and as each piece commences to grow, let it be potted up. The pots used should be of small sizes, and they should be filled to quite three-parts of their depth with crocks, over which place a layer of sphagnum-moss. Keep the base of each plant on a level with the rim of the pot, and fill up to the rhizome with equal parts of peat and sphagnum-moss, cutting it up together rather roughly, and mixing with it a moderate quantity of broken crocks. After the potting process, the principal object of the grower should be to keep the plants cool and their immediate surroundings moist, so that they will not require heavy waterings until each plant is well rooted in the compost. The surface of the soil should be sprayed over very lightly whenever it appears dry, so as to induce the moss to grow. These cool-growing Odontoglossums do not appreciate fire heat; therefore, unless sharp frosts or very cold winds occur, they are better without it, and when heat has to be used let it be as little as will suffice. If during very cold nights the water pipes are made just lukewarm, and the house is covered as was advised in my last Calendar, a suitable atmospheric temperature of about 50° will be easily maintained. Shade the plants from all direct sunshine, and ventilate freely through the bottom ventilators whenever the outside atmosphere is above 45°. In mild, damp weather, with the thermometer in the screen above 50°, we open the top ventilators also. Without doubt, O. crispum is a lover of pure fresh air at all times, and it is essential to their healthy development. If all goes well with these imported pieces of Odontoglossum they will, by the autumn, have made new pseudo-bulbs, and be ready to start growing again, when they will require to be shifted into larger pots, where less drainage and more material to root into can be supplied.

Anthurium Scherzerianum.—Any plants that require re-potting should now be given attention. If any have become of too large a size to be conveniently used for decorative purposes, let these be at once separated and re-potted into pots 6 or 7 inches in diameter, as this size will be found most useful. The brilliant coloured spathes are always of much value in grouping, whether in the stove, intermediate, or dwelling house. If a few spathes be cut with long stems, and associated with Arum Lilies, they will have a charming effect when arranged in large vases. The lasting quali-

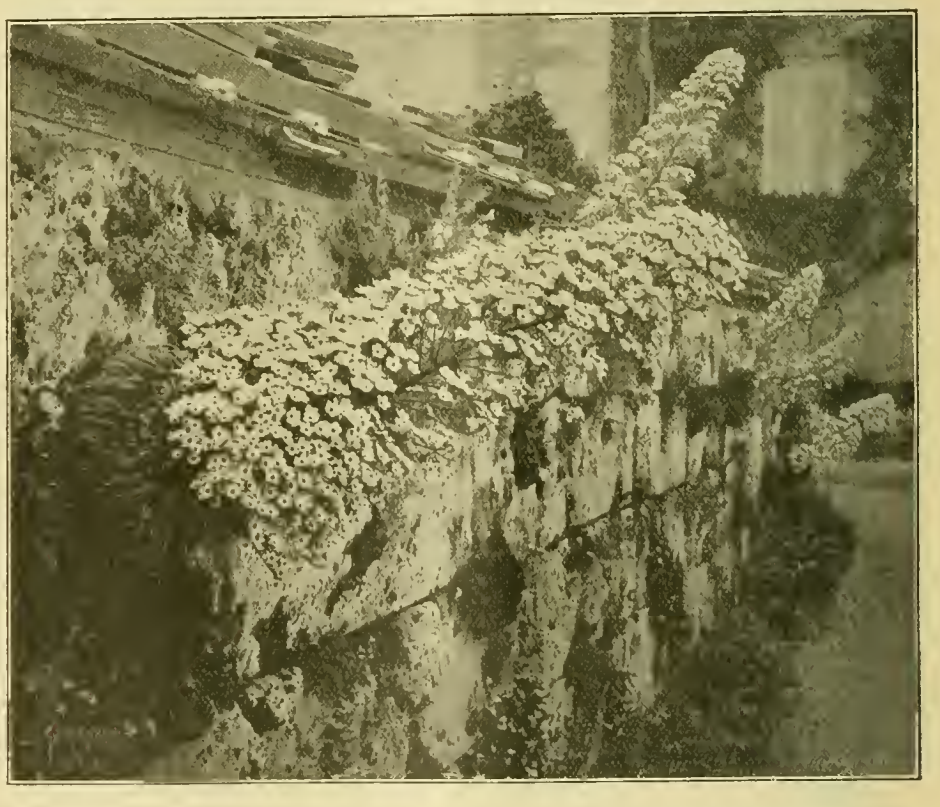

Fig. 60.—Saxifraga longifolia in the Jardin Alpin d'Acclimatation, Geneva.

(For text see page 148.)

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Caladiums.—The resting period being over, shake out the tubers from the old soil, and if they are intended for exhibition, select the strongest and place them in pots, 6 or 7 inches in diameter, from which they will need to be transferred to larger pots later on. The smaller-sized tubers may then be placed into 5-inch pots for use in furnishing. If Caladiums are subjected to the temperature of a greenhouse before using them for grouping in house decorations, they will serve very well. The compost I use when potting the plants consists of good turfy loam one-third, and the remainder of leaf-mould, turfy peat, and a liberal quantity of coarse sand, charcoal, and crock siftings. A small quantity of Standen's manure is used in the soil, and I find it helps to develop the rich colouring in the leaves and increase their size.

Alocasia Sanderiana and other varieties will now need to be re-potted. The provision of perfect drainage is a most important item, as these plants, when growing, require abundant root waterings. A humid atmosphere should be maintained for them, but avoid syringing the foliage, for should the water contain a small percentage of lime, it will leave a deposit, and thus destroy the effect of the beautiful metallic hues usually seen on these plants. In potting use a very porous compost, consisting of rough, fibrous peat, half-decayed oak leaves, dried cow manure, some ½-inch crocks and charcoal, and a fair proportion of living sphagnum-moss and coarse sand. If the compost is surfaced with sphagnum-moss, it will give a neat appearance to the plant.

Anthurium Scherzerianum.—Any plants that require re-potting should now be given attention. If any have become of too large a size to be conveniently used for decorative purposes, let these be at once separated and re-potted into pots 6 or 7 inches in diameter, as this size will be found most useful. The brilliant coloured spathes are always of much value in grouping, whether in the stove, intermediate, or dwelling house. If a few spathes be cut with long stems, and associated with Arum Lilies, they will have a charming effect when arranged in large vases. The lasting qualities of the spathes when cut are sufficient reason for increasing the stock of this useful stove plant. Success will be attained if the plants be grown in a mixture of good fibrous loam, from which the finer particles have been excluded, peat, dried cow-manure, coarse sand, and charcoal, with sphagnum-moss added. Perfect drainage is essential, and liberal supplies of liquid manure and soot should be afforded the plants when the spathes are advancing.

General Remarks.—Careful ventilation is of the highest importance; the underground or wall ventilators should be used at the present time in preference to those in the roof. Maintain a humid atmosphere to encourage free growth in all newly-potted plants. Hippeastrums (Amaryllis) that have passed out of flower should now be encouraged to make good leaves and a strong bulb for flowering next season. Syringe the plants freely, and keep them close to the glass, bearing in mind that a bulb is the store-house for the flower. Take every opportunity to prevent insect pests by employing light fumigations; don't wait for their appearance.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Melons.—Plants that were raised early in January and grown on the cordon system should be stopped when about halfway up the trellis, which will hasten the formation of side shoots and encourage the plants to come into flower more quickly. By allowing three blooms to open on each plant before pollenising them, an even "set" will be secured, and the fruits will be likely to swell simultaneously. Ripe fruits can be had in 15 weeks from the time of sowing at this time of year. Seeds should again be sown for succession, if house accommodation can be provided. Close the houses early in the afternoons and maintain the atmosphere in a moist condition.

The Orchard House.—If the trees were given attention in the autumn as regards repotting and top-dressing they will be in a satisfactory condition for fruiting, and may now be transferred from the plunging material where they will have been all winter, to the cool house, where they will soon commence to expand the blossoms. Afford each tree plenty of space for the fruit and foliage to obtain sunlight. Artificial heat is not necessary, especially during the early stages of growth. If the atmospheric temperature of the house can be kept below 50° at night so much the better. The houses must be freely ventilated at all times when external conditions are favourable, and more particularly when the trees are in flower. When the trees are in flower it will be necessary to distribute the pollen each day by giving the trees a gentle shake. The trees do not require much water at the present time.

Pot Vines that were started in November are fast swelling their fruits and will now require liquid manure, well diluted, for if applied too strong it would turn the feeding roots black and ruin the crop. To alternate with the liquid manure use Peruvian guano by sprinkling a little on the top of the soil and watering it in with tepid water. Continue to maintain a bottom heat of 70° and keep all sub-laterals pinched as they appear.

Successional Vines.—Black Hamburghs will now demand close attention in regard to disbudding, stopping, and tying, for if a quantity of surplus growths are cut out all at once it must interfere with the root action. Ventilation is important and should be applied gradually as the atmosphere of the house becomes warmer, avoiding cold draughts always.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Half-hardy Annuals.—Phlox Drummondii is one of our most useful and effective half-hardy annuals, and because of its varied and brilliant colours is indispensable in the flower garden. The dwarf compact varieties are invaluable for planting beneath Roses, or as surface plants under other tall growing species, while the grandiflora sections can be used in masses by themselves, or as appropriate subjects for the mixed flower border. Seeds of varieties, in distinct colours, should be sown at the present time in shallow boxes in light, sifted soil pressed firm, and placed in a warm, moist atmosphere. As soon as the seedlings are large enough, they should be pricked out into larger boxes filled with rich soil, allowing sufficient space between the plants to save the necessity of further pricking off. If afforded a temperature of 55° to 60°, the seedlings will soon be fit for removing to cool frames to harden off.

Salpiglossis.—The sowing of seed now in boxes is a better method of culture for this beautiful plant than that of sowing later out of doors, as advocated by many growers. If sown now, the seedlings will flower in the warm dry weather of summer and early autumn, and are then seen to the best advantage. When sown later, the bloom is usually destroyed by rain and bad weather, and the plant also, under these conditions, gives off an objectionable odour. The best plan is to sow very thinly in boxes in light, sandy soil, and allow the seed to germinate in moderately brisk heat; but when the seedlings are through the soil, plenty of fresh air must be admitted, as the Salpiglossis is very liable to damp off. When strong enough, prick them off into boxes, placing them in gentle warmth to induce them to root readily, and when established harden off preparatory to planting them out at the end of April. If massed in their different shades, the display is goregous, so rich are the colours and markings of this beautiful flower.

Nicotiana Sanderæ, notwithstanding adverse criticisms, is undoubtedly—when well cultivated—a valuable acquisition to our gardens. Its rose-coloured flowers, conjointly with the bold appearance of the plant, makes it a most desirable ornament for the border, while a bed devoted solely to it is extremely attractive. If the hybrids in distinct colours, the seed of which is sent out this spring for the first time, grow as luxuriantly, and flower as profusely, they will prove invaluable. Sow the seeds of all the Nicotianas now in heat. When large enough, prick off the seedlings into large boxes, and again when necessary pot the seedlings into 5 or 6-inch pots.

The Japanese Pinks (Dianthus Heddewigii) either mixed or in colours are splendid in beds by themselves, or in conjunction with other flowering plants. Although the species is often used as a bi-annual, it is easier grown and more useful treated as a half-hardy annual. Sown now in heat, plants can be had fit for planting out in May, and will be in flower by end of June.

The Corsican Daisy (Erigeron mucronatus), with its pretty white flowers shaded with rose colour, is a beautiful, dwarf plant suited for the hardy flower border, or the rock garden, as it remains in flower for a long time during the summer months. It is perennial, but if sown now in heat will flower early in summer.

Marguerite Carnations, and the new quick-flowering varieties of this plant, should, if not already done, be sown at once for flowering in the autumn. If sown now in shallow boxes and placed in heat, the seedlings will be soon ready for potting into small thumb pots. When rooted sufficiently they should be again moved into slightly larger pots, using a prepared compost of rich, gritty soil. They will then make sturdy and strong plants fit for planting out, or for using in vases, by the end of the month of May.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leopardslee, Sussex.

Figs.—Fig trees will grow in nearly any soil, but in well-manured ground they grow too rapidly and fruit but little. They require to have the roots somewhat confined; in instances where they are not already restricted they should be made so. If the trees are planted against a wall and the soil appears to be too rich, make a border about 6 feet in width, and build a concrete wall, or one of rough bricks, below the ground level to confine the roots to the border. Fig trees growing in sandy soil are not excessively vigorous, and may be fed with liquid manure when the fruits are swelling. The trees need a hard bottom for the roots, and I know of several cases where good crops are obtained annually from very old trees whose roots have apparently nothing but a hard road to grow in. These trees make the necessary amount of wood, but there is not much pruning needed beyond thinning out the shoots. As a general rule, however, trees planted against walls require more pruning than they get. All the gross wood should be thinned out, retaining the well ripened, short jointed shoots. These latter should be laid in straight, leaving ample room to lay in other shoots during the growing season. In many cases the shoots will require pruning; especially should this be done when one or more shoots are more vigorous than others, for it is these long sappy shoots that fail to ripen well, and are therefore unproductive. The bearing shoots should be laid in their whole length. Others may be pruned back to one or two eyes, and if both "break" and are not required, rub off the one less favourably placed. Aim at getting a supply of fruiting wood in the middle of the tree. In regard to protecting the trees, I may say that I have not found much benefit to follow the practice of covering them, though I have experimented with trees on the same walls. If you cover up sufficiently to protect the trees from severe frost, growth will commence whilst they are so covered, and the last state will be worse than the first. I have given up protection except in rare instances, such as when a sharp frost is foreseen in May; those on a south wall may then be covered. Growers in various districts, however, must be guided by circumstances. Brown Turkey is the most reliable variety, and when grown well the fruits attain to a large size and are delicious.

Black Currant Mite (*Phytoptus ribis*).—Examine the plantations of Black Currant bushes, and if any more big buds are noticed have them at once picked off and burnt—a couple of men or boys will destroy a lot in a short time. I discovered a few on the bushes here and had them picked off and the ground well dressed with lime. Several trees that were badly infested were rooted up, and up to the present no other swollen buds have been seen. The trees will be all the better if sprayed again with Richards' XL-All Winter Wash.

Fruit Room.—Throw out all decaying fruits. Apples are keeping well, especially the varieties Blenheim Pippin, Cockle Pippin, Barnack Beauty, Beafin, and Dumelow's Seedling.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Brassica Seeds.—Seeds of many varieties of Cabbage and similar plants may now be sown extensively out of doors. Select an open piece of ground, and fork it over on a dry day, in order to get it into first-rate tilth. If the ground is of a heavy nature sow the seeds in lines, and cover them with finely sifted soil. But if the soil is more suitable, mark out a bed 4 feet wide and scatter the seeds broadcast, but thinly. If birds are troublesome it is best to afford protection by netting the whole bed over straightaway, otherwise much damage may be done before it is noticed. Cauliflowers, in various varieties, Brussels Sprouts, Savoys, Kales, Kohl Rabi, Cabbages, both white and red, Broccoli, &c., should be sown, together with any other kinds that there is a demand for. Make another sowing three weeks later for succession. It is of the utmost importance to sown thinly and not allow the plants ever to become overcrowded. Avoid sowing on the same ground as was used for this purpose last year.

Slugs.—These are troublesome during mild weather in the spring, and often the plants from a whole seed bed may be cleared in a very short time. Where this is feared let some slacked lime be forked into the soil when preparing the seed bed. It is well to repeat the application of lime when the seedlings appear, but the operation then should take place after dark when the slugs, being already on the surface in search of food, will immediately come into contact with the lime. It is next to useless to sow lime on the surface through the day with a view to killing the slugs, as they are then in their shelters, and will wait there until the strength of the lime becomes exhausted. Make a determined effort early in the season to lessen their numbers.

Tomatos.—Sow seeds for raising plants to fruit out of doors. I do not recommend sowing earlier than this date, as such early plants usually become "leggy" and starved before danger from frost is past. Select an early variety, preferring one that produces smooth-skinned fruits. A good selection of Ham Green is suitable. In very late districts it may not be worth while attempting to grow Tomatos in the open unless for the purpose of making ketchup of the green fruits, for which they are quite suitable. Sow the seeds in heat, and pot the young plants on in the usual way, finally hardening them off in frames in readiness to plant out by the end of May or early in June.

Carrots.—The main crop of these may be sown as soon as the state of the soil will permit. A deep, light soil is best, but good crops can be secured from most soils if the cultivation is modified to suit the particular circumstances. It will be quite useless to expect fine root crops of any kind on very heavy or stony land unless it be thoroughly loosened to its greatest depth by trenching, afterwards making boles and filling these with finely sifted soil in which to sow the seed. I have seen heavy crops of roots of the finest description obtained from such soils after this treatment. On more suitable soils the seeds should be sown in lines drawn at 12 inches apart. Before filling in the lines a sowing of wood ashes or soot should be made. New Red Intermediate is a standard selection of that type, but a stump-rooted variety should also be sown as part of the main crop. Early Nantes and Early Gem should be sown at intervals of a fortnight throughout the season to provide the kitchen with young tender roots regularly. In order to have them in the best condition, these should be pulled when they have only just attained their full size.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	Mar. 10	Dutch Gard. Soc. meet.
MONDAY,	Mar. 12	Ann. meet. Unit. Hort. Ben. & Prov. Soc., 8 p.m., at the Roy. Hort. Hall, Westminster.
THURSDAY,	Mar. 15	Linnean Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—42·2°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, March* 7 (6 P.M.): Max. 66°; Min. 48°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 8 (10 A.M.): Bar., 30; Temp., 51°; *Weather*—Drizzly rain.

PROVINCES.—*Wednesday, March* 7 (6 P.M.): Max. 57° England S.E.; Min. 47° Liverpool.

SALES.

MONDAY—

Herbaceous plants, Roses, Begonias, &c., at Protheroe & Morris' Rooms, at 12.

WEDNESDAY—

Japanese Lilies, Carnations, Begonias, 3,000 Roses, Ornamental and Decorative plants, at Protheroe & Morris' Rooms, at 12.

Nursery Stock at Elvaston Nurseries, Borrowash, near Derby, by order of Messrs. W. Barron & Son, by Protheroe & Morris, at 12.

FRIDAY—

Gloxinias, Greenhouse plants, Ferns, &c., at Protheroe & Morris' Rooms, at 12.

Imported and Eestablished Orchids at Protheroe & Morris' Rooms, at 12.30.

Events of the Week. The precociously fine weather on Tuesday last ensured a remarkably pretty and interesting display in the New Hall of the Royal Horticultural Society. With the customary propensity to grumbling, said to be a British characteristic, though we think we have observed it elsewhere, people were found complaining of the heat and of the overpowering fragrance of the Hyacinths and other spring flowers. For the details of the show we must refer to another column, wherein it will be seen that ample compensation in the way of beauty and interest was afforded for the trifling inconvenience complained of. The three o'clock lecture was on the well-worn subject of the nomenclature of garden plants, but we do not gather that any further light was thrown on the subject or any practicable proposal suggested for remedying the errors and anomalies which have the all-potent sanction of custom. Certain plants will, in gardens, be called Lilies or Laurels in future, as they have been in the past, although, for the most part, the names are absolutely inaccurate, and, like the popular "geraniums," are "terminological inexactitudes."

The great event of the day, however, was the complimentary dinner to Mr. William Marshall at the Hotel Windsor, and which was not in the official programme. It was not the less important on that account. The committees had fairly earned their dinner, and they enjoyed it the more because it was made the means of paying a thoroughly merited compliment on their part to Mr. William Marshall, who has acted as Chairman to the Floral Committee for twenty years. During that period he has won the esteem of his colleagues for his disinterested impartiality, his wide knowledge, his geniality, and his firmness where occasion demands. Mr. Harry Veitch, who occupied the chair at the dinner, had an easy task before him, for his experience of the Royal Horticultural Society and of the work which Mr. Marshall has accomplished for horticulture generally is necessarily intimate. Several of the speakers indulged in reminiscences of the "then and now" order. Mr. Marshall himself was proud to recall the fact that he was a disciple of Wilson Saunders, a scientific horticulturist venerated in his day but known only by name to the present generation. No less justly proud was he to remind his auditory that he it was who had the satisfaction of being the first to flower Odontoglossum Alexandræ, or, as it is now called, O. crispum.

The Committee had also availed themselves of the opportunity of presenting Mr. Marshall with his portrait, which was exhibited in the course of the day in the Floral Committee Room at the Hall, and was generally approved.

Amongst other news of the week we may mention that the Veitch Memorial Trustees have awarded medals to Baron Sir Henry Schroeder in grateful recognition of his invaluable services in the erection of the Horticultural Hall, and to Sir Thomas Hanbury for his munificence in bestowing on the Society the beautiful garden at Wisley, which is destined to more than replace the time-honoured establishment at Chiswick.

Another medal was unanimously awarded to Mr. E. H. Wilson in commemoration of his remarkable services to horticulture and botany whilst in the service of Messrs. James Veitch and Sons. The details of Mr. Wilson's journeyings in China are in course of publication in these columns, as well as descriptions of numerous plants introduced by him. The grand Meconopsis integrifolia and the remarkable series of Primulas are by no means the only results of the adventurous journeyings of Mr. Wilson and of his intelligent zeal as a collector. The Trustees have also made a most acceptable grant of £25 in aid of the funds of the Lindley Library.

OUR SUPPLEMENTARY ILLUSTRATION represents an example of the Wych Elm growing on a site at about 100 yards distance from the River Dart at Sharpham House, in Devon, the residence of Miss DURANT. It will be seen on reference to the picture that the tree possesses a remarkable spread of branches, and when we state that these cover an area of over ¼-acre, some idea of the extraordinary size of the tree may be gained. The height, although not exceptional, is 80 feet, but the longest branch measures the great length of 104 feet. The girth, at a distance of 6 feet from the ground, is 18 feet, and thereabouts spring four of the largest branches. These branches and the other smaller ones are covered by dense patches of ferns on their upper surfaces. The tree was planted over 200 years ago, and is still in good vigour. For the opportunity of illustrating this remarkable tree we are indebted to our correspondent Mr. JOHN MAEERS, The Gardens, Sharpham, near Totnes.

SMALL HOLDINGS. The Departmental Committee appointed by the President of the Board of Agriculture and Fisheries to enquire into the subject of Small Holdings, held a sitting on the 28th ult. Evidence was given by Mr. W. MACKENZIE, Secretary of the Crofters Commission, and Mr. ISAAC CONNELL, Secretary of the Scottish Chamber of Agriculture.

HORTICULTURAL EXHIBITIONS AT BIRMINGHAM.—At a meeting held in the Botanic Gardens, Edgbaston, Birmingham, on the 1st inst., NEVILLE CHAMBERLAIN, Esq., in the chair, the following Resolution proposed by Mr. JOHN POPE, King's Norton, and seconded by Mr. T. G. BAKER, Wolverhampton, was carried unanimously: "That this meeting of practical horticulturists cordially approves of the proposal of the Birmingham Botanical and Horticultural Society to hold Flower Shows in the months of June and July, and pledges itself to further the scheme in every respect." Subsequently a committee was formed to make the necessary arrangements, and June 13 and July 4 were selected as the most suitable dates for the shows.

LINNEAN SOCIETY.—The next evening meeting will be held on Thursday, March 15, 1906, at 8 p.m., when there will be a discussion on the "Origin of Gymnosperms," to be opened by Prof. F. W. OLIVER, F.R.S., F.L.S. &c.

THE BOTANICAL MAGAZINE.—The plants figured by Miss SMITH and described in the March number are the following:—

ARACHNANTHE ANNAMENSIS, *Rolfe*, in *Gardeners' Chronicle* (1905), i., p. 391; tab. 8,062.—Introduced to the nurseries of Messrs. SANDER & SONS from Annam and flowered at Glasnevin in June, 1905. The five segments of each flower measure nearly 3 inches in length, are narrow with recurved edges, and all except the dorsal sepal, which is erect, are curved downwards. The colour is yellow thickly barred with red. The lip is much shorter, mobile, and three-lobed, and of complex structure, details of which are given in the text by Mr. ROLFE.

ERICA TERMINALIS, *Salisbury*; tab. 8,063.—This is the E. stricta of Donn, and has various other synonyms. It has small linear leaves in groups of four, and flowers in heads towards the ends of the branches. Each flower is about a quarter of an inch long, deflexed, urn-shaped, of rosy pink colour. It is a native of Corsica and Southern Italy, and has been in cultivation at Kew as a hardy species for many years. It is now described by Mr. SKAN.

LONICERA TRAGOPHYLLA, *Hemsley*; tab. 8,064.—Discovered by Dr. HENRY, introduced from Hupeh, China, to Messrs. VEITCH'S nurseries by WILSON, and described and figured in these columns 1904, ii., p. 151.

POLYGALA APOPETALA, *T. S. Brandegee*; tab. 8,065.—A very remarkable species, acquiring the dimensions of a small tree, with shortly-stalked lanceolate leaves and flowers that might well be taken as pea-shaped. They are of a rosy lilac colour and arranged in long racemes at the ends of the branches. It was first found in Lower California by Mr. BRANDEGEE. The specimen figured came from the garden of Sir THOMAS HANBURY at La Mortola, Ventimiglia, and is described by Mr. T. A. SPRAGUE.

CEROPEGIA FUSCA, *C. Bolle*; tab. 8,066.—The stems and branches of this curious Asclepiad are ascending (not climbing), succulent, and cylindrical, with narrow, lanceolate leaves. The flowers are in clusters from the sides of the branches, each rather more than an inch long, ascending, dull reddish-brown in colour, the tube cylindric, slightly dilated at the base, the limb

dividing into five ovate acuminate segments whose long tips are incurved and united at their extremities. It is a native of Grand Canary, and was introduced to Kew by the agency of Mr. Ledger. A detailed description is furnished by Mr. N. E. Brown.

Royal Horticultural Society.—Intending candidates for the Society's annual examination in the principles and practice of horticulture to be held on March 28 are requested to send in as soon as possible their entry forms, with the name of their proposed supervisor, to the secretary, from whom the syllabus, with entry form attached, may be obtained. Entries cannot be accepted after March 19. If any candidate desires to sit in London for this examination, he must say so on his entry form, and the Society will then make arrangements for him to attend at their hall in Vincent Square, Westminster. A scholarship of £25 a year for two years is offered by the Worshipful Company of Gardeners. The Society will hold an examination for school teachers in Cottage and Allotment Gardening on Wednesday, April 11. This examination is intended for, and will be confined to, elementary and technical school teachers. Teachers and assistants desiring to sit for the examination should apply at once for a copy of the syllabus to the secretary, R.H.S., Vincent Square, Westminster, S.W.

Worthy of Imitation.—Very recently Mr. and Mrs. F. C. Stoop, of West Hall, Byfleet, Surrey, kindly intimated to their garden and estate staff, through Mr. G. Carpenter, the head gardener, their intention to grant to all their employees a Saturday half-holiday. This kind consideration took effect on March 3 at 1 p.m. The employees have since made a presentation to Mr. and Mrs. Stoop as an expression of their thanks.

Flowers in Season.—From Messrs. C. Brooks & Co., The Firs, Worting, Basingstoke, we have received a number of "pips" of "Stellate," or star Primulas. White, pink, blue, crimson, salmon and other colours are included, and, judging by the flowers sent, the strain appears to be a desirable one. Messrs. Ed. Webb & Sons, Stourbridge, Staffs, send us a box containing samples of their strain of Cinerarias. The deep sheen of the "blues," "maroons," "crimsons" and other colours remind one of rich velvet. The size of petals, substance and form are alike good in those sent, but we can have no manner of judging the habit, floriferousness of the plants, &c., from single "pips" only.

Mendelism.—When adverting recently to the literature of this subject we omitted to mention a short treatise by Mr. R. C. Punnett, published by Messrs. Macmillan & Co. We can now commend it to the notice of those of our readers who desire to familiarise themselves with a somewhat intricate subject. "Eating peas" would have been better designated as edible peas, whilst "the albumen of the cotyledons" is a still more unfortunate expression, as it tends to create in the minds of botanists an impression of the value of the book which would be essentially unmerited. It is in reality an excellent introduction to the study of heredity.

Windsor Chrysanthemum Society.—The King has presented the Windsor Chrysanthemum Society, of which His Majesty is patron, with a silver challenge cup of the value of 10 guineas, for competition by growers in the society's district.

Climbing Plants.—Mr. John Murray has published a popular edition of Charles Darwin's work on "The Movements and Habits of Climbing Plants." The book when it first appeared in 1865 was a veritable revelation to all but professed botanists, and even furnished them with many additional illustrations and much valuable suggestion. To students and those desirous of prosecuting still further research into this fascinating subject the present edition will be invaluable.

Forcing Cherries and Strawberries by means of Ether.—According to M. Bultel, in the *Revue Horticole*, the flowering of Cherries may be advanced by a period of three weeks by means of etherisation, whilst the ripening of the fruit is advanced by 15 days. Strawberries properly treated also produce their fruits much earlier, but flower more regularly and abundantly. When is that experiment station at Wisley to be set in action to test such statements as these?

Fig. 61.—Yucca nitida now flowering at Kew.

Scape 7 feet in height; flowers greenish yellow (see text on page 154).

Royal Botanic Society.—We are informed that Her Royal Highness Princess Alexander of Teck has consented to open the Horticultural Exhibition, to take place in the gardens of this Society at Regent's Park on Wednesday, June 13.

The Surveyors' Institution.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, March 12, at 8 p.m., when a paper, entitled "The Means of Locomotion and Transport in London," will be read by Mr. William Woodward (Fellow). The next Junior meeting will be held on Monday, March 19, at 7 p.m., when Mr. R. G. G. Reed will read a Paper, entitled "The Surveyor and Fire Insurance." All inquiries with reference to the Junior meetings should be addressed to Mr. Sydney A. Smith, 22, Chancery Lane, W.C. Percival Currey, Hon. Secretary; Alexander Goddard, Secretary.

Publications Received.—*Annual Report on the Taj and other Government Gardens at Agra*, 1904-5: By A. E. P. Griessen, Esq., Superintendent. The most notable and satisfactory feature of the year's administration has been the large increase in receipts from sales of the produce of the Gardens and Nurseries.—*The Queensland Agricultural Journal*; January. Contains the usual articles on crops and stock. Certain beautiful and useful native weeds are recommended to the notice of Queensland readers.—*Agricultural Bulletin of the Straits and Federated Malay States;* November. Edited by H. N. Ridley. Contents: Bark fungus on Para Rubber, by the Editor; Experimental Tapping, &c.—*Jamaica Bulletin of the Department of Agriculture*; January. Edited by William Fawcett, B.Sc. Contents: Notes on Economic Plants, Yams, Imported and Native Corn, &c.—*Agricultural Journal of the Cape of Good Hope*; February. Leading features: Poisoning of Horses by Ornithogalum thyrsoides, Extra-tropical Forestry (continued), by D. E. Hutchins, &c.—*Thirty-first Annual Report of the Ontario Agricultural College and Experimental Farm*, 1905. The year has been one of steady progress, experiments out of doors and investigations in the laboratories having been largely and

successfully carried on.—*Thirty-sixth Annual Report of the Entomological Society of Ontario*, 1905. (Published by the Ontario Department of Agriculture). Contains many useful, illustrated papers on injurious and other insects, and details many experiments made in various districts.—*Working Plan, 1905-1919, of the Castle Hill Woodlands, North Devon.* By W. R. Fisher, M. A. A report on the Castle Hill Estate, the property of the Right Hon. Earl Fortescue, mentioning its present condition and its proposed future.—"*Haven.*" A horticultural paper published at Aarhuz (Denmark) and including an account and illustration of the Vilmorin Memorial.—*The Kew Bulletin.* Appendix iv., 1905, of the *Kew Bulletin of Miscellaneous Information*, contains a list of the members of the staffs of the several Botanical Departments at home and in India and the Colonies. We need hardly comment upon the value of this pamphlet for purposes of reference.—*Illustrations of Chrysanthemums.* Messrs. W. Wells & Co., Merstham, Surrey, send us a sheet containing illustrations of new Chrysanthemums. The pictures are two-thirds natural size, and represent some good novelties for 1906.

NEW AND NOTEWORTHY PLANTS.

YUCCA NITIDA (Wright, M.S.).

This is a new species of Yucca in the way of Y. Whipplei, from which it differs mainly in having longer, wider, and more rigid leaves, the flower spike and flowers being identical with those of Y. Whipplei as represented in the *Botanical Magazine*, t. 7,662, see also fig. 62. It is possible that the last-named species as known to American botanists includes forms as varied in leaf characters as these two. Dr. Trelease, in his monograph of the Yuccas published in the Thirteenth Annual Report of the Missouri Botanical Garden (1902), says:—"Y. Whipplei is the name proposed by Dr. Torrey, and still commonly employed, for a plant which, when in bloom, forms one of the most striking and beautiful features of the coast-range vegetation of Southern California. From all other Yuccas it differs in the slender style rising abruptly from the top of the ovary and capitately enlarged into a papillate stigma, and in possessing somewhat glutinous pollen, as well as in certain capsular characters which led Dr. Engelmann to give it the sectional name Hesperoyucca, which both Dr. Baker and the writer have proposed to employ as a generic name. Though the mountain and valley forms vary greatly in amplitude of panicle, &c., only one species of Hesperoyucca appears capable of characterisation, and this has long been in cultivation in European gardens, partly under the name of Yucca Whipplei and partly under the name of Y. californica, which has further been applied to very diverse things."

There can be no doubt that the plant at Kew is either one of those diverse forms of Y. Whipplei or a new species allied to it. At the same time it is certainly not the plant known in European gar-

Fig. 62.—inflorescence and floral details of yucca whipplei.

dens as Y. Whipplei, of which there is a figure and description by Mr. Baker in the *Gardeners' Chronicle*, August 1876, p. 196, from a plant flowered in the collection of the late Mr. Peacock, of Hammersmith. (See fig. 62.) This has linear leaves 18 to 20 inches long, the lower ones measuring half an inch wide at the base, glaucous green and triquitrous at the back; whereas the plant at Kew has rigid ensiform leaves 3 feet long, slightly sinuous, flat, save a slight keel below, 2 inches wide at the clasping base, narrowing gradually to an acute horny brown tip, the margin barely rough to the touch. The scape is 7 feet in height, the upper half clothed with flowers and branches forming a compact pyramidal head a foot in diameter at the base. The flowers are fragrant, 3 inches across, pale greenish-yellow, appearing white a short distance off, with a bright purple tip to each of the segments. Stamens and ovary pure white, the latter crowned with a bright crystalline green stigma. This is one of the most beautiful Yuccas, and from its behaviour under cultivation at Kew it is much more easy to manage than Y. Whipplei, of which I have never seen a healthy example at Kew, although I have seen fine plants of it in gardens on the Riviera. Y. nitida was purchased from Messrs. F. Sander & Sons two years ago. *W. W.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Salad Potatos.—Perhaps in the future our countrymen will take more kindly to the humble Potato as an ingredient in mixed salads, or alone as do the French and Germans. The Potato as a salad goes well with boiled Beetroot, Celeriac, and raw Onions, if oil, vinegar, coarse pepper, and salt be added according to taste. The varieties white and purple Fir Cone were at one time occasionally grown in this country, but more as curiosities than for consumption, and now are but rarely found in gardens, and for any other use than in salads they can scarcely be recommended. The tubers will attain to a length of 6 inches with a lateral diameter of 1½ inches; and the texture of the flesh being waxy, they may be sliced like a Cucumber, the shape of the slices being retained, even when vigorously stirred about with the other ingredients in the salad bowl. *F. M.*

Rhododendrons.—Rhododendron barbatum is one of the most beautiful subjects now in flower in the open in these gardens. Blood-red in colour, the inflorescences are of striking and handsome appearance, especially when the sun shines on the flowers. During severe frost, a little tiffany is arranged over the top of the plant and supported by poles. This method of erection answers well. They are planted in a mixture of peat, leaf soil, and the natural loam, which is clayey, and this mixture suits them. A mulching of manure is placed over the roots in summer. R. caucasicum Nobleanum has been in flower for the past two months, the fine red colour of the flowers and the general features of the plants making the American Garden a source of pleasure. It is planted in the same compost as R. barbatum. R. præcox, a hybrid between R. ciliatum and R. dauricum, is quite hardy, and has been flowering for some weeks past in sheltered spots in these gardens. It makes a charming bush about 3 to 4 feet in height and flowers with great freedom. The two parents were recently in flower here. R. ciliatum does well when gently forced in heat, and the flowers are white. It is a suitable plant for both the conservatory and the drawing-room. R. argenteum grande is finely in flower in the Rhododendron house at South Lodge, the residence of F. D. Godman, Esq. The plant measures 14 feet by 14 feet. The trusses of bloom are magnificent in appearance (see double-page supplementary illustration in our issue for June 10, 1882). This variety is not hardy, excepting, I believe, in a few very sheltered spots in Cornwall. At night time by artificial light the spots on the petals shine like small nuggets of gold. The foliage is particularly handsome, more especially the under side of the leaves, which is covered with a silvery down. R. Fosterianum is now a grand feature in the conservatory. It should be grown outside all through the summer months and housed during the winter months until slightly forced in heat. The beautiful white flowers are deliciously fragrant, and each possesses a pretty fimbriated edging. In point of beauty it is far superior to Lady Alice Fitzwilliam, which, with its variety fragrantissimum, is now opening its flower buds. The flowers are white, and are sweet scented. By slight forcing a succession of trusses can be obtained for a long period. *W. A. Cook, Leonardslee Gardens, Horsham.* [An excellent truss of R. argenteum grande and another of R. barbatum accompanied these notes. —Ed.]

Montbretias.—Referring to the remarks by Mr. G. Buckley on p. 124, I think the better plan is that generally adopted, namely, that of lifting and dividing them as soon after the flowering season in the autumn as possible. There is then less fear of damaging the young growths which spring from the base of the old bulbs than if left till spring. The young growths are extremely brittle. *G. F. Hallett, Easton Neston Gardens, Towcester.*

Potatos at Inveresk.—Inveresk is six or seven miles east of Edinburgh, and within a few hundred yards of the railway station are the stores of Messrs. Scarlett. Visiting them the other day I saw 14,000 boxes of seed Potatos. There were 50 tons of Southern Queen in boxes, also 10 tons of Dalmeny Radium, 10 tons of Diamond, and 15 tons of Midlothian Early, the new first early. In the centre of the building a squad of men and women were dressing a 100 ton lot of Warrior. Many early sorts were cleared out entirely. Three hundred tons of Epicure or British Premier had been sold, and 200 tons of Sir John Llewelyn. I saw 10 tons of the latter, which were kept for planting. They were all large tubers, and Mr. Scarlett said they would be planted whole. The more valuable varieties are boxed in the field at raising time and taken direct to the store. Planting will begin as soon as the land is in good condition. Asked what was going to be the greatest main crop variety of the future, Mr. Scarlett said he did not yet know. The Factor certainly stood at the top at present, but it was impossible to obtain sufficient tubers of proper seed size. Table Talk would eclipse The Factor. The huge building is well built of brick and the roof is supported by brick pillars. No artificial heat is used. No damage has ever been done by frost. This is partly accounted for by everything being dry. In the event of severe frost sacks, mats, and sheets are in readiness to cover up the stacks of boxes. *Traveller.*

Horticultural Examinations. — The remarks by W. Watson, in a recent issue, concerning the R.H.S. examinations will, I feel sure, be endorsed by many who read them. I for one maintain that the examinations are not so satisfactory as they might be. In nine cases out of ten the practical man is beaten by the theoretical student in paper work. I am confident a man's abilities cannot be justly gauged from what he may put on paper. The student at college is trained mainly so that he or she may succeed in examinations, and so reflect credit on their teachers and themselves. Such credit is certainly not misplaced; but what a sorry figure such a person would look if placed in a position where he was made responsible for the maintenance of a constant supply of fruit, flowers, and vegetables for a large private establishment or for market purposes. The class of gardener I admire is one with an aptitude for his work and intelligence to make the best use of his knowledge. The holding of certificates does not show that the holder has these very necessary qualifications. The man who is interested in his profession will naturally be observant and study what applies to his work. What man can expect to get on without? I sat at the last examination held by the R.H.S. for gardening dealing with work in public parks, etc. I considered the questions were excellent. The practice of verbally questioning the candidates will, I hope, in the future be the principal form of examination. An examiner can form a much better idea of the amount of the intelligence and the knowledge a candidate has of his work by that means than by the inspection of any answers on paper. The time allowed is not sufficient, and I believe this was the general opinion. *B. Attersea.*

London County Council Gardeners.—An examination held by the Royal Horticultural Society can be of little use in ascertaining the qualifications of gardeners employed by the London County Council. Evidence of previous horticultural training has to be forthcoming before a gardener is employed in the parks in a temporary capacity, then he has to work for three months as a probationer, and obtain the approval of the park superintendent by the satisfactory performance of his duties. It is utterly unreasonable that more than this should be expected, but, in addition, a medical examination has to be passed before a gardener is placed on the permanent staff. Now a further examination is proposed. According to the requirements of the London County Council the social status of the gardener has fallen to a level with the resources of his pocket. No other conclusion is admissible when practical gardeners, and scientific botanists withal, are expected to pick up dirty paper and orange-peel, and generally act as scavengers in the parks, for 27s. or even 30s. per week. It would, however, be interesting to see how the men employed by the Board of Works as labourers, and now classed as gardeners, would figure in such an examination. And yet in many instances a park superintendent will say these are just the men he wants. *Straight Tip.*

Proposed Federation of Gardeners' Societies.—With the exception of one dissentient review of my proposals, the replies have been very gratifying. The following suggestions will perhaps lead us nearer to our goal:—(1) Will all Secretaries of Gardeners' Mutual Improvement Societies kindly post me the name of the Society they represent, with their own address, and add a few supplementary remarks as to their members and their ideas of the proposed federation outlined in my letter in the *Gardeners' Chronicle* for February 17. (2) The fixing of a suitable date and place when representatives can attend and discuss the matter, and appoint a provisional committee to draw up a scheme, which could afterwards be submitted to another meeting at a later date for confirmation. *Harry Boshier, 62, High Street, Croydon.*

The Weather in Co. Kildare.—It may interest some readers to hear of the very severe February that we have experienced in this cold, ungenial locality. There was frost on twenty-five nights, and as a rule from 9° to 13° of frost, with a total for the month of 225°. This is by far the most severe February experienced here since 1895, when the total for the month was 333°, and on the coldest night, February 7th, there was 30° of frost. *F.B.S., Straffan Station, Co. Kildare.*

The United Horticultural Benefit and Provident Society. — The special general meeting which will precede the ordinary general meeting on Monday next, the 12th inst., will be of more than usual interest, and it is hoped that country members will attend if possible The object of the special meeting being to confirm the amended rules as compiled by the committee, it would be a considerable gain to them to feel that members generally took sufficient interest in the society to come forward and support a work which has given them a considerable amount of trouble, and though the alterations are not likely to in any way affect the general working of the society, there are a few important points which all members should consider. The special general meeting is called for 5 p.m. The ordinary annual general meeting takes place at 8 p.m. *A. H.*

The Late George Norman.—I have no intimate knowledge of his early career further than he was for some time at Linton Park, Maidstone, with, I believe, "Mr. Ballantyne" as his foreman, and I think I shall be right in saying that "Mr. Groom" was head at that time there. His next move was to Bedford, as gardener to — Maguire, Esq., M.P., whence he went to Hatfield in May, 1876, where he succeeded Mr. Ed. Bennett, who eventually established a name as a grower of Grapes for market at Potter's Bar and elsewhere. At the time of Mr. Norman's appointment much had been done, and much more remained to be done, in the thorough competition of the then comparatively new garden. On my last visit to Hatfield he called my attention to the fact that on his taking charge the fruit trees, both Apples and Pears, were so severely trained (goblet fashion) that little, as well as inferior, fruit was the result. He saw this was a wrong practice, and allowed the trees greater freedom, with the result that finer or more prolific trees than those now to be seen there

could not be imagined. The wall trees, too, were grandly trained, and in first-class fruiting condition. Mr. Norman had few equals in the culture of indoor fruit, Grapes, Peaches, Figs, Strawberries. The writer was once told that Mr. Norman had never been without Grapes "old or new," for 20 years. He was a great believer in copious supplies of water, both for Vines and Peaches. In the culture of Strawberries he was unexcelled, and annually grew between 7,000 and 8,000 plants in pots, and in the early eighties he used annually to take the 1st prize at Kensington with the then standard varieties, President, Sir J. Paxton, and Sir C. Napier. For picking at this period Black Prince was grown largely. The call upon the resources of Hatfield for decorative plants and flowers in the great receptions held by the late Marquis of Salisbury during his career as Prime Minister was very great. When one considers the work and anxiety attendant upon the carrying out of these and many other duties it is not to be wondered at that the strain proved too much for even such a fine physique as Mr. Norman possessed, and after a severe illness he had to recruit his health in the south of France. Turning again to plants, all classes, stove and greenhouse, were well represented. At one time he had at least 200 plants of Adiantum Farleyense in robust growth, the finest I ever saw. Orchids too were well grown, and of later years Carnations claimed his attention. He confined the varieties to two or three, but grew them by the thousand. All round the master-hand was apparent. The flower gardens were kept up well, the east with Roses, the south with Fuchsias, Cannas, Heliotrope, Ricinus, &c., and the west garden with ordinary bedding plants, the whole numbering 30,000 plants. Mr. Norman was a man of untiring energy, full of tact and resource, a strict disciplinarian, yet tender-hearted and sympathetic in time of need. As a member of the Fruit Committee he was respected and beloved by all his colleagues, and it was owing to his ability that the V.M.H. was conferred upon him. *Geo. Dyke, The Gardens, Garston Manor, Watford.*

——The deeply lamented death of this eminent and truly genial gardener creates a great void in the fruit committee of the Royal Horticultural Society. He was one of the oldest members, one of the most esteemed, and a very regular attendant. Few, if any, of his colleagues, although most of them had observed in him some evidence of occasionally highly strung nervousness, realised that his end was so near. Of his merits as a servant it is for others to speak, but many of his fellows can testify to his great ability as a gardener, and of his devotion to and love for his profession. Those of us who were his colleagues on the Gardeners' Dinner Committee of 1903 had opportunities to know and appreciate him beyond those possessed by others. How thoroughly he enjoyed the work the arrangements for that dinner imposed upon him! He entered into it all with almost boyish interest. It is a strange coincidence that the first one taken from our number, and also an old and esteemed member of the Fruit Committee, James Smith, should, like George Norman, have been a faithful servant and head gardener to an ex-Prime Minister. May many years elapse 'ere we shall have to mourn a farther break. That dinner committee became more than a mere combination of British gardeners. It was literally a brotherhood, knit together by the warmest ties of friendship and fellow-feeling. Whether at Hatfield, or on the fruit committee, or as a V.M.H., may any successor be as worthy our esteem as was our old friend George Norman. *A. D.*

FUMIGATION WITH HYDROCYANIC ACID GAS.—Notwithstanding *A. D.'s* criticism of Mr. Dobson's article on the above subject, it is a well-known fact amongst scientists and horticulturists that hydrocyanic gas is both cheaper and more effectual for the destruction of insect life than any known insecticide, and if it is used in the proper quantities with the temperature of the house low and the foliage of the plants dry it is perfectly harmless to the plants. I have had some experience in the use of this gas, and consider there is as much difference between it and ordinary insecticides for the extermination of mealy bug, ants, scale, &c., as there is between the old-fashioned aphis brush and nicotine vaporisers; but, unfortunately, the gas is so deadly to human beings that it has not been generally used. To overcome this difficulty I have invented a machine which enables the operator to drop the cyanide into the acid whilst he is outside the house and after the door is locked, thus preventing any risk to those using it. I shall feel pleasure in forwarding the Editor diagrams of the same after a week or two if he will insert them in the *Gardeners' Chronicle*. The machine may be had for a few shillings. *F. C. Edwards, Nurseryman, Leeds.* [We shall be pleased to see the drawings. ED.]

——"If insect life in a plant house be destroyed, what matter even if a few human lives be taken also" (see *A. D.* on p. 140). At last the great problem of solving the unemployed question seems likely to be solved—the great philanthropist who advises cyaniding the surplus gardeners must receive some public recognition. *A. D.* is not to be commended, however, in the use of such sarcasm. I should be sorry to lose any of my brother gardeners by fumigation, but I wish this philanthropic gentleman *A. D.* would give cyaniding a trial. His idea of the present day gardener is a poor one; possibly cyaniding may interfere with or supersede some existing interest, but the day for the rag and paper is gone. *W. H. Clarke, Aston Rowant, Oxon.*

——*A. D.* says on p. 107:—"One is tempted to ask the question whether the game is worth the candle on account of its grave dangers to both human and plant life." Is this the only poisonous insecticide in use amongst gardeners to-day? What about the arsenical and nicotine compounds—are they not dangerous to human life, though to a less degree? I fully agree with *A. D.* in respect to the danger by cyaniding to human life, and I fully warned others of the danger and the necessity for taking proper precautions, and if this is done—which I think it will be by most gardeners, whom I credit with being a broad-minded and level-headed class of men—there need be very little fear of fatal results. *A. D.* infers that no one of good sense would be disposed to dabble with such a dangerous article. It is very comforting to me to learn from letters received and articles which have appeared in the *Gardeners' Chronicle*, that there are others who share this compliment with us, but may I claim the credit of having "sufficient good sense" to get rid of the bug and scale, and turn the labour to better account? *A. D.* says it was my misfortune having the bug, I knew it to my sorrow; it was here before I came, but in won't be here when I go away. In conjunction with two first-class foremen, I had striven vigorously from the first to free ourselves of the pests, but all to no purpose. We could check it, but nothing more, and where bug is plentiful and labour scarce one is tempted to resort to drastic measures. As regards the danger to plants, I fail to see that there is more danger in this insecticide than in other "patent insecticides," for all are more or less dangerous to plant life if they are not used with the necessary precautions, and I am convinced (with all due appreciation of other fumigants for general work) none of them is so effectual in ridding plants of bug and scale. The harm done to the plants here by cyaniding from first to last is practically nothing, the most is a very few leaves touched, and I gave my experience in full in order that others might avoid even this small amount of harm. I lost a number of plants by the constant syringing, sponging, with other insecticides. On looking up my notes taken in past years, I note the entry, "men sponging, &c." Alas, too often this was to all intents and purposes waste labour, and very discouraging to all concerned, because no headway was being made with other work, and one must make some attempt to cope with the ever increasing amount of work at this time of the year. I am thankful to say, so far this year no time has been wasted on sponging. I am hoping henceforward to be included amongst those gardeners who are enabled to keep their house clean with patent insecticides; further that these gardens may be included amongst those where gardening is well done. I am afraid that a great many gardens could not be so described if the line of demarcation between good and bad gardening is the presence or absence of bug and scale. *W. H. Dobson, Stapleton Gardens, Pontefract.*

GRAPE DIAMANT TRAUBE (see p. 138).—If reference be made to the issue of *Gardeners' Chronicle* for August 26, 1905, p. 175, the officers of the Royal Horticultural Society may find full particulars of this Grape. I am glad that the reputation of the R. H. S. for the cultivation of choice varieties of Grapes will be maintained at Wisley. If I can help I shall be glad to do so. *W. Roupell, Harvey Lodge, Roupell Park, S.W.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 6.—After an interval of three weeks the Royal Horticultural Society's Committees met on Tuesday last in the Hall, at Vincent Square, Westminster. The display was more extensive even than usual, and all the available space for exhibits appeared to be pressed into service.

The most imposing group of Orchids was contributed by W. A. BILNEY, Esq., who was awarded a Gold Medal. The Orchid Committee inspected many novelties and awarded three First Class Certificates, seven Awards of Merit, and one Botanical Certificate, exclusive of the Diplomas given for Dendrobiums.

The Floral Committee recommended five Awards of Merit to novelties which are mentioned below, and in respect to the very large number of groups exhibited were seventeen medals awarded, including one of gold to Messrs. CUTBUSH & SON.

The Fruit and Vegetable Committee had little to inspect, and their only award was that of a Silver Banksian Medal.

At the general meeting of Fellows in the afternoon 114 candidates were elected to the Society, and a paper on the "Nomenclature of Plants" was read by Mr. G. W. Bulman.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. H. B. May, Geo. Nicholson, R. Wilson Ker, Jno. Green, C. J. Salter, J. H. Barr, T. W. Turner, Jno. Jennings, W. Howe, H. J. Cutbush, W. Bain, Chas. Jeffries, Chas. Dixon, R. C. R. Nevill, W. Cuthbertson, H. J. Jones, Chas. E. Pearson, Chas. E. Shea, E. H. Jenkins, W. J. James, Jas. Walker, Jas. Douglas, C. T. Druery, W. G. Baker, C. R. Fielder, R. Hooper Pearson, G. Reuthe, R. W. Wallace, and Jas. Hudson.

Some very good varieties of Hippeastrum were shown by Lord ROTHSCHILD, and one, named Pomona, a white flower, with bright red-coloured stripes, and a flower in which the natural green colour had been quite eliminated, was perfectly distinct and attractive. All the plants were very strongly-grown specimens, and the variety Pomona had five flowers on the spike. Lachenalia glaucina, from the same garden, is a very old but little-known species, having very pale blue, erect flowers produced on spikes which grow 14 or 15 inches in height.

Messrs. W. CUTBUSH & SON, Highgate, London, N., set up a collection of forced flowering plants that formed an outstanding feature of the exhibition; indeed, it was quite the largest group that the Hall has so far accommodated, and occupied the major portion of the side of the building opposite the entrance. Not alone by reason of its size was the display noteworthy, but boldness of grouping, excellence of material, and taste in arrangement all contributed to a magnificent effect. The design was that of an undulating bank, in which a central bay was prominent, with other smaller bays at either end. The usual subjects were included—Azaleas, Ribes, Wistarias, Spiræas, Viburnums, Magnolias, showy species of Cerasus, Pyrus and Prunus, Deutzia, and a host of other beautiful flowering trees and shrubs. Especial reference must be made to the Magnolias, which were shown in splendid form, and the examples of such beautiful species as M. Soulangeana, M. Lenné, and M. Alexandrina would be difficult to surpass. In another part of the Hall Messrs CUTBUSH arranged a temporised rockery, and here again was seen an example of good skill and effective planting, many beautiful spring flowers being thus presented in a natural manner. (Gold Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, filled the Concert platform with forced flowering shrubs. A batch of white Lilac—Mad. Lemoine—looked well in the centre, while other showy plants, such as Azaleas, Laburnum, Deutzia, Almonds, Cherries, Forsythia suspensa, etc., were arranged on either side. Some small plants of Clematis formed a pleasing edging. (Silver Gilt Banksian Medal.)

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, staged a mixed group of plants and flowers. At the back were a number of large plants of Rhododendrons—R. Cunningham's White being very fine—Bamboos, Lilacs, etc., and in the foreground a rock-garden with

suitable Alpine plants. Hippeastrums were also included in the display.

Messrs. Thos Cripps & Son, Tunbridge Wells, Kent, displayed a group of ornamental Maples, having many handsome forms of the palmatum and japonicum types. (Silver Gilt Banksian Medal.)

Messrs. W. Paul & Son, Waltham Cross, Herts., staged a very pretty group of flowering Almonds and Peaches, the small trees being literally covered with their showy flowers. (Silver Banksian Medal.)

Messrs. R. Veitch & Son, Exeter, showed an example of Prunus Mume flore plena. The flowers are pale in colour and have but little doubling. Erica carnea was also shown by Messrs. Veitch.

Messrs. Sutton & Sons, Reading, entirely filled one of the extensive side tables with Cinerarias of the ordinary florists' type. The plants were dwarf, but sturdy in habit, and they carried neat, compact trusses of flowers of many beautiful shades of colour, especially handsome being some of the "blues" and "reds." (Silver Flora Medal.)

Messrs. Cannell & Sons, Swanley, Kent, also exhibited Cinerarias, but of the taller growing "stellata" type. The dense cymes of small, bright flowers possessed a wide range of colouring, and gave evidence of careful selection. The same firm also displayed trusses of Zonal Pelargoniums, Coleus Shirensis, and a new flaked Carnation named Duchess of Marlborough, the ground work being buff, pervaded and striped with rosy red. (Silver Banksian Medal.)

Mr. H. B. May, Dyson's Road Nursery, Upper Edmonton, had a group of decorative plants, in which we noticed the sweet-scented Pelargonium Clorinda, Boronia megastigma, Clematises, and a nice batch of Cinerarias in flower. (Silver Flora Medal.)

From the gardens of A. de Rothschild, Esq., Halton, near Tring (gr. Mr. Sanders), was exhibited a group of plants of Hippeastrums, the variety being Crimson Prince, with self-coloured flowers from which the natural green colour is entirely eliminated. (Silver Gilt Flora Medal.)

Messrs. James Veitch & Sons, Ltd., King's Road, Chelsea, staged miscellaneous greenhouse flowering plants—Streptosolen Jamesoni, Coleus Shirensis, Eupatorium petiolare, Camellia reticulata, Rhodondron Veitchianum, etc. (Silver Banksian Medal.)

Messrs. William Bull & Sons, King's Road, Chelsea, showed a collection of small Palms, all, or almost all, of which were of different species.

The exhibit of Messrs. R. & G. Cuthbert, Southgate, Middlesex, formed an innovation in the matter of arrangement. The group consisted of beds of Hyacinths, and was arranged on the floor of the Hall. The beds were diamond shaped, the intervening spaces being worked out in Moss, while cocoa-nut fibre did duty for soil in the beds. The trusses of flowers were well developed, and the blending of the colours was in good taste, one of the best combinations being seen in a bed with a pink centre and an edging of white. (Silver Gilt Flora Medal.)

Mr. John May, St. Margaret's, Twickenham, had a large batch of Cyclamen in the East Annexe. Mr. May is a most successful cultivator of these plants, judged by the examples exhibited, many of the specimens having their foliage entirely hidden by the masses of flowers, which were of large size and very pure in colour. (Silver Gilt Flora Medal.)

Roses, the first of the season, were shown by Mr. George Mount, Canterbury, Kent, in the usual style for which this grower is famed. The varieties were Mrs. R. G. Sharman Crawford, Capt. Hayward, and Mrs. John Laing.

Messrs. Hugh Low & Co., Low's Nursery, Enfield, had a very pretty display of Carnations, principally of the American type, and some plants of "Low's Salmon" Cyclamen.

Mr. A. F. Dutton, Iver, Bucks, displayed a group of Carnations similar to those he exhibited at the last meeting. A fancy basket, decorated with coloured ribbon, and filled with blooms of the variety Mrs. T. W. Lawson, was much admired. (Silver Gilt Banksian Medal.)

Messrs. J. Hill & Son, Barrowfield Nurseries, Lower Edmonton, Middlesex, staged many rare and choice Ferns, the whole forming an excellent exhibit of these plants. Several large plants of such species as Osmunda gracilis, Platycerium grande, P. Veitchii, etc., were elevated above the general collection, which included such choice things as Polystichum triangulare laxum, Adiantum reniforme asarifolium, Todea pellucida, Lomaria attenuata, Davallia canariensis elegans, etc. (Silver Gilt Banksian Medal.)

The Guildford Hardy Plant Nursery Co., Millmead, Guildford, staged a neat collection of hardy plants in flower. We noticed a nice clump of Erica carnea, the colour of the flowers being well developed. Iris reticulata was also shown well; Doronicum Columnæ was nicely flowering, the inflorescences being scarcely more than an inch above the ground level.

Messrs. Barr & Sons, 11, 12 and 13, King Street, Covent Garden, displayed hardy and other flowers. A batch of Lachenalias contained many improved forms, one of the best being the variety Ruth Lane, which has large pendulous flowers tipped with purple. Daffodils, including N. minimus, Irises, Saxifrages, and Hellebores, and numerous other early-flowering subjects found a place in the collection. Among the many species of Helleborus was the curious H. argutifolius, not the least beautiful feature of which is its deeply-serrated, trifid leaves. (Silver Banksian Medal.)

The Misses Hopkins, Mere, Knutsford, displayed a small group of Alpine flowers.

Messrs. John Peed & Son, West Norwood, London, S.E., staged a collection of rock-garden plants, also Lachenalias.

Messrs. Geo. Jackman & Son, Woking, Surrey, also contributed to the displays of Alpine plants, having many interesting plants in flower, including a fine batch of Shortia galacifolia. A double-flowered form of Adonis amurensis was pleasing. (Silver Banksian Medal.)

Messrs. J. Cheal & Sons, Crawley, staged three boxes containing Alpine plants, among which were some well-coloured Primroses, especially one named P. rosea. Dwarf Conifers and small-growing shrubs were staged as a background to the exhibit.

Messrs. G. & A. Clark, Ltd., The Nurseries, Dover, Kent, set up a temporary rockery, on which were arranged suitable subjects for a rock-garden. A nice batch of Iris reticulata was noticed; coloured Primroses were also shown well in this group.

Mr. G. Reuthe, Fox Hill Hardy Plant Nursery, Keston, Kent, made a bright display with Irises, Hepaticas, Scillas, Crocuses, and other spring flowers. Rhododendron ciliatum was shown in good form by this exhibitor. (Silver Flora Medal.)

Mr. M. Pritchard, Christchurch, Hants, exhibited a small collection of hardy flowers. We noticed Tulipa Kaufmani nicely in flower, and sprays of Hamamelis Zuccariniana.

A pan of Pinguicula caudata, with very deeply-coloured flowers, was shown by J. T. Bennett-Poe, Esq., Holmwood, Cheshunt (gr. Mr. Downes). The form was shown under the name of P. c. superba.

Messrs. T. S. Ware, Feltham, Middlesex, contributed an exhibit of hardy plants and flowers that bloom earliest, and several representatives of Primula species, Narcissus, etc. (Bronze Flora Medal.)

AWARDS OF MERIT.

Carnation Elliott's Queen.—This is a moderately fragrant flower, of large size, commendable form, and has non-splitting calyces. The colour is of a shade of rose, and the petals are only very slightly fringed. Shown by Mr. H. Elliott, Hassocks, Sussex.

Carnation Nelson Fisher.—This variety, like that already mentioned, belongs to the tree or winter-flowering section, and was shown on this occasion by Mr. A. F. Dutton, but was raised in America. The flowers are of large size and of violet-rose colour or a deep shade of cerise.

Davallia canariensis elegans.—A very elegant variety of this well-known species, having very finely-divided fronds and pinnæ. Shown by Messrs. J. Hill & Sons.

Freesia Tubergeni.—Some Freesias exhibited under this name by Mr. C. G. van Tubergen, Haarlem, Holland, were of violet colour, with whitish throat, and had a spot of bright yellow at the extreme end of throat. Some of the inflorescences bore as many as ten flowers each, showing that the variety is a good grower. The flowers are very pretty, and will be sure to meet with appreciation.

Polypodium phymatodes corymbosum.—A corymbose variety of this most distinct species, which, in the habit of growth, reminds one of a slender-growing Platycerium, or a crested Pteris. The plant shown was growing over an old stem of tree Fern. From Mr. H. B. May.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, the Right Hon. the Earl of Tankerville, Jas. O'Brien (hon. sec.), Harry J. Veitch, H. Little, W. Boxall, W. H. Young, H. G. Alexander, H. A. Tracy, H. G. Morris, T. W. Bond, W. H. White, A. A. McBean, Arthur Dye, W. A. Bilney, J. W. Potter, H. T. Pitt, W. Cobb, R. G. Thwaites, F. M. Ogilvie, S. Briggs-Bury, G. F. Moore, N. C. Cookson, H. Ballantine, E. Ashworth, J. Colman, De B. Crawshay, and Francis Wellesley.

The Society's Gold Medal was awarded to W. A. Bilney, Esq., Fir Grange, Weybridge (gr. Mr. Whitlock), for a splendid group occupying one side of the central staging in the Hall, and composed principally of Dendrobiums, among which a very great variety of the best forms of D. nobile and D. Ainsworthii were represented. The centre was of the pure white form of D. nobile album, behind which were large masses of the finely coloured D. nobile nobilius, specimens of which were also displayed at intervals along the group. Forms of D. Cybele were varied and good, the best being D. Cybele nobilius. The D. Ainsworthii class included the fine D. A. Hazlebourne variety, and some excellent D. splendidissimum. Other good displays were of D. Wardianum with some hybrids of it; D. pallens, D. xanthocentrum, D. Wiganiæ, and Wiganianum varieties; D. thyrsiflorum, D. albo-sanguineum, D. Melpomene, D. Brymerianum, &c.; Cymbidium eburneum, various Odontoglossums, Oncidiums, &c.

From the Right Hon. Lord Rothschild's gardens, Tring Park (gr. Mr. Arthur Dye), came a group of the stately Lissochilus Horsfallii, imported from West Africa, and in the culture of which the Hon. Walter Rothschild instituted a special method, which has been successful in the highest degree. This fine plant seems only to be known from the original specimen which flowered in 1864 with Mr. Horsfall, of Bellamour Hall, Staffordshire, and which was figured in the *Botanical Magazine*, t. 5486, and was soon lost. It has probably been imported in a few examples since, but never was grown and flowered again until now at Tring Park. Mr. Walter Rothschild's plan was to grow it as a river-bank plant, with the Nymphæas, or in tubs of water, and when strongly growing frequent waterings of liquid manure were given. The result has been that the specimens formed broad, bright green plicate leaves and stout spikes some 5 feet in height (branched in some instances), and bearing from 70 to 100 large flowers and buds on each spike. The four fine specimens shown were arranged with the pretty Zululand Asparagus myriocladus, and with tall Palms at the back; the group was voted a Silver Gilt Flora Medal and the species given a First Class Certificate. (See Awards.)

Messrs. Charlesworth & Co., Heaton, Bradford, secured a Silver Gilt Flora Medal for a very fine group rich in hybrid Odontoglossums, among which were the new O. Gladys (cirrosum × Harryano-crispum), a prettily spotted flower; O. amabile Charlesworthii, tinged with rose and spotted with red-brown; fine O. Harryano-triumphans, O. Rolfeæ, O. Loochristyense, and many others. The Cattleyas included a good selection of C. Trianæ, two pretty C. Enid; and other good things were Zygopetalum crinitum cœruleum, the fine white Brasso-Cattleya Queen Alexandra, several fine yellow and crimson Lælio-Cattleya Myra, the rich reddish L.-C. Lucasiana Jeanette, &c.

Baron Sir H. Schroder, The Dell, Egham (gr. Mr. Ballantine), was awarded a Silver Flora Medal for a splendid group of magnificently-grown Calanthes, the bulbs being of enormous size and in perfect condition. The centre was of Calanthe Baron Schroder, the best of its class, raised at the Dell. The tall spikes bore numerous large flowers, with white sepals and petals tinged with rose at the base, and rose-purple lip with dark maroon eye. The outer five or six rows were of Calanthe Regnieri, which has never, perhaps, been seen so well grown.

Messrs. Jas. Cypher & Sons, Cheltenham, obtained a Silver Flora Medal for an excellent group displaying great variety. The Dendrobiums were very fine, especially D. Wardianum hololeucum and other albinos, and with them were scarlet Epiphronitis Veitchii, and Sophronitis; Phalænopsis Rimestadtiana, some good forms of Cattleya Trianæ, Lælia anceps Schroderiana, Lælio-Cattleya Dominiana of fine dark colour, Odontoglossums, hybrid Cypripediums, &c.

Messrs. Sander & Sons, St. Albans, secured a Silver Banksian Medal for an interesting group of good things, in the centre of which was a fine specimen of Ansellia africana with three large, branched spikes. Dendrobium nobile nobilius and other Dendrobes were good; varieties of Cattleya Trianæ well represented; Brasso-Cattleya Empress of Russia, Lælio-Cattleya × Berthe Fournier, Cymbidium eburneo-Lowianum, Phaius Marthæ, forms of Cœlogyne cristata, and good varieties of Cypripedium insigne were also noted

R. Briggs-Bury, Esq., Bank House, Accrington (gr. Mr. Wilkinson), was awarded a Silver Banksian Medal for a small group, including three of the fine Cypripedium Beekmanni, C. Maudiæ, one of the varieties having a peculiar yellow tinge; C. villosum magnificum and others. Of Odontoglossums noted were O. crispum Empress of India, a finely-blotched flower; two O. Loochristyense, &c.

Messrs. Stanley & Co., Southgate, were voted a Silver Banksian Medal for a group of very fine specimens of the beautiful cool-house Oncidium concolor, each with three or four stout sprays of large clear yellow flowers.

M. Chas. Vuylsteke, Loochristi, Ghent, was given a Silver Banksian Medal for a small group of rare hybrid Odontoglossums, including O. bellatulum, O. Wiganianum, O. Wilckeanum, O. Rolfeæ O. Vuylstekei, and others all of fine quality.

Francis Wellesley, Esq., Westfield (gr. Mr. Hopkins), showed Lælio-Cattleya Mrs. R. A. H. Mitchell (callistoglossa × Martinetti), a large flower of a bright rose tint with purplish crimson lip, L.-C. Marnhami (callistoglossa × Aphrodite), a pretty hybrid with broad petals. Sepals and petals pale rosy lilac, lip broad and marked with purplish crimson. Cypripedium Miss Marian Sillem, pure white densely spotted with purple, and C. Mrs. W. E. Dickson, a fine C. Rothschildianum cross.

C. J. Lucas, Esq., Warnham Court (gr. Mr. Duncan), showed a group in which the showy Lælio-Cattleya Warnhamensis was specially fine; with them were Phaius maculatus, Angræcum sesquipedale, Cymbidium Lowio-eburneum, Cypripedium Warnhamense, C. calypso, with six flowers, &c. (Bronze Banksian Medal.)

Messrs. Hugh Low & Co., Enfield, staged a group in which were good Dendrobium Boxalli and D. crassinode, Pleurothallis Roezlii, Saccolabium Harrisonianum, Oncidium sarcodes, Epidendrum Endresio-Wallisii, Cypripedium Helen II. with four flowers, the fine white Lycaste Skinneri alba magnifica, Phalænopsis Schilleriana, &c. (Bronze Banksian Medal.)

Messrs. Heath & Sons, Cheltenham, showed a small group, including two nice specimens of D. Cassiope × Dominianum, the fine D. nobile Heathii, several D. barbatulum, Cœlogyne cristata, Odontoglossums, &c.

Sir Trevor Lawrence, Bart., Burford (gr. Mr. W. H. White), showed very fine specimens of Dendrobium Sybil, D. Wiganiæ album, D. W. illustre (see Awards), and D. Euryalus Apollo album.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed Dendrobium Ainsworthii Thompsoni, and a good Schneiderianum.

Jeremiah Colman, Esq., Gatton Park, showed finely-flowered specimens of Dendrobium Wiganiæ, D. Wiganianum, D. Ainsworthii, D. Venus, D. Othello, D. nobile nobilius, D. n. alba, and other Dendrobes, including the fine white D. × Colmanæ.

M. G. Vincke-Dujardin, Bruges, sent Cattleya Trianæ cœrulea, with a slaty-blue front to the lip, &c.

Norman C. Cookson, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), showed the fine Phaius Clive which had previously obtained an Award of Merit.

Elijah Ashworth, Esq., Harefield Hall (gr. Mr. Holbrook), showed Dendrobium Haywoodæ Harefield Hall variety, and Cypripedium George Hackenschmidt (tenebrosum × insigne, Harefield Hall).

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), showed Chysis lævis superba, a fine form with orange-red outer halves to the segments.

H. S. Goodson, Esq., Putney (gr. Mr. G. Day), sent Cypripedium H. S. Goodson (Spicerianum magnificum × Lathamianum).

R. G. Thwaites, Esq., Streatham (gr. Mr. Black), showed the handsome Dendrobium Thwaitesiæ.

H. T. Pitt, Esq. (gr. Mr. Thurgood), showed Odontoglossum Wilckeanum, Pitt's variety, one of the very best Wilckeanum varieties, with very large, pale yellow, heavily blotched flowers of fine substance, the colours being enhanced by the polished surface.

De B. Crawshay, Esq., showed the unsurpassed Odontoglossum triumphans Lionel Crawshay, O. t. Crawshayanum, and O. Andersonianum Youngi.

AWARDS.

First Class Certificate.

Lissochilus Horsfallii, from The Hon. Walter Rothschild, M.P. A noble species with lanceolate, bright green leaves and tall stout spikes of 70 or more flowers of good size. Sepals upturned and recurved at the tops, tinged and lined dark purple. Petals orbicular and extended forward, white suffused with rose. Side lobes of the lip erect, greenish with purple markings; front lobe deep rose purple; base of the lip white streaked with purple; callus ivory white. A most remarkable and handsome species. Four plants were shown, one bearing three spikes.

Sophro-Cattleya Warnhamensis "*Cerise*," from Sir W. H. S. Marriott, Blandford (gr. Mr. Denny), flowers of good size, bright reddish scarlet. The spike bore four flowers.

Odontoglossum Fowlerianum (Rossii rubescens × cirrosum), from Messrs. Sander & Sons. A very pretty hybrid with narrow sepals and petals densely spotted with dark purple and tipped and margined bright rose purple, the long blade of the lip being of the same colour, the base and callus being yellow.

Award of Merit.

Dendrobium Wiganiæ illustre, from Sir Trevor Lawrence, Bart. (gr. Mr. W. H. White) A model flower, cream-white tinged with rose; disc of the lip orange with heavy maroon blotch.

Dendrobium nobile "*Perfection*," from Messrs. Jas. Cypher & Sons. Probably the broadest and roundest form of D. nobile, and finely coloured magenta rose with a dark base to the broad lip. A home-raised seedling between D. nobile elegans and nobilius.

Odontoglossum Rossii immaculatum, from De B. Crawshay, Esq. (gr. Mr. Stables). A very pretty variety with whitish sepals tinged with rose and entirely unspotted. Petals and lip white with a faint blush tint. Pretty and unique.

Dendrobium Wiganianum, Gatton Park variety, from Jeremiah Colman, Esq., Gatton Park (gr. Mr. W. P. Bound). A large and finely formed flower of a cream-white tinted with rose, and a purplish disc to the lip.

Brasso-Cattleya Digbyano Mendelii, var. Fortuna, from J. Bradshaw, Esq., Southgate (gr. Mr. G. G. Whitelegge). Flowers with a slight greenish tint.

Pleione yunnanensis from Messrs. Sutton & Sons, Reading. The pretty rose-lilac species described in the *Gardeners' Chronicle*, Feb. 24, p. 115.

Odontioda Heatonensis from Messrs. Charlesworth & Co., Heaton, Bradford. A most interesting hybrid between Odontoglossum cirrosum and Cochlioda sanguinea. Flowers white, densely spotted with rose-pink and similar in size to those of O. odoratum, but broader in the segments.

Botanical Certificate.

Cynorchis compacta, from Baron Sir H. Schroder. A pretty dwarf tufted species with many erect spikes of white flowers.

Cultural Commendation.

To Mr. W. H. White (gr. to Sir Trevor Lawrence, Bart.), for a splendid specimen of Dendrobium Sybil.

To Mr. W. H. White for a fine plant of the blush-white Dendrobium superbum Burkei.

To Mr. W. P. Bound (gr. to Jeremiah Colman, Esq.), for Masdevallia Pourbaixii, with many flowers.

Diploma Awards.

Dendrobium nobile Varieties.—*1st Diploma:* Dendrobium nobile "Perfection" from Messrs. Jas. Cypher & Sons. *2nd Diploma:* Dendrobium nobile Dormanianum from Jeremiah Colman, Esq.

Hybrids of D. nobile and D. aureum.—*1st Diploma:* Dendrobium Wiganianum, Gatton Park variety, from Jeremiah Colman, Esq. *2nd Diploma:* Dendrobium Ainsworthii intertextum from Baron Sir H. Schroder.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (in the chair), and Messrs. Jos. Cheal, Geo. Woodward, S. Mortimer, A. Dean, H. Parr, A. R. Allan, W. Pope, R. Lye, W. Crump, H. Markham, H. J. Wright, Ed. Beckett, Jas. Vert, J. Lyne, Jos. Davies, F. Q. Lane, Geo. Reynolds, J. Willard, Geo. Wythes, J. McIndoe, C. Foster, W. H. Divers, O. Thomas, P. C. M. Veitch, W. Poupart, and J. Jaques.

The lamented death of the late Mr. George Norman has removed a prominent member of this Committee. Expressions of sympathy with the members of the family were made at the meeting, and it was decided to send a formal letter of condolence to Mrs. Norman.

The principal exhibit brought to the notice of the Committee was a collection of 33 dishes of Apples and Pears, shown by J. B. Fortescue, Esq., Dropmore, Maidenhead (gr. Mr. C. Page). Some good plates of fruit were noticed, but it was apparent that the majority were quite past their season. Bramley's Seedling, Hambling's Seedling, Hambledon Deux-Ans, and Gascoigne's Scarlet were among the best samples. The specimens of Catillac Pears had the mellow appearance seen in choice dessert varieties. (Silver Banksian Medal.)

Mr. J. Cook, Forde Abbey Gardens, Chard, showed a dish of Veitch's Early Wonder Dwarf Beans.

Mr. Wythes, Syon House Gardens, Brentford, had a plate of Carter's Sunrise Tomato, exhibited to show its use for winter fruiting. The fruits were of moderate size only.

Mr. Foster, University College Gardens, Reading, displayed excellent samples of forced Chicory.

The Superintendent brought specimens of Snow's Winter White and of Brydon's Peerless Broccolis from the trial grounds at Wisley. The inflorescences were lax and yellowish in colour, and the general opinion of the members was that the varieties were not equal to the old type of Snow's Winter White, consequently no award was made.

COMPLIMENTARY DINNER TO MR. WILLIAM MARSHALL, V.M.H.

There are few men who are better known or more respected by habitual visitors to the Royal Horticultural Society's meetings than Mr. William Marshall, who has just entered upon his 21st year as Chairman of the Floral Committee. In order to show their respect and express their congratulations on this auspicious event, Mr. Marshall was entertained at dinner at the Hotel Windsor on Tuesday evening last by the Floral Committee and their friends. The Committee has also presented Mr. Marshall with his portrait in oils, which, although not perfectly finished, promises to be a very faithful representation. Mr. Harry J. Veitch presided, and at his right hand were Mr. W. Marshall, Mr. H. B. May, &c., and on his left Dr. M. T. Masters, F.R.S., W. A. Bilney, Esq., &c., the company present numbering 75. Mr. Veitch, in proposing the toast of "Our Guest," said that he had known Mr. Marshall for more than 40 years. He had respected him a little as an entomologist, much as a philanthropist, and very greatly as an amateur horticulturist. Reference was made to Mr. Marshall's successful cultivation and exhibition of stove plants in the early sixties. These were subsequently partly given up for hardy Ferns and hardy plants generally. He had the honour of flowering Odontoglossum crispum (Alexandræ) first in this country, and two Orchid species at least bore Mr. Marshall's name. These were Thunia Marshalliana and Oncidium Marshallianum. Mr. Veitch went on to speak of Mr. Marshall's efforts in helping to found the United Horticultural Society, and of the unusually successful exhibition which was held in the Guildhall in 1865 (see *Gardeners' Chronicle*, Oct. 14, 1905, p. 287). The proceeds from that show, said Mr. Veitch, were the means used for establishing the United Horticultural Benefit and Provident Society, which has developed so much in its degree of usefulness. Mr. Marshall was one of those who helped to found the Royal Gardeners' Orphan Fund, and on Mr. Deal's death he was chosen as chairman of the executive committee. In addition to all this, Mr. Marshall has been a member of the Royal Horticultural Society's Council for many years, and, as we have already stated, chairman of the Floral Committee for 20 years.

Mr. Marshall, on rising to respond, was received with great enthusiasm and cheering. He commenced by thanking those present for the great honour they had done him, but he said they had placed him in a "deliciously difficult corner," because he had to speak of himself, which was not an agreeable subject. He showed a side

light on to the circumstances that led to the Council abstaining for some years from recommending any of its own members as recipients of the Victoria Medal of Honour in Horticulture. They have departed from the custom as the circumstances have now become quite different, and as the gentlemen for which this was done were Mr. Harry J. Veitch and Mr. Marshall, the Council's decision will be generally approved. Mr. Marshall cordially recognised the kindness and loyalty that had always been shown him by members of the Floral Committee, and said that in the 20 years he had only been obliged to call a member to order on two occasions.

The next toast was proposed by Dr. M. T. Masters, F.R.S., and was that of "The Royal Horticultural Society." He said that his recollections extended further back than those of either Mr. Marshall or Mr. Veitch. His first recollection was of rather a painful character. The society was selling its library, museum, and everything possible. He was then deputed by the authorities of the Botanic Garden, Oxford, to buy some of the books, and now after a long stretch of time he had that day (Tuesday) assisted at a meeting held to consider the better management of the Lindley

WILLIAM MARSHALL, V.M.H.,
who has entered on his 21st year as Chairman of the R.H.S. Floral Committee.

Library, which, however, was much more extensive than the original library. About 1860 he (Dr. Masters) joined the Floral Committee. In view of these reminiscences he was proud and pleased to see the measure of success the society was now enjoying. Mr. George Paul responded. Other toasts included "The Chairman," proposed by Mr. W. A. Bilney; "The Dinner Committee," proposed by Mr. R. W. Kerr, and responded to by Mr. George Gordon, V.M.H.; and "The Artistes and Donors of Floral Decorations," proposed by Mr. A. Dean, and responded to by Mr. Tom Powley.

The tables were most tastefully decorated with winter flowering Carnations, but in front of the guest of the evening was placed a bowl plenteously furnished with flowers of Odontoglossum crispum. The musical part of the programme was contributed to by Messrs. R. and A. Marshall, Messrs. J. H., P. J., and Ted Berry, and Mr. Tom Powley. It was a matter of regret that Mr. J. F. McLeod who had done much towards securing a good programme was prevented from attending by reason of indisposition.

Obituary.

Thomas H. Sutton.—Deceased, who died after a painful illness at Sturford Cottage, Corsley, Wiltshire, on the 2nd inst., was well known in horticultural and agricultural circles. After obtaining good experience, which included some years spent at Keele Hall, Staffs., and at Blenheim Palace, he was appointed to the charge of the gardens and farm at Worksop Manor, the residence of the late W. I. Cookson, Esq., which position he retained for nearly 20 years. During the past 15 years Mr Sutton has had charge of the Wiltshire and Somersetshire residence and estates of that gentleman's son, Theodore Cookson, Esq. Under his management the Sturford shorthorn herd attained to a wide celebrity and met with many successes at the Royal and other shows.

GARDENERS' DEBATING SOCIETIES.

CHELMSFORD & DISTRICT GARDENERS'.—At the weekly meeting of this association, held on March 3, Mr. E. Hammond, gardener at Widford Lodge, read a paper on "Spring Bedding." The paper furnished a list of suitable plants for simultaneous flowering, and for choice effects of colouring. *W. C. S.*

LIVERPOOL HORTICULTURAL.—The fourth and last of a series of lectures delivered to the members of this society was held on Saturday, 3rd inst., Mr. Mercer occupying the chair. The lecture, entitled "Ancient and Modern Gardens," illustrated by a number of lantern slides, was delivered by Mr. Barnes, gardener to the Duke of Westminster, Eaton Hall. The paper dealt with some of the most interesting gardens in the country, and compared the styles of flower beds adopted in those gardens. *J. P.*

THE WEATHER.

GENERAL OBSERVATIONS.

The Following Summary Record of the weather throughout the British Islands, for the week ending March 3, is furnished from the Meteorological Office:—

The *weather* was of a variable type; more or less rain, sleet, or snow fell on most days, but there were frequent intervals during which the sun shone brightly. Thunder was heard at Swarraton on Monday morning.

The *temperature* was below the average generally—as much as 3° in the north and east of Scotland, but just equal to the normal in England E. and slightly above it in England S. and S.W. and the Channel Islands. The highest of the maxima occurred on varying dates, and ranged from 55° in the south and south-west of England and the south of Ireland to 48° in the west and north of Scotland. The absolute minima, which were mostly registered either at the beginning or end of the period, were as low as 18° in Scotland E. (at Balmoral), but elsewhere varied from 22° in the Midland Counties and 23° in Scotland N. to 28° in Ireland and to 36° in the Channel Islands.

The *rainfall* somewhat exceeded the average in most districts, but was less in Scotland E., England S. and Ireland S., and about equal to in England E. and Scotland W.

The *bright sunshine* differed little from the average, the aggregate number of hours being only slightly higher or lower than the normal. The percentage of the possible duration ranged from 35 in Scotland E. and England S., and 33 in Ireland N. to 27 in the Midland Counties and England N.W., and to 22 in Scotland N.

THE WEATHER IN WEST HERTS.

May weather in March. During the past week the day temperatures were all above the average, but on one night the exposed thermometer registered 13° of frost. On the two warmest days the temperature in the thermometer screen rose to 64°, which is the highest reading as yet recorded here so early in the spring, and on the warmest night the exposed thermometer did not fall lower than 41°—a high night temperature for the time of year. The ground has now become warm, and at the present time is about 2° warmer at 2 feet deep, and 5° warmer at 1 foot deep than is seasonable. There has been virtually no rain during the past week; the percolation through both the soil gauges is now rapidly declining. The sun shone on an average for nearly 4½ hours a day, or for about an hour a day longer than is usual at this season. On two days no sunshine at all was recorded, but, on the other hand, on three days the record exceeded 7½ hours a day. The wind was, as a rule, of about moderate strength, and came principally from some point between south and west. The mean amount of moisture in the air at 3 p.m. was 3 per cent. less than a seasonable quantity for that hour. An Early Rivers Peach growing on a south wall in my garden came first into blossom on the 6th, or 17 days earlier than its average date in the previous 20 years, and, with three exceptions, earlier than in any of those years.

February.

Persistently wet and yet exceptionally sunny. Taken as a whole this was a month of about average temperature. On the warmest day the highest reading in the thermometer screen was only 49°, and on the coldest night the exposed thermometer showed only 17° of frost. Both of these extremes are very moderate for February, and more particularly the highest day temperature. Although there were no exceptionally cold nights, on all but three nights during the month the exposed thermometer registered readings below the freezing-point. Rain, hail, snow, or sleet fell on as many as 22 days, or for a greater number than in any previous February, and yet the total measurement, 2½ inches, was less than half an inch in excess of the February average. On one occasion in the middle of the month the ground was covered with snow for a short time to the mean depth of an inch. Nearly the whole of the rainfall came through the percolation gauges. The sun shone, on an average, for nearly three hours a day, or for more than half an hour a day longer than usual. In fact, with four exceptions, this was the sunniest February during the past 20 years. The winds were on the whole rather high, but in the windiest hour the mean velocity reached only eighteen miles—direction W. N. W. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by two per cent.

The Winter.

Exceptionally warm and sunny. This was a warm winter, indeed, there have been only three warmer in the last 20 years. At no time did the thermometer, exposed on the lawn, show more than 17° of frost. The total rainfall exceeded the average by only about half an inch but there was an unusual number of days when rain fell. The record of clear sunshine averaged two hours a day, which is about 20 minutes a day in excess of the mean.

Our Underground Water Supply.

Since the winter half of the drainage year began in October, the total rainfall has been 12½ inches, or about half an inch in defect of the average for the same five months, equivalent to a deficiency in rainfall on each acre in this district of 8,370 gallons. At the same time last year the deficiency amounted to 126,680 gallons. *E. M., Berkhamsted, March 7, 1906.*

MARKETS.

COVENT GARDEN, March 7.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Remarks.—The last consignment of Peaches from the Cape was of poor quality, the fruits being colourless and unripe, consequently they met with no great demand. Grapes from the Cape are arriving in good condition, and meet with a ready sale. A consignment of Asparagus from Spain met with a good demand, in fact, Asparagus from all sources is selling well. English and Channel Islands Beans are much cheaper. Trade in fruit and vegetables has much improved owing to the prevalence of exceptionally fine weather. *E. H. Rides, Covent Garden, March 3.*

Potatos.

Blacklands, 55s. to 60s.; Bedfords, 65s. to 75s.; Lincolns, 45s. to 60s.; Kents, 70s. to 80s.; Dunbars, 80s. to 95s. per ton. —*John Bath, 32 and 34, Wellington Street, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

The trade in plants is still very quiet, and growers of imported Azaleas and Dutch bulbous plants can scarcely be receiving returns sufficient to pay for the cost of the stock. Azalea indica in all the best varieties continues over plentiful. On Saturday last plants which usually cost fully £5 per 100 in Belgium were being sold in the London streets at 1s. each. Hyacinths are also sold for equally low prices. Spiræas are now plentiful and well developed. Well-flowered Genistas are sent by several growers, and are cheaper. Cinerarias are good; the flowers of the type grown for market are not of the most perfect form, but they are bright, while the habit of the plants is all that can be desired. Cyclamen are remarkably good, but returns are low. Good Begonias are not over plentiful. Marguerites are very good in quality, but these plants are not in great demand. Erica Wilmoreana is moderately good. E. gracilis vernalis can be had in dwarf, bushy, well-flowered plants. A few E. hyemalis are still coming in the market. Also E. melanthera in tall pyramidal plants. Dendrobium Wardianum is noticed in well-flowered plants, but there seems little demand for them. There is little variation in the trade and supply of Ferns, Palms, and other foliage plants, but with the mild weather there is an increased trade among hardy flower roots. Pansies in flower sell readily. Polyanthus, Primroses, and Daisies, with a few flowers open, are also in demand.

Cut Flowers.

I have never heard more grumbling among the salesmen than I did when going round the market this morning. The very large supplies of foreign flowers materially affect the sale of English grown specimens. Roses are now coming from all the usual sources, and fine blooms on long stems of the varieties Mrs. J. Laing, Caroline Testout, and others are now more plentiful; indeed many were left unsold at closing time this morning. Supplies of Carnations are excessive, and returns have fallen considerably. Lilium auratum of good quality are now seen. L. longiflorums are cheaper. L. lancifolium vary considerably; many blooms are of poor quality, but the best make good figures. Eucharis are not quite so numerous. Azalea Fielderi is over plentiful. Callas are good and cheap. Tulips continue over plentiful; some very fine double varieties of these flowers are seen, and these make better prices than the "singles." Daffodils in best varieties from English growers, and the large quantities from the Scilly Islands and Guernsey, considerably exceed all demands. Lily of the Valley with good green foliage can be had in plenty. Taking the market all round supplies are exceedingly good, but meet with a very slow trade. *A. H., Covent Garden Market, March 7, 1906.*

ANSWERS TO CORRESPONDENTS.

Apple Trees on Chalk: *C. N. M.* We have seen Apple trees planted on chalk, but these have never been satisfactory. The growth is stunted and the produce very poor compared with the fruits that are cultivated on more suitable land. Much can be done, however, to improve the top spit of even chalky soil by heavily manuring it and by top dressing with dung, affording copious supplies of water, and pricking over the surface of the ground once each year with a fork so as to encourage the roots to the surface. If you give each tree a good start at the time of planting by surrounding it with fresh, turfy loam, and afterwards treat the ground as already mentioned, you may obtain moderately good results. The following varieties are amongst the best for cultivation on the paradise stock:—Dessert: Mr. Gladstone, Beauty of Bath, Benn's Red*, Lady Sudeley, Worcester Pearmain*, James Grieve, Gravenstein, Wealthy*, Cox's Orange Pippin, Allington Pippin, Mother*, Cockle Pippin, Adams Pearmain, Blenheim Pippin, Mrs. Phillimore*, Claygate Pearmain*, Beauty of Kent, Lord Burghley, and King's Acre Pippin. Cooking: Lord Grosvenor, Ecklinville Seedling, Lord Derby, Warner's King, Lane's Prince Albert, Newton Wonder, and Bramley's Seedling If we have named too many dessert varieties you may omit those marked with an asterisk.

Grubs: *W. B. S.* The grub you send is the larva of the common cockchafer, and it is very injurious to vegetation.

Names of Fruits: *Noel.* 1, Claygate Pearmain; 2, Round Winter Nonsuch; 3, Annie Elizabeth; 4, Gascoyne's Scarlet Seedling.

Names of Plants: *F. T. Bourton.* 1, Pinus, probably ponderosa; 2, 3, 4, 6, all dwarf forms of Picea excelsa (such as ericoides, Clanbrassiliana, &c.); 5, probably Picea orientalis. —*F. F.* Galax aphylla.—*A. J. C.* Garrya elliptica.—*F. S.* 1, an Evergreen Oak of which we will give you the true name next week; 2, Juniperus sinensis; 3, Azara integrifolia.—*Rex.* We do not undertake to name varieties of Roses; send to some Rose grower who will probably have them in his collection. The other specimen is a Viburnum, probably V. Sandankwa as far as we can tell without flowers. —*Babul.* Acacia Farnesiana.—*W. L.* 1, Cymbidium eburneum, it varies in the character of the purple spotting on the lip; 2, Stauropsis gigantea, often called Vanda gigantea.—*C. S.* Rhododendron Veitchii and Adiantum peruvianum.—*A. E. B.* 1, send when in flower; 2, Ruscus Hypophyllum; 3, Cornus Mas; 4, Elæagnus pungens variegata; 5, Andromeda floribunda; 6, Genista next week.

Peaches: *H. W.* The branches are attacked by a Botrytis. Keep the house as well ventilated as possible without causing injury to the trees. Spray with potassium sulphide, one ounce to three gallons of water.

Pyrus japonica injured: *A. G. S.* Probably the effect of frost on the young growth. Cut the shrubs hard back. As they get established they will become more hardy.

Rose Mildew: *H. G. K.* The shoots are covered with the spawn of a Rose mildew which has killed the bark. You can do nothing but cut away and burn the affected shoots and spray the healthy ones with liver of sulphur dissolved in water in the proportion of 1 oz. of the sulphur to 2 gallons of water.

Superphosphate of Lime: *J. T. and S.* A very light dressing of this manure would not be injurious to freshly-planted Carnations provided none is thrown over the leaves, which are liable to be burned if so treated. At the same time, and assuming that the ground was properly prepared before planting was done, such manure is not yet required. Superphosphate may be applied later on if it is thought to be desirable, especially if lime and phosphates are somewhat lacking in the soil, but its application will not kill the wireworms.

Temperatures in Plant Culture: *C. E.* The various temperatures mentioned in the Calendar for "Plants Under Glass," which appeared in the issue for January 6, included the rise by day caused by sunshine. The maximums then given for each house should not be exceeded at present. As the growing season advances you may quite safely increase each week very slightly the degree of atmospheric temperatures at night, and also by day, till the maximum summer temperatures are reached. The maximum day temperature should be maintained until sunset, and from this point the atmosphere should very gradually become cooler until the minimum is reached. Guard strictly against high temperatures during the night. The atmospheric temperature of the stove during the summer months should range from 70° to 80°, that of the intermediate house from 65° to 70°, and of the conservatory from 60° to 68°, allowing a rise by sunshine of from 5° to 10° in each house, and making use of the blinds and ventilators to regulate the warmth of the atmosphere in the houses as much as possible. If a varied collection of plants is grown in the stove the temperature even now may be allowed to run up to 80° with sun-heat when closing the house. If Ixoras, Dipladenias, and Codiæums are the principal inmates 10° to 15° more heat will be an advantage.

Vines: *J. G.* We can form no definite opinion from the specimens you send. As the disease progresses send us further shoots.

Violets Diseased: *J. J. S.* Yes, it is the same disease as that described on p. 80 in answer to *W. B.*

Weed Killer: *H. O. F.* Most weed killers are very poisonous. If you want something that is not so poisonous you had better apply common salt which is effective, and if not sprinkled on Box or other living edge plant will do no injury.

GARDENING FOR THE PEOPLE.

IT is generally admitted that one means of counteracting the townward trend of the countryman and his family is to endeavour to induce him to retrace his steps, if that be possible, and take up rural occupations of various sorts. Amongst those that hold out the greatest amount of promise for him and his is the congenial matter of vegetable and fruit cultivation on small holdings. Not everyone has the necessary knowledge and skill, still there are various agencies at hand, ready and desirous of affording the one and teaching the other. Then there comes the important question, "What shall he cultivate?" A mere glance at the list of imported products, published in the Government Reports, and often copied into this and other journals, seems to indicate numerous vegetables and fruits which can be grown in this country equally well as regards size, appearance and quality as the imported productions with which many of our towns are now supplied. Our own growers living on the spot, or within a comparatively short distance, can surely undersell the vendor of imported stuff, handicapped as is the latter by transit costs by sea and land, and the middleman's charges, these, of course, being reckoned in to the retail customer. Is there any need for a native of this country to buy his first Blackcurrants from the Dutch grower, or his unripe Gooseberries for tarts and puddings from the same source, these growing just as well and just as abundantly on our own soil, and as early, if not more so, in the warmer counties?

How many cottage walls are simply wasted? Few persons seem to realise the potential wealth in these warm surfaces when utilised for cultivating the choicer varieties of Pears, Figs, Grapes, as the Black Cluster, the Parsley leaved, and other Sweetwater varieties—all things easy to grow and make productive. How few persons in the small towns and villages know of the flavour and lusciousness of the Nectarine, Peach, and Apricot, and yet these fruit trees are not more difficult to prune and train than a Gloire de Dijon Rose. Moreover, the trees are sold at prices from 2s. 6d. to 5s. by the nurseryman. It is cause for wonder that the "trade" do not press the cultivation of the finest kinds of fruits on their neighbours possessing small gardens and available walls; the warmer aspects for those already named, and the colder ones for May Duke, Morello, and Belle Magnifique Cherries, all good bottling fruits, and for cooking purposes. The peripatetic County Council lecturers might do worse than teach country girls, as well as men, how to prune, nail, and tie fruit trees. They are now taught to cook in many of the schools, why should they not be taught how some of the things that they use in the cookery classes are cultivated? Red and white Currants, Gooseberries for gathering in the green state, and also ripe, should receive attention from small holders. Raspberries are a paying crop everywhere in this country, either as a dessert fruit, gathered adhering to the stalk, or detached if for preserving as jam, and making Raspberry vinegar, a commodity which even in the country districts is not readily to be obtained at a moderate price. The Apricot ripens its fruit in most parts of England and southern Scotland, but singularly its cultivation is not so widely spread as it should be, at the least in gardens other than those of the gentry. Even in far away Northumberland, certain varieties, such as the Moorpark, and the early form of it; the Royal, a rich, juicy, and hardy variety, and Hemskerk succeed on south aspects, fruiting freely if some kind of light protection against the sun's rays be afforded early in February. Failing this screen the blossoms open very early and often get destroyed by frost. The most appropriate covering is that afforded by the flat branches of Balm of Gilead or common Spruce Fir, tacked sparingly to the wall, their needles falling off as the sunshine increases with the season, until, at the period when the fruits are of the size of Horsebeans, the Fir branches are almost bare. The Apricot affords the best return in soils abounding in lime, as in the counties of Sussex, Surrey, Kent, Berks, Oxford, Wilts. In those soils that are poor in lime it can be readily afforded in the form of lime rubble and old plaster, and mixed intimately with the staple or in the compost in which the trees are planted.

Many persons with available walls facing to the south, west, east, and even north, may elect to cultivate Pears, good fruits of which are not too common in country places, and if these are worked on the Quince, on which stock many varieties produce good crops, the holder will not have long to wait for returns from his venture. He will be wise if his selection consists of early and midseason varieties, these ripening on the trees or soon after being gathered. In most parts these ripen on bushes as well as on wall trees. The following names are given in the order of ripening; Citron des Carmes, for July; Jargonelle, a large, favourite Pear, good on Pear or Quince stock; Beurré Giffard, Clapp's Favourite, a handsome Pear of great excellence, for August; Williams' Bon Chretien, a well-known variety, highly perfumed and melting; Buerré d'Amanlis, a capital variety for a wall, large and melting; B. Superfin, a delicious melting Pear; and Autumn Nelis, for September. For cultivation by those having storage room, the following may be recommended: Louise Bonne of Jersey, Jersey Gratioli, Fondante d'Automne, Beurré Hardy, B. d'Aremberg, Brown Beurré, Doyenné Boussoch, Marie Louise, one of the best; Comte de Lamy, Beurré Bosc, Baronne de Melo, Glout Morceau, Doyenné du Comice, Beurré d'Anjou, Winter Nelis, Nouvelle Fulvie, Easter Beurré, and Beurré Rance, are good late ripening Pears. The list might be greatly increased, but it is sufficiently lengthy for our purpose, and not many first-class varieties have been omitted. Baking and stewing Pears should be grown generally by cottagers, for, besides being palatable additions to their winter fare, the fruits are always saleable in the towns. Of these may be mentioned Catillac, Summer Compote, Uvedale's St. Germains, and Winter Orange. A farming man, woodman, or general labourer renting on lease an acre or two of land of fairly good quality, by working on odd days when his employer did not need his services, and for an hour or two in the evening, with perhaps the assistance of his boys and big girls in doing the lighter sorts of work, would be able to add materially to his income, and increase the comfort and well-being of the family. With crops of Potatos, Parsnips, Carrots, Onions, Leeks, Haricot Beans, Dwarf Peas, Cabbages and Kales, and with a pig or two killed annually and turned into bacon, and several goats to afford milk, and occasionally a kid for the table, the man would be enabled to look with equanimity on his lot during the seasons when employment at his calling was not too regular. He should be encouraged to take up bee-keeping, for honey and bees-wax, always in demand at fair prices, and the propagation of fruit bushes for sale in his neighbourhood should come within the scope of his labours. *Countryman.*

NEW OR NOTEWORTHY PLANTS.

ANTHURIUM FORGETI, N. E. BROWN (*N. Sp.*).

THE novelty now described is a handsome foliage plant allied to the well-known A. crystallinum, but differing first in its much smaller size, since it is stated to attain only to about one quarter of the size of A. crystallinum, and secondly by its constantly peltate, entire leaves, which are of a beautiful rich, deep green, overspread with a velvety sheen, and are exceedingly pleasing to the eye. The veins are also fewer, with a somewhat different curvature, and are less frosted-white than in A. crystallinum. Messrs. Sander & Sons have introduced a large stock of A. Forgeti from Columbia, where it was discovered in the province of Cundinamarca by their collector, Monsieur Forget. They inform me that the plant is quite constant in its peltate, entire

leaves, and that they have never observed any approach to a lobing or a sinus at the base of the leaves on any of their plants. The following is a description of this new species.

Stem short, erect, freely rooting, the whole of the plant seen, excluding the peduncle and spadix, being about 15 inches high. Leaves closely placed, glabrous; petiole erect, 6-10 inches long, including the geniculus, which is 5-6 lines long, quite terete, without a groove down the face, sheathing at the base, green; blade drooping, 10-14 inches long, 6-9½ inches broad; peltate, elliptic-ovate, shortly acuminate, quite entire and broadly rounded at the base, or but faintly emarginate, not in the least cordate or notched, of a rich and pleasing deep green, overspread with a velvety sheen, with very pale green nerves and primary veins, which often have a frosted-white border; underside pale green, sometimes with a faint purplish hue; primary nerves (including the midrib) 6-7, all radiating from the insertion of the petiole, prominent on the upper side, very slightly so beneath; when there are 6, one is directed straight back in a line with the midrib, forking about an inch from the margin of the leaf into two branches (when there are 7, this backwardly directed nerve is divided to the base into two) which sweep in bold curves out to the margins below the middle of the leaf; the lowest pair are first directed backwards in a widely-spreading manner, then curve forward out to the margin, and become excurrent near the apex of the leaf; the inner pair are widely ascending, spreading at the base, then curve, and form a slightly looped nerve about ¾-1 distant from the margin at the lower half, and becoming excurrent at the apex; the midrib gives out three or four primary veins on each side, which unite and form loops with the inner pair of nerves. Peduncle rising to about twice the height of the leaves, 1½-2 feet long, terete, glabrous, green. Spathe 4-6 inches long, ½-⅔ inch broad, broadly linear or strap-shaped, acuminate, amplexicaul or shortly decurrent at the base, spreading, glabrous, green. Spadix about 6 inches long, ¼ inch thick at the base, terete, gradually tapering to the obtuse apex, ochreous yellow, with a wax-like shining surface. Flowers 4-angled, about 1 line in diameter. Ovary green at the top, two-celled; stigma sessile very small. *N. E. Brown.*

COREOPSIS GRANTII.

A Coreopsis from tropical Africa, with characters that are likely to recommend it to gardeners, is represented in the illustration at Fig. 64, which has been prepared from a photograph of a plant in the Kew collection, where it flowered for the first time in February. It was raised from seeds collected in Uganda by Mr. M. T. Dawe, who described it as "a good thing." Some plants of it were tried in a border outside last summer, and although they grew freely, they did not flower before the frost killed them. Others that were kept in pots and received the protection of a greenhouse formed compact leafy bushes about 2 feet high, with elegant dark green, bipinnate foliage, and they flowered freely last month. The flowers are about 2 inches in diameter, and of a bright, pleasing shade of yellow. They are not equal in beauty to those of C. grandiflora or C. lanceolata, but the habit of the plant and its winter-flowering character are its recommendations for the garden. We are not yet able to say if it is a perennial.

C. Grantii was discovered in Nile-land by Speke and Grant during their expedition in 1860-3 to the sources of the Nile. According to Mr. Dawe it flowers in December in Uganda. There are dried specimens at Kew of a big-flowered, beautiful species of Coreopsis named speciosa, which was found in Angola by Welwitch, and again quite recently by Sir Evan James in Uganda. It ought to be a good garden plant. Perhaps Mr. Dawe or his assistant can obtain it for us. *W. W.*

THE LONDON MARKETS AND THEIR SUPPLIES.

(Continued from page 15.)

COVENT GARDEN.

Few markets concerned with garden produce possess a fraction of the interest with which Covent Garden is invested, and in many respects it is probably one of the most remarkable in the world. In some features it is surpassed by the great Parisian market, les Halles Centrales, especially in May, when the wonderful supply of Asparagus at the latter is probably unique. But to comprehend the business transacted in the London market, a good deal more than a cursory view or a superficial acquaintance is essential. It is somewhat like the great metropolis it so largely supplies, disappointing to many strangers on a first inspection, and it is only by prolonged experience that an adequate idea can be formed of Britain's greatest city, or of its greatest market.

Since the days when *Punch* stigmatised Covent Garden as "Mud-salad Market," considerable improvements have been effected, and there can be no question that the authorities, namely, the officials who represent the Duke of Bedford, have striven earnestly not only to remove the reproach which long rested upon it from a sanitary point of view, but also to facilitate the inner working. In the former they succeeded; in the latter they have been confronted with enormous difficulties, though many useful regulations have been introduced to aid the object in view. The whole market is cramped by its surroundings, narrow streets, and totally inadequate standing space for sellers and buyers. At busy periods of the year the streets, from the Strand on the south to Long Acre on the north, are packed with vehicles in early morning, and some hours often elapse before they can obtain their supplies. No one but the official porters may remove goods from the market premises to the carts and vans of the retailing fruiterers and greengrocers, and scores of men with heavy head-loads of boxes or baskets can be seen plunging up and down the streets shouting the names of the purchasers they are trying to find. A stranger might imagine that there must be endless confusion with numberless wrong

[Photo by E. J. Wallis.

Fig. 64.—Coreopsis grantii, a new species from Uganda; flowers 2 inches in diameter; colour, yellow.

deliveries, and that night would arrive before the buyers could obtain their goods. Yet in a few hours all are cleared away, the streets around the market are hose-washed and cleansed, and the bustle has subsided to the ordinary daily routine. To all quarters of a gigantic city, fruits, flowers, and vegetables for millions of people have been conveyed by a vast array of vehicles ranging from the imposing motor wagons of the leading stores to the humble costermongers' barrows, which supply the multitude in the densest centres of population. It is a wonderful business altogether, and an early morning visit to Covent Garden, especially in the spring and summer months, when the flower market is at its best, affords one of the most interesting of London's characteristic spectacles.

As a depot or mart for the highest quality fruit, vegetables, and flowers, Covent Garden stands unrivalled, and it is the reputation in this respect which brings so many sellers and buyers together within its narrow limits. For the best produce substantial prices are almost always obtainable, for fashionable novelties, or for anything of exceptional merit, prices which appear fabulous are secured. When Laxton's Royal Sovereign Strawberry was under trial before it had reached the public, a small consignment of fruits from the open ground was sent as samples to a Covent Garden salesman. The receipt was acknowledged by a telegram, requesting an immediate supply of as large a quantity as possible for a special function at 10s. per lb. The yield of a small plot of outdoor plants at this rate was sufficient to buy the land many times over. That is only one example, and though the days are long past when choice Grapes were sold at 15s. to 20s. per lb., Pineapples at 21s. each, and Pears at 10s. 6d. each, astonishing prices are still often obtained for special products extra early, or of unusual quality.

Of course, the market is subject to the same disadvantages as all others, occasional periods of "glut," usually following those when good prices have ruled, and then even high quality goods have to share in the depression of value. But it is rare that the market is overstocked with first-class produce during the time the London season lasts—mainly the spring months up to June or July. The principal cause of rapid falls in prices is excessive supplies of second or third-rate samples, or, in the case of fruits, those which are indifferently packed, or not efficiently graded. Growers cannot make a greater mistake than to send such produce to Covent Garden; there are other centres where the demand is considerable for low-priced fruit and vegetables, and we have known many cases where the prices realised for such grades have been materially better at Stratford, Spitalfields, or the Borough, than for the same quality at Covent Garden. The leading salesmen do not want to be troubled with goods which their regular customers will not buy at any price, and we have known whole consignments transferred to costermongers at the end of the market for prices which did not pay the carriage to London when the salesman had deducted his charges. An amateur grower, or some inexperienced person, then writes a letter to the daily papers, and cites his case as an example of the impossibility of making land cultivation pay.

We are acquainted with growers and retailers who have tried all the London markets, but who in the course of 40 or 50 years' experience have found Covent Garden invariably superior in all respects. But then the former are cultivators who do not believe in wasting time, space, and money over inferior produce; nothing short of the best results the most skilful cultivation can produce will satisfy them. The buyers at Covent Garden are those who have to provide wealthy and exacting customers with the highest quality procurable. For those two classes Covent Garden is an ideal market, and if the inferior produce which is not required there could only be excluded, the congestion, which is commonly a most distressing feature during the hours of business, would be considerably diminished. *R. Lewis Castle.*

(To be continued.)

ODONTOGLOSSUM × FOWLERIANUM.

At the meeting of the Royal Horticultural Society, held on the 6th inst., much interest was excited by the hybrid Orchid illustrated at fig. 65. The flowers were attractive by reason of their unusually rich colouring, for, as will be seen, the petals and sepals are very narrow, and in form, therefore, the flowers are not equal to many others. But the dense spotting of dark purple, and the rosy purple colour on the tips and margins of petals and sepals are in every respect noteworthy. The long blade of the lip is also of rosy purple colour, but the base and callus are yellow. The hybrid is from a cross between O. Rossi rubescens and O. cirrosum, and it was shown by Messrs. F. Sander & Sons.

Fig. 65.—Odontoglossum fowlerianum; flowers spotted with dark purple colour, and having the sepals and petals tipped and margined with rose purple.

ORCHID NOTES AND GLEANINGS.

DENDROBIUMS AT WOODHATCH.

A visit to Woodhatch, Reigate, the residence of Mrs. Haywood, at any time of the year is interesting. There is always something for the studious to learn, and something delightful to observe. The chief feature at the present time are the Dendrobiums, which are uncommonly well cultivated and exceedingly floriferous. The collection is remarkable for the vigorous, well developed plants of some of the most beautiful hybrids in cultivation. Imagine a rather lofty house, with a lean-to roof facing to the south and more than 60 feet in length, the back stage between 5 feet and 6 feet wide, upon which are arranged about sixty specimen plants covered with bloom, and a general idea will be had of the beautiful floral scene there is now at Woodhatch. The front stage also contains a large number of smaller plants in bloom, which comprise for the most part the newer and rarer varieties. The larger plants on the back stage average from 2 feet to 4½ feet in height from the rim of the pots, and have from 5 to 12 flowering growths, some of which carry from 40 to 50 flowers each, many of the pseudo-bulbs producing a mass of bloom extending over 2 feet in length. A specimen of D. Virgil, which was raised here, has between 400 and 500 flowers, and is an indication of what may be done by good culture. D. Edithæ superbum, D. Cybele nobilior, D. Ainsworthii picturatum, D. splendidissimum grandiflorum, D. nobile nobilius, D. Euryalus var. Apollo grandiflorum, etc., also form masses of bloom. D. splendidissimum var. Mrs. Haywood is conspicuous and attractive, its flowers being of large size and heavily marked with purple-lilac colour, and with a dark maroon blotch on the lip. D. Ainsworthii Woodhatch variety is also very fine. The collection comprises nearly all of the best varieties of the D. melanodiscus crosses, including the new hybrids raised by Mr. Salter as D. m. Salteri, D. m. gloriosum, D. m. Sunray, D. m. giganteum, also the Burford hybrids as D. Luna, D. pallens, D. Rainbow, D. Juno, etc. The last-named variety as a rule is not a profuse bloomer; the flowering nodes oftentimes produce young plants instead of bloom, but here there are plants carrying over a score of richly-coloured flowers. All of the varieties enumerated are in bloom, together with such well-known hybrids as D. Schneiderianum, the sweet-scented D. endocharis, D. Ainsworthii, D. Cassiope, D. Wigania; also some fine varieties of D. nobile as Ballianum, Amesiæ, and others. Suspended from the roof is a pretty plant of the old D. crepidatum, with 5 pendulous growths all laden with white and yellow flowers. A fine plant of D. fimbriatum is also in bloom, one of the racemes producing two lateral branches with several flowers on each. This charming display of bloom is well worthy of the inspection of anyone having a love for beautiful flowers, and especially by those who have an interest in Dendrobiums and their culture. *W. H. White, Burford, March 6.*

"DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDEES."

The issue of this publication for January, 1906, is the first of the eighth series, and eight of the subjects illustrated and described are well-known species; the other five are hybrids.

Barkeria spectabilis commences the genus Barkeria, which is kept distinct from Epidendrum, under which it is generally included. A pretty cool-house species, with white flowers tinged with rose and spotted with purple on the lip and column. Native of Mexico and Guatemala. The plant illustrated was imported by MM. J Van de Putte, of Ledeberg, Ghent.

Cattleya Marie Henriette de Wavrin (Rex × Loddigesii).—Raised by M. De Geeste in the gardens of the Marquis De Wavrin. Flowers blush-white, with yellow and purple front to the lip, which is veined as in Cattleya Rex. It was given an Award of Merit at the Royal Horticultural Society, October 24, 1905.

Cattleya triumphans, var. Ch. Maron.—The original, from a cross between C. Dowiana aurea and C. Rex, flowered with Messrs. Sander in 1904; the variety illustrated, with M. Ch. Maron, Brunoy, France. Flowers yellow, and much resembling C. D. aurea, but with reddish-crimson lip bearing numerous yellowish lines and veining as seen in C. Rex.

Cymbidium sinense.—One of the oldest species. Inflorescence erect, flowers purplish-brown with yellow front to the lip.

Cypripedium Fairrieanum.—A pretty variety flowered by M. Ginot, St. Etienne, Loire (gr. J. W. Dard) is figured, but in the accompanying note nothing new is revealed.

Epidendrum aromaticum.—A very old species, with whitish, fragrant flowers, with purple markings on the lip.

Lælia De Geestiana (Jongheana × flava).—Raised in the gardens of M. le Marquis de Wavrin, and flowered in four years from the time the cross was made. Flowers formed like those of L. Jongheana: white, with crimped, yellow lip.

Lælia Eugène Boullet.—The result of a cross between Lælia harpophylla and Brassavola glauca, and consequently a Brasso-Lælia. Flowers yellow, with dark red lines at the base of the lip.

Stanhopea oculata.—Sepals and petals yellowish, spotted with purple. Lip white, with a dark purple blotch at the base.

Lælio-Cattleya Ernesti (C. Percivaliana × L. flava).—Raised by M. Ch. Maron. A pretty yellow flower with reddish-purple markings on the lip.

Lycaste Deppei.—A well-known, free-flowering species with greenish sepals spotted with red-brown. The petals are white, and the lip yellow marked with crimson spots.

Odontoglossum cordatum.—Flowers yellowish, barred and spotted with red-brown; lip white with reddish markings.

Oncidium graminifolium.—Sepals and petals greenish, heavily marked with chocolate colour; lip light yellow. Native of Mexico and Guatemala, the specimen figured having been imported from the latter country by MM. Van de Putte & Co.

It is pleasing to see that such fine old species are still commanding attention and considered worthy of illustration.

RHODODENDRON PARVIFOLIUM

This species (by some considered synonymous with R. Anthopogon) is an excellent little plant for the filling of small beds or for planting in the rock garden, as here, where it fills a small recess of about three yards in length at the base of a perpendicular piece of rock-work devoted principally to the Callunas.

It grows about eighteen inches or less in height, and is of a rather straggling habit, the stems being wiry. We find it a good plan to peg down these wiry stems and cover them with a little peaty soil, in which they soon make roots. By this process a well-covered bed is soon obtained.

The species is closely allied to R. lapponicum and to R. dauricum. From the first it is distinguished by its taller habit, and by the filaments of the stamens being hairy at their base, while from the latter species it differs in its evergreen character.

It is the earliest of the Rhododendrons to bloom here, commencing about the latter end of December, while flowers may still be found upon the plants at the end of February. In the colour of the flower it resembles R. dauricum, and, like that species, it is liable to be injured by frost, but a welcome display is sometimes secured if the weather is favourable. It is very amenable to cultivation, and, indeed, seems to develop a vigour not obtained in its native habitat, if we may judge by the imported plants. The plants delight in a peaty soil, like others of the genus.

I am indebted to Professor Balfour for the use of the photographs. *R. L. Harrow, Royal Botanic Garden, Edinburgh.*

Fig. 66.—Rhododendron parvifolium, flowering in Edinburgh Botanic Garden.

COLONIAL NOTE.

SEED PACKING.

The letter on seed packing in your issue for January 20, 1906, is one of the most unsatisfactory pieces of evidence which it has ever been my lot to discuss. We recognise the effort made, and the growth of the seeds, but the result could easily have been anticipated; in fact there is nothing improbable in the seeds growing on a single occasion, but the experience of men longer in the tropics is, that unless seeds are sent in something more than ordinary paper packets, they will be found to "succumb" to "severe" attack. On the other hand, there is abundant evidence that seeds, which formerly could not be used to advantage in the tropics, can, when properly sealed in dry air, be kept for a considerable length of time and maintain undiminished vitality, while if left in paper packets for even short periods they become utterly useless. Several eminent seed firms have recognised the fact, and are now sending out to the tropics seeds properly protected against climate, insects, and fungi, which will certainly replace the old style of paper packets. Some merchants do not appear to understand that a buyer of thirty years' tropical experience can possibly know what he wants. Trade is obtained by supplying to the buyer what he wants, and not with what the British merchant thinks is good for him. Considerable evidence on seed packing is being collected, and I shall be happy to forward it as soon as ready. It is sufficient at present to justify the placing of orders with those who will give attention to a buyer's wants. *J. H. Hart, Botanical Department, Trinidad.*

FOREIGN CORRESPONDENCE.

THE GULF STATES AND THE SARRACENIAS.

I had a most instructive trip of nearly 3,000 miles during the past summer, circling round all the Gulf States, and from there gradually northward to some of my old Dionaea haunts near Wilmington. Some of my results have been of special interest, and could I have transported them to great Savannahs in Mississippi, where the genuine Sarracenia Catesbaei covered an area thickly for a length of 7½ miles, I am sure your readers' mouths would have watered. Equally so in southern Alabama, where thousands of acres waved crimson and white with continuous expanses of Sarracenia Drummondi, paved at the base of the myriad pitchers with millions of plants of S. psittacina, while S. flava, S. purpurea, and S. rubra helped to vary the landscape. Here I first got four lots of genuine wild hybrids—crosses of S. Drummondi × S. flava (magnificent), of S. Drummondi × S. purpurea, and of S. flava × S. purpurea. But from the hybrid point of view my great and surpassing experience was at a delightful but very malarial spot—Ponce de Leon—where in a day's botanising of about 17 miles I encountered 117 genuine hybrids of Sarracenia flava × S. purpurea, of which I have a fine lot now coming into flower in our Sarracenia house. Curiously enough this is undoubtedly the plant that Elliott had before him when he described S. Catesbaei, as a

recent inspection of the type specimen in the Charleston Museum shows. What I have called his S. Catesbaei—and which so far as his description goes could not be distinguished—seems to be wholly restricted to the Gulf States and west of the Alabama river. *John M. Macfarlane.*

ARIZONA.

We concluded to step off the train at Tucson in Southern Arizona, and to re-explore the noble range of Santa Catalina mountains.

Sickness interfered often with our work, and we had to confine ourselves to obtaining information in regard to little known regions and the best ways to reach them on future trips.

Of course the Oaks were the most numerous and accessible trees, and we secured many specimens—not yet fully determined. Of Pines we found two forms of P. Montezumæ, one of them with cones nearly a foot long: others were the beautiful and widely disseminated pseudo-strobus, the Teocote, the leiophylla, the oöcarpa, the Hartwegi in two forms, and one not yet determined for want of sufficient material. We also collected specimens of the sacred and only Abies of the Republic, A. religiosa, several Taxodiums, Cypresses and Junipers, with a host of Acacia, Mimosa and other pod-plants so abundant in tropical countries.

Arriving home as late as Christmas, we have had much to do of other business, while our collections have had to wait. *J. G. Lemmon, Oaklands, California.*

JAPAN.

A New Genus of Conifers.

I enclose a curious specimen of Conifer which is found on Morrison, the highest peak in Formosa. As far as my knowledge extends, this does not seem to belong to any described genus. I think this will be a new genus, just intermediate between Cunninghamia and Cryptomeria. The cones are very much like those of Cunninghamia, while its vegetative parts bear most resemblance to Cryptomeria. I have named this new plant "Taiwanites," as the plant comes from the island of Formosa. I hope you will be so kind as to examine this species and to let me know your opinion about it. I am going to publish this genus in the Botanical Magazine of Tokyo. I shall be very glad to send you my paper about this new genus and its affinity to other genera (with diagnosis and a plate) if this genus should fortunately be recognised by an authority like you. *B. Hayata, Botanical Institute, Science College, University of Tokyo.*

[We hope Prof. Hayata will be able to send us seeds of this very interesting plant, which would be a great addition to our collections, and possibly, owing to the elevation at which it grows, hardy in the warmer parts of these islands. The technical description of this new Conifer, which has the foliage of an Athrotaxis and the cone of a Tsuga, will, at Prof. Hayata's request, be laid before the Linnean Society.—Ed.]

THE ALPINE GARDEN.

SAXIFRAGA FERDINANDI COBURGII.

This plant is undoubtedly one of the gems among the early flowering members of this interesting and beautiful genus. Dwarf, even diminutive in growth, the species at once strongly appeals to all who take delight in choice, early flowering plants. The minute rosettes of leaves approach somewhat to S. aretioides primulina, but with a pronounced incrustation almost equal to that of S. cosia. The peduncles are not more than one inch in height, 2-3 flowered, the half-inch wide blossoms coloured a shade of greenish yellow. In size the blossoms are not unlike the form of S. aretioides above-named, but in the deeper yellow colour they are quite distinct. This extremely rare species comes from Macedonia, and is an ideal subject for pot culture in sandy loam.

SAXIFRAGA SCARDICA.

In the issue of the *Gardeners' Chronicle* for February 10, p. 89, a quotation from the *Botanical Magazine*, having reference to the above, stated that "it may be expected to supersede, to some extent, the well-known S. Burseriana, as it is more showy and stands damp weather better." As these two species rarely flower at the same time in the open, one can hardly imagine the two in competition. S. Boydii alba is more often in flower at the same time as Burser's Saxifrage, and, opening its blossoms like this species quite close upon the tuft, suffers from rain and frost. S. scardica is one of the most beautiful of later flowering species, and in stature and flowering would be best compared to S. Boryi and S. marginata, all white flowering forms and very beautiful. *E. Jenkins.*

Fig. 67.—Single plant of Rhododendron parvifolium.

(For text see page 164.)

GALANTHUS NIVALIS FLAVESCENS.

Galanthus nivalis flavescens is one of the few of what are popularly called "yellow" Snowdrops, although the segments of the flower are not yellow, but white, and the only portions which are yellow are the ovary, the markings of the inner segments, and the stems themselves, which are more yellow than green. Of the three or so varieties which prove constant in colouring, the best and most vigorous is that known as flavescens, which was found in a cottage garden in Northumberland some sixteen or seventeen years ago by Mr. W. B. Boyd, of Faldonside, Melrose. It is both larger and brighter than lutescens, and, as it is apparently a better "doer" in most gardens, it will likely grow in favour, although much scarcer at present than the smaller yellow variety. I have grown the variety for several years, but it seems to prefer the stronger soil of my present to the more peaty one of my former garden, and this season it is more vigorous than I have seen it before. Some people are sceptical as to the beauty of these flowers with yellow markings until they see them in bloom, when they generally admire them.

SCILLA BIFOLIA RUBERRIMA.

Among the earliest forms of the valuable Scilla bifolia which I have in my garden here is a pretty form raised by Mr. James Allen, and called by him ruberrima. It is much brighter in the bud when it first opens than the typical S. bifolia or the greater number of its forms, opening rather red than blue, while its leaves are also quite chocolate-coloured. It seeds freely, but the seedlings are not reliable in their colour, and they frequently revert to the type. A hardy little flower, when S. bifolia ruberrima finds its way into commerce, it will be appreciated by the lover of out-of-the-way bulbs. *S. Arnott, Sunnymead, Dumfries.*

LEAVES FROM MY CHINESE NOTE-BOOK.

The Flora of the District.

(Continued from page 139.)

About six o'clock the rain ceased, and we began to think of the day's excursion, in which I hoped to find Meconopsis integrifolia, the plant I had travelled from England to these wilds in quest of. We instructed the soldiers who were with us to go down and commandeer one of the farmhouses a thousand feet below, and get our baggage and sick cook carried down there. Most of the men seemed better, but the cook was neither better nor worse than he was the night before.

This Ya-chia pass enjoys an unenviable reputation, and is much dreaded on account of its violent and asphyxiating winds. It is said to be the only pass in the neighbourhood which "stops people's breath." Seized with faintness, many porters lay down by the roadside, lose heart, and soon die. The Chinese attribute the ill-effects to the presence of malignant demons, against whom it is powerless to fight. I have not the slightest doubt but that our cook would have died had he been left to himself. He had quite lost heart, and would exert himself for nothing. There is indeed something very peculiar about this pass. It is not mere altitude, for I had this same cook with me at much higher elevations, and he was never affected in the same way.

At 7 o'clock we set out for our day's collecting. We were not more than a hundred yards from our hut ere we were again drenched to the skin, but later the sun came out and things improved.

The ascent from the hut to the head of the pass (13,100 feet) is of the easiest. The road lays through a sloping valley, half a mile or so wide, flanked by steep spurs from the snow-clad heights. A considerable torrent flows through the valley, and being much swollen in consequence of last night's heavy rains, fording this torrent was not the simplest of matters. Parts of this valley are heath-like and covered with a dense scrub. Other parts consist of Alpine meadows intersected by numerous streamlets and ponds. These meadows were gay with flowers of every hue, and a right pleasant time we spent among them!

On this side of the pass the tree limit is roughly about 11,000 feet, but trees are very scarce. Around this altitude the vegetation consists largely of scrub, composed chiefly of bushes of evergreen holly-like Oak, 4 to 6 feet high, three species of Spiræa, Berberis spp., Lonicera spp., and a few Rhododendrons. This belt quickly gives way to Rhododendrons, which at 12,000 feet and upwards form dense impenetrable thickets.

It is, however, the Alpine meadows that rivet

and fascinate one's attention. These are carpeted with Anemones, Primulas, Pedicularis, Delphiniums, Gentians, and I know not what besides, each taking unto themselves large areas and transforming them into masses of blue, yellow, white, red, and purple. I wish I had the ability to describe this floral paradise with all its glories, but this is beyond me. All I can do is to enumerate a few of the outstanding features, and leave the rest to the imagination of my readers.

Individually, Primula sikkimensis, Rheum Alexandrae, and Trollius yunnanensis demand a place in the front rank. The Sikkim cowslip is well known to plant-lovers, and I would that these good people could see it as it occurs in these regions. In moist meadows, and by the sides of streams and ponds, it grows in thousands and hundreds of thousands, like the common Cowslip in an English meadow. On many a plant I counted 20 scapes, each with huge umbels, and the air was laden with the soft delicious odour of the flowers. Rheum Alexandrae is in these regions what R. nobile is in Sikkim. Sir Joseph Hooker* thus describes the Sikkim plant: "On the black rocks, the gigantic Rhubarb (Rheum nobile) forms pale pyramidal towers, a yard high, of inflated reflexed bracts, that conceal the flowers, and overlapping one another like tiles, protect them from the wind and rain; a whorl of broad green leaves, edged with red, spreads on the ground at the base of the plants, contrasting with the transparent bracts, which are yellow, margined with pink. This is the handsomest herbaceous plant in Sikkim." This description might well have been written in the valley of the Ya-chia col, so well does it cover the Chinese plant. The differences are mainly in the leaves and bracts, which are longer and much less rounded in the Chinese plant. Whilst I am not prepared to grant to R. Alexandrae the first place amongst the herbs of this region, its right to a foremost place cannot be denied. I have in mind as I write, a sloping mountain-side, somewhat spongy and boggy, with boulders jutting out here and there, whereon grew thousands of these plants with their "pale pyramidal towers." The Chinese name for this plant is "Ma Huang" (Horse Rhubarb); they do not use it medicinally. Let us hope that this Chinese species will prove more amenable to cultivation than its Sikkim congener has hitherto done. Like the last, Trollius yunnanensis is also peculiar to these regions. Imagine Ranunculus cortusaefolius, with small leaves and slightly larger flowers, and you have this plant. This Trollius is essentially a social plant, and to see thousands of plants massed together, one mass of lovely yellow, is to remember it. I have used Franchet's original name for this plant, as I consider it a good species and not merely a variety of T. pumulus, to which he subsequently reduced it.

Pedicularis is the genus *par excellence* of these Alpine meadows. Altogether, about 130 species of Pedicularis are recorded from China, of these fully two-thirds occur in the far west. During the day I gathered 17 fresh species; some of these were prostrate, others a few inches high, others, again, were a foot or more high. All were a mass of flowers, embracing every colour save blue; it is a great pity we cannot cultivate this most charming genus. The difficulty is that all are more or less parasitic—very often on the roots of grasses.

Corydalis is another genus which deserves more than mere passing reference. Some 58 species of this genus have been recorded from China, and fully half of these are found in the west. The majority of the species favour rocky or heathy places. All the cardinal colours, save green, are represented in this genus. A species 4-8 inches high, with lovely deep-blue flowers, is one of the features of the highland flora around the Ya-chia col.

I have already mentioned several species of Primula, and on another occasion I shall have something to say about many other species which abound hereabouts. I must, however, enumerate two species which are very striking constituents of the Ya-chia col flora, viz., Primula involucrata and P. amethystina. Acres of moist grassland were carpeted with the pink flowers of the former, and even larger areas of heath-land with the dark-blue or purple flowers of the latter.

Alongside streams and on the heaths I collected several species of Senecio (Ligularia), some with handsome flowers and foliage. One fluviatile species (S. nelumbiifolius), with huge rounded leaves and large cymose clusters of small yellow flowers was particularly attractive.

Amongst scrub in heathy places the handsome Cypripedium tibeticum occurs in thousands. This species, with its large, dark-red flowers, should prove a valuable addition to the list of hardy Cypripediums. Lilium lophophorum, various species of Anemone, with white, blue, and yellow flowers, many species of Gentiana, and many leguminous herbs and sub-shrubs help to swell the list.

Above 12,000 feet an occasional plant of the medicinal Rhubarb (Rheum officinale) was encountered. This is a handsome and conspicuous plant; its much-branched inflorescence of white flowers is often 7 feet high. On another occasion I met with it in hundreds. This Rhubarb occurs as high up as 14,000 feet, the highest altitude of any tall-growing herb in this neighbourhood. On dry, heathy ground, several typical Tibetan plants are found, such as stemless Composites, various species of Allium, Androsace, Saxifraga; the tiny Ephedra Gerardiana var. sikkimensis, and the pretty Stellera Chamæjasme, with its terminal globular heads of variously coloured flowers. This latter plant grows about a foot high, and is very ornamental.

E. H. Wilson.

(To be continued.)

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Temperatures.—During the spring months the gradual increase in the warmth of the atmosphere out of doors renders it necessary to pay particular attention to the admission of air to the different divisions. The constantly increasing power of the sun is very beneficial to Orchids generally, but when cold, drying winds prevail, with alternative spells of strong sunshine, it becomes almost impossible to maintain anything like regular temperatures in the houses. Even the experienced grower will need to exercise careful judgment to discriminate between the dangers of admitting too much air or too little. The state of the weather outside should be the principal guide, and should be carefully studied by growers. Many of the plants have already re-commenced to grow, therefore large volumes of air, especially if admitted from the roof ventilators, cause a down draught, which is injurious to many tender species. As a guide to the beginner the following remarks may be useful:—The atmospheric temperature of the Odontoglossum or cool house, under the sun's influence, will often rise considerably above 65°, or what is thought to be higher than is necessary for the well-being of the plants. Especially may this happen on bright, cold days when the external air is at or below 40°, and is therefore unsuitable to be allowed in sufficient quantity to keep down the temperature inside, especially when admitted through the top ventilators. On such occasions it is advisable to let down the blinds, and gradually increase the ingress of air through the lowermost ventilators. When the atmosphere outside is congenial and moist, and has a temperature of 50°, ventilate more freely in every department. In the other divisions, when the wind is in a cold quarter and the sun shining brightly, it is also advisable to shade the plants, and to keep up the requisite degrees of warmth by means of the heating apparatus, also to give all the ventilation the weather will permit. On several occasions lately the sun has been rather bright and powerful, and on looking through a small collection of Orchids a few days ago I noted several leaves which have been scorched through flaws in the glass. When this happens the flaw should at once be found, and then thickly daubed with white paint, or a pane of good, clear glass substituted for the faulty one.

Preparations for Re-potting.—During the next few weeks many plants will require to be repotted; therefore a sufficient quantity of peat, turfy loam, &c., should be obtained and made ready for use. Preserve and dry all the Fern rhizomes taken from the peat, as they are useful for drainage purposes. Plenty of sphagnum moss should be got in, and it is advisable to pick out all dead leaves, all particles of grass, and other rubbish. Have plenty of crocks broken up small, and procure a quantity of leaf-soil, and coarse silver sand. Old flower pots that are to be used again should be made scrupulously clean, also any old crocks that may be needed for drainage purpose. Get the loam inside and pull it to pieces, and lay it in a suitable place so as to get warm before it is used.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Chrysanthemums.—These should now be shifted into pots measuring six inches in diameter, and from these be transferred into their "flowering pots" about the middle of May. In consequence of pressure of work in all departments of the garden at this season of the year, it sometimes happens that the repotting is delayed, and there is no plant that sooner suffers from the stunted condition of the roots than the Chrysanthemum when confined in small pots. Make an effort, therefore, to transfer them into larger ones as soon as the plants have filled their pots with roots. Following this operation, let the atmosphere be kept close for a few days to encourage root action, after which period gradually increase the quantity of air admitted, and remove the glass lights when the weather continues fine. Firm potting is necessary in Chrysanthemum culture, inasmuch as it is followed by the production of a greater percentage of fibrous roots and shorter-jointed growth, which will mature perfectly, and flower satisfactorily.

Shading.—In the cultivation of a mixed collection of plants it is difficult to give to each plant a suitable position as to exposure to direct sunshine or shade. A fixed shading is not desirable where flowering plants are concerned; there is a marked improvement in the substance and colour of the flowers of Allamandas, Bougainvilleas, Ixoras, Dipladenias, and Gloriosas, when grown in sunshine. By a little careful study in arrangement, many plants can be so placed as to have their peculiar requirements fulfilled even in the same compartment. There are many beautiful stove flowering plants such as Eucharis, Anthuriums, and Gloxinias, which require partial shade, and if exposed to the direct influences of sunshine, the evaporation of moisture from the leaves would be too great, and would ultimately change their colour to a pale shade, through loss of chlorophyll. It is, therefore, necessary to syringe frequently such plants as are growing under the influences of sunshine, but in the case of plants which are heavily shaded, evaporation being slower, less syringing is necessary. Roller blinds should be fixed, to be in readiness when required for use.

General Remarks.—Increase the atmospheric moisture in the stove and intermediate house. Moderate the fires on bright mornings and thus economise the fuel—remembering that plants do not improve in growth when subjected to much heat from the hot-water pipes when the sun's rays are shining on the roof glass at the same time. Continue to pot off from the seed pans young plants of Cyclamen. Keep a sharp look-out for insect pests on Pelargoniums, Calceolarias, and Cinerarias, and take care to admit plenty of air to the Cinerarias.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Cucumbers.—Plants which were raised early in the year, and are now bearing fruit, should be afforded frequent top-dressings, applying these as soon as the roots appear on the surface, and using two parts loam, one part leaf-soil and one part horse manure. Such young plants should only be allowed to develop as many fruits as are really

required, for if over cropped in the early stages, exhaustion will soon follow. Continue to pinch the shoots, and each day regulate all the young growths in such a manner that they may cover the trellis-work quickly. Now that the days are longer, and the amount of sun-heat is increasing, the plants may be lightly syringed over three or four times each day. Red spider can be prevented by syringing the plants occasionally with water containing a small quantity of soft soap and sulphur, and this will be also a good remedy for mildew. Close the house early in the afternoons, and syringe the plants in order to secure ample atmospheric moisture. Let the roots be fed liberally with diluted cow-manure water. Where there is only limited house-room, preparations should be made for cultivating Cucumbers in frames. Excellent crops can be grown in this way at a very small cost and trouble. Make up a hot-bed of leaves and long litter, place a two-light frame over it, and put in each light a mound of rich, turfy soil. When the bottom heat is at 80° and not rising, the young Cucumber plants can be safely planted, shading them from sunshine for a few days until they have become established.

Figs.—The earliest batch are now in flower, and there will be very little progress in the swelling of the "fruits" until that stage is passed. Maintain a steady temperature at night of 60°, and allow a rise to 75° during the day. Do not allow the trees to get dry at the roots, or many of the fruits will fall from the branches. When extra large Figs are desired, only one or two should be left on each bearing shoot, but do not remove all the others at one time, it being better to take away a few each day, as Fig trees are very subject to bleeding. Stop the shoots at the fifth leaf, and cut out any weakly growths. Afford liberal ventilation when the weather is favourable. Keep a sharp look-out for red spider, and, if this pest is discovered, sponge the leaves with a solution of soft soap or Gishurst compound made very weak.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Sweet Peas.—The present is a good time to sow seeds of these beautiful and deservedly popular flowers. It is unnecessary to attempt an enumeration of the best varieties in this short note, but the cultivator will be wise to restrict himself to a few varieties, and those of the very best and most distinct colouring. It is better to sow the seeds singly in 2½-inch pots, placing the pots in boxes to facilitate handling rather than to sow them in their flowering quarters. If germinated in a little heat the seedlings can be immediately removed to cold frames, and before the plants are anything like root-bound, or drawn, they should be planted out in the ground previously prepared for them. Six inches apart in a single row is quite close enough distance to plant. In doing this they should be placed well into the soil, covering the stem, and pressing with the feet all round to make them perfectly firm. When 3 or 4 inches in height they must be supported with stakes in the manner preferred by the cultivator. By removing the newly-formed seed pods, incessantly cutting the blooms, and by affording plentiful supplies of water during dry weather, the natural flowering period of the Sweet Pea can be much extended. The advantage of sowing in pots is that the plants, being raised in frames, are to a great extent exempt from the attacks of birds and slugs. A more satisfactory growth is thus obtained, and no gaps in the border are left unfilled.

Callistephus hortensis.—The China Asters are amongst our best half-hardy annuals for making the flower garden bright and gay during the summer and autumn months, and of them all none surpasses Callistephus hortensis—more often catalogued as sinensis—for beauty and usefulness. It can be obtained in distinct colours of dark blue, mauve, pink, and white. The flowers are large and single, and in a cut state are invaluable for bold decoration in vases. The plant itself is of bold habit, attains a height of 2 feet, and is admirably adapted for using as an autumn bedder. The seed of all the China Asters can be sown at the present time in shallow boxes in a slight heat, or in a frame having a very little bottom heat.

The Ten-week Stock is another delightful half-hardy annual, which is much admired because of its fragrance and its varied colouring. A week or a fortnight hence will be time enough to sow the seeds either in shallow boxes or in a cool frame. Care should be taken to ensure the plants making sturdy growth, by placing them near to the glass. If, instead of pricking them into boxes as a final shift, the seedlings are potted up singly, so that transplanting into the open ground may be done without the roots being disturbed, the extra trouble will be recompensed by better results.

Delphinium "Queen of the Blues," though a perennial, is best treated as a half-hardy annual. If sown now in heat it can be had in flower by the end of June. Too much cannot be said in praise of this lovely plant, either for use in the mixed border or as a bedder. In masses it is most effective. Its habit is dwarf, hardly exceeding 18 inches in height, and the colour of its flowers is a clear intense blue—a colour so rare but so desirable in flowers. D. "Porcelain Blue" is similar to the above, but its flowers are of a lighter shade, yet very attractive.

Other half-hardy annuals to be sown at the present time are Alonsoa, Arctotis, Browallia, Cosmea, Helichrysum, Marigold, Mesembryanthemum, Petunia, Rhodanthe, Schizanthus, Scabiosa, and also Abronia, Antirrhinum, and Gaillardia, which can be treated as half-hardy annuals.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Peaches and Nectarines.—Proceed with the training of these and get the work done before the buds commence to open. Leave plenty of space for subsequent growths to be nailed in properly, and do not hesitate to cut away the worst shoots wherever any thinning may be necessary. In pruning take care to cut to a wood bud, for it will be noticed that a fruit will drop, even after setting, if there is no growth beyond it. When pruning has been finished clean over the surface of the border and put the labels into good condition and suitable positions. Means for protecting the blossom should be provided. If blinds are used, these should be at once erected and made ready, and when once they have been drawn down at night they should be drawn every succeeding night until danger from frost has passed. A double thickness of fish netting is sometimes put over the trees by means of straining it over long poles. These should be fixed at the top and bottom in order to prevent the covering from getting entangled in the branches, and the poles should be put at least 3 feet or even 4 feet from the wall at the base, and it will then be possible to walk under the net and examine the trees.

Apricot Trees.—Means for protecting the blossom should be got ready at once, just as in the case of Peaches and Nectarines.

Early Pears.—Trees showing flower may have some netting thrown over them, for this will shield them from several degrees of frost. Clapp's Favourite is one of the earliest varieties to flower with us.

Labelling.—Attend to the labels on all fruit trees. If very many are required the "Acme" is one of the best, and when fastened on the tree by means of copper wire will last for a long time. If they become disfigured or dirty they may easily be cleansed by washing them with paraffin. Suspend them on the branches in a position easily seen when used for bush or pyramid trees, but in the case of wall-trees they should be nailed to the wall. The "Ideal" label for fixing at the base of wall-trees has a very good appearance, and affords pleasure to visitors to the fruit garden.

Mulching.—When the trees against the wall have been put in proper condition for the season rake over the surface of the border, and either supply a mulch of long manure or a good thickness of coal ashes. These latter serve as a good mulch, and are easy to keep clean during the summer. A four-foot path under the wall should always be left clear of crops.

Late-planted Strawberries.—Hoe over the surface of the ground between the rows on a fine day. Strawberries may still be planted from store-pots. Apply a mulch to older plantations if this has not already been done.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Ridges for Celery.—One great advantage in having these ridges made early is that it permits the use of the tops of them for the cultivation of dwarf Peas, French Beans, or Lettuces. If the seeds of these be sown as early as possible, the crops will mature before the soil is required for earthing up the Celery. In clayey land it is a mistake to make the trenches very deep, because the roots of the Celery are then in a colder medium than would otherwise be the case. For general purposes, two lines of Celery can be conveniently grown in one trench, thus economising space over the single-line system. A trench 2 feet in width is ample for two lines, and there is no need to make it more than 1 foot in depth. Six inches of well-rotted cow manure, or the same amount of decayed vegetable refuse, will be sufficient manure for the crop. If the bottom soil is good this can be dug into it, but if not then it is better to dig the bottom of the trench before adding the layer of manure, and finishing off on the top with 6 inches of soil.

Sowing the Seeds.—The main crop must now be sown indoors, according to previous directions. When the seedlings commence to show the rough leaf, the plants will not require more than an intermediate temperature. Guard them from suffering the least check to growth from the first, and they will then be less likely to run prematurely to seed. Seed of Celeriac should also be sown and treated in the same way as far as the first stages of growth are concerned. A successional sowing may be made where the crop is to mature, and although the roots will hardly be so large, they will become of a serviceable size.

Vegetables in Frames.—Young crops, such as Turnips, Carrots, Globe Beet, &c., will require prompt thinning, although there is no need to thin severely, as these roots will be used small and in quantity. Ventilation must be afforded with extra care during the present month. A moderate damping down early in the afternoons will be conducive to quick growth. Potatos will need earthing up, and if the haulms are inclined to topple over, let them have the support of a short stake. A few well-sprouted tubers may still be planted to yield new tubers before a crop will be ready in the open. Seedling Cauliflowers and Cabbages, growing in frames, may be given a fresh supply of water, and more air, as they continue to increase in size. Let little batches of Lettuces, and also the Turnip-rooted and long Radishes be planted to meet the requirements of the near future. Peas that were sown in December should now be showing their first flowers. Syringe them heavily in the afternoon of sunny days. Among a number of varieties that were sown here at the period mentioned, Early Giant is the first to show its blossoms, but I expect some of the dwarfer varieties will overtake it, as they usually fill their pods more quickly.

THE APIARY.

By Chloris.

Spring Notes.—In looking through a file of local papers a few days ago, I saw recorded that a very early swarm of bees had been taken during the first few days of March, and this was regarded as wonderful luck. As the winter has been unusually mild we may hear of other early "takes," for these swarms, so called, have only turned out because there is an empty cupboard. No brood, queen cells, &c., would be found if the hive from which the bees had emerged were examined, as is the case during the swarming period. Those who desire a good store in the supers of honey from the fruit bloom should commence feeding with syrup, and all hives should be well examined when the weather permits to make sure that their inmates have plenty of food, and to spare. Keep a good supply of quilts on the frames, taking care that the corners are filled, so that no leakage of heat may take place. Remember that those bees are on the wing most that need food, and often during very unsuitable weather. There is no economy in keeping bees on the border of starvation. Commence the year well by taking time to examine the contents of the bee home. Last year a friend of mine, who always does things in a hurry, especially bee work, lost several queens, and such loss at this season is almost irreparable; at the least, much time is lost, which can be ill-spared. Remember then to do the work leisurely, thoroughly, and above all gently. Nothing in bee-keeping pays so well as gentleness in handling.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c. but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	Mar. 20	Roy. Hort. Soc. Coms. meet.
WEDNESDAY,	Mar. 21	Roy. Bot. Soc. Show, Regent's Park.
THURSDAY,	Mar. 22	Exhibition of Colonial-grown fruit at the Roy. Hort. Soc. Hall, Vincent Square, Westminster (3 days.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—43·2°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, March* 14 (6 P.M.): Max. 44°; Min. 30°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 15 (10 A.M.): Bar., 29.9; Temp., 53°; *Weather*—Overcast.

PROVINCES.—*Wednesday, March* 14 (6 P.M.): Max. 50° Ireland S.W.; Min. 32° Scotland N.E.

SALES.

MONDAY—
Hardy Border Plants, Perennials, Lilies, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—
Herbaceous and other plants, Liliums, Hardy bulbs and plants, &c., at 12.
4,000 Roses, at 1 and 3, followed by Palms and Plants, Azaleas, &c., at 67 and 68, Cheapside, by Protheroe & Morris.

WEDNESDAY—
Roses, Shrubs, Palms, Lilies, &c., at Steven's Rooms, King Street, Covent Garden, W.C.

THURSDAY—
Unreserved Sale of Duplicates from the well-known "Rosslyn" collection of Orchids, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Unreserved Sale of Duplicates from the "Bank House" collection of Orchids, 1,000 Cypripedium Fairrieanum, 6,000 Odontoglossum crispum, Cypripedium, Lælio-Cattleya, and Cattleya Hybrids, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

Examinations in Horticulture.

The letter from Mr. Watson, published in a recent issue, has elicited many more letters than we could publish even were it desirable to do so. Speaking generally it appears as if the writers looked on one side of the question only and are disappointed because the results are not such as they hoped for. A little reflection would show them that such consequences as they seem to expect are unattainable by any method of examination. If we do not misinterpret their views, they seem to think that experience can be gained, or even tested, in the examination-room, at least they write as if that were their opinion. A lad has had the advantage, we will say, of attending lectures and demonstrations; perhaps he has had to work for a short period under a competent instructor; he passes the examination in such a way as to satisfy the examiners—a few pass with distinction. But supposing these things to have happened, what guarantee can they possibly afford of a man's practical ability? Little or none. What they do show is that the man has made the endeavour to equip himself with a certain amount of knowledge. That knowledge by itself is a means, not an end. A child learns the alphabet not for the mere sake of knowing letter A from letter B, but for the purpose of turning this knowledge to account in the business of life. If he is unable or unwilling to do this, his knowledge of the alphabet can be of no service to him or any one else.

So the garden-student in the examination room is expected to have acquired at least a rudimentary acquaintance with the structure of plants, of the work they do, and of the conditions under which they do it. No one, we should have thought, would have questioned the supreme value of such knowledge properly applied. But to our astonishment some writers, holding high places in the fraternity and for whose opinions in general we have the highest respect, write that their experience of these "highly-certificated and college-trained individuals" is anything but satisfactory. We have often heard similar expressions of opinion from nurserymen and others who want cheap labour, and are only concerned with the progress of horticulture in so far as it contributes to their commercial prosperity. We have always thought that such opinions were the result of that imperfect appreciation of what it is reasonable to expect from an examination, to which we have already alluded. The writers from whose letters we quote speak of "college-trained" lads proving unsatisfactory. Is that not an evidence that, however highly certificated the pupils may have been, they have *not* been trained? That, surely, is a defect not to be credited to the examination or to the examiners. The training has to come after. Doctors have, in their student days, to attend all sorts of lectures, but it is not until they have been well grounded in the principles of their science that, under the guidance of their seniors, they undergo actual practical training in their art in the hospital wards. But even after two or three years' work in the lecture room and laboratory, followed by as many more passed in applying the knowledge they have obtained there, they still lack that most valuable degree of experience which comes only to a man when he is left to his own resources. Surely the same remarks apply to a young gardener.

We have been told of a gardener entrusted with the collection and labelling of hardy plants who is most efficient, and never puts a plant behind a wrong label, though he can neither read nor write, and cannot even sign his own name! If this be the type of man required in a garden, we shall despair of the attempt now being made by the British Gardeners' Association to improve the condition of gardeners, to raise the profession to a higher level, and to secure to the practitioner a higher reward for his services. If we are to remain hewers of wood and drawers of water, why, then, let us not be troubled with examinations, let us not repine at our lot or yearn for more ample recognition. We are worth what we get, and no more. But, if we are concerned in the advance of horticulture, if we want to be better practitioners than our fathers, owing to their lack of the advantages we possess, could have been, then, by all means, let us give our young gardeners the opportunity of being able not only to appreciate, but to turn to practical account, the resources which advancing science is always placing at our disposal, if only we could, or would, make use of them.

It was our experience on one occasion to have to examine several candidates for a public appointment. The examination was partly written, partly oral. One of the candidates whom we had reason to believe was a good all-round practical gardener appeared in due course at the table for his oral examination. The table was strewn with plants, seedlings, grafts, fruits, vegetables, and the like, which formed the subjects on which the candidate was questioned. These things were what the man must have been in the habit of handling in his daily work for several years. Nevertheless, his answers were extremely unsatisfactory, till at last, wearied by the negative results obtained by previous attempts to elicit information, a question was asked concerning the difference, from a cultural point of view, between a Cauliflower and a Broccoli? Still no answer. It was then suggested by the examiner that the one was hardier than the other. "Yes," was the reply, "didn't you know that!" We have forgotten the result, but we expect the questionings were put an end to as soon as possible. The examinee in this case was a practical gardener of middle age and much experience, but utterly unable to express his ideas in an examination-room. We hardly think this was the fault of the examination system, although it is true the examiner failed in his attempt to make manifest the qualifications he had other reasons for believing the candidate to possess.

We were reminded of this circumstance by reading the annexed report of the examiners told off in January last by the Royal Horticultural Society to conduct the examination:—

"Examination of Men employed in Public Parks and Gardens.

"The examination was partly written and partly *viva voce*, and occupied three hours and 20 minutes in all. . . . .

"Ninety candidates entered their names, and of these only one was absent. . . . .

"Speaking generally, the answers, both written and *viva voce*, revealed a distinctly remarkable absence of observation and thought, combined with by no means too high a degree of ordinary education. Most of the candidates appeared to possess a rough and elementary knowledge of the subjects inquired of, but were unable to give expression to their ideas in coherent and intelligent language. This may be accounted for perhaps by the fact that it was, to the great majority, their first experience of an examination, and many of them showed evidence of a quite unnecessary degree of nervousness.

"The examiners have given credit wherever possible for good intentions, and regret that, even so, they are unable to include more names in the class list.

"The examiners desire to impress on the candidates the absolute necessity of observation as they pursue their daily work, and the application of thought as to the why and the wherefore of what they do and what they notice. A man can never be really fit for high place in any calling in life unless he both thinks and observes. Rules are good, but only so long as they lead to the inquiry as to why in each case they should be followed, and what effect they are intended to produce.

"The examiners urge the unsuccessful candidates not to be disheartened by failure in their first attempt, but to set themselves carefully to observe the things about them, and to think out for themselves the reasons of their different operations. Twelve months of this, coupled with inquiry from their superiors on points which seem difficult to fathom, will probably result in their success at the next or at some subsequent examination.

"William Crump, C. R. Fielder, Geo. Nicholson, Owen Thomas, Edward White, W. Wilks, *Examiners*."

Could a better set of examiners have been found?

We may compare the state of things here revealed with our knowledge of certain "college-trained" gardeners in Belgium and

France. One such case is before us now—that of a highly-trained youth speaking and writing fluently French, German, English, and probably Flemish. It has not been our lot to meet with many, if any, young English gardeners of corresponding position who could speak any language but their own, and this is by no means a solitary instance. But then we have been often told that young men of this type when tried here are found to be failures so far as practical work is concerned. We suspect, as we have said, that some employers do not want high-class labour. At any rate, we know that many of these young men are now filling with ability responsible positions at home and abroad, which they could hardly do were their practical training as deficient as it is sometimes assumed to be.

The examination system should serve as one method of raising the gardening profession in the eyes of the employers, and thus benefit the employed. If it does not do this effectively, some means must be taken of making it do so. At any rate, let us not depreciate any honest attempt to raise the intellectual and social condition of the gardener, such as is being made, not only by examiners, but by the British Gardeners' Association.

Our Supplementary Illustration.—The unpretentious looking building now known as Kew Palace has associations with royalty that give it a special interest. It is also "a good characteristic example of old English architecture." Built in the latter part of the 17th century by Sir Hugh Portman, a "Dutch merchant," it was in his time known as the "Dutch House." In 1730 it was leased by Queen Caroline, wife of George II., "when she began her alterations and works in Richmond Park and the gardens of Richmond Lodge," and was afterwards the residence of Frederick Prince of Wales. After his death his widow occupied it "while engaged in laying out and extending her famous exotic gardens—the origin of the present world-renowned Kew Gardens." In 1781 Queen Charlotte acquired it and used it as a sort of nursery for her children. She and the King preferred Kew to Hampton Court, living there with their family "as the simplest country gentlefolks." At that time the public were admitted to Kew Gardens on Thursdays only, when the green was crowded with carriages, and parties came by the river with bands of music to the ait opposite the Palace. When the King, George III., became of weak mind he was domiciled at Kew, where he spent his sane spells in improving the grounds at Kew, and in farming at Richmond and Mortlake. Queen Charlotte died in 1818, and from this time forward Kew Palace remained uninhabited until the year 1898, when the late Queen Victoria decided that in commemoration of her Diamond Jubilee it should be open to the public as a show place. It is now open on every day except Fridays. The rooms contain pictures and other objects of art and interest, mostly relics of royalty. *A Guide* to the Palace* and its contents, with a catalogue of the pictures, is on sale in the Palace. Until a few months ago the view of the Palace from the gardens was spoilt by the old Royal stables and yard, which were partially screened by trees. Trees, stables, and yard have now been swept away, the result being a great improvement, as will be seen from the photographic view taken from the Broad Walk. The view from the Principal Entrance on Kew Green suffers at present from a ladies' cloak room which is partly hidden by shrubs, but we understand that this will shortly be removed.

* We are indebted to this Guide for some of the particulars here given.

Royal Horticultural Society.—The next meeting of the committees will be held on Tuesday, March 20, in the Society's hall, Vincent Square, Westminster. The Narcissus Committee will meet on this occasion. A lecture on "Parasites and Saprophytes among Flowering Plants," illustrated by lantern slides, will be given by the Rev. Prof. G. Henslow, M.A., V.M.H., at 3 o'clock. The exhibition of Colonial-grown Fruit and Vegetables, both fresh and preserved, will be held, as already announced, in the Society's hall, on Thursday, Friday, and Saturday, March 22, 23, and 24. The exhibition will be opened at 1 o'clock on March 22, and at 10 a.m. on the two following days.

Scientific Committee.—We learn with great pleasure that Mr. Charles C. Hurst has kindly consented to give a simple statement of the Mendelian Laws of Inheritance before the Scientific Committee of the Royal Horticultural Society at the next meeting on March 20, 1906. Mr. Hurst will illustrate his remarks by means of specimens, and will show how the laws affect the practice of hybridisation. Fellows who are not members of the committee, but who are desirous of attending the meeting, should communicate their wishes to the acting president or secretary of the committee.

Small Holdings.—The Departmental Committee appointed by the President of the Board of Agriculture and Fisheries to enquire into the subject of Small Holdings held a sitting on March 7. Evidence was given by Mr. H. Rider Haggard.

Nature-Printed Postcards.—The Country Press, of 19, Ball Street, Kensington, are issuing a very pretty series of postcards showing British Ferns, nature-printed on a black background. These pictures (seven cards representing 42 species) are from the plates of Mr. Francis Heath's book, *The Fern Paradise*. We understand that these cards will be succeeded by others representing various natural history subjects. It is mentioned that the pictures have an educational value, but this is greatly lessened by the facts that only the popular, not the scientific, names of the subjects mentioned are given, and that only single fronds of the Ferns shown with no allusion to size or habit or details of fructification.

Irish Gardening.—With so many distinguished gardeners and so many interesting gardens, both private and professional, it has been a matter of surprise to us that Ireland should not long since have had its gardening journal. That deficiency is now to be supplied. We have before us the first number of "*Irish Gardening*, a monthly educational journal devoted to the advancement of horticulture in Ireland." For some time past the need of such a journal has been felt, especially by those who are directly concerned in the work of horticultural instruction in the counties. The proposed "monthly" is issued at the repeated request of the entire body of county instructors in horticulture who have individually volunteered to take an active part in its production and circulation. *Irish Gardening* will be an educational journal appealing to all classes of the community interested in the cultivation of plants, either for purposes of profit or for the beautification of Irish homes. In addition to seasonable cultural directions for fruit, vegetable, shrub and flower cultivation, a feature will be made of short articles in clear, non-technical language upon the scientific principles underlying good garden practice, contributed by authoritative writers on the subjects chosen. Special attention will be given to the review of current horticultural literature, and to works on botany and entomology and other sciences bearing upon garden work. Arrangements for a monthly series of papers on seasonal operations are being made. The periodical is well printed on good paper, and freely illustrated, and its cost is placed at such a low rate that we earnestly hope the aspirations of its founders will be well supported by the public. The articles, as might have been anticipated from the assistance rendered by the horticultural instructors, are of a high class, and destined to be of permanent value. After a "send-off" of an appreciative character from Sir Horace Plunkett, we find an article by Mr. F. Moore on the condition of Horticulture in Ireland. The article is written in an optimistic tone, and is accompanied by a portrait of the writer. What the better class Irish gardens and nurseries are our readers have frequent opportunities of judging, but they are not so conversant with the good work which is being done by the horticultural instructors. Following the example set by Belgium, these gentlemen are conferring substantial benefits on the rural population by their lectures, and still more by their demonstrations. There seems to be no reason why the practice of profitable gardening should not be carried out on a large scale in Ireland to the great advantage of the community. Every effort to that end will meet with sympathy on this side of the Channel, and for that reason we cordially wish all success to *Irish Gardening*.

Narcissus "Poetaz."—This name applies to a race derived by crossing N. poeticus and N. Tazetta. The *Revue Horticole* speaks of the race as having more of the general characters of the Tazetta group, but as being more hardy and with fewer flowers to a truss than in N. Tazetta. The flowers are larger than those of Tazetta, and the cup is almost exactly like that of poeticus.

Florist's Business in the Rocky Mountains.—At present in our own establishment in Denver, says a writer in the *American Florist*, we have ledger accounts with more than a thousand people scattered over all the mountain country. There is hardly a day in the year that we do not send retail orders to places from 300 to 500 miles distant; and on holidays, especially before Memorial Day, these express packages go out literally by the wagon-load. Often these orders come in by telephone from some mining camp hundreds of miles away on the opposite side of the mountains. We must be in a position to know, as far as possible, the financial standing of the people scattered over this wide area, and keep the information so readily accessible that we can look up a man's credit while he holds the long-distance telephone at so much per minute. This is made possible by index cards which show at a glance what experience, if any, we have had, and also the reports as to credit received from other sources.

Peaches and Nectarines.—Writing in the *Revue Horticole* for March 1, M. Charles Baltet puts on record some facts which ought to be interesting to students of Mendelism. The Nectarine called Lily Baltet, of which a figure is given, is a "free stone" variety, of which the parentage is as follows:—In 1884 a stone of Amsden Peach was sown. Three years after the seedling produced fruits—Nectarines—which ripened in the first fortnight of August; that is to say, earlier than other Nectarines. This variety was put into commerce under the name of Précoce de Cronceels, and received commendation as the largest and earliest Nectarine. In 1890 kernels of Précoce de Cronceels were sown, and ultimately produced fruits which were all Nectarines, some "cling stones," others "free stones." Among them was found one which ripened a little earlier than the rest, and which had a smaller stone. This variety was propagated and sent out under the name of Lily Baltet, which also won the suffrages of the electors. In 1896 M. Charles Ingouf in his turn sowed kernels of Lily Baltet. Seedlings were produced, grafted in 1899, and ripened fruits three years later. Some of this last batch—all originating from the same source—proved to be Peaches, others Nectarines. These are still under

observation, but one of the Peaches has proved so distinct that it has been named Charles Ingouf. It is described as having fruits larger than the early American varieties, in colour carmine-red on a cream-coloured ground, and with shorter down, so that the fruits do not require the application of the brush to remove some of the down, as is demanded for market purposes in France. It ripens between Amsden and Hales' Early; that is, after the first earlies and before the second earlies, thus filling up an interval which is inconvenient to growers, dealers, and consumers. In fine, we have here examples not only of the development of Peaches and Nectarines on the same branch, but also of the production of Peaches alternately with Nectarines from seed. Peaches and Nectarines seem, therefore, to be good subjects for the students of Mendelism to investigate.

The Supply of Nitrogen to Plants.—We have received from Mr. T. Jamieson, the Director of the Aberdeen Research Association, a report in which he claims to have discovered that all plants can feed upon the free nitrogen gas of the atmosphere by the agency of the hairs that are found upon the leaves. The "proof" of this remarkable discovery appears to be as follows:—The hairs, empty at first, show, as the plant develops, a little "albumen" (i.e., nitrogen-containing material) near their tips, which increases in amount, and gradually extends further down the hair to its base. Later on, when the leaf ceases its activity, this albumen is withdrawn, and the hair becomes again empty. From this fact alone Mr. Jamieson concludes that the hairs manufacture the albumen he finds in their tips from the air and then pass it on to the plant. Mr. Jamieson makes no attempt to show by analysis that his plants have "fixed" any nitrogen whatever during their growth. He dismisses the whole mass of work that has been done on this subject during the last sixty years merely because he misinterprets certain facts of a type familiar to any physiological botanist. In an earlier chapter he disposes to his own satisfaction of the theory that leguminous plants fix nitrogen by the agency of the bacteria living in the nodules in their roots. As Mr. Jamieson begins by denying the existence of these bacteria, further argument becomes hopeless. The whole report derives whatever importance it may possess from the fact that its author is backed by a large and distinguished body of gentlemen in Aberdeen, and receives a subsidy from the Board of Agriculture, and that, further, on the strength of his "discovery," he is giving advice to practical farmers to alter the character of their cropping and manuring.

Tomatos.—From the results of numerous experiments made on the growth of Tomatos under glass by the authorities of the Massachusetts Agricultural College, it appears that "undoubtedly the best system of growing greenhouse Tomatos is to plant 12 to 16 inches apart in the rows, prune to the one stem system, and head in or cut back the leaders above the fourth or sixth cluster of fruit, as circumstances require. The physiological effects of pruning or mutilating manifest themselves at first in the retardation or cessation of the growth activities, which are eventually followed by an accelerated growth. The degree of response is determined by the nature of the organs mutilated and the extent of the injury."

Manuring Potatos.—Under the superintendence of the Midland Agricultural and Dairy Institute, field-trials on the manuring of Potatos have been carried out at seven centres; three in Nottinghamshire, two in Derbyshire and one on the Institute Farm at Kingston, Nottingham. The objects of these trials were three; the first and greatest to demonstrate that the best crop of Potatos is to be obtained by the use of a moderate dressing of farmyard manure supplemented by artificial manures, rather than by a heavy dressing of farmyard manure alone; the second object was to find out the most suitable artificial manures to be so used; and the third to attempt to illustrate the fact that farmers ought not to purchase "compound manures," but should blend for themselves whatever manurial constituents their crops may specially require. The correctness of two of the aims was instructively demonstrated by the average results—namely, the advisability of applying smaller dressings of farmyard manure supplemented by artificials rather than a large dressing of farmyard manure alone; and, further, that a decided advantage is gained by discarding "compound manures" and becoming one's own blender.

The Greenwich Ratepayers' Association have recently adopted a resolution expressing appreciation of the services rendered to the public in the development and beautifying of Greenwich Park by the present superintendent, Mr. Marlow, and strongly urging upon H.M. First Commissioner of Works the desirability of establishing winter gardens in the park.

Marriage of Miss Paul.—On March 10, at the parish church, Cheshunt, by the Rev. Folliott Sandford Keysell, M.A., Vicar of Weedon, brother of the bridegroom, Miss Edith Jean Paul, daughter of Mr. George Paul, J.P., of Nursery House, Cheshunt, was married to Mr. Francis Olney Keysell, eldest son of the late Francis Price Keysell, of Grove House, Cheshunt.

Publications Received.—From the Board of Agriculture and Fisheries: *Agricultural Returns, 1905. (Produce of Crops.)* Tables showing the total produce and yield per acre of the principal crops in each County of Great Britain, with Summaries for the United Kingdom.—From the Royal Gardens, Kew: *Bulletin of Miscellaneous Information;* 1906. Contents: Decades Kewensis, XXXVI.-XL.; Diagnoses Africanæ XIV., New Orchids, 26.—*Bulletin of Miscellaneous Information;* October-December, 1901. Contents: Ground-nut or Pea-nut, Miscellaneous Notes, Title-page, Contents, and Index to Volume.—*Grass:* Pamphlet on the making and maintenance of Golf Courses, Lawns, and other Grassy grounds. From James Carter & Co., High Holborn.—*The Garden City;* Official Organ of the Garden City Association; March. A record of progress.—*Thirty-Seventh Annual Report of the Fruit-Growers' Association of Ontario;* 1905. The year was one of fair crops and good prices, as the reports from various districts show.—From the U.S. Department of Agriculture, Division of Entomology, Bulletin No. 55. *The Rearing of Queen Bees:* by E. F. Phillips, Ph.D.—*The Forest Flora of New South Wales.* Vol. II.; Part 9 of Mr. J. H. Maiden's useful work deals with Flindersia Oxleyana, the Yellow-wood, Eucalyptus dives, or Broad-leaved Peppermint, and Casuarina Luehmanni, or the Bull Oak.

NURSERY NOTES.

THE CARLISLE NURSERY.

The Nursery of Messrs. Little and Ballantyne at Carlisle is one of the best-known establishments of a similar character in this country. Particularly devoted to the cultivation of trees and shrubs, it has many features in common with those of the best Scotch nurseries, where coniferous and other forest trees are raised from seeds in such quantities as are seldom or never seen in the more southern counties. Messrs. Little and Ballantyne's new offices and seed establishment are situated close to the Carlisle railway station, but the nursery at Knowefield is further afield, though within walking distance, being within one mile from the centre of the city. Electric cars run from this point almost to the nursery. It is an old-established business, having been founded in 1812 by Messrs. Hutton. It was purchased from Messrs. Little and Ballantyne in 1871 by the present proprietor, Mr. James Watt, J.P., who has now associated with him his two sons, while he has retained the names of his predecessors as the title of the firm. Very much has been done in the thirty-five years that have since elapsed to develop both the nursery and seed business, and Mr. Watt might point to the offices and to the nursery as instances in which radical improvements and extensions have been effected. The firm have in their own occupation and worked by them over 1,000 acres of land: 250 acres of this area is at or near Knowefield.

The entrance to the nursery is by a well-kept drive one quarter of a mile long, on either side of which are trees and shrubs of an ornamental nature. Many of these are stock plants of particular varieties, from which cuttings, buds, and grafts are obtained for use in propagation. Among Conifers we noticed an interesting specimen of Pinus Balfouriana about 15 feet in height, said to be one of the largest of this species in the country. Also a very distinct form of Cupressus Lawsoniana, of markedly spreading habit; Abies excelsa clanbrassiliana, suitable for cultivation on rockeries, owing to its extremely dwarf-growing character; and A. inverta, only 3 feet in height, but so unmistakably "weeping" that it, too, is among those species that may be grown among rocks or stonework and its effect be in keeping with the surroundings. Thuya dolabrata, Cryptomeria japonica var. spiralis, and Cupressus Lawsoniana lutea were all interesting in this portion of the nursery, the latter variety on account of the unusually good colour it had developed. In the portions of the nursery that may be described as the growing quarters, large breadths of almost every forest and ornamental tree may be seen. English Yews are grown remarkably well, and there were thousands of newly transplanted specimens that appeared in the best condition at the commencement of the winter. Of the number of Larches grown it is almost impossible to give numbers, for there appeared to be many millions. To those who are not familiar with the routine of raising forest trees, it may be of interest to know that Larch seeds are sown in May, in beds, and a few of those that make the most growth are transplanted after the first season. But only the "top growths," as they are termed, are thus treated, and the beds remain until the following season, when the remaining plants, having had more room, and another season's growth, are also transplanted. The Japanese Larch seems to find special favour in the Carlisle establishment, as many as two millions being raised this year alone. We were told that this species practically came unscathed through frosts which have proved disastrous to the European species. It grows more quickly, and if the plant or tree loses its leader it quickly forms another, which the European species rarely does.

Immense numbers of Corsican, Austrian, and Scotch Pines, also Spruce in its different varieties, attracted our attention, all being remarkable for their clean and strong growth. Some were what are known as "two year two" or "two × two" plants, which means that they were in the seed bed for two years, and have since been transplanted for an equal period, being four years old. "Two × one" would mean two years in the seed bed and one year transplanted. The Corsican Pine has to be handled skilfully, for it is not the easiest species to transplant successfully, but if the operation is done when the conditions of the weather are suitable and at the correct time the result is satisfactory. It is worthy of remark that the Scotch Pine, though the commonest species, has been in greater demand during the past year or two than the supply of good plants has satisfied, and the stock we saw at Carlisle was therefore regarded with satisfac-

tion by the owners. We were told that the cones are bought from the Highlands of Scotland, and are treated in a kiln, specially used for the purpose by their own staff, where a dry atmosphere of a temperature at about 65° causes the scales to separate and seeds to become liberated.

Many of the choice varieties of Conifers, of course, have to be propagated by grafting, and an inspection of these plants, and of young stock of various kinds, in low pits, the sides of which were built of turf, was very interesting. The turf walls, being non-conducting, are looked upon with more favour than the material usually employed. Near by were young plants of Cupressus Lawsoniana Knowefieldensis glauca, for which a certificate was obtained in September last at the International Horticultural Show in Edinburgh. Some golden Yews were admirable examples of this highly decorative shrub, both in the English and Irish varieties. Of very many other trees and shrubs we saw, but of which specific mention cannot now be made, was a fine stock of seedling Oaks.

Roses are an important feature of the nursery, and about 40,000 to 50,000 plants are budded each year, in addition to the standards. There is a good stock of hardy fruit trees of the popular varieties, especially of such as succeed best in the North of England. The firm will distribute a new variety of Strawberry during the coming autumn. It is named "Bountiful," and is described as from a cross between Sir Joseph Paxton and Viscomtesse Hericart de Thury. It is recommended as an excellent main-crop Strawberry, and from the description we were given of its cropping qualities the variety may be expected to become very popular.

The glass houses cover a considerable area, and comprise in their stock well-grown pot Vines, Figs, &c., also flowering and foliage plants. Herbaceous and Alpine plants are also grown in large numbers. The nursery is divided up and re-divided by miles of Beech hedges, under 6 feet in height, which doubtless serve as good wind-breaks in this much exposed position, and so provide shelter for the plants.

CULTURAL MEMORANDA.

EUPATORIUMS.

These easily cultivated plants are deserving of attention wherever early spring flowers are in request. They succeed well in the cool greenhouse, and do not need, nor will they stand, forcing. Pot them in smallish pots in almost any kind of light soil, and as the plants are most abundant rooters, do not afford them a great number of crocks as drainage. From June to September the plants should be stood in a sunny plunging bed of gravel or fine coal ashes, and be well looked after in the matter of affording water at the root and syringing the leaves. When going out of flower cut back the older shoots rather severely, and afford the plants but little water for a few weeks, keeping them in a cold frame in a half shady place. Useful varieties are odoratum, riparium, and vernale. *F. M.*

ANTHURIUMS.

The recent introduction of new varieties of the well-known Flamingo plant (Anthurium Scherzerianum) into cultivation has not only extended our list, but at the same time added to the value of all previously introduced stove plants suitable for decorative purposes. A. Andreanum album, in habit of growth and shape is a duplicate of the type, but the spathes are of a shining ivory white, continuing a long time in perfection, a delightful acquisition to our list of stove plants.

A. A. Roseum is of great value, the spathes being of a bright rose-pink colour, ornamented by a tri-coloured spadix, the basal portion being white, the centre golden, and the tip lemon-green. A. A. salmoneum produces cordate-shaped spathes of a clear salmon colour, the corrugation in the spathe being well defined. The basal half of the spadix is white, the apical portion yellow. A. A. sanguineum is a fine variety of the type, with rich, dark crimson spathes, ornamented with a golden yellow spadix, and shining as if varnished; the spathes are of good shape, and the corrugations are well defined.

A. Scherzerianum maximum produces flower spathes of intensely brilliant colour, measuring 9 inches in length and 4 in breadth. A. Scherzerianum roseum freely produces its well-shaped, beautiful, rose-coloured spathes that are flushed with salmon, a striking contrast to the rich scarlet spathes of the type.

A. S. Sanguineum is a very distinct variety. It differs from the type in the colour of its spathes, which are of a deep blood-red or crimson colour.

Owing to the enduring nature of the spathes the Anthuriums are desirable, as well as most attractive, plants for the embellishment of plant-stoves and conservatories, as they also are for room and table decoration. The Anthuriums mentioned above are easily grown. Young offshoots, with few roots, detached from established clumps and potted up into well-drained 3-inch or 4½-inch pots, according to the size of the plant, in peaty soil, with which some pulverised potsherds have been previously mixed, will soon become established. Keep the crowns of the plants in the centre of the pots well above the rims of the receptacles, and make the soil fairly firm in potting. Place the plants in the plant-stove or in any structure in which a minimum atmospheric temperature of 65° is observed, and afford water to settle the soil about the roots. Shift the plants into one size larger pots before the roots become matted, using the peat in a rougher state, with the addition of silver sand at each succeeding shift. *H. W. Ward, Rayleigh.*

THE BULB GARDEN.

SOME BULBOUS IRISES.

Some of the bulbous Irises are among the loveliest of our spring flowers, but unfortunately it is not in every garden that they will succeed. An ideal position for them is a sunny border in front of a wall, facing due south and sheltered from the north and east; but even in such a site they often fail to thrive, and die out in a year or two. A high authority on these plants attributes this failure to the use of leaf-mould in the compost, and recommends the use of pure loam mixed with a large proportion of coarse sand. Considerable difference of opinion exists on the question of lifting the bulbs after the foliage has withered, and replanting in the autumn. One eminent authority advocates this course, two other equally reliable experts advise the contrary.

Amongst the best garden species are:—

I. alata, sometimes known as the Scorpion Iris.—This is a very early-flowering species, generally blooming before Christmas. The blossoms are lilac-blue, veined with a deeper shade, the falls blotched with bright yellow. Diameter of flower, four inches; foliage leek-like. This is a very uncertain bloomer, in some gardens refusing to flower after the first year, though remaining in perfect health.

I. reticulata.—This is the commonest of the early-flowering bulbous Irises, and is a universal favourite. The standards and falls are of a rich violet shade, the falls bearing a deep golden blotch. The flower-stems are often over a foot in height, and the fragrant blossoms are from three inches to four inches across. There is a variety styled Major. It has larger blooms than the type, and usually flowers early in March.

I. persica.—This is a very dwarf species, often not more than two inches in height. The type bears pale, greenish-blue flowers with a yellow blotch on the fall, and margined with a wide band of deep violet, three inches in width. There are many named varieties of this species.

I. Histrio.—This is now held to be a variety of I. reticulata, though of very distinct appearance. Flowers purple-blue, falls bearing a yellow blotch and heavily spotted with violet. Diameter of flower 3 to 4 inches. This is now over, having bloomed in the first week of January.

I. histrioides.—Also a variety of I. reticulata. Flowers purple, marked with bright blue blotches and spots, the falls bearing a narrow yellow band. This also flowered early in January.

I. Heldreichi, now known as I. stenophylla, is a beautiful Iris, and one of the easiest to grow. The flowers are variable in colour. In the dozen or so blossoms now open considerable difference in tint occurs. In one of the handsomest forms the standards and falls are violet-purple with slight white veining round the yellow band on the fall, in others the standards are sky blue, and in still others the falls are lavender margined with violet. Diameter of flower 3 inches.

I. Rosenbachiana.—This is perhaps the most beautiful of all the dwarf bulbous Irises, but, as in the case of I. Heldreichi, it is very variable in colour. In one flower the standards are lilac-blue, deepening into crimson at the base, and the falls are terminated by a wide band of deep violet edged with white. In another the falls and the standards are maroon-crimson, the raised golden band on the former being margined with pale blue heavily spotted with violet. Diameter of flower 3 inches.

I. Danfordiæ.—A pretty little flower having bright yellow standards and falls, the latter bearing a narrow orange band surrounded by faint pencillings of purple. Flowers 2 inches across. This species is now in bloom.

I. Kolpakowskiana.—The colour of the standards in this species is lilac-blue, the falls being purple-red with a narrow band of rich yellow, and white veined violet at the base. Diameter of the flower 3 inches.

I. Bakeriana has bright lilac-blue flowers, the falls of which are white splashed with purple and edged with a broad band of the same colour. Diameter of flower 3 inches.

I. Tauri.—Standards dark blue, falls purple-black spotted with white around the central yellow band. Diameter of flower 3½ inches. It is in flower during February.

I. Warleyensis.—This is a member of the I. orchioides group. The standards are blue, as are also the upper portions of the falls, the extremities of which are terminated with a broad blotch of deep violet edged with white. Diameter of flower 3 inches.

I. pavonia.—This, though popularly termed an Iris, is not an Iris at all, its correct name being Moræa glaucopis. It flowers in summer, the flowers being whitish with a blotch of bright blue at the base of the falls. The spathes carry several flower-buds, which open consecutively.

In the same border with the Irises already named is growing a very different species, and one rarely met with in cultivation, namely, I. cretensis. This has been in flower all through the winter. Its blossoms are smaller and not so showy as those of I. stylosa or unguicularis, to which species it is believed to be allied. The standards are lavender coloured, and the greater portion of the falls is white veined with purple, while they terminate with a blotch of lavender-blue about half-an-inch in depth and edged with a narrow margin of white. The blooms are about 3½ inches across.

One other bulbous Iris I must allude to is growing in another part of the garden. This is I. tingitana, and I am convinced by experience that, whatever may be the correct practice with regard to the dwarf bulbous Irises, this species requires annual lifting. Many find it impossible to flower the Tangiers Iris, and I have known plants that have grown 20 years in a garden without blooming. In only one season have they failed to flower with me, and that was when I had neglected to lift them the preceding year. I lift as soon as the foliage has died down and replant in very rich soil at the end of October. A thick layer of rotten manure is placed about 9 inches below the surface, while old mushroom-bed manure is added liberally to the upper soil. The bulbs are planted 3 inches deep and are surrounded with sand. They generally flower in March, but I have had blooms as early as February. The blossoms are of lovely appearance and very large, often measuring over 6 inches across. The standards are violet-blue, and the falls a delicate French grey set off by the glowing yellow of the central blotch. *S. W. Fitzherbert, S. Devon.*

[Many of the species above named have been figured in these pages.]

KEW NOTES.

Interesting Hardy Plants in Flower.

Encouraged by the warm, bright weather that we have experienced recently, many rare and interesting plants have come into flower in the Alpine house. The Crocus family supplies the greatest proportion of colour, amongst the most conspicuous being C. versicolor, C. ancyrensis, C. Weldeni, in variety, and C. aureus. Chionodoxa also in its various forms helps to make the house bright, along with Cyclamen coum, Shortia galacifolia, and the double form of Adonis amurensis. The latter is a most interesting plant, with its curious flowers composed of yellow and green series alternately arranged. The Androsaces are represented by A. Laggeri and A. ciliata. One of the prettiest plants is Primula marginata, a native of the Alps of Dauphiny and Piedmont, with toothed, mealy leaves, and clustered heads of pale mauve-blue-coloured flowers. It is also one of the easiest of Alpine Primulas to grow at Kew, thriving well in the rock garden planted in a sunny fissure in the rock. There are also several Saxifragas in flower, including S. Elizabethæ. This is a plant of hybrid origin, having for its parents S. sancta and S. burseriana. It somewhat resembles the latter in general appearance, without the glaucous colour of the foliage, but is of closer and more tufted habit. Of very free habit, it forms cushions of dark green foliage, and bears pretty yellow flowers of the colour of those of S. sancta. It was raised by and obtained from F. Sundermann, of Lindau, in Bavaria about four years ago. Also in flower is S. Ferdinandi-Coburgi. This charming little species is a native of Macedonia, where it is found at high elevations growing in rocky fissures and forming neat tufts of somewhat silvery foliage. The flowers are bright yellow, succeeding buds richly suffused with red, and are borne on stems about 2 inches high. It is closely allied to the better-known S. aretioides, but comes into flower earlier, and promises to be easier to manage. Another hybrid Saxifraga in flower is S. Salomoni, a cross between S. Burseriana and S. Rocheliana. It is of compact habit and free growth, with tufted, glaucous foliage, like the smaller forms of the former parent. The flowers are more like those of S. Rocheliana, and are produced three or four together on pubescent stems about 2 inches high. The whole of the stem and buds are suffused with pink, making it a charming little plant. It was also raised by F. Sundermann, and has proved more hardy outside than S. Burseriana. S. scardica is a native of the Balkan Peninsula, among other places being found on Mount Scardus, in Albania, whence it receives its specific name. It is closely allied to S. Rocheliana, but comes into flower some time before that species. It also differs in its narrow, less spatulate leaves. Very free flowering both in the rock garden and in the Alpine house, it will probably become a favourite plant when better known, as its flowers are of good substance and last for a long time. It has recently been figured in the *Botanical Magazine*, t. 8,058, and was also sent out by F. Sundermann. Other Saxifragas in flower include the red-flowered Macedonian S. Grisebachii and S. porophylla.

On a sunny border at the foot of a south wall are some hybrid Irises of the bulbous section in flower, which were raised by C. G. van Tubergen, Junr. I. purpureo-persica, a cross between I. persica purpurea and I. persica, is a beautiful plant, with very large flowers, rich ruby-red in colour, with dark maroon falls and orange crest. It is evidently of robust habit, very hardy, and sweet-scented. I. sind-pur (I. sindjarensis × persica purpurea), with robust habit like the former, is very free flowering, producing several flowers to each bulb. The flowers are large and of good substance, dark lilac-mauve in colour, with a light yellow crest. It is a valuable addition to an already numerous but charming family of early-flowering plants. *W. I.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

The Royal Horticultural Society's Exhibition of Table Decorations, &c. Like "Decorator" (see page 140), I think the exhibition the Society is going to hold on June 20 should prove very interesting and instructive to those who have much of this kind of work to do and who may be expected to visit the show for the purpose of getting fresh ideas. The practice of decorating tables appears to be increasing continually, and the ability to do this well forms an important item in a gardener's qualifications. It is most unfortunate that the R.H.S. Council should fix the date for this show on the same day as that on which the York Gala Exhibition will be held, it being a pity that these two important shows should clash. The York Show has been held about the same date for many years, and cannot, I believe, be altered, as the Gala rules the date for the show, which must be well known to the Council of the R.H.S.—*Another Decorator.*

Fumigation with Hydrocyanic Acid Gas.—In spite of the danger this process entails, it is assuredly an advance in the right direction, and Mr. Dobson (see p. 85) is to be congratulated on his experimental efforts. For a number of years we were quite content to run the risks to ourselves and plants by using the now "time expired" tobacco paper and rag, and we all hailed with joy the advent of the solution of nicotine; and although this extract performs its work well, care is necessary in its application. The same will be required in the use of hydrocyanic acid gas, but I anticipate a reduction of 50 per cent. in the cost of fumigating. When this vaporiser can be placed upon the market in a portable and simplified form of application, gauged ready for immediate use, it will be generally used not only because it will be cheap, but because also it will be extremely effective. *W. H. Clarke, Aston Rowant, Oxon.*

The Late George Norman.—The note on page 155 contains some inaccuracies which ought not to pass uncorrected. He commenced at Colworth Hall, Sharnbrook, Beds., at that time the residence of — Magniac, Esq., M.P., the gardens being under the charge of Mr. McKellar. From this place he went to the Dell, Englefield Green, the seat of Baron Schroeder, the gardens being then—as now—under Mr. Ballantine's charge. Mr. Norman always referred in pleasant words to his stay there; he looked upon Mr. Ballantine with almost filial respect, and spoke very highly of Baron Schroeder as an example of a good and kind employer. After staying there a considerable time, during which he rose to be foreman, he took a journeyman's place under the late Zadok Stevens, at Trentham, where he had charge of some of the vineries. There was a great deal of work to be done at Trentham, but Norman never objected to work. Each journeyman had charge of his houses entirely, Sundays and week-days, without change, and was responsible to Mr. Stevens alone, as there was no foremen kept. Stevens did not mince matters. Norman has often told me he did not get a chance to put on his Sunday clothes for six months. He also told me of one man in charge of the early vines who had allowed the fermenting material on the border to get too hot. He was fetched out one Sunday morning and made to turn the whole of it over. But although the work was hard it was a good school for those who could stand it. After a time Norman's health began to suffer, and he spoke to Mr. Stevens about making a change. "Stop until I get my Strawberries potted, and I will recommend you to Mr. Harry Veitch," was the reply. He stopped as requested; but an attack of low fever, which laid him up for six weeks, was the result. He recovered, and on December 11th, 1873, came to Linton Park, Kent, as foreman. He soon made alterations in the plants and indoor fruit trees. Mr. Robson was head gardener, and left the houses entirely in Norman's hands. Table decoration was then a very important thing at Linton. Norman had good taste and judgment in arranging flowers. Lady Holmesdale was very pleased with what he did, and when a head gardener was required at Hatfield in 1876 she personally recommended him to the Marchioness of Salisbury. Hatfield Gardens were then in a very rough state. Several head gardeners had only stayed a short time—Mr. Record for about three years, then Mr. Bennett for another three years, a Mr. Thomson for one year. Then another one was engaged, but did not stay more than one night! I saw the gardens about three months after Mr. Norman took charge, and made a note in my diary at the time: June 26th, 1876—"Things rougher than in any garden I have ever seen." Nettles and thistles were growing all about the kitchen garden, and were higher than the fruit bushes in some places. Mr. Norman set to work with a will. He soon altered the appearance of things, and when I saw the place again in 1877 it looked very different, and has steadily improved ever since. Few people who are not acquainted with the place can have any idea what the work has been in carrying on such a large garden so well, under many difficulties, for thirty years. Mr. Norman has succeeded where several others failed. At one time a very strong man, he did not spare himself in any way, but did the work of two men easily. He had the satisfaction of knowing his work was appreciated by his employers, which was a great help to him. His thoroughness in all he did, and his conscientious, straightforward character stand out conspicuously. We shall miss his welcome face and sound advice at the Royal Horticultural Meetings. The Garden Charities will miss his untiring exertions on their behalf. His employers say he cannot be replaced. All his friends will miss him much, and none more than his old friend—*W. H. Divers.*

Unusual Flowering of Cœlogyne cristata.—I have just had the opportunity of seeing a fine plant of Cœlogyne cristata, and another of C. cristata var. Lemoniana, cultivated at Broomfield Lodge, Chelmsford, by Mr. Pragnell, which are now in magnificent flower for the third time within 13 months. The plants, which were originally in the possession of Mr. Warner, have been grown at the cool end of a stove for some years, being removed to the house when in flower and kept slightly dry for a short time of rest. Last March they bloomed profusely, again in the autumn of last year, and are now a third time covered with fine flowers. The unusual production of more than one good crop of blossom within a year has induced me to ask whether any readers of the *Gardeners' Chronicle* have noticed a similar thing, and, if so, under what conditions? *Fred Chittenden.*

Rhododendron præcox.—In the note upon the early Rhododendrons at Leonardslee, I observe the statement so frequently made about *R. præcox* that its height is 3 to 4 feet. I do not know what may be the limit of its height, but I enclose a photograph of one fully 7 feet high, taken in my own garden in Wigtownshire last January, when the bush was in full flower. It is a slow grower; this one was planted nearly 25 years ago, but it still increases a few inches in height every year. *Herbert Maxwell, Monreith.*

Photinia serrulata.—At Pengreep, Cornwall, is a handsome specimen of this plant which has been in flower for the past seven weeks. It is one of the finest early-flowering sub-hardy plants that I am acquainted with, and in districts where the climate is suitable for its culture it is useful for furnishing a supply of cut flowers. The latter, which are borne on large corymbs, are pure white, and remain in a fresh condition for some days when cut. The young growths at this season of the year are red, and when seen at a distance might easily be mistaken for flowers. The specimen above referred to is 35 feet high and as much through. It is growing in rich loam, and appears to enjoy a sheltered, well-watered position. Further north than Cornwall or in an exposed position it would probably fail to develop its flowers successfully. A good effect is produced by planting Prunus Pissardi in the foreground with Photinia serrulata behind *H. W., Trevince.*

A Destructive Bird.—The hawfinch does more damage to garden Peas than sparrows, slugs and mice combined. His wonderful dexterity in riddling Peas is remarkable. The species, I believe, is a native of Germany, but regularly visits this country every summer. The birds arrive in this locality at about the beginning of July, and are well known by their peculiar "Twit-twit," but more especially by their depredations among the Peas. They pierce the pods opposite the Peas with their powerful bills and take out the Peas, leaving the pod hanging like a piece of torn ribbon, and will go through the whole length of the rows in a very short space of time. Last year we had a flock of about a dozen, and they practically ruined all the early Peas, leaving nothing but riddled pods. I was obliged to resort to netting the main crop, with the result that I caught seven, two fine specimens of which I have at the present time in full song. Though I do not advocate the slaughter of this beautiful bird, it is absolutely necessary to take some means of precaution to safeguard the Peas. *Wm. Brooksbank, Coniston Hall Gardens, Bell Busk, Leeds.*

Foreign Apples.—In reference to Mr. J. S. Fowley's note on p. 140, I may state that when living in the near vicinity of London I have had occasion to purchase many foreign Apples and have frequently met with bad ones, and with two cases in which 95 per cent. were bad and worthless, yet I paid the full and best price for selected fruit. It is well known that British fruit will soon decay if bruised. Great care should always be exercised in gathering and storing Apples, then decay is prevented. *W. A. C.* [On Saturday last we saw Apples in a fruiterer's shop which had the appearance of being covered with mildew. A closer inspection revealed the fact that they had all been coated with, presumably, a salt of copper. We purchased some of the fruit. On applying a test the identity of copper sulphate was confirmed. The shopkeeper informed us that the "stuff" was put on the Apples to preserve them from rotting in transit. Sufficient of the salt was in the depression round the stalk to cause inconvenience to adults, and possibly danger to children if eaten. We welcome and value these supplies of foreign Apples when we have none of our own, but we must beware of these poisonous coatings. —Ed.]

Apples.—The cry at the Fruit Committee is "still they come." Probably some 50 Apples, more or less of seedling character, have been shown on the Fruit Committee's table during the autumn and winter, and certainly no fewer than a dozen of such came up on February 13. It matters not that we have already 500 or more varieties in existence all named. Any moderate person might well imagine that 500 were ample. Had all the seedlings or assumed seedlings sent to the committee during the past 20 years, and not getting recognition, been named, the number might have been 1,000. There seems to be a belief abroad that, with all our existing fine varieties of Apples, there is still room for material improvement. If only the commendations of senders as written were to be credited, there is not only great room for improvement, but their special varieties have qualities which place them far ahead of any others now in commerce. There is evidently either great faith in personal estimates of Apple excellence, or very little in the capacity of the Fruit Committee to detect deficiencies. Yet these wonderful swans commonly turn out to be but ordinary ducks. Not a few are very handsome in appearance, indeed quite merit the term "beautiful." They would look so nice in a fruiterer's shop or on the dessert table; but the members of the committee are practically minded persons who look not to externals so much as to internal excellence, and when an otherwise handsome apple is tested, in how many cases is the flesh found to be dry or flavourless? At a recent meeting a sample of the Spice apple, far indeed from being handsome, was sent for the committee to taste. Although the fruit was almost ugly, and the flesh firm, it was juicy and rich flavoured. Will raisers of Apples not concentrate their efforts on securing flavour more and mere form or beauty less. Only a really remarkable variety now can be said to excel all others. If no better than others, of what value is it? *Pomona.*

Arundinaria nobilis.—A fine specimen of this Bamboo is now flowering here, and several young plants taken from it three years ago are also in flower. According to precedent these plants are doomed, but as they are flowering thus early in the year I am hoping they will ripen some seeds, so we may not lose this beautiful species. *A. C. B., Pencarrow, Cornwall.*

A French Market Garden at Evesham.—It will be remembered that in January of last year a number of Evesham market gardeners paid a visit to Paris to see for themselves the methods adopted by the French gardeners to produce Lettuce and other vegetables at a time when such delicacies are not usually to be procured. The Englishmen were very much struck with the efficiency of the system carried out by the Frenchmen, and studied with great interest the making of the seed bed which, after all, is one of the most important parts of the business. At the same time serious doubts were expressed as to whether it would be possible to adopt this plan in England with financial success, it being felt that the climate was too humid and also that it was not possible to obtain the same variety of Lettuce which the Frenchmen grew. Consequently, of the score or so of Evesham men who took the journey, only one has experimented since his return. [!] This is Mr. John Idiens, or rather the Avon Orchard Co., of which he is the leading spirit. Mr. Idiens was most enthusiastic about the matter, and on his return he at once set to work to lay out a garden on the approved French plan. He procured the services of a practical Frenchman from Vitry, and under his directions somewhere about two acres on the Bengeworth side of the river Avon at Evesham have been laid out in the approved French way. I had the opportunity of going through this garden last week and was very much struck with what I saw. I might have been back at Vitry again, everything is so French. There are the low glass frames, and the cloches, and all the implements which are to be seen about looking strange to an Englishman. The seed bed has been prepared as it is done in France, but, of course, the soil has not got into the best condition after only one year's working. It may be as well perhaps to briefly state how this important work is carried out. All the top soil is first of all removed from where the frames are to be placed, and a good thickness of stable manure is put here to be covered with a coating of last year's soil. As soon as the crops have been marketed, the soil and manure are removed, made up into ridges and allowed to rot till the following year, when this forms the soil. As a consequence, every year the soil used becomes more fertile. It says a good deal for the natural productiveness of Evesham land that such excellent results have been produced in this garden after one year's working. Messrs. Watkins and Simpson, the head of which firm, Mr. C. D. Mackay, was mainly instrumental in organising the Paris trip, soon procured the right Lettuce seed, and when I visited the garden the other day they were marketing Lettuce of good size and excellent quality. These have been on the market now for at least a month and are still selling at 1s. 6d. a dozen. As in Paris, these Lettuces are in various stages of growth, and as soon as one lot is cleared another lot will be ready. Those that are being marketed are Cabbage Lettuces, but it will not be long before some Cos varieties, which are under the cloches, will be ready. In the same frames Radishes are being pulled, and these have made up to 3s. a dozen bunches. Of course Radishes grown in the open will not be on the market for some little time yet. The French foreman is very pleased with the Lettuce he is now cutting, and assured me that no finer quality Lettuce was to be found in France at the present time. Turnips, Carrots and Cauliflowers are also in various stages of advancement in the same frames and will soon be ready. As to Cauliflowers, the foreman told me, he should have first-class ones ready early in April. That hardly looked likely when I saw the plants last week, but he was certain that he should accomplish it, and we shall see. Tomato-growing is a special hobby of his, and he had some last year grown in the frames as early and as good as those grown in glasshouses after the expenditure on artificial heat. All the heat he gets is from the manure. The Tomato seed he plants in a cool frame, and then he transplants three times into heat. Every time he shifts the plant he removes a certain portion of the root, and by so doing he assures me that he gets a stronger, although shorter, plant, and that the fruit comes to maturity much earlier. He gave me a practical illustration. He took a small plant from one of the frames, and this particular plant had three what may be called "spur roots." He pinched off the root so as to leave only one of these spurs and then replanted. The next time of moving he will remove more of the root. Cucumbers are grown extensively in the frames, and last year they sold exceedingly well, and were quite as early as the greenhouse variety, and were also as straight and free from discoloration. The foreman told me that Frenchmen laugh at the idea of using artificial heat for the cultivation of Tomatos and Cucumbers. Melons were tried last year with great success, and are to be grown again this year on a larger scale. Many gardeners of the district and from long distances have been to see the result of the experiment and express themselves as very much impressed. Some of the principal men of the Toddington Orchard Co. have paid more than one visit to the garden, and I am told that the system is to be given an extensive trial in these plantations. The way the Lettuce and other vegetables are sent into market is an object lesson to local growers. I saw them packing Lettuces, which are placed in small shallow crates carrying two dozen, a dozen in a row, and between each row paper is placed. There is no crushing, and the Lettuces travel to their destination most securely, and come out of the crate ready to go on the table. It is the same with everything else sent away from here, and there is no "topping." With regard to the question of climate, I enquired from the Frenchman most closely as to whether he found more humidity here than in France, and therefore a greater tendency to "damp off." He assured me that there was no more tendency to this in Evesham than at Vitry. The climate of the two countries, he said, was very similar, but he added that Evesham has not so much sun as Vitry. The land, too, is first class, and he hopes in the course of another year or so to have a seed bed of which any Frenchman would be proud. There is no lack of stable manure, and while he can obtain that he has no fear of the result, but, as he told me, "No muck, no Cucumbers." I am going to watch the progress of the garden closely for the remainder of the season, and will keep you informed of what is going forward. *H. H. S.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

March 6.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Dr. Somerville; Rev. W. Wilks, M.A.; Messrs. Worsley, Worsdell, Massee, Michael, Odell, Gussow, Saunders, Veitch, Hooper, Douglas, Bowles, Holmes, and Chittenden (hon. sec.).

Mealy Bug on Bananas.—Mr. Saunders reported that the mealy bug on Bananas from Jamaica, shown by Mr. Worsley at the last meeting, appeared to belong to the same species as the commonest of our greenhouse mealy bugs (Dactylopius longispinus, D. adonidum, or Coccus adonidum).

Grubs in Ash Stem.—Mr. Saunders also reported that the Ash shoot from Dunmow, shown at the last meeting, had been bored "by one of the small fossorial Hymenoptera, probably one of the many species of Crabro. These insects fill the cells which they make with insects to supply their grubs with food. Having formed the cell and duly provisioned it, the female lays an egg in it and seals it up and forms another just above it, treats it as she did the first, and goes on in this way until she has completed her task. In this instance one of the grubs had died before it had consumed

its stock of provisions, and the cell was more than half-full of the remains of a number of small Dipterous flies; from the other cells the perfect insects had made their escape, and the cells only contained empty pupa cases."

Variation in Narcissus, var. princeps.—Mr. E. H. Jenkins, of Hampton Hill, sent specimens of this well-known Narcissus having the corona contracted at the mouth. Dr. Masters said this condition was due in all probability to the plant having received some check during its development, but exactly at what stage and from what cause was not apparent. The specimens differed from the typical Princeps in being paler, both in the corona and perianth, but as Mr. Jenkins pointed out, the height, flimsy perianth segments, flat stem and leafage, were unmistakeably those of N. Princeps. He also said that he had been able to select from those he had grown two pale yellow selfs, another with segments almost as white as in Horsfieldi, another having much bigger bulbs than is usual in N. Princeps, and still another which retains its foliage when all others have disappeared; all these being apparently sports from N. Princeps. In addition to this, a sport has been selected having a frilled rim to the corona; this has proved constant and the stock is increasing.

Oranges Decaying.—Mr. Chittenden reported that some Navel Oranges had been received from the Western Orchards Produce Co., with the request for some information as to the cause of the rot that had set in. He had reported that the Oranges are attacked by the fungus Penicillium, a frequent cause of loss with Oranges. The trouble usually appears after the Oranges are packed and on their way to England, and this appears to have been the case with those sent. Navel Oranges are very frequently attacked, the open eye of this fruit forming a convenient place for the entry of the minute fungus spores; sometimes, indeed, they are infected before they leave the orchard, but more frequently in the curing house. After packing, the disease may spread throughout a box from one fruit to the next.

The conditions for the growth of a fungus such as this are, particularly, the presence of moisture, warmth, and a suitable substance upon which to grow. In the Navel Orange, a drop of water will often condense in the open end and there the fungus finds a very suitable place for growth.

The best means of preventing the growth of the fungus in the fruits appear to be as follows:—(1) Wrapping fruits in tissue paper, a means which combined with some amount of ventilation in the boxes, has proved, within certain limits, valuable as a preventive of decay. (2) Careful destruction of decaying fruit (by deep burial or by fire) in the orchard or the packing house, since by this means the number of spores likely to be floating in the air will be greatly reduced. (3) This should be combined with disinfection of the packing houses, either by thorough drying, by whitewashing or by burning sulphur therein.

Galls on Bramble.—Dr. Masters showed on behalf of Mr. Nicholson galls on Bramble very similar to those shown at the last meeting on Ash and Birch, and caused, like them, by a species of mite, Eriophyes.

Palm Leaves Diseased.—Dr. Masters also showed some leaves of a Palm apparently attacked by a fungus which Mr. Massee took to examine.

Primula sinensis malformed.—Mr. Odell showed specimens of this plant (intermediate between the "stellata" group and the ordinary sinensis) having green or purple flowers in which the calyx had become foliose, the ovary had grown into a tube, but contained no ovules, while the stamens were present. Dr. Masters took them to examine further, and will report upon them at the next meeting.

Pelargonium Leaves Diseased.—Mr. Massee said that the leaves Mr. Worsley had shown at the last meeting were not attacked by a fungus, but that the brown spots upon them had evidently been produced by a concentration of water at these points owing to an interference with proper transpiration. Chlorosis had also occurred. It was found that watering with a 1 per cent. solution of sulphate of iron and the standing of the plant in abundant light would cause growth to proceed in a proper and healthy manner.

Beetle Grubs in Elm Bark.—Lieut.-Col. Rogers sent Elm bark bored by the grubs of a beetle, which Mr. G. S. Saunders took to examine further.

Hardy Eucalyptus.—Messrs. Treseder & Co., of Truro, sent branches of a Eucalyptus from their nursery, an introduction from Australia, which they say has stood 20° of frost without injury. Some account of the tree is given in *Gardeners' Chronicle* (July 1, 1905, p. 3), with a figure of the young state, which is somewhat like that of E. cordata. Messrs. Treseder have coined the name Eucalyptus Beauchampiana for this form, but is is probably referable to E. cinerea, F. v. Muell, see Bentham "Flora Australiensis," iii., 239 [E. pulverulenta is closely allied, if not identical]. In the mature state the leaves are linear lanceolate, of a glaucous green with a reddish tinge and about 3 inches long.

Soil Uncongenial.—A sample of soil with roots of plants quite dead or dying was received. On using the soil a second time after rest, it was found that the roots of Cucumbers, Melons, Violets, Tomatos, Roman Hyacinths, etc., were quite destroyed. Mr. Chittenden said he had tested the soil, and found that it contained abundance of lime, so that the death of the roots could not be put down to soil acidity. Mr. Douglas pointed out that there were pieces of clinker and cinder in the soil, and the presence of these suggested sulphur as a possible cause of injury.

Cultures of Nodule Bacteria.—Mr. Chittenden said that experiments had been carried out in Essex during the past year with cultures of nodule bacteria from America and Germany on Beans, Peas, Lucerne, Clover, etc., but in every case without yielding any increase in crop either in pot cultures, or in the field, in spite of the fact that in every case the cultures were proved by means of control cultures to be alive and capable of vigorous growth. Dr. Somerville said that this had been the experience throughout the country, just as it had with "nitragin" a few years ago.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

March 12.—The annual general meeting of the above society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on the above date. The general business was preceded by a special meeting, presided over by Mr. H. B. May, to consider the adoption of the new rules as revised by the committee. The recommendations of this body were accepted with slight alterations, arising from the recommendations of the actuary in his quinquennial valuation. The actuary, in his report, also said in regard to the weekly grants paid from the Benevolent Fund, "7s. and 8s., as at present granted, are too high, and I would recommend that the allowance should in no case exceed 5s. weekly to every member coming on the fund in future." It was decided by the meeting to retain the rule as at present, which reads, "not more than 8s. per week." Mr. May was again elected to the chair at the meeting held at 8 o'clock, about 40 members being present. The report and balance-sheet were presented, and of these we give the following extracts:—

Extracts from the Report of the Committee for 1905.

"Each year the society increases in usefulness, as it also does in numbers. Financially the society is sounder than ever, and its membership is such as to give the committee and members the greatest possible encouragement for continuing and extending their efforts to induce gardeners to join early in life and secure to the full the many advantages the society offers.

"For several years the annual addition of new members was about eighty, and once ninety was reached, but during the past year no less than 120 new members were elected, by far the largest number elected in one year. The losses during the same period consisted of ten deceased and twenty-three lapsed members, the net increase being therefore eighty-seven, leaving the total membership at the end of the year at 1,163.

"In sick pay the sum of £401 17s. was paid out during the year, while payments from the Benevolent Fund amounted to £134 4s., and from the Convalescent Fund, £3 10s. The sick pay deductions amount to 8s. 4d. for higher scale members, and 5s. 6d. for lower scale members. Eighty-nine members received sick pay; ten members received assistance from the Benevolent Fund, and three from the Convalescent Fund during the year.

"The sum of £2,200 was invested during the year, and in this connection the committee wishes to once more record its high appreciation of the services so long and ably rendered to the society by its treasurer, Mr. James Hudson, V.M.H.

"The annual dinner was again a success; it was held at the Holborn Restaurant, and presided over by William Marshall, Esq., V.M.H., who did more than any one other person to found the society.

"After long and careful consideration by the committee, and with the kindly assistance of W. A. Bilney, Esq., the rules of the society have been revised, and placed in better order relative to each other, altered in some cases, and slightly added to. It is hoped that, subject to confirmation by the special general meeting and the Registrar General, these rules will serve for many years to come. It is also believed that the opportunity the alterations afford for a member to draw upon his deposit account to a limited extent under special circumstances, and the transfer of chronic sick cases from the Benevolent Fund to the Sick Fund—the chief alterations—will in the first place be an additional inducement to young gardeners to join, and in the second be the means of further strengthening the fund that provides for infirm old age.

"During the year, in fulfilment of the requirements of the Friendly Societies' Act, the quinquennial valuation of the society was taken. The valuation was again made by Mr. Thomas G. Ackland, and his report will be printed and circulated in the society's usual annual publication. But one or two sentences in the valuation report are deserving of special emphasis. Mr. Ackland points out that according to the actuarial tables, £3,590 should have been paid for sick benefit during the previous five years, whereas the amount actually paid 'was £1,531, or about 43 per cent. of the expectation. The remarkably light rate of sickness thus shown doubtless arises from the healthy occupation of the members, and from their careful selection; and the society is to be congratulated upon the result.' Referring to the Benevolent Fund, Mr. Ackland points out that if half the members estimated to reach the age of seventy years 'come on the fund, the continuous allowance should not exceed 5s. weekly,' and he urges that no higher allowance than 5s. per week should be granted in future.

"Mr. Ackland heartily commends the gradually increasing Depreciation Fund, and recommends that every effort should be made to raise it to an amount equal to the difference between the nominal and the market values of the stocks in which the monies of the society are invested. £26,800 is now invested, which averages over £20 per member."

The chairman complimented the members upon the sturdy independence shown by them in not relying upon the nation for old age pensions, but in providing their own.

The adoption of the report and balance-sheet was carried unanimously. Messrs. Winter, Hemsley, and Hawes, the three retiring members of the committee, were all re-elected, while Mr. Frogbrook was selected to fill the place of Mr. Kelf, who wished to retire.

Mr. William Collins was again elected secretary.

SOCIETES ROYALES DE FLORE ET LINNEENNE.

Brussels, February 18.—The last meeting was held on the above date, 29 members of the jury being present, amongst them M. Truffaut, from Versailles, and the two French Orchidophiles, Messrs. Le Moinier and Fanyan.

Four Diplomas of Honour, 49 certificates, and 17 honorary mentions were awarded, and several Orchids will be painted for the stud book.

We may also mention Debregeasia velutina, an extraordinary plant in full bloom, Cynorchis Kewensis, exhibited from the Brussels Botanic Garden; also Pteris Grevilleana variegata, Pteris generosa, from M. Draps-Dom. *L. G.*

SHROPSHIRE HORTICULTURAL.

(Annual Meeting.)

March 2.—At the annual meeting of this society, held on the above date, the committee had another marvellous year's record to add to their already remarkable list. The total receipts from the great floral fête in The Quarry this year reached £5,238 6s. 11d.—a record, the highest sum taken hitherto being £5,001 in 1902. The Mayor (Councillor R. E. Jones) was voted to the chair.

The report stated that the first day of the summer show in August proved very wet, and there was a falling off in the amount taken at the gates. The second day fully made up for it, and resulted in the highest amount taken in a period of thirty-one years, the total receipts from all sources amounting to the large sum of £5,238 6s. 11d. against those of 1902, hitherto the largest, £5,001 15s. 5d. The following figures in explanation will be interesting:—Subscriptions, 1905, £507 2s., against £433 18s. in 1902; cheap tickets, £539 18s. 2d., against £428 11s. 4d.; first day gates, £873 7s. 4d., against £1,004 16s. 3d.; second day gates, £2,229 18s. 3d., against £1,918 5s.; sundry receipts, including interest, £1,148 1s. 2d., against £1,216 4s. 10d. The entries received in the classes for horticultural exhibits reached nearly 3,000, being some 200 in excess of any previous year, thereby necessitating an increase in tent accommodation. The society enjoyed the happy position of always having made a profit, and never once a loss since its formation in 1875. The committee had had under consideration the present position of the society with regard to their landed and other property, and were now being advised as to the best course to adopt.

The balance sheet showed a profit on the summer show of £1,020.

Alderman Peele moved the adoption of the report and balance sheet, which was carried unanimously. He congratulated the members on the strong financial position of the society and, amid cheers, recalled the contribution the society made last year of £1,000 towards the purchase of the Priory property that had been added to The Quarry grounds, an improvement, said Alderman Peele, that he had no doubt the public would appreciate.

Mr. Peele moved, amid applause, the election as president of Mr. Alfred Darby of Little Ness, the new high sheriff for the county. Mr. Darby had been an exhibitor at the show for many years, and took a keen interest in it.

Mr. J. D. Southam touchingly referred to the death of their friend, Mr. William Phillips, who was their treasurer from the time of the starting of the show. He moved that Mr. Phillips's nephew, Mr. Wm. Phillips, be elected to the vacancy. In the death of Mr. Phillips, their late treasurer, the society had had a severe loss. Mr. Wm. Adams seconded the motion which was carried.

The retiring members of the committee, together with the Mayor were all re-elected.

Messrs. Adnitt and Naunton will continue to act as honorary secretaries.

The total takings of this society, since its first show in 1875, amount to £93,797 15s. 7d., and the list of donations to various public improvements and monuments in Shrewsbury reaches the munificent sum of £8,530.

COVENTRY CHRYSANTHEMUM AND FLORICULTURAL.

March 9.—The Coventry and District Chrysanthemum and Floricultural Society held its annual meeting on the above date, the Mayor (Ald. A. H. Drinkwater) presiding. The annual report stated that the committee had the satisfaction of recording the fact that the last exhibition was the best ever held. The show was held in the Baths Assembly Hall, which lent itself admirably for the purpose. The committee regretted to report there was a slight falling off in the balance. This was accounted for by several circumstances, among them being a change in the place where the show was held, the fact that the subscriptions were less than in the previous year, and the prize money being more than usual. The balance-sheet showed that the amount brought forward from 1904 was £12 6s. 4d., and at the end of 1905 this had decreased to £7 5s. 6d. The subscriptions amounted to £46 16s., and the cash taken at the doors and from tickets sold was £47 10s. The prize money totalled £54 11s. Mr. W. T. Browett was elected treasurer, and Mr. W. T. Brown, secretary.

Obituary.

James Allen.—It was with deep regret that I learned through a letter from Miss Allen that Mr. James Allen, of Highfield, Shepton Mallet, died there, at an advanced age, on March 8.

Mr. Allen was for many years interested in Snowdrops, and by hybridising and selection he has given us many remarkably beautiful varieties of these early flowers. His work among the Snowdrops has long been well known, and the paper he read at the Conference of the Royal Horticultural Society in March, 1891, attracted considerable attention. It was about that time that I had the pleasure of entering into correspondence with Mr. Allen. The last communication I had from him, in his handwriting, was a long and valuable pencilled note containing his observations upon some of the flowers of his raising and selection. This was in 1903, and is the last of a long series of deeply interesting letters in my possession which tell much of his work, and which reveal his true love for, and knowledge of, his flowers. I am also the fortunate possessor of a number of his flowers, although Snowdrop disease and my removal from Carsethorn cause me to regret the loss of some choice plants.

Although Mr. Allen's work is best known through his Snowdrops, he improved other flowers. A series of Anemones, derived directly or through the variety Robinsoniana from Anemone nemorosa, will, in time, keep Mr. Allen's memory even fresher than his Snowdrops. One may mention as two of the best A. n. Alleni and A. n. Romance, while there are several others of great beauty. In Scillas also Mr. Allen worked to secure good red varieties of S. bifolia. One of these is called Pink Queen and another is Pink Beauty, both of which are very fine of their kind. A pretty white variety, much superior to the ordinary white form of S. bifolia, was also raised. The hybrid Chionoscillas he raised are very beautiful also. Crocus iridiflorus in his hands yielded some fine varieties of the type of C. iridiflorus major, and a selected Erythronium called "The Queen" is the best of the Dens-Canis varieties we have. Mr. Allen also selected several Narcissi. All this was done for pure love of flowers, for Mr Allen was a man of considerable means who carried on this work for pleasure alone. He was a delightful correspondent, and, clouded though his last years were by illness and helplessness, his cheerfulness was wonderfully maintained. But a short time before his illness took a more acute form, Mr. and Mrs. Allen celebrated their golden wedding. All who had the pleasure of Mr. Allen's acquaintance will join with the writer in expressing their deep sympathy for his widow and family. *S. Arnott, Sunnymead, Dumfries.*

Henry Ernest Milner.—It is with great regret that we have to announce the death, on the 10th inst., in his 61st year, of this gentleman, at Gipsy Hill, Norwood. He was the distinguished son of a distinguished father, and an admirable representative of English landscape gardening. With vast experience at home and abroad, he combined good taste and judgment, knowing how to make the best of the conditions afforded him and how to adapt his plans to the surroundings, for, as he said, "fitness to surrounding conditions is a measure of beauty to both." In this way he avoided the extremes of the formalists and the occasional incongruities of the picturesque designer. "It is the province of the landscape gardener," says Mr. Milner in his classical work on the "Art and Practice of Landscape Gardening," "to appreciate the multitudinous means whereby Nature expresses her beauty, and so to use those means artistically as to arrange their force for producing the delightful result he desires to achieve. To servilely copy Nature's forms is to incur the pettiness of mere reproduction in little, with the penalty of a falsification. To utilise her means and to let the spirit of her works influence her art in every practicable way is the true practice of the art of landscape gardening." By many of our readers Mr. Milner will be remembered for his connection with the Earl's Court Exhibitions in 1892, where he came in contact with many gardeners and others who quickly learnt to appreciate not only his skill but his charming personality. Mr. Milner was one of the first upon whom the Victoria Medal of Honour was conferred, so that his death leaves a vacancy in the ranks of the distinguished company entitled to call themselves V.M.H. Mr. Milner was of Derbyshire extraction, his father having been associated with Sir Joseph Paxton at the Crystal Palace, and elsewhere. Among the very numerous English gardens constructed or remodelled by him we may mention Bagshot Park, Friar Park, Paddockhurst, the Buxton public gardens, as well as works in Hungary and Sweden.

The management of the business in which Mr. Milner was interested has been for some years in the hands of Mr. E. B. Milner and Mr. Edward White, and will be continued by them.

William Sowerby.—Many of our readers will hear with regret of the death of William Sowerby, for many years Secretary of the Royal Botanic Society. Deceased, who died on the 9th inst. at Gardenhurst, Ware, was the son of John E. Sowerby, and inherited the family talent for draughtsmanship.

Mr. Thomas Kennedy Newbigging.—It is with regret that we have to announce the death of Mr. Thomas Kennedy Newbigging, the head of the firm of Messrs. Thomas Kennedy & Co., nurserymen and seedsmen, Dumfries, which sad event took place at his residence, Stewart Hall, Dumfries, after a short illness. Mr. Newbigging was in the prime of life, and his death will be a surprise to many, as, although not very robust in late years, he was looking well and was transacting business as usual until lately. He was attacked by pneumonia, and succumbed to it early on the morning of March 14.

Mr. Newbigging was well known to a wide circle of horticulturists and others, although for long his attention was much taken up with the extensive farm seed department of the business, until the death of his brother, Mr. John Newbigging, which was recorded in these pages last April, compelled him to exercise a supervision over the other departments, a duty he performed with his customary energy and ability.

The business of which Mr. Newbigging has latterly been the sole member has been for many years the leading one of its kind in the south-west of Scotland, the various departments of the nursery and seed trade being all of an extensive character, forest trees, ornamental shrubs, and other nursery stock being grown in great quantities Originally established by a relative, the business was for long carried on by the late Mr. Newbigging, father of the now departed gentleman, and Mr. Robert Cowan, who again were succeeded by Mr. T. K. and Mr. J. Newbigging, descendants of the original founder of the firm.

Although somewhat brusque in manner at times, he was of a genial and social disposition, and was a favourite with all who knew him. Mr. Newbigging is survived by his wife and several young children, and general sympathy will be extended to them in their bereavement.

National Fruit Growers' Federation.—The monthly meeting of the Council was held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, the 12th instant. Col. C. W. Long, M.P., presided. Important correspondence on the subject of rebates on large consignments of fruits and vegetables on the Kentish lines having been read, it was decided that all members concerned should be made acquainted with the conditions under which they can obtain the reductions of 10 and 15 per cent. The question of how best to further the carrying out of the recommendations of the Departmental Committee on Fruit Culture was discussed at length, and finally it was decided that a deputation to the Board of Agriculture should be arranged, and that the selection of points to be specially urged should be the principal subject of discussion at the annual general meeting in May. The Bill which has been drafted by the Joint Railway and Parliamentary Committee was briefly explained by the Chairman, and many of its provisions were highly approved. The next Council meeting was fixed for Monday, April 2nd, at 2 p.m.

ENQUIRIES AND REPLIES.

PINUS MALLETTI.—In answer to an enquiry as to this Pine, February 3, p. 80, I may say that it is in my opinion nothing but a robust form of P. ponderosa. The history of the plant, so far as it is known, is given in my "Conifères et Taxacées" (1902), p. 186, and was based upon information given me directly by Baron Mallet of Jouy en Josas. *S. Mottet, Verrières le Buisson.*

ANSWERS TO CORRESPONDENTS.

ACALYPHA: *Dulwich.* The leaves are affected with a scale like mealy bug. Treat the plants as you would do to rid them of mealy bug.

CALCEOLARIAS: *P. A.* We suppose you mean Calceolarias of the shrubby section, and such as are generally used for bedding out. The usual method of propagation is by cuttings, but if seedlings are raised the seeds are generally sown in February, in a frame or greenhouse. When planting them in the open put them in good soil that has been enriched with well-rotted manure, selecting a half-shady position.

CLOVER: *C. G.* The Clover is killed by the fungus called Sclerotinia trifoliorum. The disease comes under the designation of "Clover sickness." The little black lumps on the root are sclerotia. These remain in the ground and infect plants the following season. In fact, they are known to retain their vitality for four years. Deep ploughing is useful, because it buries the sclerotia and destroys them. No leguminous crop should be grown on infected land for four years afterwards, and weeds belonging to the same natural order should be kept down.

COMMERCIAL GARDENING: *A. P. B.* You ask us what branch of market gardening is the best to take up: the growth of plants, flowers, fruits or vegetables. Also, what amount of income you could expect from each, and the capital that would be required to commence with. You omit to state in what part of the country you thought of settling, what size nursery you expected to purchase, and we have no means of estimating the business capacity you possess; but instead of giving us such information, you enquire where you may obtain what professional experience would be necessary! In these circumstances we can offer you very little advice. If you are a young man (you do not state your age) and have serious thoughts of entering into the field of commercial horticulture, let no time be lost before getting employment in a first-class market-garden, where indoor and outdoor crops are cultivated, and, after you have gained some practical experience as a gardener and an insight into the general methods of market-gardening, it will be sufficient time for you to choose of which class of culture you will make a speciality. Some amateurs have succeeded exceedingly well as market-growers, but the practice of embarking in a profession or trade without sufficient practical experience is at least dangerous, and its adoption may lead to financial ruin.

CROCUS: *Mrs. S. E.* Yellow Snowdrops do occasionally produce seed, but why they are less fertile than other varieties we do not know. Souvenir de la Malmaison Carnation being so double could hardly be expected to produce much pollen, or perhaps always a pistil, but hybridisers have, we believe, succeeded in crossing this section with other sections of Carnations, for there are now many varieties. The hybridiser, however, can make successful use of means that, if unaided, would not be sufficient to bring about fertilisation.

DENDROBIUM WARDIANUM BUDS IMMATURED: *A. E. M.* Several causes may produce similar bad results. As a rule, buds go off in that manner if the plants are kept in an atmosphere that is too hot, close, and moist after the first flowers begin to expand. Such treatment is conducive to growth for the next year, and consequently detrimental to the flowers. The plants require a tolerably dry atmosphere while expanding the blooms. Watering overhead or syringing will sometimes produce the bad results complained of. So will bad gases in the air, such as might arise from drains, or a gas-stove, or from the plants being in close proximity to the hot-water pipes.

DOUGLAS FIR: *W. G.* The appearances are consistent with some faulty detail in transplanting; but we will let you know more fully later on.

FRUIT TREES AND CANKER; *M. M. N.* Old lime rubble is excellent material for mixing with turf used when planting fruit trees, and we do not think a layer several inches deep if put at the bottom of the holes would have a bad effect, especially as older trees in the same garden suffer badly from canker. At the same time, much depends upon the conditions under which planting is done. If it is a clay subsoil through which water can scarcely pass, the layer of mortar rubble would be likely to collect and hold the surplus water from the surface soil, and unless means were taken to prevent the roots getting into this water holding rubble, harm would certainly be caused them. The better plan in such a case would be to carry out a system of draining with a pipe leading from below each tree into larger pipes laid in the centre between the rows of trees. Having thus placed drain pipes on the clay to take away the water as it accumulates, and rough mortar rubble and other good drainage material between the roots of the trees and the water pipes, the soil about the roots will be kept in good condition and the roots confined to a thoroughly drained area. But if the subsoil is porous, then the use of the rubble may have good results, and in any case it will not affect injuriously the quality of the fruits.

GRAFTING VINES: *Anxious.* March is the best month in which to graft the Vine. Make a careful selection of the scions, choosing those which are hard, well ripened, and contain but very little pith, as success will much depend upon the quality of the scions. If the operation is to be done on one of the spurs, this spur should have been left sufficiently long for the purpose. The scion ought to be of about the same size as the spur. Whip grafting is the better method to employ, and the union of stock and scion should be made to fit perfectly. Secure these together firmly, either with budding cotton or raffia. In order to prevent possible bleeding cover the operated part with a dressing of notting or grafting wax. The operation will be the more successful if the point of union is clayed over in a similar manner to that generally adopted when grafting is done out of doors. The parts can afterwards be kept at an equable temperature, and the clay prevented from cracking by a covering of moss secured in position with string, and kept in a moist condition by occasional damping.

HOW TO BECOME A PUPIL TO FLORIST: *S. F. D. H.* We imagine it would be quite easy to obtain such a position, but you must first advertise the fact that you are anxious to fill a vacancy of the kind. Scan the advertisement columns also, for occasionally florists have some difficulty in meeting with suitable apprentices.

LAWN AND FLOWER BORDER: *K. A.* It is frequently the case that small lawns in more or less confined areas in towns cause their owners considerable trouble, and the conditions being quite unsuitable for the growth of Grasses the result is not surprising. We have found that it is best to make up one's mind to sow seeds every spring, and if this is done, and every care taken afterwards to encourage the Grasses, the lawn may be made to appear in first-class condition, at least during the summer and autumn months. Cut the Grass rather close, then apply a thin top-dressing of light soil to which has been mixed a little nitrogenous manure. Rake this over evenly and roll it moderately hard. When this has been done sow seeds at the earliest opportunity wherever the Grass appears to be thin and cover very thinly, or not at all, as may seem desirable. In urban gardens the Sparrows are usually so daring that a slight covering over the seeds is to be recommended. The position you describe appears to be very unsuitable for Roses, which certainly require sunshine. If the sun's rays do not reach the wall at all you had better plant varieties of Ivy. The border may be planted with strong-growing herbaceous plants, as Phloxes, Dahlias, perennial Asters (Michaelmas Daisies), Anemone japonica, perennial Sunflowers, Solidagos, &c. In the summer the effect could be further brightened by planting a few tender bedding plants where there is room for them.

"LOCO": *R. C. H.* The "Loco" is Astragalus mollissimus. We do not think the poison is a quality possessed by the plant itself, but is a ferment developed in it from force of circumstance.

MURIATE OF POTASH: *E. S.* This form of potash is very extensively used in America for applications to fruit trees, but it has not found so much favour in England, the fact being that it is a chloride, and so sets the lime of the soil free, which thus gets washed away by heavy rains or artificial waterings. For soils that are deficient in lime (chalk) muriate of potash is not to be recommended, unless lime in some form be also added. As your soil is stated to be a "rather heavy garden soil," presumably containing a considerable amount of clay, and not, therefore, altogether deficient in lime, you may be recommended to use a manurial mixture of three parts of basic slag and two parts of muriate of potash for your Apple or other fruit trees. Apply 8 ounces of the mixture per square yard, distributing the manure for about 3 or 4 feet from the trunk of the trees, and well fork in. If there is any doubt as to a sufficiency of lime in the soil, use sulphate of potash instead of the muriate, and in the same proportions, and with the basic slag. If any difficulty exists in procuring small quantities of basic slag, superphosphate may be used in its place, mixing in also one part of quicklime.

NAMES OF FRUITS: *G. Monro.* We think your Pear is "Flemish Beauty," or possibly it might be "Directeur Hardy," both are very much alike. You will understand how difficult it is to name Colonial grown fruits, and for several reasons, but principally that almost all English grown Pears are now past, and comparison with them therefore cannot be made.

NAMES OF PLANTS: *C. W. S.* Ochna multiflora. —*F. S.* (from last week). 1, Quercus Ilex var. macrophylla.—*A. B., Tamworth.* Cœlogyne cristata, Chatsworth variety. When well-grown it often produces two flower-spikes from a single pseudo-bulb.—*P. S.* A seedling form from R. arboreum. We do not know if it has a distinct name or not.—*A. E. B.* 6, Genista hispanica.

ODONTOGLOSSUMS: *H. T. Pitt.* We thank you for the examples of rare Odontoglossum flowers. O. Wilckeanum, Pitt's variety, is certainly a very remarkable form.

PALM LEAVES: *W. Y. X.* It is not unusual for Palms to have the leaves turn brown in winter as shown on your specimen, especially if they have been used for indoor or conservatory decoration. Repot the plants and induce them to make fresh leaves.

PEACHES: *C. J. C.* Your trees are affected with the "silver leaf" disease, supposed to be due to a fungus. Cut the shoots back; perhaps the new shoots will come healthy, but we greatly doubt it. Water with a weak solution of iron sulphate, using ½ ounce of the iron salt to 2 gallons of water.

TOMATOS: *T. H. G.* We expect that failure has resulted from lack of sufficient ventilation, and of exposure to the sun's rays. Tomatos must be given no shading at all. Let the plants be planted in very firm and only moderately rich soil, then you will be able to obtain short-jointed growths that will flower freely. Keep each plant to a single stem by pinching off all laterals at the first leaf. You may cultivate the plants in pots, or in the border, but do not permit Cucumbers or anything else to shade them.

VIOLETS: *Dulwich.* The Violet disease so often described and figured in these columns. Burn the old plants and plant fresh stock in a fresh portion of the ground.

THE HIPPEASTRUM.

THIS handsome hothouse plant will now be coming into flower. It is one I used to exhibit successfully some 20 to 25 years ago. Messrs. James Veitch and Sons, of Chelsea, had some years previously introduced two very distinct and handsome species from the Andes of Peru through their collector, Mr. Pearce. H. pardinum was the first of the two to produce flowers in the Chelsea nursery in 1867. H. Leopoldi flowered in 1869. And when we see the superb garden varieties now exhibited by Messrs. Veitch and others it is as well to know that their origin can be traced to these two species. Mr. John Seden was the first to cross-fertilise them, and the initial attempt was remarkably successful. H. Ackermanni pulcherrimum was a great favourite at that time, and it was crossed with the pollen of H. pardinum. Three very good garden forms were produced from this cross—viz., Chelsoni, Brilliant, and Maculatum. The work of cross-fertilising soon passed into the hands of Mr. John Heal, and many of the beautiful garden varieties in existence 20 years ago were raised by him at Chelsea. The characteristics of H. pardinum and Leopoldi were the very short tubes they possessed, and the habit of producing two flowers on a scapé. They lacked somewhat of the vigour possessed by some other varieties in cultivation at the time.

The family of Mr. de Graaff, of Leiden, had also been working for many years in hybridising and cross-fertilising the Hippeastrum. As long ago as 1790 the De Graaffs had raised hybrids, and they are still continuing this work. Amongst others they raised a truly handsome variety named Empress of India, which was raised by crossing a dark-coloured seedling from H. psittacinum with another seedling of their own named H. gravianum. This handsome variety, Empress of India, produced large crimson-coloured flowers, four and five on a scape; and another variety named "The Giant" was introduced at the same time. Other growers had been working in the same direction with such material as was available. As early as 1799 a watchmaker of Prescot, in Lancashire, named Johnson, began the work of hybridising, and made a cross between H. reginæ and H. vittatum and produced H. × Johnsoni. Dean Herbert asserts that Johnson raised this hybrid in 1810, and it was also raised by himself at Mitcham in 1811. Herbert was a most indefatigable hybridist, and could not be satisfied with merely cross-fertilising garden varieties. There were a number of interesting and some handsome varieties and species in cultivation before the year 1810. H. striatifolium had flowered in Messrs. Lee's nursery, Hammersmith, in 1781. The type forms of H. reticulatum was in cultivation in 1777 H. equestre was introduced in 1698; H. reginæ in 1728. H. vittatum, used so much by Herbert as a parent, was introduced in 1769. The splendid strains produced by Ker, of Liverpool, and Williams, of Holloway, are known to all lovers of these plants.

The modern cultivator in nearly every instance looks to the production of beautiful garden varieties, and obtains the best he can find in the market for this purpose, and it is not important to him what were the original species from which the existing garden varieties were obtained. His object is gained if he improves upon existing forms, either by obtaining better or brighter colours, or better form in the flower, etc. Herbert's work was entirely different; he, working from a scientific standpoint, made crosses from original species, and many of them must have been of great interest. Amongst others he raised H. Henslowi, named after the Professor of Botany at Cambridge. Several interesting crosses were made at the same time by others. Sweet, at Colvill's nursery, a Mr Griffin, and also Mr. R. Harrison were all co-workers, and the result is given at pages 142 to 144 of the *Amaryllidaceæ*. There are 31 examples of the hybridist's art described, many of them from H. reticulatum. A very pretty form of the Habranthus section is figured in the *Botanical Magazine*, t. 7,344. It is named H. brachyandrum, and was described by Mr. Baker from examples that flowered at Kew: "The first flowers opened in July, and they continued till September, so that the plant proves to be a valuable acquisition to horticulture." The plants seem to have been flowered in an open border with a southern exposure. The colour of the flower is a deep claret red, fading to pale pink at the top of the funnel-shaped perianth.

As is well known, the garden varieties of the Hippeastrums are really hothouse plants. They do not require a very high temperature, but luxuriate in a bottom heat of 80 degrees to 85 degrees, and an atmospheric temperature of 60 degrees when they are approaching the flowering stage. How it would rejoice the hearts of thousands of amateurs who can afford a greenhouse, but object to the expense of a hothouse, if a strain of plants of this genus could be obtained that would be at home in a greenhouse! I have seen only the coloured plate of H. brachyandrum, which shows it to be a handsome species, and a fair rival to Vallota purpurea, a well-known greenhouse plant. Another charming greenhouse plant is the Jacobean Lily, Amaryllis formosissima. This species does not seed freely. Indeed, Herbert states that no instance had come to his knowledge of its having borne seed in England. This is so near Hippeastrums that one would think it might be hybridised with them. Ripe seed was obtained from it by the late Colonel Trevor Clarke. I believe he gave seeds to Kew nearly twenty years ago. Amateurs with time to spare might obtain much enjoyment by working out scientific experiments on the hybridising of these comparatively hardy species. Cyrtanthus hybridus is stated in *Gardeners' Chronicle*, 1885, vol. xxiv., p. 391, to be a hybrid between the Vallota and Cyrtanthus sanguineus. No one can tell what might be accomplished by the intercrossing of these allied genera.

How to Raise Seedlings.

A few remarks may be useful on the raising of seedlings and the general culture of Hippeastrums. In order to obtain any measure of success, cross-fertilisation must be resorted to. When Empress of India was first introduced I obtained a plant and fertilised the flowers with their own pollen, and obtained over 400 plants, but they proved very disappointing; very few were as good as the parent, none was better, and not one in fifty was so good. There was also but little variation in colour, whereas if cross-fertilisation had been attempted many distinct and beautiful varieties would have been forthcoming. The stigma and stamens are so conspicuous that it is quite easy to cross them. The stamens, of course, must be removed from the seed-bearer before the pollen-cases burst, and in 24 hours the stigma will be in condition to have the foreign pollen applied. The capsules swell rapidly, and the seed will be ripe in June or July. Sow it as soon as it is ripe in a hothouse in bottom heat. The young plants will soon appear, and if they are potted off in good soil, a dozen or so in six-inch flower-pots, they will make excellent growth the same season, and good bulbs will be formed. They will be all the stronger if the flower-pots are placed over a little bottom heat. The plants do not require a long season of rest, but should be kept dry at the roots during November and December and part of January. They will not lose their leaves during the winter, and in January three of the plants may be potted into six-inch flower-pots, and, if placed in a moderate hothouse atmosphere, with a gentle bottom heat, some of them will form flowering bulbs by the end of the season. The potting soil may be good yellow loam four parts, decayed stable manure one part, and leaf-mould or peat one part. At the end of the season all the bulbs may be rested until potting time in January, when they should be repotted singly and treated as ordinary named varieties. It is not absolutely necessary that these plants should be grown and flowered with their pots

plunged over the rims in spent tan from a tan-yard, but those who cannot afford to treat them so will not be able to obtain such satisfactory results as those who can.

I would warn those young gardeners who aspire to success in the culture of these plants that they must be very careful as regards watering, especially after the bulbs have been recently repotted. If the potting compost is fairly moist to start with, no water should be given for two or three weeks afterwards. By that time some growth will have been made, and water of the same temperature as the atmosphere of the house may be applied at first round the sides of the rims, so as not to allow any to lodge at the base of the bulbs. When the pots have become full of roots water may be applied freely; but if the flower-pots are plunged they will not require a very great quantity of water. The garden varieties of Hippeastrum have now attained to such a high standard of excellence that fewer varieties receive certificates than heretofore. I have looked through the reports of the Floral Committee of the Royal Horticultural Society, and find that one only was certificated in 1904 and none in 1905. That in 1904 was a truly handsome variety named Snowdon (see fig. in *Gardeners' Chronicle*, April 30, 1904), pure white, and raised by Mr. Fielder, the very able gardener at North Mymms Park. This received a first-class certificate for its vigorous habit, large size of the flowers, and their perfect form. Other white varieties have been raised, but none at all approaching this. Many very fine varieties were exhibited, but the committee evidently thought that none of them were advances on previously raised varieties. *J. Douglas.*

CHINESE CONIFERS.

A NEW CHINESE LARCH.*

Botanists have described two Larches as native to the province of Szechuan. One was described by Batalin in 1894 under the name of L. Potanini, another collected by Prince Henry of Orleans was called L. thibetica (1899). Judging from the descriptions only, it seems most probable that the two names refer to one and the same species, and, if so, the earlier name, that of Batalin, must be adopted. Specimens were collected by Wilson in the same district, and were considered by him to belong to the same species as that above mentioned. Seedling plants are in cultivation at Messrs. James Veitch & Sons' Nursery at Combe Wood, on which account it is desirable to give a description and illustration taken from Wilson's n. 3,009. Mr. Wilson tells us that it is a tree ranging from 20 to 60 feet in height common around Tatien-lu at an altitude ranging from 7,500 to 11,000 feet. It is the Hung Sha of the Chinese, and is the most valuable timber tree in Western China.

The bark on the young shoots is of an orange yellow colour and slightly hairy, on the older shoots the bark becomes glabrous and of an ashen grey colour; the leaf cushions or pulvini are slightly prominent, linear. The leaves, which measure from 20-25 mill. (occasionally much shorter), are glabrous, linear, apiculate, flattish, with a prominent midrib. The mature cones are 35-40 mill. long, 18 mill. broad, sessile, deflexed, oblong-ovoid, obtuse. The bracts are conspicuous as long as, or, in the young state, longer than the scales, membranous lanceolate, often markedly acuminate, and frequently recurved; cone-scales brownish grey, rounded truncate, seeds winged. Beissner's Larix chinensis is from a different district (northern Shensi) and differs materially from the present species in its cones.

* Larix Potanini, Batalin in *Act. Hort. Petrop.* xiii., p. 385 (1894).
L. thibetica, Franchet in *Journ. de Bot.* (1899), p. 262.

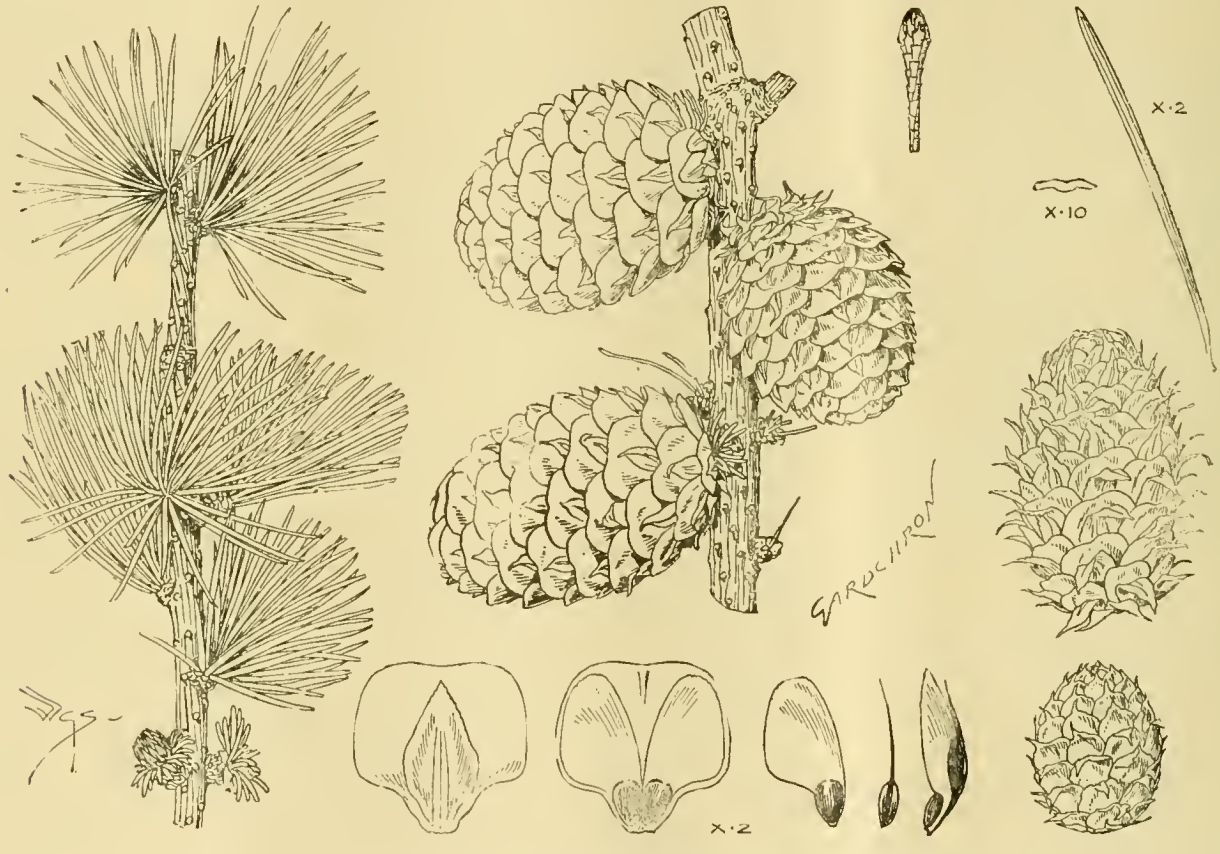

Fig. 68.—Larix potanini.

To the left, branch with tufts of leaves; in the centre, three mature cones of real size; to the right, a bud, a leaf of twice the natural size with a transverse section magn. 10 diam., young cones; in the lower line, bract, cone-scale and seeds magn. 2 diam., and young cone.

THE ADVENT OF THE DAFFODIL.

The Narcissus, in all its myriad forms, is an eminently satisfying flower. An imperfect Daffodil would be a kind of anomaly; such a phenomenon is hardly conceivable, especially in this age of hybridisation. No bulbous plant is so marvellously accommodating; it can be planted almost anywhere, on grassy lawns, picturesquely in leaf-mould at the feet of venerable trees—in which situations it is uniquely beautiful—or wherever there is adequate drainage—a matter of supreme importance—in ordinary garden loam. The finest and most impressive of modern Narcissi succeed admirably in such positions, and, as a general rule, are not greatly affected, unless where shelter is utterly unattainable, by atmospheric influences. Like Henry Kirke White's Early Primrose, they are, only too often for the composure of their ardent cultivators, "nursed in whirling storms, and cradled in the winds." Shakespeare, the greatest of poetic thinkers, has told us that "they come before the swallow dares, and take the winds of March with beauty"; and Wordsworth, the high priest of Nature, has declared that "they gleam into that inward eye which is the bliss of solitude"; thus memorably emphasising their moral suggestiveness. Much of the purest and loftiest inspiration of which mankind is capable is derived from such exquisite vernal flowers. Such being the case, I think it is quite a misfortune for the ordinary cultivator of limited resources that many of the most recently introduced Narcissi should be advertised at quite prohibitive prices, so far at least as humble amateur gardeners are concerned, and that they will not be accessible to men of modest means for many years. For these, however, there remains this enduring consolation, that many glorious varieties such as Emperor and Empress, Maximus and Grandis, Queen of Spain, Barri Con-

spicuus and Duchess of Westminster, not to speak of the many lovely forms of Narcissus poeticus, are quite within their reach. They have also the assurance that such much-envied varieties as Peter Barr, whose price has fallen vastly within the last year, Weardale Perfection and Madame de Graaff (which I had the pleasure of planting last September for the first time in front of my study window) will ere long be equally accessible. Hitherto, unless perhaps at the nurseries, I have only had the privilege of seeing individual flowers of these, or of Mr. Engleheart's or Mr. Haydon's most recent creations. But even to study such flowers at a metropolitan exhibition is a veritable refining horticultural education. During the season that here, with Narcissus scoticus and Telemonius plenus, has just begun, I hope to see my namesake, a grand derivative from Emperor, described by a great specialist as "a bold and noble flower," for the first time in bloom.

Other uniquely interesting varieties whose appearance on our lawn I await with great interest are the queen of white Daffodils—Madame de Graaff, the exquisitely beautiful Narcissus Johnstoni, Queen of Spain, that finest of the delicate Leedsi forms, Duchess of Westminster, the great Bicolor Victoria, with bright yellow trumpet and massive, cream-like perianth; the moschatus of Haworth, a miniature beauty, invariably sweetest in aspect, and most enduring in existence, when thus naturalised in grass; Narcissus albicans, one of the most charming of all natives of Spain; and the silvery-white, pendulous Colleen Bawn.

However familiar to our consciousness such flowers may appear, their vernal advent is always a radiant revelation. *David R. Williamson.*

CULTURAL MEMORANDA.

NIDULARIUM INNOCENTI STRIATUM.

This Brazilian Bromeliaceous plant has bright green leaves, each from 8 to 12 inches in length, beautifully striped with a central white variegation, deepening off to a creamy-yellow, broad, arching, lanceolate in shape, the margins being furnished with small spinose teeth. It is, therefore, an attractive and very elegant plant. It may be propagated by suckers detached from the parent plant and potted into small sixty-size pots in a mixture of equal parts leaf-mould and fine sandy loam, with a liberal addition of silver sand, the whole being well mixed together before being used. Place the plant on a shelf in the plant-stove or propagating pit, and afford water through a fine rose to settle the soil.

GMELINA HYSTRIX.

This climbing plant is most suitable for clothing the roofs, pillars, and walls of plant-stoves, warm greenhouses and conservatories. It was introduced from the East Indies, and resembles the Bougainvillea in habit of growth. The flowers are freely borne in dense, terminal, drooping spikes, and have acuminate bracts, effectively veined with purplish red, the corolla being nearly 3 inches long and of a beautiful golden yellow colour. The plant may be propagated from cuttings of the young growths, about 3 inches long, taken off with a little wood of the previous year's growth attached. The cuttings should be inserted in suitably crocked 3-inch pots filled with light sandy mould. Place the pots in the propagating pit, or in any structure in which a warm, moist, atmosphere is maintained, where they will soon form roots. After the little plants have made some top growth they should be potted off singly into the same size pots in the same description of mould as before, returned to heat, and watered. *H. W. Ward.*

TREES AND SHRUBS.

GROUP PLANTING OF CONIFERS.

Some gardeners are prone to dogmatise overmuch in regard to the manner in which trees should be planted, and other matters; not recognising or admitting there may be cogent reasons for departures from the methods and practices which they think to be right. Let us take the planting of trees in groups, or singly on lawns and in pleasure parks and grounds. The proprietor may be desirous of securing immediate effects, and the fact is generally known that trees make more rapid growth upwards when planted in company with others than planted singly at wide distances apart owing to the mutual shelter afforded against wind and storms; the more equable temperature enjoyed, and the greater abundance of moisture found in the air in a group, and the hindrance to evaporation afforded by the foliage of the trees composing the group. Let anyone compare the growth made by the same kinds of trees planted in groups and singly at the same date. Moreover, the closer the planting the more rapid the rate of growth. I have observed groups of Red Cedar (Juniperus Virginiana), the tree which affords wood for making pencils, which measured from 20 to 40 yards in diameter, and the trees stood at less than 3 feet apart. These groups were symmetrical in general outline 60 years after planting, contained no perceptible gaps, never admitted the full force of the wind into the interior of the groups, and carried good healthy crowns, although all below 15 feet high consisted of bare, branchless poles of 6 to 8 inches in diameter at man's height; and as the groups were set out at distances of 100 to 200 yards apart, they supplied capital wind breaks, and agreeable if dark coloured furnishing for an extensive pleasure ground.

Where space could be afforded, I would recommend the planting of this rapid-growing Conifer at 2 feet apart, for affording poles and stakes for garden use; especially for supplying "rustic" supports for creeping and climbing plants out of doors; fencing, etc.; the wood when felled in the winter and seasoned in airy sheds for two years being very durable. The tree at any age has but little sapwood; and in lasting properties excels Hazel, Sweet Chestnut, Ash, or any other coppice woods which I know of. A good example of group planting was carried out in the gardens at Aston Clinton by the late Baron Anthony de Rothschild many years ago, the species of Conifer planted being Sequoia gigantea (Wellingtonia). It is some few years ago that I observed these two groups, and the trees were at that time in perfect condition and about 40 feet in height, with stems at 3 feet from the ground of 1 foot in diameter. A good deal of conifer planting was carried out at about the same time on that portion of the estate situated on the Chiltern Hills above Aston Clinton, but I do not know if choice Conifers alone were planted in close order, or nurse plants of quick-growing kinds were also employed. This extensive plantation right on the top of the hill contained many magnificent Conifers, which were largely drawn upon when Halton was being laid out for Alfred de Rothschild, Esq., about a quarter of a century ago.

Another Conifer which groups grandly, and grows rapidly, is Sequoia sempervirens (Redwood). The columnar habited Conifers are always best for solitary or group planting, and flat-headed Firs, such as the Weymouth Pine and Scots Pine, and others of that class, which soon lose their lower branches, and then admit wind and sun, are less well suited for forming small groups in pleasure grounds, these being the more effective when the outer lines of trees preserve their branches down to the ground level. *F. M.*

LEAVES FROM MY CHINESE NOTE-BOOK.

The Flora of the District.

(Continued from page 166.)

The Meconopsis at Last.

At 11,000 feet I came across the first plant of Meconopsis integrifolia! (See *Gardeners' Chronicle*, October 1, 1904, p. 240.) It was growing amongst scrub and was past flowering. I am not going to attempt to record the feelings which possessed me on first beholding the object of my quest to these wild regions. Messrs. Veitch despatched me on this second, and very costly, journey to the Tibetan border for the sole purpose of discovering and introducing this, the most gorgeous Alpine plant extant. I had travelled some 13,000 miles in 5½ months, and to be successful in attaining the first part of my mission in such a short time was a sufficient reward for all the difficulties and hardships experienced en route. The second part of my mission was easily accomplished in due season, and to-day this plant is well known to all readers of the *Gardeners' Chronicle* and other horticultural journals.

As we continued the ascent, Meconopsis integrifolia became more and more abundant. At 12,000 feet and upwards, miles and miles of the Alpine meadows were covered with this plant, but only a few late flowers remained. Associated with the above species I found Meconopsis Henrici. This is a charming plant with medium-sized, dark violet-purple flowers, borne on scapes 6 inches to a foot high. Like M. integrifolia, M. Henrici is a social plant, and occurs in thousands.

With the Rhododendrons above 12,000 feet, at least four species of Salix occur; one of these species of Willow grows prostrate over rocks, and is not more than an inch high. Beneath the gnarled and twisted trunks of the Rhododendrons, Cassiope selaginoides occurs in myriads. On bare, exposed rocks, Potentilla fruticosa is plentiful. Three forms of this plant are distinguishable, having respectively white, lemon, and deep yellow flowers. The white form attains the highest altitude. The Rhododendron bushes are only 4-6 feet high, and though they flower freely enough, but few seed-pods are produced. A dwarf species of Rhododendron, with small purple flowers and minute leaves, cover these uplands as heather does the Scottish moors.

The summit of the pass (13,100 feet) is flat, about a quarter of a mile across, and flanked on the right and left with grassy mountain slopes.

Several ponds of good size occur on the summit, and two or three large cairns of stones mark the boundary of the kingdom of Djiala in this direction. Snow lays for eight months of the year on the top of the pass. A row of stakes 10 feet high marks the path across, but in spite of these, lives are often lost on this pass in winter.

Very few Rhododendrons occur on the summit, and save an occasional Willow and Juniper no other shrub. This exposed summit, over which the wind sweeps pitilessly, was at the time of my visit one carpet of herbs: Gentians, Anemones, Primulas, Meconopsis, Corydalis, Senecios, Fritillarias, Orchids, Pedicularis, Potentillas, Oxytropis, dwarf Delphiniums, various species of Compositæ, Leguminosæ, and Labiatæ—flowers of every hue in myriads! Dense mists prevented an extensive view of this fairyland; the thermometer stood at 48° F. Wet to the skin and shivering with cold, yet we were loth to turn our backs on a scene so enchanting. A glance at the watch showed 4 o'clock; this meant that unless we wished to be benighted we had better return with all speed.

It was with many misgivings that we approached our new lodgings at 6.30 p.m., but to our glad surprise everything had favoured us. We were accommodated in a nice weather-proof room, with a fairly clean boarded floor.

Our cook was quite strong again, and had a nice warm meal ready for us, to which we speedily did justice. The previous night's experience was soon forgotten, and a sound night's sleep rewarded the exertions of the day.

The next day we attempted to climb up to the snow-line, but only succeeded in reaching 15,000 feet. This climb enabled me to make out the zones of vegetation more clearly, and to better understand the limits of certain species. To my collection I added several fresh plants of interest, including Spenceria ramalana, Meconopsis horridula, M. sinuata var. Prattii, Incarvillea Principis, Braya sinensis, Trollius ranunculoides, two species of Cyananthus, various Composites and Labiatæ, and the curious Himalayan trefoil Parochætus communis.

The Meconopsis were growing in the niches of bare granite cliffs between 13,500 and 15,000 feet. The Incarvillea has bright crimson flowers and was abundant in grassy places between 13,000 and 14,000 feet. Meconopsis integrifolia ceased at 14,500 feet. At this altitude this plant is very much reduced in stature and occurs on tops of humus-clad rocks and in the niches of cliffs.

At 15,000 feet, which is practically the limit of vegetation hereabouts, I gathered Meconopsis horridula, Arenaria sp., Ranunculus glacialis, Draba sp., Primula sp., Saxifraga sp., Carex sp., a very curious Composite, and the lovely Myosotis Hookeri. With the exception of the Composite, all the above are small, tufted, cushion-like plants. Hooker's Forget-me-not forms cushions a foot or more across—one mass of lovely blue flowers—and is a most charming Alpine.

At 14,200 feet we encountered the moraine of an enormous glacier. Over this we scrambled and ultimately reached a ridge at 15,000 feet. In front of us was another desolate moraine, or series of moraines, and immediately above us towered bare, inhospitable cliffs of granite and gneiss. The day was bright and sunny, and the radiation from the bare rocks excessive. At 3 p.m. the thermometer registered 80° F. The moraine in front of us terminated in tremendous fields of ice, glaciers of a virgin peak, 21,000 feet high.

The sun shone brilliantly, and we got a magnificent view of the surrounding mountains. South, south-west of us lay a gigantic peak, several thousand feet higher than the one mentioned above; its summit crowned with snowfields of enormous size. On every side, as far as the eye could range, towered mighty snow-clad peaks. When this *terra incognita* is properly surveyed, it will probably be found that many of the peaks equal the highest peaks of the Indian Alps. *E. H. Wilson.*

(To be continued.)

TREE CARNATIONS.

We seem to have lost sight of the varieties to which the name "Tree" was originally applied, but I have previously suggested that it has been from such as we grew forty years ago that the Americans have obtained such signal success. I believe most of those with the flowers more or less fringed originally came from the Continent. La Belle Rose, one of the first I remember, had flowers somewhat similar to those of the American variety G. H. Crane, but not so large in size. The white variety, with fringed flowers, I believe, was called The Bride. Then, later on, we had Laura, of blush-pink, and Andalusia, primrose-yellow. La Belle was of the same habit, but the flowers were not fringed. Mrs. Keen, a very tall-growing variety, with crimson flowers, was an old favourite. I think if we had kept to those just referred to we should have been quite even with the Americans; but the aim of English raisers was to discard varieties with irregular petals in favour of those with broad, smooth petals, having a "regular" edge. Yet from France we got other good varieties. A. Alegatière was a great favourite about 25 years ago; but before this Mr. Charles Turner, so well known as a Carnation specialist, had introduced other varieties of a dwarf habit. Foxhunter, of bright scarlet, was one of the first I remember; then we had Miss Joliffe, which for a long period enjoyed a higher reputation than any other variety grown for market purposes. Lucifer was another of the dwarf-growing section. Irma, pink, was for a long period a favourite. La Zouave, Vulcan, and others were too much of the habit of the border sorts, and it was by introducing such as these into the winter flowering section that we lost ground. Winter Cheer, though a dwarf variety, proved to be most valuable for winter flowering, and for the past 15 or 16 years has remained a favourite, during which time it has been the parent of many other useful sorts. Further perseverance may be recommended with this type, for if not quite so valuable for producing flowers for cutting, they make useful flowering plants. It was after the introduction of this variety that I commenced to cross-fertilise Carnations, and found it one of the most prolific seed parents. One of the first crosses made was from pollen of Uriah Pike, secured from flowers bought in the market before plants of the variety were sold. From the first cross the variety Henry Gibbons was obtained. The flowers were not very full, but the variety had the free habit of Winter Cheer, with the rich crimson colour of Uriah Pike. I never could recognise this latter variety as a proper Tree Carnation, for in plants propagated in the spring it was only the main stem that would flower in the winter, all the side shoots remaining until late in the spring before starting to

Fig. 69.—English-raised Tree Carnation "Elliott's Queen," which obtained an award of merit at the R.H.S. meeting on March 6; flowers, rose coloured.

(See note on page 181.)

show flower stems. This is the most important distinction between the Border and the Tree varieties. In the latter the side shoots follow on. Taking Winter Cheer as one example, when planted in the open ground I have seen the same plants maintain a regular succession of bloom right on to nearly Christmas, and if the weather had been favourable they would have continued longer; while the Border varieties in the next beds produced but one crop of blooms, the lateral growths failing to develop flower stems.

Mr. H. B. May, of Edmonton, sent out a set of very useful varieties, many of them having been obtained from Winter Cheer. Countess of Warwick was an improvement on H. Gibbons, and later still was Prince of Wales. W. Robinson, which is still grown extensively, was a considerable improvement on scarlet varieties. Primrose Day, a fine yellow flower, The Shahzada, Zenobia, and several others were good, and have been followed by later varieties from the same parentage.

Mr. Godfrey, of Exmouth, is another grower who raised some good things a few years ago, but he seems to have worked more on the Madame Therèse Franco type. His "Pride of Exmouth" is recognised as one of the most useful pink varieties for market, and Godfrey's King is a good crimson flower. Madame Therèse Franco is still extensively grown for supplying the market with cut blooms. It was first shown in August, 1892, under the name of Mrs. Leopold de Rothschild, and an award of merit was given by the Floral Committee of the R.H.S. In October of the following year it was shown by Messrs. Veitch and Sons, Chelsea, under its proper name, and was again given an award of merit. It appears to have been of French origin. Only the last time I was in the market I noticed a splendid lot of blooms of this useful variety; but the older favourite, Miss Joliffe, seems to have almost died out.

Of the more recent additions some varieties from Messrs. Cutbush and Sons show evidence of American blood in them. General Kuroki is much after the American type, the large, bright scarlet flowers having stiff stems. Mrs. S. J. Brooks, the pure white flower of earlier origin, also belongs to the American type. The firm have added a good many other useful sorts which indicate the same parentage.

Mr. W. E. Boyes, of Leicester, has for some years been a successful worker. He has on several occasions exhibited his own raised varieties, both as pot plants and as cut blooms. I have before me some fine blooms received from him, and these indicate some relationship to the Americans. One of the finest is Dr. W. G. Grace, of intense scarlet colour; the large spreading petals are fringed, the calyx is good, and the stems long and erect. The Hon. A. Lyttelton, red, with petals of good substance, G. A. Boyes, white, with a slight blush tint, large full flowers, with stem and general form favouring Enchantress, Lady Carlisle, rosy pink, and Lady Lonsdale, white, suffused with pink, with several other good sorts, are all of a strong-growing type.

Mr. A. Smith, of Enfield Highway, is another successful raiser. He has sent me blooms of Britannia, a large scarlet flower, of perfect form, with good calyx and strong stem. Liberty, another good scarlet variety, which was well shown last November, Coronation, a very pretty pink variety, but the flowers rather small, Progress, a cerise coloured flower, with fringed petals, and, as recently seen, a most promising variety, are only some of Mr. Smith's seedlings.

Mr. H. Elliott, of Hassocks, Sussex, is another raiser. Elliott's Queen, of deep rosy-pink colour and large size, is quite of the American type, and gained an award of merit on March 6. H. Elliott is a deep pink flower, something after Mrs. T. W. Lawson, very large, well-filled flowers. Mr. Elliott speaks very highly of some newer seedlings I have not seen.

Messrs. R. H. Bath, Ltd., Wisbech, are working on the American varieties, and they have sent me blooms of a seedling raised from Mrs. T. W. Lawson, the pollen parent being Lord Roberts, a good yellow variety. The flowers received have a buff ground, flaked with red, and it appears probable that another generation may produce a good yellow flower, which is wanted more than any other winter-flowering variety. From the same seed-pod yellow varieties were secured, but they were not good on all points. Having so many now working on these useful flowers, we may expect further good results; but it may prove difficult to make selections when they become so numerous.

(To be concluded.)

Fig. 70.—American-raised carnation "Nelson Fisher," which gained an award of merit at the R.H.S. meeting on March 6; colour of flowers, deep shade of cerise.

FORESTRY.

CLIMATE and TREE GROWTH.

As communications have appeared from time to time on this subject in the *Gardeners' Chronicle*, all of which are apparently intended to prove that the comparison I draw between the climate of Belgium and that of the North of England and Scotland amounted to a libel on the latter, perhaps I may be permitted to sum up a few of the statements made by different correspondents, and note how far they go to disprove my original statement published in the *Gardeners' Chronicle* of November 18, 1905. This st to-

ment was as follows: "As regards climate, it was apparent that the rate of growth of all species was much more rapid than that seen, say, north of the Midlands."

Sir Herbert Maxwell gave instances of the growth of several species which I did not consider as proving or disproving the point I raised, as they referred rather to the growth of individual trees than to that of crops of timber several acres in extent, and growing at what we consider high elevations. It is only by duly taking this question of elevation into account that the real point at issue can be discussed at all. When we find forest crops growing well in one country at 2,000 feet above sea level, and in another ceasing to grow profitably at 1,000 to 1,200 feet, the only reasonable deduction that can be made from such a fact is that the climate of the former is warmer than the latter during the growing season or summer months. Whether this extra warmth is an advantage or not depends upon the species grown and the quality of timber desired. This question of quality was never raised by me at all, but simply the rate of growth of such species as Scotch Pine, Spruce, Oak, Beech, or other hardy and common forest trees when growing north of the Midlands. If anyone can give me instances of crops of Scotch Pine or Spruce growing at the average rate of 2 feet yearly for the first thirty years at an elevation of 1,000 feet or over, and in that part of the British Isles I specified, then the question may be considered settled, as a parallel to the case I quoted will have been found.

Dr. Henry tells us that the absence of cold drying winds during the winter months is a feature of the British climate favourable to tree growth. And is not the absence of such winds during May and June of equal importance? He also points out that his investigations have proved the suitability of the British climate for the growth of most indigenous and a few introduced forest trees. Cæsar came to the same conclusion 2,000 years ago, and made a note of it, but it is rather the comparative rates of growth of these trees than their healthy existence and normal development that we want to get at.

Mr. John Booth states the growth of certain Conifers at Bicton and Dropmore surpasses anything he has seen in Germany, but both these places are a long way south of the line I laid down. Meeting him on his own ground, however, I should like to ask him where his studies of tree growth in Britain have been made. Have his arboricultural visits been chiefly made to places famous for fine specimens, or to the ordinary woodlands of the country growing on hill-sides, where such species as Cedrus Deodara, Taxodium sempervirens, Pinus Hartwegii, and many others would be failures? A few weeks back he told us that Cobbett was right when he stated that the Locust tree was superior to the British Oak for forest planting. If Mr. Booth will give the dimensions of individual trees and their number growing on ten acres of ground, half of which have been planted with our species and half with the other, and allowed to mature, I think I can show him not only that Cobbett was wrong, but where he was wrong. The list of trees Mr. Booth states his ability to draw up, and which will contain the names of trees able to grow in this country, but not in Germany, is no great wonder, when we consider the difference in the winters of the two countries, but how many of the trees in this list will attain their normal dimensions here, and how many are superior to the native trees of the country? Many species again which are successful in such sheltered spots as may be found in abundance in most hilly districts are complete failures when planted on high and exposed ground in the same districts. In the Lake district of Cumberland, and parts of Perthshire, many trees, especially Conifers, reach large dimensions, but a few miles away similar results are not obtained. In the one case we have a purely local climate, or conditions of growth; in the other the average climate of the country exerts its full influence upon growth, and the real hardiness of a species is put to the test.

As a matter of fact, no one who has paid any attention to the growth of ordinary forest trees, whether indigenous or introduced, doubts the fact that the vast majority of trees grow faster in the South of England than in the north. Where can we find such specimens of Oaks, Spanish Chestnuts, English Elms, Planes, Limes, and many other trees in the north, which are so common in the south? Why does hedgerow timber never reach the length and size in the former as it does in the latter? Sylviculture does not come into play with this class of timber, and climate alone can make the difference. I am not referring so much to the small proportion of "show" trees, which are more or less famous in their particular countries, but to the average timber, which can be seen in any parish, or, when felled, in a timber merchant's yard. With Conifers of most kinds, the same difference can be noted, although it may not be quite so marked, and with a few species which like a cool, moist climate may disappear altogether, but these do not affect the question generally.

If the growth of timber in the south is more rapid than in the north, then I think we may take it for granted that Belgium is equally superior to the latter, and a careful examination of facts will prove this to be the case. I have no wish to disparage the British climate for timber growing, and as regards the quality of the timber it can grow, it is probably better than most parts of Europe, so far as the production of strength and durability are concerned. But when the truth of a simple statement, such as the one which gave rise to this discussion, is called into question, I may be excused for defending myself. *A. C. Forbes.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. White, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Thunias.—There are many deciduous or semi-deciduous Orchids which having had a decided rest during the winter months are now re-commencing to grow and will need immediate attention. Thunia Marshallii, T. Bensonæ, T. candidissima, T. alba, T. pulchra, and the hybrids T. Brymeriana and T. Veitchiana should be shaken out of their old compost and be repotted. The usual and most convenient method is to plant six or eight pseudo-bulbs about 3 inches apart, into pots of 7 or 8 inches in diameter. Use clean pots and make them nearly half full with crocks, over which place a thin turf of fibrous loam with the grass side downwards. The rooting medium should be of good yellow fibrous loam, with a moderate quantity of chopped sphagnum-moss, and sufficient small crocks to maintain porosity. Place the base of the new growths level with the surface of the soil, which should be at about half an inch below the rim of the pot. Secure each pseudo-bulb to a neat stake to hold it firmly in its proper position. Place these Thunias in the lightest position in the East Indian house or plant-stove, with the tips of the pseudo-bulbs as near to the roof glass as possible; if these bulbs have grown to an unreasonable length, cut off a portion from the top, so that the young growths at their base may be brought nearer to the light. For several weeks after repotting, very little water will be needed, but as the growths advance and the roots are seen to be spreading through the compost, gradually increase the supply, and when firmly established, occasional waterings with weak liquid cow manure will be useful. The pretty Arundina bambusæfolia and A. Philippii may be repotted in the same kind of compost and be treated as the Thunias as regards the water supply, but they thrive best in the more freely ventilated atmosphere of the Cattleya house.

Spathoglottis, Chysis, Bletias, &c.—Such plants as Spathoglottis Lobbii, S. aurea, S. Fortunei, S. plicata, S. Vieillardi, and their hybrids may be treated as advised for the Thunias, but they require rather more shade while growing. Such species as Chysis bractescens, C. aurea, C. Limminghei, C. lævis, and the distinct hybrids C. Chelsoni, C. Sedeni, and C. Langleyensis, also Anguloa Clowesii, A. Ruckeri, A. uniflora, and its varieties, develop flower-buds with the young growths, and should therefore not be disturbed by repotting until after the flowers have faded. Suspend the Chysis in a light position in the Cattleya house. Keep the Anguloas in the intermediate house. Both Chysis and Anguloas will require sufficient water to keep their roots just moist. After the flower-spikes have been cut the Chysis may be repotted into a well-drained compost of fibrous peat, leaf soil, and chopped sphagnum-moss in equal parts. Keep them in the same house throughout the growing season. Immediately the young leaves commence to unfold let the plants be placed in a house that is being vaporised, as opportunity occurs, so as to destroy small yellow thrips that may be lurking low down in the young growths. The same kind of soil will suit the Anguloas with the addition of fibrous loam in the same proportion to the other materials. Bletia hyacinthina is a deciduous plant now commencing to grow, and should at once be repotted in the same compost as used for the Anguloas. Keep the plant well exposed to the light in the coolest house. It will, if needs be, do well in an ordinary greenhouse. A liberal supply of water is needed at the root till the flowering period is past, when the quantity should be gradually decreased. Other species of Bletia when growing require the atmospheric temperature of the Cattleya or intermediate house.

PLANTS UNDER GLASS.

By B. Cromwell, Gardener to T. Sutton Timmis, Esq., Cleveley, Allerton, Liverpool.

Franciscea (Brunfelsias).—These are evergreen shrubs of great beauty, and most accommodating whether required for exhibition or for decorative purposes at home. By placing several plants in varying degrees of heat, they may be brought forward at intervals to flower at any season of the year. Franciscea grow freely if potted in a compost of fibrous peat three parts, leaf-mould three parts, and good loam two parts, with a liberal quantity of sand and crock siftings. During the growing season copious supplies of water should be afforded both to the roots and foliage. If the plants need repotting this should be done immediately after they have flowered, disturbing the roots as little as possible during the operation. Let the plants make their growth in an atmospheric temperature of 60° to 68°, and when the shoots have each made five or six leaves pinch out the points, and the result will be a greater profusion of flowers. When coming into bloom the plants should be removed to an atmosphere of 55° to 60°, as this will improve the quality and colour of the flowers. F. calycina and F. eximia are both desirable plants, and natives of Brazil.

Euphorbia pulcherrima (*Poinsettias*).—The old stools which have been at rest should now be prepared for making new growths to be used as cuttings. Cut back to firm-jointed wood the unripened portion of the stems, and remove the plants into an atmospheric temperature of 65° to 70°, giving the roots at the same time a good soaking with tepid water. When the shoots have grown about 2 inches or so in length, and it is seen that the roots are active, the atmosphere may be allowed to become a little cooler, and by keeping the plants close to the glass the growths will be short jointed, and in the best condition to make roots after their insertion as cuttings. These cuttings should be taken off with a small portion of the old wood attached and inserted singly into small 60 sized pots, plunging the pots in the propagating pit in mild bottom heat. A little shading may be required when repotting takes place, but every care should be exercised to secure that the plants shall not be drawn up weakly by overshading. Poinsettias are often grown in an atmosphere that is too warm and moist, and without sufficient ventilation. When the cuttings are once rooted avoid causing them any check to growth by removing them too suddenly to cooler conditions. When they have become established in their pots

air should be liberally admitted to them, and the plants exposed to all the sunshine possible; such treatment will result in the growth of dwarf plants with hard wood that will not fail to produce at the proper season large, brilliant bracts.

General remarks.—Propagate a good batch of Zonal Pelargoniums for flowering in winter. For this purpose the Improved F. V. Raspail is still one of the best. All the late tubers of Gloxinia and Gesnera should be potted up. Young seedlings of these, as well as those of Begonias, should be closely attended in respect to affording water, and when large enough should be pricked off into pans. Keep the young stock of all winter flowering plants regularly potted and the shoots stopped in order to produce a bushy growth. Libonias should be trimmed over but not cut too closely. The old plants generally flower much better than younger ones. Expose them fully to the sunshine during the summer months. Celosias, Browallia elata, Petunias, Schizanthus, Balsams, &c., should be grown on into pots 7 or 8 inches in diameter to be ready to furnish the stages of the conservatory when Azaleas, &c., pass out of flower. Pot on Fuchsias, and assist herbaceous Calceolarias coming into flower by affording them frequent applications of liquid manure. Sow seeds of Primula sinensis for flowering early in autumn.

FRUITS UNDER GLASS.

By T. W. Birkinshaw, Gardener to Lt.-Col. Sir Chas. Hamilton, Bart., Hatley Park, Bedfordshire.

Pineapples.—Some of the fruits will now be approaching ripeness, and should be moved to a light, dry house, where they will improve both in colour and flavour. The earliest batch of "Queens" should now be afforded liquid manure from the farmyard and guano water alternately twice a week. Maintain the atmosphere in a humid condition by damping the paths and walls frequently, but when the plants flower less atmospheric moisture will be needed. Let the house containing plants that were potted last month be closed early in the afternoon, and the plants be given a syringing overhead at the same time. The roots will now be spreading in the new compost, and they should be given a good watering to thoroughly moisten the soil. Afford ventilation with great care, and especially during the spring months. The atmospheric temperature may be kept at 75° on mild nights, but if the weather is cold 5° lower will be sufficient.

Planting Vines.—If it is intended to plant young Vines, new borders are generally made for them during the preceding autumn, so that the soil may settle down and become warmed through. In cases where this was not done, the work should now be carried out without delay, as the time is close at hand when the Vines will need to be planted. Canes that are one year old are the most suitable, and the best time for planting is just when the buds are about to break into growth. It will be necessary to lay out the roots carefully in tiers near to the surface of the border. After they have been planted water them well with a rose-can, and syringe them two or three times each day, closing the house early on fine afternoons. Maintain an atmospheric temperature of 62° at night. When the Vines expand their foliage, and if they show signs of flagging, it will be advisable to syringe a little whitening and milk over the glass to provide a slight shade from sunshine until the plants have become established in the soil. Encourage them to make as much growth as possible during the season, for the more wood that is made, the better will the roots develop. If the borders are entirely inside, which is the best system for Vines intended for forcing very early in the season, they will require an abundant supply of water at their roots when in full growth.

THE FLOWER GARDEN.

By Hugh A. Pettigrew, Gardener to the Earl of Plymouth, St. Fagan's Castle, Glamorganshire.

Nemesia strumosa, introduced by Messrs. Sutton, with its profusion of Linaria-like blossoms and graceful habit, is such a delightful hardy annual, and so simple in its culture, that it is impossible to use it too freely. It is singularly well adapted for growing in shallow flat vases, or decorated boxes for placing on low walls and terrace balustrades, where if the vases are filled each with a distinct colour, they are decidedly effective. The flowers are of large size, and can be had in five distinct colours of crimson, rose-pink, rich orange, pale yellow colour, and white, while the varied tones and tints of the matured foliage are also attractions. Nemesia strumosa nana compacta is similar to the above, but the flowers are smaller, and, as its name denotes, is more compact in habit. The seed may be sown almost any month of the year, but the present is a good time to sow to have the plants in flower during May and June. They will quickly germinate without the aid of much heat. When strong enough, the seedlings should be pricked off into the vases or boxes in which it is intended to flower them, using a good rich compost of loam, leaf-mould, and cow-manure, and allowing two to three inches between each plant. They usually remain in flower for a long time, and are exceedingly attractive.

Ipomæa versicolor, a half-hardy annual, generally known as Mina lobata, a South Mexican plant, is another desirable subject for using in vases. As the plants are of climbing habit, they require staking with neat twiggy branches. The flowers, which at first are of bright rosy crimson colour, change as they expand to an orange shade, and then fade to a pale yellow colour. A square-shaped vase well filled with this Ipomæa has a very pleasing effect. The seeds should be sown now in heat, placing two or three seeds each in small pots, and then when growing freely, plant them into the vases in a compost of fibrous loam, leaf-mould, and cow-dung. The vases should remain under glass until the weather is warm enough to allow of the plants being put out without incurring the risk of receiving a check.

Salvia farinacea, though seldom seen in gardens, is an ideal plant for growing either in borders or vases. Like S. patens and S. splendens it requires protection in winter, but, like the former, it is amenable to treatment as a half-hardy annual. Seed sown now will produce strong flowering plants by June or July. The spikes of violet-blue flowers resemble very strongly Lavender spikes, for which at first glance they might very easily be mistaken. The beautiful blue colouring of the stem is an attractive feature. By selecting seedlings possessing the deepest colour and the best habit, from which to propagate by cuttings in the autumn, a very fine form could be obtained for future years. Being a strong grower, this Salvia requires liberal treatment as regards soil.

Anagallis grandiflora Phillipsii and Commelina cælestis are two beautiful blue-flowering plants that should be sown now in heat, to plant out to flower in the summer. The latter is a perennial plant, but can be flowered in the first season from seed.

Diascia Barberæ, a perennial, is another flowering plant that can be treated as a half-hardy annual, and be sown at the present time, in heat, to flower in the coming summer. The rosy-pink, double-spurred flowers are produced abundantly during July and August. It is an excellent, dwarf plant for the front of borders, or for use in shallow boxes to be placed on low walls.

THE HARDY FRUIT GARDEN.

By W. A. Cook, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Newly Planted Trees.—These should now be pruned and trained in their proper positions. In the pruning of newly-planted trees, all the long, weak growths should be cut back to a prominent bud that will produce a strong shoot. Trained trees will possibly require to be shortened, and this will certainly be necessary in bush and standard trees, in order to get thoroughly good "leads." If the trees were not pruned, the sap would rush to the top of the shoots, leaving nearly the whole length more or less bare. At the same time no hard and fast line can be given, as all trees are not alike, and therefore the operator must be guided by circumstances. Autumn-planted trees generally "break" much better and stronger than those planted in spring, and may therefore need less pruning. In the making of any ties be careful to leave sufficient space for the shoots to swell, as young trees especially should grow very rapidly. If the shoot has not room to swell, "gumming" and other diseases may result. After this work has been completed, rake over the surface of the soil and apply a mulch, this being essential for newly-planted trees. Strawy manure from the stables is very suitable, and should be laid on thickly. If the weather is dry, a watering will be serviceable, and no trouble should be spared in getting young trees to make a thoroughly good start.

Japanese Wineberry (Rubus phœnicolasius), Logan Berry, and Raspberry.—If not already done, the growths of these should now be tied firmly to stout stakes or to strained wire. The Wineberry, which ripens between the main season of the Raspberry and Blackberry, makes it a valuable addition to this class of fruit. Newly-planted specimens should be cut to the ground line in order to promote strong growths for another season.

Preparation for Grafting.—As was advised in a previous Calendar, the scions should have been cut off and laid in under a north wall, as it is advisable to have the scions fully a fortnight later than the stock. Prepare sufficient clay, which should be free from stones, and mix with this some horse or cow manure, working it well together. This preparation is more generally used in private establishments than grafting wax, but either will answer the purpose. Those who are not familiar with the art of grafting would do well to practise the various cuts during leisure moments in the evenings. Successful grafting depends on the getting of a perfect union between stock and scion, and nothing but practice can make the operator efficient. A very sharp knife and a good eye are necessary requirements.

THE KITCHEN GARDEN.

By J. Gibson, Gardener to His Grace the Duke of Portland, Welbeck Abbey, Notts.

Spinach.—A large sowing of this vegetable may now be made with every hope of obtaining a good return at about the end of May. More often than not the seed is sown too thickly, and the thinning of the plants is neglected, with the result that the leaves are not so large or succulent, nor is the produce so plentiful as it should be. Employ the hoe on the ground between the rows of winter Spinach.

Peas.—Continue the periodical sowings of the best varieties on well-trenched ground, and sow the seed less thickly than was done for earlier sowings. There is no need to sow closer than 3 inches from seed to seed, these forming two lines. A greater percentage of well-filled pods will result from this method than from closer sowings. I have seen the haulm over 3 feet wide at the top of the stakes from a single line of seeds placed at 3 inches apart, so strongly did they branch. The distances allowed between the lines should be the same as the height of the particular variety of Peas. If the Peas will grow 6 feet in height allow the same between the lines.

Broccoli.—The sprouting varieties are now yielding plentiful supplies for the kitchen, and a note should be made of those varieties that give the greatest satisfaction. These sprouting varieties should be grown in greater numbers, as no matter how severe the frost may be they usually stand well, although most other vegetables fail. The same may be said of the old Cottagers' Kale. With so many changes in the weather Broccoli has in many places become damaged, especially where the growth had become strong and sappy. I strongly advise the planting of these on firm ground to prevent such growth.

Parsley.—Make another sowing to have plants that will yield a good supply through the summer months. I prefer to sow in boxes or frames, and transplanting the seedlings in lines drawn at a foot apart by placing each plant 18 inches from the next one. They have then a very pleasing appearance all season, especially if a good variety is used, of which "Dobbie's Selected" is a very fine strain.

Winter Onions have had a bad time lately, for having become quite large through the mildness of the winter, they are consequently not sufficiently hardy. The almost daily changes in weather have caused the plants to become somewhat brown in appearance. An extra plantation of spring-grown plants should be arranged for, and planted about the middle of April.

Red Cabbages.—Plants raised from seeds sown in the autumn should now be finally planted, to be followed in succession by those sown in boxes in the spring. They will succeed in any exposed position.

The weather.—The most severe frost of the winter or spring experienced here was on the morning of the 14th inst., when 14° were registered.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY,	Mar. 28	Liverpool Spring Flower Show (2 days).
THURSDAY,	Mar. 29	Torquay Gard. Soc. Flower Show.
FRIDAY,	Mar. 30	Roy. Bot. Soc. meet.
SATURDAY,	Mar. 31	Dutch Gard. Soc. meet.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—44·6°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, March* 21 (6 P.M.): Max. 43°; Min. 34°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March* 22 (10 A.M.): Bar., 30.2; Temp., 41°; *Weather*—Bright sunshine.

PROVINCES.—*Wednesday, March* 21 (6 P.M.): Max. 45° Ireland N.W.; Min. 37° Southampton.

SALES.

MONDAY and FRIDAY—
Plants, Roses, Azaleas, Lilies, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—
664 cases Japanese Lilies, Iris, Acers, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 1.

WEDNESDAY—
Perennials, Lilies, Hardy bulbs, &c., at 12. Roses, Azaleas, Palms, &c., at 1 and 3, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
Roses, Palms, Shrubs, &c., at Stevens' Rooms, King Street, Covent Garden, London, W.C.

FRIDAY—
Orchids in large variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Count Kerchove. The death of Count Oswald de Kerchove is one of those events which will engender not only profound sorrow among those who had the pleasure of his acquaintance, but will create dismay in horticultural and botanical circles in Belgium, more particularly in the Société Royale d'Agriculture et de Botanique de Gand. That society, so well known in this country for the splendour and interest of its quinquennial exhibitions and its overflowing hospitality to strangers, was sorely tried by the death of Edward Pynaert, and quite recently of its excellent secretary, M. Fierens. It now reels under the staggering blow caused by the death of its president. The Count threw himself with such zeal and energy into whatever he undertook that it is hard to imagine how his place can be filled. In the very last letter which he addressed to us, on the occasion of the death of M. Fierens, he said "We are asking ourselves whether we shall be enabled to say '*uno avulso non deficit alter?*'" With even deeper significance may this question now be asked.

It is many years since we first made his acquaintance at one of the Ghent Quinquennials, where his father, the late Count, presided. The father was Burgomaster of Ghent, and his memory is perpetuated by a monument erected at the entrance of the Park at Ghent. He it was who erected and maintained the noble winter garden so familiar to visitors at Ghent in former years, and which has been illustrated in our columns on more than one occasion.

The son followed in his father's footsteps and has for many years presided over the Society with dignity and tact. His energy, powers of work, and faculty of organisation were extraordinary. His eloquence was remarkable, and his insight and progressive ideas most stimulating. He was an ardent politician, but found time to conduct a monthly horticultural journal, in which he was the consistent advocate of the necessity for infusing scientific principles and scientific method into the operations of horticulture. A work on Palms, and a similar one on Orchids, testify to his prodigious industry and to his faculty for seizing, amid a chaos of detail, the points of most pressing importance as regards practical horticulture.

THE LATE COMTE DE KERCHOVE DE DENTERGHEM.
(From a portrait taken in middle life.)

Many of his articles were unsigned, others, chiefly cultural, were written over the signature of Eugène de Duren.

He was the chief of the Directing Council of the State Botanic Garden at Brussels, and the leading spirit in all public horticultural affairs in Belgium. He was a foreign member of our Royal Horticultural Society and one of the select band of Veitch medallists.

Of his personal kindness and ready helpfulness we cannot bring ourselves now to speak more at length. We can but join in the vast concourse of horticulturists who are mourning the death of the energetic, the learned, the genial, the sympathetic Oswald de Kerchove.

Particulars of his last illness have not as yet reached us, but those who knew him and were aware of the precarious state of his health will not be greatly surprised that the end has come.

M. de Kerchove was born at Ghent on April 1, 1844, and died in the same city on March 20. The funeral took place on March 22, and, at the expressed wish of the Count, was as simple as possible, neither military honours being paid nor public discourses delivered.

Our Supplementary Illustration.—In continuation of a series of views of Sandringham which have been reproduced in these pages from time to time, by permission of His Majesty, our Supplement to the present issue affords a peep into "The Dell," which is one of the less formal portions of the garden. In our Coronation Number, published on June 21, 1902, "The Dell" was described as "a charming little scene, in which a winding stream flows rapidly through rising banks on either side. Several tall Birches, Bamboos, Rhododendrons, Ferns, etc., adorn the banks, and the view is not only a grateful retreat from brilliant sunshine, but it is a most delightful foil to the more formal features of the garden." There have been some improvements made since then, and greater variety may now be seen in the plants. One of the best of the new features is that of a bank of Bamboos on a site previously occupied by Portugal Laurels. The Bamboos are thriving well. Vitis vinifera and Clematis Vitalba climb to the top of some of the Birch and Thorn trees, and their effect in the autumn is exceedingly good. Rhododendrons, Osmunda regalis, Foxgloves, Lilium candidum, Cypripedium spectabile, and numerous spring-flowering bulbs are all pleasant features of "The Dell," which is regarded at Sandringham with much appreciation.

The Surveyors' Institution.—The next Ordinary General Meeting will be held in the Lecture Hall of the Institution on Monday, March 26, 1906, at 8 p.m., when the discussion on the paper read by Mr. WOODWARD will be continued.

Flowers in Season.—From Messrs. W. B. HARTLAND & SONS come flowers of a noble bicolor Daffodil, named Baylor Hartland. The flower is symmetrical, fragrant, some 4 inches across, the outer segments broadly ovate, the inner somewhat narrower, all whitish or of very pale sulphur yellow, the perianth as a whole resembling that of a Eucharis. The crown is bold, deep canary yellow, longer than the segments, cylindric with projecting angles, and the limb deeply scalloped and fringed. The perianth tube between the ovary and the segments is ½ inch in length, greenish and broadly funnel-shaped.

Colonial Show in the Vincent Square Hall.—Sir THOMAS FULLER, Agent-General for the Cape, held a reception on Wednesday night at the hall of the Royal Horticultural Society on the occasion of the opening of the Cape Colony exhibition of fruits and other products. In introducing the Earl of Elgin, who was present, Sir THOMAS FULLER said that the Cape was going to enter the lists against the other great food-producing colonies of the Empire, and the spirit of the new movement which had arisen in the colony had been demonstrated by a show in London. The Earl of ELGIN, in reply, said that he was exceedingly glad to see what the Cape Government had been able to send for exhibition, as the colony would have to take a prominent part in the industrial work of the Empire. A day might come when he could offer suggestions, but at present he could only offer his congratulations and best wishes for the future to Sir THOMAS FULLER and the Cape Government. The show was opened to the public on Thursday last after these pages had gone to press.

Horticultural Education in Monmouthshire.—The report of the Director of Agricultural Education of the Monmouth Education Committee is highly satisfactory. In the Horticultural Department the instruction at the Farm School, Little Mill, is highly appreciated, and the interest shown by the lads is most encouraging. Arrangements are being made to carry out demonstrations upon the pruning, planting and renovating of orchards and fruit plantations, upon lines similar to those carried on for some years past. Lessons given upon the grading and packing of fruit for market in cheap, ready-made boxes of a convenient size were again appreciated by those who grow fruit for sale.

Models of Insect Pests.—We have received for inspection some cases containing various insect and fungus pests of gardens. The execution of the models is admirable, and they would be useful to county council lecturers or any engaged in teaching horticulture. The codlin moth, winter moth, "Canker," &c., were easily recognisable. Many are natural specimens which have been preserved. The descriptions are in German. However, the labels could easily be translated. The person to whom we are indebted for the opportunity of inspecting these is Mr. William Frank, 12, Red Lion Square, Holborn.

Hybrid Vines.—The *Œnophile* records the death of M. Amedee Jurie, the raiser of various hybrids between the European forms of Vitis vinifera and some American forms of V. rupestris × monticola. He chose this last-named hybrid as the pollen parent, having found by experience that fructification was more satisfactory when a cross was effected between V. vinifera and a hybrid raised between two American species. His cross, known as No. 102, was compounded of one-half French and one-half mixed American sap, was very prolific, but not sufficiently resistant to the Phylloxera or to the attacks of fungous parasites. He therefore crossed this No. 102 with another American form whose powers of resistance to the attacks of Phylloxera were well-established, with the result that he obtained a cross, No 251, which showed immunity from Phylloxera, but at the expense of fertility. To remedy this latter defect he crossed this same hybrid 251 with the pollen of V. vinifera. The result of this last cross, which he indicated by the number 580, presented five-eighths American and three-eighths French sap, and combined important qualities, such as immunity from Phylloxera, great vigour, and sufficient productiveness. Having arrived at this result from ordinary cross-breeding, M. Jurie then, availing himself of M. Daniel's researches establishing the existence of graft hybrids and the power of securing either amelioration or deterioration by means of grafting, endeavoured to find a stock capable of transmitting to a graft the desired qualities, or of enhancing those qualities which are not sufficiently developed. Acting on these lines M. Jurie succeeded in raising forms showing variation in form of leaf, bunches and berries, changes of sex, separation of previously mixed characters, increased power of resistance to Phylloxera, and especially improved quality of vine. It will thus be seen that M. Jurie has exercised a certain designed control over the phenomena of ordinary hybridisation. Anxious to eliminate personal bias, M. Jurie submitted the wines made from his various crosses to the judgment of experts, who confirmed his own observations.

Agriculture in the Sand Deserts.—The difficulties of the agriculturist whose land consists of acres of practically unirrigated sand have to be met by special treatment. Mr. Thomas Kearney, in a Bulletin written for the United States Department of Agriculture, describes his visit to northern Africa, undertaken for the purpose of studying the Date Palm and its method of cultivation. This excursion was from Nefta, in south-western Tunis, to the Oued Souf, a remarkable and little known part of the Sahara desert, and the information gleaned there by him should prove valuable to agriculturists in other arid regions. In the country of the Souf there is, practically, no rainfall, and there are no streams nor springs nor flowing wells to furnish water for irrigation. The soil is a pure hard sand devoid of organic matter, and blown about in clouds by every wind, so that increasing vigilance is needed to keep the gardens free from it; also the summer heat is almost as great as anywhere in the world. Yet here the Date Palm grows in perfection, yielding fruit of better quality and in larger quantity than elsewhere in the Sahara. These are plants requiring much moisture, yet here are artificially irrigated in their first summer only, being able afterwards to obtain for themselves ground water, which is sufficiently abundant some feet below the surface of the sand. The Palms are planted in holes some 2 to 4 feet deep, and require constant watching and labour to keep them free from the drifting sand which, otherwise, overwhelms and buries them. Manure is applied to them, otherwise the plants receive but little cultivation. It is suggested that even in less tropical countries planters on sandy soils and among sand-hills should note that ground water is essential and sufficient for crops not otherwise irrigated, and that the sand-hills concentrate and reflect so much heat that the hollows among them are veritable forcing houses. Therefore, fruit grown therein might be ripened some weeks before the bulk of the crop, and would, in consequence, be of greatly enhanced value.

The Cotton Plant and Weevils.—A curious instance of adaptation to circumstances has been brought to light by the study of the Cotton plants in Central America, which have been found to have developed numerous weevil-resisting adaptations. In comparing these specimens from Guatemala with others cultivated in the United States a series of protective adaptations has been revealed, of such number and nicety as to furnish a unique and well-nigh incredible instance of selective development. Mr. O. F. Cook, who has visited Guatemala and studied the Cotton there grown, publishes the results of his researches in a recent Bulletin of the United States Department of Agriculture. He confirms a statement previously made that the presence of the weevil-eating "kelep," or ant, has enabled the Indians of Eastern Guatemala to maintain, since very ancient times, field culture of Cotton in the presence of weevils, with the result that there has been developed a dwarf, annual, short-season variety with numerous features which, in the absence of sufficient numbers of "keleps," afford material assistance in protecting the crop against the ravages of the weevil. The Cotton plant appears to have modified even such distinctive and important characters as its involucre, nectaries, oil glands, large bolls, even the very lint itself, the better to resist its enemy. The adaptations may be divided into four groups:—1. Those calculated to avoid the weevils by general habits of growth. 2. Those which exclude the weevils, or at least hinder their operations in the buds and bolls. 3. Those which attract insect enemies, such as the weevil-eating "kelep." 4. Those which prevent the development of the weevil larvæ, even after the eggs have been laid.

Compounds (Poisonous) for Horticultural and Agricultural Purposes.—Mr. G. H. Richards writes:—"I am pleased to inform you that the Lord President of His Majesty's Privy Council has introduced into the House of Lords a Bill known as the 'Poisons and Pharmacy Bill.' Clause 2 of this Bill reads as follows:

> 2. (1) So much of the Pharmacy Act, 1868, as makes it an offence for any person to sell or keep open shop for poisons, unless he is a duly registered pharmaceutical chemist or chemist and druggist, and conforms to regulations made under Section 1 of that Act, shall not apply in the case of poisonous substances containing arsenic, tobacco, or the alkaloids of tobacco, for use exclusively in connection with agriculture or horticulture, if the person so selling or keeping open shop is duly licensed for the purpose under this section by a local authority, and conforms to any regulations as to the keeping, transporting, and selling of poisons made under this section.

The principle of this clause is precisely that for which the Traders in Poisonous Compounds Protection Society has for some years been contending. It will be noted that the Bill provides to authorise persons (who are not chemists) to be licensed for the purpose by the local authorities to sell insecticides, weed killers, sheep dips and other poisonous substances for use in connection with agriculture and horticulture, thus carrying into effect the recommendations of the Privy Council Departmental Committee."

Publications Received.—From the Royal Botanic Gardens, Kew: *Bulletin of Miscellaneous Information*. Appendix II. 1906. Contents: Catalogue of the Library. Additions received during 1905. —Also Additional Series V. *The Wild Fauna and Flora of the Royal Botanic Gardens, Kew.*—Central Experimental Farm, Ottawa. *Results obtained in 1905 from trial plots of Grain, Fodder, Field Roots, and Potatos.* By Dr. William Saunders and Dr. Chas. E. Saunders.—*Advancement of Agriculture in Canada.* Evidence of Dr. William Saunders, Director Dominion Experimental Farms, before the Select Standing Committee on Agriculture and Colonisation, 1905.—*Bulletino della R. Società Toscand di Orticultura*, Febbraio 1906.—*Handleiding voor het Snoeien van Rozen*, J. K. Budde. A translation, by Mr. Budde, into Dutch, of the handbook lately published by our National Rose Society.

NEW OR NOTEWORTHY PLANTS.

DENDROBIUM WILSONI, Rolfe, n. sp.*

This is a beautiful and deliciously fragrant Chinese Dendrobium, which was collected by Mr. E. H. Wilson during his recent expedition on behalf of Messrs. James Veitch & Sons, and which has now flowered with the latter. Mr. Wilson met with it only in one small wood near Ya-chow, West Szechuan, at an altitude of 3,800 feet, growing chiefly on Oak trees, but occasionally on rocks, and he remarks that it was very conspicuous from a distance, and exceedingly free-flowering. It was collected in flower on May 12, 1904, and on one plant 400 fully expanded flowers were counted. It belongs to the section Eudendrobium, and is allied to the Indian D. transparens, Wall., but has considerably larger flowers of a very delicate shade of pink, with a small yellow blotch on the disc of the lip, on which occur a number of minute dark purple dots, and these extend in a broad line to the base. They vary somewhat in colour, for Mr. Wilson records them as self pink, sometimes nearly white, with a chocolate blotch at the base of the lip, over 3 inches across, borne on the old and leafless pseudo-bulbs, which latter are thin, and 1½ to 2 feet long. It is certainly a very charming thing, and an interesting addition to the ranks of cultivated species. The flowers sent by Messrs. Veitch are not equal to the wild dried specimens in size, showing that they are not yet fully established. *R. A. Rolfe.*

PRIMULA FORTUNEI.

This interesting plant, which is of doubtful origin, has been in cultivation nearly 50 years, having been figured by T. Moore in the *Floral Magazine*, 1860, t. 7. It there states that the figure was drawn from a plant which flowered in

* *Dendrobium Wilsoni*, Rolfe. Pseudo-bulbs cylindrical, slender, 1½-2 feet long. Leaves oblong or lanceolate oblong, unequally bidentate and obtuse at the apex, 2-3 inches long, 6-10 lines broad. Racemes on the old leafless stems, axillary, ½ inch long, 2-3-flowered. Bracts ovate, apiculate or the lower obtuse, imbricate, 3-5-nerved, 3-4 lines long. Pedicels slender, 1-1½ inches long. Sepals lanceolate-oblong, obtuse, 1-1½ inches long. Petals elliptical-oblong, obtuse, rather broader than the sepals and about as long. Lip elliptical, obtuse, somewhat narrowed near the base, rather shorter than the sepals, 7-8 lines broad; disc tuberculate at the base. Column very short and stout. Mentum curved, obtuse, 4-5 lines long. Colour of flower blush pink, with a buff yellow blotch on the disc, minutely dotted with purple, the dots extending in a broad line to the tuberculate base. Foot of column yellow, with some purple dots and streaks. Native of West Szechuan, where it was collected at 3,800 feet altitude by Mr. E. H. Wilson, collector for Messrs. James Veitch & Sons. *R. A. Rolfe.*

the nursery of Messrs. G. Henderson & Son, Wellington Road, St. John's Wood, and that it also received a certificate at one of the meetings of the Royal Botanic Society. Owing probably to its half-hardy nature it is still a very rare plant, the only one possessing it to my knowledge being Col. Beddome, Sispara, West Hill, Putney, who lately presented a plant of it in flower to the Kew authorities. P. Fortunei may be described as somewhat intermediate between P. denticulata and P. formosa. It has the coarsely dentate leaves of P. erosa without any meal, and in the present plant the stems are between 3 and 4 inches high, bearing a somewhat loose umbel of flowers. The figure in the *Floral Magazine* shows a more robust plant, much taller, and with large, dense heads of flowers after the style of P. denticulata. The upper part of the stem, as well as the pedicels and calyx, is covered with a mealy powder. The flowers are about ½ inch in diameter, bluish-lilac in colour, with a primrose yellow eye, reminding one of P. farinosa. Col. Beddome says that it requires a cold frame during the winter as it is not hardy enough to stand outside, while in the summer it is plunged outside in a somewhat shady, moist position. It produces seed although not freely, and it may also be increased by division of the crowns after the plant has done flowering. In bloom in February it is a useful plant for the cold house, and a distinct member of a large and popular genus. *W. I.*

KEW NOTES.

Rhododendron indicum obtusum.

This plant, better known in gardens, perhaps, by the name of Azalea obtusa, is worthy of more attention from plant cultivators. Several plants in No. 4 Greenhouse are a mass of flower. In fact, so thickly are they covered with flowers that very few leaves can be seen. The flowers are about an inch across, and may be described as of a dark brick-red colour. It is easily propagated from cuttings, branches very freely, and forms a dense bush.

Under cool greenhouse treatment it flowers in March, but if placed in a little heat it can easily be obtained in flower six weeks or two months earlier. Except in very favoured localities it is not to be recommended for open-air cultivation.

Several plants of the white variety are flowering in the same house. A curious feature of this plant is that the flowers are often streaked with red. Sometimes whole branches revert to the type; a red patch or two amongst a mass of white flowers gives it a novel appearance. *A. O.*

Tecoma Smithii ×.

A note on this plant in the issue for March 10 speaks of it as a greenhouse climber. At Kew a number of plants are flowering in No. 4 at the present time. Here it is grown as a pot plant from 1 foot to 3 feet in height; the taller plants are two years old. Treated as a climber, unless in a very sunny position, it seldom flowers well, the growths failing to ripen sufficiently.

The best method of growing it is to insert cuttings in spring. Restrict each plant to one shoot, grow them singly in 5-inch pots, near the roof-glass in a house till the beginning of July. The plants may then be stood outside in a warm, sunny position. Being in small pots, they require an abundance of water. By the end of September the growths will be well ripened, and each plant may be depended on to produce a good head of flowers. When developing the flower spikes the plants should be fed liberally with manure. Remove all the lateral shoots as they appear.

Some of the plants here are cut back after flowering and grown on a second year. Potted into 7-inch pots, each plant is restricted to three or four growths, receiving similar treatment to those in 5-inch pots. *A. O.*

MR. THOMAS SMITH, V.M.H.

Among the last batch of gardeners honoured by the receipt of this distinction is Mr. Thomas Smith, of Newry. This gentleman is well known to our readers as an enthusiastic cultivator of interesting hardy plants. The receipt of a box from him always excites curiosity, for there is sure to be something novel or interesting in it, something which makes us wonder whence he could have procured it. Mr. Smith is, we believe, of English birth, but went to Ireland many years ago, and was for several years manager of the nurseries of Messrs. Rodger McClelland and Co., of Newry. On leaving their establishment he first occupied a couple of fields facing south-east on the slope of a hill, and he has gradually extended his nursery by the purchase of the whole hill, from the top of which a splendid view of Carlingford Loch and the adjacent mountains is obtained. His nursery is now in the very foremost rank so far as hardy plants are concerned, and the proprietor is so enthusiastic and so genial that a visit is a real treat to the connoisseur. Mr. Smith devotes much of his time to landscape gardening, and has laid out and planted several interesting and beautiful gardens.

MR. THOMAS SMITH, V.M.H.

As was announced on p. 104, the other three gentlemen recently elected to receive this honour are Mr. R. 1. Lynch, Curator of the Botanic Garden, Cambridge, Mr. William Marshall, and Mr. Harry J. Veitch, portraits of all of whom have already appeared in these pages.

THE PROTECTION OF FRUIT AND OTHER CROPS FROM FROST IN SPRING.

The problem of how to protect our fruit tree blossoms and embryo fruits and early vegetables from destruction by frost in spring seems as far from being solved in these days of horticultural progress and advanced scientific knowledge as it was in the rule-of-thumb days forty or fifty years ago.

The industry of fruit-growing in England has loomed large before the public mind of late. The incidental conditions bearing for and against its prosperity having been vigorously and freely discussed in lectures, public meetings, and in the Press, and, more important still, the Government has recently appointed a committee of experts to receive evidence, and to report on the fruit industry of England. Again, last autumn we had an important conference on the same subject lasting three days. Every topic that could be thought of as bearing in any way on the prosperity or otherwise of the industry was ably discussed and expounded in great detail by many of the cleverest and ablest exponents of the subject in Britain. Let us hope that their labours will bear good fruit in the near future.

The question represented by the heading of this note, namely, the protection of fruit tree blossoms and early vegetable crops from destruction by spring frosts, is worthy of the most searching inquiry and the deepest study and consideration of those engaged in horticulture. The man who finds out a practical and successful solution to this—certainly the greatest of all hindrances in the way of successful fruit growing in England—will prove to be a national benefactor.

The seasons as they come round, almost without exception, bring us rich and over-abundant quantities of fruit blossom, far more than is ever required to provide good crops. Almost with the same certainty does the cruel spring frost dodge the heel of this abundance of promise, and, with few exceptions, every season we have to deplore the partial destruction of our crops, and often, as was the case last year, nearly their complete obliteration.

I do not think this question has ever been previously considered or looked at full in the face with the object of finding a remedy. Let me relate my experience with regard to the visitation and duration of destructive spring frosts. I do not now speak of two or three degrees, of which we have frequent experience through the spring. This does comparatively no harm. It is when we have from six to ten and even fifteen degrees that the great destruction takes place. Now it so happens that this wave of severe frost sweeps across the country, according to my experience, between May 20 and 29, and, as frequently as not, the whole damage is done in one night, and certainly these severe frosts seldom extend beyond five. There are exceptions, of course. To be forewarned is to be forearmed, and the time of this visitation being thus focussed should naturally help the cultivator to successfully cope with it. I remember very well some years ago a gardener in the neighbourhood of London was very anxious for the safety of his crops on a Sunday night, May 23 or 24, owing to the indications of coming hard frost apparent early in the evening. There was much at stake—Strawberries in full bloom, Potatos, and other young and tender vegetable crops in active growth. He decided to call his men together in the evening, and, with a strong force, and a team of horses and carts, as much littery straw and other covering material as was available were carted on the ground and spread over the most valuable crops. Thus several acres were protected and saved, whilst others in the neighbourhood were totally destroyed. There were 15 degrees of frost that night and none to speak of afterwards. Coming events cast their shadows before them, and the observant man can generally tell from the appearance of the early evening whether there is going to be a hard frost during the night or not. Few people are aware how slight a covering of material is necessary to protect trees and other tender subjects from frost. A handful of strawy litter spread thinly over Strawberry plants or rows of Potatos is ample protection from a frost such as that mentioned above. I am happy to know that the precaution is now taken by most up-to-date gardeners to have some litter laid in preparation between the rows of crops at this dangerous season, so that it can be applied when danger is apprehended. For the protection of dwarf crops I do not think there is a better or more economical way than this; but in the case of fruit trees of high or moderate growth, this method would not apply, and this brings me to the method advocated and practised by Mr. Martin, of the Toddington Orchard Co., as mentioned by him at the Fruit Conference last autumn, namely, by creating sufficient

heat in the atmosphere to dispel the frost by the burning of lamps at night while hard frost lasts. He states that by burning 100 lamps to the acre for four hours he was able to raise the temperature 9 degrees, namely, from 24 degrees to 33 degrees, and thus secure the safety of his crops, and at the comparatively small cost of 30s. A more detailed statement of Mr. Martin's practice, giving a few details of the size of his lamps, their price, and for how many nights, as a rule, he finds it necessary to use them, would be gratefully hailed by many readers of the *Gardeners' Chronicle*.

Some few years ago this idea occurred to me, and I had it tried on a small scale one cold night in a plantation of Strawberries in bloom. There is no doubt that the temperature can be appreciably raised in this way, provided there be sufficient lamp power; but in my case the wind was rather high, and it quickly dissipated the heat from the small area of land tried before it had time to appreciably warm the air. Sir Albert Rollit stated in these pages (see page 312, October 28, 1905), writing of this system of protecting tender crops from frost: "I have seen a similar plan in Florida applied to the culture of Pineapples in the open. There, faggot fires are kept ready to be lighted among the growing Pines, which are also protected against the effect of radiation by an open horizontal lattice-work, the open sections being about one foot square. Evidently the Florida Pine growers have discovered the same difficulty that I did in respect to the too rapid dissipation of the heat by wind, and it is evident that before this system can be successfully applied, some protection must be provided against this contingency, especially on the windy side. Let us hope that the system will be put to the proof by many this spring, so that its value or otherwise may be practically demonstrated. *Owen Thomas.*

THE MENDELIAN LAWS OF INHERITANCE.

In view of the general interest now taken in Mendel's theory of inheritance, and of the able explanation of the results of experiments given by Mr. C. C. Hurst at a meeting of the Scientific Committee of the Royal Horticultural Society on Tuesday last, the following note on the subject may hold our readers the better to understand the nature of the problem. Mr. Hurst, who has obligingly contributed this communication, has himself conducted very numerous experiments in respect to animals as well as plants, some of which have served to prove the truth of certain laws laid down by Mendel.

(1) Law of Dominance.

"Mendel experimented with seven pairs of pure bred "characters" in Peas, viz., yellow and green seeds (cotyledons), round and wrinkled seeds, purple and white flowers, tall and dwarf stems, inflated and constricted pods, green and yellow pods, axial and terminal flowers. In each pair, when crossed, Mendel found the first-named character dominant over the other, which he called recessive; e.g., yellow crossed with green gave seeds all with yellow cotyledons. In this case yellow is dominant over green, which is recessive.

Mendel's law of dominance has been found to hold good in a large number of characters in many species of plants and animals; e.g., in my own experiments I have tested the following, among others (the dominant character is the one first mentioned.

Peas.—Round and wrinkled seeds; yellow and green cotyledons.

Sweet Peas.—Tall and dwarf stems (Cupid); sap-coloured and white flowers.

Primula.—Palm and fern leaf; thrum and pin-eye.

Orchids.—Sap-coloured and white flowers; spotted and striped flowers.

Poultry.—Rose and single comb; white and black plumage.

Rabbits.—Coloured and white coat; short and angora coat.

Horses.—Bay and chestnut colour; brown and chestnut colour.

(2) Law of Segregation.

In the second generation, when the hybrid dominants (D× R) (D standing for dominant, R for recessive) were self-fertilised, Mendel found that segregation or splitting of the characters took place in the ratio of three dominants, D, to one recessive, R; e.g., the hybrid yellow Peas (Y × G) self-fertilised, gave on the average 75 per cent. yellows and 25 per cent. greens, both types often appearing in the same pod. The law of segregation was also confirmed in the above experiments with various plants and animals; the recessive character, after "skipping a generation," re-appeared apparently unchanged.

(3) Law of Purity.

In the third generation Mendel found that the extracted recessives bred true, without reversion to their dominant parents or ancestors; e.g., the green Peas extracted from the hybrid yellows (Y × G) bred true greens, with no trace of yellow. Mendel also tested the dominants of the second generation, and found them to be of two kinds, in the ratio of one pure, two hybrid. The pure dominants bred true, while the hybrid dominants segregated again into 3 D : 1 R; e.g., the yellows bred from the hybrid yellows (Y × G) were one-third pure yellows which bred true, with no trace of green, and two-thirds hybrid yellows which gave 75 per cent. yellows and 25 per cent. greens.

Mendel continued these experiments through several generations, with the same result. The Mendelian formula for segregation is therefore 1 D : 2 DR : 1 R, i.e., 25 per cent pure dominants, 50 per cent. hybrid dominants, and 25 per cent. pure recessives. The law of purity was also confirmed in the above experiments with various plants and animals, the extracted recessives in all cases breeding true, with no trace of the dominant parents and ancestors.

The Mendelian Theory.

Mendel did not apparently offer any explanation of the facts of dominance, nor has any satisfactory theory of dominance yet been propounded. Mendel, however, brought forward a simple theory, which fully accounts for both the facts of segregation and purity, viz., the segregation of the gametes (germ cells) of the hybrid, so that on the average one-half of the gametes carry the dominant character and one-half the recessive character; no gamete carries both.

This is known as the theory of gametic segregation or gametic purity. On this hypothesis, the gametic constitution of the offspring of the hybrid dominants (D × R) will be, on the average, DR × DR = 1 DD : 2 DR : 1 RR, i.e., 25 per cent. pure dominants, 50 per cent. hybrid dominants, and 25 per cent. pure recessives. This result is in close agreement with the actual numbers Mendel obtained in his experiments.

Practical Application of the Mendelian Laws.

When the Mendelian characters coincide with the "points" desired by the breeder, as they do in many cases, a knowledge of the Mendelian laws will enable him to get what he wants in the shortest possible time. If the desired character is a recessive, it will breed true at sight. If it is a dominant, several individuals may have to be bred from before the pure dominant is found, but *once found it will breed true.* When several Mendelian characters are desired in combination, a much larger number of individuals will be required to secure the pure form, but once found, no "fixing" will be required; it will breed true at once. The old system of "fixing" by many years' selection leaves all to chance, and in the light of present knowledge is largely a waste of time.

When the desired "point" of the breeder is not a simple Mendelian character, but rather a compound one made up of more than the simple Mendelian unit, as is evident in certain cases, the breeder must rely on the assistance of the Mendelian experimenter, who will proceed to analyse it by exact methods; once the Mendelian elements are discovered, the compound character will be as easily worked by the breeder as a simple one.

The phenomenon of dominance apparently explains the oft-observed facts of characters "skipping a generation."

The results of recent experiments show that the law of dominance is apparently not universal, for in some cases the hybrid dominants do not exactly resemble the pure dominant parent, there being some traces of the recessive character, the dominance being incomplete. In other cases, the hybrid appears to be intermediate, and in a few cases the hybrid is different from either of its parents, and perhaps a "reversion." These exceptional cases have not yet been fully worked out, but, so far, most of them follow the Mendelian laws of segregation and purity.

The facts of dominance show that the outward appearance of an individual is often no guide at all to its breeding potentialities, and that a knowledge of its gametic constitution is the only guide to its heredity; this can only be secured by a Mendelian analysis. Recent experiments with mice, rabbits, Sweet Peas and Stocks show clearly, e.g., that the gametic constitution of albinos (whites) is often very complex.

When more than one pair of Mendelian characters are concerned in the cross, the average result can be easily calculated, e.g., a hybrid round yellow Pea will give :—

$$(3R + 1W) \times (3Y + 1G) = 9RY + 3RG + 3WY + 1WG.$$

The Mendelian laws show the necessity of breeding from single individuals, or if more than one be bred from, care should be taken that each individual of the batch has the same gametic constitution.

The facts of correlation or coupling of characters should be carefully watched and noted by the breeder, or his calculations may be upset. Last, but not least, Mendelian experiments with plants and animals have shown clearly that, as a rule, reciprocal crosses give similar results. These may serve a useful purpose in exposing once more the popular delusion that the "male parent gives the colour, while the female parent gives the form."

Many other questions of practical value are involved in the Mendelian laws of inheritance, but further experiments are necessary before one can venture to deal with them confidently. *C. C. Hurst.*

NURSERY NOTES.

ORANGE CULTURE AT MESSRS. RIVERS' SAWBRIDGEWORTH NURSERIES.

A day in early March with a strong "north-wester" blowing is not the time one would ordinarily select for visiting a fruit nursery, but even on the most inhospitable day the visitor to these nurseries can, without discomfort, enjoy a round of sightseeing, for is not this establishment famed for its orchard houses, which at the present time are both interesting and beautiful? In some the trees are in full flower, others have the fruit already set, and are pushing their young growths; potting is in operation here, budding there, and so on all through the various stages of indoor fruit culture. But perhaps the most interesting sight of all at the present time is a small house measuring 60 feet in length containing the major portion of a crop of over 500 Oranges. This Orangery is now in its full beauty, for in addition to being laden with these beautiful, golden-coloured fruits, the trees are also carrying their fragrant flowers from which next season's crop of fruits will arise, while the

green of the young shoots is scarcely less beautiful. It is indeed a glorious sight, and after seeing it we wondered why Oranges are not more often grown in gardens in this country, seeing the splendid results that can be thus obtained, and at comparative little trouble and expense—certainly not more than in Peach culture under glass. It may, perhaps, be remarked that Oranges can be purchased cheaply, and, if so, why go to the trouble and expense of growing them? But how different in flavour are these hothouse fruits to imported ones! Then, again, the season when Oranges are available is one which finds our fruit houses empty, and we have little, almost nothing, in the gardens to place upon the dessert table. Oranges can be had before Christmas, and their season extends far into the spring. Another feature in their favour is that they ripen their fruits at intervals, so that one tree will furnish a succession in itself, while the fruits hang for a long period when ripe, and some that were in condition in this Orangery at Christmas time were still hanging at the time of our visit. Several houses at Sawbridgeworth are devoted to the raising and general culture of Oranges, but it is of this one fruit house that we wish more particularly to speak. It may be stated at the outset that there is nothing remarkable about the structure—indeed of the many glass houses at Messrs. Rivers' establishment this is one of the least pretentious. It is by no means new, nor does it differ in any respect from hundreds of similar span-roofed structures in gardens. Its length as stated is 60 feet, the width 15 feet, and the height, roughly speaking, about 10 feet. It is furnished with side, bottom and top ventilators, and with two sets of hot water pipes, one being level with the border to supply bottom heat, and the other is at a level with the bottom ventilators to warm the admitted air. The trees are planted, after the manner of Peach trees, at a distance of 6 feet apart, and are trained about the same distance from the glass as is usually allowed for these latter trees. We may here remark that the culture of Oranges and Peaches indoors have much in common, and, substituting one fruit for the other, one might easily imagine oneself looking down a well-furnished Peach house when viewing this Orangery. The trees are trained to the wires, the shoots being disposed evenly, and kept at about 9 inches from the glass. The branches are not allowed to reach the full height of the house owing to the dense nature of the foliage, which would, were they allowed to grow to the top, exclude almost all the light. The temperature of the house in winter is not allowed to fall below 50°, and it may be allowed to run up several degrees higher in sunshine before admitting ventilation, for the Orange does not like cold draughts. The trees are planted in the borders in a mixture of strong turfy loam and leaf-mould; no manure is incorporated in the compost, as the Orange dislikes organic manures, a little soot-water applied occasionally being all they require in this respect. Water shoud be applied judiciously, and in a somewhat similar manner as to Peach trees in borders, allowing drier or wetter conditions, according to the seasons of active growth or rest. The great secret to success in Orange culture is cleanliness; once allow the trees to become infested with mealy bug, scale, or any other pest, and the result is disaster. With clean stock at the start, however, it is a simple matter to keep them in order, and, providing they are sponged as soon as the first signs of these enemies appear, little apprehension need exist on this account. Bug is perhaps the chief source of mischief, and plants at all susceptible to the ravages of this pest should never be permitted in the house. Not much pruning is necessary if the trees are bearing freely, for like other fruiting trees the Orange does not make much growth when cropping heavily. It does not, however, mind the knife, and it is quite safe to cut hard into the old wood without fear of danger. We were shown an instance of how readily these trees will break into new growth when cut hard back. In one of the houses some trees used for furnishing scions for propagating purposes had outstripped their quarters, and it was decided to reduce their "heads" and shift them from the borders into tubs. They had been pruned severely both at their roots and branches, and placed in their receptacles. Each tree broke away into new growth, and when we saw them the young growths were full of flower buds.

Propagation.

The Orange is propagated from seed, and the ease with which it is thus increased accounts for the small advance which, until lately, was made in the quality of varieties in Orange-growing countries. But to perpetuate the best kinds—for there are named varieties—it becomes necessary to practise grafting. The Orange is worked upon the Lemon as a stock, the Lemons being raised for the purpose from "pips" or seeds. Messrs. Rivers annually raise numbers of seedling Lemons, the seeds being obtained from one of the large preserve manufacturers. These are grown for a couple of years, when they are ready for grafting. The scions are grafted in the ordinary way, and as the Orange is an evergreen the foliage is present on the graft The stock in a small pot is cut back, the scion inserted and bound with grafting cotton—a kind of coarse worsted—and the juncture smeared with a little grafting wax. The plants are then placed in a close propagating frame in a warm pit, and kept close and moist for several weeks, the light being carefully excluded with an Archangel mat. We peeped into one of these "cradles"; the plants were lying on their sides on cocoanut fibre, and all showed evidence of successful union between stock and scion. After a time a little ventilation is allowed, and this is increased as time proceeds, but they are not removed from bottom heat for several months Messrs. Rivers raise large numbers of these trees annually, many being sold to colonial governments for distribution among the colonists. The stock at the time of our visit numbered over one thousand trees, contained in two large houses.

The Orchard Houses.

Orange culture forms but a small part of the work of the nursery. Dozens of large orchard houses are full of all kinds of fruit trees in pots, Apples, Pears, Peaches, Nectarines, Plums, Figs, Cherries, Grape-Vines, Strawberries, etc., being grown in hundreds. There are about thirty fruit houses in all, which number gives one a good idea of the extensive nature of the culture of orchard-house trees in Messrs. Rivers' nursery. One house measuring 100 feet by 20 feet, filled with Peach and Nectarine trees, was started at the commencement of the New Year. The fruits are now at their stoning period, and picking is expected to commence at about the end of next month. Every tree was well furnished with fruits, and although some thinning has been done more will be necessary. The orchard houses have floors formed of the natural soil, which is quite hard and solid; the path is rammed gravel and clay. The beds are surfaced with a thin layer of cinders. The Cherry house is a lovely sight when the trees are in full flower. These trees, many of them of great age, make but little wood, the long spurs continuing forming fruit buds year after year until they are a foot or more in length. Contrary to what might be expected, these pot trees do not wear out soon, and we were shown a tree of Magdalen Peach that had been grown continuously in a pot for 30 years. Mulberries are also seen in pots, and one grand specimen which annually bears a very large crop of fruits is about 40 years old.

Messrs Rivers have long been engaged in the raising of new varieties of fruit trees, and one may see seedling trees in all stages. Seedlings in pans were just bearing their cotyledons, while others further advanced were promising fruit for this season. It is a long and expensive undertaking, and often disappointing. Sometimes the seedling tree will produce a fruit of great promise the first year of fruiting, but the next year and after, the succeeding fruit is worthless. However, when a prize is secured, much disappointment is compensated for, such as when their newest Peach Peregrine was secured. This is a mid-season variety, said to be of robust constitution, prolific in fruiting, and described as a good all-round variety.

The trees for pot culture are selected from the nursery, only the very best shaped examples being used, and these must have a good root system, plenty of fibrous roots being essential. The work of potting trees was proceeding at the time of our visit. The roots are carefully trimmed, all broken ends severed with a clean cut, and the stoutest shortened back. The compost was rough loam with plenty of manure, and for stone fruit some mortar rubble. The potting is done very firmly, the rammer being freely worked, so that when the work is completed the tree can be lifted by the stem without drawing the plant from the pot. The trees are allowed to become established for a year or more, after which they are ready for the market.

Before concluding our visit we made a round of inspection of the outdoor departments. The extent of the nursery is, roughly, about 300 acres, and here are grown fruit trees of every description by the thousand. In addition to fruit trees, Messrs. Rivers do a large trade in Roses and shrubs. Grafting was in operation, but budding is preferred and more largely practised. Nothing is gained by the former process, and it requires 50 per cent. more labour. Two men can bud an enormous quantity of trees in the season, one inserting the bud and the other tying, whereas it takes four men to do the work of grafting—one to prepare and insert the scion, another to tie, one to place the clay on the graft, and still another to shape the "pug." In two Apple trees seen, the one grafted in the springtime and the other budded later, no difference whatever was apparent. An old Plum tree that appeared to be valued for more than its decrepitude excited our curiosity. It was split in two, and supported by props to bear the weight of the branches. This was the original seedling tree of Early Prolific Plum raised by the late Mr. Thos. Rivers in 1834. Its progeny is found in many gardens, and it is surrounded where it stands by numerous descendants, many of them venerable trees themselves. The old tree itself was full of fruit buds, although its days appear to be numbered. It is interesting as furnishing a criterion of the length of life of a Plum tree from the seed—in this case 72 years.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Independent Sectional Saddle Boilers.—It would be useful to have the opinions of gardeners, who have the above boilers in use, as to their merits and demerits, and how their capacity for heating compares with boilers of other shapes and principles. I refer to the somewhat new form which has been introduced of late years, where the boiler is made of sections which connect together by rods and screws. It is somewhat dome-shaped, with one or two flues through it above the fire, and stands quite independent of any brickwork whatever. Doubtless many are in use, as they are advertised by various firms under as many different names; but all are practically the same in principle. I was induced to try one in 1904 to replace an ordinary flued saddle-boiler with the usual brickwork setting, and so far I have nothing but praise for the newer form. It gets up heat quickly, and retains it well; there appears to be no more loss of heat from the boiler being exposed than there is from those set in brickwork, which has somewhat surprised me; and it has decided advantages over the old form in having all its joints and surfaces fully open to inspection—the fact that a section can be taken

out and replaced by a new one whenever a leakage appears, the easy and economical plan of setting without any brickwork, and the certainty of finding a leakage as soon as it appears, without the delay caused by cutting away brickwork. Owing to alterations in the piping when the new boiler was put in I cannot compare its consumption of fuel with that of the previous one. If anyone has one of these boilers working with the same amount of piping that another kind had, I shall be glad to know how it compares in this respect with the previous boiler. My own idea is that it is more economical, but for the above reason I cannot prove it. Is it not time we had an independent trial of all the principal boilers, carried out side by side, under carefully arranged and exactly similar conditions? I ask this question because I think we gardeners are often too conservative in our ideas; we are too timid to leave the beaten track and take up a fresh plan; and when a thing has done well we stick to it, forgetful of the fact that all things around us are in a state of change. When there is an improvement to be had it is a wise plan to secure it as soon as possible. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

Packing Seeds for the Tropics.—The discussion which for some weeks has been carried on in the *Gardeners' Chronicle* on the above important subject must be my excuse for making the following observations. A few years ago an officer in the Indian army stationed at Ferozepore wrote to me and asked me to purchase for him a set of common, old-fashioned flower seeds and forward them to him. As I lived within a few minutes of Mr. Russell's shop in Richmond at the time, I called in, and his assistant sorted out for me between 20 and 30 different sorts, including Mignonette, Carnation, Pansy, Sweet William, Wallflower, Sweet Peas, Polyanthus, etc., etc. These I had in ordinary paper packets, wrapped in brown paper. I simply addressed the parcel and sent it away. The following year I received a letter from the gentleman asking me to forward him another set from the same place, as everything had done so well. The second set was sent in exactly the same manner, and the result was quite as satisfactory. Now, if seeds of this description travel so well and germinate so well, in the hands of the veriest amateur, surely there is not so much need for any special preparation, hermetically sealed tins and so forth, as is set out as essential by the extract from Mr. Hart's letter published in the *Gardeners' Chronicle* for February 17. I may add that during the last 15 years I have had the handling of many thousands of packets of seeds coming from almost every part of the world and packed in a great many different ways, but principally in paper packets enclosed in paper wrappers, and I have found seeds from Australia, New Zealand, India, China, North and South America, Africa, and other far-away countries germinate quite as well as those received from France or from establishments in England. The greatest losses from improper packing that have come under my notice have been in such sorts as Acorns and Chestnuts; these quickly lose their vitality in a dry atmosphere and should never be packed dry; an ordinary wooden box with cocoanut fibre for packing forms an excellent means of transit. It is also well known among people who have had much to do with hardy seeds that, in some cases, a very decided change of temperature rather than being detrimental to their vegetative qualities is beneficial; for instance, such seeds as those of Cratægus, Pyrus, Rosa, Ilex, Viburnum, Acer, etc., that have been allowed to dry before being sown often take two years or more to vegetate, if sown in pots and placed in a cool house, but, if seeds that have been sown, say in March of one year, and have not germinated, are plunged out of doors in October and left quite unprotected until February of the following year, and are then placed in a temperature of 60°, germination will often take place at once. I have some recollection of seeing an article to the effect that seeds taken out on a Polar expedition and brought back after 2½ or 3 years' absence germinated well. At any rate, in the "Voyage of the Discovery," by Captain Scott, R.N., a description is given of the growing of Mustard and Cress in the ship after a winter had been spent in the ice. It would be interesting to know how those seeds were packed, as they must have been subjected to great extremes of heat and cold. A few years ago the result of some interesting experiments on the vitality of seeds after being subjected to great heat, both dry and moist, made by Sir Daniel (then Dr.) Morris, were published in the *Gardeners' Chronicle*, and quite recently the result of experiments with seeds subjected to intense cold have been published. The results of these experiments should go far to prove that extremes of heat and cold, whether dry or moist, to properly ripened seeds are not of such moment as is often supposed. *W. D.*

——Your Trinidad correspondent (see Colonial Note on page 164) seems to be greatly annoyed with my letter in your issue for January 20 last, characterising it as being "one of the most unsatisfactory pieces of evidence which it has ever been my (his) lot to discuss," suggesting, I suppose, that no reliance can be placed upon it, although, strangely enough, your correspondent immediately goes on to say that there is nothing improbable in seeds growing on a single occasion. Well, if so, "what has been shall be again." However, I have no personal experience of seeds in the tropics, and merely gave the facts as stated. In the *Gardeners' Chronicle* of the previous week there was a long and full statement from Mr. Watson, giving interesting accounts of the behaviour of seeds sent to the tropics in paper packets; but although the evidence there adduced coincided with mine to which Mr. Hart takes exception in such strong terms, he, strangely enough, ignores it! Can it be that he hesitates to cross pens with Mr. Watson and is content to fall foul of poor little me? This recalls the advice said to have been given by an old lawyer to his junior: "If you have no case, abuse plaintiff's attorney." The quoted words at the end of Mr. Hart's second sentence have no connection with the subject, but, read in conjunction with the conclusion of my letter, at least show bad taste. *A. C. Bartlett.*

Birds and Peas (see p. 173).—I have frequently lost two-thirds of the crop of early varieties by the persistent attacks of hawfinches. The jay, however, is certainly more destructive, doing almost incredible damage, and unless checked a large crop would be ruined in a few days. As with the hawfinch so with the jay; they bring the young birds with them, and I have seen several families of both amounting to dozens at once; but fortunately the attack only lasts three weeks—the time that the youngsters cannot feed themselves. After that time the birds leave the Peas alone, although odd ones may visit them through the season. Mr. Brookshank's remarks about migration can only refer to them being partial migrants, as they are resident here all the year round, more common south than north, but increasing with protection in many counties. They have also a wide geographical range over Europe to Siberia, and Japan, and India, with only slight difference in size and a few markings of plumage, comparatively like the English goldfinch and the Russian. The call notes and song of the hawfinch are very insignificant, as most naturalists describe both as little better than a chatter, and such is my experience with it both as a cage bird and in the wild state; it is regarded as one of the most mute of British birds. *G. Abbey, jun., Fanhams Hall Gardens, Ware, Herts.*

SOCIETIES.

ROYAL HORTICULTURAL.

March 20.—On Tuesday last the Hall in Vincent Square was again conveniently filled with exhibits, on the occasion of the usual fortnightly meeting of the Committees. The subjects shown included a considerable number that were dominant features at the preceding meeting, and the general effect of the show therefore was not materially different. Forced shrubs were again shown plentifully, and were very rich in floral effect. Pot-grown Clematis, flowers of Tree Carnations and Zonal Pelargoniums, also a great variety of hardy plants were among the exhibits. But Messrs. Rivers' collection of Oranges, and Messrs. Low's Acacias were not seen at the earlier meeting, nor were Messrs. Veitch's greenhouse Rhododendrons quite so fragrant, or Narcissus flowers so numerous. This was the first occasion on which the Narcissus Committee have met this season, and I they failed to find a new variety exhibited that was worth an Award of Merit.

The Orchid Committee found scarcely so many plants and flowers as there were at the last meeting, but their awards included one First Class Certificate and three Awards of Merit.

The Floral Comittee recommended three Awards of Merit, two for Roses, and one for a new Tree Carnation named Britannia.

The Fruit and Vegetable Committee had not many novelties to consider, but a good collection of well-preserved Apples was staged by the King's Acre Nursery Co., Hereford.

At the afternoon meeting upwards of sixty Fellows were elected, and Professor Geo. Henslow gave a lecture on "Parasites and Saprophytes among the Flowering Plants," which was illustrated with lantern slides.

Considerable interest was excited by Mr. C. C. Hurst's discourse before the Scientific Committee on "Mendelism."

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. C. T. Druery, Geo. Nicholson, R. Wilson Ker, T. W. Turner, Jno. Green, C. J. Salter, C. R. Fielder, H. J. Cutbush, J. F. McLeod, Jno. Jennings, W. Howe, W. P. Thomson, Chas. Jeffries, Chas. Dixon, Jas. Douglas, George Gordon, Chas. E. Shea, W. Cuthbertson, Chas. E. Pearson, W. J. James, C. Blick, and R. Hooper Pearson.

Haemanthus mirabilis grandiflorus was shown by Messrs. Linden et Cie, Brussels, and although but one small plant was sent, it was sufficient to show that the flower segments were broader than those of the type of which a supplementary illustration was published in these pages, May 25, 1901. Messrs. Linden's hybrids are among the very best plants of this genus.

From the King's Acre Nursery Company, Hereford, was shown a new Clematis of the "patens" section, with very large, pale mauve-coloured flowers, and named King's Acre Fairy. It was not thought to be sufficiently distinct to be given an Award; but the variety is evidently one that forces well, and the flowers are of very attractive colour.

Messrs. Thos. Cripps & Son, Tunbridge Wells, exhibited a collection of Japanese Acers, which was very attractive, for it included numerous varieties that had just developed their first leaves.

Messrs. R. & G. Cuthbert, Southgate Nurseries, London, were awarded a Silver Gilt Flora Medal for a brilliantly-gay group of forced flowering shrubs. Well up above the level of the dwarfer plants were standard specimens of Wistaria sinensis, Pyrus atrosanguineus, Prunus triloba, Azalea Daviesii, with smeet-smelling white flowers, and Magnolia Soulangeana. Below these the Mollis Azaleas, including such richly-coloured varieties as Anthony Koster, J. C. van Tol (red), and numerous others presented quite a thicket of flowers. There were also good plants of Spiræa Thunbergi and Cytisus purpureus flowering abundantly. Some tall plants of Palms and Lilac at the back helped to increase the effect of the exhibit.

Messrs. W. Cutbush & Son, Highgate, London, and Barnet, Herts., who showed at the last meeting an extremely large collection of forced shrubs in flower, contributed a smaller collection on this occasion, the double and single "Ghent" Azaleas and a fine new hardy Rhododendron aureum being all we noticed that were not represented in the more exhaustive exhibit. (Silver Gilt Banksian Medal.)

Messrs. Cutbush also showed Alpine plants and other hardy flowers, including a splendid batch of Iris Susiana and baskets of Roses Mrs. F. W. Flight and Mrs. William H. Cutbush.

Mr. L. R. Russell, Richmond Nurseries, Richmond, Surrey, staged a large collection of forced shrubs and other plants. These showy species—Azaleas, Laburnums, Magnolias, Spiræas, Clematis—and many similar subjects, brightened the west end of the hall. (Silver Flora Medal.)

Mr. H. B May, Upper Edmonton, London, N., showed some nice plants of Polyantha Roses. Madame Levavasseur was included, and a free-flowering white variety named Schneewittchen. The remainder of the group was composed of Clematis in pots, relieved by a groundwork of choice Ferns and a batch of Pelargonium "Clorinda." (Silver Banksian Medal.)

Messrs. Hugh Low & Co., Bush Hill Park, Enfield, showed vases of General Jacqueminot,

La France, Mrs. W. J. Grant, Capt. Hayward, Mrs. J. Laing, and other first-class Roses. These, together with some well-grown Carnations and Cyclamen, completed an exhibit of considerable beauty. In another part of the building Messrs. Low staged a batch of Acacias, some being quite large specimens. They were evenly-balanced in growth, and were carrying a good crop of flowers. Three large plants of longifolia magnifica deserve mention; the other species were A. armata, A. Drummondi, A. cordata, and A. lineata. (Silver-gilt Banksian Medal.)

Roses were also staged by Messrs. FRANK CANT & Co., Rose Nurseries, Colchester. They had a number of charming buds of the bronze-coloured Lady Roberts in the centre of the display, others of Mad. Jean Dupuy, some perfect specimens of the rich Papa Gontier (of true rose colour), Peace (cream yellow), Frau Peter Lambert, &c.

Messrs. WILLIAM PAUL & SON, Waltham Cross, Herts, put up a group of white and yellow Banksian Roses. (Silver Flora Medal.)

Messrs. GILBERT & SON, Dyke, Bourne, Lincolnshire, showed Anemone Pulsatilla and A. fulgens in the usual first-class style one is accustomed to see from Dyke. Some seedling forms of A. fulgens were included. (Silver Gilt Flora Medal.)

The CAPE GOVERNMENT, in view of the forthcoming Colonial Exhibition, staged a number of branches of the well-known Silver Leaf Tree (Leucodendron argenteum). Leaves of this plant are largely used for ornamental purposes, bookmarkers, &c. (Silver Flora Medal.) An exhibit of living succulent plants and Heaths from this Colony, and another of paintings of indigenous flowers of Cape Colony, also received awards of medals.

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, presented a mixed group of flowering subjects. They had a number of improved forms of Clivia (Imantophyllum); a batch of the pretty Crowea angustifolia, the plants being almost hidden by their flowers; the showy Rhododendron Veitchii and others of this type; Streptosolen Jamesoni; Eupatorium petiolare, and two or three plants of Kalanchoe Dyeri. The last-named species has large corymbs of long tubular white flowers, but the habit is straggling, and it would only be effective when used with a setting of other plants beneath. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, showed inflorescences of their strain of stellata Cinerarias, bunches of Zonal Pelargoniums, and their new flaked Carnation "Duchess of Marlborough." Among the newer varieties of Pelargoniums is Mentmore. This has very large flowers almost three inches in diameter. The colour is rosy-cerise. Frogmore has a bright scarlet marking, probably guiding-lines for insects, on a magenta ground. (Silver Flora Medal.)

Messrs. JARMAN & Co., Chard, Somerset, showed a type of stellate Cinerarias, in which the petals were almost revolute. They were labelled "Cactus stellatea Cinerarias."

Lord ALDENHAM, Elstree (gr. Mr. E. Beckett), exhibited a large batch of Thyrsacanthus rutilans. The long pendulous racemes of this old stove-plant were well developed, and the flowers, moreover, were very deeply coloured. Adjoining were sprays of many species of Willow, some in flower, and others to show the varied colours seen in the bark of the different varieties. (Silver Flora Medal.)

Alpine plants were shown by many growers, one of the best arranged collections being staged by an amateur, E. A. HAMBRO, Esq., Hayes Place, Hayes, Kent. The plants showed excellence in culture, a pan of Daphne Blagayana being one of the best examples we remember having seen of this rock-garden plant. The usual subjects were included—Primulas, Ericas, Saxifragas, Scillas, Primroses, &c., and a setting of taller subjects at the background of such things as Cytisus purpureus incarnatus, Magnolia stellata Halleana, Daffodils in pots, &c., completed a first-class display.

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, showed many good things among Alpine and other hardy flowers.

Mr. G. REUTHE, Keston, Kent, had, in addition to a display of alpines, a number of inflorescences of hardy Rhododendrons — R. Falconeri, R. arboreum, &c. R. a. cinnamomeum has pleasing flowers mottled and suffused with pink on a pale ground. Mr. REUTHE had also a display of early flowering varieties of Narcissi. (Silver Banksian Medal.)

Mr. MORTIMER, Rowledge, Farnham, Surrey, displayed Carnations of first-class quality, also a white Stock named All-the-Year Round.

Messrs. GEO. BOYES & Co., Aylestone Nurseries, Leicester, showed Carnations, including some seedling varieties, one of which, named Dr. W. G. Grace, has very fragrant flowers but is not of the best form.

Mr. H. ELLIOTT, Hassock Nurseries, Hassocks, Sussex, brought several seedling Carnations, but none was of exceptional merit.

Messrs. RICHARD SMITH & Co., Worcester, showed a batch of a lavender-coloured variety of Hepatica angulosa, labelled H. A. lilacina grandiflora. The variety is very floriferous and pleasing in colour.

Messrs. T. S. WARE, LTD., Feltham, Middlesex, filled one of the centre tables with Carnations, Alpines and Daffodils. Some good things were seen among the Alpine plants; we may mention Iris fimbriata, Sarracenia flava nicely in flower, Trillium sessile, Tropœolum tricolor, Eccremocarpus scaber, &c. We also noticed a good batch of Narcissus Queen of Spain among the Daffodils. (Bronze Flora Medal.)

Messrs. JOHN PEED & SONS, West Norwood, London, staged Alpine plants, a batch of Narcissus, and some well grown pot Freesias.

Small exhibits of Alpine plants were also staged by Messrs. J. CHEAL & SON, Crawley; Mr. H. C. PULHAM, Elsenham, Essex; Mr. A. R. UPTON, Millmead, Guildford; and Sir EDWARD LODER, Bart, Leonardslee, Horsham, Sussex (gr. Mr. W. A. Cook).

AWARDS OF MERIT.

Carnation Britannia.—A bright red, self-coloured Tree Carnation of large size, good petals, with very little fimbriation, but only faintly perfumed. The stems are erect, and the calyces remain unsplit. From the plants exhibited it was evident the variety is of first-rate growing habit. From Mr. A. SMITH, Enfield Highway.

Polyantha Rose "Princess Ena."—This is a charming new variety of the dwarf-growing Polyantha section, being a sport from the crimson-flowered variety Mad. Levavasseur. The plant shown had growths of about 15 inches in height, and each growth bore a strong spray of rich rose-pink coloured flowers, with small, white centres, and pale yellow stamens. The individual flowers are about 2 inches across. The plant would have a very good effect in a vase. From Mr. H. B. MAY.

Rose, Climbing, Frau Karl Druschki.—Those who have grown the charming new Rose, Frau Druschki, of which an illustration was published in these pages on Dec. 6, 1902, p. 42, will be likely to appreciate a climbing form of the variety, in which the flowers appear to be identical with those of the type. They are almost, but not perfectly, white, and on the plant exhibited they were produced very freely and well, although it is still only March. Shown by Messrs. W. LAURENSON & SON, Egglescliffe, Yarm-on-Tees.

Narcissus Committee.

Present: H. B. May, Esq. (Chairman), and Messrs. W. Poupart, Jno. Pope, E. A. Bowles, G. Reuthe, Jean de Graaffe, A. M. Wilson, C. T. Digby, P. R. Barr, J. T. Bennett-Poë, W. F. M. Copeland, A. R. Goodwin, W. A. Milner, R. W. Wallace, W. T. Ware, A. Kingsmill, Jas. Walker, Robt. Sydenham, W. B. Young, P. D. Williams, Rev. S. Eugene Bourne, Rev. G. H. Engleheart, Joseph Jacob, Rev. Canon Fowler, and C. H. Curtis.

Messrs. BARR & SONS, 11, 12, 13, King Street, Covent Garden, had Daffodils and hardy flowers. The former embraced many of the best of the early-flowering varieties. We noticed the fine Ajax, King Alfred, with splendid trumpet of deep yellow colour; Isolde, a substantial flower with sulphur-yellow trumpet, surrounded by a cream perianth, Peter Barr, the incomparable white Ajax, Seraph, a fine bold flower, the pale yellow of the big trumpet merging into the white of the perianth, King Alfonso, Victoria, Henri de Vilmorin, etc. (Silver Banksian Medal.)

Sir JOSSLYN GORE-BOOTH, Bart., Lissadell, Sligo, Ireland, staged a collection of standard and popular varieties. (Silver Banksian Medal.)

Mr. KENDALL, Newton Appleford, near Ottery St. Mary, Devon, showed some remarkably fine flowers of Narcissus Sir Francis Drake. The specimens were finely coloured and were exceptionally tall.

Mr. CHAS. DAWSON, Rosemorran, Gulval, Penzance, staged a couple of rows of vases of Daffodils. They were quite the best of these flowers in the show, and many were varieties not in commerce. Chiquita is a well-shaped flower, with a soft yellow trumpet surrounded by a white corolla; Gannett is a fine Leedsi, the chalice being beautifully tipped with bright orange; Cachalot has an almost straight trumpet at right angles to the corolla; Goldseeker is intensely yellow; Marshlight is a beautiful Leedsi, with a grand chalice; Barkal possesses a very open, short, crenated trumpet; Cyclet and His Excellency are but a few of the many fine sorts shown by Mr. DAWSON. (Silver Gilt Banksian Medal.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, H. Little, W. Boxall, W. H. Young, H. A. Tracy, H. G. Alexander, F. J. Thorne, H. J. Chapman, J. Coleman, J. W. Potter, A. A. McBean, J. W. Odell, H. G. Morris, T. W. Bond, W. H. White, A. Dye, H. T. Pitt, R. G. Thwaites, W. Cobb, G. F. Moore, F. M. Ogilvie, F. Wellesley, W. A. Bilney, N. C. Cookson, De B. Crawshay, H. Ballantine, F. Sander, and A. A. Peeters (visitor).

The largest group, which secured a Silver Gilt Flora Medal, was staged by Baron Sir H. SCHROEDER, The Dell, Egham (gr. Mr. Ballantine). The bulk of the group was of fine Dendrobiums, which included all the best forms of D. nobile, D. splendidissimum, and other hybrids. Of fine varieties noted were D. superbum Burkei, good D. Wardianum, Findlayanum, Brymerianum, &c. At one end was a pretty arrangement of cut spikes of the handsome Calanthe Baron Schroeder, in the centre a selection of good Cypripediums, including C. Lawrenceanum Hyeanum, C. Mastersianum, C. Olivia, &c. Other rare plants noted were the pretty Odontoglossum Leeanum, the handsomely blotched O. Pescatorei Shroederianum, and O. P. Veitchianum, which are well-known plants of many years' standing, and, strangely enough, nothing yet has appeared comparable with them out of the many large importations. Bright Masdevallias were arranged along the group, and Eulophiella Elizabethæ and other rare species were included.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver Gilt Flora Medal for a fine group principally of hybrids. Among the Odontoglossums were O. Elaine (cirrosum × Harryanum), a pretty novelty with the colours of O. crispo-Harryanum, but more of the form of O. cirrosum, and with its apiculate segments. Others were forms of O. excellens, O. loochristyense, O. Rolfeæ, O. Hallio-crispum, and a few good O. crispum. At one end was the pure white Brasso-Cattleya Queen Alexandra and a few others of its class. Among the Cattleyas were the white C. Mendeli Duchess of York and other rare forms, and others noted were Lælio-Cattleya × illustris (Latona × aurea), the very dark L.-C. Dominiana, L.-C. Wellsiana, L.-C. × Sunray var. superba, of a rich orange colour with crimson lip, and other showy hybrids.

Messrs. JAMES CYPHER & SONS, Cheltenham, were awarded a Silver Flora Medal for an effective group, in which the best plants were Cattleya calummata magnifica, a large blush-white flower finely marked with purple; Odontoglossum Adrianæ punctatum, pale yellow densely spotted with red-brown; Dendrobium nobile Perfection, D. n. Fisheri, and other fine D. nobile; D. Apollo album, D Clio, &c.

Messrs. SANDER & SONS, St. Albans, secured a Silver Banksian Medal for a good group, in which were Zygopetalum Gottianum magnificum, with blackish purple sepals and remarkable lip, violet at the base, shading to magenta-rose; Cypripedium villosum annamense, very remarkable in colour; C. villosum Golden King, a large yellow-tinted flower; C. Persephone (Lathamianum × exul); some twenty distinct varieties of C. insigne; Schomburgkia undulata, Cymbidium grandiflorum, the curious little Notylia multiflora, and other species.

Messrs. HUGH LOW and Co., Enfield, obtained a Silver Banksian Medal for a nice group, in which the Dendrobiums were well displayed. Among the rarer were the pure white Dendrobium Wardianum ochrolenucum, the fine white Diacrium bicornutum, Angræcum citratum, Cypripedium aureum Hyeanum, C. Winifred

Hollington, C. Winnianum, C. microcheilum; Cattleya Trianæ cœrulea, the white C. T. Mrs. Edward Soncheim, &c.

Major G. L. Holford, C.I.E., C.V.O., Tetbury (gr. Mr. Alexander), showed a finely-coloured Cattleya Cecilia (Trianæ × Lawrenceana) and the noble white Odontoglossum crispum Iolanthe. It was a finely-grown plant, heavily flowered, and Mr. Alexander, his Orchid grower, was voted a Cultural Commendation.

Norman C. Cookson, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), showed Dendrobium Ainsworthii, Oakwood variety, fine in form and of the colour of D. nobile nobilius; Odontoglossum ardentissimum, Cookson's variety, a broad-petalled white variety, heavily marked with purple; the rare O. excellens Prince of Orange, and O. crispum Princess Maud, a good white flower prettily spotted with light brown.

J. S. Moss, Esq., Wintershill, showed Odontoglossum amænum (Pescatorei × sceptrum), pale yellow spotted with brown. Sir Trevor Lawrence, Bart., Burford, sent the handsome yellow Dendrobium Melpomene inversum and a large branched spike of Phalænopsis Aphrodite with about 80 flowers and buds, and for which Mr. W. H. White, his grower, was accorded a Cultural Commendation.

Jeremiah Colman, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound), sent Spathoglottis aurea, Gatton Park variety, a fine form raised at Gatton with large, orange-coloured flowers, from which the red on the lip of the type has been eliminated.

Francis Wellesley, Esq., Westfield (gr. Mr. Hopkins), sent a pretty hybrid between Cattleya Mossiæ and C. Hardyana, with rosy-lilac sepals and petals tinged with yellow and rich purple lip; Cypripedium niveum Wellesleyanum, much broader than the ordinary form; and C. villosum "The Premier." (See Awards.)

F. A. Bevan, Esq., Trent Park, New Barnet (gr. Mr. Parr), sent Odontoglossum elegans, Trent Park variety.

F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed Dendrobium Thwaitesiæ, Veitch's variety, for which Messrs. Veitch obtained a First Class Certificate on April 19, 1904, and which is still the finest rich yellow hybrid Dendrobium; also a fine species of Eriopsis rutidobulbon.

R. Briggs-Bury, Esq., Bank House, Accrington (gr. Mr. Wilkinson), sent Cypripedium Victor Cavendish, a large flower of a greenish tint, finely spotted, and with white tip to the dorsal sepal.

O. O. Wrigley, Esq., Bridge House, Bury, Lancashire, showed the rare white Miltonia Warscewiczii alba and Odontoglossum Adrianæ Marian Bruce, a good well-marked flower.

M. Draps-Dom, Laeken, Brussels, sent two spotted forms of Odontoglossum crispum, a good O. Adrianæ, Cypripedium Leeanum aureum, C. nitens aureum, C. nitens Tarron, and other good hybrids.

M. A. A. Peeters, Brussels, sent the rare Cypripedium aureum "Pomone."

Messrs. Linden & Co., Brussels, showed Odontoglossum crispum Lucien Linden, a home-raised seedling with large, broad-petalled flower serrated at the edges, white, densely blotched with rose purple; Cochlioda vulcanica, Linden's variety, a large bright magenta-rose flower; Oncidium Phalænopsis Lindeni; Cypripedium præstans, and a yellow tinted variety of it named aurosum.

G. F. Bird, Esq., Manor House, West Wickham (gr. Mr. H. Redden), sent Odontoglossum triumphans, Bird's variety, a fine, large flower.

Captain R. P. Pureroy, R.N., Shalstone Manor, Buckingham (gr. Mr. Cordery), sent Dendrobium Dalhousieanum.

Eustace F. Clark, Esq., Teignmouth, sent three hybrid Cypripediums.

J. Bradshaw, Esq., Southgate, sent Lycaste Skinneri armeniaca, and another of the same class, named Princess Ida; the white L. S. Lady Gladys, and the finely-coloured L. S. Vulcan.

AWARDS.

First-Class Certificate.

Odontoglossum Lambeauianum roseum (Rolfeæ ardentissimum × crispum Madame Falcke).—A fine advance on the previously shown varieties. Exhibited by the raiser, M. A. A. Peeters, Brussels. A grand broad-petalled flower of a pale rose tint, heavily blotched with rose purple, the tips of the segments being unspotted.

Award of Merit.

Cypripedium villosum The Premier, from Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins).—A very massive form of much thicker substance than other villosums. The large dorsal sepal had a broad chocolate-purple band from the base, the sides of which are emerald green, the upper part white.

Lælio-Cattleya Sunray superba (L. cinnabarina × C. superba).—A showy orange-coloured flower with crimson front to the lip. There were several flowers on a spike and they were well displayed by Messrs. Charlesworth & Co.

Cypripedium aureum Hycanum, from F. Menteith Ogilvie, Esq., Oxford (gr. Mr. Balmforth).—A large, green-tinted flower, with a brownish band on the dorsal sepal, the upper half of which is white.

Diploma Awards.

Various exhibitors showed plants of Lycastes. A *2nd Diploma* was awarded to Lycaste Skinneri Beauty, from J. Bradshaw, Esq.—A large and finely-formed, blush-white flower, with rosy crimson markings on the lip.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (Chairman), and Messrs. Jos. Cheal, W. Bates, S. Mortimer, Alex. Dean, Geo. Kelf, H. Parr, A. R. Allan, Ed. Beckett, Jos. Davis, Jno. Lyne, F. Q. Lane, G. Reynolds, C. Foster, Owen Thomas, H Somers Rivers, and A. H. Pearson.

The Committee had brought to their notice a new kind of fruit preserving bottle, in which the usual tin cap was replaced by a glass plate, and this was screwed tightly by an outer lid, consequently the fruit was always in contact with glass. The Committee awarded the invention an Award of Merit. It was shown by the Flint Glass Bottle Company, Aldersgate Street, London, E.C.

A beautiful display of Apples was shown by the King's Acre Nursery Company, Hereford. They staged over 60 dishes, all, or almost all, in splendid condition and coloured to a high degree. The latest keeping varieties appeared at their best, grand dishes of Annie Elizabeth, Tyler's Kernel, Newton Wonder, Lane's Prince Albert, Dumelow's Seedling, Sandringham, Barnack Beauty, etc., being seen. (Silver Gilt Banksian Medal.)

Messrs. Thos. Rivers & Son, Sawbridgeworth, Herts, exhibited a collection of home-grown Oranges (see p. 187). They displayed both trees and fruits in many varieties and types. The Shaddock and the Lemon were also included. (Silver Gilt Banksian Medal.)

A cultural commendation was awarded Mr. W. A. Cook (gr. to Sir Ed. Loder, Bart., Leonardslee, Horsham, Sussex) for half-a-dozen well-grown heads of Carter's Spring White Broccoli.

Lecture on Mendel's Theory of Inheritance.

In the afternoon, Mr. C. C. Hurst delivered a lecture on this subject before the members of the Scientific Committee and others. The meeting took place in the Council room, which was more than half filled with fellows interested in this subject. We refer our readers to Mr. Hurst's article on p. 187. Considerable discussion followed Mr. Hurst's discourse.

HORTICULTURAL CLUB.

Hybrid Orchids.

March 20.—Fresh from the interesting meeting of the Scientific Committee held in the afternoon, the members of the Horticultural Club and a number of guests spent a very pleasant and instructive evening at the Hotel Windsor. The subject for discussion was that of "Hybrid Orchids," and Mr. H. J. Chapman, Orchid grower to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne, showed those assembled such a series of lantern slides illustrative of seedling and other Orchids, as we have never previously seen. There were something like 150 slides, and these were not merely reproductions of good photographs in which the effects of light and shade were unusually fine, but the pictures were all coloured in the shades natural to the flowers. Everyone present was greatly surprised at the excellent effect Mr. Chapman obtained, for each photograph had been coloured by himself and by the use of aniline dyes in water. His system was first to show the two parents, and then the resulting hybrids, which occasionally were all upon one plate, and were followed by illustrations of the secondary hybrids. After exhibiting several species of Odontoglossum and Selenipedium, a slide appeared, showing the wonderful Odontioda which resulted from crossing Odontoglossum Pescatorei with Cochlioda Notzliana, and these were also shown on the sheet. Phaius simulans and P. Sanderiana, with their hybrid × Norman, were much admired, and P. Chapmani and P. c. superba were wonderfully good. A round of applause greeted the appearance of Cypripedium Fairrieanum, which, with C. Spicerianum, produced × Niobe, having for a secondary hybrid × Norma, which was from C. Spicerianum and C. × Niobe. C. Fairrieanum, when crossed with C. callosum, produced × Juno, which is certainly one of the best of the hybrids. Passing to Cattleyas, the beautiful Lælio-Cattleya × Doris, the offspring of Cattleya Trianæ, crossed with Lælia harpophylla, was shown, and following this were all the best varieties of Dendrobium nobile. A splendid plant of D. Falconeri, suspended in a basket and carrying an unusually large number of flowers all coloured quite naturally, was much admired, the picture being perfect in respect to its light and shade effects. D. thrysiflorum was almost as good. On presenting an excellent portrait of C. Godefroyæ leucochilum, Mr. Chapman, who had something interesting to say of each picture, stated his opinion that this plant is a natural hybrid between C. niveum and C. bellatulum, although the accuracy of this view has been challenged of late. C. Chamberlainianum having given an opportunity for a humorous allusion, Mr. Chapman subsequently presented Odontoglossum crispum "Harold," one of the best florist's varieties of O. crispum, for, as was said, the flowers are almost "as round as a penny," and the colours are charming. Its petals are so imbricate that, in the Orchid grower's language, they offer a strong contrast to those through which one could "shoot sparrows." This portrait of "Harold" is considered by Mr. Chapman to be his best, but the succeeding one, O. crispum Cooksonæ, was, in our opinion, quite as good. This last-named variety was shown as a spike of blooms, and in several stages as the flowers were opening in Mr. Cookson's Orchid house.

We have only referred to some of the photographs, but, in addition, there were several that illustrated the interior of the Orchid houses at Oakfield in a most appreciable manner.

As was natural, after Mr. Hurst's explanation of the Mendel theory earlier in the day, many of those present, as well as Mr. Chapman himself, referred to the question during the discussion which took place on the hybrid Orchids. We can only refer to this discussion in very brief terms. Mr. N. C. Cookson took occasion to remark that he had found it to be impossible to cross such large and small flowers as Sophronitis grandiflora and Brassavola Digbyana with each other, unless the bigger flower was made the pollen parent, and he had come to the conclusion that the smaller grains of pollen from the smaller flower were not capable of producing tubes sufficiently long to reach the ovule of the larger flower, and were therefore ineffective. Mr. W. Watson (Kew) subsequently said that the late Mr. Mangles had told him of similar experience in the crossing of Rhododendrons, and Mr. R. A. Rolfe (Herbarium, Kew), said that in Messrs. Charlesworth's Nursery at Bradford he had been shown seed vessels in which the seeds at the upper part of the vessel alone were fertilised, which also seemed to show that the tubes were only able, even in those cases, to just enter the ovule and fertilise the seeds immediately at the top. Another gentleman (Mr. Thwaites) said that he had been able to raise seedlings from Sophronitis and Brassavola, and, as we understood him to say, he had used the Sophronitis as the pollen parent. These plants have not yet flowered. Further contributions to the discussion were made by Mr. Harry J. Veitch, Mr. William Marshall, Mr. Bunyard, jun. (who begged members to further consider the theory advanced by Mendel), Mr. H. Little, and others.

Sir John T. D. Llewelyn presided, and there were forty-five present, including a large number of guests from the R.H.S. Orchid Committee. Mr. Veitch described the evening as one of the best and most instructive he had spent in the club.

ROYAL BOTANIC.

March 21.—The first of this Society's shows for the present season was held on the above date in their gardens at Regent's Park. Unfortunately the weather during the earlier part of the proceedings was wintry in the extreme. The show itself was very bright, large masses of forced flowering trees and shrubs, Roses, Camellias, Carnations, Daffodils, and other showy subjects contributing to a pleasing display. The great conservatory was gay with many winter flowering plants arranged on the stagings and about the beds, while the permanent occupants of the beds and borders seem to improve each year under the care of the present superintendent, Mr. E. F. Hawes. There is a general improvement in the condition of the gardens and grounds.

Messrs. R. and G. Cuthbert, Southgate, Middlesex, filled the greater portion of one side of the long corridor with a display of forced flowering shrubs. (Large gold medal.)

Messrs. Wm. Cutbush and Son, Highgate, London, N., staged a grand display of forced flowering shrubs in the large conservatory. Messrs. Cutbush also had a numerous collection of Alpine plants. These were arranged in a natural manner, and embraced many of the best of these flowers now in season. (Gold medal.)

Messrs. Wm. Paul and Son, Waltham Cross, Herts, had a group of pot plants of Camellias in flower, and a number of Banksian Roses, both yellow and white varieties. The Camellias were greatly admired. The group was fairly representative, no fewer than forty-five distinct varieties being shown—Beauty of Waltham, soft blush-pink, and fine of form; Cup of Beauty, white, with just a splash of red; Jose Marques Loureiro, white; Duchess of Teck, rosy-pink, and comparatively new; Donckelaarii, one of the oldest and finest semi-double flowers, were some of the best shown. (Large silver gilt medal.)

Messrs. Thos. S. Ware, Ltd., Feltham, Middlesex, staged a large number of Alpine and hardy plants in flower, and a number of early varieties of Daffodils. Several vases of Carnations were also prominent. A batch of Corydalis bulbosa was nicely flowering. (Silver gilt medal.)

Mr. John May, Gordon Nursery, Twickenham, staged a grand collection of Cyclamen, the flowers, which were in profusion, being clean and of many beautiful tints and shades of colour. The plants were certainly well cultivated, and represented a desirable strain. The variety Excelsior, of deep crimson colour, received a certificate of merit. (Large silver gilt medal.)

Mr. A. Smith, Enfield Highway, also received a certificate of merit for Carnation Britannia. (See p. 190.)

Messrs. Jarman and Co., Chard, Somerset, displayed a type of Cineraria called Cactus stellata cineraria. The petals are rolled back, giving the flowers a quilled appearance. The selection of colours was good, and the strain was granted a certificate of merit.

Mr. S. Mortimer, Farnham, Surrey, had some charming flowers of winter flowering Carnations, and a number of spikes of a new stock named All-the-Year-Round. (Silver gilt medal.)

Messrs. Barr and Sons, 11, 12, 13, King Street, Covent Garden, had a large display of Narcissus, also boxes and vases of Alpines and hardy flowers and plants. Among the Narcissi were several new varieties, and of these three received the Society's certificate. These were Eldorado, a large yellow Ajax; Isolde, a fine Ajax variety, with sulphur-yellow trumpet and paler perianth; and Alice Knights, also of the Ajax type, with white or cream perianth and tube; awarded the distinction for its early period of flowering. (Large silver gilt medal.)

Sir Josslyn Gore-Booth, Bart., Lissadell, Sligo, had a nice stand of Irish-grown Daffodils. The varieties were not rare or new introductions, but they embraced many of the older and finer kinds of this spring flower. Thus there were Madame de Graaff, Victoria (Ajax), Oriflamme, C. J. Backhouse, Empress (fine flowers), Emperor, Stella superba, etc., all in first-class condition. (Silver medal.)

Mr. Robert Sydenham displayed a number of pots of Daffodils, the plants being grown in moss fibre without drainage.

The Royal Botanic Society exhibited a number of economic plants, many in flower—Piper nigrum, Black Pepper; Eugenia jambos, Rose Apple; Saccharum officinarum, Sugar Cane; Cinnamomum cassia, Cassia Bark, etc.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

March 8.—There was only a small display of plants at the meeting held on the above date.

Messrs. Cypher & Sons, Cheltenham, obtained a Silver Medal for a nice collection of plants.

M. Ch. Vuylsteke, Loochristi, Gand, sent a good lot of hybrid Odontoglossums, O. × Lawrenceanum being the most effective. (Vote of thanks.)

Messrs. Cowan & Co., Gateacre, displayed a nice group, and there were groups from Messrs. Keeling & Sons and Mr. D. McLeod, all of whom received votes of thanks.

The following awards were made:—First Class Certificates were awarded to Odontoglossum × Fowlerianum from Messrs. Sander & Sons, and Oncidium Weltoni var. album from O. O. Wrigley, Esq. Awards of Merit were awarded to Dendrobium × Wiganæ var. xanthochelum from Messrs. A. J. Keeling & Sons, and D. nobile var. Perfection from Messrs. J. Cypher & Sons. *P. W.*

NATIONAL CHRYSANTHEMUM.

March 14.—A meeting of the executive committee was held at "Carr's," 264, Strand, on the above date. A financial statement was produced by the secretary showing a substantial balance in hand. The schedule revision sub-committee were given power to add a sum of £20 to the Prize List, as several new classes are being added to the schedule.

ANSWERS TO CORRESPONDENTS.

*** Editor and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the Publisher; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the Editor. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Astilbe (Spiræa) Leaves Damaged: *H. W.* We find no trace of disease on the leaves. Their injury has been caused by scorching, either from the sun's rays when the foliage was wet, or from being placed too near the hot-water pipes in the plant house.

Book on Carpet Bedding: *Hortus.* We believe Messrs. Cannell & Sons, Nurserymen, Swanley, Kent, publish an inexpensive pamphlet on the subject.

Books: *G. C. O.* The *Glossary of Botanic Terms* would be of no use for the purpose. You need a book. You will do well to procure a copy of the *Dictionary of Gardening*, by George Nicholson, in five volumes, price £4 2s., or Johnson's *Gardeners' Dictionary*, price 9s. 6d. Either may be obtained from our publishing department.

Cucumbers Failing: *E. T.* The plants are badly infested with eel worm, which shows itself in the swollen nodules of the roots, hence it is often called root knot disease. You should not grow Cucumbers in the same structure again until you have thoroughly cleansed it, using as a wash carbolic acid mixed with water in the proportion of eight parts of water to one of the acid. Do not allow the old infested soil to be placed near the potting loam; it will be best to treat it with gas lime or a weak solution of carbolic acid, in order to destroy the pests.

Dendrobium Devonianum: *J. N. M.* This species should be cultivated in a basket or pot, which can be suspended from the roof of a warm house. Afford water freely until the new growths are completed, then gradually lessen the supply until water is withheld for the plant to rest.

Douglas Fir Failing: *Scots.* The Douglas Fir appears to have died from transplanting in a careless manner, as the roots of those forwarded possess little "fibre" or few fibrous roots. As far as appearances go they seem to be plants which have stood in the nursery for several years without transplanting, and then to have been carelessly lifted. There may be other reasons for the high percentage of deaths, but what they are it is impossible to say from the samples alone. Were the roots exposed to sun or wind for any length of time?

Grape Appley Towers: *M.* This variety is a good all-round Grape. The vine grows well and the flowers act freely. The fruits possess good flavour, and they keep well. Appley Towers is a little less prolific than some of the more popular Grapes, but it well deserves to be cultivated.

Hippeastrum (Amaryllis) Bulbs: *A. D.* We suspect the injury is caused by "mite." Meanwhile we will submit the bulbs to an examination, and reply in our next issue.

Insecticide and Peritonitis: *X.* The insecticide is of a poisonous nature, but we do not think its use in the manner described would cause peritonitis.

Mushrooms: *R. F.* It is impossible to give a decided answer without knowing the exact conditions of cultivation, but it would appear that the atmosphere in which the Mushrooms have grown was deficient in moisture. The beds have probably suffered from the same cause. Mushrooms are always tough if grown in such conditions. The syringings mentioned may not have been enough. In any case, toughness in Mushrooms is usually the result of dryness, and the best Mushrooms that are gathered from the meadows are those grown at a time when the atmosphere is well charged with moisture. We would suggest that you procure soil from another source, and obtain it moderately heavy. You might mix a small quantity with the manure during the course of fermentation. Employ a slight covering of straw for the beds, or, better still, cover them with brown paper; the moisture rising from the soil will then collect in the immediate vicinity of the young Mushrooms.

Names of Plants: *W. W.* 1, Pyrus japonica, so far as we can tell without the flowers; 2, Cupressus Lawsoniana; 3, Abies Pinsapo; 4, Cupressus Lawsoniana var. erecta viridis; 5, Cupressus, which we cannot name without the cones; 6, Skimmia japonica.—*A. Y. L.* Bletia patula and Phaius grandifolius.—*Lyminster.* Maranta Makoyana.—*Hortus.* A poor specimen, much shrivelled—probably Iris fimbriata.

Peach Shoots: *Cymrw.* The somewhat soft wood has been attacked by *Botrytis cinerea.* Remove the badly diseased shoots, and syringe the tree thoroughly with a solution of sulphide of potassium, using 1 ounce of sulphide in 3 gallons of water.

Roses; *C. R. F.* The stems have been attacked by the Rose mildew *Sphærotheca pannosa*, which has been arrested in its external development, and has consequently injured the shoots more than if it had fruited. Remove all decayed branches, and destroy any trace of mildew by spraying with a solution of permanganate of potassium at such a strength that the liquid is of a pale rose colour.

Tomatos: *T. J. H. & Chas. D.* There is no fungus disease present. We believe the injury to be due to scorching.

Tulip Mould: *S. C.* The plants are attacked by a fungus Botrytis parasitica. Burn all the diseased bulbs. Do not plant bulbs on the same piece of ground, as the black lumps or sclerotia in the soil will perpetuate the disease.

Violet: *J. McG.* Procure the variety Amiral Avellan, which, being an improvement on odorata rubra, has flowers of a reddish shade of colour.

ONCOCYCLUS IRISES AND THEIR ALLIES.

TO a very large number of those who cultivate good hardy plants comparatively few genera are so full of interest as the Iris, and to those who cultivate the Iris no section of it is more fascinating than that popularly known as "Cushion Iris," the Oncocyclus Irises of the botanist. In more ways than one are these Palestine Oncocyclus Irises fascinating, for in great measure they attract by the unique beauty of their well-nigh indescribable forms, and they further possess a deeper interest for those would-be special cultivators of them who never tire in their endeavours to cultivate them better than formerly, and to solve, if possible, the problem of how best to treat them, so as to make them a permanent success in British gardens. If this very desirable stage in the cultivation of these plants should ever be reached, the gardeners of that time will be more indebted, than possibly they will then be aware of, to such indefatigable workers in this particular field of study as Sir Michael Foster, the late Rev. H. Ewbank, Mr. Lynch, of the Cambridge Botanic Gardens, and Mr. John Hoog, of Haarlem, among others. Each and all of these have worked earnestly in the endeavour to elucidate the difficulties attending the permanent cultivation of these plants.

If we compare experiences to-day with those of a score of years ago, we feel bound to admit that progress has not been great, so far as this relates to the making of these Oncocyclus Irises more permanent plants in the garden. Whether this is unattainable is a question that can only be answered after further years of experience and experiment. How far on the road to this desired haven the raising of seedlings at home may bring us is an item worthy of greater thought than the subject now receives. At the present time this phase of the work is partially neglected. I am not now referring to the raising of cross-bred seedlings, but rather suggesting that those interested in these plants should try to obtain seeds direct from the native habitats of these Palestine Irises, and in this way, and by raising seedlings at home, endeavour to perpetuate the beauty of these plants for the benefit of the rising generation of gardeners. How increasingly difficult the task becomes each year is well known to those who endeavour to grow the plants from the too frequently insignificant rhizomes now received. Nor is the difficulty diminished by a knowledge of some of the facts. The plants are lifted too early from their native haunts, have a prolonged and enforced rest, and are subsequently hurried into growth in England so soon as planted, and always in the most uncongenial of our four seasons. For let not the fact be overlooked that these imported plants in their first year in this country have obviously to make all their growth between November and April; hence it is small wonder, with weaklings only at the start, that so large a percentage flower and perish almost as a result of the same. It is in these circumstances and with these facts in mind that I suggest that these Cushion Irises may yet be grown in British gardens provided seeds be obtainable from the native habitats of the plants, and the seedlings raised in this country. Such a step, I submit, would have a sort of acclimatising effect, and by growing the young plants on quickly there would be some hope of securing that which we now lack—viz., a good, well-developed rhizome, with the expectation of it flowering in the near future. Given the well-developed rhizome—the plant—I am one of those who would emphatically declare for the annual lifting and drying as the only really effective means in this country of insuring or enforcing that absolute rest which I believe to be essential to increased longevity in these plants. I know that there exists some diversity of opinion on this point, and that some growers cover their plants with lights to throw off the wet and to give them the rest which they believe to be necessary.

This, of course, reduces the resting period to a question of degree, since all growers of Cushion Irises are agreed that rest is essential to the plant, and in imitation also of what the plant would receive in its Palestine home. When favouring a period of absolute rest out of the ground each year one's thoughts naturally incline to the yearly importations of the roots of these plants, and which rarely—very rarely—exhibit any tendency to shrivelling. Then we have the additional fact that the stronger roots produce a good flower-spike a few months later. But whether such evidences would afford sufficient proof of the utility or advantages of absolute rest to those who believe this condition is met by covering over the plants is another matter. The chief gain in my experience is in a deferred growth, thus keeping the growing point below the surface until severe frost is past, and, by assisting the plant by these means to a more deliberate, unchecked growth under more congenial conditions, assist it also to a somewhat extended longevity. Of one thing I am assured—viz., that a fairly well-developed rhizome of any Iris will endure a great amount of drying off with impunity. In so far as the annual lifting and drying off are concerned, it is interesting to record that Mr. C. G. Van Tubergen, jun., of Haarlem, has practised it from the beginning with all the hybrid and cross-bred forms now known as Regelio-Cyclus Irises. In some degree, however, M. Tubergen's method is justified by the average severity of the Dutch winter, and by the moisture-laden character of the soil. Apart from these circumstances, however, no grower of these Irises could desire better rhizomes than those I received from M. Tubergen in September, 1904, and the clean, sturdy roots, with plump growth, and buds well in check, afforded ample proof that the method of lifting each year in no sense diminished or minimised the vigour of the plant. It should here be stated that at the time of which we speak M. Tubergen had behind him the experiences of several years with these hybrid forms. That these new Regelio-Cyclus hybrids possess a vigour all their own there is no gainsaying. Here, in West Middlesex, planted in the company of some of the newer as well as the older of the Palestine Irises, the hybrids of the new race were a great success, not merely in their first growth and flowering, but equally so in the fine root development that has resulted therefrom. Indeed, the development of the rhizomes gave the impression rather of a small flag Iris, than which I think I could hardly pay a greater tribute to their vigour.

Some of the tufts I have lifted and replanted, others I have permitted to grow unchecked, unprotected, and without any attempt to enforce a resting period upon them. My motive in doing this is to estimate their probable value to British cultivators when permanently planted in our gardens, and while many will admire them as seen in flower and be tempted to grow them, others, should the lifting and drying even for a short period prove a necessity, will assuredly be debarred from making the attempt. At the present time I greatly incline to the belief that these Regelio-Cyclus hybrids are likely to prove both valuable and permanent subjects for British gardens, preferably in a sunny position. M. Tubergen has not yet given us in the new race all the unique or peculiar beauty of the choicest of the older Cushion Irises, and we have, for example, no substitute for I. Lorteti or I. alba, or even I. Gatesi; yet the group does contain some exceedingly beautiful varieties, and one at least, "Charon," I believe to be quite unique, and there are others near akin, and, again, other kinds in which the influence of I. paradoxa is clearly traceable, are very fascinating. In so far as size of blossom is concerned, the new race possesses an advantage, and still another meritorious point is that each scape is two-flowered.

In all probability, however, the time of their flowering will in the near future be

cited as the greatest gain to the garden, seeing that their coming and going practically link together in one unbroken chain the Irises of the pumila group, on the one hand, with the earliest of flag Irises on the other, the new Regelio-Cyclus forms worthily filling the long-existing void, and the more worthily if, in the near future, they are found to be as good from the standpoint of permanent perennials as they are to-day good from the standpoint of intrinsic merit and beauty. *E. H. Jenkins, Hampton Hill.*

A MONSTROUS PRIMROSE.

The Primrose of which we give illustrations (fig. 73) was handed to us by Mr. Odell, and was exhibited by him at a recent meeting of the Scientific Committee. It was, in some respects, intermediate between the "stellata" forms and the ordinary sinensis, and the foliage and stem were of a deep reddish-purple colour.

But the greatest peculiarities were observable in the flowers. No two flowers showed exactly the same conditions, but, speaking generally, the calyx was much enlarged, distended at the upper portion, and of a purple colour (see fig. 73 B). Within the calyx was a corolla, the limb of which projected beyond the calyx and consisted of five purplish hairy lobes, shown at B and in section at fig. D and E.

Within the corolla and detached from it, except at the extreme base, were five stamens opposite the corolla lobes, with hairy filaments and abortive anthers occupying the mouth of the tube (thrum-eyed), or in some flowers not projecting beyond the tube (fig. F). The insertion of the stamens in the flowers represented by Mr. Worthington Smith (fig. D, E, F) was higher than in the flowers we examined, the stamens being given off from about the middle of the tube, but, as we have said, no two flowers were exactly alike.

Within the stamens was the ovary, elongated into a long pod-like organ (fig. C), with a short style, more like the pod of a Crucifer than the usually globose ovary of a Primrose. In some flowers instead of a short style the ovary terminated in five petal-like lobes (fig. D). In fig 'G is shown a placenta which, instead of being raised on a long shaft, is almost sessile. Within the ovary was a basal placenta, column-like in form, and of varying length in different flowers (fig. D, E, F, G). This shaft-like placenta was surmounted by a globular head of ill-formed ovules (fig. H), a portion of which is shown more highly magnified at fig. J. *M. T. M.*

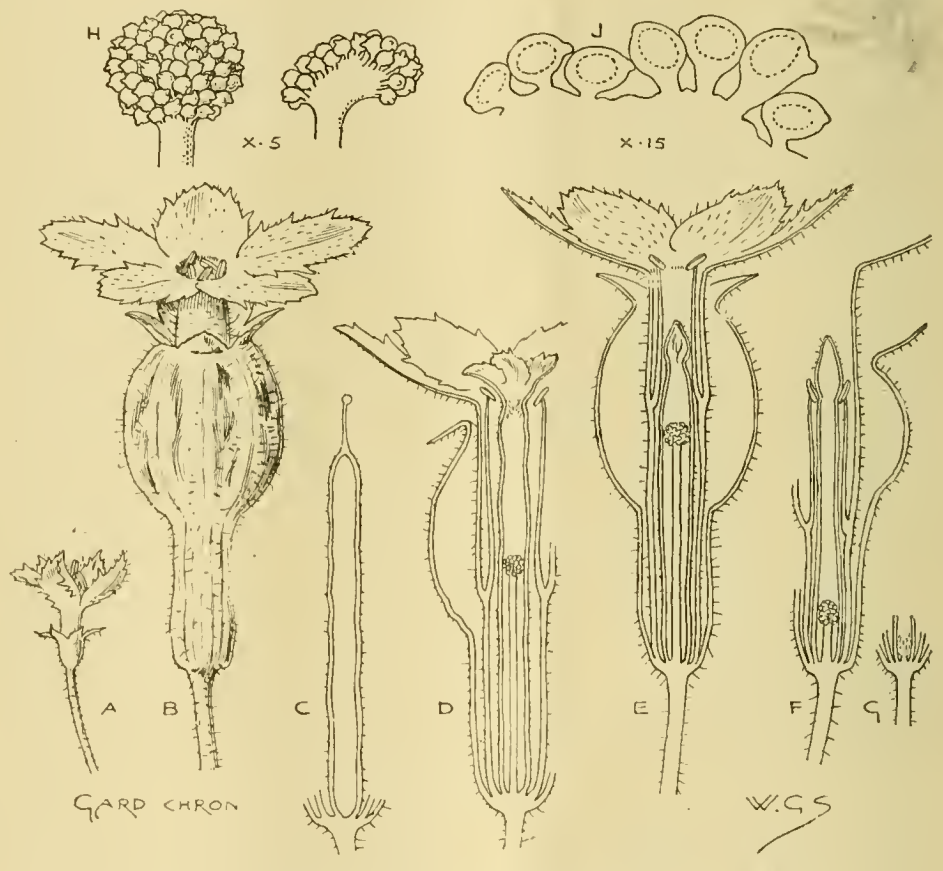

Fig. 73.—Monstrous Chinese Primrose, with calyx and corolla leafy, with ovary prolonged with a long tube, etc.

(For details see text. The figures are of real size except where otherwise indicated.)

THE MANUFACTURE OF SAMSHU (CHINESE SPIRIT) FROM SORGHUM VULGARE.

In reply to a Colonial correspondent, who, after reading Mr. Wilson's note, asked for fuller information on the subject, Mr. Wilson has kindly written us as follows:—

"This industry is largely carried on in North China and Manchuria, and in a lesser degree all over China. The process, though intricate in detail and not easily described, is really very simple. Briefly, the main points are as follow:—The Sorghum grain is first crushed, then moistened, and a quantity of the ferment agent ground fine is thoroughly mixed with it. The mixture is then put into concrete pits, and trampled firmly layer upon layer. When the pit is full it is covered over with boiling husks or chaff, and a layer of adhesive clay is spread over all. (These pits are usually 10 feet deep, 7 feet long, and 2½ feet broad, and capable of holding 1,680lb. of grain.) The clay forms an air-proof cover, beneath which the chemical changes antecedent to distillation proceed. Great heat is generated, and from time to time an opening is made in the clay cover and an iron bar thrust to the bottom of the pit to test the state of the mixture, and to allow of the escape of superfluous gases.

"After 18 days the mixture has undergone sufficient chemical change, and is ready for the first distillation; the grain is partially decomposed, and has a sweet spirituous taste. The grain is now moved from the pit, and placed in a wooden steamer fitted with a lid having a round opening in the top, whereon rests a condenser with its overflow pipe and draining-tube. This steamer is fixed to a grating resting over the top of an iron pan filled to within a foot of the steamer with water. A fire is then started beneath the iron pan, and, as the water boils, the steam passes up through the spirit-laden grain, vaporising and carrying with it the spirit to the bottom of the condenser, whence it trickles down the draining tube to the receiver. The condenser is filled with cold water, and as this gets heated and escapes through the overflow pipes a fresh supply is added. After two hours the whole of the spirit has passed over, and the contents of the steamer are removed and re-packed in an empty pit for a further period of 18 days, when they are ready for a second distillation. Four or five distillations are made ere the grains are finally flung to the pigs, a certain quantity of fresh grain being added for the second and third distillations. The quantity of spirit yielded by one stilling, in which 1,680lb. of grain are used, averages about 650lb.

"The spirit is tested by adding water, and watching the quantity of froth which forms when the mixture is shaken; if one-fifth of its weight can be added to the liquor without considerable froth forming it is considered 'proof spirit.' Rectification is unknown in the distilleries, but a more palatable and stronger liquor may be procured in medicine shops, where re-distillation on a small scale is practised.

"The Samshu is packed in earthenware jars carefully stoppered with clay, and also in wicker baskets lined with tough paper. The ferment used is made in summer by mixing Barley and Peas in the proportion of three of Barley to one of Peas. The mixture is coarsely ground, and water added until a consistency of putty is reached. It is then pressed firmly into wooden moulds in size and shape like brick-moulds. The 'bricks' are then piled 4 to 5 feet high, in a room just as are bricks in a kiln, with interstices for the free passage of air. The room is kept at an equable temperature, and draughts are rigorously excluded. Fungoid growth soon appears, and the correct temperature being maintained, gradually permeates the whole brick. About forty days are necessary to complete the culture. When properly dried and stored, these ferment-bricks retain their active properties for four to five years.

"The above methods are those employed in North China and Manchuria, and I would refer those in search of further detail to 'Manchuria; Its People, Resources, and Recent History,' by Alex. Hosie, published by Methuen and Co.

"In Western China, especially Szechuan, considerable quantities of Samshu are manufactured, but here, unhusked Barley, Maize, and Sorghum, in equal proportions and all mixed together, are used. Rice-husks are added in the proportion of one part to twenty of the mixture. This mixture is first well steamed for an hour; then piled in heaps on a clean concrete floor, and boiling water added liberally. It is allowed to remain in these heaps until fairly dry, when it is spread over the floor, and pulverised ferment is thoroughly mixed with it. The whole mixture is next put into a concrete pit and covered over with clay. In this pit it remains

for a month (being occasionally examined by aid of an iron bar) and is then ready for distillation.

"The process of distillation is similar to that detailed above. Four distillations are made, at intervals of a month, a small quantity of fresh grain and rice-husks being added for the second and third stillings. The quantity of spirit yielded by this mixture is much less than is obtained from the pure Sorghum in Manchuria, but of a stronger nature. The ferment used in the West of China is prepared from wheaten flour." *E. H. W.*

TREE CARNATIONS.

(Concluded from page 181.)

Culture.

My experience has been that all Carnations grown in pots for winter flowering are more or less inclined to deteriorate, but this can be checked to a great extent by careful selection of stock. When I first handled them in large quantities it was for growing plants for selling to the trade, and all the stock plants were potted on and grown under cool treatment, and not allowed to flower. The cuttings were taken while they were short and thick, that is, the side shoots before they had run out thin, and from these there was no difficulty in establishing plants that would branch out naturally and produce well-furnished specimens. There are few subjects easier to propagate than Tree Carnations, provided they are properly treated; but many fail with them through some slight neglect. In the first place, they must be taken while the stock plants are fairly moist at the roots. If the cuttings once get withered they become hard in the stem, and are sure to fail. Too much surface heat will draw them up and take the sap from the base: this is a common cause of failure. A moist, cool surface, with a good bottom heat, is what is needed, and as soon as the cuttings are rooted they should be removed to a light, airy, well-ventilated position, and potted off singly before the roots get too much matted together. From the start to finish afford them plenty of light and air. In clear, frosty weather a moderate degree of artificial heat will do no harm; but in dull weather such heat will cause weakly growth, and the flowers will not advance. The imperfect, or "sleepy" flowers, as the Americans call them, are, I believe, caused chiefly by allowing the plants to get too dry at the roots while in the bud state. The time of flowering will depend on when the plants were started and the time of stopping. With many of the sorts those propagated from good cuttings in March may be grown on without stopping; the terminal shoots will flower in the autumn, and the side shoots will follow on later. But for flowering later it may be desirable to stop all the plants at about the middle of June. Those who have taken up the culture of the American sorts have been impressed with the fact that they require plenty of root room, and I think better success would follow if our English sorts were grown in larger pots, or planted on benches in the same manner as practised by the Americans. In growing the plants on benches it is advantageous to lime-wash all the wood before putting on the soil. Some rough drainage should be used, and the soil made moderately firm when the planting is done. I have found that some are inclined to overlook the fact that it is as necessary to make the soil firm when planting them out as it is when potting plants.

Cross-Fertilisation.

For some years I was very successful in raising seedlings, but circumstances prevented me from carrying on this interesting work.

In the various crosses made I found the seed parent was of the most importance. Some varieties yield but a small percentage of good seedlings, while from others almost all would be fairly good. The first thing necessary is to select those of good habit. The pollen parent will have the most effect on colour. Indiscriminate crossing of various colours may secure some fairly good results; but the progeny is more liable to sport. A brighter hue of the same colour may be secured by taking the pollen from flowers of inferior quality, but of better colour, for fertilising those of better habit, etc. I have found it easy to get a good crimson from a scarlet flower. In all cases it is better to use the lighter shades for seeding with the pollen from those of deeper shades for fertilising with. One of my correspondents writes to me that he is crossing a yellow on Mrs. T. W. Lawson, with the idea of getting a good yellow. This may be accomplished in two or three succeeding generations; but I think it would be much easier to get a good yellow by working on to a white, or on such an one as Enchantress, which has very little colour and all other desirable qualities, and should prove a useful parent.

Substance in Carnations.

We often hear that one variety is better or will keep longer than others, but very little is said about the reasons for this peculiarity. In the first place much depends upon how and when they are cut. A bloom that has been fully expanded for some days and then cut while the plant may be dry will last but a

Fig. 74.—An English-raised Tree Carnation "Britannia," which received an Award of Merit from the R.H.S. on March 20 when shown by Mr. Smith, Enfield Highway. Colour of flowers, bright red.

(See *ante*, page 190.)

short time; but if the plant has been watered overnight, and a bloom that is barely expanded be cut early in the morning, the bloom would last fully a week. I do not mean to suggest that there is no difference in the varieties, for I have found that there is. In those with thick fleshy stems the water is taken up freely, and consequently the flowers last better than those with the thin wiry stems. Also those which have some pollen and are readily fertilised fade quickly. I have found when pollenising for seed purposes, that as soon as a flower is properly impregnated, the petals fade quickly, while those which prove abortive last much longer. With a little observation it becomes easy to tell when a flower is successfully fertilised. A very dry, heated atmosphere will cause Carnation flowers to curl up quickly. *A. H.*

ORCHID NOTES AND GLEANINGS.

MESSRS. JAMES CYPHER & SON'S COLLECTION.

The nurseries of Messrs. Cypher in the Queen's Road, Cheltenham, have for many years been reckoned among the attractions of that health resort. Orchids have always been well grown there, and they have gradually required more space until now they occupy twenty of the seventy plant-houses on the place, and the plant-houses find occupation for forty of the seventy men and boys employed by the firm. It is one of the few remaining nurseries in which all branches of the trade are carried on successfully, and although the Orchids take the lead they have never been allowed to exclude other equally worthy plants. The Orchid houses are chiefly commodious span-roofed structures, and in the arrangement of the plants in them as many as possible are suspended from the roof, and the others brought well up to the light by elevated staging. Tanks for storing rain water are arranged beneath the central staging or in other convenient parts of the houses, and in most of the Orchid houses there are small rockeries arranged beneath the staging, in which Begonias and other foliage plants grow, and assist in preserving a moist atmosphere. The material used for potting Orchids has here varied but little from the first. Good fibrous peat and sphagnum-moss are used when obtainable for most epiphytal Orchids, but, as good Orchid peat is not always procurable, Polypodium fibre is found to be an excellent substitute. All classes of Orchids are grown with less heat than in most gardens, a reasonable amount of ventilation is given, and shading is as little used as possible. The plants make good growth and large pseudo-bulbs, having hard tissues, and the colours of the flowers are developed in their brightest tints.

In the first large span-roofed intermediate house there is at the present time a display of fine varieties of Cattleya Trianæ, varying considerably in colour. With them in bloom are some examples of the scarlet Epiphronitis Veitchii, Lælio-Cattleya luminosa, a very handsome L.-C. × Dominiana, the white Cattleya intermedia nivea, a quantity of varieties of Cypripedium Lathamianum, and C. Leeanum, of which the finely formed C. Leeanum Cypher's variety, C. L. giganteum, and C. L. virginale are the best. Overhead are suspended a very large number of hybrid Lælio-Cattleyas, Brasso-Cattleyas, etc., of flowering size, and the whole of one side of the house is filled with a great variety of hybrids approaching the flowering stage. As a remarkable instance of the quantity of flowers to be obtained from vigorous and well-grown Lælio-Cattleyas, Mr. John Cypher called attention to one strong and beautifully grown plant which had produced from a single lead three stout pseudo-bulbs, each with a large flower-sheath sending up bloom. Other examples of good culture were some magnificent specimens of Lælia purpurata and of Cattleya Bowringiana furnished with flower-sheaths.

The next, and rather warmer division, has some strong plants of Phalænopsis Rimestadtiana in bloom, several plants of Cypripedium niveum, a remarkably fine C. Chamberlainianum, the reddish-scarlet Renanthera Imschootiana, Angræcum citratum, A. articulatum, a distinct and pretty hybrid between Cypripedium Lathamianum and a dark C. Leeanum, of fine colour; C. villoso-exul, C. aureum Lambianum, like a green-tinted C. a. Surprise, C. Mastersianum, and a rather effective hybrid from it, together with some other unnamed hybrids.

Another large Cattleya house has a number of the fragrant Cattleya Schröderæ in bloom, also C. amethystoglossa, and a very fine variety of C. calummata with four finely coloured flowers on one spike; brightly coloured Epidendrum O'Brienianum and the yellow E. xanthinum. Overhead are suspended numbers of Odontoglossum citrosmum with enormous pseudo-bulbs, the young growths being ready to send out spikes. With regard to these it is a common belief that unless the plants are severely dried off, the growths get ahead of the flower spikes and the flowers are not produced. Mr. Cypher merely reduces the supply of water and finds the spikes are freely produced nevertheless in his well ventilated intermediate house. If rigorously dried off annually such large bulbs would not be made.
